MULTIPEDÆ. Multipeds. They are ſuch as have more feet than four. It is the ſame as millepedes.

MULTIPES. A polypus.

MULTISILIQUOUS PLANTS. They are ſuch as have after each flower many diſtinct, long, ſlender, and many times crooked caſes, or ſiliquæ, in which their ſeed is contained; and which, when they ripen, open of themſelves, and let the ſeeds drop. Of this kind are columbines, houſleek, &c.

MUMIA. Mummy. This name is variouſly applied. It is given to a human carcaſe that is dried by the ſun and ſands. Theſe bodies by drying are of the conſiſtence of horn, and light, and are called white *mummies*. Other carcaſſes are embalmed, and then are called *mummies*; of this kind are thoſe which are called Egyptian. *Mumia* medullæ is the marrow of the bones. *Mumia* elementorum; ſo Paracelſus and Helmont name a balſam, which is defined to be the balſam of the external elements. *Mumia* tranſmarina; thus ſome have called manna. *Mumia*; thus water is called which is collected in a phial from the breath of a man received therein, after waſhing his mouth with water. *Mumia*; it is a ſubtil, ſpirituous, ætherial ſubſtance, innate in every body, and remaining therein in ſome meaſure after death. *Mumia*, that which is taken from a human body is a reſinous matter, hath an hardened, black, ſhining ſurface, is acrid and bitter to the taſte, and of a fragrant ſmell. *Mumia*, that which is particularly called *mummy* of the Arabians, is a concreted liquor, obtained in ſepulchres by exudation from carcaſſes embalmed with aloes, myrrh, and balſam. *Mumia*, that which is called Egyptian, is what runs from bodies that are ſeaſoned with piſſaſphaltos, as well as the carcaſe itſelf that is ſo ſeaſoned.

MUMPS. It is a ſpecies of quinſy. Dr. Cullen names it cynanche parotidæa. This name is given to a diſorder which manifeſted itſelf by a ſlight fever, ſoon after the appearance of which, the face, neck, and particularly the throat, were conſiderably ſwelled, and of a ſomewhat deeper colour than a damaſk roſe, but the tumor rarely extended to the eyes. This ſwelling was chiefly external, and ſometimes ſo increaſed in a few days, as to obliterate the features; and yet this quick and extraordinary diſtenſion of the parts was rarely attended with pain.

This diſorder was of the inflammatory kind; it chiefly affected the young and the poor; it was very rarely mortal, and ſeldom terminated in an abſceſs, but gave way to general antiphlogiſtic methods.

Sometimes the tumor ſubſided in three or four days, and from the face was tranſlated in men to the teſticles; but this circumſtance required no alteration from the general method of cure, nor did the ſwelling in the teſticles ever ſuppurate.

The patients bore bleeding, purging, and nitrous medicines very well. In ſome a thickneſs and hardneſs remained upon the parotid and maxillary glands, after the patient was very well in all other reſpects; theſe yielded to ſmall doſes of merc. dulc. with gentle purging, the affected part being kept warm, and the patient to a ſuitable regimen. Sometimes a mild mercurial ointment was uſeful. See Gooch's Caſes and Remarks, p. 74—76, and Appendix to the ſame, p. 13, &c.

MUNDICATIVA, or Mundificativa. Cleanſing, deterging, purifying.

MUNDIFICATIVUM PARACELSI. ℞ Mel Brit. tereb. venet. ää ℔ ß. ſs. vitel. quatuor. ov. coq. ad conſiſt. ung. & ſing. ℥ i. adde merc. precip. rub. ʒ i.

MUNDUY-GUACU. The Barbadoes nut.

MUNTINGIA. It is a roſe-ſhaped flower, of which Miller enumerates three ſpecies. Father Plumier diſcovered it, and gave it this name in honour of Dr. Muntingius, profeſſor of botany at Groningen, in Holland.

MUOIDES, i. e. Platyſma myoides.

MURALIS. Pellitory of the wall.

MURECI. A berry-bearing tree in Braſil; the berries are purging. See Raii Hiſt.

MURIA. Brine. It is made of common ſalt, and ſo of the ſame nature and uſe. An acrimony in the juices reſembling that of *brine*, is called a muriatic acrimony.

MURUCUIA. A name of ſome ſpecies of granadilla.

MUSA, alſo called muza, mauz, palma humili, ficus Indica, bala, banana, platanus. The plantain tree.

Muſa is the Arabic name; bala is the Malabarian name. Though called a tree, it hardly deſerves the name of a ſhrub, ſince it hath an annual ſtalk, which is like a reed. The leaves are an ell long, and three ſpans broad; of theſe leaves it is ſuppoſed that Adam and Eve made aprons. The fruit is a delicious food, and reſembles meal and butter. It is found in all the eaſtern countries, and in Africa. See Raii Hiſt.

MUSADI. Sal ammoniac.

MUSCARI. Muſk or grape hyacinth. Boerhaave enumerates twelve ſpecies, but no medicinal virtues.

MUSCIPULA, alſo called lychnis viſcoſa rubra, viſcaria. Catch-fly. It grows among corn, and is cultivated in gardens, but not uſed in medicine, though ſome ſay its ſeeds are warm and diuretic. See Raii Hiſt.

MUSCO-FUNGO. A name of ſeveral ſpecies of lychnis and lychnoides.

MUSCOVADO. See SACCHARUM.

MUSCOSÆ GLANDULÆ. Some of the conglobate glands are thus called, to diſtinguiſh them from the conglomerate, which are called glandulæ vaſculoſæ.

MUSCULARIS ARTERIA, i. e. Scapularis externa arteria.

MUSCULARIS VENA. A branch of the poſterior or upper branch of the external jugular; it ſpreads in the muſcles, which cover the ſcapula and joint of the

humerus. Winſlow ſpeaks of its riſing alſo from the axillaris.

MUSCULI OBLIQUI SUPERIORES NERVI, i. e. Pathetici.

MUSCULO CUTANEUS NERVUS. See CERVICALES.

MUSCULORUM COMMUNIS MEMBRANA, alſo called muſculoſa. Winſlow denies its exiſtence, but others deſcribe it as conſiſting of ſome ſmall fibres glued together, a proper quantity of which is connected by the cellular membrane, which fills up the interſtices of muſcles. Winſlow ſays, that the elongations of the lamina of the cellular membrane may have given riſe to the notion of a muſc. com. memb. for in ſome places this membrane is cloſely united to the proper membrane of the muſcles.

MUSCULOSA, i. e. Muſculorum communis membrana.

MUSCULOSI. External or muſcular inflammations.

MUSCULUS, from *μυς*, either a *mouſe* or *muſcle*. The ſhell fiſh called muſcle, or muſſel. See MYTILUS. The whale, according to Pliny. Alſo thoſe bundles of fleſhy fibres by which the motions of all animal bodies are performed; or, as ſome deſcribe it, "it is a bundle of thin and parallel plates of fleſhy threads or fibres incloſed by one membrane; an original part of an animal body, framed of its proper membrane, fibrous fleſh, a tendon, vein, artery, and nerve: it hath the power of contracting and lengthening, and is the chief inſtrument of voluntary motion."

Generally the word *muſculus* is ſaid to be derived from *mus, a mouſe*; but the true derivation is from *μυειν, to draw* or *contract*.

A *muſcle* is divided into the head, belly, and tail. The head is the tendinous part which is fixed on the immovable joint, and is called its origin. The belly is the middle, fleſhy part, whoſe fibres are the true muſcular fibres, and have the power of motion. The tail is the tendinous part, which is inſerted into the part to be moved by it, and is called the inſertion.

A *muſcle* is compoſed of the ſame number of fibres in all its parts, only thoſe of the tendon are more compact than thoſe of the belly.

The uſe of the tendon is, 1ſt, To avoid a large quantity of fleſh, near the joint, which would have obſtructed the motion of the limb. 2dly, To prevent clumſineſs in particular places, for fleſh in the hand would have been inconvenient. 3dly, That the fleſhy part of the muſcle might be nearer the centre of motion. 4thly, For the better admitting of that friction, which in leſs compact parts would have been injurious.

The arteries, veins, and nerves, generally enter the middle of muſcles, but this is not certain or conſtant; they ramify alike throughout their whole ſubſtance. The large arteries and veins run according to the direction of the muſcular fibres; the leſs anaſtomoſe and run tranſverſe. The uſe of the nerve in a *muſcle*, is to bring the immediate cauſe of motion thereto; that of the arteries is to diſtribute the blood through the part: but a *muſcle* hath more blood conveyed to it than is required for its nouriſhment, and, therefore, the free influx of blood ſeems neceſſary to the contraction of the *muſcle*. Albinus ſays, that the arteries in the *muſcles* terminate in the cellular membrane and the muſcular fibres; but this latter termination is not to be proved.

Thoſe *muſcles* which are deſtined for the moſt action, have the larger quantity of nerves imparted to them, and vice verſa.

The *muſcles* are commonly attached to the bones, and the tendons are inſerted into the ſubſtance of the bone. When a *muſcle* is fleſhy at its inſertion, it is only fixed to the periоſteum. Some *muſcles* are fixed to cartilages, but do not ſink into them, being only attached to the perichondrium. Some are fixed to ligaments: as thoſe in the fore-arm; others into membranes, as thoſe of the eye; and others again into fleſhy parts, as thoſe of the tongue.

There are many diviſions of *muſcles*, ſuch as the oblong, hollow, and mixt; the oblong are ſubdivided into the rectilinear, half penniform, the penniform, the complex penniform, the radiated, &c.

The appendicles of muſcles, are, 1ſt, The faſcia, or aponeuroſis. 2d, The frænum, or annular ligament, by which the tendons of ſome *muſcles* are confined. 3d, The ſacculi mucoſi.

Amongſt the many phænomena relating to *muſcles*, the following are a few which deſerve ſome attention. 1 A *muſcle* in action grows tenſe and ſhorter; it can contract itſelf ſo as to be ſhortened one third. 2. The diameter of a *muſcle* in action is not greatly increaſed. 3. If the brain is injured to a certain degree, all the *muſcles* ſubſervient to the will become paralytic. 4. If the cerebellum is injured, all the involuntary motions ceaſe. 5. If a nerve, or an artery, going to a *muſcle*, is tied, or deſtroyed, the *muſcle* becomes paralytic. 6. Irritation upon the *muſcle* produces motion. 7. Some *muſcles* continue to act, after all communication with the nerves and blood veſſels is taken away. 8. The action of *muſcles* is inſtantaneous, and, in moſt parts of the body, ſubſervient to the will. This laſt phænomenon alone, Dr. Hunter obſerves, is ſufficient to confute the various hypotheſes of Crowne, Mayow, Borelli, Keil, Boerhaave, Baglivi, Cowper, Nichols, Vernoulli, &c. as the numerous apparatus which they ſuppoſe neceſſary, can never account for that inſtantaneity which is obſervable in muſcular motion. See Brown on the Muſcles; Winſlow's Anatomy; Cooper's and Albinus's Tables of the Muſcles.

MUSCULUS ANTERIOR MALLEI, i. e. Muſculus externus auris.

MUSCULUS EXTERNUS AURIS DU VERNII, called by Winſlow muſculus anterior mallei. It is placed in a fiſſure on the temporal bone, above the glenoid cavity, where the lower jaw plays, runs inward, and is inſerted into the Ravian proceſs of the malleus irregularly forwards from the incus, and by taking off from the vibratory motion of the bones, it is ſuppoſed to fit the ear for receiving weaker ſounds.

MUSCULUS EXTERNUS MALLEI, i. e. Tenſor membrana tympani.

MUSCULUS INTERNUS MALLEI, i. e. Luxator membrana tympani.

MUSCULUS SUPERIOR MALLEI, i. e. Tenſor membrana tympani.

MUSCULUS TUBÆ NOVUS, i. e. Circumflexis palati.

MUSCUS. Moſs. Numberleſs almoſt are the varieties of this kind of production; but as they ſhare little or nothing in medical worth, the curious are referred to Ray, Dale, Miller, and other botanic writers.

MUSCUS ARBOREUS, called alſo uſnea, muſcus quernus. Hairy tree moſs. Three ſorts of moſſes were formerly kept, viz. the *hairy tree moſs*, which is whitiſh, and compoſed of filaments; the green common moſs, which is picked from human ſkulls; and the cup moſs from the ſides of banks. But preſent practice diſcards theſe with all the tribe of moſſes. See Raii Hiſt.

MUSCUS. A name of ſome ſpecies of coralloides, of lycoperdon, of fern, of liverwort, and ſome other vegetable productions.

MUSCUS PULMONARIUS, called alſo pulmonaria arborea, oak-lungs, and lung-wort. It is made up of flat, wrinkled, rough leaves, greeniſh above and aſh-coloured underneath, having ſeveral round, reddiſh, brown ſpots on the ſuperficies, in which the ſeed is ſuppoſed to lie. It hath a bitteriſh and reſtringent taſte. It grows ſpontaneouſly on the oak tree. See Miller's Bot. Off.

MUSCUS PIXIDATUS, called alſo muſcus pyxoides terreſtris, lichen pyxidatus major. Cup moſs. It is a ſpecies of *lichen*, hath many hoary, whitiſh green, ſmall leaves, ſpread on the ſurface of the earth, among which ariſe little, whitiſh, duſky, hollow cups, a quarter of an inch high, ſhewing neither flower nor ſeed; they grow upon dry barren ground. A decoction of this is reckoned a ſpecific againſt the hooping cough.

MUSCÆ HISPANICÆ. Spaniſh flies.

MUSIA-PATTRÆ, i. e. Moxa.

MUSTUM. Muſt. By *muſt* is meant the ſaccharine juice of ſeveral fruits, ſuſceptible of the ſpirituous fermentation, and particularly of grapes, before the commencement of this fermentation; accordingly *muſt* is, properly ſpeaking, what is called ſweet wine.

MUSTUS. The white calx of urine.

MUTELLINA. Mountain or German ſpignel.

MUTITAS. Dumbneſs. The want of power to articulate

culate words. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order dyſcineſiæ. He diſtinguiſhes three ſpecies. 1. *Mutitas* organica. As when the tongue is taken away, or ſomehow injured. 2. *Mutitas* atonica. As when the nerves of the tongue are wounded, or become paralytic. 3. *Mutitas* ſurdorum. As when children are born deaf.

MYACANTHA. Butcher's broom.

MYAGRO. A name for the rapiſtrum, and of the turritis.

MYAGRUM. This plant hath a turbinated fruit, like an inverted pair, unicapſular, preſſing in the ſtalk, containing one ſeed with two empty cells. Boerhaave mentions two ſpecies. Their virtues are the ſame as thoſe of rapiſtrum.

MYAGRUM. A name for a ſpecies of turritis, and of alyſſon.

MYCE, from *μυω, to wink, ſhut up,* or *obſtruct*. A winking, cloſing, or obſtruction. It is applied to the eyes, to ulcers, and to the viſcera. eſpecially the ſpleen, where it imports obſtruction. In botany it imports a fungus. In ſurgery it is a fungus, ſuch as riſes in ulcers or wounds. Some writers ſpeak of a yellow vitriol which is called myce.

MYCHTHISMOS, from *μυζω, to mutter* or *groan*. In Hippocrates it is a ſort of ſighing or groaning during reſpiration, whilſt the air is forced out of the lungs.

MYCONOIDES. An epithet for an ulcer which is full of mucus.

MYCTER. The noſe.

MYCTERES. The noſtrils, *μυκτηρ*, i. e. a Greek primitive.

MYDESIS, from *μυδαω, to abound with moiſture*. It imports in general, a corruption of any part from a redundant moiſture. But Galen applies it particularly to the eye-lids.

MYDON. Fungous fleſh is a fiſtulous ulcer.

MYDRIASIS. A preternatural dilatation of the pupil of the eye. The ſame as AMAUROSIS, which ſee.

MYLACRIS. The knee-pan.

MYLE. The knee-pan, or a mole in the uterus.

MYLO-GLOSSI, from *μυλη, dens molares*, and *γλωσσα, lingua*. Theſe muſcles are often wanting. They are ſmall fleſhy planes, ſituated tranſverſely on each ſide, between the ramus of the lower jaw and the baſis of the tongue; they riſe from near the inner ſide of the dentes molares, and thence run to the baſis of the tongue.

MYLOHYOIDES. Theſe muſcles riſe with a large baſis from the inferior part of the lower jaw, and are inſerted at the baſis of the os hyoides.

MYLON. See STAPHYLOMA.

MYLO-PHARYNGÆI. So Dr. Douglaſs calls the genio-pharyngæi. So alſo the cephalo-pharyngæi are called.

MYOCEPHALUM, from *μυια, a fly*, and *κεφαλη, the head*. A tumor in the uvea tunica of the eye, which reſembles the head of a fly.

MYOCOILITIS. So Vogel names inflammation of the muſcles of the belly. See INFLAMMATION.

MYODES PLATYSMA, from *μυς, a muſcle*, and *πλατης, broad*, i. e. platyſma myoides.

MYOLOGIA, from *μυς, a muſcle*, and *λογος, a diſcourſe*.

MYOPIA, or Myopiaſis, from *μυω, to ſhut*, and *ωψ, the eye*. Short ſight. Becauſe people ſo affected generally half *ſhut* their *eyes* when they intenſely look at an object. The ſight of *myopes* is ſo ſhort that they can neither read nor diſtinguiſh objects without concave glaſſes; this is owing to the too great convexity of the cryſtalline humour of the eye, whereby the rays, unleſs the object is placed cloſe to the eye, are united before they reach the retina; conſequently viſion muſt be indiſtinct in ſuch. The concavity of the ſpectacles muſt be proportioned to the ſight, and *myopes* ſhould begin with the leaſt concave glaſſes, and when they read they ſhould uſe them as little as they conveniently can. It is a ſpecies of dyſopia; which ſee.

MYOPS. A perſon who is ſhort ſighted. It is the dyſopia diſſitorum of Cullen.

MYORESHALON. A growing of the tunica uvea over the ſight.

MYOSITIS. In Sagar's Syſtem of Noſology this word is uſed to ſignify the rheumatiſm, particularly when it affects the muſcles of the limbs proceeding from the joints.

MYOSOTIS, from *μυς, a mouſe*, and *ους, an ear*. Mouſe-ear cheek weed. Becauſe it hath hairy leaves, and grows longitudinally like a mouſe's ear. It reſembles the alſine in every reſpect, only the flower is larger, and the fruit, which is like the horn of an ox, opens at the apex. Boerhaave mentions ſix ſpecies, but they are not remarkable for any medical properties. See Raii Hiſt.

MYOSURUS, called alſo cauda muris, holoſteum, holoſtes, ranunculus. Mouſe-tail. The leaves are gramineous; it flowers in May; it grows on the way ſides; its virtues are like thoſe of plantain.

MYOTOMIA, from *μυς, a muſcle*, and *τεμνω, to cut*. A diſſection of the *muſcles*.

MYREPSICA OLEUM. The oil of ben nut.

MYRICA. A ſpecies of tamariſk.

MYREPSUS. The laſt very eminent among the Greek phyſicians, at leaſt of thoſe who have left their works in the Greek language; but hitherto, as Galen follows or keeps near to Hippocrates, all to this author keep cloſe to Galen. After theſe the Arabians added many articles to the materia medica; they deſcribe the ſmall-pox, meaſles, and ſpina ventoſa. The orientals have the ſpirit of Hippocrates in their copies of his writings, but they have nothing but what is in the Greek and Latin handed down to us. From *Myrepſus* we may proceed to Paracelſus.

MYRINGA, or Myrinx. A barbarous word for the membrane of the ear called the drum.

MYROPHYLLON, called alſo milleſolium aquaticum. Water fennel, It grows in marſhy ſoils, flowers in April, and is ſaid to be vulnerary. See Raii Hiſt.

MYRIOPHILLUM. Pond-weed.

MYRISTICA. See NUX MOSCHATA.

MYRISTICA NUX. Nutmeg.

MYRMECIA. A ſort of wart about the ſize of a lupine, with a broad baſe, deeply rooted, and very painful. It grows on the palms of the hands, or on the ſoles of the feet. It is a ſoft and often moiſt ſort of wart.

MYROBALANI. Myrobalans. They are a dried fruit of the plum kind, and are brought from the Eaſt-Indies. There are four kinds, and are brought from Bengal, Cambaia, and Malabar. They have been recommended as ſomewhat aſtringent and ſtrengtheners of the ſtomach, but are not now in uſe. Myrobolanos is in the Greek the ſame as nux or glans unguentaria in the Latin, which, in plain Engliſh, is a nut or acorn fit for making precious ointments. Out of the *myrobalans* deſcribed by Dioſcorides, Pliny, and Galen, they uſed to expreſs a fragrant oil, which was uſed in ointments.

MYROBALANI CHEBULÆ. Chebul myrobalans. Theſe reſemble the yellow ſort in figure and their ridges, but are larger and darker coloured, inclining to brown or blackiſh, and with a thicker pulp.

MYROBALANI CITRINÆ, vel Flavæ. Citron or yellow mirobalans. They are ſomewhat longer than the Belliric ſort, have generally five large longitudinal ridges, and as many ſmaller between them, ſomewhat pointed at both ends.

MYROBALANI BELLIRICÆ, called alſo Arabibus Belleregi, Bellileg, Bellegu. Bellirick myrobalans. They are of a yellowiſh grey colour, and an irregularly roundiſh or oblong figure, about an inch long, and three quarters of an inch thick.

MYROBALANI EMBLICÆ, called alſo Arabibus embelgi, embleg, or ambegu. Emblic myrobalans. They are of a dark blackiſh grey colour, roundiſh, about half an inch thick, with ſix hexagonal faces opening from one another.

MYROBALANI INDICÆ, vel Nigræ, alſo called Arabibus aſuar. Indian or black myrobalans. They are of a deep black colour, oblong, octangular, differing from all the others in having no ſtone, or only the rudiments of one, from whence they are ſuppoſed to have been gathered before maturity.

All the ſorts have an unpleaſant, bitteriſh, auſtere taſte, and ſtrike a black colour with a ſolution of vitriol. They are gently purgative and aſtringent. The doſe in ſubſtance is from ʒ i. to ʒ ſs. m. in infuſion or decoction from ʒ ſs. to ʒ iſs. Water extracts their ſtyptic virtue, and the extract is aſtringent. The Indians tan leather with them. The faba Bengalenſis, or the Bengal bean,

is a vitiated fruit of the myrobalan kind; it is round, flattiſh, wrinkled, and of the ſize of a ſmall fig, hollow in the middle, of an irregular ſhape, hard, tough, brown outwardly, and blackiſh within, of but little ſmell, and an auſtere and aſtringent taſte. It is vitiated by the puncture of an inſect, by which it is often hollowed like a gall. It is a powerful aſtringent, it alſo incraſſates and allays acrimony. See Raii Hiſt. Tournefort's Mat. Med.

MYROBALANUS ZEYLANICA. The gum elemi tree.

MYRON. An ointment, medicated oil, or unguent.

MYRRHA. Myrrh. It is alſo called ſtacte. It is a gummy reſinous concrete. It is brought immediately from Alexandria, Smyrna, and Aleppo; but from what plant it is obtained is uncertain. It is ſaid to be a produce of the Scandix odorata, or Scandix ſeminibus ſulcatis angulatis, floribus albis, Linn. Sweet fern, or *Myrrh.* Curtis, in his catalogue of the medicinal, &c. plants, in the London Botanic Garden, calls it *myrrha.* It is brought to us in globes or drops of various colours and ſizes. Chuſe ſuch as is of a reddiſh brown colour, not verging too much to yellowiſh or blackiſh; ſuch as is uniform on the outſide, internally ſpeckled or ſtreaked with white, clear and bright, ſomewhat unctuous to the touch, but not tenacious ſo as to ſtick to the fingers.

This drug is ſubject to a variety of frauds; it is mixed with hard, ſhining, yellow pieces of a gum which reſembles gum arabic, and is void of ſmell or taſte. Pieces of bdellium are mixed with it, and are known by their darker colour, and their being ſoft within, which *myrrh* never is, alſo by their different ſmell and taſte. Sometimes an unctuous gummy reſin, of a moderately ſtrong, ſomewhat ungrateful ſmell, and a bitteriſh, very durable taſte, obviouſly different both from thoſe of bdellium and *myrrh.* Alſo pieces of a hard, compact, dark coloured kind of tears, leſs unctuous than *myrrh,* of an offenſive ſmell, a moſt ungrateful bitterneſs, and of a very reſinous nature. The *myrrh* itſelf is either, 1. Blackiſh, which is gathered from old trees, and being more reſinous, is fitter for tinctures. 2. Yellow, which is from young trees; this ſort contains much gum; it eaſily diſſolves in the mouth, hath a much more agreeable aromatic ſmell, and is what ſhould be uſed for pills, powders, and watery ſolutions.

Myrrh is eſteemed as being balſamic, vulnerary, antiſeptic, attenuant, deobſtruent, powerfully promoting the fluid ſecretions, &c. Its doſe may be from gr. v. to ʒ ſs.

It diſſolves almoſt totally in boiling water, but as the liquor cools, the reſinous part ſubſides; and if the ſolution is evaporated to an extract, the bitter of this drug only remains. By diſtillation with a boiling heat in water, the whole of its flavour ariſes, partly impregnating the diſtilled water, and partly collected and concentrated in the form of an eſſential oil, which is in ſmell extremely fragrant, and rather more agreeable than the *myrrh* in ſubſtance; in taſte remarkably mild, and ſo ponderous as to ſink in water. From ʒ ii. to ʒ iii. of this oil are obtained from ℥ xvi. of the gum. Rectified ſpirit diſſolves leſs *myrrh* than water does; but it extracts more perfectly that in which its bitterneſs, flavour, and virtue conſiſt. The ſpirituous ſolution contains all the active matter; in diſtillation nothing is carried away by the ſpirit, ſo that the extract obtained from a ſpirituous ſolution is a very fragrant bitter, tenacious reſin, and poſſeſſes all the virtue of the *myrrh.*

The London College directs the tincture of *myrrh* to be prepared with proof ſpirit. It may be obſerved that rectified ſpirit takes up all the active parts, and proof ſpirit the whole of the *myrrh,* except its impurities; ℥ iii. of *myrrh* is ordered to be added to ℔ ii. of ſpirit.

Elixir Myrrhæ *Compoſitum.* *The Compound Elixir of* Myrrh.

Take of the extract of ſavine, one ounce; of the tincture of caſtor, one pint; of the tincture of *myrrh,* half a pint. Digeſt and ſtrain off the tincture. This was formerly called elixir uterinum.

Tinct. Myrrhæ & *Aloe.*

℞ *Myrrh.* pulv. ʒ iſs. aloes hepat. ʒ i. ſp. vini R. ℔ ii. m. This is frequently uſed externally as a vulnerary.

Pulv. e Myrrha *Comp.* *Compound Powder of* Myrrh.

Take of the dried leaves of rue, dittany of Crete, *myrrh,* of each an ounce and a half; aſſa fœtida, ſagapenum, Ruſſia caſtor, opoponax, of each an ounce, mix and beat them into a powder.

This is a reformation of the troches of *myrrh,* which were contrived by Rhazi againſt uterine obſtructions.

Oleum Myrrhæ *per Deliquium.*

Boil an egg very hard, take out the yolk, and fill the cavity with *myrrh,* bind the divided ſides together, ſet it in a cool moiſt cellar, and it will all run into a liquid.

It is uſed for removing freckles on the face. It poſſeſſes all the ſmell and taſte of the *myrrh;* it may be precipitated and coagulated by ſpirit of wine; and this coagulum is again diſſolved by water. See Raii Hiſt. Miller's Bot. Offic. Tournefort's Mat. Med. Lewis's Mat. Med. Neumann's Chem. Works.

MYRRHINE. The myrtle.

MYRRHIS, called alſo cerefolium Hiſpanicum, cicutaria odorata, ſweet cicely, great chervil. It is the ſcandix odorata, Linn. Boerhaave enumerates fifteen ſpecies, and gives the following as characters; the petals are unequal, the ſeed is ſtriated, reſembles the beak of a bird. This plant is cultivated in gardens, and agrees in virtues with chærefolium. It alſo hath ſomething of the taſte of cloves, and, like them, is uſeful in the ſcurvy. The branches reſemble thoſe of fern, have a pleaſant aromatic ſmell, the ſtalks are hairy, the flowers are white, and appear in May or June. It is more an eſculent than a medicinal plant, though it is ſomewhat diuretic. See Raii Hiſt.

Myrrhis is a name of the chærophyllum.

MYRRHIS SYLVESTRIS. A name of the caucalis ſylveſtris folio chærophilli.

MYRTIDANON. By this Hippocrates means the berry of the Indicum, which he ſays the Indians call pepper. But Dioſcorides means by it an excreſcence which grows on the trunk of the myrtle, and which is more aſtringent than the myrtle itſelf.

MYRTOCHEILIDES. A name for the nymphæ of the female pudenda.

MYRTON. The clitoris.

MYRTUS. The myrtle Some derive the name from *myrrha,* becauſe it ſmells like myrrh; others from *Myrtha, a virgin,* ſaid to be turned into this tree after her death; ſhe was beloved by Pallas.

MYRTUS COMMUNIS ITALICA. Common myrtle. The *myrtus communis,* Linn. It is an evergreen ſhrub, with oblong leaves, pointed at both ends, in the boſoms of which ſpring ſolitary white pentapetalous flowers, followed by black oblong umbilicated berries, full of white crooked ſeeds. It is a native of the ſouthern parts of Europe; the berries, which are called myrtilli, rarely come to perfection with us.

The berries are recommended in alvine and uterine fluxes, and diſorders from laxity and debility; they have a roughiſh not unpleaſant taſte, and are accompanied with a ſweetiſh aromatic flavour. The leaves are aſtringent, and if rubbed they yield an aromatic flavour. See Raii Hiſt. Lewis's Mat. Med.

MYRTUS BRABANTICA, called alſo rhus myrtifolia Belgica, gale, frutex odoratus ſeptentrionalium, elæagnus cordo, chamælæagnus Dodonæo. Gaule, ſweet willow, Dutch *myrtle.*

It is a ſmall ſhrub, much branched, with oblong, ſmooth, whitiſh green leaves, ſomewhat pointed or converging at each end; among which ariſe pedicles bearing ſcaly cones, which include the ſeeds, one little ſeed being lodged in each ſcale. It grows wild in waſte watery places in many parts of England. It flowers in May or June, ripens its ſeeds in Auguſt, and loſes its leaves in winter. The leaves, flowers, and ſeeds, have a ſtrong fragrant flavour, and a bitter taſte; they are uſed to deſtroy moths and cutaneous inſects, of which they are reckoned deſtructive of all kinds. An infuſion of them, taken inwardly, deſtroys worms, and ſtrengthens the ſtomach. They are a good ſubſtitute for hops, as they preſerve malt liquor very well, but render it very inebriating. See Raii Hiſt. Plant. Lewis's Mat. Med.

MYTILUS. The muſſel. As from muſhrooms, ſo from this ſhell-fiſh very alarming ſymptoms are often produced. Some attribute theſe effects to a quality in the *muſſels*, either proper to this fiſh, in general, or accidentally acquired from the ſituation in which they derive their nouriſhment: others charge the pea crab, which is often found in them, as the injurious cauſe: but as ſimilar effects are obſerved to ariſe from various other cauſes beſides muſhrooms and *muſſels*, the peculiarity of the perſon's conſtitution ſeems to be that to which the whole is owing. On undoubted evidence it appears, that ſimilar complaints have often been produced by eating ſalmon, by taking the Peruvian bark, by waſhing the hands in water after fiſh hath been boiled in it, bathing in the ſea, cantharides applied to the ſkin, the internal uſe of wild valerian root, &c. When an itching, &c. affects the ſkin from external applications, it may be ſaid that ſuch effects ariſe from a mechanical cauſe. When the ſame ſymptoms airſe in the ſame parts from various kinds of aliment and medicine received into the ſtomach, is it not from the influence of ſympathy that they are produced? This idea ſeems to be ſtrongly confirmed by the relief that ſoon follows from diſcharging thoſe aliments or medicines by an active emetic.

The ſymptoms conſequent on eating muſſels, are accurately deſcribed in the ſecond volume of the Memoirs of the Academy at Bruſſels; a tranſlation of which, the Editor of the Lond. Med. Journal hath inſerted in that uſeful Work; ſee vol. iii. p. 136. It is as follows. "The ſigns which announce the noxious effects of boiled *muſſels*, are an univerſal uneaſineſs or numbneſs, that commonly takes place three or four hours after they have been eaten. Theſe ſymptoms are ſucceeded by a tightneſs of the throat, a ſenſe of heat about the head and eyes, immoderate thirſt, naufea, and ſometimes vomiting. If the patient hath the good fortune to vomit up the whole of the venomous matter, this evacuation is generally ſufficient to ſtop the progreſs of the complaint; but if he brings up none, or only a part of the noxious ſubſtance, the diſorder becomes more or leſs alarming, according to the quantity of deleterious matter in the firſt paſſages, and according to the particular conſtitution of the patient. The want of a ſufficient evacuation by vomit encreaſes the tightneſs of the throat, and the ſwelling of the face, eyes, and tongue; all the parts within the mouth appear inflamed, and as it were excoriated, and the redneſs ſoon ſpreads to the outer ſurface, appearing firſt in the face, and extending from thence to the neck, breaſt, and abdomen, and by degrees over the whole body. This particular eruption is the ſymptom the moſt diſtinguiſhing and characteriſtic of the malignancy of *muſſels*; it is conſtantly accompanied with a kind of delirium, with a ſingular uneaſineſs, and an inſupportable itching; it has no affinity with the eruption produced by the eryſipelatous fever, with the ſcarlatina, meaſles, purpura urticata, or any other known ſpecies of red eruption: it has theſe particularities, viz. that it never appears unleſs *muſſels* have been eaten; that it is not preceded by fever; that it is accompanied by ſymptoms which appear united in no other diſeaſe; and laſtly, that the whole ſurface of the body, though redder than in any other eruptive diſeaſe, appears as it were ſpotted with an infinite number of red ſpots of a deeper red than the reſt of the ſkin. Theſe points are infinitely ſmaller than a millet ſeed; if we examine them through a lens, we ſee diſtinctly that they are the openings or pores of the cuticle, which leaves minute ſpots of the cutis expoſed to our view, while the redneſs which is ſeen only through the epidermis, appears of a paler hue."

In general, when people are thus affected by eating *muſſels*, the ſame treatment will be proper that is directed when muſhrooms are the offending cauſe. See AMANITA. The itching is conſiderably allayed by waſhing the whole ſurface of the body with vinegar and water for about half an hour.

The author of the above account of the ſymptoms that are the effect of eating *muſſels*, adviſes, as a preventive of their injuries, to waſh them with water, and afterwards with vinegar, and then to boil them for uſe in an earthen pot with vinegar and water, and a few grains of Jamaica peper.

MYTTOTUM. A kind of food made of garlic, onions, and cheeſe, bruiſed together.

MYURUS. An epithet for a ſort of ſinking pulſe, when the ſecond ſtroke is leſs than the firſt, the third than the ſecond, &c. Of this there are two kinds; the firſt is when then pulſe ſo ſinks as not to riſe again; the other, when it returns again and riſes in ſome degree. Both are eſteemed bad preſages.

MYXA. Mucus. But in botany it is a plant which is alſo called ſebeſten, myxara, ſebeſtina domeſtica, myxas. The SEBESTEN, which ſee.

MYXOSARCOMA. A ſort of tumor, alſo called mucocarneus.

N.

N. In preſcription ſignifies number.

NABEA, i. e. Œnoplia.

NABIT. Powdered ſugar-candy.

NACTA. An apoſtemation of the breaſts, particularly thoſe of women.

NADUCEM. So Avicennna calls a mole in the womb.

NÆVUS. A mole on the ſkin, generally called a mother's mark; alſo the tumor known by the name of a wen. Dr. Cullen gives the wen as the general name lupia, and conſidering it as a genus, he places it in the claſs locales, and order tumores.

All preternatural tumors on the ſkin, in the form of a wart or tubercle, are called excreſcences; by the Greeks they are called acrothymia, and when they are born with a perſon they are called nævi materni, or marks from the mother. A large tumor depending from the ſkin is denominated ſarcoma. Theſe appear on any part of the body; ſome of them differ in their colour from the reſt of the ſkin, whilſt others are red, black, &c. Their ſhapes are various, ſome reſembling ſtrawberries, others grapes, &c. Heiſter adviſes their removal by means of a ligature, a cautery or a knife, as circumſtances beſt ſuit.

As to the tumor called a wen, its different ſpecies are diſtinguiſhed by their contents. Dr. Aitken, in his Element of Surgery, divides the wen into the following ſpecies. 1. Atheroma. 2. Meliceris 3. Steatoma. They are encyſted tumors; the matter contained in the firſt three following is inſpiſſated lymph, and that in the fourth is only fat. Monſ. Littre is the firſt who hath particularly deſcribed the fourth kind; and to the following purpoſe he ſpeaks of them all. A wen is ſaid to be of three ſorts, according to the kind of matter it contains; that whoſe contents reſemble boiled rice, or curds, or a bread poultice, is called atheroma; if it reſembles honey, it is named meliceris; and if it is like ſuet it is denominated ſteatoma: but there is a fourth ſort, which may be called liponie, becauſe of its fat contents reſembling greaſe. He ſays that he hath ſeen one on the ſhoulders of a man which

was

was a thin bag, of tender texture, full of a ſoft fat, that it had all the qualities of common greaſe; and though the fat in the lipome reſembles that in the ſteatoma, yet they cannot be the ſame, for the matter of the ſteatoma is not inflammable, nor does it melt, or if it does, it is with great difficulty, and imperfectly; whereas it is the contrary with the lipome. When the man who had the above named lipome was fatigued, or had drank freely of ſtrong liquors, his lipome was inflamed for ſome days after, and its contents rarifying increaſed the ſize of the tumor. See Mem. de l'Acad. Roy. des Sciences l'Ann. 1709.

The lipome ſeems to be no other than an enlargement of one or more of the cells of the adipoſe membrane, which is filled only with its natural contents. Its ſoftneſs and largeneſs diſtinguiſh it in general from the other ſpecies, though ſometimes the fatty contents will be ſo hard as to deceive. As this kind of wen does not run between the muſcles, nor is poſſeſſed of any conſiderable blood veſſels, it may always be cut off with eaſe and ſafety.

As to the other kind of wens, their extirpation may or may not be attempted, according as their ſituation is with reſpect to adjacent veſſels, the wounding of which would endanger the patient's life.

See Wiſeman's Surgery; Turner's Surgery; Heiſter's Surgery; Warner's Caſes in Surgery; Gooch's Caſes and Remarks, p. 281, &c. Cullen's Noſology.

NAGAM. A pod-bearing tree in the Eaſt-Indian iſlands.

NAI CORONA. Coubage. See PHASEOLUS.

NAKIR. According to Schenkius it is a violent flatulence which paſſes from one limb to another, and is attended with pain.

NALUGN. A bacciferous ſhrub which grows in Malabar, and flowers twice a year. Its different parts are uſed by the natives in flatulent and ſome ſpaſmodic diſorders, &c. See Raii Hiſt.

NANA, or Nanas. The pine-apple. See ANANAS.

NANDI-ERVATAM. A ſmall Eaſt-Indian ſhrub, the whole of which is lactefcent; the juice deſtroys worms, and is uſed with many other intentions. See Raii Hiſt.

NAP, or Napeca. A ſpecies of jujube. See ŒNOPLIA.

NAPELLUS, i. e. Anthora, and luparia. See ACONITUM.

NAPHA. Orange flower water.

NAPHTHA. It is the thinneſt of the liquid bitumens; it is a perfectly fluid, thin bitumen or mineral oil, clear and colourleſs as cryſtal, of a ſtrong ſmell, extremely ſubtil, ſo light as to ſwim on all known liquors, ſpreading to a vaſt ſurface on water, exhibiting rainbow colours, and is highly inflammable. This name is given to this kind of thin oil, whether it is ſeparated by nature or art from petroleum or other bituminous matter. Petroleum is a groſſer oil of this kind. The true naphtha is uſeful as an external application for removing old pains, nervous diſorders, ſuch as cramps, contractions of the limbs, paralytic affections, &c. See BITUMEN and PETROLEUM.

NAPIFOLIA. Boor cole.

NAPIUM, i. e. Lampſana.

NAPO BRASSICA, i. e. Braſſica radice napiformis.

NAPTA, i. e. Naphtha. It is alſo a name for the tumor called nata or natta.

NAPUS. See BUNIAS.

NAPY. Muſtard.

NARCE, from ναρκη, *the torpedo fiſh*, which is ſaid to ſtupefy in its touching, whence narcotica. A torpor, ſtupor, or dulneſs of ſenſation. It alſo ſignifies a ſtupefaction of the ſenſes by medicines, in order to render a perſon leſs ſenſible of pain.

NARCISSO-COLCHICUM. A ſpecies of lilio-narciſſus, remarkable for nothing but the beauty of its flower. Boerhaave calls it lilio narciſſus luteus autumnalis minor.

NARCISSO-LEUCOIUM. The flowers conſiſt of ſix leaves, in the form of a lily, and the root is bulbous. Boerhaave mentions ſix ſpecies; but they are not noted for any medical virtue.

NARCISSUS. The daffodil. Botaniſts enumerate many ſpecies; Boerhaave mentions forty-ſeven; but their virtues as a medicine hath not gained them a place in practice.

NARCISSUS PALLIDUS CIRCULO LUTEO. Common pale daffodil, or primroſe-peerleſs.

NARCISSUS LUTÆUS SYLVESTRIS, alſo called bulbocodium, codianum, codiaminum flore codii, bulbus ſylveſtris, pſeudo-narciſſus Anglicus. Wild daffodil.

The roots of theſe are ſomewhat purgative and emetic; the doſe is two drams in infuſion.

NARCOSIS, from ναρκη, *torpor, ſtupor, numbneſs.* A ſtupefaction.

NARCOTICA. Narcotics, from ναρκαω, *to affect with a ſtupor or torpor*, or ναρκη, *torpedo*, a fiſh which ſtupefies what it touches. Narcotics are ſoporiferous medicines which induce ſtupefaction. See ANODYNA.

NARDUS INDICA, called alſo ſpica, ſpica Indica, ſpica nardi, nardus Syriaca. Indian ſpikenard, nard, or Syrian nard. It is the andropogon nardus, Linn.

Dioſcorides makes the India and the Syrian nard to be different, but they are the ſame. They are the buſhy top of the root, or the remains of the withered ſtalks and ribs of the leaves of an Indian graſſy leaved plant, of which we have no particular account. The nard, as brought to us, is a congeries of ſmall, tough, reddiſh brown fibres, cohering cloſe together, but not interwoven, ſo as to form a bunch or ſpike about the ſize of a finger: ſometimes two or three bunches iſſue from one head, and ſometimes bits of leaves and ſtalks in ſubſtance are found among them. The ſpikenard of India and Syria alike reſemble valerian in their virtues; but the Indian is warmer and more ſpicy than the Syrian; it is alſo ſomewhat pungent and bitteriſh. It alſo agrees very nearly in its virtues with cyprus.

NARDUS CELTICA, alſo called ſpica Celtica, ſalinuca, Celtic ſpikenard. It is the valeriana Celtica, Linn. It is a ſmall ſpecies of valerian, with uncut, oblong, obtuſe, oval leaves; it is a native of the Alps, from whence we have the dry roots, conſiſting of a number of blackiſh fibres, with the lower parts of the ſtalks adhering, which laſt are covered with thin yellow ſcales, the remains of the withered leaves. Its virtues reſemble thoſe of valerian.

There is a mountain nard, but it is only the root of the large valerian. Non of theſe are in much eſteem in practice. See Raii Hiſt.

The wild nard, i. e. aſſarabacca, is chiefly uſed amongſt farriers; but it is uſed as a ſternutatory in medical practice.

NARDUS ITALICA. Broad leaved lavender.

NARDOSTACHYS. Spikenard.

NAREGAM. A name of two ſorts of Indian lemon tree.

1. Mal-Naregam. A ſort of dwarf lemon-tree growing in Zeylon and Malabar. It differs from a lemon only in its having but one ſeed.

2. Tſjeron-katou-neregam. This ſpecies hath always flowers and fruit upon it. It is found in the ſame countries with the firſt kind. See Raii Hiſt.

NARES. The noſtrils. The internal nares, or cavity of the noſe, comprehend the whole ſpace between the external *nares*, and the poſterior openings immediately above the arch of the palate, by which a probe may be paſſed from the noſe to the fauces, from whence thoſe cavities reach upward as far as the lamina cribroſa of the os ethmoides, where they communicate forward with the ſinus frontales, and backward with the ſinus ſphenoidales. Into the noſtrils, the two frontal ſinuſes, the two antra Highmoriana, the cellulæ of the os cuneiforme under the upper ſpongeous bone of the noſe, open into the noſtrils, and excrete the mucus thereinto. The ſpongeous bones, which are two in each noſtril, are covered with the mucous membrane alſo; whence mucus is collected and diſcharged, and thus the ſurface of the mucous membrane of the noſtrils is enlarged. The olfactory nerves, without their duramatral covering, pierce through the holes in the os ethmoides, and ſpread themſelves on the mucous membrane of the noſtrils; a branch from the fifth pair is alſo ſent here.

In Heiſter's Surgery is an inſtance of cure, when the noſtrils, after the ſmall-pox, were cloſed up. An opening was made into them with a ſmall knife, and kept diſtended until the wound was healed.

NARIFUSORIA. Medicines which are inſtilled into the noſtrils.

NASA. See NATA.

NASALE. An errhine.

NASALIS ARTERIA. See MAXILLARIA EXTERNA ARTERIA.

NASALIS, alſo called compreſſor naris, and rinæus. It riſes fleſhy from the extremity of the os naſi, and adjacent parts of the os maxillare, and is inſerted into all the cartilages of the ala. It dilates the noſtrils.

NASALIS PROCESSUS. See MAXILLARIA SUPERIORA OSSA, and OS FRONTIS.

NASCALE. A ſort of peſſary made of wool or cotton.

NASCAPHTHON, i. e. Caſcarilla.

NASDA, i. e. Naphtha.

NASI OSSA. The bones of the noſe. Theſe are the two ſmall bones which compoſe the upper part of the noſe, and are ſupported by the ſeptum naſi.

NASITAS. A ſpeaking through the noſe.

NASO PALATINI DUCTUS, i. e. Inciſorii ductus.

NASTOS. The walking cane.

NASTURTIUM. Quaſi naſi tormentum, to be the torment of the noſe, becauſe the acrimony of the ſeed, whilſt it is bruiſing, excites ſneezing. In all reſpects it reſembles the mithridate muſtard with a leſs foliaceous margin, and multifid leaves to diſtinguiſh it. Boerhaave enumerates eleven ſpecies.

NASTURTIUM HORTENSE. Common garden creſſes. A low plant, with variouſly cut, winged leaves, bearing on the top of the round ſtalk and branches tufts of tetrapetalous white flowers, which are followed by roundiſh capſules, flatted on one ſide, and full of reddiſh round ſeeds. It is annual, and raiſed in gardens. It is an uſeful dietetic herb in ſcorbutic caſes, when viſcid juices are the fault in the conſtitution, and when the chylopoetic organs are weak. It is nearly of the ſame qualities as water creſſes, but ſomewhat milder. The ſeeds are more pungent than the leaves, and agree in their general qualities with thoſe of muſtard.

NASTURTIUM AQUATICUM, called alſo laver odoratum, ſiſymbrium, cardamine. Water creſſes. Siſymbrium naſturtium. Or ſiſymbrium aquaticum, foliis pinnatis, foliolis ſubcordatis, floribus albis tetrapetalis, ſiliquis declinatis, Linn. A juicy plant with browniſh, oblong, obtuſe leaves, ſet nearly in pairs, without pedicles, on a middle rib, which is terminated by an odd one, larger and longer pointed than the reſt. The ſtalks are hollow, pretty thick channelled and crooked; on the tops grow tufts of ſmall tetrapetalous white flowers followed by oblong pods, which burſting, throw out a number of roundiſh ſeeds. It grows in rivulets, and the clearеſt ſtanding waters, and flowers in June. The leaves remain green all the winter, but are in the greateſt perfection in ſpring.

The leaves are, to the taſte, moderately pungent; when rubbed betwixt the fingers, they emit a quick penetrating ſmell like that of muſtard, but weaker. This herb is a mild, acrid, aperient antiſcorbutic, of the ſame general virtues with the garden ſcurvy-graſs, but much leſs pungent, and, in a great meaſure, free from the peculiar flavour thereof. The expreſſed juice carries with it all the virtue of the plant; but whether the leaves are eaten as a ſallad, or the juice taken alone, their uſe ſhould be continued ſome time, and the quantity of either, not ſparing, if much benefit is expected.

NASTURTIUM INDICUM, alſo called acriviola, flos ſanguineus Monardi, naſturtium Peruvianum, cardamindum minus. Indian creſs, or yellow lark-ſpur. The leaves are round and umbilicated, and placed alternately; the ſtalks are trailing, the flowers conſiſt of fine leaves, formed like violets; the ſeeds are round and rough, three of them ſucceed in each flower. It is a native of Peru. Miller enumerates five ſpecies. Their young ſhoots are uſed as pickles. Their medical virtues are ſimilar to thoſe of the common ſort with us. See Raii Hiſt. Lewis's Mat. Med.

NASTURTIUM. A name for a ſpecies of thlaſpi, of araliaſtrum, and of ſeveral other plants.

NASUS. The noſe. The external parts of the noſe are the root, the arch, the back or ſpine, the ſides, the tip, the wings, the external nares, and the part under the ſeptum. The internal parts are, the internal nares, ſeptum narium, the circumvolutions, the conchæ ſuperiores, the conchæ inferiores, the poſterior openings of the internal nares, the ſinus frontales, ſinus maxillares, ſinus ſphenoidales, ductus lachrymalis, and ductus palatini. The nerves are the olfactory, and a branch from the fifth pair. The cartilaginous part of the noſe keeps alway open to admit of reſpiration. It grows narrower a little above like a funnel. The membrana pituitaria, which lines the noſe, is very vaſcular and papillous at thoſe parts where it is moſt expoſed to the ſtream of the air. The whole membrane is full of ſmall glands which ſeparate mucus; and this membrane gives riſe to polypous excreſcences.

The noſtrils of infants are ſometimes obſtructed, and it is common to greaſe the *noſe* in order to relief in this caſe; but three or four grains of white vitriol diſſolved in half an ounce of water, anſwers much better for ſoliciting a diſcharge of the too viſcid mucus.

NATA or NATTA. A ſort of tumor of the wen kind; it hath a narrow baſis, but a much larger body. Linnæus ſpeaks of it as rooted in a muſcle.

NATARON, i. e. Natron.

NATATIO. Swimming. It is uſeful in ſummer, is promotes perſpiration, and attenuates the fluids, but it injures the head. Oribaſius gives ſome further directions on this ſubject in lib. vi. cap. cap. 27.

NATES. The buttocks. Alſo a name of two prominences of the brain, which are alſo called teſtes.

NATRON. See ANATRON.

NATSIATAM. The tree which bears the coculus Indicus.

NATURALIA. The pudenda.

NAUSEA, from ναῦς, *a ſhip*. This is properly the ſickneſs perceived on ſailing; but it is uſed to expreſs all ſorts of ſickneſs, and propenſities to vomit, whether called ſickneſs, nauſea, qualm, loathing, or whatever elſe.

Nauſea may be defined to be an approach to ſickneſs. It is ſuch a ſubverſion of the ſtomach, as that it reſts not in its natural, eaſy ſtate. Sickneſs is that affection of the ſtomach, whence there is an inclination of the actual ejection of it contents.

Sea-ſickneſs depends on nervous irritability and ſpaſms; it is a diſeaſe of the brain from the unuſual motion which the ſhip gives it, and from thence, by conſent of parts, it is carried to the ſtomach, where it occaſions vomiting. Long voyages uſually overcome this diſorder, but ſhort ones ſeldom do. Keeping the bowels ſolutive is always found to relieve; and drinking ſea-water with wine is a preventive from ſea-ſickneſs in many.

A nauſea is deſcribed by ſome as a gentle convulſion of the œſophagus, accompanied with an inverſion of its periſtaltic motion, and producing an inclination to vomit. Others again ſay, it is the idea of ſome ungrateful ſubſtance, accompanied with ſpaſms of the œſophagus and ſtomach. Generally it is an attendant on dyſpepſia.

The lips are covered with the continuation of the inner coat of the ſtomach, whence whatever vellicates this coat, either in the ſtomach, or œſophagus, and often in the mouth, occaſions a *nauſea*, or a ſickneſs.

A *nauſea* always precedes a vomiting, and then it is attended with a tremulous motion of the lips. It attends all inclinations to vomit, and cardialgias. It is often attended with a diſcharge of a limpid mucus from the ſtomach, or œſophagus, or both, when no inclination to vomiting is preſent; and this happens from the ſpaſms affecting the glands there. It often indicates worms in the primæ viæ. It generally ſucceeds crudities in the ſtomach, which, as they are acrid, when the ſtomach is empty, they then particularly excite a *nauſea*, which, however, is alleviated by taking any kind of aliment. It precedes violent diſorders in the head, eſpecially ſuch as derive their origin from the upper orifice of the ſtomach. It attends hypochondriac diſorders, and others, the ſomes of which lodge in the primæ viæ; and in the beginning of malignant fevers it is generally attendant.

According to the variety of cauſes, the remedies will be, when acrid ſordes in the primæ viæ produce a *nauſea*, preſent relief is obtained from a freſh ſupply of food, and a gentle emetic, or a few aloetic purges will often remove

move the diſorder. Indeed, in general, after theſe general evacuants, warm, ſtrengthening, ſtomach medicines, ſeldom fail to cure.

If an exceſſive uſe of ſpirituous liquors is the cauſe, the warmth of the bed, riding, and the elixir of vitriol, ſucceeds the beſt.

In the beginning of fevers, when bile regurgitates into the ſtomach, and in many other inſtances of *nauſea*, and even of vomiting, the colombo root is almoſt a ſpecific.

A *nauſea* may be relieved, in general, by the ſame means as a vomiting. See VOMITUS.

NAUTICUS, i. e. Tibialis poſticus. It is ſo called from the uſe which ſailors make of it in climbing.

NAVICULARE OS, or Naviforme, from *navicula, a little veſſel*, See SCAPHOIDES.

NAVIGATIO. Sailing. It is beneficial to weak perſons. In a calm, when the ſhip's motion is gentle, an uncommon alacrity, an increaſed perſpiration, a keener appetite, and a quicker digeſtion, are excited; but when a patient is very weak, the violent agitation of a ſhip in a rough ſea is not very ſafe.

See Obſ. on Diſeaſes incident to Seamen, by Lewis Rouppe, M. D. The Uſe of Sea Voyages in Medicine, by E. Gilchriſt, M. D.

NEAPOLITANUM UNGUENTUM. Neapolitan ointment. Take of lard, waſhed with the juice of ſage, one pound; quickſilver, four ounces; oil of bays, chamomile, and worms, of each two ounces; oil of ſpike, one ounce and a half; ſpirit of wine, one ounce; wax, two ounces; turpentine, waſhed with the juice of elecampane, three ounces; the powder of ground pine and ſage, of each two drams: mix, and make an ointment.

This is now never made, the ung. coerul. mit. being ſubſtituted for it, as well as called by the ſame name.

NEAPOLITANUS MORBUS. A name for the lues venerea.

NEBI POULI. A ſpecies of bilimbi.

NEBULA. A wafer. Alſo a white ſpot in the cornea of the eye

NECESSARIÆ RES. The non-naturals.

NECROSIS, from *νεκρος, dead.* A mortification. It is called the dry gangrene. A mortification gradually takes place without much preceding inflammation; the dead parts become hard and dry.

NECROSIS OSTILAGINEA, i. e. Raphania.

NECTAR. The ancients fabled this to be the drink of the gods, whence many ſorts of liquors have been thus called.

NEDUM-SCHETTI. The name of a bacciferous ſhrub which grows in the Eaſt-Indies, of which an ointment is made by boiling in oil, and is then uſed againſt pruriginous diſorders.

NEDYIA. The abdominal viſcera.

NEDYS. The ſtomach, or the belly.

NEDYUSA. An epithet for thirſt, ſignifying its being violent.

NEFRENDES. Properly it is ſucking pigs; but it is applied to young children, or old people, who have no teeth.

NEGUNDO MAS & FŒMINA, i. e. Vitex trifolia minor Indica ſerrata, & vitex trifolia Indica rotundifolia.

NEIÆRA. The lower part of the belly.

NEIEM-EL-SALIB. An Egyptian name for the croſsgraſs, which is alſo called gramen dactylon Ægyptiacum, gramen crucis. Egyptian cock's-foot graſs, and graſs of the croſs.

NELUMBO. A name for the Egyptian bean.

NEMOROSA, i. e. Anemonoides.

NENUFAR, i. e. Flor. nymphæa, and leuco nymphæa.

NEPA, a crab, a ſcorpion, and a ſpecies of broom.

NEPENTHES, from *νη*, importing *negation*, and *πενθος, mourning.*

The *nepenthes* of the Egyptians was, according to Olaus Borrichius, a preparation of opium and dutroy, both the produce of Egypt. Romantic accounts are given of it. See Schultz's Hiſt. Med.

NEPENTHES, called alſo planta mirabilis, the wonderful plant, bandura, utricaria, priapus vegetabilis, aromatico. It is a plant which grows in thick foreſts, in the iſland of Ceylon, where its long fibres ſupply it with water, and where no ſun comes to exhale it. Its root is ſaid to be aſtringent, and the herbs cooling; but it is moſt remarkable for its appendages at the ends of the leaves, which turn up, and contain a cooling limpid liquor.

NEPETA. Catmint. See Cataria auguſtifolia major.

NEPETELLA, i. e. Cataria minor vulgaris.

NEPHRALGIA. Pain in the kidneys or ureters; alſo inflammation there.

NEPHRALGIA RHEUMATICA. The rheumatiſm in the muſcles of the loins. The ſame as lumbago.

NEPHRELMINTICA (ISCHURIA). A ſuppreſſion of urine from worms.

NEPHRITICA (ISCHURIA). A ſuppreſſion of urine from inflammation of the kidneys.

NEPHRITICA AQUA. See NUX MOSCHATA.

NEPHRITICUM LIGNUM, alſo called lign. peregrinum, nephritic wood. Dale thinks it to be the wood of the tree which bears the ben nut. It is the guilandina moringa, Linn. It is brought from America in large compact pieces; the out-part is of a whitiſh, or pale yellowiſh colour; the medullary ſubſtance is of a dark brownifh, or reddiſh colour. If it is bruiſed, and macerated in water for half an hour, or an hour, it imparts a deep tincture, appearing, when placed betwixt the eye and the light, of a golden colour, but, in other ſituations, of a fine blue colour; a property in which it differs from all other known woods. Pieces of other woods are often mixed with it, which only give a yellow tincture. If this wood is ſteeped in rectified ſpirit of wine, the ſame blue tincture is obſerved as when water is the menſtruum; if an acid is joined to the tincture, it becomes yellow, but the blue is again reſtored by an alcali. It is the only vegetable blue that is deſtroyed by acids.

To the taſte it is ſlightly bitter, and the raſpings have a faint aromatic ſmell. A ſtrong infuſion of it in water is gently aſtringent, and is recommended in diſorders of the urinary paſſages. It does not, like the warmer diuretics, heat, or otherwiſe offend the parts; but its efficacy hath not obtained it a place in general practice. See Raii Hiſt. Lewis's Mat. Med.

NEPHRITICUS, from *νεφρος, a kidney.* Belonging to the kidneys. It is uſed with reſpect to diſorders of theſe, or to medicines adapted to their cure.

NEPHRITICUS LAPIS, called alſo lapis Indicus nephriticus. Nephritic ſtone. It is a greeniſh, tranſparent, foliated ſtone, of the nature of French chalk. It hath been worn as an amulet againſt diſorders of the kidneys. See Neumann's Chem. Works; Dict. of Chem.

NEPHRITIS. Any diſtemper in the kidneys, from *νεφρος, a kidney.* An inflammation in the kidneys. This diſorder is not very frequent, for a determination of the fluids to the kidneys occaſions an increaſed ſecretion of urine, ſometimes mixed with blood, which prevents inflammation. Dr. Cullen places this genus of diſeaſe in the claſs pyrexiæ, and order phlegmatiæ.

The general cauſes are, whatever hinders the extremities of the arteries from tranſmitting their fluid; as a wound, contuſion, abſceſs, a tumour, a long continued defluxion, a ſmall ſtone, &c. whatever hinders the conveyance of the urine into the pelvis, ureters, and bladder; ſuch as forcibly convey the thicker parts of the blood into the urinary ducts, as running, violent riding, exceſſive heat, an effort of the body, a plethora, acrid diuretics, poiſons, &c. a long continued ſpaſmodic contraction of theſe veſſels. When theſe veſſels are ſeized with a violent inflammation, they are often ſo conſtricted, that no urine can be diſcharged; or if a ſmall quantity is evacuated, it is pellucid, thin, and aqueous, which is an unpromiſing ſign; the nerves cohering to theſe veſſels, and lying contiguous to them, being often irritated, pains and convulſions are produced in the ſtomach, meſentery, inteſtines, and uterus; hence ariſes eructations, nauſeas, vomiting, fluxes, iliac paſſions, retentions of urine, ſtupor, immobility of the legs, &c. preternatural heat in the loins.

A ſtone in the kidney uſually excites inflammation in the internal membrane thereof, and in the tubuli uriniferi.

The inflammation begins with a pungent burning pain in the region of the kidney, that is in the back, near the

articulation of the ſhort ribs, higher up on the left-ſide than on the right, often ſhooting down by the ureters to the bladder, and by the ſpermatic cord to the teſticle; a fever; the urine is ſometimes red at the firſt, but ſoon becomes pale, and is frequently diſcharged in ſmall quantities, and that with difficulty, pain, and heat. Sometimes a redneſs appears externally; the thigh and leg of the affected ſide is ſeized with a ſtupor; the pain is increaſed upon ſtanding, walking, couching, lying on the oppoſite ſide, or in any other caſe where the kidney is moved, or the ſurrounding part extended; there is pain in the groin, and in the teſticle next adjacent; the pulſe is hard and frequent, and, as the pain encreaſes, it often becomes ſmall, quick, and ſometimes intermittent, with coldneſs of the extremities, cold ſweats, ſickneſs, bilious vomitings, fainting, delirium, convulſions, &c. The patient lies with the moſt eaſe on the affected ſide.

An inflammation in the kidnies ſhould be diſtinguiſhed from the gravel, a ſtone obſtructing the ureter, an inflammation of the pſoas muſcle, or other adjacent parts, from the colic, and other inflammatory and ſpaſmodic pains in the inteſtines.

If the diſeaſe is protracted beyond the ſeventh or eighth day, and there is a ſtupor or heavineſs of the part, with frequent returns of chillineſs and ſhivering, &c. there is reaſon to ſuſpect that matter is forming in the kidney, and that an abſceſs will enſue.

If the urine becomes higher coloured, is ſecreted in a larger quantity, and at laſt is copious, thick, and mixed with mucus, a gradual relief follows, and thus the cure is effected. It may go off by a metaſtaſis, or terminate in an abſceſs, mortification, or a ſchirrhus. Inflammations in this part often ſuppurate on the fourth day, if not prevented by either a natural, or an artificial attempt towards a cure; but yet theſe failing, an abſceſs may be began ſo late as the fourteenth day. This abſceſs may be diſcharged into the pelvis, the abdomen, or externally through the integuments and the ſkin; in the firſt caſe, if the matter is kindly, a cure may follow, but otherwiſe an hectic deſtroys the patient; in the ſecond caſe it is fatal; and, in the third, an ulcer, of very uncertain cure, is formed.

When the preſence of this diſorder is once manifeſted, immediately bleed, and in general proceed as in other internal inflammations.

Decoctions of parſley roots, infuſions of line-ſeed, or the Arabic emulſion, with a double quantity of the gum, are convenient as common drink; and to prevent their palling the appetite, a little lemon juice and ſugar may be added to render them grateful.

A moderately warm ſemicupium, and laxative clyſters frequently injected, contribute much to promote the ſecretion of urine.

If inflammation appears externally, apply fomentations and poultices to the part ſo affected.

In caſe of a ſuppuration, the treatment is nearly the ſame as in a ſuppuration of the liver. After the abſceſs is burſt, the patient ſhould drink freely of a decoction of marſhmallow roots, or ſuch like liquors, and take the bark freely. In this caſe the bark is preferable to the uſual method of adminiſtering balſamics.

If pains are exceſſive, give opiates to moderate them; and if vomiting is troubleſome, give tepid water, ſweetened with honey, and let the patient drink ſmall quantities frequently.

If a gangrene takes place, it is known by the violence of the cauſe of the ſymptoms, the want of relief by remedies, and the ſudden remiſſion of the pain without apparent cauſe, cold ſweats, a weak intermittent pulſe, hiccoughs, either no diſcharge of urine, or ſuch as is livid, black, full of hairs, fetid, and foul, with a ſudden and conſiderable loſs of ſtrength. In thoſe caſes, no cure can be expected.

See Boerhaave's Aphoriſms, and Van Swieten's Comments thereon; Fordyce's Elements, part the ſecond; Brooks's, and the London Practice of Phyſic.

NEPHROLITICA (Ischuria). A ſuppreſſion of urine from the ſtone in the kidneys.

NEPHROMETRÆ. The pſoæ muſcles.

NEPHROPLETHORICA (Ischuria). A ſuppreſſion of urine from a plethora.

NEPHROSPASTICA (Ischuria). A ſuppreſſion of urine from a ſpaſm in the kidneys.

NEPHROTHROMBOIDES (Ischuria). A ſuppreſſion of urine from grumous blood in the kidneys.

NEPHROPYICA (Ischuria). A ſuppreſſion of urine from purulent matter in the kidneys.

NEPHROPHLEGMATICA (Ischuria). A ſuppreſſion of urine from pituitous or mucous matter in the kidneys.

NEPHROPLEGICA (Ischuria). A ſuppreſſion of urine from a paralytic ſtate of the kidneys.

NEPHROS. A kidney.

NEPHROTOMIA. Nephrotomy. It is the extracting of a ſtone from the kidneys by a wound made for that end. Rouſet was the firſt who adviſed this operation. In Mezeray's Hiſtory of France is the following narrative: "The doctors of the faculty of phyſic at Paris, knowing that an archer of Bagnolet, who had been very much afflicted with the ſtone, lay under ſentence of death, begged of the king that he might be put into their hands, to make an experiment whether they could open the kidney, and take out the ſtone. They obtained their requeſt, and the operation ſucceeded ſo well, that the man lived many years after in good health."

Many writers ſpeak in favour of this operation, and aſſert that it is practicable with ſafety; but from the courſe of the renal artery it does not appear to be poſſible, without deſtroying the patient. See Renes. Beſides the objection from the renal artery, there are others apparently inſurmountable. See Avicenna, Scrapion, Wedelius, Meckren, Heiſter, Med. Muſ. vol. ii. p. 370.

NERANTIA. An orange.

NERION, called alſo nerium, rhododaphne, rhododendron, oleander, laurus, roſea, roſe-bay. It is called nerion, from *νι*, a privative particle, and *ϛεργω*, *to love*; that is to ſay, a plant not to be loved. *Nerium*, from *νερον*, *humid*, becauſe it grows in moiſt places. Rhododaphne, from its flowers reſembling a roſe, and its leaves a bay-tree. Rhododendron, becauſe it ſometimes grows to the ſize of a little tree, and hath a flower like a roſe. The branches are divided and ſubdivided by threes, and the leaves grow three together. It grows in maritime places. The leaves and flowers are poiſonous; if any of them are ſwallowed, deglutition is immediately ſtopped, but vomiting and purging ſoon comes on. Vinegar is an antidote in this poiſon. See Raii Hiſt.

NEROLI OLEUM. It is the eſſential oil of orange flowers. See Aurantium.

NERONIANA. An epithet for veneſection, when more than one vein is opened in a day.

NERVALIA OSSA, i. e. Arcualia oſſa.

NERVEA SPONGIOSA, i.e. Corpora cavernoſa penis.

NERVI. The nerves. *Nerve* was a name among the antients given to a genus, of which there were three ſpecies, viz. the *nerves*, ſo called by the moderns, the tendons, and ligaments; but afterwards the word was confined to thoſe productions of the brain, which are the means of ſenſe and motion in every part. They are continuations of the medullary ſubſtance of the brain; and, like the brain, they have an infinite number of blood veſſels diſperſed about them. They receive their ſtrength from the membranes that ſurround them. They have two coats, at leaſt as far as the eye can trace them, one from the pia mater, the other from the dura mater. The *nerves* are ſuppoſed to depoſit their coats when they arrive at the place of office. In their riſe and progreſs from the brain they are ſuppoſed to decuſſate each other, that is, thoſe which riſe on the right ſide of the brain paſs out on the left, and thoſe which riſe on the left paſs out on the right; their origin, however accurately traced, cannot be found out: that they decuſſate each other, is ſuggeſted at leaſt from a concuſſion of the brain, in which caſe, a blow is received on one ſide, and the injury done is on the other; but again, there are many exceptions to this. Frequently the nerves form plexuſes in their courſe, in which they become one. In their courſe through the body they commonly branch with the blood-veſſels, but ramify more regularly. That junction which in the arterial and venal ſyſtem is called anaſtomoſis, in the *nerves* is denominated communication. From this communication of *nerves*

ſome

ſome inſtances of ſympathy are accounted for; but how far this is the truth is not eaſy to aſſert, as there is hardly a *nerve* but in its paſſage communicates with ſome branch of almoſt every *nerve* in the body. In the ganglions of the *nerves* there is always a particular redneſs, on which conjectures are formed by different anatomiſts, but their opinions are not well ſupported: Lanciſi ſays that theſe ganglions are only on thoſe *nerves* which are governed by the will.

All the *nerves* in the body originally proceed from the cerebrum or cerebellum, by means of the medulla oblongata, or medulla ſpinalis. They go out in pairs, and are afterwards divided into branches to be diſtributed on all parts of the body.

From the head there goes out ten pair of *nerves*; the firſt and ſecond pair proceed from the cerebrum, and are called the olfactory or firſt pair; and the optic *nerves*, or ſecond pair. The reſt proceed from the cerebellum, and are called motores oculorum, or third pair; pathetici, or fourth pair; trigemini, or fifth pair; motores oculorum externi, or ſixth pair; auditorius, or ſeventh pair; par vagum, or eighth pair; hypogloſſi externi, or ninth pair; ſuboccipitales, or tenth pair.

From the ſpinal marrow there goes out about twenty-four pair, which have the general name of vertebrales; ſeven of which paſſing through the vertebræ of the neck, are called cervicales; twelve paſs through thoſe of the back, and are called dorſales; five paſs through thoſe of the loins, and are called lumbares; and there are five or ſix pair which, paſſing through the os ſacrum, are called ſacri *nervi*.

The *nerves* that ſubſerve the vital functions ariſe from the cerebellum; thoſe that are ſubſervient to the ſenſes proceed chiefly from the baſis of the brain; and thoſe that are deſtined to the voluntary motions of the touch, are principally from the ſpinal marrow.

In many inſtances, if a nerve is cut, compreſſed, or deſtroyed, all motion, ſenſation, and nutrition in that part to which the nerve is diſtributed is loſt; yet this does not always happen, for if all, or at leaſt the principal *nerves* in the part are not deſtroyed, it recovers its health and vigour. This is evident in performing the operation for the aneuriſm, in which caſe, if the nerve is tied with the brachial artery, a temporal numbneſs only is felt, and ſenſation in any degree below the ligature is not loſt. If a ligature is made on the *nerve* on the ſide of the windpipe, the animal will be dumb. If a pointed inſtrument is puſhed between the occiput and atlas of a dog, he dies inſtantly. The ſame ſymptoms happen in wounds of the cerebrum, cerebellum, and medulla ſpinalis. All nerves which have their origin from below an injury of the medulla ſpinalis, loſe their ſenſe and motion. A member may be deprived of its motion, and yet not loſe its ſenſation, or it may loſe its ſenſation and retain its motion. Senſation remains ſome time after the limb is amputated. Preſſure makes a part paralytic. As the *nerves* are continuations of the medullary part of the brain and ſpinal marrow, it is probable that they are partly nouriſhed by thoſe veſſels which are ſpread on that production of the pia mater which ſurrounds them, in like manner as the brain derives it nouriſhment from the arteries of the pia mater; if this be the caſe, we may readily ſee why the *nerves* loſe their powers when they are wholly deprived of the arterial blood, and alſo retain them, in ſome meaſure, after the brain is oſſified and petrified.

The *nervous* fluid is often ſpoken of as ſynonimous with the animal ſpirits, &c. But Dr. Kirkland obſerves, in his Inquiry, vol. i. p. 433, that, by *nervous* fluid, we mean what we diſcover upon diſſecting the brain or *nerves*; and which a rupture in the tumour, accompanying the biſid ſpine, diſcovers to be eſſentially neceſſary to life: for we may eaſily ſuppoſe a fluid reſiding in the *nerves*, of ſuch high importance to life as it evidently appears to be, to bring on (when both the *nerves* and itſelf are diſeaſed) the *nervous* ſymptoms we diſcover before the gouty matter is thrown off into the extremities, &c. in other inſtances of diſeaſe.

There are many claſſes of *nerves* differing in ſmallneſs, and it is ſuppoſed that one claſs may remain entire, while another is ſomewhat hurt, and perhaps this is the cauſe of a gradual decline of the ſenſes.

It is alſo to be obſerved that ſome *nerves* are ſuſceptible of one impreſſion only, or with ſuch at leaſt as many others are not affected by; e. g. the ſemen ſtimulates the *nerves* of the teſticles and veſiculæ ſeminales, but of no other part; ſome aſſiſt in viſion, others ſmell, &c.

On the *nerves*, their uſe, &c. ſee Winſlow's Anatomy, where the *nerves* are very accurately deſcribed; Monro's Diſſ. on the Nerves; it is annexed at the end of his Oſteology; beſides theſe, the curious may conſult Steno, Vieuſſens, Willis, Ridley, Leuwenhoeck, and Ruyſch. See alſo Hale's Stat. Eſſays, vol. ii. p. 59, 60; Whytt on the Sympathy of the Nerves and Nervous Diſorders; Kirkland's Diſſ. on the Brain and Nerves, and on the Sympathy of the Nerves. Monro on the Structure, &c. of the Nerves.

NERVOSUS FEBRIS. The nervous fever. Under this name we may conſider nervous diſeaſes in general; they are a numerous kind of complaints. Sydenham ſays that fevers make two thirds of the diſorders to which men are ſubject, and the hyſteric (or, as we may ſay, nervous diſorders) one half of the reſt. From difference in degrees, or other circumſtances, the different denominations ariſe, and from a ſimple yawning to the outmoſt extreme of madneſs is the extent in which theſe varieties are manifeſted. In ſome the fever is latent, in others it is leſs obſcure, ſo that with its epithet it denominates the diſeaſe; whence ſome have defined nervous diſorders in their oppoſite extremes to be, the habitual or chronical, and the acute, nervous fever. Dr. Cullen places the nervous fever under the name of typhus, in the claſs pyrexiæ, and order febres.

When theſe diſorders are chronical, though the ſtomach, or guts, or other particular part may moſt be complained of, the cellular membrane is probably their immediate ſeat. When the caſe is acute, a contaminated lymph is the ſource of every morbid ſymptom.

The chronical kinds are called vapours, hyſterics, hypochondriac diſorder, &c. The acute is uſually denominated the *nervous fever*, little fever, ſlow fever, a fever on the ſpirits, &c.

Thoſe who have diſordered viſcera, lead ſedentary lives, are ſtudious, oppreſſed with long anxiety, who are eaſily affected by external occurrences, &c. are the moſt ſubject to nervous complaints.

The ſymptoms attendant on nervous complaints reſemble almoſt every diſorder that the human body is ſubject to: according to the part more immediately affected, and the peculiarities of the patient's conſtitution, the different diſeaſes proper to that part, will ſeem to preſent themſelves. As the occaſional cauſe then is, and the part in which its influence is exerted, the ſymptoms will be, wind in the ſtomach and bowels, heart-burning, ſour belching, ſqueamiſhneſs, and ejection of a watery fluid or other kind of matter from the ſtomach, a want of appetite, and indigeſtion, or an uncommon craving of food, and quick digeſtion, debility, faintneſs, a ſenſe of emptineſs about the ſtomach when hungry, a ſtrong deſire for uncommon food, inflations of the ſtomach, pain and cramp in the ſtomach, oppreſſion about the præcordia, uneaſy though not painful ſenſations about the ſtomach, low ſpiritedneſs, anxiety, timidity, ſtrong pulſations within the belly, ſpaſms in the bowels, diſtenſions of portions of the bowels, colic pains, a grumbling noiſe in the bowels from wind, the belly often lax, but more frequently coſtive, pains in the back and belly reſembling the gravel, a ſenſe of irritation and heat in the neck of the urethra, with a frequent deſire of making water, a copious diſcharge of limpid urine, frequent ſpitting, ſudden ſluſhes of heat all over the body, ſhiverings, a ſenſe of cold in certain parts as if water was poured on them, and at other times an univerſal glow, flying pains in the limbs, pain in the back and between the ſhoulders, pains attended with a hot ſenſation, ſhifting often from the ſides or back to the interior parts of the abdomen, cramps or convulſive motions of the muſcles, or of a few of their fibres, ſudden ſtartings of the legs or arms, frequent involuntary motion of the muſcles of the neck, or head, or arms, or legs; a general convulſion affecting at once the ſtomach, bowels, throat, legs, arms, and almoſt the whole body, in which the patient ſtruggles as in an epileptic fit; long faintings, which, in ſome inſtances, follow one another after ſhort intervals, palpitation of the heart, pulſe variable, a dry cough, with difficult

ficult breathing, or a conſtriction of the lungs, which in ſome perſons return periodically; yawning, hiccough, ſighing, a ſenſe of ſuffocation as if from a ball or a lump in the throat, crying, laughing; in the day the patient is moſtly cool, with a ſlow or natural pulſe, but in the time of ſleep hot flushes often ſpread over the whole body; the pulſe is quicker and ſtronger, and faintneſs or ſickneſs is felt; a giddineſs, eſpecially after riſing up haſtily; pains in the head, which in many return periodically; pain in a ſmall part of the head, which generally fixes on the crown, as if a nail was drove in; ſinging in the ears, dimneſs of ſight, miſt before the eyes, objects ſeen double, unuſual ſmells perceived, obſtinate watchings, ſometimes attended with uneaſineſs which is not to be deſcribed, but which is leſſened by getting out of bed; diſturbed ſleep, frightful dreams, night-mare, drowſineſs, fear, peeviſhneſs, ſadneſs, deſpair; at intervals the ſpirits are too active and gay, wandering thoughts, impaired memory, ridiculous fancies, ſtrange perſuaſions of their labouring under diſeaſes of which they are free, and imagining their complaints as dangerous as they find them troubleſome.

After being long afflicted with ſome of theſe (for they never are all attendant in the ſame perſon), the patient ſometimes becomes melancholy or mad, or goes into the black jaundice, a dropſy, the phthiſis pulmonalis, palſy, apoplexy, or other fatal diſtemper.

A fever coming on in patients much affected with theſe ſymptoms, or that is the effect of cauſes which will alſo produce them, forms the acute ſpecies of nervous diſorders, and the patient is then ſaid to labour under a *nervous fever*.

Thoſe who are liable to the above ſymptoms are diſtinguiſhed into the following claſſes.

1. Such as, though uſually in good health, are yet on account of a preternatural irritability of the nerves, apt to be affected frequently with violent tremors, palpitations, faintings and convulſions from fear and grief, ſurprize or other paſſions, and from whatever diſagreeably affects the more ſenſible parts of the body. Theſe may be called ſimply *nervous*.

2. Such as, beſides being liable to the ſymptoms mentioned in the firſt claſs, from the ſame cauſes, are always troubled with indigeſtion, flatulence, &c. may be ſaid to be hyſteric.

3. Thoſe who from a leſs delicate feeling are ſcarce ever affected with palpitation of the heart, fainting, &c. from diſturbed paſſions; but, on account of the diſordered ſtate of their ſtomach and bowels, are ſeldom free from indigeſtion, flatulence, want of appetite, or too great craving, and ſuch ſymptoms as therefrom ariſe; ſuch as belching, coſtiveneſs, oppreſſion about the precordia, low ſpirits, diſagreeable thoughts, diſturbed ſleep, &c. may be ranked as hypochondriac.

4. When a fever is manifeſt in a patient attended with nervous ſymptoms, or when a fever coming on from a cauſe which induces nervous ſymptoms, the diſorder is called a *nervous fever*. The ſymptoms of which are well deſcribed by Hippocrates as follow: "There are frequent tranſient chillineſſes in the day; a giddineſs or miſt before the eyes; a liſtleſſneſs, with great laſſitude and wearineſs all over the body; frequent yawnings, with little flying pains; dozing; inappetency; dryneſs of the lips and tongue; ſighings, with great and unaccountable anxiety; deliriouſneſs and forgetfulneſs by fits; oppreſſion and pain about the region of the heart and ſtomach; difficulty of breathing by intervals; the tongue generally white, but ſometimes redder than ordinary, together with a heat in it; a low, quick, unequal pulſe; heat and thirſt, but moderate; pale urine, often and ſuddenly made; frequent nauſeas and flushings; faintings on every the leaſt motion and ſurprize; cold clammy ſweats by turns; theſe, more or leſs, uſually accompany the *nervous fever*, and will continue thirty or forty days, unleſs ſtupors, ſyncopes, and death, end the ſcene before." Huxham deſcribes the *nervous fever* admirably; and Sir Richard Manningham, in his Febricula, is very particular in his deſcription of it, and to the above ſymptoms he adds, that the pathognomonic ſigns are:

1. A low, quick, and unequal pulſe, that is, it is ſwift, frequent and large, then preſently it becomes low and quick, &c. alternately; this, he obſerves, is its greateſt inequality, and is a characteriſtic of this fever.

2. A heat in the tongue, without much thirſt.

In all diſeaſes the nerves ſuffer more or leſs; but nervous diſeaſes are ſuch as ariſe firſt from a peculiar or preternatural irritability of the nerves in general, or of thoſe in any part in particular; whence, what is applied to them, whether of a morbid quality or not, may alike be productive of that variety of ſymptoms which form the deſcription above given; or, ſecondly, from the peculiar quality of ſuch morbid humours, &c. whoſe moſt manifeſt effects are from the diſorders which they excite in the nervous ſyſtem. But, perhaps, the firſt may more ſtrictly be called nervous, though the ſecond enlarge the liſts of diſorders ſo called, conſiderably.

The remote cauſes are numerous; they are violent paſſions; long continued ones in leſs degrees, ſuch as grief, fear, &c. indolence; exerciſe beyond the ſupplies received for a due ſupport; eager purſuits, whether of pleaſure or buſineſs, irregularity in diet, or in the general manner of living, a cold damp, or a hot and moiſt air, ſudden and great changes in the climate, defective perſpiration, exceſſive evacuations, and indeed whatever much leſſens the vis vitæ.

The immediate cauſes are a defect of vital heat, an acrimony from contagion, or from ſome other cauſe; and ſometimes the remote cauſe, viz. the peculiar or preternatural ſenſibility of the nerves is the immediate cauſe, as when nervous affections are excited by what in a natural or healthy ſtate of the nerves would be unperceived.

Many circumſtances occur to, or are attendant on, perſons ſubject to nervous diſorders, which prove occaſional cauſes; ſuch are flatulence in the ſtomach and bowels, worms, &c. there; ſchirrhous obſtructions in any of the abdominal viſcera, &c.

And as to the acute ſpecies, or *nervous fever*, if whatever can excite fever, is attendant on any of the immediate cauſes of nervous diſorders in general, there will no more be required to produce it.

Nervous diſeaſes, it is already obſerved, reſemble almoſt every other diſeaſe which affect the human frame, and oftentimes it is very difficult to diſtinguiſh thoſe ſemblances from thoſe which are reſembled; for, as ſcarce any part of the body is without nerves, and very few altogether without feeling, the nerves muſt not only ſuffer, when they themſelves, or the brain, or the ſpinal marrow are primarily affected, but alſo when the other parts are diſeaſed; and hence the difficulty, perhaps impoſſibility, of fixing a certain criterion by which nervous diſorders may at once be diſtinguiſhed from all thoſe not ſo called; though, in ſome inſtances, a ſmall degree of attention will enable us ſo to do.

The prognoſtics in nervous diſorders, of the chronical as well as of the acute, are both difficultly formed and uncertain; in the firſt, if the diſeaſe is recent and left to itſelf, it is rather troubleſome than dangerous; but a faulty treatment may be productive of other complaints, that are both difficult of cure and dangerous. In the ſecond, the favourable ſigns are, the ſymptoms being ſlight; the pulſe becoming fuller on the uſe of cardiacs; if toward the end of the diſeaſe a gentle ſweat or diarrhœa, but particularly if a ſalivation without aphthæ break out; or if miliary eruptions appear, without any preceding profuſe ſweat: the leſs favourable ones are, a coldneſs of the extremities, whilſt the reſt of the body is warm and perſpires; the fauces becoming livid; and reddiſh or purple ſpots appearing on the ſkin; but the following are fatal, viz. a trembling of the tongue, the nails becoming livid, the ſight failing or being nearly loſt, the delirium changing to a coma, the excrements diſcharged involuntary, and the tendons twitching.

However troubleſome *nervous* diſorders are, they have this advantage, viz. that their ſubjects are not very liable to thoſe of the inflammatory kind, and rarely, if ever, ſuffer much from them. But, before a cure is attempted, the patient ſhould be informed that his diſorder admits of relief, but hardly of a radical cure; for the remaining diſpoſition to be ſtrongly affected by ſlight cauſes, not being changed, relapſes are ſo eaſily occaſioned, that a continuance of health, when all manifeſt ſymptoms are removed,

moved, cannot be promiſed. Secondly, that without perſeverance in the uſe of means, no advantage can be expected. Theſe patients poſſeſs a degree of deſpair which makes them catch at every means of relief, more as charms than medicine; to this, and not to the inſufficiency of well ordered preſcriptions, the frequent want of ſucceſs is to be imputed. Mankind are highly pleaſed with ſudden miraculous cures, but their adherence to them is often fatal. Indeed, when nature fails, and ſtrength is inſufficient for co-operating with medicines, no expectations can be indulged.

The general indications of cure will be,

1. To palliate the ſymptoms.

2. To leſſen or remove the morbid irritability of the *nerves*.

3. To correct the occaſional cauſes, eſpecially the morbid ones.

1. To palliate the ſymptoms, the moſt remarkable of which, with the method of relief, are as follow:

Convulſive motions, or fixed ſpaſms. In theſe caſes, if ſlight, a gentle opiate given an hour before the approach of the fit, when its return can be gueſſed at, will often prevent it; but, in the more violent inſtances, bleeding ſhould precede, and then opiates muſt be given freely, both as to the largeneſs of the doſe and the frequency of the repetition. Beſides this, which of all others is the moſt powerful, the following in different degrees, and on different occaſions, afford the wiſhed-for relief; they are camphor, caſtor, muſk, fetid gums, æther, volatile alkaline ſpirits, &c. To theſe may be added, the warm bath, ſemicupiums, pedilaves, emollient clyſters, and warm fomentations. Sometimes the ſpaſms in one part are relieved by painful applications on another, ſuch as bliſters, acrid cataplaſms, and frictions; fear or ſurprize, when they can be prudently excited, may produce the moſt deſirable effect. Bandages tightly applied to the part affected, and continued for a ſhort time, will often procure relief. The particular cauſe being diſcovered, and the particular diſpoſition of the patient being attended to, will aſſiſt in determining which of theſe methods may moſt likely be ſucceſsful.

Fainting with convulſions. If the pulſe admits of it, bleeding ſhould be the firſt means uſed; the ſtrongeſt acid ſpirits ſhould be held to the noſe, or, in want of them, take the fetid and volatile alkaline ſpirits; hot bricks may be applied to the feet, and the legs, arms, and belly may be ſtrongly rubbed; or, if convenient, the legs may be put into water that is blood warm, or rather more ſo; and as ſoon as the patient can ſwallow, if the conſtitution is ſanguine and plethoric, give a draught of water, with a large ſpoonful or more of ſharp vinegar in it; but if the habit is lax and feeble, a gentle cordial is to be preferred.

Pain with cramps in the ſtomach. If there is a tendency to vomit, waſh the ſtomach with a few draughts of chamomile tea, after which give from fifty to eighty drops of the tinct. Theb. in ſix ounces of warm water, by way of clyſter. If the cramps return the clyſter ſhould be repeated; muſk ſhould be given in large doſes with ſome cordial liquid, the anodyne balſam may be rubbed on the region of the ſtomach, or the patient may be put into a warm half bath. Except great weakneſs forbids, bleeding ſhould be uſed, if the pain is violent.

Indigeſtion and vomiting, with pains in the ſtomach. When theſe happen from faulty humours in the ſtomach, vomits, gentle bitter purges, the teſtacea, elixir of vitriol, &c. are proper. If too great ſenſibility in the ſtomach is the cauſe, beſides ſtrengthening the ſtomach with the bark, bitters, &c. from five to thirty drops of laudanum may be taken an hour before dinner and ſupper. In ſome inſtances, a draught of warm water with a little brandy, after the principal meals, prevents thoſe ſymptoms.

An hyſteric or flatulent colic. If there is coſtiveneſs, give a laxative clyſter with a dram or two of aſſa fœtida diſſolved in it; and if there are troubleſome vomitings, after ſeveral draughts of water in which toaſted bread hath been boiled, give the ſame draughts with pepper-mint water, and a few drops of Thebaic tincture in each: or, if the Thebaic tincture was given clyſter-wiſe in warm-water, and the ſaline mixtures few allowed whilſt in the act of effervescence, the effects will be more certain and ſpeedy; beſides, if a thorough paſſage can be procured by means of a few pills with calomel and aloes, this operation will be much favoured by the opiate clyſters, and thus the ſymptom is, for this moſt part, effectually removed.

Flatulence in the ſtomach and bowels. Beſides keeping the body ſolutive, draughts of warm water may be taken, in which is a ſmall quantity of pepper-mint water, brandy, ſpirit of nitre, or ſpirit of hartſhorn, according as one or other are obſerved to be moſt generally uſeful; with ſome a little elixir of vitriol anſwers this purpoſe, and others require a few drops of laudanum.

The *nervous* or ſpaſmodic aſthma. Bleeding according to the ſtate of the pulſe, and repeated doſes of the paregoric elixir, uſually ſucceed. Or if the wind in the ſtomach cauſes or increaſes this ſymptom, a ſolution of aſſa fœtida with a little ſpirit of hartſhorn will be a uſeful help. But if the aſthma is attended with fixed obſtructions of the lungs, or a conſiderable accumulation of phlegm, opiates muſt be omitted, and bleeding, with bliſters, uſed in their ſtead; the lac ammon. with aſſa fœtida, will alſo be proper. To prevent returns, be careful to ſupply the patient with every proper means for recovering and eſtabliſhing the ſtrength of the conſtitution in general.

A palpitation of the heart. If this ſymptom ariſes from ſympathy when the ſtomach is weak and diſordered, for preſent relief give an opiate; and then go on to recover the healthy ſtate of the ſtomach. If the matter of the gout, &c. be repelled, and occaſions this diſorder, the proper means of relief will be warm ſtomachics, laxatives, camphor, volatile ſalts, warm pedilaves, bliſters on the legs, ſinapiſm on the feet, and, if plethoric, bleeding. If ſuppreſſed evacuations are the cauſe, they are not to be reſtored, or if polypi, &c. produce it, the beſt palliatives are, frequent ſmall bleedings, gentle purges, cooling attenuants, a light diet, and the avoiding of all that hurries either body or mind.

An immoderate diſcharge of pale urine. An opiate, mixt with any convenient vehicle, gives the ſpeedieſt relief.

Periodical head-achs. After thoſe general methods which uſually remove diſorders in the ſtomach, ſuch as crudities and indigeſtion, give the bark in an infuſion of valerian root; but, if the caſe is ſymptomatic, regard muſt be had to the original diſeaſe.

Low-ſpiritedneſs. The cold-bath is, in general, the beſt help in this caſe; but, beſides this, the particular cauſe of the *nervous* diſorders in general which affect the patient, ſhould be adverted to, and alſo of this ſymptom in particular; ſuch as a diſordered ſtomach, grief, obſtructed uſual evacuations, &c. each of which muſt be remedied before ſucceſs can be expected.

2. To leſſen or remove the morbid irritability of the nerves.

The medicines adapted to this end are, ſuch as not only ſtrengthen the ſtomach in particular, but alſo the whole conſtitution; and alſo thoſe which, by their peculiar action on the *nerves* to which they are applied, leſſen for a time the too great ſenſibility of the general ſyſtem; and of this kind are,

Bitters. Of which the propereſt are gentian root, the tops of the leſſer centaury, and the yellow rinds of Sevil oranges; theſe may be infuſed in ſtrong white wine; but if the ſtomach is diſturbed with acidities, in which caſe a peculiar coldneſs is alſo felt there, an infuſion in boiling water will be the beſt, and to this a proper quantity of brandy may be added: if theſe heat too much, add a little of the elix. vitr. to each doſe. Sometimes it happens that bitters lie heavy on the ſtomach, and leſſen the appetite, in this caſe omit and proceed with other means.

Bark. This ſtrengthens more and heats leſs than any of the bitter kind of medicines. It may be given in ſuch forms and in conjunction with any other means as preſent circumſtances render neceſſary. Joined with bitters, and given in a ſpiritual vehicle, it generally anſwers the intention of preſcribing it.

Elixir of vitriol. When this kind of preparation agrees with the ſtomach, twenty or thirty drops may be taken twice a day in a glaſs of water or brandy and water. It ſtrengthens the ſtomach, reſtores a decayed appetite, and

both allays flatulence, and helps digeſtion. When the tongue is white, and ſome degree of thirſt attends, from a heat in the ſtomach, it moderates the ſame, and relieves all its conſequent ſymptoms.

Iron. Few, if any, medicines ſo remarkably ſtrengthen the ſtomach and bowels, and indeed the whole habit, as preparations of this kind. The beſt preparation is the ſimple filings, juſt as they fall from under the file, if they can be complied with, notwithſtanding the ſymptoms which they ſometimes excite. From five to twenty grains or more may be taken three times a day; but if the filings offend, the tincture, or other preparations, may be tried. Preparations of iron ſometimes ſucceed beſt in conjunction with the bark and bitters. The Bath waters excel in diſorders of the *nervous* kind.

As theſe medicines require a long continued uſe before any good can be expected from them, the bark and bitters may be taken during the winter and ſpring, now and then intermitting their uſe for a week or two; and in ſummer uſe ſuch preparations of iron as are found moſt convenient; this direction is principally to be regarded when the waters are drank from ferrugineous ſprings.

Cold bathing. This ſhould be regularly continued during the ſpring, ſummer, and autumn quarters. Thoſe with ſpare habits may go into the bath twice or thrice a week; but the more corpulent or fleſhy may go in daily.

It ſhould be noted that, though all theſe are recommended, they are not all to be uſed at once, but ſingly or in conjunction, at the diſcretion of the preſcriber; and further, when the patient hath a quick pulſe and a preternatural heat, inſtead of bitters and iron, the bark with the vitriolic elixir will be moſt proper.

Air. If the air is hot, whether from the ſun or a fire, it injures *nervous* patients; and, whether hot or cold, if it is moiſt, the worſt nervous ſymptoms will thereby be produced; ſo that a dry air is always to be choſen, and a cool or warm one, as the ſenſations of the patient may direct.

Food. The ſolid part of diet ſhould be ſuch as affords a due degree of nouriſhment with the leaſt trouble to the ſtomach. All exceſs is hurtful, ſo are fat meats, and rich ſauces.

Wine. Much wine, and indeed of any liquid, after eating, retards digeſtion in weak ſtomachs. The beſt time to take wine or other cordials is when the ſtomach is nearly empty. If thoſe whoſe ſtomachs are weak, and upon motion, have hot qualms, are languid, and apt to ſweat, were, on ſuch occaſions, to eat a morſel of bread and drink a glaſs or two of wine, their ſtrength would be ſpeedily recruited, and every diſagreeable affection would vaniſh.

Exerciſe. Without this the beſt remedies may fail. Riding ſhakes the body equally, and more than walking does, and fatigues it leſs: and, whatever mode of exerciſing is engaged in, the laſt meal ſhould be nearly digeſted before attempting it.

Amuſement. As nothing injures the ſtomach more than depreſſing paſſions, chearfulneſs muſt be contained.

3. To correct the occaſional cauſes, eſpecially the morbid ones, ſuch as

Morbid matter in the blood. In many inſtances we cannot diſcover this; but when it is manifeſt, as when a wandering gout attends, ſuch means as leſſen its increaſe, or determine it to the extreme parts, are immediately to be preſcribed, and ſteadily perſiſted in. If there is a ſcorbutic, leprous, or other kind of acrimony, means adapted to each reſpectively will be the proper method for removing thoſe *nervous* ſymptoms depending on it.

A diminution or ſuppreſſion of natural evacuations. When theſe are obſerved to give riſe to *nervous* diſorders, they muſt be recalled; and in the mean time the *nervous* ſymptoms muſt be palliated.

The drying up of old ulcers, and the ſudden retiring of pimples on the face. In theſe caſes gentle purging, perpetual bliſters, and iſſues, are the only means, except the ulcers can be made to diſcharge afreſh, and the pimples to return.

A want of craſſamentum in the blood. In this caſe, whilſt troubleſome *nervous* ſymptoms are palliated by means of cordial and anodyne medicines, whatever attending diſorder can conduce to the diminiſhing of the craſſamentum, muſt be removed: and by means of ſuch medicines and aliments as are beſt adapted to this end, the blood muſt be repleniſhed. Beſides a light cordial and nouriſhing diet, moderate exerciſe, a dry air, the bark, aromatics and preparations of iron, will be the beſt.

Tough phlegm in the ſtomach and bowels. Gentle but repeated emetics, after which, to ſtrengthen the ſtomach, bitters, chalybeates, and exerciſe, will be neceſſary; and to reſtore the ſecretory veſſels to an healthy ſtate, give the tinct. facr. frequently in ſmall doſes. According as the phlegm abounds, more or leſs, repeat the emetic every ſecond or third week, and work it off with warm water, in which is a little flower of muſtard. Beſides theſe, as lime water diſſolves phlegm in the ſtomach, a quart at leaſt ſhould be drank at three times every day; the firſt draught may be taken an hour before breakfaſt, the ſecond as long before dinner, and the third the ſame diſtance of time before ſupper.

Aliments noxious from their quality or quantity. Whether a habit is formed of eating too freely or too ſparingly, let the error be gradually avoided. Valetudinarians ſhould never eat ſo much at a time as to incommode them either for buſineſs or ſtudy. As to the quality of what is eaten, ſuch things ſhould be avoided as reſt uneaſily on the ſtomach, creates flatulence, or is very fat.

Violent affections of the mind. Beſides other general methods recommended in *nervous* diſorders, diverting the mind by proper objects in the day, and an opiate at night, are the moſt proper, except it be the fruition of the object in caſes of diſappointment.

When a fever attends, or in the *nervous* fever. Bliſters ſhould be applied early; by their ſtimulus and the drain they occaſion, their advantage overbalances their inconveniences; the patient ſhould be kept in bed: light cordials, with diaphoretics, volatiles, and as early a uſe of the bark as poſſible, are the principal remedies. To moderate the feveriſh heat, Clutton's febrifuge ſpirit, joined with any proper cordial, and taken in all the patient's drink, is a moſt agreeable medicine. The ſp. nitri D. very effectually abates the ſickneſs which often attends.

In this kind of fever there is rarely any extraordinary degree of plethora, ſo there is as rarely any remarkable critical diſcharge obſerved. In giving the cordial, diaphoretic medicines with volatiles, as above directed, their too free uſe will produce a ſweating, which keeps up the fever; therefore, to ſecure the proper medium, obſerve the urine; if from being pale, it aſſumes an amber colour, the doſes are duly proportioned, and that more eſpecially if when in bed a kindly moiſture comes on without reſtleſſneſs. As ſoon as a turbidneſs appears in the urine, give the bark with cordials. For procuring ſleep in *nervous* fevers, a few grains of flor. mart. are by many preferred to every other means. A ſymptom of all others the moſt to be dreaded in this diſorder, is madneſs, which ſometimes comes on when women are much reduced in child-bed; is this caſe carefully avoid bleeding and all elſe that can leſſen the vis vitæ, and ſteadily adhere to the cordial diaphoretic method in general uſed to remove the *nervous* fever, and to theſe add the extract of bark with the flor. mart.

On *nervous* diſorders, amongſt the ancients, ſee Hippocrates, Aretæus, Fernelius, Duretus, Hellerius, Mercurialis, &c. Among thoſe of later date, ſee Sydenham, Hoffman, Shebbeare's Practice of Phyſic, Smith's Diſſertation on the Nerves and Nervous Diſeaſes, Whytt on Nervous Diſeaſes, Huxham, Hume, and Sir Richard Manningham on the Nervous Fever.

NERVORUM RESOLUTIONES, i. e. Comata.

NERVINUM OLEUM, i. e. ol. viride Ph. Lond.

NESTIS. A name of the inteſtinum jejunum.

NEURAS. A name for the poterion, a ſpecies of tragacantha.

NEUROCHONDRODES, from νευρον, *a nerve*, and χονδρος, *a cartilage*.

NEUROLOGIA. Neurology. A deſcription of the nerves.

NEUROMETERES. The pſoai muſcles.

NEURON. A nerve.

NEUROSES, from νευρον, *a nerve*. Nervous Diſeaſes. Theſe form a claſs in Dr. Cullen's Noſology; and under this

this title he comprehends thoſe preternatural affections of ſenſe or motion, which are without fever, as a part of the primary diſeaſe; and all thoſe which do not depend upon a topical affection of the organs, but upon a more general affection of the *nervous* ſyſtem, and of thoſe powers on which ſenſe and motion more eſpecially depend.

NEUROTICA. Nervous medicines.

NEUROTOMIA, from *νευρον, a nerve.* An anatomical diſſection of the nerve.

NEUROTROTOS, from *νευρον, a nerve,* and *τιτρωσκω, to wound.* A perſon who labours under a *wound* of a *nerve.*

NEUTER. Neutral. In chemiſtry this word is applied to ſuch ſalts as are formed of ſuch proportions of acid and alkali that neither of them predominate in the compound. There are many ſalts of this kind, which yet have different qualities from each other; ſome of them are natural, and others are artificial. They have a more extenſive uſe in medicine than any other kind. In general they are cathartic, and when mixed with human fluids, they produce no change there.

NEUTHA. Thus that part of the membrane is called which is torne away, and covers a part of the whole face of a child at its birth.

NHAMBI [Brasiliensibus]. A plant in Braſil, whoſe leaves, when chewed, taſte like muſtard or maſturtium, and if rubbed on a bubo preſently remove it. See Raii Hiſt.

NHANDU, alſo called piper caudatum. It is a ſmall ſhrub which grows in the woods in Braſil, and bears a ſpecies of katkins, full of round blackiſh ſeeds, as large as thoſe of the poppy, and with a taſte much reſembling that of pepper. See Raii Hiſt.

NICKEL. It is a kind of ſemi-metal. It is contained in the reddiſh yellow mineral, called kupfernickel, which, beſides *nickel,* contains iron, regulus of cobalt, arſenic and ſulphur. See Dict. of Chem.

NICOLAUS PRÆPOSITUS. He was of Tours, and was the firſt who writ a general Diſpenſatory, which was publiſhed about the middle or latter end of the fifteenth century.

NICON. A name for hellebore.

NICOTIANA, called alſo petum, tabacum, hyoſciamus Peruvianus, picelt. Tobacco. It is the *nicotiana* tabacum, Linn. It is a plant with alternate leaves and monopetalous tubulous flowers, divided into five ſections; the flowers are followed by an oval capſule, which opening longitudinally, ſheds numerous ſmall ſeeds. Its root is annual. It is ſown in ſpring, and flowers in July. Boerhaave mentions four ſpecies, but there are ſeveral more.

NICOTIANA. Tobacco. It hath large ſharp pointed pale green ſoft leaves, about two feet in length, joined immediately to the ſtalk without pedicles. It was brought into Europe by M. Nicott, a Frenchman, from whom it is called *Nicotiana*; he brought it from the iſland of Tobago, in America, about the year 1560; but is now cultivated in many parts of Europe. Sir Francis Drake firſt brought it into England, and Sir Walter Raleigh firſt made its uſe a ſort of faſhion amongſt us.

The leaves have a ſtrong diſagreeable ſmell, and a burning acrid taſte; they give out their active parts both to water and to ſpirit, but moſt perfectly to the latter, but yield nothing conſiderable by diſtillation with either; nevertheleſs their acrimony is much abated in inſpiſſation of the tincture, the watery extract being leſs pungent than the leaves themſelves, and the ſpirituous not much more ſo. The American *tobacco* is ſtronger than that which is raiſed in England, and affords a more fiery extract, though in leſs quantity.

If *tobacco* is taken inwardly in a ſmall doſe, or if a decoction of it is uſed as a clyſter, it proves violently cathartic and emetic, occaſioning extreme anxiety, vertigoes, ſtupors, and diſorders of the ſenſes; however, ſome have ventured on it in ſome obſtinate chronical diſorders. By long boiling in water its deleterious power is abated, and at length deſtroyed. The ſmoke of *tobacco* received by the anus is of ſingular efficacy in obſtinate conſtipations of the belly, for deſtroying aſcarides, and for recovering men that ſeem to be drowned.

Tobacco is ſometimes uſed in lotions and unguents for cleanſing foul ulcers, and deſtroying cutaneous inſects; it is deſtructive to all inſects whether in the vegetable or animal world. Beat into a poultice with vinegar, and applied to the hypochondres, it hath diſcuſſed tumors there.

A conſtant chewing of *tobacco* deſtroys the appetite by depriving the conſtitution of too much ſaliva; however, though it is improper for lean, dry and hectic habits, it is uſeful to the more groſs, to thoſe of very moiſt temperaments, and thoſe who are ſubject to diſeaſes of the colder kind. When the gums are ſurcharged with rheum, or when the lungs are œdomatous, *tobacco* may be uſeful as an errhine. Snuff never hurts, if not ſwallowed, but is better omitted by thoſe who are inclined to an apoplexy. The oil of the *tobacco* which aſcends in the ſmoak, blackens the teeth, and decays them.

NICOTIANA MINOR, called alſo hyociamus luteus, priapeia. Yellow henbane, Engliſh tobacco. Its leaves are ſhort, and ſomewhat oval, and ſet on pedicles; by theſe three characters it is diſtinguiſhed from the American ſorts, with which it agrees in their qualities, but is weaker. See Raii Hiſt. Lewis's Mat. Med. Neumann's Chem. Works; Edinb. Med. Eſſays, vol. ii. art. 5.

NIDOR. The ſmell of burnt animal ſubſtances; hence eructations, which have a ſavour like putrefied fleſh, are called nidorous.

NIGELLA. It is a plant whoſe root is annual, leaves capillaceous, and flower roſaceous. Boerhaave enumerates ten ſpecies. The ſort formerly uſed as a medicine, was the *nigella* ſativa, Linn.

NIGELLA ARVENSIS, alſo called melanthium. Wild fennel flower.

NIGELLA ROMANA, alſo called gith, melanthium. Fennel flower.

It is called *nigella,* as it were nigrella, from the black colour of the ſeeds; alſo melanthium, i. e. black flower, though the flowers are not black; and melaſpermum, black ſeed.

This plant in none of its ſpecies, are in uſe with us; they are ſaid to be aperitive, reſolvent, diuretic, and carminative. The ſeeds poſſeſs ſimilar virtues, but are alſo expectorant. See Raii Hiſt.

NIGELLASTRUM, called alſo pſeudomelanthium, lychnis ſegetum major, nigella officin. lychnoides ſegetum, cockle, or corn campion. It is Boerhaave's ſixth ſpecies of lychnis; the ſeeds are uſeful in flatulent diſorders, but are rarely uſed. The plant grows amongſt corn, and flowers in June and July. See Raii Hiſt.

NIHIL ALBUM, i. e. Album Græcum.

NIHIL GRISEUM. See Spodium.

NIGRA VITIS. The black vine.

NIGRA FABRILIS. Black lead.

NIGRITIES [Os]. So the antients called a caries.

NIGUAS. So the Spaniards call the worms which get under the toes off the Indians, and which are deſtroyed by the oil from the ſhells of caſhew nuts.

NIIR-NOTSJIL. A kind of tree, or ſhrub, in Malabar; the leaves of which when eaten with rue, are ſaid to cure the lues venerea. See Raii Hiſt.

NIIR-PONGELION. A tree which reſembles the pear-tree, and grows in Malabar. The fruit is eaten by parrots; the ſeeds are uſed, with other ingredients, for making an antiſpaſmodic liniment. See Raii Hiſt.

NIL, i. e. Indicum, and colinil.

NILA HUMMATU. A name for two ſpecies of the datura Malabarica. Both theſe ſpecies very much reſemble the ſtramonium. See Raii Hiſt.

NILENT SIUNDA. Common night-ſhade.

NILICA-MARAM. A kind of Indian plum.

NIMBO ACOSTÆ, called alſo aria bepou; azedarach. It is a tall tree in the iſland of Zeylon, and other parts of the Eaſt Indies. It reſembles an aſh; the fruit is like an olive, and from it an oil is expreſſed, for ſtaining cottons with. The leaves are uſed to deſtroy worms. See Raii Hiſt.

NINDSIN, Ninzen, or Ninzin, i. e. Ginſeng.

NIRLES. So the meaſles are called in the north parts of Great Britain.

NIRUALA. A large tree in Malabar, whoſe leaves provoke urine, though only externally applied. See Raii Hiſt.

NIRURI. An Indian bacciferous ſhrub, of which there are two kinds.

NISI. Blancard ſays, it is ginſeng.

NISSOLIA. Crimſon graſs vetch. It reſembles lathyrus in every thing, except that the leaves ſtand ſingle, and have no tendrils, but are like the leaves of the geniſta fagittalis. It is alſo called lathyrus ſylveſtris minor, and ervum ſylveſtre.

NITRIALES. All things capable of reducing to a calx, as nitre, ſulphur, &c.

NITRUM. Nitre. Called alſo Sal Petræ, Helinitrum, and Salt Petre. It is a neutral ſalt, formed by the coalition of the common vegetable fixed alkaline ſalt, with a peculiar acid; it hath a ſharp penetrating taſte; it is compoſed of near equal quantities of volatile and fixed nitrous aerial ſalts; it is ſoluble in eight times its weight of very cold water; and in leſs than three times its weight of water, which is temperately warm; and in one third its weight of boiling water. Dr. Alſton obſerves, that when the atmoſphere is temperate, two ounces of water diſſolves half a dram of *nitre*. A ſaturate ſolution of *nitre*, ſet to cryſtallize, ſhoots into cryſtals like ſprig cryſtals; but on evaporating part of the fluid firſt, it concretes into tranſparent colourleſs cryſtals, of an hexagonal priſmatic ſhape, terminating in pyramids of the ſame number of ſides. In a moderate heat it melts as thin as water, and when heated to ignition, it deflagrates on the contact of any inflammable ſubſtance, with a bright flame, and a conſiderable hiſſing noiſe; and leaving, after detonation, its fixt alkaline ſalt, the acid being deſtroyed by the act of accenſion, and thus is produced the

Nitrum *Fixum*.

Take of powdered *nitre*, four ounces; of powdered charcoal, five drams; mix them well by rubbing in a mortar; then inject the mixture by a little at a time, in a red-hot crucible. A deflagration, with a hiſſing noiſe, happens on each injection; the whole quantity being thus deflagrated, continue the fire ſtrong for half an hour. Thus the acid of the *nitre* is either deſtroyed, or changed to another nature, and the remaining ſalt differs not from the ſalt of tartar, except that a very minute portion of the *nitre* generally remains unchanged. This *nitrum fixum* is purified by ſolution in water, filtration, and evaporation. It muſt be kept cloſe from the air. Dr. Alſton ſays, it is a ſtyptic, and of the nature of alum; but it is rarely uſed, except for the making the tinct. nitri, which does not appear to differ from the tinct. ſal. tart.

The origin of the acid of *nitre* is unknown. It is true, that common waters, both atmoſpherical and ſubterraneous, often contain a little of this acid in combination with earthy and other bodies, ſo as to yield by cryſtallization, on ſupplying the vegetable fixt alkali, a perfect *nitre*; and that when animal and vegetable ſubſtances, mixed with porous and abſorbent earths, have been expoſed to the air till they are thoroughly rotted, they are found in like manner to contain a ſmall portion of *nitre*, or of nitrous acid, ſo as to give out a little *nitre* to water, either without addition, or on being ſupplied with the proper alkaline baſis. On this foundation *nitre* is prepared in ſeveral parts of Europe; where they expoſe earth, wet with urine, or animal dung, to abſorb the aeral acid; on ſea coaſts, ſheds are made over heaps of vegetable ſubſtances, both the marine and others; of animal ſubſtances, as the entrails, &c. of beaſts and fiſhes, the rubbiſh of old buildings, &c. promiſcuouſly jumbled together, and open to the air, but covered from rain: on the ſurface of theſe heaps, a nitrous cruſt is found. The greateſt quantities are brought to us from Perſia and the Eaſt Indies; but whether it is there a natural or artificial production, is not known. It is brought to us crude, and of different complexions, as grey, blackiſh, &c. but that which is of a blackiſh caſt is the beſt, as it requires only a bare ſolution, colation, and cryſtallization for purifying it. Very often it is mixed with ſea-ſalt, from which it is purified as follows:

Nitrum *Purificatum*.

Boil *nitre* in water until it is diſſolved; filter the ſolution through paper, evaporate, and ſet it to cryſtallize in a cool place. The liquor which remains after cryſtallization may be further evaporated, and ſet to ſhoot as before; but this proceſs muſt not be too long protracted. The uſual method of evaporating for cryſtallization is till a pellicle appears; but this direction fails in *nitre*, for it does not contract a pellicle: here, when the liquor is become ready for ſhooting, a little ſhould be taken up in a ſpoon; as it cools, the ſalt will begin to ſhew itſelf in threads. In this proceſs, the ſea-ſalt is all ſeparated, for it remains diſſolved, after the greateſt part of the *nitre* hath cryſtallized. The cryſtals which ſhoot after the ſecond evaporation, are not totally free from the ſalt; but the refiners purify it ſo well, that ſuch as is found in the ſhops is perfectly fit for uſe.

Geoffroy ſays, that *nitre* loſes in melting half its weight of watery moiſture, and recovers this again on being diſſolved and cryſtallized; whence, it ſeems, that one part of melted *nitre* is equal to two parts of the cryſtals; but on making the experiment, his obſervation is not found true.

To improve the virtue of *nitre*, it is deflagrated with ſulphur; by which a portion of the nitrous acid paſſes off with the ſulphur; and as Dr. Alſton obſerves, the *nitre* is thus rendered a little leſs cooling. The proceſs is as follows, and when finiſhed, the preparation is called

Sal Prunellæ.

Take two pounds of pure *nitre*; melt it in a crucible, or in an iron pot; then ſprinkle into it by little, and little, the flowers of ſulphur, waiting each time until the deflagration is over, and then add more, until an ounce has been thus conſumed; then with an iron ladle take it out, and caſt it into moulds of what ſhape you pleaſe. If the ſulphur is in a larger proportion, its effects will be to change the *nitre* into a different medicine; as is inſtanced in the

Sal Polychreſtum.

Take of pure *nitre*, melt it in an iron pan, and then add by little and little, an equal weight of the flowers of ſulphur, waiting until the deflagration of one portion is over before another is added; when all the ſulphur is expended, continue the *nitre* over the fire for an hour. Thus the acid of the *nitre*, and the inflammable principle of the ſulphur, detonate together, and are diſſipated; whilſt the acid of the ſulphur (which is the ſame as the vitriolic acid) remains combined with the alkaline baſis of the *nitre*. For this ſal polychreſtum, the *nitrum vitriolatum* is ſubſtituted; Dr. Alſton ſays, that this ſalt much reſembles the tart. vitr. but is rather more acid, and that a doſe of half a dram is diaphoretic; a dram, is diuretic; and two drams cathartic. The ſalt may be obtained by pouring gradually on *nitre*, the pure acid of vitriol, or ſulphur; this acid decompoſes the nitrous acid, which flies off immediately in yellow or red fumes, and may be collected in a retort, with a moderate heat, and is the

Spiritus Nitri, or Spiritus Nitri Glauberi.

Put two pounds of *nitre* into a retort; add, by degrees, one pound of the oil of vitriol, diluted with an equal quantity of warm water; diſtil it in a ſand-heat gradually increaſed, till the matter remains dry. The ſpirit is rectified, by a ſecond diſtillation, with the heat of a water-bath, in a glaſs cucurbit, with its head and receiver; the phlegm ariſes, leaving the ſpirit behind.

One pound of the oil of vitriol expels all the acid from about two pounds of *nitre*, but not from more: ſome add equal parts of the two; but in both caſes, the ſpirit is the ſame, the difference affecting only the reſiduum. If two parts of *nitre* are taken, to one of oil of vitriol, the remaining alkaline baſis of the *nitre*, is completely ſaturated with the vitriolic acid; and the reſult is a neutral ſalt, the ſame as the vitriolated tartar: if more *nitre* is uſed, a part of the *nitre* in ſubſtance will remain behind, blended with this vitriolated ſalt; if leſs *nitre* cannot afford alcali enough to ſaturate the vitriolic acid, and the reſiduum will not be a neutral, but a very acid ſalt. In this laſt caſe, one advantage attends; the acid

ſalt is readily diſſolved in water, ſo as to be got out without breaking the retort, which the other cannot.

The acid of *nitre* is next in ſtrength to the vitriolic, and diſlodges all but that from the alkaline ſalts and earths. It differs from all the other acids, in deflagrating with inflammable matters; if it is dropped on ol. carui, it will flaſh, and make an ebullition as ſtrong as though on the fire, and will yield ſuch fumes, as by mixing with air, will be ſenſible for three or four hours. If a ſolution of any inflammable ſubſtance, as hartſhorn, &c. in this acid, be ſet to evaporate, as ſoon as the matter approaches to dryneſs, a violent detonation enſues. This acid is chiefly uſed as a menſtruum, and as the baſis of ſome other preparations. Diluted in water it hath been given as a diuretic from ten to fifty drops.

If three parts of *nitre* be uſed, to one of the vitriolic acid, a part of the *nitre* remains unchanged, after the ſpirit is diſtilled from it. On diſſolving the whole reſiduum in hot water, and ſetting the filtered ſolution to cryſtallize, the vitriolated ſalt ſhoots firſt, the greateſt part of the *nitre* continuing diſſolved; and this is the

Nitrum *Vitriolatum*.

The reſiduum, after diſtilling the ſp. nitri Glaub. of the Lond. Pharm. being diſſolved in warm water, filtered, and then ſet to cryſtallize, is the general method of obtaining the preparation, which, as already obſerved differs not from the tart. vitr. except in being a little more acrid; nor is its difference from the ſal polychreſtum conſiderable.

Aqua Fortis Simplex.

Take of *nitre*, and of green vitriol, not calcined, of each three pounds; of calcined green vitriol, a pound and a half, mix them well, and diſtill them with a ſtrong fire, as long as any red vapours ariſe. The ingredients ſhould be perfectly well mixed together, before they are put to be diſtilled, or elſe but a ſmall quantity of the aqua fortis will be obtained. Mixing the vitriol requires ſomewhat more heat than when the oil of vitriol is uſed, for its acrid ſpirit muſt be ſeparated before it can act on the *nitre*; but then, too much heat may force over ſome of the metallic part of the vitriol. The produce of the proceſs is, a ſpirit of *nitre*, containing ſo much more phlegm, or watery moiſture than Glauber's ſpirit, as the vitriol employed does more than an equivalent quantity of the oil of vitriol, and is liable to an admixture with the vitriolic acid, more or leſs of which is generally forced over.

Aqua Fortis Duplex.

Take equal parts of *nitre*, green vitriol calcined to redneſs, and of dried clay. Diſtill them in an earthen retort. The making of this is a diſtinct trade, on account of the large demand for it amongſt the dyers, and other artiſts. But when this is intended for medicinal uſes, or for the nicer chemical experiments, it requires to be purified; for the rough *nitre* is uſed, and a great heat, whence both the ſpirit of ſalt and a ſolution of iron are contained in it.

Aqua Fortis Purificata.

Drop into the impure aqua fortis, a ſmall quantity of the tincture of ſilver, and when the cloudineſs or milkineſs, which it occaſions, ſubſides, drop in more, and thus continue until a freſh addition occaſions no farther change; then pour the liquor into a glaſs retort, and diſtill it in a ſand-heat to dryneſs. The ſilver abſorbs both the marine and the vitriolic acids, and forming a concrete with them, they all fall together.

Good aqua fortis diſſolves about half its weight of ſilver.

Aqua Fortis Compoſita.

Take of aqua fortis ſixteen ounces in weight, of ſea-ſalt one dram, diſtill to dryneſs. This is deſigned as a menſtruum for quick-ſilver, for the preparation of merc. cor. rub. which the marine acid in this compoſition renders of a more ſparkling appearance, and more beautiful to the eye, than when made with the nitrous acid alone.

Aqua Regia.—Regalis Regis.

Put an ounce of crude ſal ammoniac powder, into a large cucurbit, and add to it, by little and little, four ounces of the ſpirit of *nitre*, or of double aqua fortis; let them ſtand in a ſand heat until the ſalt is entirely diſſolved. Or, the ſalt may be powdered fine, and gradually added to the acrid ſpirit, which ſhould be of a middle ſtrength, between ſingle aqua fortis and ſtrong ſpirit of *nitre*.

The nitrous ſpirit obtained from rough *nitre*, contains ſome of the marine acid, as well as the vitriolic; the firſt is diſcovered and ſeparated by dropping in a little ſolution of ſilver; the latter by a ſolution of chalk, or any other calcareous earth, made in the pure nitrous acid; the ſilver abſorbing the marine acid, and the chalk the vitriolic, and forming with thoſe acids, indiſſoluble concretes, which immediately render the liquor milky, and then fall to the bottom. The ſolutions may be ſlowly dropped in, until no more milkineſs appears; and in caſe of an exceſs of their quantity, and the ſpirit is required pure, it muſt be re-diſtilled.

The nitrous ſpirit, combined with vegetable fixed alcalies, reproduces common *nitre*; with the mineral fixt alcali it produces

Nitrum *Cubicum*.

Diſſolve chalk or lime in purified aqua fortis, and add the ſolution, by degrees, to a ſolution of Glauber's ſalt in water, ſo long as a freſh addition produces any milkineſs; a white powder will precipitate; after which, the liquor is to be filtered, and after due evaporation, ſet to cryſtallize. Thus a ſpecies of *nitre* is formed, not much different from the common ſort; it cryſtallizes into cubical, inſtead of priſmatic figures; but as a medicine, this, and the common ſort, may be indifferently uſed.

Nitrum *Flammans*

Is a combination of the nitrous acid, and volatile alcaline ſalt. It is alſo called *nitrum* volatile, and *nitrum* ammoniacale; it is very ſubtil, pungent, and diſſolves in rectified ſpirit of wine.

The nitrous acid in its moſt concentrated ſtate, ſaturates about five-ſixths its weight of vegetable fixt alcali. Solutions of calcareous earths in this acid are bitteriſh and pungent, difficultly aſſume a cryſtalline appearance and when evaporated, and exſiccated by heat, it ſoon deliquates again in the air. The nitrous acid diſſolves zinc, iron, copper, lead, biſmuth, mercury, and ſilver, the moſt readily of all the acids; it diſſolves tin imperfectly, and it only corrodes the regulus of antimony. Aqua fortis diſſolves ſilver, mercury, iron (and that beſt when mixed with equal parts of common water), copper, lead, regulus of antimony, biſmuth, zinc, tin imperfectly, gold not at all: but by the addition of ſal ammon. crud. it loſes this name, and becomes aqua regia, ſo called becauſe it diſſolves gold, which chemiſts call the king of metals; it alſo diſſolves iron, copper, tin, mercury, regulus of antimony, biſmuth, zinc, and lead, more than the ſpirit of ſea-ſalt does; but does not diſſolve ſilver.

The concentrated acid combined with ſpirit of wine loſes its acidity, the coalition of the two producing a new compound called,

Spiritus Nitri *Dulcis*.

Take of rectified ſpirit of wine one quart, of Glauber's ſpirit of *nitre* half a pound. Mix them by pouring the ſpirit of *nitre* on the other, and diſtil the mixture with a gentle heat, as long as what comes off will not raiſe any fermentation with a lixivial ſalt.

This dulcified ſpirit is held in juſt eſteem for quenching thirſt, promoting the natural ſecretions, expelling flatulencies, and moderately ſtrengthening the ſtomach; it is ſtrongly antiſeptic. Mixed with a ſmall quantity of ſp. C. C. or ſp. vol. arom. or any volatile alcaline ſpirit, it proves mild, yet efficacious, diaphoretic and diuretic, eſpecially in fevers. The ſp. nitri D. allays vomiting when ſaline mixtures fail. It is often adulterated with water, which diminiſhes its grateful ſcent. A ſmall proportion of ſp. nitri D. gives a French brandy flavour to malt ſpirits.

Nitre makes no impreſſion on blue paper, nor tincture of turnſol, nor ſyrup of violets; a violent fire is neceſſary, to draw the ſpirit from this ſalt; it flames upon the fire, and kindles readily, though its ſpirit extinguiſhes fire; it does not curdle milk; *nitre* and oil of tartar makes an almoſt inſenſible ebullition. It is one of the principal of the antiphlogiſtics, of general uſe where inflammations attend them from the ardency of the blood; it is an antiſpaſmodic, when irritation, or inflammation is excited by ſtimulating drugs, for if mixed with regulus of antimony, gamboge, ſcammony, &c. their uſual ill effects are prevented. When uſed in gargariſms for inflammations of the fauces in acute fevers, it thickens the ſalival fluids into a mucus, which keeps the part moiſt for ſome time, whereas if *nitre* is not added, a dryneſs of the mouth preſently enſues. It promotes urine, tends too looſen the belly in hot diſpoſitions, and checks diarrhœas from the acrimony of the bile; it is of ſingular ſervice in the cholera morbus when accompanied with anxiety, and in the cardialgia of hypochondriacs; its virtues are ſimilar to thoſe of neutral ſalts in general, but exceed them in degree in many inſtances; in the ſmall-pox, if the fever runs too high, *nitre* ſoon reduces it; ſometimes it is aſſiſted in its efficacy by a conjunction with volatile ſalts, or camphor, at the ſame time that it is often by this means rendered more grateful to the ſtomach; thus managed it is uſeful in removing pains in the limbs; it checks bloody urine from an inflammatory cauſe; hæmorrhages from rarefaction, and inflammation are reſtrained by its internal uſe; in hæmoptoes and other diſorders of the lungs, *nitre* is generally uſeful; as an alterative, it hath been uſeful, by a long continuance of it, in the leproſy, and particularly ſo in the cure of old ulcers in the legs; joined with warm carminatives, it carries their efficacy though the inteſtines, which otherwiſe would be confined to the ſtomach.

Nitre, however, ſhould not be given without caution; though uſeful in moſt diſorders of the lungs, if the vis vitæ is defective, it is better omitted; the ſame may be obſerved in almoſt all other caſes. It often occaſions a nauſea, or a pain in the ſtomach if taken in a ſolid form; in this caſe, plentiful dilution, or warm medicines accompanying its uſe, theſe are prevented, or removed, if they happen to come on.

The doſe of *nitre* may be from three grains to two ſcruples, or more, every hour or two. And if each doſe is given as ſoon as it is diſſolved, its efficacy will be greater, and thus it alſo reſts more eaſy on the ſtomach.

Decoctum Nitroſum.

Take half an ounce of *nitre*, one ſcruple of cochineal, boil them in a quart of water until the *nitre* is diſſolved, then add two ounces of ſugar; and when cold, ſtrain off the clear liquor. This is palatable, and agreeable to the eye. Three or four table-ſpoonsfull may be taken for a doſe, and repeated according to the intention of giving it. In ſome inſtances *nitre* produces pain, nauſea, and even ſickneſs. It is ſaid that, when it is boiled before it is adminiſtered, no ſuch effects are obſerved; and farther, that when *nitre* has excited a nauſea, &c. it may afterwards be given as above preſcribed, and it will remove the ſickneſs previouſly excited.

See Hoffman de Salium Medicorum, & de præſtantiſſima *Nitri* Virtute. Stahl de Uſu *Nitri* medico. Neumann's Chem. Works. Lewis's Mat. Med. Dict. of Chem.

NITRUM ANTIQUORUM, i. e. Anatron.

NITRUM ARTIFICIALE HOFFMANI. It is made of the ſpirit of ſal ammoniac and ſpirit of *nitre*. It perfectly diſſolves in rectified ſpirit of wine.

NITRUM CALCAREUM VERUM. It is a ſolution of calcareous earth, in the nitrous acid.

NITRUM CAUSTICUM. The amber-coloured ſcoriæ, ariſing in the purification of the regulus antim. martialis with *nitre*, are a ſtrong cauſtic alkali, and are thus named.

NITRUM FACTITIUM, i. e. Borax.

NITRUM NATIVUM, i. e. Borax.

NITRUM STIBIATUM. After making the calx of antimony, it is directed to be waſhed in ſeveral waters, until they become inſipid; theſe waters being mixed, then evaporated over a gentle fire till a cuticle forms on the ſurface, they yield in the cold, cryſtals which are thus called. They poſſeſs but little of the antimony.

NIX FUMANS. Quick-lime.

NIX ANTIMONIALIS. Thus the white flowers of the regulus of antimony are called.

NOBILIS VALVULA. See Cor.

NOCHETZLI NOPALLI, or Nocheznopatli. The cochineal plant.

NOCTAMBULATIO, i. e. Somnambulo.

NOCTAMBULO. One who walks when aſleep, i. e. Somnambulo.

NOCTUINI OCULI. Grey eyes.

NODOSA. Knotted. In ſurgery, it is an epithet for a ſort of ſuture; and for various bandages. The gout is alſo called *knotted* when it forms knots at the joints.

NODULUS. In pharmacy, it is a knot tied on a rag, including ſome medicinal ingredient, with which the liquor this *nodulus* is ſuſpended in, is intended to be impregnated. It is alſo a bag, in which ingredients are included, in order to be ſuſpended in a diet drink, or medicated wine.

NODUS. A node. See Tophus.

NOEL VALLI. See Valli.

NOELA TALI. The Indian barberry-tree, with an orange leaf. It grows in Malabar, it is ever-green, its fruit reſembles barberries; they are cooling and antiſeptic. See Ray's Hiſt.

NOLI ME TANGERE. Touch me not. In botany, it is a ſpecies of balſamina, of perſicaria, and a name for the ſenſitive plant. In ſurgery it is a ſpecies of ulcer, and a kind of wart on the eye-lid which appears blackiſh, in which caſe it preſently mortifies; or a cancerous ſore, which, becauſe it is uſually provoked by medicines, is called *touch me not*. It is alſo a name of a ſpecies of herpes.

NOMA. A phagedenic ulcer, from νεμω, *to eat away*.

NOME. A phagedenic ulcer. Alſo a ſpecies of herpes.

NONANA. An erratic intermitting fever returning every ninth day.

NONNATURALIA. The non-naturals. They are ſix, viz. air, meat and drink, ſleep, waking, motion and reſt, things excreted, and things retained, and paſſions of the mind. Theſe things affect man without entering into his compoſition, or conſtituting his nature; but yet are ſo neceſſary that he cannot live without them.

The luxury of moſt climes conſiſts very much in the exceſs of what is needful in its kind, and in the requiſites to correct that exceſs. In hot climes they ſurfeit themſelves with fruits, and other vegetables, they cool their fruits, creams, wines, &c. to an unſalutary degree, with ice, &c. Then, to correct the inconveniences of theſe exceſſes, they uſe brandy, hot tea, high ſauces, &c. In cold climes they ſurfeit with animal diet, fermented liquors, exerciſe, cloathing, &c. for which they uſe oppoſites to moderate their exceſſes, or rather the inconveniences thereof.

There are very few diſorders happen to our frame, in which an error in one or more of the *non-naturals* have not an influence as a cauſe thereof.

Beſides what is ſaid on each article of the *non-naturals* in theſe ſheets, ſee Dr. Fr. Cliſton's tranſlation of Hippocrates on Air, Water, and Situation; Wainwright on the *Non-naturals*; Sanctorius's Med. Static. Keil's Animal Œconomy.

NONUS HUMERI, (Muſc.) i. e. Coraco Brachiæus.

NONUS HUMERI MUSCULUS PLACENTINI, i. e. Teres minor.

NOPAL, & Nopalnocheztli. The cochineal plant.

NORTHAW, or North-hall water. It is of the purging kind, and ſimilar to that of Epſom.

NOSOCOMIUM, from νοσος, *a diſeaſe*, and κομεω, *to take care of*. An hoſpital.

NOSODOCHIUM, from νοσος, *a diſeaſe*, and δεχομαι, *to take*. An hoſpital.

NOSOLOGIA, from νοσος, *a diſeaſe*, and λογια, *a diſcourſe*. Noſology. It is an explication of diſeaſes, or a diſcourſe concerning the nature and properties of them. The ſolids are conſidered as the proper ſeat of diſeaſes; as the

the contamination of the fluids are only manifeſt by their effect on the ſolids; and from the rigid or lax fibres, diſeaſes are uſually traced. See Tonicus. alſo ſee this ſubject concifely and ſatisfactorily treated of in Haller's Phyſiology.

NOSOS. A diſeaſe.

NOSTALGIA. Broken heart. Longing for home; or national inſanity. As when abſent from one's native country, the deſire of returning is vehement.

Dr. Cullen places this genus of diſeaſe in the claſs locales, and order dyſorexiæ. He obſerves two ſpecies. 1. *Noſtalgia* ſimplex. When no other diſeaſe attends. 2. *Noſtalgia* complicata. When it is attended with ſome other diſeaſe.

NOSTOCH, i. e. Cœlifolium.

NOSTRATIBUS LIGNUM, i. e. Flavum lignum.

NOTHÆ COSTÆ, from νοθος, *ſpurious*. The ſpurious ribs.

NOTIÆUS, from νωτος, *the back*. An epithet for the ſpinal marrow.

NUBA. A ſpecies of manna which is of a roſy colour; alſo braſs.

NUBECULA. See Nubes. It is alſo a cloud in the urine.

NUBECULA SUSPENSA, i. e. Enæorema.

NUBES. Clouds. In ſurgery it is the ſame as albugo and encauma.

NUCAMENTA. Catkins.

NUCES GALLÆ. See Gallæ.

NUCHA. The back of the neck. Properly the region upon the firſt vertebra of the back. It is an Arabic term.

NUCIOSITAS, i. e. Myopia.

NUCIPERSICA. The nectarine.

NUCI-PRUNIFERA. See Saponaria and Nux Virginiana.

NUCIS MOSCHATA, vel

NUCISTA. The nutmeg. See Nux Mosch.

NUCLEUS. A kernel. In botany it is that part of the fruit which is incloſed in a hard ſhell, as the kernels of almonds and apricots.

NUCULA TERRESTRIS. See Bulbocastanum.

NUMMULARIA. This plant is ſo called from *nummus*, money; becauſe its leaves are round. It is alſo called centimorbia, becauſe it is ſaid to be uſeful in an hundred diſeaſes. In Engliſh it is named herb two-pence, and money-wort.

It is a low creeping plant with ſquare ſtalks, and ſmooth, little, roundiſh, or heart-ſhaped leaves, ſet in pairs at the joints, upon ſhort pedicles; in their boſoms appear yellow ſolitary monopetalous flowers, each divided into five oval ſegments, and followed by a ſmall round capſule, full of minute ſeeds. It is perennial, grows wild in moiſt paſture grounds, and flowers from May to the end of ſummer. It is reſtringent, antiſcorbutic, and vulnerary. Boerhaave thinks it ſimilar to a mixture of ſcurvey-graſs and ſorrel; but it is weaker than either of them.

NUMMULARIA RUBRA; called alſo Lyſimachia. The ſpecies formerly uſed in medicine was the lyſimachia nummularia, Linn. The juice of this ſpecies of money-wort, is like that of becabunga; it hath a ſaponaceous, aromatic, and balſamic taſte; its virtues are the ſame as a mixture of cochlearia with acetoſa. See Raii Hiſt. Lewis's Mat. Med.

NUSCHIOSUS. See Nyctalops.

NUTRICATIO. Nutrition, accretion, or growth. It hath generally been thought that *nutrition* is chiefly performed by means of the nervous fluid, becauſe thoſe parts whoſe nerves are deſtroyed, or wholly deprived of their uſual power, are obſerved to become ſmaller; but this is without foundation, for from certain experiments it is known, that the motions of the fluids in the very ſmall veſſels, depends in a great meaſure upon the influence of their nerves; and that when this is wanting, the fluids either do not circulate at all through the veſſels, or at leaſt in a very languid manner; whence the parts to which they belong collapſe, and are not properly nouriſhed. See Phyſiological Eſſays, edit. 2. p. 22, &c p. 49. and 50. The ſtandard of *nutrition* varies in perſons of different ages, for, during infancy, more is added to the body than is thrown off from it; but to old age, the conſumption is greater than the addition. The firſt of theſe is the growth, the latter the decreaſe, and ſo decay of the body. In infancy and youth the fibres are extenſible; and the force of the circulation proportionably greater than in later life: on the arrival of maturity, the laſt leſſens, and the firſt is totally at an end. See Haller's Phyſiology.

NUTRITUM UNGUENTUM. It was formerly made by mixing certain proportions of vinegar, oil, and litharge; but the London College hath ſubſtituted, as a nearer application, the ungt. ſaturninum.

NUX CATHARTICA. See Cataputia.

NUX INDICA. The cocoa-nut.

NUX MEDICA. The Maldiva nut.

NUX MOSCHATA; alſo called nux myriſtica, nuciſta, pala, chryſobalanus Galeni, unguentaria, nux aromatica, the nutmeg. Weſton, in his Univerſal Botaniſt, names the tree, myriſtica moſchata, and deſcribes it myriſtica arbor nuces moſchatas, and macem gerens. The nut-meg and mace-tree. Linnæus in his Suppl. 265, names the tree myriſtica officinalis.

It is the aromatic kernel of a large nut, produced by a tree, ſaid to reſemble the pear-tree; it grows in the Eaſt Indies, principally on the iſle of Banda, and on the Molucca Iſles. The outer part of the fruit which is the ſize of a peach, is a ſoft fleſhy ſubſtance like that of the walnut, which ſpontaneouſly opens when ripe; under this lies a red membrane, called mace, forming a kind of reticular covering, through the fiſſures of which is ſeen the hard woody ſhell that includes the nutmeg. C. Bauhine ſpeaks of three ſorts; but there are two which are frequently enough met with; one of them is of an oblong figure, called male, the other roundiſh called female; this laſt is the officinal ſpecies, being preferred to the other, on account of its ſtronger and more agreeable flavour, and its being, as is ſaid, leſs ſubject to become carious. The Dutch monopolize this part of trade, as well as the reſt of the ſpices in general, whence we ſeldom have them genuine.

The nutmeg is moderately warm, grateful to the taſte, and unctuous: but when too freely taken, it fits uneaſy on the ſtomach, occaſioning heart-burn and uneaſineſs in the head.

The London College directs a gallon of proof ſpirit, to be drawn by diſtillation, from two ounces of nutmegs, and this is called aqua nucis moſchatæ; but when a few hawthorn flowers are added, it is called aq. nephritica.

By diſtillation with water, nutmegs yield nearly one-tenth their weight of a limpid eſſential oil, which is very grateful, and poſſeſſes the flavour of the ſpice in perfection; it is recommended as antiſpaſmodic and hypnotic. It is ſimilar in quality to the oil of mace, but not quite ſo grateful.

On the ſurface of the remaining liquor in the ſtill, after the aſcent of the eſſential oil, is found floating an unctuous concrete, like tallow, of a white colour, nearly inſipid, not eaſily corruptible, and hence commended as a baſis for odoriferous balſams; the decoction, freed from this ſebaceous matter, and inſpiſſated, leaves a weakly bitter ſub-aſtringent extract.

Rectified ſpirit takes up the whole ſmell and taſte of the *nutmegs*, and receives from them a deep bright yellow colour; the ſpirit drawn off from the filtered tincture is very ſlightly impregnated with their flavour; the greateſt part of the ſpecific ſmell, as well as the aromatic warmth, bitterneſs, and ſubaſtringency of the ſpice, remaining concentrated in the extract.

Both the oil, the ſpirituous tincture, and extracts, agree better with weak ſtomachs than the *nutmegs* itſelf.

Ol. N. M. *per Expr. commonly called Ol. Macis per Expr.*

When *nutmegs* are heated, and ſtrongly preſſed, they give out a fluid yellow oil, which concretes on growing cold, into a ſebaceous conſiſtence. We are informed, that in the Spice Iſlands, the imperfect and damaged nuts are ſeparated for obtaining this expreſſed oil from. In the ſhops we find there ſorts, under the name of oil of mace. The beſt is brought from the Eaſt Indies in ſtone jars; it is ſoftiſh, of a yelloviſh colour, an agreeable fragrant ſmell greatly reſembling that of the nutmeg itſelf; it is of the

colour

colour of mace. The next comes from Holland in ſolid maſſes, generally flat, and of a ſquare figure; it is paler coloured, weaker in its ſmell, and inferior in its quality to that of India. The laſt is the worſt; it ſeems to be a compoſition of ſuet, palm-oil, and ſuch like expreſſed ones, flavoured with a little of the genuine oil of nutmeg. The beſt is the ſebaceous matter of the nutmeg and its eſſential oil; by diſtillation in water, and maceration in rectified ſpirit of wine, the eſſential oil is ſeparated and the ſebaceous matter is left quit inſipid. The chief uſe of theſe are for liniments, &c. to be applied to the ſtomach, or as a part in anodyne and nervous ointments See Tournefort's Mat. Med. Lewis's Mat. Med. Newman's Chem. Works

NUX UNGUENTARIA. See Ben.

NUX VIRGINIANA, called alſo prunifera, nucifera, nuciprunifera, maſtichen odoratum fundens, maſtich of Ligon, and Virginia nut. Its leaves ſhine like thoſe of the bay tree, and differs from other pruniferous trees in its fruit, which is ſmall, turbinated, and contains but a little pulp.

The fruit is of the ſhape and ſize of a filbert, ſmooth, of a brown colour, with an eye near one end, containing a hard ſtone, with a white globular kernel, of a bitteriſh taſte and an aromatic ſmell It is antiſcorbutic, deobſtruent, and warming. See Raii Dendr.

NUX VOMICA, called alſo nux metella, vomic nuts. It is a flat roundiſh ſeed, or kernel, about an inch broad, and a quarter of an inch thick, with a prominence in the middle, on both ſides of a grey colour covered with a kind of woolly matter, internally hard and tough like horn. It is the produce of a large tree growing in the Eaſt Indies, which Plukenet calls cucurbitifera Malabarienſis cœnoplix foliis rotundis fructu orbiculari rubro cujus grana ſunt nuces vomicæ officinarum. The *nux vomica* is the fruit of the ſtrychnos *nux vomica*; vel ſtrychnos Indica, foliis ovatis quinque nerviis, caule inermi, Linn.

They have no place in the preſent practice; to the taſte they are bitter, but have no ſmell. Fallopius ſays, in doſes to 3 ſs they procure ſweat; but Hoffman informs us, that two doſes of ſeven or eight grains each, were fatal to a girl of ten years old. They poiſon dogs, crows, &c. When imprudently ſwallowed by men, they produce great anxiety, convulſions, paralytic ſymptoms, reaching, an increaſed motion of the heart and of the lungs. The poiſonous matter is probably the ſame as that of bitter almonds, which acts chiefly on the nervous ſyſtem. See Raii Hiſt. Lewis's Mat. Med. Newmann's Chemical Works.

Dr. Hagſtrom, a Swediſh phyſician, commends the uſefulneſs of the *nux vomica* in the dyſentery; he ſays, that, the dyſentery began to appear in the autumn of 1772, and ſoon became general. He preſcribed the uſual remedies without the wiſhed for ſucceſs, and recollecting the theoretical propoſition of ſome celebrated phyſicians, that the epidemic dyſentery is an hæmorrhage of the inteſtines brought on by animalculæ, he was led to imagine that the *nux vomica*, which is known to be fatal to large animals, might alſo prove equally deſtructive to theſe animalculæ. He began by cleanſing the bowels with rhubarb and cream of tartar; after which, he preſcribed a ſcruple of *nux vomica* in powder to be taken once a day. The good effects exceeded his moſt ſanguine expectations. In many inſtances a very few doſes anſwered the end. See the Lond. Med. Journal. vol. iii. p. 189, &c.

NUX VOMICA SERAPIONIS, called alſo faba ſancti Ignatii, nux pepita igaſur, faba Indica. St. Ignatius's bean. It is the produce of a tree of the ſame kind as that on which the *nux vomica* grows. It is met with in the Eaſt Indies and the Philippine iſlands. The fruit reſembles a gourd, in each of which is from twenty to thirty ſeeds, improperly called beans. They are of a roundiſh figure, irregular, and uneven, the ſize of a middling nutmeg, ſemi-tranſparent, of a horny texture, and of a colour betwixt white and a ſky blue. Theſe ſeeds have a bitter taſte, but no ſmell, except a degree of a muſty ſcent whilſt freſh. The inhabitants of the Philippine iſlands uſe them as a medicine, but they affect the Europeans violently, producing the ſame effect as do the vomic nuts. See Act. Phil. Lond. No. 249. p. 44. Med. Muſ. vol. iii. p. 428—435.

NYCTALOPS, from νὺξ, *night*, and ὤψ, *an eye, night blindneſs*. Sometimes theſe patients are called luſcitioſus, or nuſcitioſus, but improperly; for luſcitioſus is one who ſees but little through ſome defect of the eye, and ſees better in the evening than at noon. But amongſt both the Greek and Latin writers, there is a direct oppoſition in the uſe of the word nyctalops, ſome ſaying it ſignifies thoſe who ſee by night, and others expreſs by it thoſe who cannot ſee during the night. However, at preſent it is underſtood to ſignify that diſorder, in which, as the night approaches, the patient loſes his ſight, he remains blind until the morning, at which time the ſight returning, it continues all the day, and ſo continues to return with the day, and to depart at night.

The difference in the account of this diſorder, as to its appearing in the night, or in the day, is reconciled by conſidering it as of the intermitting kind; the difference then will conſiſt in the different times of its approach, ſo may be called periodical blindneſs. Intermittents appear in a variety of modes, and the ſucceſs of the bark, in ſome inſtances of this ſort of blindneſs, both favour the opinion of its being an intermittent diſeaſe of the eyes. See Lond. Med. Tranſ. vol. i. and Lond. Med. Obſ. and Inq. vol. i. p. 111, &c.

NYMPHÆ. They run down on each ſide of the clitoris, and with the frænum of the perinæum they form what ſome call the foſſa magna, or entrance into the vagina. In midwifery this is called os externum. Sometimes the *nymphæ* are large, and appear cancerous; when this happens, the part may be cut off with ſciſſars, and it will then heal as a common wound. Galen, and other ancient writers, ſometimes call the clitoris, and ſometimes the hymen, by the name of *nymphæ*; but what the moderns call *nymphæ* or criſtæ clitoridis, or alæ minores ſive internæ, are two prominent folds of the inner ſkin of the greater or external alæ, reaching from the præputium of the clitoris, to the two ſides of the great orifice of the uterus: they begin narrow, grow broader, then at their lower end they grow narrow again, and are loſt about the orifice of the vagina, in the labia externa.

NYMPHÆA, called alſo nenuphar, leuconymphæa. The great white water lily. *Nymphæa* alba, Linn. It is called *nymphæa*, becauſe it lives in waters where the nymphs are feigned by the poets to inhabit. There are ſeveral ſpecies, diſtinguiſhed by their white and yellow flowers, &c. but their virtues, which are ſaid to be anodyne and demulcent, are too inſignificant to demand any notice in medical practice. See Raii Hiſt.

NYMPHÆA. The name of a preternatural excreſcence on the nymphæ, alſo of the plant called frog-bit.

NYMPHOIDES, alſo called nymphæa lutea minor, and nymphæa alba minor. It is thus named from its reſemblance to the nymphæa, both in its form and virtues.

NYMPHOMANIA, from νυμφὴ, *nymphæ*, and μανία, *furor*. i. e. furor uterinus. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order dyſorexia. See Furor Uterinus.

NYMPHOMANIA PRURIGINOSA. A variety of the *nymphomania*.

NYMPHOTOMIA. A ſection of the clitoris when too large; for the ancients called the clitoris by the name of nympha.

NYSTAGMOS. A winking, or twinkling with the eyes, ſuch as happens when a perſon is very ſleepy. When a diſeaſe, it is an inſtance of the clonic kind of convulſion.

O.

OB. Selden ſays that *Ob* was uſually tranſlated Python, or magician. This *Ob* is as a ſpirit, or demon, that gave anſwers which ſeemed to come from the pudenda, the head, or the arm-pits, but with a voice ſo low, as not often to be diſtinctly heard.

OBELÆA, from ὀβελὸς, *a dart* or *a ſpit*. Obelæa faturas or ſagittalis. An epithet for the ſagittal ſuture of the ſkull, alſo called the ſtrait future of the head.

OBELCHERA. A cucurbit.

OBELISCOTHECA. Dwarf American ſun-flower. There are two ſpecies, one from Virginia, the other from Carolina. They are of no medical uſe. See Miller's Dict.

OBESITAS. Corpulence, or fatneſs. See POLYSARCIA. It is obſerved that for one fat perſon in France or Spain, there are an hundred in England and Holland. This is ſuppoſed to be from the uſe of new malt liquors, more than from the difference of climes, or degrees of perſpiration. Indolence may cauſe fatneſs in ſome conſtitutions; but, in general, thoſe who are diſpoſed to this habit will be fat in ſpite of every endeavour to the contrary, but that of deſtroying health. Vinegar never prevents fatneſs, but by inducing a worſe diſorder. One of the beſt methods of emptying the cellular membrane of its oil, ſeems to be a gentle mercurial ſalivation, and decoctions of guaicum wood at proper intervals. See a remarkable inſtance of fatneſs in the Lond. Med. Obſ. and Inq. p. 69—84.

OBLATE PURGENTES. They are figured purging cakes, made of flour, ſugar, and purging ingredients.

OBLIQUUS. A name for ſeveral pairs of muſcles; alſo a name of the pronator.

OBLIQUUS ASCENDENS, called alſo obliquus internus, and acclivis. Theſe muſcles of the belly receive their name from the oblique aſcent of their fibres. They lay under the *obliquus* deſcendens. The ſame error which many anatomiſts have taught with reſpect to the *obliquus* deſcendens, they have declared with reſpect to theſe muſcles; they have no communication with the lumbal vertebra; they ariſe fleſhy from the ſpine of the os ilium and ligamentum pubis, and the upper edge of the os ſacrum, according to Dr. Hunter; but ſome others ſay, that there is no part of them comes from the os ſacrum, but paſſing forward and upward from the oſſa pubis and ilii, they form a broad membranous thin tendon, implanted into the whole length of the linea alba, and the cartilages of the 8th, 9th, 10th, 11th, and 12th ribs. Their tendons divide into two lamellæ, one of which joins the rectus on each ſide, and the other the tranſverſalis. Theſe muſcles are not perforated by the ſpermatic cord. Beſides their uſe in compreſſing of the belly, that part which ariſes fleſhy towards the back part of the edge of the os ilium, and goes to the cartilaginous endings of the ribs, not only depreſſes them, and ſtraitens the thorax in expiration, but alſo the order of the fibres of theſe muſcles interſect thoſe of the oblique deſcending muſcles, and counteract them in the turning the trunk of the body, on the axis of the vertebræ, as on its contrary ſide, its ſeries of fleſhy fibres being parallel to thoſe of the ſaid oblique deſcending on the oppoſite ſide, may act in concurrence with them in diſcharging of their office.

OBLIQUUS DESCENDENS. This pair of muſcles is alſo called declivis & obliquus externus. They are the external muſcles of the belly, and derive their name from the progreſs of their fibres, which run obliquely downwards. They ariſe by productions partly fleſhy, and partly tendinous, from the lower edge of the fifth, ſixth, ſeventh, and moſt of the inferior ribs, which indent themſelves into the fleſhy dentiform proceſſes of the ſerratus anticus major. Their fibres run forward and downward, terminating in the ſpine of the ilium, os pubis, and linea alba. Part of theſe fibres, which run toward the ilium, are loſt in the faſcia of the thigh, and thoſe which run towards the os pubis, are doubled under themſelves. This duplication (being ſuppoſed to be a ligament) goes by the name of ligamentum Poupartii, and through it the ſpermatic veſſels of men, and the round ligaments of the womb in women perforate. The ring through which theſe paſs, is formed by the tendinous fibres parting. From their origin, which are moſtly fleſhy, their oblique deſcending fleſhy parts expand themſelves into a broad membranous tendon, before they go over the rectus to their inſertion in the linea alba and os pubis, from whence ſtill deſcending, they end partly tendinous in the ligamentum pubis, but chiefly fleſhy on the ſuperior and forepart of the circular edge of the os ilium. They do not adhere to the tranſverſe proceſſes of the vertebræ lumbares, but their largeſt, laſt, and moſt fleſhy digitation, leaving the loweſt baſtard rib at its extreme point, in their oblique deſcent going forwards, ſtill recedes gradually from the vertebræ, forming a triangular interſtice, which is taken up by the ſacrolumbus, os ilium, and its lower ſide; in this area the fibres of the ſubjacent muſcles plainly appear. Theſe muſcles give ſtrength to the parietes of the belly, ſuſtain and compreſs the viſcera, propel the fæces, urine, and the fœtus; that part of them which is interjacent, between the linea alba, os pubis, and the ſpine of the os ilium, bearing an analogy in its poſition to the maſtoideus of the head, ſerves for the circumrotation of the trunk, upon the axis of the vertebræ, when we turn the body to the contrary ſide, and the feet remain unmoved.

OBLIQUUS INFERIOR, alſo called obliquus major. One of theſe muſcles riſes on each ſide, from the ſide part of the ſpinal proceſs of the vertebra dentata, then goes upward and outward, and is inſerted into the tranſverſe proceſs of the atlas. They are the principal rotators of the head, and run in a contrary direction to the *obliquus* ſuperior.

OBLIQUUS INFERIOR OCULI, i. e. Obliquus minor oculi.

OBLIQUUS MAJOR OCULI, alſo called obliquus major, and trochlearis. It is called trochlearis from its tendon paſſing through a cartilaginous pulley, that is ſituated in the orbit of the eye to the inſide of the internal angular proceſs of the os frontis near the inner angle. This muſcle riſes tendinous from the bottom of the ſocket near the entrance of the optic nerve, and paſſing towards the upper part of the ſocket near the great angle of the eye, its round tendon runs through a cartilaginous pulley, which is there fixed to a depreſſure in the os frontis, from thence it is reflected, and runs obliquely backward, incloſed in a ligamentous ſheath, and is inſerted tendinous into the ſclerotica, upon the upper part of the globe of the eye, a little more backward than the inſertion of the rectus ſuperior. When it acts ſingly, it rolls the eye about its axis, drawing the globe forward and the pupil downward; when it acts in conjunction with the *obliquus* minor, the eye is drawn outward or forward.

OBLIQUUS MINOR, i. e. Rectus minor.

OBLIQUUS MINOR OCULI. It riſes chiefly fleſhy, juſt within the edge of the lower and anterior part of the ſocket, near the caruncula lachrymalis, and paſſing obliquely backwards under the globe, it is inſerted into the ſclerotica on the external ſide of the eye, near the optic nerve.

OBLIQUUS NASI. Theſe are thin muſcles running along the ſides of the pyramidales naſi; they are fixed to the apophyſis naſalis of the oſſa maxillares, and are inſerted into the alæ narium.

OBLIQUUS PALPEBRARUM. The muſcles of the eye-lids thus named, are all that extent of fleſhy fibres, which by a thin ſtratum ſurrounds the edge of each orbit, and from thence, without any interruption, covers the two *eye-lids*, all the way to the cilia. Theſe fibres are moſtly tranſverſely oval. They adhere to the ſkin of the *eye-lids* and wrinkle them.

OBLIQUUS SUPERIOR. Theſe muſcles are on each ſide, covered by the head of the trachelo-maſtoideus, they each riſe from the tranſverſe proceſs of the atlas, and have their inſertion into the os petroſum and os occipitalis, near the proceſſus maſtoideus; they ſerve to bend the head backwards.

OBLIQUUS SUPERIOR OCULI, i. e. Obliquus major oculi.

OBLIVIO. Forgetfulneſs. Synonymous with amentia.

OBOLUS. A weight of about nine grains.

OBSIDIANA. They are ſpecies of glaſs, ſo called from their reſemblance to a kind of ſtone, which one Obſidius diſcovered in Ethiopia, of a very black colour, though ſometimes they are pellucid, and of a muddy water. Pliny ſays, alſo, that Obſidianum was a ſort of colour with which veſſels were glazed. Hence the name is applied by Libavius to glaſs of antimony.

OBSIDIANUS LAPIS. Canal coal.

OBSTETRICATIO. Midwifry. The firſt mention that is made of this is in Gen. xxxv. 16, 17. And then it appears to have been in the hands of women. Amongſt medical writers, Hippocrates was the firſt who gave any account of it, either as a branch of ſcience, or of art; after Hippocrates, Celſus, Moſchion, Rufus Epheſius, Galen, Oribaſius, Aetius, Paulus Ægineta, Avicenna, Alberſis, and others, have enlarged on this ſubject; but the laſt improvers are Mauriceau, the Chamberlains, Chapman, Daventer, La Motte, Giffard, Heiſter, Smellie, &c.

It may here be obſerved, that the Engliſh and the French are not peculiar nor unprecedented, in calling in the aſſiſtance of men. When women fell in labour, it appears in hiſtory, that the Athenians had a law to forbid ſlaves and women to practice *midwifry*; afterwards, indeed, a law was made, by which free-women were allowed to practiſe it.

Midwifry, at preſent, is taught and practiſed as a diſtinct branch of art; and in order to a proficiency therein, the practitioner is ſuppoſed to poſſeſs a competent knowledge of the following particulars, moſt of which are, more or leſs, noticed in the reſpective parts of this work. They are as follow:

The parts of the pelvis, its dimenſions, the depth of its cavity, its various diſtortions, &c. The parts of women, ſubſervient to generation. The ſtate of the womb and its neck, in the different periods of geſtation. Twins. Monſters. Superfœtations. Extra uterine fœtuſes. Moles. The progreſs of a child's head thorough the different parts of the pelvis in a natural labour. The ſecundines. The various complaints which uſually attend pregnancy. The manner and uſe of touching. The difference betwixt falſe and true labour pains. The different kinds of labour. The various modes of the child's preſenting, with the methods of delivery. The diſorders of child-bed women. The management of the child and its mother during the time of lying-in, &c. on which ſee the articles PELVIS, PARTURITIO, GESTATIO, INVOLUCRA, PRÆSENTATIO, &c.

See Treatiſes of Midwifry by Chapman, Mauriceau, Dionis, La Motte, Smellie, Memis, &c. Caſes of Midwifery, by Giffard and Smellie, Hamilton, &c.

OBSTIPATIO. Coſtiveneſs. Thus Dr. Cullen names this genus of diſeaſe. He places it in the claſs locales, and order epiſcheſes. Its ſpecies are, 1. Obſtipatio debilium; it happens in lax and weakly men who have generally but a weak digeſtion. 2. Obſtipatio rigidorum; it happens to men who have rigid fibres, who often are hypochondriac. 3. Obſtipatio obſtructorum; when there are ſymptoms of the ſpaſmodic colic, the colic of Poictiers, the accidental colic, or the colic from ſtony concretions in the bowels. See CONSTIPATIO.

OBSTIPITAS. The ſame as contractura primaria. This word, with any other annexed, is only one or other variety of contracting; this is the inſtance known by the name of wry-neck.

OBSTRUCTIO. Obſtruction. It is when the fluids can no longer paſs through the veſſels of a particular part; and may happen from the increaſed viſcidity of the fluid; a diminution of the capacity of the veſſels; or a concurrence of both theſe cauſes. Theſe are more or leſs difficultly removed, according to the age, conſtitution, &c. of the patient.

OBTUNDENTIA. Medicines which leſſen the acrimony of the humours.

OBTURATOR EXTERNUS. Some call it marſupialis. This muſcle covers the foramen magnum iſchii, and riſing from the bone before the foramen, runs backwards under the head of the os femoris, covered by the quadratus femoris, and is inſerted into the trochanter major, contiguous to the internus, and is, like it, a rotator.

OBTURATOR INTERNUS, or Marſupialis. This muſcle takes its origin from the inner circumference of the foramen magnum iſchii, and goes out playing round the iſchium as on a pulley, and is inſerted into the trochanter major, contiguous to the pyriformis, and is a rotater of the thigh. The tendon of this muſcle plainly grooves the bone in its paſſage.

OBTURATOR NERVUS. This nerve is a branch of the crural; it paſſes through the foramen ovale, and is loſt in the inner muſcles of the thigh.

OBTURATRIX ARTERIA. It is a branch of the hypogaſtric. It perforates the obturator muſcle, whence its name; and goes out of the pelvis, at the upper part of the ligament of the foramen ovale, having firſt ſent a branch over the ſymphyſis of the os ilium, and os pubis, to the inguinal glands and integuments. It ſends out a branch which communicates with a branch of the ſciatica arteria; and gives out branches to the adjacent muſcles, and ſends many ſmall ones by the neck of the thigh bone.

OBTURATRIX VENA. It is a branch from the hypogaſtric vein, and receives this name, where it enters into the internal obturator muſcle.

OCCIPITALIS ARTERIA. It is the firſt external, or poſterior branch of the external carotid. It paſſes obliquely before the internal jugular vein; and having ſent out twigs to the adjacent muſcles, it runs between the ſtyloid and maſtoid apophyſes, along the maſtoid groove, and goes to the muſcles and integuments, which cover the occipital bone. It communicates with the temporal, vertebral, and cervical arteries.

OCCIPITALIS MUSCULUS. This is mentioned by Columbus, and accurately deſcribed by Fallopius. There are two of them; they are ſhort, broad, thin, and fleſhy; they are ſituated on the occiput, where the maſtoideus and ſplenius muſcles are inſerted; they ſoon become tendinous, join with the pericranium, which firmly adheres to the hairy ſcalp on the ſinciput. When they act they pull the hairy ſcalp backwards.

OCCIPITALIS NERVUS. A branch from the tenth pair of nerves which proceed from within the ſkull; they run on the upper and lateral parts of the head.

OCCIPITALIS POSTERIOR ARTERIA. It is a branch from the vertebral. It ſpreads on the occiput.

OCCIPITALIS VENA. A branch from the poſterior, or upper external jugular; but it ſometimes proceeds from the vertebralis, or axillaris. It ſpreads on the occiput.

OCCIPITIS OS. This bone is of a rhomboidal figure, a tranſverſe ridge running from the maſtoid proceſs of one ſide to that of the other, divides it into two parts. Its external ſurface is convex, except at the cuneiforme proceſs, at the baſe of which, on each ſide of the foramen magnum, are the condyles which connect the head to the ſpine; on the outſide of theſe condyles the bone makes a projection, and there is a notch where the internal jugular vein paſſes. The bone is divided into four cavities in its inſide, by a crucial ſpine, which hath four canals in it; the ſuperior, for the longitudinal ſinus; the

inſe-

inferior frequently hath the occipital ſinus; theſe on each ſide, for the lateral ſinuſes, which are continuations of the longitudinal. There are five foramina proper to this bone; the firſt is the foramen magnum; juſt above the condyle there is a hole on each ſide for the ninth pair of nerves, and generally there are two holes which pierce from behind the condyles to the foſſæ of the lateral ſinuſes. Beſides theſe, there are two common foramina which are one on each ſide, between the proceſſus cuneiformis and os petroſum.

OCCIPITO FRONTALIS. Albinus calls it epicranium. It riſes from the poſterior part of the occiput, goes over the upper-part of the os parietale and os frontis, and is loſt in the eye-brows. It is a very thin muſcle, its office is, to raiſe the eye-brows, and wrinkle the forehead. It is antagoniſt to the corrugator Coiterii.

OCHEUS. The ſcrotum.

OCHRA, called alſo vitriolum abortivum. Yellow ochre. Some is found of a brown colour; and ſome is red. The darkeſt red ſort is called red *oker*, rubrica Græcis, Creta rubra, marking ſtone, rudd and ruddle. They are an argillaceous earth, leſs tenacious when moiſtened than the clays and the boles; impregnated with a ſmall portion of iron, and thence their colour. By burning, their argillaceous nature is diſcovered; and by digeſting in aqua regis their iron is extracted, and then the ochre remains white. Their chief difference from bole is in their being leſs viſcid. See Lewis's Mat. Med. Neumann's Chem. Works.

OCHRA NIGRA. Black-lead.

OCHREA. The fore-part of the tibia.

OCHRUS, alſo called Lathyrus, and ervilia. Boerhaave mentions this plant. It bears cylindrical pods with round ſeeds as large as peas, which are eatable, but not very eaſily digeſted

OCHTHODES, from ὀχθος, importing the tumid lips of ulcers, callous, tumid; or from ὀχθη, *a bank*. It is an epithet for ulcers which are difficult to heal.

OCIMASTRUM, alſo called ocymoides, lichnis ſylveſtris, alba ſimplex. Wild white campion.

It is Boerhaave's fourteenth ſpecies of lychnis. It is found in hedges and borders of fields; it flowers in May. The flower is ſaid to check the fluor albus, and inward bleedings; the herb boiled in poſſet, is ſaid to cure convulſions in children; but its virtues hath not obtained it a place in practice. See Raii Hiſt.

OCOLOXOCHITL, i. e. Tigridis flos.

OCTANA. An erratic intermitting fever, which returns every eighth day.

OCTAVUS HUMERI MUSC. i. e. Teres minor.

OCTAVUS HUMERI PLACENTINI MUSC. i. e. Teres minor.

OCULARES COMMUNES. A name for the nerves, which are alſo called motores oculorum.

OCULARES EXTERNI. Motores oculorum externi.

OCULARIA. Eye-bright.

OCULI CANCRORUM. Crabs-eyes. They are ſtony concretions, of what, at firſt, was but a milky juice, found in the head of the aſtacus fluviatilis, or river craw-fiſh; they are lodged in a bag on each ſide the ſtomach, which alſo is in the head of this fiſh, two of them are lodged in the head of each. Theſe ſtones are roundiſh, flatted on one ſide, in colour white, having ſometimes a reddiſh, and at others, a bluiſh caſt; the blue are the beſt, the white are taken out after the fiſh hath been boiled; they are internally of a leafy texture. The largeſt quantities are the produce of Muſcovy, particularly of the river Don; great quantities are alſo found in other parts of the Ruſſian empire.

They are uſed as an abſorbent of acid humours in the primæ viæ, and are ſuppoſed, when combined with the acid, to be more aperient and reſolvent than moſt of the other abſorbent earths; however this may be, it is certain that the earth of *crabs-eyes*, differs much from the earth of crabs-claws, for the firſt is not convertible into quick-lime. The medical difference of their earths, diſſolved in any acid of the vegetable or animal kingdom, do not appear to be great; the ſolutions of the two are alike in taſte. The earth of *crab's-eyes*, as to its chemical characters, is the ſame as the earth of hartſhorn.

Theſe ſtones are counterfeited with pipe clay, or with chalk, mixed with glutinous materials, or with the ſhells of fiſhes; but theſe compoſitions are eaſily diſtinguiſhed from true *crabs-eyes*, by their texture being uniform, and not leafy; by their ſticking to the tongue, which *crabs-eyes* will not do; by their ſoftening with water, which *crabs-eyes* will not do; by their diſſolving in acids, while *crabs-eyes* ſteeped in vinegar, retain their form; but when the artificial ſort are made with ſhells, the want of the lamellated coats is the beſt method of diſtinguiſhing them. See Tournefort's Mat. Med. Lewis's Mat. Med.

OCULUS. The eye. The external parts are, the eye-brows, the eye-lids, the cilia, the forepart of the globe, the membrana conjunctiva, the cornea lucida, the iris, the pupilla, the caruncuiæ lachrymales, and angles of the eye-lids, &c. The internal parts are the globe of the *eye*, the adnata or albuginea, the ſclerotica, the choroides, the retina, the aqueous humour, the vitreous humour, the muſcles that move the *eye*, and the optic nerve, &c.

Notwithſtanding this enumeration of parts, and their deſcription reſpectively in the courſe of this work; the following ſhort deſcription may have its advantage, by giving a collected view of thoſe parts as forming one whole body.

The globe of the *eye* is compoſed of three tranſparent humours, which, from their ſuppoſed reſemblances, bear the ſeveral denominations of the aqueous, the cryſtalline, and the vitreous. The vitreous humour fills by far the largeſt part of the cavity which contains it; the cryſtalline humour is included in a capſule, and placed anterior to the vitreous; the aqueous humour is betwixt the cryſtalline and the pupil. All theſe humours are contained within the three proper coats called ſclerotica, choroides, and retina.

The coats of the *eye* are three proper ones, and two which only cover the forepart of it, and are exterior to all the proper ones.

The firſt of the proper coats is the ſclerotica, which is alſo the outermoſt of them. This, in the poſterior and far greater part of its circumference, is white and opake; but in the anterior, is tranſparent, and takes the name of cornea.

The choroides is ſituated on the inſide of the ſclerotica, between it and the retina. It is ſtrongly attached to the ſclerotica, round the margin, where the cornea begins; whence it paſſes on, and becomes viſible through the tranſparency of that coat. This part of the choroides is called iris, being of various colours in different perſons; and in its center is a round perforation, to admit the rays of light, called the pupil.

The retina, or internal coat, appears to be an expanſion of the medullary part of the optic nerve, being a white thin membrane, of a very ſoft and tender texture. It lies immediately behind the vitreous humour, round which it is continued to the borders of the cryſtalline, and is generally believed to be the immediate ſeat of the ſenſe of viſion.

The globe of the *eye* reſts in the orbit, upon a large body of adipoſe membrane; and is moved in different directions, by four ſtraight and two oblique muſcles. Five of theſe take their origin from the bottom of the orbit; the inferior oblique alone ariſing from its edge: and they are all continued forward, to be inſerted by a tendinous expanſion into the anterior part of the tunica ſclerotica; which expanſion, having a white colour, has acquired the name of tunica albuginea.

The tunica conjunctiva is a thin tranſparent membrane, which lines the inner ſurface of the eye-lids, and, at the edge of the orbit has a fold, and is continued forward, over the anterior half of the globe of the *eye*. It is exterior to all the other coats of the *eye*, and connected with the tunica albuginea, by means of a cellular ſubſtance; from which it may eaſily be ſeparated in the dead ſubject, by diſſection. According to Winſlow, it is perforated by innumerable and almoſt imperceptible pores.

Its continuation from the eye-lids to the *eyes*, prevents the ill conſequences which might otherwiſe enſue, from the inſinuation of extraneous bodies between them.

The tears are ſecreted by a conglomerate gland, called glandula lachrymalis, which is ſituated in a ſmall depreſſion of the orbital proceſs of the os frontis, near the outer

angle of the orbit; from which they are poured out by ſmall ducts, and continually ſpread over the ſurface of the *eye*, to keep it clear and tranſparent. They paſs from the *eye*, through two minute orifices, at the inner angle, called the puncta lachrymalia, which open into a ſmall bag called ſaccuius lachrymalis; and this bag is continued thence, through a bony channel, and opens immediately into the noſe.

The little red body, at the great or inner angle of the *eye*, is called caruncula lachrymalis: as to its ſtructure or its uſe, not any thing certain is diſcovered. It may be ſaid to direct the tears into the puncta lachrymalia; and, in that office, is much aſſiſted by a reduplication of the tunica conjunctiva, which has been called valvula ſemilunaris. This valve is ſeen by turning the *eye* toward the noſe. It is ſituated cloſe to the caruncle, and is ſhaped like a creſcent, with its points inclined to the puncta lachrymalia.

The ſituation and figure of the eye-lids are too obvious to need deſcription.

The edge of each of the eye-lids is principally formed by a thin cartilage, called tarſus; which is adapted to the ſhape and roundneſs of the *eye*. The lower edge of the ſuperior cartilage, and upper edge of the inferior, meet each other; and are termed the ciliary edges. Theſe cartilages do not terminate in a line, like the ſharp edge of a knife; but rather flat, like the back of it; forming two edges, one external, and the other internal. When the *eyes* are ſhut the external edges meet: but the internal are preſerved at a ſmall diſtance from each other; leaving a gutter or groove, through which the tears are ſuppoſed to paſs from the lachrymal gland to the puncta lachrymalia while we are aſleep.

The cilia, or eye-lathes, ariſe out of the external edge of the termination of this cartilage; and on the internal, at an evident diſtance from them, is a line of ſmall orifices, which are the excretory ducts of ſmall glands that lie on the inner ſurface of the tarſus, and are called glandulæ ciliares, or glandulæ Meibomii. The uſe of theſe glands is to ſecrete a ſebaceous matter, ſimilar to ſoft wax, which conſtantly covers the edges of the lids, and keeps them ſupple.

A new born child ſhall be obſerved, perhaps, never to keep its *eyes* fixed on any one ſubject, but continually changing from one to another, and if you put your hand before them, the children will not wink; hence ſome have thought, that new born infants have no ſight; but this is a miſtake, and the true reaſon why their *eyes* are in perpetual motion is, that they have not yet acquired the habit of examining one thing at once with their *eyes*; their not winking at the approach of the hand ariſes from their want of experience how eaſily their *eyes* may be hurt; but in a few days, they get the habit of winking, ſo that afterwards their *eyes* do it ſpontaneouſly at the approach of danger

See a Deſcription of the Eye, and its adjacent parts, by J. Warner, Surgeon; Remarks on the Ophthalmy, &c. by J. Ware, Surgeon; Winſlow's Anatomy; Cheſelden's Anatomy, &c.

Artificial *eyes* are made of concave plates of gold, ſilver or glaſs, and are ſtained ſo as to reſemble the natural *eye*. They muſt, when fixed in the orbit, be taken out and cleaned every night, and replaced in the morning. If no more of a diſeaſed *eye* is removed, than what is preternaturally projected, or if enough is left, to leave the muſcles unhurt, the artificial eye will have a little motion from the muſcles that remain. If the *eye* does not fit well, it irritates and inflames the other *eye*, in which caſe, lay it aſide, until one can be had that fits better.

On Diſorders of the Eyes, ſee St. Yves; Benedict Duddell; and J Warner, Surgeon; Ware's Remarks on the Ophthalmy, &c

OCULO MUSCULARES. The nerves called motores oculorum.

OCULO MUSCULARES EXTERNI. The nerves called motores oculorum externi.

OCULUS. See COLIQUAMENTUM.

OCULUS BOVINUS. See PROPTOSIS.

OCULUS BOVIS. The great daiſy.

OCULUS BUBULUS. See PROPTOSIS.

OCULUS CATI, alſo called aſteria, and cat's-eye. It is a ſpecies of agate.

OCULUS CHRISTI. Wild clary.

OCULUS ELEPHANTINUS. See PROPTOSIS.

OCULUS GENU. The knee-pan.

OCULUS LACHRYMANS, i. e. Epiphora.

OCULUS MUNDI. It is a ſpecies of opal; generally of a yellowiſh colour. By lying in water it becomes of an amber colour, and alſo tranſparent.

OCYMASTRUM, i. e. Ocimaſtrum. It is a name for the circæa Lutetiana; and of ſeveral ſpecies of lychnis.

OCYMASTRUM VERRUCCARIUM. The inchanter's night-ſhade.

OCYMOIDES, alſo called lychnis ſylveſtris five aquatica purpurea ſimplex. Red wild campion.

It is Boerhaave's twentieth ſpecies of lychnis. It grows in hedges, and flowers in ſummer. The ſeeds are purging, but it is not known in preſent practice. See Raii Hiſt.

OCYMOIDES. It is a name for ſeveral ſpecies of lychnis, of the ocimaſtrum, and of a ſpecies of the myoſotis.

OCYMUM, ωκυς, *ſwiftly*. It is thus called from its ſudden growth. It is alſo called baſilicum, becauſe of its excellent ſmell. It is the *ocymum* baſilicum, Linn. Boerhaave enumerates twenty-four ſpecies. The chief uſe of *ocymum* is for improving the flavour of ſp. vol. arom.

OCYMUM AQUATICUM. A ſort of water thiſtle.

OCYMUM SYLVESTRE, i. e. Acinos.

ODAXISMOS, from οδους, *a tooth*. A biting ſenſation, pain, or itching in the gums. Hippocrates uſes this word principally with reſpect to the gums when the teeth are forcing a paſſage through them.

ODONTAGOGOS, from αγω, *to draw*, and οδους, *a tooth*, and αλγη, *pain*. An inſtrument for drawing the teeth.

ODONTAGRA. It is either an inſtrument for drawing the teeth with, or the gout in the teeth.

ODONTALGIA, from οδους, *a tooth*, and αλγος, *pain*. The tooth-ach. Dr. Cullen places this genus of diſeaſe in the claſs pyrexiæ, and order phlegmaſiæ. This happens either from external or from internal cauſes. The external are ſuch as rot the teeth, by deſtroying their enamel, and thus procuring an acceſs of air to their bony part. Hot liquors, frequent picking of the teeth with hard inſtruments, as pins, &c. ſoon deſtroy this enamel; and when once the tooth is carious, the only cure is to extract it. The internal cauſes are acrid particles excreted from the blood, in which caſe an emollient gargariſm ſhould be frequently held in the mouth as warm as is convenient; bliſters behind the ears are alſo uſeful, and if the gums ſwell, leeches may be applied, or ſmall ſcarifications made in them with a lancet.

ODONTIASIS, from οδους, *a tooth*. Dentition.

ODONTICA. Remedies for pains in the teeth.

ODONTIRRHOEA. Bleeding from the ſocket of the jaw after tooth drawing.

ODONTIS, & Odontitis. Names for ſeveral ſpecies of lychnis.

ODONTOGLYPHON, from οδους, *a tooth*, and γλυφω, *to ſcrape*. An inſtrument for rubbing or ſcaling the teeth.

ODONTOIDES, from οδους, *a tooth*, and ειδος, *form*. The tooth-like proceſs of the ſecond vertebra of the neck.

ODONTOPHYIA, from οδους, *a tooth*, and φυω, *to grow*. Dentition.

ODONTOTRIMMA, from οδους, *a tooth*, and τριβω, *to wear away*. A dentrifice.

OLFACTUS. The ſenſe of ſmell. See OLFACTUS.

ODORIFERÆ GLANDULÆ. Theſe are about the pudenda, arm-pits, &c. They are of the ſame kind as the ſebaceous glands. Dr. Hunter ſays he never could diſcover the orifices of theſe in the axilla, therefore he ſuppoſes the diſcharge to be from innumerable ſmall pores that are imperceptible.

OE. The ſervice-tree.

ŒCONOMIA, from οικος, *an houſe*, and νομος, *a law*, or *rule*. Hippocrates uſes this word to expreſs the management of a ſick perſon. The animal *œconomy* is the conduct of nature in preſerving animal bodies.

ŒDEMA. See TUMOR.

ŒDEMA, from οιδεω, *tumeo*. It ſignifies properly any tumor

tumor, but is now generally confined to thoſe ſerous tumors that are ſeated in the cellular membrane, and form partial anaſarcous ſwellings. See ANASARCA.

When the glands are diſeaſed, the lymph cannot paſs towards the heart, but goes to the lower extremities merely from gravitation; and for want of a due abſorption the limbs ſwell.

When the veſſels are not too much debilitated, rollers, or laced ſtockings, are ſometimes uſeful.

ŒDEMA ERYSIPELATOIDES. It is that œdematous tumor which is white, pellucid, and accompanied with heat.

Dr. Kirkland, in the firſt volume of his Inquiry, ſpeaks of an inflammatory *œdema* which comes on ſuddenly, and is ſometimes accompanied with an eryſipelas, or more commonly a ſimple inflammation of the ſkin. He deſcribes it as a cold, indolent, doughy humour; and in order to its cure, requiring diſcuſſion. He obſerves, that an *œdema* is always local; it is always confined to one place, or member.

It is ſometimes cauſed by a metaſtaſis of inactive matter from the blood and other juices; ſometimes from nervous affection.

Diſtinguiſh this diſeaſe from the anaſarca.

In an *œdema*, which comes on ſuddenly, and is of ſhort duration, the fluids have not had time to become viſcid in the cellular membrane; they are therefore eaſily ſet at liberty, and the inflammation diſappears as the ſwelling ſubſides.

As an external application, a cerate may be made of the empl. e min. f. cera f. & ol. oliv. As ſoon as the ſwelling begins to ſubſide, apply a bandage, and gradually increaſe its tightneſs as circumſtances will permit. Over night give ſmall doſes of calomel, and next morning a purging draught, in which is diſſolved a proper quantity of the ſoluble tartar. Sudorifics, or diuretics, may be given to haſten the cure; which, when tolerably advanced, will require the bark; this at firſt ſhould be accompanied with the ſal diuret. but when evacuation is no longer required, the bark may be given alone.

ŒDEMA-ŒDEMATODES. It is that ſerous tumor which is ſimply called *œdema*, or, according to ſome, the cold *œdema*.

ŒDEMOSARCA. A ſpecies of tumor mentioned by M. A. Severinus, of a middle nature, betwixt an *œdema* and ſarcoma.

ŒLNIZIUM, i. e. Œlſnitium.

ŒLSNITIUM, called alſo olſenichium, œlnizium, Thyſſelinum Plinii, apium ſylveſtre. Milky parſley. The root of this plant is perennial, large, and full of milky juice, as is the whole plant. The leaves reſemble thoſe of the ferula; the ſeed is oval, flat, large, ſtriated, marginated, and ſometimes caſts it huſks. There is another ſpecies called thyſſelinum paluſtre, and ſeſeli paluſtre. They are both hot and acrid, the roots are aperient and detergent, their milky juice is of the nature of ſcammony. See Raii Hiſt.

ŒNANTHARIA. Sweet-ſcented ointments. Paulus Ægineta ſays they are not thus named becauſe they have *œnanthe* in their compoſition, but becauſe they are ſweet-ſcented and fragrant, or on account of the wine and lilies which are ingredients in it.

ŒNANTHE, from οινη, *a vine*, and ανθος, *a flower*. Vine flower. So the ancients called ſome plant which was in flower at the ſame time as the vine, or whoſe flower had the ſame ſmell as thoſe of the vine, *œnanthe*.

ŒNANTHE CHÆROPHYLLI FOLIIS, Œnanthe petroſelidi folio venenoſa, Œnanthe cicutæ facie Lobelii, Filipendula cicutæ facie. G. Hemlock drop-wort. Dead-tongue. It is the *œnanthe* crocata of Linn. Near Clonmell, in Ireland, it is called tahow.

The root is long, thick, tuberous, extremely ſucculent, and on expoſure to the external air, the juice becomes of a yellow complexion. The ſtalk is ſtriated, round, branched, of a yellowiſh red colour, about three feet high. The leaves are of a pale green, ſome are winged, but more are doubly winged; the little leaves are wedge-ſhaped, ſmooth, ſtreaked, and jagged at the edges. The flowers are very ſmall and white; diſpoſed in umbels, placed among the principal ſtalks, with ſhort ones at the ſubdiviſions: each flower is compoſed of five petals, ſome of them are bent inwards and heart faſhioned; tips, purple or brown; fruit ſtalks angular, ſcored; the general fence not always preſent. The ſeeds are ſtriated on one ſide, and dented on the other.

It is found on the banks of rivers; is perennial; flowers in June or July.

The whole of this plant is poiſonous. It is ſaid that the root is the moſt virulent of all the vegetable poiſons that Great Britain produces. It is one of the claſs of poiſons which produces epileptic ſymptoms, &c. See VENENUM. The general effects of this poiſon are convulſions, locked jaws, giddineſs, ſome inſtances of furious madneſs have occurred, loſs of hair and nails, violent heat in the throat and ſtomach, vertigo, ſickneſs, purging: one or more of theſe ſymptoms ſoon attack after ſwallowing any part of this plant, and the conſequence is often fatal in a few hours.

This herb hath been miſtaken for wild celery, water-parſnep, ſmallage, and for Macedonian parſley. The root hath no ill taſte; hence the more apt to be unſuſpected.

In Pembrokeſhire the root is called five-fingered root; and is much uſed in cataplaſms for whitlows, &c. In Cumberland it is called dead-tongue, and applied in cataplaſms to ſome diſeaſes in horſes. An infuſion of the leaves, or three tea-ſpoonfuls of the juice of the root taken every morning, hath been effectual in curing ſome obſtinate cutaneous diſeaſes, but not without greatly diſturbing the conſtitution.

On ſuſpicion of this poiſonous plant being ſwallowed, give an active emetic as ſpeedily as poſſible, and aid its operation with warm water and oil. If the ſpaſms prevent the patient's ſwallowing, there is no hope.

Withering's Bot. Arrang. Wilmer's Obſ. on poiſonous Vegetables; a caſe of a boy poiſoned by the root of hemlock dropwort, related by Dr. Houlſton, in the Lond. Med. Journal, vol. ii. p. 40, &c.

ŒNANTHE AQUATICA, called alſo filipendula aquatica. Water drop-wort. It grows in meadows, and on the ſides of brooks. It is bitteriſh, and ſlightly aſtringent, hot, dry, and diuretic.

Theſe plants are not in uſe; inſtances are recorded of their poiſonous quality.

ŒNANTHE. Water-hemlock. Alſo a ſpecies of thalictrum.

ŒNAREA. The aſhes prepared of the twigs, &c. of vines.

ŒNELÆUM. A mixture of oil and wine.

ŒNOGALA, from οινος, *wine*, and γαλα, *milk*. A ſort of potion made of wine and milk; but according to ſome, it is wine as warm as new milk.

ŒNOPLIA, alſo called nabea, paliurus, nap, and the great jujube. This fruit is produced in Egypt and Crete; it is aſtringent before it is ripe. When ripe it is agreeable to the palate, and like cherries is ſubject to corrupt in the ſtomach. They are eaten as delicacies in Egypt and Turky.

ŒNUS. Wine.

ŒNUS ANDRIUS. Generous wine, or elſe wine of the iſland of Andros.

ŒNUS ANTHINOS. Flowery wine. Galen ſays it is either *œnus* anthoſmias, or wine impregnated with flowers, in which ſenſe it is an epithet for the cyceon.

ŒNUS ANTHOSMIAS, from ανθος, *a flower*, and οσμη, *a ſmell*. Sweet-ſcented wines.

ŒNUS APODÆDUS. Wine in which the dais or tæda hath been boiled.

ŒNUS APEZESMENUS. A wine heated to a great degree, and preſcribed among other things, as garlic, ſalt, milk, and vinegar.

ŒNUS GALACTODES. Wine with milk, or wine made as warm as new milk.

ŒNUS DEUTERUS. Wines of the ſecond preſſing.

ŒNUS DIACHEOMENUS. Wine diffuſed in larger veſſels, cooled, and ſtrained from the lees, to render it thinner and weaker. Wines thus drawn off are called faceus, and faccata, from the bag through which they are ſtrained.

ŒNUS MALACUS, ſive Malthacus. Soft wine. Sometimes it means weak and thin, oppoſed to ſtrong wine; or mild, in oppoſition to auſtere.

ŒNUS MELICHROOS. Wine in which is honey.
ŒNUS ŒNODES. Strong wine.
ŒNOS SIRÆOS, i. e. Sapa.
ŒNOS STRAPHIDIOS LEUCOS. White wine made from raiſins.
ŒNOS TETHALASMENOS. Wine mixed with ſea water.
ŒNOSTAGMA. Spirit of wine.
ŒNOTHERA, i. e. Lyſimachia.
ŒPATA. The anacardium. Alſo a tall tree in China, the kernels of whoſe fruit are uſed in a diſh which is called carii by the Indians. This fruit much reſembles the anacardium. See Raii Hiſt.
ŒSOPHAGÆÆ ARTERIÆ. Theſe are generally two or three, and ſometimes but one. They riſe anteriorly from the aorta deſcendens, and are diſtributed to the œſophagus. Sometimes the uppermoſt œſophagæ produce a bronchial artery.
ŒSOPHAGÆUS. The ſphincter œſophagi. See ŒSOPHAGUS.
ŒSOPHAGISMUS. Impeded deglutition, or ſpaſm of the œſophagus.
ŒSOPHAGUS, from ἐσω, the future tenſe of φερω, *to carry*, and φαγω, *to eat*, becauſe it carries the meat into the ſtomach. The gullet. It is the contracted continuation of the pharynx. The *œſophagus* beginning at the laſt part of the fauces, has, at its beginning, a large cavity, called by the Greeks pharynx, and by the Latins infundibulum. Its anterior part is connected with the root of the tongue, the os hyoides, and the larynx; and its poſterior part cloſely adheres to the vertebra of the neck. It is moved by various muſcles, which elevate and dilate the pharynx, and by their conſtrictory muſcles which ſhut it. There is one pair of theſe muſcles, which ariſing by three origins from the os hyoides, the cartilago cricoides, and the cartilago thyroides, totally ſurrounds the pharynx, and is called the ſphincter of the *œſophagus*. There are principally three pair of theſe muſcles, viz. the cephalo pharyngæus, ſpheno pharingæus, and ſtylo pharyngæus. At the end of the pharynx the *œſophagus* begins, which firſt of all runs ſtrait between the aſpera arteria, and the vertebræ of the neck and back, but turns to the right about the fifth vertebra of the back, and to the left about the ninth; then proceeding through the middle of the thorax, and the muſcular part of the diaphragm, behind the little lobe of the liver, it is united with the ſuperior orifice of the ſtomach. The *œſophagus* itſelf conſiſts of four coats, the outermoſt coat of which being membranaceous, thin, vaſcular, and cellular, derives its origin from the pleura, and joins the gullet to the adjacent parts. Some reckon the cellular membrane in the number of its coats, but this is not peculiar to it. The coat next to the outer is muſcular, furniſhed with annular or orbicular fibres, and above theſe with longitudinal ones. The third coat is nervous, common to the mouth and fauces, and reaching three fingers breadth within the ſtomach; it is thick ſet with glands, to which, on the oppoſite ſide, are diſtributed ſome veſſels, from which they receive a certain liquor, more pinguious than the ſaliva, and which drops into the cavity of the gullet. The fourth coat, or innermoſt, is covered with a ſlippery mucus, villous, and every where perforated like a ſieve, with many emunctories. The cuticle lines the *œſophagus*, but is too thin to be demonſtrated. The *œſophagus* is furniſhed with numberleſs glands, partly thoſe which being ſmaller than the eggs of ſilkworms, are lodged in the nervous coat, and are eaſily perceived, if upon taking off the nervous coat, the fleſhy coat is expoſed to the ſight, or the gullet is macerated in water; and partly with other glands placed without the *œſophagus*, amongſt which the moſt conſiderable are the dorſal glands about the fifth vertebra of the back, adhering to the gullet, and the thyroid gland ſituated between the thyro-cricoide cartilage and the *œſophagus*. Its upper part receives arteries from the internal carotids, its middle part from the aorta and intercoſtal, and its inferior part from the gaſtric arteries. The ſuperior part receives veins from the jugulars, its middle from the vena ſine pari, and its inferior from the coronary veins of the ſtomach. The nerves proceed from the par vagum. The function of the *œſophagus* is, ſwallowing; obſtructions to which may happen from various cauſes. See DEGLUTITIO.

Spaſms in the *œſophagus* ſometimes prevent deglutition. Hoffman obſerves, that ſpaſms of the *œſophagus* are accompanied with the general ſymptoms of other diſtentions of the upper parts; a coldneſs of the extremities, particularly the feet; tremor of the limbs, ſuppreſſion of the alvine evacuations, regurgitation of flatulencies upwards, ſtrictures, pains, and rumbling of the belly, ſtraitneſs of the præcordia, retchings to vomit, cardialgia, thin watery urine, and a hard and large pulſe. The ſymptoms peculiar to ſpaſms of the pharynx, are, a difficulty, or a total inability of deglutition; a rigid conſtriction and pain of the parts cohering with the pharynx, as the tongue, the larynx, and the whole neck; a ſuffocative uneaſineſs; a ſenſation, as of a ſtake thruſt into the fauces, or of ſomething endeavouring to get out; and a loſs of voice. Theſe complaints return at intervals, and ſometimes terminate in convulſions of the whole nervous ſyſtem. In ſpaſms of the *œſophagus* itſelf, the aliment is ſwallowed freely, but a kind of reſiſtance is perceived to its deſcent, about the upper orifice of the ſtomach: cold liquors are particularly reſiſted, and increaſe the conſtriction, whilſt warm ones often paſs freely into the ſtomach. A pain is felt on the ſpine, between the ſcapulæ; often anxious retchings or vomitings are joined, with naufea, and a diſcharge of limpid mucus from the mouth, diſtinct from the vomitings. A combination of theſe ſymptoms with thoſe above enumerated, denote the whole canal to be affected. Spaſms of the pharynx are diſtinguiſhed from a paralyſis or relaxation of the part, by the difficulty of ſwallowing being in the latter continual, in the former intermitting: in the paralyſis, ſolids are more eaſily ſwallowed than liquids; in ſpaſms the difficulty of ſwallowing ſolids and liquids is equal: ſpaſms of the pharynx are diſtinguiſhed from inflammations, by the latter being accompanied with ſwelling, redneſs, heat in the fauces, thirſt, and fever. Spaſms of the gullet have alſo one ſymptom, the reſiſtance to the deſcent of food, in common with ſome other diſorders, as an obſtruction of the *œſophagus* from ſome ſolid bodies ſticking in it, tumors, excreſcences, ſwellings of the glands joined to the *œſophagus*, about the fifth vertebra of the back. But in theſe caſes, though ſolid foods ſtop, and are thrown up again, liquids, both cold and hot, paſs down with a greater or leſs degree of freedom; whilſt, in ſpaſmodic ſtrictures, cold liquors paſs with remarkably greater difficulty than ſuch as are warm: ſpaſms in the *œſophagus* are alſo accompanied with pains in the ſcapulæ.

Idiopathic ſpaſms of the pharynx are apt, from improper treatment, to become obſtinate and habitual. Thoſe which ariſe from acrid ſubſtances threaten an inflammation; from hyſteric paſſions, an apoplexy. Etmuller obſerves, that a difficulty of ſwallowing from a convulſion, in wounds is dangerous; and Hippocrates, that a ſudden contortion of the neck, obſtructing deglutition, without any ſwelling in fevers, is mortal. Spaſms of the gullet from paſſion at meals, are apt to lay the foundation of cholera, and bilious fevers. The general indications of cure, are, to alleviate the ſpaſms, and remove their cauſes. The firſt is anſwered by antiſpaſmodics and anodynes, mixed with diſcutients, both given internally, and applied externally. The more violent the conſtriction, the more neceſſary it is to begin with externals. Emollient glyſters, with the addition of corroborants, are to be two or three times repeated; and the feet bathed in pretty warm water, to invite the humours downwards; when pediluvia are called in aid, be careful that the feet be not too cold; if they are, they muſt firſt be warmed by frictions, and bottles of hot water. To the part affected apply paregoric nervine liniments, compoſed of vinous ſpirit, ſpt. of ſal ammon. eſſent. croci, eſſ. nucis Moſchat. campbor. liquor. minor. anod. &c. The balſ. vitæ, and the lig. miner. anod may be dropped on ſugar, and kept in the mouth, to be ſlowly ſwallowed. A bladder of warm water may be applied to the throat. If the face is red, the veſſels inflated, with ſtrong pulſation in the arteries of the head, and at the ſame time there are conſtrictions of the fauces, a vein may be opened to prevent an apoplexy. The ſpaſms allayed by means of antiſpaſmodics externally and

internally uſed, proved to ſubdue the cauſe. If acrid ſubſtances, draſtic purgatives, or emetics, have given riſe to the diſeaſe, their acrimony muſt be immediately obtunded by mucilages, oils, milk, fat broths, warm water drank plentifully, ſo as to promote a gentle vomiting. In ſpaſms of the *oeſophagus*, from a violent fit of anger during a meal, there is generally an effuſion of bile into the ſtomach; in this caſe give abſorbents, and mucilaginous ſubſtances, as water-gruel, or barley-water; and afterwards evacuate by means of manna, or rhubarb, or other gentle laxatives; or emetics, as tart. emet. gr. i. vel ij. with one of theſe laxatives. But never give either emetic or purgative immediately after paſſion: in caſe of flatulencies offending, oily and carminative glyſters are to be preferred. In chronical ſpaſms of the gullet, from a general bad habit, or from crudities in the ſtomach and bowels; the firſt muſt be obviated by ſuitable alteratives and abſorbents, the latter by manna, rhubarb, &c. In very obſtinate caſes mineral waters are extolled. In hypochondriacal caſes, where uterine or hæmorrhoidal hæmorrhages are obſtructed, the ſulphureous mineral waters, with bleeding and proper exerciſe, are the principal remedies. Chronical ſpaſms of the *oeſophagus*, from a debility of the nervous ſyſtem, are chiefly to be cured by dietetics; a light ſlender food; balſamic elixirs to ſtrengthen the ſtomach; moderate, but frequent exerciſe, occaſional bleedings, the hot ſulphureous waters both for drinking and bathing in. In ſpaſms of the lower gullet, externals are beſt applied to the ſpine, with which the *oeſophagus* is immediately connected. If the ſpaſms are ſo violent that the patient cannot ſwallow, he muſt be ſupported by nouriſhing glyſters.

See Hoffman's Practice of Phyſic, tranſlated by Lewis, vol. ii. p. 147, &c. Percival's Eſſays, Medical and Experimental, vol. ii. p. 141, &c. Lond. Med. Tranſ. vol. ii. p. 90.

ŒSTRUM VENERIS, i. e. Clitoris.

ŒSTROMANIA. The furor uterinus.

ŒSYPE, Œſypos, or Œſypum. The greaſy ſordes of wool

OFFA ALBA HELMONTII. If rectified ſpirit of wine be poured gently into a fully ſaturated volatile alkaline ſpirit, the ſpirit of wine running on the ſide of the glaſs, which muſt ſtand in a cold place, immediately an opake denſe coagulum is formed, which on gently ſhaking falls into a conſiſtent maſs; this maſs ſoon reſolves, by warmth, into a ſolid and a fluid part; the ſolid part is called offa alba. It is ſuppoſed to be a volatile ſoap, compoſed of the volatile ſalt of one ſpirit and the oil of the other; but it is no more than the alkaline ſalt diſlodged by the vinous ſpirit.

OFFICINALIA. Officinals. In pharmacy it is an appellation given to ſuch medicines, whether ſimple or compound, as are required to be conſtantly kept in the apothecary's ſhop.

OFFUSCATIO. The ſame as amauroſis. Aitken.

OLAMPI. The name of a gum which reſembles copal, and is brought from America. Lemery ſays it is ſweet to the taſte, and ſomewhat aſtringent. It is not in uſe with us.

OLDENLANDIA. It is a plant to which father Plumier gave this name, in honour of B. Oldenland, a German botaniſt.

OLEA. The olive tree. It is the olea Europea, Linn. It is an evergreen, with oblong narrow willow-like leaves, and monopetalous whitiſh flowers, cut into four ſections, followed by cluſters of oval black fruit, containing, under a fleſhy pulp, a hard rough ſtone. It is a native of the ſouthern parts of Europe, and bears the ordinary winters of our own clime. Boerhaave mentions five ſpecies.

The fruit hath a bitter, auſtere, diſagreeable taſte: pickled it proves leſs ungrateful, and is ſuppoſed to promote an appetite, help digeſtion, and attenuate viſcid phlegm in the firſt paſſages. The Lucca olives are the ſmalleſt and weakeſt, and the Spaniſh are the largeſt and ſtrongeſt taſted. The middling ſize, which are brought from Provence, are generally moſt eſteemed: but the principal conſumption of this fruit is, for the obtaining their oil. When ripe it is ground and preſſed, the purer and finer oil iſſues out firſt, by gentle preſſure; and inferior ſorts, on heating the reſiduum, and preſſing it more ſtrongly. See OLEUM.

OLEAMEN. A thin liniment compoſed of oils.

OLEANDER. The roſebay.

OLEASTER. The wild olive. It differs from the olea, or garden olive, only in culture.

OLEASTER GERMANICUS. A ſpecies of rhamnoides.

OLECRANON, from ωλενη, *cubitus*, and κρανον, *the head*. The elbow. It is the largeſt of the two apophyſes at the upper end of the ulna; it ends in a rough tuberoſity and an obtuſe point. The tuberoſity makes the corner of the elbow; the point is lodged in the poſterior cavity of the lower extremity of the os humeri, when the fore-arm is extended. Alſo the head of the humerus.

OLENE. The cubit.

OLEOSACCHARUM. Eſſential oils, ground with eight or ten times their weight of ſugar, becomes ſoluble in water, and may be diluted to any aſſigned degree; and thus *oleoſaccharums* are formed, and kept in well ſtopped bottles for making extemporaneous diſtilled waters, either ſimple or compound. Mucilages render them miſcible with water into a milky liquor; they diſſolve alſo in a little more than their weight of rectified ſpirit of wine. The extemporaneous waters which are made by means of *oleoſaccharums*, are not ſo grateful as thoſe that are diſtilled, for want of the volatile ſaline parts which remain in diſtillation.

OLEUM. Oil. *Oils* are animal, vegetable, and mineral. Animal *oils* are the fat of animals, which are originally vegetable *oils*. All animal ſubſtances yield this *oil* by diſtillation. Vegetable *oils* are principally procured by expreſſion, diſtillation, and by boiling. The mineral ones are obtained ſpontaneouſly, and by diſtillation.

Among the ſubſtances naturally contained in vegetables, and ſeparable by art, without alteration of their native qualities, are the following:

1. Groſs, or expreſſed *oils*. Theſe abound chiefly in the kernels of fruits, and in certain ſeeds, are commonly extracted by expreſſion, and hence are diſtinguiſhed by the name of expreſſed *oil*. This *oil* is contained in all parts of a vegetable, and may be forced out by the action of fire, but thus their qualities are altered. Expreſſed *oils* are not diſſoluble in water, nor in ſpirit of wine, without firſt being mixed with ſome ſuitable medium. If expoſed to the cold they loſe much of their fluidity, ſome of them congealing into a conſiſtent maſs with a ſmall degree of cold. If they are kept ſome time in a warm air, they become thin and rancid, their ſoftening quality is changed into an acrid one; and in this ſtate, inſtead of allaying irritation, they occaſion it: this rancidity is attracted even in the kernels, &c. in which this oil reſides before its being expreſſed; yet on triturating thoſe ſeeds, &c. with water into an emulſion, this emulſion, inſtead of growing rancid, turns ſour. In ſuch a degree of heat as will occaſion a ſmall evaporation from theſe *oils*, a pungent vapour ariſes, ſeemingly of the acid kind; and when ſuffered to grow cold again, they are found to have acquired a greater degree of conſiſtence than they had before, together with an acrid taſte. In a heat approaching to ignition, in cloſe veſſels, greateſt part of the oil ariſes in an empyreumatic ſtate, a black coal remaining behind.

In order to obtain theſe *oils*, the ſeeds, &c. which contain them, muſt be ground or powdered ſmall, then included in proper bags, and wrapped in hair cloths, then committed to the preſs, by which the oil is forced out. To facilitate the expreſſion, it is uſual to warm either the preſs, or the plates betwixt which the ſeeds, &c. are ſqueezed; or to heat the ſubject which is to be preſſed. But heat occaſions rancidity, ſo ſhould only be admitted when this circumſtance interferes not with the uſe for which the *oil* is deſigned. Many are the different ſeeds, &c. which afford *oil* by this treatment, but the preſent practice attends but to few, viz. the olive, almond, linſeed, and muſtard ſeed. Indeed, there is not much difference betwixt the expreſſed *oil* of one and another, the diſcriminating quality of the ſubjects not reſiding in the *oil* which is thus obtained; the *oil* of muſtard is as ſoft, inſipid, and void of pungency, as that of ſweet almonds, the pungency of the muſtard remaining in the cake left behind after expreſſion; it is true, that there are certain

ſpecific

ſpecific differences betwixt them, but, as medicines, they are ſo nearly alike, that they may generally be indiſcriminately uſed; they are emollient, they ſoften and relax the ſolids, and they obtund acrimony in the humours, and thus may be uſed internally when ſuch diſorders attend as ariſe from rigidity and acrimony, provided the body is not greatly heated thereby, for then the mild *oil* becomes ſo acrid as to be very irritating.

As to the *oils* that are expreſſed from aromatic ſubſtances, they are of a very different nature from theſe. See Essential Oils

Though expreſſed *oils* may be combined with water, by the intervention of gum or mucilage, yet they do not act upon, or unite with the gummy or mucilaginous parts of vegetables; hence the ol. e. mucilaginibus, does not contain any of the mucilage with which its ingredients ſo much abound. Expreſſed *oils* may be tinged by vegetable matters of almoſt all colours; in making the officinal *oils* by decoction, in order to have the colour clear and ſtrong, the beſt method is to ſtrain off the *oil* as ſoon as it hath acquired a ſufficient depth of colour, and then again to boil it until no aqueous vapours exhale. If the water is not all exhaled, the *oil* will have a dingy colour, and ſoon be mouldy; and if the leaves that are boiled in the *oil*, continue after they are criſp, they occaſion a diſagreeable blackneſs.

2. A groſs ſebaceous matter. From the kernels of ſome fruits, as that of the chocolate-nut, inſtead of a fluid *oil*, a ſubſtance is obtained which is of a butyraceous conſiſtence. Theſe are moſt commodiouſly extracted by boiling the ſubject in water; this ſebaceous matter, liquefied by heat, ſeparates and ariſes to the ſurface, and reſumes its proper conſiſtence as the liquor cools. The ſubſtances of this claſs have the ſame general properties with expreſſed *oils*, but are leſs diſpoſed to become rancid in breaking than moſt of the common fluid *oils*. It is ſuppoſed that their thicker conſiſtence is owing to a larger admixture of an acid principle; for in their reſolution by fire, they yield a vapour more ſenſibly acid than the fluid *oils*; and fluid *oils*, by the admixture of concentrated acids, are reduced to a thick and a ſolid maſs.

3. *Eſſential oils*. They are obtained only from thoſe vegetables, or parts of vegetables, that are conſiderably odorous. They are the direct principle in which the odour, and oftentimes the warmth and pungency, and other active powers of the ſubject reſide, whence their names of eſſences and *eſſential oils*. *Eſſential oils* unite with rectified ſpirit of wine, though ſome of them require for this purpoſe a much larger proportion of the ſpirit than others; water alſo, though it does not diſſolve their whole ſubſtance, may be made to imbibe ſome portion of their more ſubtil matter, ſo as to become conſiderably impregnated with their flavour, as happens in diſtillation; by the admixture of ſugar, gum, &c. they are totally diſſolved with water. Digeſted with volatile alkalies, they undergo various changes of colour, and ſome of the leſs odorous acquire conſiderable degrees of fragrancy, whilſt fixed alkalies univerſally impair their odour. In the heat of boiling water theſe *oils* totally exhale, and on this principle they are commonly extracted from ſubjects that contain them; for no other fluid that naturally exiſts in vegetables is exhalable by that degree of heat, except the aqueous moiſture, from which greateſt part of the oil is eaſily ſeparated. Some of theſe *oils* riſe with much leſs heat than others. In their reſolution by a burning heat, they differ little from expreſſed *oils*. When expoſed for ſome time to a warm air, they ſuffer an alteration very different from that which the expreſſed undergo; inſtead of growing thin, rancid, and acrimonious, they gradually become thick, and at length harden into a ſolid, brittle concrete, with a remarkable diminution of their volatility, fragrancy, pungency, and warm ſtimulating quality. In this ſtate they are found to conſiſt of two kinds of matter, a fluid *oil*, volatile in the heat of boiling water, and nearly of the ſame quality as the original *oil*, and of a groſſer ſubſtance, which remains behind, not exhalable without a burning heat, or ſuch a one as changes its nature, and reſolves it into an acid, an empyreumatic *oil*, and a black coal. The admixture of a concentrated acid, inſtantly produces in *eſſential oils* a change nearly ſimilar to that which time affects.

The oils expreſſed from aromatic ſubſtances differ from thoſe which are thus obtained from olives, almonds, &c. Theſe retain for the moſt part an admixture of the aromatic matter of the ſubject; thus aniſeed, mace, and nutmegs, yield, upon expreſſion, an *oil* impregnated with the flavour of the ſpices, and an *oil* expreſſed from aniſeed hath a great ſhare of the peculiar ſmell of the ſeeds. A purgative *oil* is expreſſed from the ſeeds of the ricinus. The rinds of oranges, lemons, and citrons, yield, by a kind of expreſſion, their *eſſential oils*, almoſt as pure, and nearly ſimilar to thoſe which are obtained from them by diſtillation. The *eſſential oils*, in which the fragrance, and aromatic warmth of theſe fruits reſide, are contained in numerous cells, or veſicles, which may be diſtinguiſhed by the naked eye, and are ſpread all over the ſurface of the peel; it is moſt conveniently obtained by rubbing a piece of lump ſugar on the ſurface of the freſh peel; the veſicles are thus burſt, and the ſugar imbibes the *oil*; when the ſurface of the ſugar is ſufficiently moiſtened therewith, ſcrape it into a phial, and keep it cloſe until it is uſed.

Moſt eſſential *oils* are drawn by diſtillation. A quantity of water is added to the ſubject, ſufficient to prevent its burning, and in this water it is macerated a little before the diſtillation; the *oil* comes over with the water, and either floats on its ſurface, or falls to the bottom. The water employed in diſtilling *eſſential oils* imbibes ſome portion of them; it cannot, however, retain above a certain quantity, and therefore ſuch as hath been already uſed, and almoſt ſaturated itſelf, may be advantageouſly employed inſtead of common water in future diſtillations of the ſame ſubject.

Eſſential oils are very often adulterated. If the mixture is with an expreſſed *oil*, the fraud is diſcovered by adding a little rectified ſpirit of wine to a few drops of the ſuſpected *eſſential oil*, and, ſhaking them together, the ſpirit diſſolves all the *eſſential oil*, and leaves the expreſſed untouched; or if it is the heavier *eſſential oils*, the ſuſpected one may be dropped into water, and the *eſſential oil*, after a briſk agitation, falls to the bottom, and the expreſſed *oil* ſwims at the top, or evaporate a little in a ſilver ſpoon, by which the *eſſential oil* will leave the expreſſed behind. If the adulteration is with rectified ſpirit of wine, drop a little of the ſuſpected *oil* into water, or into ſpirit of turpentine; and if a milkineſs appears on the mixture being ſhaken, there is ſpirit of wine in the *oil*. If the *eſſential oil* is mixed with other cheaper *eſſential oils*, dip a rag into the ſuſpected *oil*, and then hold it before the fire; thus the flavour of the genuine *oil* paſſes off, and leaves that of the added one ſufficientldy diſtinct behind. The cheap *eſſential oils* that are added, are uſually thoſe of the turpentine kind, which are alſo diſcovered by dropping the ſuſpected *oil* into ſpirit of wine, for then a milkineſs is produced, but not if the *oil* is genuine.

Eſſential oils, medically conſidered, agree in the general qualities of pungency and heat, though in theſe they differ in their degrees; in particular virtues they differ, as the ſubjects do from which they are obtained. Some of theſe *oils* are uſed to correct reſinous purges; they make them eaſy in the ſtomach at the firſt, but ſo far from abating their irritating quality, they add a freſh ſtimulus. Theſe *oils* are beſt adminiſtered with powders, pills, boluſſes, or electaries.

4. Concrete *eſſential oil*. Some vegetables, ſuch as roſes and the roots of elecampane, inſtead of a fluid *eſſential oil*, yield a ſubſtance poſſeſſing the ſame general properties, but of a thicker and ſebaceous conſiſtence. This ſubſtance appears of as great volatility and ſubtilty as the fluid *oils*; it equally exhales in the heat of boiling water, and concretes upon the ſurface of the collected vapour. The total exhalation of this matter, and its concreting again in its original conſiſtent ſtate, without any ſeparation of it into a fluid and a ſolid part, diſtinguiſhes it from *eſſential oils* that have been thickened or indurated by age or by acids. See Hoffman's Obſ. Phyſ. Chem. lib. i. Neumann's Chem Works. Dict. of Chem. The New Diſpenſatory.

OLFACTORII NERVI. The olfactory nerves. They were formerly called proceſſus mammillares. They are the firſt pair of *nerves* from the brain. They ſeem to approach nearer each other as they paſs towards the criſta galli. They divide into many ſmall filaments, which paſs through

through the foramina of the os ethmoides. On theſe *nerves* no covering from the dura mater can be traced. See Olfactus.

OLFACTUS. The ſenſe of ſmelling. The mucous membrane which lines the noſtrils, hath its ſurface greatly enlarged by its ſpreading into the two frontal ſinuſes, the antra of Highmore, the cells in the ſphenoid bone, and on the ſpongy bones of the noſtrils. The olfactory nerves, without their dura matral coat, pierce the holes in the ethmoid bone, and ſpread themſelves in the mucous membrane of the noſtril. Theſe nerves are widely expanded, and no where are the nerves ſo ſoft, naked, and conſequently ſo eaſily affected and injured as in this; yet an inſipid mucus is conſtantly ſeparated in the membrane of the noſe to defend the nerves. A branch from the fifth pair is alſo ſent to this membrane, by the irritation of which ſneezing is excited when the mucus is not duly diſcharged. The objects of *ſmell* are thoſe parts of ſubſtances which are lodged in their ſpirit, oil, ſalt, or ſoap, if they are ſo divided as to become capable of floating in the atmoſphere; but from experiments it is plain, that the ſpirit lodged in the *oil*, is that which excites the *ſenſe of ſmelling*; for when this ſpirit is ſeparated, the ſubject is inodorous, and to whatever ſubject this ſpirit is communicated, there the odour is alſo. The *ſenſe of ſmell* is only excited when the odorous effluvia contained in the air, and attracted through the noſtrils, are impreſſed on the olfactory nerves. The longer the noſtrils, the more the ſurface thereof, and of the ſpongy bones there are enlarged, the more acute is the *ſenſe of ſmelling*.

OLIBANUM, called alſo thus, thus maſculinum, frankincenſe. It is a gummy reſin brought from Turkey and the Eaſt Indies. Dale ſays he found a ſpecies of cedar in Carolina which afforded a gum ſo like this, that he could not perceive any difference in it. The tree is the juniperus lycia, or juniperus foliis ternis undiquæ imbricatis ovatis obtuſis, Linn. It is uſually in drops or tears, like thoſe of maſtich, but larger, of a pale yellowiſh colour, which by age becomes reddiſh. It hath ſeveral names, according to its different appearances; the ſingle tears are called ſimply olibanum, or thus; when two are joined together, they have been called thus maſculinum; and when two were very large, thus fœminium; ſometimes four or five have adhered together about as big as filberts, and, perhaps, found on the bark of the tree; theſe have been named thus corticoſum; the finer powder which rubs off from tears in carriage is called manna thuris. This drug, however, is not in any of its ſtates what is now called thus, or frankincenſe, in the ſhops.

This gummy reſin hath a moderately ſtrong, not very agreeable ſmell, and a bitteriſh pungent taſte. In chewing it ſticks to the teeth, becomes white, and renders the ſaliva milky. Laid on a red hot iron it readily catches flame, and burns with a ſtrong diffuſive ſmell, which is not unpleaſant. It is ſuppoſed to have been the incenſe uſed by the ancients in their religious ceremonies. On trituration with water, the greateſt part of it diſſolves into a milky liquor, which on ſtanding depoſits a portion of reſinous matter, and being now gently inſpiſſated, leaves a yellow extract, which retains greateſt part of the ſmell, as well as taſte, of the *olibanum*, the odorous matter appearing to be of a leſs volatile kind than that of moſt other gummy reſins. Rectified ſpirit of wine diſſolves leſs than water, but it takes up nearly all the active matter. The doſe is from ℈ i. to ʒ i. See Lewis's Mat. Med. Neumann's Chem. Works.

OLIBANUM. The Greek name for frankincenſe.

OLIDA, i. e. Abruſ.

OLISTHEMA, from ολισθαινω, *to fall out*. A luxation.

OLIVARIA CORPORA. Two eminences on the lower part of the medulla oblongata, near where it commences medulla ſpinalis. Many tables place theſe higher, but unjuſtly.

OLOPHLYCTIDES, i. e. Phlyctænæ.

OLSENICHIUM, i. e. Œlſnitium.

OLUS ALBUM, i. e. Valeriana arvenſis præcox humilior ſemine depreſſo.

OLUS ATRUM, i. e. Smyrnium.

OLUS AUREUM, i. e. Atriplex Hortenſis.

OLUS HISPANICUM, i. e. Spinacia.

OLUS JUDAICUM. See Corchorus.

OLUSATRUM. See Apium and Hipposelinum.

OLYRA. Sprat corn. It grows in Germany. It is inferior to ſpelt wheat.

OMAGRA. The gout in the articulation of the humerus with the ſcapula.

OMASUM, or Omaſus. The third ventricle of a ruminating animal.

OMELYSIS, from ωμος, *crude*. Some ſay it is the meal of barley not parched; others, that is any ſort of meal.

OMENTA. The membranes of the brain.

OMENTI. Inflammatio. The ſame as omentitis.

OMENTITIS. Inflammation of the omentum. It is the ſame as the puerperilis febris; which ſee.

OMENTUM, called epiploon by the Greeks, and by us the cawl. It is alſo called reticulum, from its ſtructure reſembling that of a net. Below the liver, floating over the inteſtines, is the *omentum*, whoſe ſuperior portion is, as it were, divided into two borders, one of which is fixed along the great arch of the colon, and the other along the great curvature of the ſtomach. The union of theſe two borders on the right ſide is fixed to the ligament, or adheſion of the duodenum and colon; that on the left-ſide to the longitudinal ſciſſure of the ſpleen, to the extremity of the pancreas, and to the convex ſide of the great extremity of the ſtomach. The *omentum* is generally larger on the left-ſide than on the right. Its uſe is, by its fat, to lubricate the parts adjacent, to prevent adheſions of the inteſtines, and as a preparatory organ for the bile.

The little *omentum*, called alſo meſo-gaſter. See Mesogastrion.

OMOCOTYLE. The cavity in the extremity of the neck of the ſcapula, in which the head of the humerus is articulated.

OMOHYOIDÆUS MUSCULUS, i. e. Coraco-hyoidæus muſc.

OMOPLATÆ, from ωμος, *the ſhoulder*, and πλατυς, *broad*. The ſcapulæ.

OMOPLATO-HYOIDÆUS, i. e. Coraco-hyoidæus muſc.

OMOS. The ſhoulder. Moſchion calls part of the uterus thus, which is beyond the neck, where it grows broad.

OMOTRIBES. Oil expreſſed from unripe olives.

OMPHACINUM. Oil from unripe olives.

OMPHACIUM. The juice of unripe grapes.

OMPHACITIS. A ſmall kind of gall, an excreſcence of oak.

OMPHACOMELI. A ſort of oxymel made of the juice of unripe grapes and honey.

OMPHALOCARPOS. The name for the aparine.

OMPHALOCELE, from ομφαλος, *the navel*, and κηλη, *a rupture*, Hernia umbilicalis.

OMPHALODES, from ομφαλος, *a navel*. This plant is thus named, becauſe the calyx is excavated in the middle, like the human *navel*. It much reſembles borage, but is not ſo ſucculent. Boerhaave enumerates three ſpecies, but they are not noted for any medical uſe.

OMPHALOS. The navel, alſo a rupture there.

OMPHAX. Unripe grapes, or their juice.

ONAGRA. The name of a plant, three ſpecies of which are noticed by Boerhaave; but no medical virtues are attributed to them. The rheumatiſm in the elbow is alſo thus called.

ONEIRODYNIA, Diſturbed or troubled ſleep. Dr. Cullen places this genus of diſeaſe in the claſs neuroſes, and order veſaniæ. He defines it be violent, or diſturbed action of the imagination during ſleep. He obſerves two ſpecies. 1. *Oneirodynia* activa; as when people riſe in their ſleep, and walk here and there, &c. See Somnambulo. 2. *Oneirodynia* gravans; as when a ſenſe of weight is felt on the breaſt. See Incubus.

ONEIROGMOS, from ονειρωσσω, *ſomno in ſomno profundere*. Venereal dreams. Thus Cœlius Aurelianus calls this diſorder, and he deſcribes it as diſturbing the patient with wild deluſive dreams, and frequently emitting their *ſemen* whilſt aſleep. He ſays it is the reſult of impreſſions on the fancy, which affect the patient during ſleep, and ariſing from extraordinary deſire of, or great abſtinence from venery. See Cœl. Aurel. Morb. Chron. lib. v. c. 7.

ONEIROGONOS. So the Greeks call an occaſional emiſſion of the ſemen in ſleep, when it only happens rarely.

ONISCI. Wood-lice.

ONISCUS. A genus of inſects of the claſs aptera; and of this genus the wood-lice are a ſpecies.

ONITIS. A ſpecies of origanum.

ONOBRICHIS, from *ονος, an aſs*, and *βρυχω, to bray*; becauſe the ſmell of this plant makes *aſſes bray*, or becauſe when an *aſs* eats the pods of this plant he is ſaid *to bray*. Botaniſts vary in deſcribing this plant, one calling one plant, and another a different one, by this name.

ONOBRYCHIS, called alſo polygalon Geſneri, caput gallinaceum, holy-hay, cock's head vetch, ſainfoin.

It grows on hills, in highways, and corn-fields, but always in dry chalky ſoil expoſed to the ſun. It is cultivated for feeding of cattle. It is ſaid to generate much milk in cows.

There is another ſpecies called campanula erecta. Beſides theſe, Boerhaave mentions other three.

ONOBRYCHIS. It is a name for ſeveral ſorts of hedyſarum.

ONOCHELIS, Onochiles, or Onoclea. A ſpecies of anchuſa.

ONOPTERIS MAS. A ſpecies of adianthum.

ONOSMA. Stone bugloſs.

ONOCHYTES. The onyx ſtone.

ONONIS. Reſt-harrow. The ſpecies formerly uſed was the *ononis* ſpinoſa, Linn.

ONYCHITIS. A ſort of cadmia, which is veined like an onyx-ſtone.

ONYCHIA. A whitlow at the ſide of the finger nail.

ONYX, alſo called ſolen, aulos, domax, dactylus. It reſembles the blatta-byzantia, but is obtained from any other ſpecies of turbinated ſhell-fiſh.

The Greeks gave this name to the diſeaſe of the eye, which is alſo called unguis.

It is the name of a precious ſtone alſo called camehnia, and onychites. It hath been called *onyx*, from the reſemblance of ſome ſpecimens, both in colour and ſhape, to the human nail. The characters of the *onyx* agate, are, that it is compoſed of agate matter, of two different colours, which run in lines, having the ſame direction; both colours ſometimes being tranſparent; both ſometimes opaque; and ſometimes the one tranſparent, and the other opaque. Edward's Elements of Foſſilogy.

OOEIDES. An epithet for the aqueous humour of the eye.

OPACARPATHON. The juice of a poiſonous herb called carpaſus.

OPALUS, called alſo pederos, opal. A ſtone which reſembles the mother of pearl, but it is harder, and of a better luſtre. Its natural ground colour is whitiſh, but it gives all the other colours in reflection. The beſt are brought from the Eaſt. It is a ſpecies of agate.

OPERCULI CONCHYLII. See BLATTA BYZANTIA.

OPERCULUM COCHILEÆ CŒLATÆ, i. e. Umbilicus marinus.

OPHIASIS. See ALOPECIA.

OPHIOGLOSSOIDES NIGER. A ſort of fungus of no medical efficacy.

OPHIOGLOSSUM, from *οφις, a ſerpent*, and *γλωσσα, a tongue*, becauſe the fruit of the plant reſembles a tongue. Adder's tongue. It is the *ophioglooſſum* vulgatum, Linn. This plant hath only one leaf, with a ſlender ſtalk ariſing from the bottom of it, dented about the edges, and ſuppoſed to reſemble the tongue of a ſerpent. It grows in meadows. The leaf is thick, of a freſh green colour, and juicy. The ſeed is in a green ſpike.

OPHIOSCORDON, or Ophioſcorodon: alſo called victorialis; allium montanum latifolium maculatum; allium alpinum; ſpotted ramſons; broad leaved mountain garlic. It is a ſpecies of garlic. It is kept in the gardens of the curious, but grows wild in moſt countries. Its virtues are ſimilar to the common garlic. See Raii Hiſt.

OPHIOSTAPHYLON. White bryony.

OPHITES, called alſo ſerpentinus, ophite, or ſpleen-ſtone. It is a hard ſort of marble, of a deep green colour, interſperſed with ſpots of a fainter green. There are three ſpecies, diſtinguiſhed by their being differently marked. Mr. Edwards, in his Elements of Foſſilogy, mentions ophites and nephritic ſtones, of the genus called marmaroproſeron.

OPHRIS, and Ophris major, i. e. Biſolium.

OPHRYS. The loweſt part of the forehead, where the eye-brows grow; and the hair of the eye-brows.

OPHRYS UNIFOLIA, i. e. Monophyllon.

OPHTHALMIA, from *οφθαλμος, an eye*. An inflammation of the membranes which inveſt the eyes; particularly the conjunctiva.

Monſ. de St. Yves diſtinguiſhes this diſorder into fourteen or fifteen different kinds, according to their different cauſes, or other circumſtances, as follow:

1. An inflammation of the tunica conjunctiva, which is attended with a violent heat, and a flux of tears; ſometimes without great heat, or an extraordinary flux of tears, the inflammation extends all over the eye, and affects the adjacent parts. In many inſtances there are pricking pains, a beating of the arteries, ſwelling, great heat, violent redneſs, ſcalding tears, at times a painful ſenſation is felt, ſuch as is occaſioned by ſand falling into the eye. This ſpecies is the moſt frequent, for it attends almoſt every diſorder to which the eye is ſubject, and, in ſhort, conſtitutes moſt of the other ſpecies of *ophthalmies*. The cauſe may be either external or internal; whatever irritates the eye, is the immediate cauſe. In the Med. Muſ. vol. i. p. 370, &c. are two inſtances of inflamed eyes from a louſe having got into the great angle of the eye in one caſe; and a ſmall inſect of ſome kind not mentioned having inſinuated itſelf into the cornea, in the other caſe.

2. The dry *ophthalmia*. In this caſe the tunica conjunctiva is inflamed; but there are neither tears nor pus. Neither ſwelling, pain, or other remarkable ſymptoms attend. This ſpecies, which St. Yves calls the dry *ophthalmia*, is the ſlighteſt kind; it is by ſome called phlogoſis; the ancients call it taraxis, which ſee. The dry *ophthalmy* of Cullen is the xerophthalmia, which ſee.

3. An humid *ophthalmia*. It is cauſed by a redundant acrid lachrymal lymph, which occaſions a ſwelling in the inner part of the eye-lids, and ſometimes ulcerates the cornea; ſhooting pains are felt in the eye, and the light cannot be borne. When it attends children, their lips are ſometimes ſwelled, and their noſes, and ſcabs ſpread on their faces.

4. An *ophthalmia* from a defluxion on the brain. In this ſpecies an itching is felt in the eye, a thick glutinous matter oozes out, and conglutinates the eye-lids in the night.

5. An *ophthalmia* attended with a dry film. This reſembles the dry *ophthalmia*; but in this caſe the eye-lids are ſmeared with dry films like gritty flour, which occaſions much pain in the eye.

6. The *ophthalmia* in the globe of the eye towards the acanthi. This kind is when the patient's eyes are red only towards the angles, whilſt the other parts are unaffected. But when the caruncula lachrymalis becomes inflamed, the veſſels which paſs under it, ſwell even to the tranſparent part of the cornea. This kind often changes to the diſorder called unguis.

7. The *ophthalmia* with pimples on the globe of the eye. In this ſpecies there is a ſwelling of the ſmall bundle of veins which are ſent from the inner ſurface of the eye-lids, and terminate where the conjunctiva is joined with the tranſparent part of the cornea; a pimple as large as a lentil appears there, which ſuppurates.

8. The *ophthalmia* with little abſceſſes on the cornea and conjunctiva. In this ſort the whole conjunctiva becomes red; ſmall abſceſſes are formed on the tranſparent cornea, and on the conjunctiva.

9. The eryſepelatous *ophthalmia*. It reddens the conjunctiva, ſwells the eye-lids, cauſes violent pains and heat both in the eyes and head. The adjacent parts, as the temple and forehead, and the noſe, are covered with ſcales and ſcabs, that leave, when they fall off, marks which remain during life, and which reſemble thoſe from the ſmall-pox.

10. The *ophthalmia*, called chemoſis, which ſee. In

this ſpecies, all the conjunctiva is ſwelled to the thickneſs of a finger's breath; this makes the tranſparent part of the cornea appear as it were ſunk into a cavity. Violent pain attends, a pulſation alſo, and often times a fever. All the tranſparent part of the cornea often comes away by ſuppuration, which deſtroys the anterior chamber of the eye. The cicatrix ſubſequent to the ſuppuration hinders the cryſtalline and vitreous humours from falling out, and generally hinders the decay of the whole globe, but ſometimes they both happen. This diſorder happens either from external or internal cauſes.

11. The venereal *ophthalmy*. The ſymptoms are nearly the ſame as attend the chemoſis, but with this difference; the conjunctiva is ſwelled, appears hard and fleſhy. It begins with a quantity of whitiſh matter, with a yellowiſh caſt, oozing through the eye. This diſorder ſometimes appears a few days after the beginning of a venereal gonorrhœa; the matter not running off by its uſual paſſage, is diſcharged through the eye; and this matter ſtains linen, as that of a gonorrhœa in the urethra does.

12. The *ophthalmia* of the choroides. In this ſpecies, the choroides and uvea are inflamed, and the conjunctiva is only ſlightly affected; it is attended with a flux of tears; the light, if admitted, occaſions great pain; pain is complained of in the temples, and the top of the head.

13. The *ophthalmia* from blows on the eye.

14. The *ophthalmia* from a rupture of the veſſels in the conjunctiva; the eye grows red, though the patient does not complain of pain; nor is the light uneaſy. The blood iſſuing from the ruptured veſſels, is diffuſed between the laminæ of the membrane.

15. The *ophthalmia* from the ſcrofula. In the eye, the ſcrofula produces an inflammation which ſometimes ends in an anchylops or ægilops: in the eye-lids it produces an epiphora, or lippitude: in the canthus of the eye a fiſtula lachrymalis is formed; and it ſometimes happens that tumors of the ſcrofulous kind thruſt out the globe of the eye. When the eye is inflamed from this cauſe, it appears of a dull red, or leaden colour; there are often white ſpecks on or near the pupil, which generally diſcharge great quantities of acrid ſerum, which ſcald the cheeks; ſmall running ulcers often are ſeated in the greater canthus, which diſcharge a whitiſh thick matter, and which glues the eye-lids in a morning; the eye-lids are ſwelled, and the veins about them appear diſtended; pain is more or leſs complained of.

16. An *ophthalmia* which follows from the ſmall-pox.

The *ophthalmia* ſubſequent to blows on the head, by which the meninges are hurt, is a ſign of death. When in the beginning of the ſmall-pox this diſorder is attendant, the conſequence is generally fatal. When attended with long and violent head-achs, blindneſs is to be feared. When *ophthalmia* is an original diſeaſe, when the temples ach, the forehead itches, and the body ſweats at nights, there is danger even of life. The humid ſpecies, the eryſipelatous and venereal kinds, that of the choroides, and the chemoſis, all greatly tend to deſtroy the ſight. Dr. Cullen places this genus of diſeaſe in the claſs pyrexiæ, and order phlegmaſiæ. He diſtinguiſhes two ſpecies. 1. The *ophthalmia* membranarum; that is, when the coats of the eye are the ſeat of the inflammation. 2. *Ophthalmia* tarſi, when the inflammation is in the ſebaceous glands in the edges of the eye-lids. The firſt he conſiders as varying according to the degree of inflammation, and according to which of the tunics are principally affected. The ſecond includes but two varieties. He further diſtinguiſhes betwixt the idiopathic and the ſymptomatic: in the firſt are included the above named ſpecies; in the laſt, he forms the varieties from the diſeaſe that cauſes the inflammation, being in the eye itſelf, or in the general habit, or ſome other part of the body ſeparate from the eye. Here, the different diſtinctions in the *ophthalmia* are ſeen at one view: and as much perplexity attends the inquirer in this particular, if unpoſſeſſed of this valuable work, his arrangement is here inſerted as follows.

Of the firſt ſpecies, and which vary according to their degree of external inflammation, are the

Ophthalmia Taraxis	Ophthalmia Eryſipelatoſa
Humida	Puſtuloſa
Chemoſis	Phlyctænodes.

Of the ſame ſpecies, but which vary according to which coat of the eye is affected, are the

Ophthalmia Choroideæ
Tenebricoſa.

Of the ſecond ſpecies which are ſeated in the tarſus, alſo affecting the eye-lids, are the

Ophthalmia Trachoma
Sicca.

Of the varieties that are ſymptomatic; thoſe that take their riſe from ſome other diſeaſe of the eye or the eye-lid, are the

Ophthalmia Angularis	Ophthalmia a Lagophthalmo
Tuberculoſa	ab Ectomate
Trichiaſis	ab Ungue
Cancroſa	a Corneæ fiſtula
a Synechia	Uveæ.

Thoſe varieties that are ſymptomatic, and take their riſe from diſeaſes in another part of the body, or of the whole habit, are the

Ophthalmia Metaſtatica	Ophthalmia Syphilitica
Scrophuloſa	Febricoſa.

For the moſt part this diſorder is in the tunica conjunctiva; but ſometimes the interior coats are affected: indeed the inner ones are ſometimes the ſeat of the inflammation.

Any of the cauſes of external inflammation, may produce the ſame in the external coat of the eye; and the ſame cauſes which produce this diſorder in other internal part, may alſo produce it in the inner membranes of this organ. Accidents from without, as cold air, duſt, too much expoſure to vivid colours, blows, wounds, &c. and as internal cauſes, the meaſles, and ſmall-pox, ſcrophula, &c. are all occaſionally the cauſes of this complaint.

In the cure of the above ſpecies of inflammation in the eye, the diſtinctions may very well be loſt in moſt of them. When a flux of humours attends, it uſually abates by whatever relieves the inflammation, and in general to conſider and treat theſe diſorders under the ſimple idea of inflammations will be the moſt proper and eaſy; as to particular circumſtances, they may be attended to, and treated according to their reſpective natures, as directed here and in other articles, or as the preſcribers particular experience may direct. It is happily obſerved by Dr. Kirkland in the firſt volume of his Inquiry, p. 480, that, "like all other inflammations, it gives way to thoſe remedies which remove the irritating cauſe, and leſſen the ſenſibility of the parts."

All heating, ſpirituous, and aromatic food muſt be avoided; a cooling liquid diet will be neceſſary; a freedom from all forcible exerciſe muſt be enjoined; and the eye may be ſhaded from the light, and all glaring objects by means of a ſtiff paper, lined with black ſilk.

Bleed according to the ſtrength and quickneſs of the pulſe; beſides taking blood from the arm, leeches may be applied to the external angles of the eyes. Opening the temporal artery is very generally adviſed; Mr. Ware obſerves, that the two following difficulties attend it. 1ſt, It frequently will not yield a quantity of blood ſufficient to anſwer the intended purpoſe. 2d, The troubleſome and dangerous hæmorrhages which have ſometimes burſt from the orifice, at the diſtance of many hours from the operation. He farther obſerves, that conſiderable advantage hath followed a complete tranſverſe diviſion of this artery; whereby the patient not only received benefit from the ſudden derivation of a large quantity of blood, but one principal ſource from which the blood circulated to the inflamed part, was cut off. The external jugular vein has alſo ſometimes been opened in this complaint; but as it does not come from the eye itſelf, it does not yield a very direct derivation. As to leeches, when they are applied to or near the eye-lids, they have ſometimes occaſioned them to ſwell to a large ſize, and have increaſed for a time the irritation of the eye; to prevent which, when they are applied

near

near the eye, confine them as near as poſſible, in the hollow of the temple, about an inch and an half from the outer orbit. Dr. Kirkland thinks that any other bleedings than that from the arm, are not attended with ſuperior advantage; as to leeches, he ſays they leave an inflammation behind, and occaſion a greater irritability in the neighbouring parts. As ſoon as blood is taken away, let a cooling purge be given; and ſmall doſes of the ſal Glaub. may be repeated every day after, ſo as to procure a few ſtools, until the violence of the ſymptoms give way. Particularly be careful to avoid ſtrong purges. A bliſter, when applied to relieve inflammation in the eyes, is moſt effectual when laid upon the fore part of the head, and kept open a few days; apply the plaſter from the crown to the forehead, having firſt ſhaved the part. Dr. Kirkland is of opinion that bliſters, like leeches, are prejudicial by increaſing irritability where they are applied, and to ſome extent around them. The feet and legs may be placed in moderately warm water every night. A ſeton is beſt fixed under the lower jaw, in the ſide where the affected eye is, or if both eyes are bad, it may be placed under the chin; when it is fixed in the ſide of the jaw, let it be betwixt the external jugular vein, and the larynx.

As an external remedy, the vegeto-mineral water of Goulard is almoſt the only one needful; begin with it very mild, and increaſe its ſtrength ſo as to avoid irritation. Whether inflammations are phlegmonous, ſcrofulous, cancerous, or eryſipelatous, from bruiſes, &c. this water is of ſingular efficacy. White vitriol is the uſual remedy in theſe caſes; it cools, dries, and reſtringes; it is very uſeful when there is a defluxion, or an inflammation in the eyes, but the diſorder ſhould be giving way before its uſe is begun with; bleeding, purging, and every proper evacuation, ſhould alſo have preceded; from ℈i. to ʒi. may be diſſolved in two ounces of water, beginning with the weaker and gradually proceeding to the ſtronger; if it is too weak, the redundant tears will waſh it away before it produces any effect. Blue vitriol is uſeful when the humours are thick, and formed into ſordes; and when they begin to form ſmall membranes in the tunica albuginea, which frequently happens after the ſmall-pox and the meaſles; in ſuch caſes, a grain or more may be added to an ounce of water: but it ſhould be omitted in all inſtances of inflammation attended with ſaline, hot, acrid defluxions, with redneſs and itching, becauſe it increaſes theſe ſymptoms. When the inflammation is deep, violent, and dangerous, the eye being almoſt deprived of ſight and ſenſibility, happy effects have been found from the uſe of tepid camphorated ſpirit of wine mixed with the Peruvian balſam. Weak ſolutions of camphor abate theſe inflammations, but a free uſe of it increaſes them. Dr. Kirkland recommends a ſmall quantity of ſal Glauberi, in fine powder, to be blown into the inflamed eye: he obſerves, that at firſt the inflammation ſeems to be increaſed by it, but ſoon a diſcharge of lymph follows, and the next day the inflammation is much abated or gone. Opium is ſaid by ſome not to eaſe pain in the eye; but that this ſymptom is relieved by the external uſe of aloes; however, it is clear from experience, that ſmall quantities of opium, mixed with any cooling liniment, ſpeedily abates inflammation in this organ. Mr. Ware ſtrongly recommends a few drops of the tinct. Theb. Ph. Lond. to be dropped into the eye, once every day; and ſupports his aſſertions in its favour, with narratives of facts, which admit of no doubt. Dr. Kirkland obſerves, with reſpect to it, that, "with due perſeverance, it ſufficiently anſwers our intention, where it can poſſibly do ſervice, without occaſioning pain. It may be uſed with advantage where the ſenſibility in the beginning is often exquiſite, and where few other remedies can be applied without giving offence." When a corroding acrimony is obſerved in the humour that is diſcharged, the eye may now and then be waſhed with a thin ſolution of gum arabic; or the mucilage of quince ſeed. If the eye remains very weak, after the inflammation abates, the beſt applications are, the alum curd, which may be ſpread thin on a rag, and applied over the eyes every night; and a ſolution of alum in the proportion of a dram to half a pint of water, to which may be added the white of one egg; and to finiſh the cure, the patient may bathe in the ſea, or cold water may be poured upon his head every morning for ſome time.

When films attend, or are followed by defluxions on the eyes, or when the tranſparency of the cornea is diminiſhed, borax proves an admirable means of relief, and may be uſed as follows. ℞ Boracis opt. ʒſs. ſacch. alb. ʒi. aq. roſar. ℥ii. m. f. collyr. Let a little of this be frequently dropped into the affected eye. When pimples on the eye attend an inflammation, the ſolution of white vitriol uſually ſucceeds; when matter is formed in theſe pimples, pierce them with the point of a lancet, and then waſh them with the juſt named ſolution, or, ℞ Ungt. alb. ʒv. ſacch. ſaturn. ʒi. quibus ſuper porphyrite ſimul tritis inſtillentur bal. traumat. ʒii. hujus paululum, linteo exceptum, oculo dolenti omni nocte imponatur. When a blow is the cauſe, and a blackneſs remains about the eye-lids, ℞ Conſ. roſar. rub. ℥iii. tinct. theb. ʒii. m. vel ℞ Acet. diſtill. ℥ii. ſp. ſal. ammon. ʒiſs. m. In Gooch's Caſes and Remarks, page 44, &c. is an inſtance of relief, when the tunica albuginea was inflamed ſo as to reſemble, if not conſtitute the chemoſis. A gouty *ophthalmia* requires that the gout, if poſſible, be brought into the extremities, and then the diſorder in the eye immediately vaniſhes; if the inflammation is violent, bleed, purge with aloetics, and waſh the eye with a mixture of tepid water two parts, and brandy one part. When a tranſlation of rheumatic matter from the hip, or elſewhere, is the cauſe, bliſters may be applied to, or near the part whence the rheumatiſm receded; a ſeton may be fixed under the lower jaw, and the bark with guaiacum may be given. In the ſcrofulous inflammation of this organ, the bark is the ſovereign remedy: if in this caſe, the glands under the ears are affected, apply a cauſtic on one of them, and then another, if there are more than one, and the conſequent diſcharge will ſoon remove the inflammation; proper alteratives as required may accompany the bark; and the head ſhould be waſhed every morning with cold water. Nitre, given to a ſcruple three times a day, hath been found to be remarkably efficacious in this as well as with the common *ophthalmias*. The venereal *ophthalmia* admits not of vitriolic collyriums; it calls for the ſpeedieſt aid, which ſhould conſiſt of bleeding in the foot; an inward uſe of mercurials; the warm bath night and morning, purges repeated every day from the firſt day of bathing, until the inflammation abates, if other circumſtances do not forbid; compreſſes ſqueezed out of brandy and water may be conſtantly kept on the eye.

See Monſ. de St. Yves on Diſorders of the Eye; Heiſter's Surgery; Eſſay on the Ophthalmia, &c. by William Rowley, ſurgeon; Gooch's Caſes and Remarks, page 44, &c. Boulton's Surgery, chap. vii. in the Appendix; Lewis's Tranſlation of Hoffman's Practice of Medicine vol. i. page 308; Ware's Remarks on the Ophthalmy, &c. Bell's Surgery; Kirkland's Inquiry, vol. i. page 473; Warner on the Eye, and its Diſeaſes.

OPHTHALMIA MUCOSA. The mucous ophthalmy. It is a variety of *ophthalmy* of the membranes of the eye, though not in Dr. Cullen's Noſological Arrangement. Mr. Ware calls it the purulent eye, but owns that the term is not to be ſtrictly underſtood; he ſays, "the diſcharge from the eye is not real pus, but only *mucus* increaſed in quantity, and altered in colour." See his Remarks on the Ophthalmy, &c. p. 111.

This diſorder rarely happens, except to new born children; in whom Mr. Ware obſerves, that it firſt diſcovers itſelf by a redneſs in the eye-lids, which quickly ſwell to a ſize ſo large as to prevent their being ſeparated, without the outmoſt difficulty; after which a conſtant diſcharge of thick yellow matter ſoon ſucceeds; which, if the lids can be ſeparated, will appear to ſpread over the eye, ſo as entirely to cover it. In common, both eyes are affected nearly in the ſame manner; and in bad caſes, whenever the child cries, the inſide of the lid is turned outwards; which is alſo the caſe, whenever an attempt is made to ſeparate them with the fingers: this is ſometimes the conſtant ſtate of the lids, and though they are reſtored by the fingers to their proper ſituation, yet on being left to themſelves, they immediately return to their former everted ſtate.

Occaſionally this complaint is accompanied with eruptions on the head and other parts of the body; and ſometimes is attended with ſymptoms of a ſcrofulous habit.

The

The ſwelling of the eye-lids, neceſſarily occaſions a tightneſs, or conſtriction of their ciliary edges, by means of which, the matter which is formed on the inſide of them, is prevented from wholly running off; and its continuing between the lids and the globe, ſerves ſtill farther to increaſe the inflammations, and is alſo the frequent cauſe of ulcers and ſpecks, which very often partially, and ſometimes totally, cover the pupil. Theſe effects may, in a great meaſure, be produced by the acrimony of the matter; but even allowing, that the retained fluid is perfectly bland and mild, its continual lodgment on the eye is ſufficient, by maceration only, to deſtroy the tranſparency of the cornea, and when it has been joined with the preſſure of the ſwollen eye-lids, it has been known to cauſe the cornea to burſt, the humours to be partially or wholly diſcharged, and the eye, of courſe, to ſink in the orbit. To this accurate deſcription of Mr. Ware's, it may be added, that uſually, if left to nature, the quantity of *mucus* gradually increaſes until about a tea-ſpoon full of it may be ſqueezed from each eye every day; ſoon after this, if no extraordinary ſymptoms attend, the *mucous* decreaſes, and without art a cure is effected.

This kind of inflammation may ariſe from any of the cauſes that produce external phlegmonous inflammations. Mr. Ware obſerves, that the tunica conjunctiva is defended from the acrimony of the tears by a ſoft thin *mucous* fluid, which is ſuppoſed to exhale from innumerable ſmall perforations diſperſed all over its ſurface. This fluid, as it naturally exiſts, is very ſmall in quantity; on which account, as it is pellucid, it is undiſcernible by the naked eye; nevertheleſs it is liable by an irritation or inflammation of the parts which furniſh it, not only to be increaſed greatly in quantity, but to be ſo altered and changed in quality, as very much to reſemble pus itſelf, both in conſiſtence and colour. This inflammation is not often connected with any other diſorder, and is moſt frequently ſuppoſed to ariſe from the child's being imprudently expoſed to the cold air.

When early aſſiſtance hath been given, its conſequences was generally ſucceſsful; but when neglected, a partial blindneſs at leaſt, and too often a total one, hath been the conſequence. Like all inflammations of the eye, it is apt to terminate in an opacity of the cornea.

In order to the cure, it is recommended by ſome to waſh the *mucus* out of the eye, whilſt in a tender inflamed ſtate, with a collyrium of equal parts of the common emulſion and julep of camphor. Others with a ſyringe waſh out the *mucus*, but prefer mild fluids, ſuch as warm barley water; and until the ſwelling of the eye-lids ſubſide, they apply to them cooling ointments and emollient cataplaſms; at the ſame time, they repeat gentle purgatives as often as the patient's ſtrength, &c. ſeems to require. Leeches are applied to the temples, and a bliſter between the ſhoulders is kept open as long as a tendency to a diſcharge of *mucus* in the eye appears. When the turgidneſs of the eye-lids abates, and the inflammation of the conjunctiva diſappears, the decoct. cort. Peruv. is given inwardly, and collyriums directed that are of an aſtringent kind, and uſed three or four times a day. Though bliſters are generally applied, ſome have from an extenſive practice concluded, that their conſtant omiſſion would be no diſadvantage to the patient. Mr. Ware propoſes on the firſt attack to begin with reſiſting the diſcharge of *mucus*, by ſtrengthening the external coat of the eye. To this end he directs the eye to be cleared of the morbid *mucus*, by injecting into it by a ſyringe, a gentle aſtringent collyrium; in particular he prefers the aq. camph. Bat. diluted with common water, in the proportion of a dram, leſs or more, to two ounces. This practice he uſes in all the ſtages of the diſeaſe. As the matter increaſes, the collyrium may be uſed more frequently, and gradually increaſed in its ſtrength: in a ſlight caſe it may be uſed two or three times a day, but in the more malignant ones it may be repeated every hour, and the ſtypticity of the collyrium may be increaſed in proportion; as the diſorder gives way, the ſtrength of the medicine, and the frequency of uſing it, may both be decreaſed. To abate the ſwelling of the eye-lids, Mr. Ware prefers a cataplaſm of the coagulum aluminoſ. & ungt. flor. ſamb. an. p. æq. this ſhould be applied cold. When the eye-lids adhere ſtrongly, they will be beſt ſeparated by waſhing their edges with freſh butter diſſolved in warm milk. If the inſide of the eye-lids turn outward, only when the child cries, and returns as ſoon as it ceaſes ſo to do, nothing more need be done than what is already recommended; but if this ſymptom is conſtant, it will require a more frequent repetition of the injection, and to employ a perſon immediately after the uſe of it, to return the lids, and to keep a compreſs dipped in the diluted aq. camph. conſtantly upon them with his finger, in order that the habit may be removed, and the eye-lids may recover their proper tone and ſtrength. When the inſide of the eye-lid is much inflamed, the tinct. theb. may be dropped on them with advantage every day; and when the quantity of *mucus* is ſo diminiſhed as that the tincture may come in contact with the eye, it may be applied there alſo once a day. If there is reaſon to ſuſpect any particular humour in the habit, give ſuch alteratives as their nature may appear to require.

Mr. Ware gives an inſtances of a caſe in which blood inſtead of *mucus* was diſcharged, and which gave way to the ſame treatment as is here recommended; on account of which, with many other important particulars, his publication deſerves the attention of every practitioner.

See Ware's Remarks on the Ophthalmy, &c. A Treatiſe on the Eye and its Diſorders, by Joſeph Warner, edit. 2.

OPHTHALMICI EXTERNI, i. e. Motores oculorum externi.

OPHTHALMICI WILLISII. The ophthalmic branch of the fifth pair of nerves. See TRIGEMINI.

OPATHALMITES. i. e. Ophthalmia.

OPHTHALMOPONIA. An intenſe pain in the eye, whence the light is intolerable.

OPHTHALMOXYSIS. A bruſhing of the eye.

OPHTHALMORRHAGIA. Bleeding from the eye or the eye-lid.

OPHTHALMOXYSTRUM. A bruſh for the eye; it was formerly made of the beards from barley or rye. It was ſo drawn acroſs the inſide of the eye-lids, as to make them bleed.

OPHYLLON. Great tooth-wort.

OPIATA. Properly medicines in which are opium; but ſoft electaries are alſo ſo called.

OPION. Opium.

OPISTHOTONOS, from *οπισθεν, backward*, and *τονος*, from *τεινω, to ſtretch*. It is a ſpecies of ſpaſm, in which the whole trunk is rigid and drawn backwards in a curve, with the head bent towards the ſhoulders. See TETANUS.

OPIUM. Probably from *οπος, juice*. This name ſeems to be by way of eminence, as by cortex is underſtood the cortex Peruv. Galen is the firſt among the Greeks who uſes the word for expreſſing this drug with. *Opium* is the milky juice which exudes from the heads of poppies when inciſions are made in them; this juice is gradually dried in the ſun, to a proper conſiſtence. The ſpecies of poppy, is the papaver ſomniferum, or papaver calycibus capſuliſque glabris foliis amplexicaulibus inciſis, Linn. It is brought from Turkey, Egypt, the Eaſt Indies, and other parts of Aſia. Neumann ſays, that the *opium* we receive from all the juſt named places, is obtained by the preſſing the juice from the heads of the poppies.

Opium is brought into Europe in flat cakes, or irregular maſſes, from four to ſixteen ounces in weight; covered with leaves to prevent their ſticking together. It is a gummy reſinous ſubſtance, ſoftiſh, and tenacious, eſpecially when warm or much handled; of a dark reddiſh brown colour in the maſs, and yellow when reduced to powder. It hath a faint diſagreeable, ſoporiferous ſmell, and a bitter taſte. If chewed a little it affects the tongue with a ſenſe of heat, which ſpreads to the palate, and then in a leſs degree to the lips, and provokes a diſcharge of ſaliva. It heats the noſe, and ſo irritates it as to excite a ſneezing.

Chooſe that in which when ſliced, no viſible impurities are lodged; when broken, appears brightiſh, of a dark red blackiſh colour; that is dry, not unctuous, but moderately ponderous and compact; that is inflammable, of an acrid bitter taſte, a faint ſmell reſembling that of unripe poppy heads, and without any empyreumatic flavour; and that communicates to water, not yellow, but a reddiſh tincture.

Hippocrates ſeems not to have been a ſtranger to its

narcotic quality. The ancients rarely uſed it. Sylvius de la Boe firſt brought it into vogue. Sydenham firſt uſed it in the ſmall pox; but now it obtains very extenſively in practice.

Bellonius obſerves, that it is ſo adulterated, that ſometimes a pound does but contain above four ounces that is pure genuine *opium*; but ſuch faulty ſorts are not brought amongſt us. Sand is added to increaſe its weight, and many foreign bodies are found mixed with it; but that the juices of other plants are added does not appear clear.

The particular matter in which its virtues depend hath not yet been produced in a ſeparate ſtate, nor is it known: but whatever it is, it may by art be acuated, concentrated, obtunded, and deſtroyed. The principles ſeparable from *opium*, are, a reſin, which Neumann ſays is of two kinds, viz. a hard and a ſoft one. Mr. Awſiter ſeems to call this ſoft reſin, its thick eſſential oil; they both agree in that this ſoft reſin, or thick oil, chiefly contains the active matter of *opium*, that is its narcotic quality, though the other parts are ſtill mildly anodyne after the ſeparation of the ſoft reſin. Beſides this reſin there is a gummy part, a ſaline one, which Dr. Alſton ſays is of the nature of ſal ammoniac, and an earth. In diſtillation with rectified ſpirit little or nothing riſes from the *opium*, but with water its particular ſmell is brought over. The moſt active parts of *opium* are ſo fixed, that it keeps many years without any ſenſible loſs; a dram of *opium* was kept in the heat of boiling water during five hours, and it ſcarce loſt a grain and an half thereby. It diſſolved but partially in rectified ſpirit of wine, or in water; but proof ſpirit, wine, or vinegar, diſſolves all that is good, the impurities only being left. Dr. Alſton ſays, that twelve parts of *opium* contain five parts of gum, four of reſin, and three of earthy, with other indiſſoluble impurities. The gum is a mild anodyne, but free from the narcotic and other diſagreeable qualities of the crude *opium*. The reſin is almoſt taſteleſs, but hath a very muſty ſmell. *Opium* is mixed with other ſubſtances into a maſs of pills: the London College give the following two forms; the firſt is a compoſition for expediting the ſolution of *opium*, the ſecond for retarding it.

Pilulæ Saponaceæ. Soap Pills.

Take the ſoap of almonds, four ounces; ſtrained *opium* half an ounce; eſſence of lemon, a dram; ſoften the *opium* with wine, and beat it with the reſt until it is perfectly mixed.

The eſſence of lemon is added to cover the flavour of the ſoap. This pill is in the ſtead of Mathews's pill; in ten grains of it is about one of *opium*.

Pilulæ e Styrace. Storax Pills.

Take of ſtrained ſtorax, two ounces; of ſaffron, one ounce; of ſtrained opium, five drams. Beat them diligently together, till they are perfectly mixed.

There is a grain of *opium* in about ſix grains of this compoſition.

Opium is purified by diſſolving it in an equal weight of water, and whilſt it is hot, preſſing it through a cloth, and then evaporating it to a due conſiſtence.

The following tincture is directed by the London College.

Tinct. Thebaica. Thebaic Tincture.

Take of *opium*, ſtrained, two ounces; cinnamon and cloves, of each ʒ i. of white wine, a pint. Infuſe without heat for a week; and then ſtrain off the wine through paper.

This was formerly called liquid laudanum.

The medical properties of this drug are both numerous and valuable; even ſo that ſome have denominated it manus Dei. Its operation is generally accompanied with a ſlow but ſtrong and full pulſe, a ſlight redneſs, heat, and itching in the ſkin; it is followed by a weak and languid pulſe, low ſpirits, ſome difficulty of breathing, or a ſenſe of tightneſs about the breaſt, a ſlight giddineſs of the head, dryneſs of the mouth and fauces, ſome degree of naufea, heat and pain in the ſtomach; but theſe ſymptoms are to be underſtood of a full doſe when no particular diſeaſe requires it; for very large doſes are taken in violent diſorders, and no diſagreeable effects are obſerved to follow.

In proper doſes, and repeated at due intervals, it is narcotic, anodyne, antiſpaſmodic; it abates inflammation both internally and externally; it moderates the heat in fevers, and aſſiſts other medicines in producing a more ſpeedy effect; it diſcuſſes ſtagnating fluids, whether externally applied, or internally adminiſtered; it removes obſtructions ariſing from ſpaſms; abates preternatural irritability, and removes convulſions which ariſe therefrom; it promotes the diſcharges through the ſkin, but retards all other evacuations; abates all kinds of pains, and totally removes ſome; as a carminative it exceeds all of the aromatic tribe, for its efficacy extends through the whole inteſtinal canal.

One grain of pure *opium* is generally a full doſe; three grains can hardly ever be taken by an healthy man who is not accuſtomed to it; but by habit an ounce in a day may be taken. Garcias ſays he knew a perſon who took ten drams a day. In Turkey, at this day, ſober people take a dram, and drunken ones take five or ſix. When violent pains, or other ſymptoms require it, Sydenham obſerves, the doſe and its repetition may be proportioned to the urgency of the ſymptoms. Frequent experience manifeſts the propriety of large doſes; in ſpaſmodic complaints twenty-two grains of pure *opium*, beſides three hundred drops of laudanum, have been given in the ſpace of thirty-ſix hours; and afterwards no remarkable inconveniences were obſerved.

When imprudent doſes have been taken through miſtake, or with an ill deſign, there follows immoderate mirth, or elſe ſtupidity, giddineſs, a redneſs of the face, ſwelling of the lips, troubleſome dreams, ſtarting, convulſions, cold ſweats, a conſiderable dilatation of the pupil, imperfect ſpeech, ſlow full pulſe, quick breathing, naufea, itching in the ſkin, vomiting, madneſs, hiccup, fainting, &c. Immediately on the happening of ſuch an accident, give a vomit of white vitriol, and repeat it four, five, or ſix times; if the conſtitution is vigorous, bleed, and after this frequently a ſpoonful of ſharp vinegar; beſides theſe, ſinapiſms may be applied to the feet, bliſters to the arms, clyſters of tobacco ſmoak may be given, frictions may be uſed, as the caſe ſeems to require. Vinegar is the antidote, yet cordials ſhould ſometimes accompany it. When *opium* is given in a ſolid form, the pure *opium*, or the pills abovementioned, will be the beſt; when a liquid form is required, ſolutions in wine, or proof ſpirit, are to be preferred.

Alkaline ſalts diminiſh the ſoporific effect of *opium*; the fixed alkaline ſalts render it diuretic; the volatile carries it through the ſkin; and acids almoſt entirely deſtroy its powers. See Kæmpfer's Amænitates Exoticæ; Wedelius's Opiologia; Lewis's Mat. Med. Mead on Poiſons; Newmann's Chem. Works; Dr. Alſton's Diſſ. on Opium in the Edinb. Med. Eſſays, vol. v. Med. Muſ. vol. i. page 473, &c. Jones's Myſtery of Opium.

OPOBALSAMUM. Balſam of Gilead.

OPOCALPASON, or Opocarpaſon. The juice of a tree called calpaſi. This juice reſembles myrrh; but is poiſonous,

OPODELDOC. The name of a plaſter ſaid to be invented by Mindererus; it is often mentioned by Paracelſus. At preſent the medicine known by this name is the linim. ſaponac.

OPODEOCELE. A rupture through the foramen iſchii, and into the labia pudenda.

OPOPONAX. The plant from whence the gum thus called is produced, is known by the names of opoponaeum, panax heracleum, panax coſtinum, paſtinaca oluſatri folio. Hercules's all-heal, and *opoponax* wort. It is the paſtinaca *opoponax*. Linn.

The medicine kept under the name of *opoponax*, is a gummy reſinous juice, obtained from the roots of the *opoponax* wort, which grows wild in warm countries, and bears the cold of our own. This gum is brought from Turkey and the Eaſt-Indies, ſometimes in little round drops, but generally in irregular lumps, of a reddiſh yellow colour on the outſide, with ſpecks of white internally of a paler colour, and often variegated with large white pieces; they have a diſagreeable ſmell, and a bitter acrid naſeous taſte; they diſſolve in water, and in ſpirit. As a medicine, this gummy reſin is ſometimes uſed as an attenuant, and deobſtruent; in large doſes it is laxative: doſes

from

from ℈ i. to ʒi. are given with the ſame intentions as the galbanum and ammoniacum are uſed. See Raii Hiſt. Lewis's Mat. Med. Neumann's Chem. Works.

OPPILATIO, from *oppilo*, of *pilo*, *to condenſe*. Oppilation is a cloſe kind of obſtruction; for, according to Rhodius, it ſignifies, not only to ſhut out, but alſo to fill.

OPPRESSIO. The catalepſy.

OPULUS. The gelder-roſe. Boerhaave mentions two ſpecies, but no medical virtues. A ſpecies of acer is thus called.

OPTICUS NERVUS, from *οπτομαι*, *to ſee*. The optic nerve. This nerve with its fellow are the ſecond pair which proceed from the brain, where they are united, but ſoon become two diſtinct cords, each paſſing through the foramen opticum of the ſphenoid bone, to their reſpective orbits. They unite on the anterior part of the glandula pituitaria, but ſoon ſeparate again, and paſs to the poſterior of the eye, into which they are inſerted obliquely towards the noſe. The optic nerves are each ſurrounded by the four recti muſcles of each eye.

OPUNTIA. It is a ſhrub or tree, whoſe flowers expand like a caſe, having each a great number of ſtamina in the centre, growing upon the tops of the ovary. The ovary afterwards becomes a fleſhy umbilicated fruit, with a ſoft pulp, incloſing many ſeeds of an angular ſhape. Boerhaave mentions eleven ſpecies. They are chiefly noted for the cochineal which are gathered from off them.

OPUNTIOIDES. It is a marine plant, ſhaped like the opuntia. It is brittle and hard; Boerhaave takes notice of two ſpecies, and reckons them among vermifuge medicines.

ORBICULARE OS. The name of a ſmall round bone in the internal ear. It reſts on the ſtapes, and the incus reſts on it.

ORBICULARES PALPEBRARUM. (Muſc.) The orbicular muſcles of the eye-lids. They lie under the ſkin about the eye-lids; they riſe from the ſide of the noſe; thoſe fibres which run on the eye-lids are elliptical, and terminate at each canthus. Theſe *muſcles* ſhut the eye-lids.

ORBICULARIS. A name of the ſphincter ani. Alſo of the fungus called crepitus lupi.

ORBICULARIS CLAUSOR. The orbicular muſcle of the eye-lid.

ORBICULARIS LABIORUM, i. e. Sphincter labiorum.

ORBITA. The orbit of the eye, or circular cavity in which the eye is placed.

ORBITALIÆ ARTERIÆ. The arteries of the orbits of the eyes. They are branches of the inferior maxillary arteries. See MAXILLARIA ARTERIA.

ORBITARE EXTERNUM INFERIUS. (FORAMEN.) See MAXILLARIA SUPERIORA OSSA.

ORBITARIA PROCESSUS. See MAXILLARIA SUPERIORA OSSA.

ORBITARIA PROCESSUS. See MAXILL. SUPE- OSSA. See Os FRONTIS, and Os SPHENOIDES.

ORBITARII NERVI, i. e. Motores oculorum externi.

ORBITER EXTERNUS FORAMEN. It is in the os maxillare, below the orbit. Through it the nerves and veſſels which come from the teeth paſs to the cheek.

ORBITER INTERNUS FORAMEN. It is a little above the os planum; through it goes a branch of the fifth pair of nerves to the noſe.

ORCHEA. Galen ſays it is the ſcrotum.

ORCHIS. A teſticle.

ORCHIS. The name of a plant with a teſticulated root; of which Boerhaave enumerates fourteen ſpecies; and Dale adds five more.

The chief of theſe is the following ſpecies;

ORCHIS, alſo called ſatyrium mas; cynoſorchis; teſticulus archis; ſerapias; male ſatyrion; dogs ſtones; fools ſtones. It is the *orchis* maſcula, or *orchis* foliis ſeſſilibus maculatis, bulbis indiviſis nectarii labio quadrilobo crenulato, cornu obtuſo petalis dorſalibus reflexis, flore purpureo, Linn. Male fool ſtones.

This plant hath ſix or ſeven long, narrow, ſmooth leaves, variegated with dark coloured ſpots or ſtreaks, iſſuing from the root, and one or two embracing the ſtalk, which is ſingle, roundiſh, and ſtriated. On its top appears a long looſe ſpike of irregular, naked, purpliſh, red flowers, conſiſting each of ſix petala, one of which is large, cut into three ſections, hanging downward; the other ſmaller, forming a kind of hood above it, with a tail behind. The root conſiſts of two roundiſh, whitiſh, tubercles about the ſize of nutmegs; one plump and juicy, the other ſungous and ſomewhat ſhrivelled, with a few large fibres at the top. It is perennial, grows wild in ſhady grounds and moiſt meadows, and flowers in May or ſooner.

The plump roots or bulbs are the only parts uſed in medicine; they have a faint ſmell, and ſweetiſh viſcid taſte. Their properties are ſimilar in general to thoſe of the rad. althæa. The dried roots are brought from Turkey, &c. under the names of ſalep, and ſaleb, but thoſe of our own growth are as good. Thoſe that are brought from Turkey are in oval pieces, of a yellowiſh white colour, clear, and pellucid, very hard and horny, of little or no ſmell, taſting like gum tragacanth. Our *orchis* roots, when robbed of their ſkin by boiling in water, and then dried in the air, gains exactly the ſame appearance. Reduced to powder, and diſſolved by boiling in water, a mucilage is formed, which is of a very nouriſhing quality; more ſo than any other known vegetable. Sometimes it occaſions coſtiveneſs, but this is remedied by a little of any vegetable acid mixed with it, or a little ſea-ſalt. Half an ounce of the powder is ſufficient for a gallon of thick mucilage. The powder ſhould be ſprinkled with a little boiling water, then ſtirred well into it, and afterwards mixed with the water in which it is to be boiled. If this powder is kept dry it never ſpoils, ſo would be an excellent part of ſeamen's diet, particularly when they are in warm countries. A dram and a half of ſalt in a pint of potable ſalep, is not diſagreeable, whence, when freſh water fails at ſea, this powder would be an excellent expedient for leſſening that inconvenience. As a diet, it far exceeds rice in every point of view, and for children particularly it is peculiarly proper. As a medicine, the ſalep is mucilaginous, demulcent, obtunds the acrimony of the ſea ſcurvy; in diarrhœas and dyſenteries it is of ſingular efficacy by lubricating the bowels, and correcting putrefaction. In ſymptomatic fevers, from the abſorption of pus, a plentiful uſe of ſalep is very demulcent. In the ſtrangury and dyſury it is of ſervice by its mucilage. See Lewis's Mat. Med. Percival's Eſſays. Med. and Exper. Georgical Eſſays, vol. iv.

ORCHIS BIFOLIA, i. e. Bifolium.

ORCHOS. The extremities of the eye-lids; where the eye-laſhes grow.

ORCHOTOMIA, from *ορχις*, *teſticle*, and *τεμνω*, *to cut*. Caſtration.

OREILLONS, i. e. Mumps.

OREOSELINUM. The galbanum plant. Boerhaave mentions three ſpecies, but the two following are thoſe which afford the gum galbanum.

Oreoſelinum Africanum galbaniferum fruteſcens anaſi folio.

Oreoſelinum aniſoides arboreſcens liguſtici foliis & facie flore luteo Capitis Bonæ Spæi.

OREOSELINUM, alſo called petroſelinum montanum; apium montanum nigrum; *oreoſelinum* apii folio minus. Mountain parſley.

Of this and the two following ſpecies, the roots are ſlenderer than thoſe of the daucus, and not lacteſcent; the leaves are like thoſe of the apium or cicuta; the ſeeds are oval, flat, large, ſtriated, marginated, and ſometimes caſt off their huſks.

The *mountain parſley* grows on the mountainous parts of Germany and other countries. It heats and is diuretic.

OREOSELINUM PRATENSE CICUTÆ FOLIO, alſo called daucus Alſaticus; angelica pratenſis apii folio.

OREOSELINUM APII FOLIO MAJUS, alſo called libanotis nigra; gentiana nigra; daucus montanus cervaria nigra; daucus ſelinoides major; laſerpitium minus paludapii folio ſemine criſtato; mountain dauke; or black herb frankincenſe.

It grows on mountains in Italy, and flowers in July. The ſeeds are opening, inciding, diuretic, and emmenagogue.

ORESTION. In Dioſcorides it is the helenium. See Raii Hiſt.

ORGASMUS, from ὀργαω, *to deſire vehemently, to be turgid*, or properly *to be in heat*, as ſome female animals are at particular ſeaſons of the year. An orgaſm; that is, a violent turgeſcence, and motion of the humours. As Linnæus expreſſes it, a ſubſultus of the arteries.

ORIBASIUS. He was a profeſſor of phyſic in Alexandria; he flouriſhed about the end of the third century, and he writ ſome of his works by order of Julian the Apoſtate. After him as eminent was Ætius.

ORICIA. A ſort of turpentine-tree, ſo called from Oricus, a city of Epirus, near which it grows.

ORIENTALIA FOLIA. The leaves of ſena.

ORIGANO COGNATA. A ſpecies of marjoram.

ORIGANUM. Wild marjoram. *Origanum* vulgare, Linn. Boerhaave enumerates eleven ſpecies, but the two following are the chief that are in uſe.

ORIGANUM ANGLICUM, called alſo orig. vulgare ſpontaneum; majorana ſylveſtris; agrioriganum; ouitis major; origanum; common wild marjoram. *Origanum* vulgare, Linn.

It is a plant with firm round ſtalks, and oval acuminated leaves, that are uncut, and ſomewhat hairy. It is ſet in pairs on ſhort pedicles; on the tops grow ſcaly heads of pale red labiated flowers, whoſe upper lips are entire, and the lower cut into three ſegments, ſet in form of a convex umbel, intermixed with roundiſh purpliſh leaves; each flower is followed by four minute ſeeds incloſed in the cup. It is perennial, grows wild on dry chalky hills, and gravelly grounds in ſeveral parts of England, and flowers in June.

The leaves and flowery tops have an agreeable aromatic ſmell, and a pungent taſte, warmer than that of the garden-marjoram, and much reſembling thyme, with which they agree in medicinal virtue, as alſo with marjoram: infuſions of them are drank as tea in weakneſs of the ſtomach, diſorders of the breaſt, to promote perſpiration and the fluid ſecretions in general: they are uſed in nervine and anti-rheumatic baths; the dry leaves powdered are a good errhine. For internal uſe, an infuſion of half an ounce of the leaves in a pint of water is the beſt preparation. In diſtillation with water they yield a moderate quantity of a very acrid penetrating eſſential oil, ſmelling ſtrongly of the *origanum*, but leſs agreeable than the herb; this oil is called oil of thyme, and is often put into hollow teeth to allay the pain of them. See Lewis's Mat. Med. Neumann's Chem. Works.

ORIGANUM CRETICUM, called alſo origanum onites; origany; or candy wild marjoram. The flowery tops were formerly brought from Crete, and are indeed ſomewhat ſtronger than ours; but inſtead of them thoſe of our own growth are now always uſed.

ORIGANUM CRETICUM. Dittany of Crete.

ORIGANUM. A name for a ſpecies of baſil.

ORLEANA, called alſo arbor Mexicana; orellana; the arnotto-tree. See ACHIOTL.

The arnotto tree is the bixa orellana of Linnæus. Dr. Brown, in his Hiſtory of Jamaica, gives the following account of it:

Bixa foliis cordatis cum acumine floribus racemoſis terminalibus. The roucou or arnotto tree. This curious ſhrub is frequently met with in the cooler vales in Jamaica; it riſes commonly to the height of eight or nine feet or more; it thrives beſt in a cool rich ſoil, and ſhoots moſt luxuriantly near ſprings and rivulets. All the ſeeds of this plant are covered with a kind of wax, which is carefully gathered in many parts of America, and is what generally goes by the name of terra orellana, roucou, and arnotto. This commodity is manufactured in the following manner, viz. when the ſeed veſſels are full grown, and in a perfect ſtate of maturity, they are picked off and opened, and the ſeeds gathered and put into convenient jars. When they have a quantity of theſe, proportioned to their veſſels and deſign, they throw in as much hot water as may be ſufficient to dilute and ſuſpend the wax or pulp, with eaſe, which is gradually waſhed away from the ſeeds, both with the hand and the ſpatula. When all the wax is waſhed off, and the ſeeds appear quite naked, they are taken out, and the waſh left to ſettle: but when the wax is thoroughly ſubſided, the clear incumbent waters are decanted off, and the ſediment put into ſhallow veſſels to be dried gradually in the ſhade. When this maſs acquires a due conſiſtence, it is made into balls or cakes, and left to dry in ſome open airy place, until it grows firm and hard, and then it is fit for uſe, or the market. The wax is a cool agreeable rich cordial, and hath been long in uſe amongſt the Indians and Spaniards in America, who ſtill mix it with their chocolate, both to heighten the flavour, and raiſe the colour. It is ſaid to be a ſucceſsful remedy againſt the bloody-flux. It is uſed as a pigment. It is often mixed with other ingredients both by painters and dyers. The roots have much the ſame properties as the wax, but the roots are ſomewhat more diuretic.

This American ſhrub is retained in hot houſes in Great Britain. It is propagated by ſeeds from America; ſown in pots in ſpring, and plunged in a bark bed; the plants are to be tranſplanted into ſeparate pots, and always retained in the ſtoves.

Father Labat ſays, that the Indians prepare an arnotto of a bright ſhining red colour, almoſt equal to carmine.

The arnotto is difficultly diſſolved in water, which it tinges of a pale, browniſh, yellow colour. It readily diſſolves in ſpirit of wine, rectified, to which it gives an orange red colour, and is uſed in varniſhes to give an orange hue to the ſimple yellows. Alkaline ſalt renders it ſoluble in boiling water, without altering its colour.

ORNITHOGALUM. Boerhaave enumerates eleven ſpecies; but only the following hath any medical properties attributed to it, viz. the ornithogalum umbellatum medium anguſtiſolium; called alſo ornithogalare. The ſtar of Bethlehem. It is cultivated in gardens; it flowers in May; the root is bulbous or tuberous, and is ſometimes, though very rarely, uſed, as are alſo the ſeeds. See Raii Hiſt.

ORNITHOGALUM, i. e. Scilla.

ORNITHOGLOSSUM. Bird's tongue. So the ſeeds of the common aſh-tree are called from their ſhape.

ORNITHOPODIUM. Bird's-foot. There is another ſpecies called telephium; ſcorpioides; ſcorpion-wort. They grow on ſandy and gravelly places; they flower in ſummer. Their ſeeds deſtroy the ſtone in the kidneys; but are very rarely uſed. Boerhaave mentions four more ſpecies, but they are not noted as medicinal. See Raii Hiſt.

ORNUS. The aſh-tree which affords manna. It is alſo a name for the ſorbus aucuparia.

OROBANCHE, alſo called ſquamaria; anblatum; dentaria major; aphyllon; Mathiolus's great tooth-wort. It grows in lanes and ſhady places, and flowers in April or May. There is another ſpecies called rapum geniſtæ, broom rape. It grows to the roots of broom, whence its name, and amongſt corn; it flowers in June. See Raii Hiſt.

OROBANCHE. A name for the hypociſtis.

OROBUS, alſo called aſtragalus; aſtragaloides; aſtragalo; chamæbalano; wood-peaſe; heath-peaſe. It grows in woody places; flowers in April; ripens its ſeeds in May; the tubera of the root taſtes like liquorice, and in Scotland is uſed as liquorice is with us. They call the plant karemyle. See Raii Hiſt.

OROBUS. See ERVUM.

ORPHEUS. He was not very eminent as a phyſician. He writ on the virtues of plants. See CHIRON.

ORPIMENT. It is a cryptometalline foſſil; a ſpecies of arſenic floſs, of a bright yellow colour, and a ſcaly ſtructure. Edward's Elements of Foſſilogy.

ORTHOCOLON, from ὀρθος, *ſtrait*, and κωλον, *a limb*. It is a ſpecies of ſtiff joint, and is when it cannot be bended, but remains ſtrait. See ANCHYLOSIS.

ORTHOPNŒA. This diſeaſe, when neither a ſpecies of aſthma nor of dyſpnœa (the inſtances of which is inſerted immediately below), is only a ſymptom of ſome other diſeaſe. It is a ſighing ſuffocating reſpiration, and the patient muſt be erect to breathe. See ASTHMA and DYSPNOEA.

ORTHOPNŒA SPASMODICA, i. e. Aſthma ſpontaneum.

ORTHOPNŒA HYSTERICA, i. e. Aſthma ſpontaneum.

ORTHOPNŒA a LIPOMATE, i. e. Dyſpnœa ſicca.

ORTHOPNŒA ab HYDROPNEUMONIA, i. e. Dyſpnœa aquoſa.

ORTHOPNŒA PINGUEDINOSA, i. e. Dyſpnœa pinguedinoſa.

ORTHOPNŒA TRAUMATICA, i. e. Dyſpnœa thoracica.

ORTHOPNŒA a VAPORIBUS, i. e. Dyſpnœa extrinſeca.

ORTHOPNŒA a DEGLUTITIS, i. e. Dyſpnœa extrinſeca.

ORTHOPNŒA a FUNGIS, i. e. Dyſpnœa extrinſeca.

ORTHOPNŒA ab ANTIPATHIA, i. e. Dyſpnœa extrinſeca.

ORTHOPNŒA a BRONCHOCELE, i. e. Dyſpnœa extrinſeca.

ORVALA. A name for ſeveral ſpecies of ſclarea.

ORVIETANUM. Orvietan. A celebrated antidote, ſo called from Orvieto, a city of Italy, where it was firſt uſed; though ſome ſay its inventor was one H. F. Orvietanus, and that it is named after him. It is an electary, made up of many ingredients mixed with honey.

ORYZA. Rice. It hath its grains diſpoſed into a panicle, which are almoſt of an oval figure, and covered with a thick huſk, like barley. Among the common kinds of grain, rice is the mildeſt and moſt nutritious. It is leſs viſcous than wheat, but it is alſo leſs nouriſhing. It is uſed as a diet in diarrhœas, but the ſalep is to be preferred. Rice delights in a moiſt ſoil, and grows even in water. In China they ferment the rice, and diſtil from it the liquor called arrack.

ORYZA GERMANICA. A ſpecies of barley.

OS. A bone. *Bones* conſiſt of a mucilage, and an earthy matter. Acids diſſolve this earthy matter, leaving the *bone* of its original ſhape, but ſoft. The earthy matter forming *bone*, is depoſited by the exhaling arteries. The number of *bones* are 304.

The *bones* are compoſed of fibres, diſpoſed in laminæ, which laminæ laid over each other, compoſe the ſubſtance of the *bone*. In the fœtus ſtate, the *bones* ſeem a network of threads, but when oſſification is farther advanced, theſe threads are not ſo apparent; the interſtices being filled up with others. The bones are compoſed of a hard, ſolid, of a cellular, and of a reticular part. The cellular part is formed by the inner laminæ of the ſolid part, departing towards the axis of the *bone*. The reticular part lies in the cavity of the *bone*, and by degrees, as it approaches the extremities, unites, ſeeming partly to form the cellular part. There are no nails to join the laminæ as ſome have deſcribed; they are rather connected by tranſverſe fibres. The cavity of the *bones* ſerves not only to contain the marrow, but by the increaſe of the diameter, the ſtrength of the *bone* is augmented. The *bones* have numerous blood-veſſels, but eſpecially in the ſpongy and reticular parts, though the ſolid part is not without them; theſe veſſels run according to the direction of the fibres of the *bone*; thus, in the long *bones* they run longitudinally. In the round *bones*, as in the os bregmatis, they run radiated, becoming leſs and leſs viſible as they approach to the centre of the *bone*, becauſe there the laminæ are the thickeſt. The bones are full of pores for the admiſſion of veſſels; in the middle theſe pores are more large and conſpicuous, in the extremities they are ſmaller. In every cylindrical *bone* there is a hole about its middle for the admiſſion of an artery and its vein, which paſſes ſlanting through the ſubſtance of the *bone*, and branches through the internal perioſteum, or membrana medullæ, which lies betwixt the medulla and the internal ſurface of the *bone*, and even branch externally again through the *bone*. Theſe branches frequently anaſtomoſe, whence the *bone* may be nouriſhed from within outwards, as well as from without inwards. This internal perioſteum is liable to the diſorders of other vaſcular ſubſtances, as inflammation, obſtruction, ſuppuration, &c. with their conſequences: but where theſe happen, the ſtructure of the *bone* is frequently quite deſtroyed, as in the ſpina ventoſa. It is ſuppoſed that *bones* are furniſhed with nerves, and yet they moſtly ſeem inſenſible; though the granulations from them are extremely ſenſible. It is probable that there are veſſels ſui generis, whoſe office is to carry *bony* matter, and occaſionally to abſorb it; as a proof of this, the mollities oſſium, from a ſcorbutic, or a venereal cauſe, ſeems rather a defect of this *bony* matter, than of marrow. The membrana medullæ, not only lines the ſurface of the *bone* internally, but alſo divides the marrow into veſicles or membranous bags, which are furniſhed with very fine minute veſſels. The middle part of the larger bones, is much leſs in diameter than the extremity, to give a greater firmneſs to the joint, and to allow a greater ſpace for the fleſhy belly of the muſcles. The middle part of the bones is not ſmaller than the extremities merely by preſſure, as we may obſerve in the fœtus ſtate; it is their original conformation, though preſſure ſeems to have ſome effect in this caſe, as we may obſerve in a weakly conſtitution, and in women of a ſedentary life. The *bones* are entirely ſmooth, though in a robuſt habit there are cavities and furrows on their ſurface formed by the action of the muſcles. The *bones* are cæteris paribus weaker in their middle part, from their diameter being leſs; whence in this part they are more expoſed to fractures; but to compenſate this, there are more lamellæ in the middle than in the extremities, and they are more compactly joined; there is a cavity alſo there which contains the marrow, and thus the ſtrength in this part is greater than otherwiſe it would be. Many *bones* have protruberances riſing out of them, which are called proceſſes; and in many there are cavities; if theſe are deep, with large brims, they are called cotylæ; if ſuperficial, glenæ or glenoid; which general claſſes are divided into ſeveral ſpecies, of which, pits are ſmall roundiſh channels, ſunk perpendicularly into the bone; furrows are long narrow canals, formed in the ſurface; niches are ſmall breaches in the *bone*; ſinuoſities are broad but ſuperficial depreſſions without brims; foſſæ are large deep cavities, which are not equally ſurrounded by high brims; ſinuſes are large cavities within the *bones* with ſmall openings; foramina, or holes, are canals that pierce through the ſubſtance of the *bones*. The uſe of theſe cavities are to allow room for heads of bones to play in; to defend and lodge ſofter parts; and to afford a paſſage for veſſels, muſcles, &c. The *bones* are deſtroyed in the living ſubjects, by the acceſs of air, or by blood lodging upon them. The claſſes into which the *bones* are divided are uſually as follow. 1ſt, The cylindrical; theſe are compact in the middle, and ſpongy in their extremities. 2dly, Spherical; theſe are entirely ſpongy, except a thin plate on the external ſurface. 3dly, The flat; they are compact on the outſide and inſide, but between the plates are ſpongy. 4thly, The irregular, which when thick, are like the round, and when thin are like the flat ones.

Mr. Sheldon obſerves, that *bones* are compoſed of fibres connected by cellular ſubſtance; there are two portions in *bone*, one the living vaſcular or organized part; the other dead calcareous earth, which, though a dead matter treaſured up in a living ſubſtance, yet does not ſtimulate or irritate. If *bone* is ſoaked in ſpirit of ſalt and water, it will leave nothing but veſſels and membranes; it appears to be an inorganic concrete, but it is very much organized. The ſource of blood to the *bone*, is from the internal and external perioſteum, whoſe veſſels copiouſly anaſtomoſe with each other in the ſubſtance of the *bone*. In the flat *bones* the veſſels anaſtomoſe in the diploe or meditullium. The arteries, veins, nerves, and abſorbents, are all in like manner. All the ſpongy bones, as the ſternum, vertebræ, ſacrum, &c. are covered with a ſtrong ligamentous ſubſtance. The earth of *bones* is conſidered by the chymiſts as the pureſt: they call it virgin earth. The whole ſenſibility of the *bone* does not reſide in the perioſteum: *bone* becomes moſt exquiſitely ſenſible, in the diſeaſed inflamed ſtate, owing to the veſſels ſwelling, and the ſubſtance round them being inelaſtic.

See Havers on the Bones; Monro's Oſteology; Thompſon on the Bones; Cheſelden and Albinus's Oſteography; Neſbitt's and Kerckringius's Oſteogeny; Monſieur Courtial's Obſ. Anat. ſur les Os. On the Diſeaſes of the Bones, ſee Petit.

OS. The mouth. Its internal parts are the lips, the angles of the mouth, the border or edge of each lip; the foſſula which runs from the ſeptum narium to the edge of the upper lip, and the tranſverſe fold which ſeparates the under lip from the chin. The internal parts are the plate, the ſeptum palati, the uvula, the amygdalæ, the gums, the frœna of the lips, and the tongue with its apex, root, ſides, and frœnum.

OSCEDO. Yawning.

OSCHEOCELE, i. e. Hydrocele. Vogel calls the rupture that deſcends into the ſcrotum by this name.

OSCHEOPHYMA. The ſame as hydrocele.

OSCITANS. The yawning fever.

OS EXTERNUM. In midwifery, the entrance into the vagina is thus called, in oppoſition to the mouth of the womb which is called the os internum.

OS INTERNUM. In midwifery, the orifice into, or mouth of the womb, is thus called in oppoſition to the entrance into the vagina, which is called the os externum. If the *os internum* is long and hard, when pains like labour come on, a clyſter and an anodyne may be given, for the pains are not labour pains. The os tincæ (ſo the *os internum* is alſo called) is ſometimes open, a month or two before the time for labour; but it ſhould be remembered that its thickneſs and ſoftneſs undergoes not ſuch alterations, but remains the ſame whether open or ſhut, until labour comes on. The *os internum* does not always point in one direction during pregnancy, nor in the beginning of labour; which ever way it points, when it can be reached, if it is not in the proper direction, the midwife ſhould gently draw it towards the vagina; at the ſame time, with the other hand, let the belly be gently preſſed, to aſſiſt the endeavours uſed. If the *os internum* is rigid, ſcooping is bad. When the *os internum* is opened by the membranes, it is ſoft, and then if contracted again from the diſcharge of the waters, it is eaſily dilated. The *os internum* ſometimes is hardened and thickened by age, or by frequent labours, and then the birth, though natural, is ſomewhat retarded. The manner of dilating the os externum and *internum* is thus; having the hand well greaſed, begin to dilate the external parts gradually, introducing the fingers one after the other, and moving them in a rotatory manner; when the hand is in the vagina, begin gradually to dilate the *os internum*, reſting at intervals, both for your own eaſe and that of the woman, who ſuffers much from this practice; proceed with the more care and patience, in proportion to the rigidity of the parts. When the hand can be introduced into the uterus, let it enter with its back to the uterus, and the palm towards the membranes.

OS LEONIS. A ſpecies of antirrhinum.

OS TINCÆ, i. e. Os Internum.

OSCHEALIS HERNIA; or, Oſcheocele. A ſcrotal rupture.

OSCHEON. The ſcrotum. Galen gives this name to the os uteri.

OSCITATIO. Yawning. Boerhaave ſays, "the effects of *yawning* (he ſpeaks of it in the healthy) is to move, accelerate, and equally diſtribute all the humours through all the veſſels of the body, conſequently to qualify the muſcles and organs of ſenſation for their various functions." Juſt after ſleep, a perſon is moſt inclined to *yawn*, and ſtretch his limbs, becauſe a greater quantity going off by the pores at this time than at any other, whenever a perſon awakes, the increaſed contraction that then happens, cloſes much of the perſpirable matter in the cutaneous paſſages, which will continually give ſuch irritations as excite *yawning* and ſtretching; and ſuch motions, by ſhaking the membranes of the whole body, and ſhifting the contacts of their fibres, and the incloſed matter, by degrees throws it off. Hence we ſee the reaſon why healthful ſtrong people are moſt inclined to ſuch motions; they perſpire moſt in time of ſleep, and, therefore have more of the perſpirable matter to lodge in the pores, and hence great irritations thereunto. The advantages of ſome little exerciſe juſt after waking in a morning are conſiderable, as it throws of all the perſpirable matter that is ready for its exit out of the body.

When *yawning* is troubleſome, Hippocrates ſays, that long deep reſpiration, or drawing in the air at long intervals, cures it.

OSCULATORIUS MUSCULUS, i. e. Sphincter labiorum.

OSMUNDA. It is a plant which bears no flowers, but bears its fruit in cluſters. See FILIX and LUNARIA.

OSSA e CORDE CERVI. The bone of a ſtag's heart. It is flat, oblong, and without ſmell or taſte. It is formed by the oſſification of the arteries.

OSSERVAZIONI, i. e. Mumps.

OSSICULUM. In botany, it is the ſhell, or hard ſtony covering of ſeeds.

OSSIFICATIO. Oſſification. Dr. Niſbet ſays, that in the blood, or a fluid ſecreted from it, there is an *oſſifying* juice, conſiſting of particles, that are not apparent; that whenever nature deſigns an *oſſification* between membranes, or within a cartilage, ſhe occaſions a more than uſual afflux of this fluid, which ſo diſtends the veſſels that were before inviſible, as to make them capable of receiving the red globules of blood, which are always to be ſeen near the place where *oſſification* is begun. In this blood, gritty bony particles are to be felt by the point of a knife, which have been formed by the attraction and cohеſion of the particles of the *oſſifying* juice obſtructed, along with the other groſſer fluids in the beginning of the veſſels prepared to receive the refluent juices. The blood being capable of forming fine membranes, the membranous parts of a bone, which act as a gluten to keep theſe particles and fibres together, if there be any ſuch that do not ariſe from the coats of its veſſels, are produced by a cohеſion round the cretaceous particles of a part of the fluid, in which they were generated and contained. Thus the membranes of cartilages ſerve as a bed between, or within which the bony particles are depoſited, or ſhoot; but without any intermixture of the particles of the bone and cartilage, or continuation of the fibres of the one ſubſtance to thoſe of the other, as is evident in cartilages containing bones kept long enough in water, and then ſlit; for the bone will, as ſoon as the large veſſels that enter its ſubſtance are divided, ſlip as eaſily from it as an acorn does out of its cup; and there is a ſmoothneſs and a poliſh of the parts of both cartilage and bone, which ſhew there is no conjunction of the fibres of the two ſubſtances. While the bones are increaſing within cartilages, the cartilages are extended and ſpread out, by which, with the preſſure which they ſuffer, and the great influx of various fluids, and the nutritious matter being hindered from flowing freely into them, they decreaſe continually, and, at laſt, may truly be ſaid to be entirely deſtroyed.

Dr. Hunter, in his Lectures, ſupports Dr. Neſbit's opinion, by curious anatomical preparations, which oppoſe Kerckringius and others, who ſay that bones are cartilages in their original ſtate.

Mr. Cruikſhank obſerves reſpecting *oſſification*, that Dr. Hunter uſed to ſend round, at lectures, a preparation of the patella, in which he demonſtrated, that the *oſſification* of that bone began by the arteries *oſſifying* in the centre of the cartilage, which, in young ſubjects, ſupplies the place of bony patella. Mr. Cruikſhank adds, that he hath proſecuted that ſubject, from the firſt appearance of an *oſſifying* artery, to the perfect formation of the patella. He ſuppoſed that the ſame thing took place in all other bones, and accordingly made preparations to demonſtrate it in every bone of the body; and can ſhow that *oſſification* is not only begun, but carried on by the *oſſifying* of the arteries.

Oſſifications frequently happen in the aorta, lungs, pericardium, and other parts.

Oſſification advances in infants in proportion to the vis vitæ: thus women judge of a child's ſtrength by the dimenſions of its fontanel.

In flat bones *oſſification* begins in the centre, and ſhoots towards the circumference. In long bones it begins in the middle, ſhooting towards the extremities.

See Kerckringius, Coiterus, Eyſſonius, Ruyſch, Neſbit, Albinus, and Monro.

OSTAGRA, from ὀστεον, *a bone*, and ἀγρα, *a laying hold of*. A forceps to take out bones with.

OSTEOCOLLA, called alſo oſteites, oſſifraga, oſteolithos, holoſteus, ſtelochites, glue-bone ſtone, bone-binder. It is the petrified root of a tree, as of the poplar, pine, &c. It is found in ſandy places in ſeveral parts of Germany; the ſand in which it is met with hath a large mixture of fine, white calcareous earth, which ſticks to the fingers, looks like meal, and when waſhed by the rains into any cavity, hath the appearance of an emulſion. Of this ſand and calcareous earth, ſo inſinuated into the roots of the trees as to make them have a ſtony appearance, is the *oſteocolla* formed. In foſſiliogy it is placed amongſt the calcareous ſtones. It hath been famed for its virtue of promoting a coalition of fractured bones. See Lewis's Mat. Med. Neumann's Chem. Works; Philoſ. Tranſact.

OSTEOCOPI, from ὀστεον, *a bone*, and κοπος, *uneaſineſs*. Pain in the bones cauſed by the acrimony of the humours in the ſpina ventroſa; theſe pains are in the internal perioſteum of the bone; they reſemble that of great wearineſs.

OSTEOGENEIA, from ὀστεον, *a bone*, and γενεια, *generation*. Oſteogeny. It treats of the geneſis or production of a bone under its ſeveral original ſtates.

OSTEOGENICA. Medicines which promote the generation of a callus.

OSTEOGRAPHIA. Oſteography, from *οστεον, a bone*, and *γραφω, to deſcribe*. It deſcribes a ſkeleton, and all the bones which compoſe the ſeveral parts thereof; or it is the doctrine which deſcribes the bones.

OSTEOSARCOSIS. It is relieved by the catapl. antiparalyt.

OSTIARUS. The pylorus.

OSTIOLA. Small doors. So Mundinus calls the valves in the veſſels of the heart.

OSTIOLOGIA, from *οστεον, a bone*, and *λογος, a diſcourſe on oſteology*. A deſcription of the bones. The doctrine relative to the bones. It includes oſteogeny, oſteography, and ſynoſteography.

OSTRACITES, alſo called oſtrea labris non crenatis, oſtracite. Hobgoblin's-claw. It is a ſtony ſubſtance, of the ſhape of an oyſter-ſhell petrified by ſparry matter. It is uſed inſtead of the pumice ſtone to take off hairs.

OSTRACITES. A name of the oſteocolla.

OSTRACITIS. A ſpecies of cadmia, which is thin, and generally earthy and black. It is alſo a name of the botryites.

OSTREA. The oyſter. It is an excellent diet if eaten raw, for thoſe who digeſt ſlowly, and whoſe ſtomachs abound with acidities. The ſhells are excellent abſorbents, and are generally uſed to correct acidity in the primæ viæ. Before they are taken into the ſtomach they ſhould be calcined in the ſun; or if burnt in the fire, they become a better kind of lime than the ſtone-lime for calculous complaints; and after being ſeveral times uſed for making the lime water with, they may be uſed as abſorbents. The hollow ſhells contain moſt of the fine white earth. The rough matter of the ſhell contains much ſea ſalt. See Neumann's Chem. Works; Lewis's Mat. Med.

OSTRITIUM, or Oſtrutium. Maſter-wort.

OSTRYA, or Oſtrys, called alſo tragus, carpenus, betulus. The horn-bean. It is a tree which is found in woods and hedges. It is not noted for any medical uſe. See Raii Hiſt.

OSYRIS, called alſo caſſia poetica, caſſia Latinorum, caſſia lignea Monſpelienſium. Poets roſemary.

The whole ſhrub is aſtringent. It grows in the ſouthern parts of Europe.

OSYRIS. A name for toad-flax, and for the ſummer cypreſs.

OTALGIA, from *ους, an ear*, and *αλγος, pain*. A pain in the ear. This diſorder affects the concha, and the whole meatus auditorius. It is attended with inflammation, tumors, punction, eroſion, tenſion, pulſation, and a ſenſe of weight. Dr. Cullen places it as a variety of phlogoſis phlegmone.

Extraneous bodies falling into the meatus auditorius, or what ever excites pain in other parts, may cauſe it here.

The quality of the wax may be faulty, and be a cauſe; but the moſt frequent cauſes are heat and cold, ſometimes an acrid ſerum is ſecreted in the glands of the ear.

When the wax, or other humours are ſaline, they excite a pricking pain; when the ſalts in theſe humours are corroſive, they excite a gnawing pain; when the wax ferments whilſt it is yet in the glands, it cauſes a tenſive pain; when the glands are very turgid, there is a ſenſe of weight; and when there is a tumor, a pulſation is perceived, eſpecially if it tends to ſuppurate.

If the pain is violent it ſeldom fails to bring on a fever, which is early attended with great reſtleſſneſs, and a delirium, fainting, and often convulſions are the conſequence; for the membrane that lines the ear is exquiſitely ſenſible, and fully ſtored with nerves, beſides membranes which adhere to bones have a more than ordinary ſenſibility.

In the beginning, whilſt the pain is not very conſiderable, a little warm olive oil dropped into the ear will often relieve. If cold is the cauſe, keep the head warm. If there is inflammation and tumor, which will be known by the throbbing pain, a ſuppuration may be encouraged by cataplaſms applied warm on the outer ear; but if the ſtate of ſuppuration is not manifeſtly near, endeavour by bleeding, purging, and diſcutients applied to the ear, to remove the inflammation and pain; if external heat was the cauſe, bleed, and give daily a moderate doſe of Glauber's ſalt as a purge until the pain abates, or until there is reaſon to ſuſpect a ſuppuration; an opiate may be given at night when the pain is violent. When acrid defluxions are the cauſe, inject a warm infuſion of poppy-heads in water. When living inſects have crept into the ear, blow the ſmoak of tobacco therein, and then pour in warm oil. If purulent matter diſcharges itſelf inject tepid water, mixed with a little ſoap, or honey of roſes. Beſides the above-mentioned, bliſters behind the ears, bladders of warm water laid on the affected ear, and the pediluvium, are occaſionally uſeful.

See James's Med. Dict. Lobb on painful Diſtempers; Brooks's, and the London Practice of Phyſic.

OTENCHYTES, from *ωτος*, the genitive of *ους, an ear*, and *εγχεω, to pour in*. A ſyringe for the ears.

OTHONNA. A ſpecies of celandine; ſome ſay it is the juice of celandine.

OTITIS. Inflammation in the internal ear.

OTOPLATOS. A ſtinking diſcharge behind the ears.

OTOPUOSIS. A purulent diſcharge from the ear.

OTORRHŒA. A diſcharge of blood or of bloody matter from the ear.

OURLES, i. e. Mumps.

OVA ZEPHYRIA. Eggs which are not impregnated by the tread of the cock.

OVALE FORAMEN. See Cor.

OVARIA. The Ovaries. They were formerly called the female teſticles; but ſince anatomiſts have thought that they perceived cluſters of eggs in them, they have named them *ovaria*. Dr. Hunter thinks they are properly teſticles ſecreting female ſeed, which is taken up and conveyed by the Fallopian tube to the uterus. The *ovaries* are two ſmall bodies ſituated behind each Fallopian tube; they are of a different ſize and figure ſometimes in the ſame body. At the age of puberty they are of a proper ſize, and continue plump and full until the menſes are about to depart. They receive veſſels from the ſpermatics, which run on to the uterus, and anaſtomoſe with the hypogaſtrics. The nerves are from the intercoſtals, lumbal, and ſacral. Beſides the liquor which reſembles the white of egg, they contain two or three vaſcular bodies called corpora lutea, and which by ſome are called the eggs.

The *ovaries* are ſubject to great diſtention from water, which conſtitutes what is called a dropſy therein, of which ſee a ſingular Caſe in Gooch's Obſ. and Remarks.

OVATUS, or Oviformis humor. The aqueous humour of the eye.

OVI-ALBOR, or Ovi-candidum. The white of egg.

OVUM. An egg. The ſhells of eggs are prepared by boiling them in water, to ſeparate the membrane which lines their inner ſurface, and then powdering them by levigation. They bind the belly the leaſt of all the teſtaceous abſorbents. Eggs are nutritious, but if hard boiled are difficultly digeſted. The yolk is uſed as a medium for uniting balſams with water, but the white is preferable, as it is leſs diſguſtful to many ſtomachs. Weak ſtomachs digeſt the white more eaſily than the yolk. Betwixt the ſerum of the blood and the white of egg there is great analogy. See Neumann's Chem. Works.

OVUM PHILOSOPHORUM. A glaſs whoſe belly is of an oval figure, by which a liquor may be diſtilled by circulation.

OXALIS, i. e. Acetoſa.

OXALME. A mixture of vinegar and ſalt.

OXELÆUM. A mixture of vinegar and oil.

OXYACANTHA. The barberry, alſo a name of ſome ſpecies of thorns.

OXYCEDRUS. A name for the cedrus folio cupreſſi, which is alſo called cedrus Lycia. The berry-bearing or cypreſs leaved cedar.

OXYCOCCUS, called alſo vaccinia paluſtria, vitis Idæa paluſtris. Moor berries. This plant grows in marſhy and putrid ſoils, and flowers in June. The fruit is cooling and aſtringent. See Dale, and Raii Hiſt.

OXYCRATUM. Oxycrate. It is vinegar mixed with ſuch a portion of water as is required, and rendered ſtill milder by the addition of a little honey.

OXYCROCEUM EMPLASTRUM, from *οξος, vinegar*, and *κροκος, ſaffron*. It is a plaſter, in the compoſition of which there is ſaffron and vinegar.

OXYGALA. Sour milk.

OXYGARUM. A compoſition of garum and vinegar.

OXYLAPATHUM. Sharp pointed dock, alſo the common ſorrel.

OXYMEL, from ὀξὺς, *vinegar*, and μὶλι, honey. Honey and vinegar, boiled together ſo as to form a ſyrup, is called ſimple oxymel. Oxymels of different denominations are made by macerating ſome medicinal ingredients in vinegar, and then boiling them up with honey.

OXYMYRRHINE, or Oxymyrſine. See Ruscus.

OXYPHLEGMASIA. An acute inflammation.

OXYPHŒNICIA, or Oxyphœnicon. Tamarinds.

OXYPHYLLON. According to Oribaſius it is the cnicus; but he ſeems to intend by it a different plant from that which we call by that name.

OXYPHONIA. The ſame as paraphonia clangens. It is a howling kind of noiſe.

OXYREGMIA, from ὀξὺς, *acid*, and ῥηγνυω, *to break wind*. An acid eructation.

OXYRRHODINON. A compoſition of vigdneanar oil of roſes.

OXYS. Wood ſorrel.

OXYSACCHARUM. A compoſition of vinegar and ſugar.

OXYSAL DIAPHORETICUM. It is a preparation of Angelus Sala. It is a fixt ſalt loaded with more acid than is neceſſary to ſaturate it. The ſalt of juniper is of this kind.

OXYSCHŒNOS. A name for the juncus acutus capitulis ſorghi.

OXYTOCA, from ὀξὺς, *quick*, and τικτω, *to bring forth*. Medicines which promote delivery.

OXYTRIPHYLLUM. Wood ſorrel, alſo the pile treſoil.

OZÆNA, from ὀζω, *a ſtench*. A fetid ulcer in the noſe is thus named,

P.

P In preſcription it ſometimes ſignifies a pugil, and ſometimes parts.

PACAL. A tree in Peru, the aſhes of which are mixed with ſoap for the cure of leprous diſorders; the mixture is uſed as an ointment. See Raii Hiſt.

PACHYS. Thick. The name of a diſorder which is not only unknown to us, but which has never been deſcribed by any phyſician ſince Hippocrates. It is ſuppoſed that the Cnidian phyſicians are the authors of the deſcription; Hippocrates condemns them for multiplying the ſpecies of diſeaſes without neceſſity; in this they make four ſpecies, and the ſymptoms are very incompatible too. The curious may ſee the deſcription in James's Med. Dict. or in Le Clerc's Hiſt. Med. lib. iii. c. 11.

PACO-CAATINGA. A coniferous ſpecies of Braſilian canna. The ſtalk of this plant, if chewed, occaſions a ſpitting; if the ſaliva is ſwallowed when this ſtalk is chewed, it cures a gonorrhœa in a few days; it is alſo a ſort of lithontriptic. Ray takes notice of three ſpecies. See his Hiſt. Plant.

PACOEIRA. The muſa or plantain tree.

PACO-SEROCA. A ſpecies of Braſilian canna. See Raii Hiſt.

PACOURII. A very large tree in the iſland of Maragnan, belonging to Braſil. See Raii Hiſt.

PADRI. A ſiliquous tree in Malabar. The juice of the leaves is a cure for the mania; the juice of the bark, mixed with the fruit of the pera, reſtrains the menſes. See Raii Hiſt.

PADUS, called alſo ceraſus avium nigra, ceraſus racemoſa. The wild cluſter cherry, the bird's cherry.

It grows on rocky mountainous places, and the fruit is uſed to hang about the necks of children, as a cure for the epilepſy. See Dale, and Raii Hiſt.

PADUS. A name for the lauro ceraſus.

PÆDANCHONE, from παις, *a child*, and αγχω, *to ſtrangulate*. A ſpecies of quinſy common among children.

PÆDARTHROCACE, from παις, *a boy*, αρθρον, *a joint*, and κακον *an evil*. The joint evil. Intimating that this diſorder frequently appears about the *joints* of children, and oftener in them than in adults, becauſe the bones of children are more ſoft and ſpongious, and ſo more eaſily corroded by peccant humours, and diſtended into tumors, ſometimes of a very ſurpriſing deformity. Severinus calls the ſpina ventoſa by this name, as alſo doth Dr. Cullen; he alſo makes another diſtinction between the ſpina ventoſa and the *pædarthrocace*, for the tumors of the firſt kind are frequently attended with pain, redneſs, and all the appearances of inflammation; but the *pædarthrocace* has little or no pain in the beginning, as is obſerved in ricketty children; but theſe names are uſed very promiſcuouſly; by ſome it is uſed to expreſs a ſort of anaſarca. See M. A. Severinus's Treatiſe De Recondita Abſceſſuum Natura.

PÆDOPHLEBOTOMIA. The bleeding of children.

PÆNOE. A large tree in Malabar. The root, bark, fruit, and all the parts yield a reſin, which is burnt inſtead of incenſe in their ſacrifices. The kernels of the fruit, made into an emulſion with warm water, ſtrengthen the ſtomach, relieve from nauſeas, allay pain in the belly, and cure the cholera. See Raii Hiſt.

PÆONIA, from *Pæon*, the phyſician who with this plant cured Pluto when he was wounded by Hercules. Boerhaave enumerates twelve ſpecies, of which the following are ſometimes, though very rarely uſed.

PÆONIA MAS. Male pæony. The *pæonia* officinalis, Linn.

PÆONIA FŒMINA. Female pæony. The *pæonia* officinalis, Linn.

Theſe plants are ſo common in gardens as to need no deſcription. The male ſort hath dark green leaves, pale red ſingle flowers, long thick roots, with red ſtreaks in the ſtalks and pedicles; the female hath longer, pale, and narrower leaves, deep red, double flowers, and irregular roots, compoſed of ſeveral tuberous pieces, hanging by tough filaments from one head. They are perennial, and flower in May. The male is preferred, but ſo little is the difference, that the female is moſt frequently uſed. The roots, flowers, and ſeeds, are anodyne, but their efficacy is very inconſiderable. The flowers impart their colour to water and to ſpirit. See Lewis's Mat. Med.

PAGANICA. A ball uſed by the Latins to exerciſe with. It was ſo called becauſe uſed only in villages.

PAIANELI A tall pod-bearing tree in Malabar. There are two ſpecies, the different parts of which are uſed by the natives againſt ſeveral diſorders. See Raii Hiſt.

PAIDATROPHIA. The atrophy in children.

PAIDION. So Hippocrates calls the child in the womb when perfected there. See Cuema.

PAIDOPOIETIC. Of the fœtus.

PAIOMIRIOBA. A name for the ſenna orientalis fruticoſa.

PAI-PAROCA. A bacciferous ſhrub in Malabar. An apozem prepared of the leaves, fruit, and roots in water, is uſeful againſt the gout. See Raii Hiſt.

PALA. Nutmeg, alſo a tall pod-bearing tree in Malabar. The natives uſe it in various diſorders. See Raii Hiſt.

PALÆTYRUS. Old cheeſe.

PALATI OSSA. Bones of the palate. They are two irregular ſquare bones, ſituated in the roof of the mouth, which join each other backwards, and the maxillary bones forward; backward there is a lunated edge, whence the velum pendulum palati hangs. The pterygoid proceſs of this bone paſſes between the os maxillare ſuperius, and the pterygoid proceſs of the os ſphenoides: it is of a triangular ſhape, broad at its baſis, and ſmall above. The naſal proceſs is very thin, it riſes upwards, and covers a large part of the aperture of the maxillary ſinus. At the ſuperior part of the naſal proceſs, the os palati divides into two proceſſes called the orbitar. The anterior is the larger, and its fore part is contiguous to the back part of the maxillary ſinus; its poſterior ſurface is cellular, and is contiguous to the ethmoid cells. It is placed likewiſe on the opening of the ſphenoidal ſinus, ſo as to leave a ſmall hole above.

PALATINA PROCESSUS. See MAXILLARIA SUPERIORA OSSA.

PALATINÆ GLANDULÆ. They are conglomerated glands, ſituated in the ſeptum and arch of the palate, near the tonſils.

PALATINUS. It is a branch of the upper maxillary branch of the fifth pair of nerves; it runs before the pterygoid apophyſes of the os ſphenoides in the canal formed by the os maxillare and os palati, and through the foramen palatinum poſterius, it ſpreads in the glandular coat of the palate, and parts adjacent.

PALATINUS DUCTUS, i. e. Tuba Euſtachiana.

PALATO PHARYNGÆUS. See CONSTRICTOR ISTHMI FAUCIUM, and PERISTAPHILO PHARYNGÆI.

PALATOSALPINGÆUS. Alſo called muſculus tubæ novus Valſalvæ. Innes deſcribes it under the name of circumflexus palati. It ariſes broad and tendinous from the edge of all the lunated part of the os palati, ſeveral of its fibres being ſpread upon the membrane that covers the foramen narium; then growing into a ſmall thin tendon, it is affected about the hook-like proceſs of the inner ala of the proceſſus pterygoides; but ſoon turning into a narrow thin fleſhy belly, it runs cloſe along the inſide of the muſculus pterygoidæus internus, and is inſerted carnous into all the fleſhy membranous and cartilaginous part of the tuba Euſtachiana. Valſalva diſcovered it, and firſt obſerved that its uſe is to dilate and keep this channel open.

PALATUM. The palate. It is that arch of the mouth which is ſurrounded before by the teeth and gums, and extending backward the whole breadth of the upper part of the mouth, as far as the great opening of the pharynx. This arch is partly hard and immoveable, and partly ſoft and moveable. The ſolid part is formed by the two oſſa maxillaria, and the two oſſa palati. The ſoft part lies behind the other. The membrane that lines the palate is full of ſmall glands. It ſometimes happens when a child is born with the hare-lip, the fleſhy and the long parts of the palate are defective, from a fiſſure, or a diviſion through into the noſtrils; the uvula alſo is ſometimes divided as into two. In this caſe, the child cannot ſuck, but muſt be fed by the ſpoon.

PALATUM MOLLE. Behind the bony palate lies the ſoft palate, from the middle of which the uvula hangs down.

PALEA DE MECHA, i. e. Juncus odoratus.

PALIMPISSA, from παλιν, *ſignifying repetition*, and πισσα, *pitch*. Dioſcorides ſays that dry pitch is thus named, becauſe it is prepared of pitch twice boiled.

PALIURUS. Chriſt's thorn, or wild jujube. It is a ſpecies of thorn met with in the ſouthern part of Europe. The leaves and roots are moderately aſtringent; but on account of the length of its ſpines, it is the beſt of all other buſhes for making hedges.

PALLIUM PURPUREUM. A purple cloak. So Baſil Valentine calls a certain powder, prepared of an amalgama of gold and mercury put into a retort, where the mercury being ſeparated, what remains is calcined with ſulphur, and turned a purple colour.

PALMA. The palm-tree. Boerhaave's characters of this tree are, that its fruit, under an eatable pulp, hath an hard ſtrong nucleus, like the ſtone of a plum. But to this may be added, that the *palm-tree* riſes up with one ſingle and individual trunk. The ſpecies are numerous; Boerhaave mentions nine, Dale adds ſix, and Ray increaſes the number by twenty more. Some of the moſt noted are the

PALMA MINOR, alſo called palma humilis dactylifera, &c. *palma* humilis Hiſpanica ſpinoſa & non ſpinoſa, palmites, chamærhiphes. The dwarf palm. Its fruit is aſtringent.

PALMA JAPONICA, alſo called ſagou, palma Indica, arbor farinifera, zagu, todda panna, monta panna. The libby-tree, Indian bread, or ſago-tree. It is the cycas circinalis, or cycas Indica, frondibus pinnatis circinatibus, foliolis linearibus planis, Linn. The pith of theſe trees being well beat in a mortar with water, forms an emulſion, the fæcula of which when dried is ſago.

The fruit of this tree is ſomewhat aſtringent, though not ſo when eaten with ſugar.

The ſago is very nouriſhing, and is uſed by the Indians when rice is ſcarce; it is demulcent, it never ferments in the ſtomach, whence it is properly preferred by many to wheat flour for the food of infants; its being eaſily digeſted, and its demulcent quality, renders it uſeful for the diet of hectic patients.

PALMA COCCIFERA, alſo called palma Indica coccigera anguloſa, coccus, *palma* Indica nucifera, *palma* nucifera arbor, nux Indica, inaja-guacuiba, tenga, polgaha. The coco, or cocker-nut tree.

From this tree the Indians extract a liquor called ſuri, and diſtil the liquor called arrac from it; alſo a ſpecies of ſugar called jagra. The milk in the ſhell of the nut is grateful and cooling. The exterior covering of the nuts are at firſt eatable, and are gratefully acid, and gently reſtringent. By boiling, an oil like that from almonds is obtained from the kernel of the nut.

PALMA OLEOSA. See PALMÆ OLEUM.

PALMA NOBILIS, alſo called regulis Jamaicenſis & Barbadenſis, palmiſte, palmeto royal. The cabbage-tree. It is a tall ſtrait tree, between two hundred and fifty and three hundred feet high. On the top is a white, tender, ſavoury, medullary ſubſtance, which, if eaten raw, is to the taſte like a wallnut, but boiled and pickled with the white leaves which ſurround it, it is one of the greateſt delicacies in the Leeward iſlands. This fruit is called the cabbage of the palm-tree. On the top of the trunk grows the involucrum of the flower and fruits called ſpatha, the fruits are round, and the ſize of an egg. See Raii Hiſt.

In Jamaica the wild cabbage-tree bark (which is alſo called worm bark of Jamaica,) is much uſed for the deſtruction of worms in human ſubjects. The following is the account which is given by Mr. Anderſon, a medical practitioner there for ſome years. He mentions two ſorts of this bark, the one much paler than the other. The paler ſort he obſerves is more rugged in its operation, occaſioning nauſea, and great uneaſineſs in the belly. The darker coloured bark, he ſays, reſembles much the caſſia lignea in colour, though it is of a much coarſer texture. But this laſt is the kind commonly uſed in the Weſt Indies: it may be uſed with ſafety in any caſe where an anthelminthic is neceſſary. The hazardous ſymptoms aſcribed to it, have moſt probably followed either an over doſe or the uſe of the paler ſort inſtead of the darker. To ſecure againſt an over doſe, it is beſt to begin with a tea-ſpoonfull of the decoction, and gradually increaſe it as often as it is repeated. The decoction is thus prepared, and adminiſtered: take of the bruiſed bark two ounces and a half; of water two quarts; let it be boiled over a gentle fire to a pint and a half. Strain off the decoction, and keep it for uſe, in a bottle well corked. Of this decoction a table-ſpoonfull is uſually given the firſt morning for a doſe to a grown perſon; one and a half the ſecond, continuing to increaſe it gradually to four or five table-ſpoonfulls, and giving it for eight or nine mornings ſucceſſively. After this, I commonly give a doſe of jalap, with a few grain of calomel, which ſeldom fails to bring away the worms, ſome dead ſome alive. If at any time I have found the decoction produce more than one or two looſe ſtools, I have added to each doſe a few drops of liq. laud. And in general I have given with each doſe, fifteen or twenty drops of the ſpirit of lavender on a lump of ſugar. Edinb. Med. Commentaries, vol. 4. p. 85, &c.

PALMA ADY. See ABANGA.

PALMA AMERICANA AYRI. The ebony tree.

PALMA AMERICANA SPINOSA. The ebony tree.

PALMA BRASILIENSIS SEXEA AIRI. The ebony tree.

PALMA CHRISTI. See CATAPUTIA.

PALMA CHRISTI MAS. Male fatyrion royal.

PALMA COCCIFERA FIGURA OVALI. The Maldivia nut.

PALMA PINUS. A tall tree which reſembles both the palm and the pine tree.

Palma is the name of many other trees and plants.

PALMA. The palm of the hand.

PALMÆ OLEUM It is the produce of the palma foliorum pediculis ſpinoſis fructu pruniformi luteo oleoſo. Sloan Jam. Dr. Brown in his Nat. Hiſt. of Jamaica takes notice of the *palma* ſpinoſa minor fructu pruniformi, &c. Slo. cat. 178. called in Jamaica the mackaw tree. He obſerves that the rind of the fruit is thick and yields a fattiſh ſubſtance, not unlike, or inferior to the real palm oil. He alſo mentions the *palma* tota ſpinoſa major, &c. Slo. cat. 177. and H. ii. 119. called the great mackaw tree, the fruit of which differs but little from that of the little mackaw tree, the huſks of the fruit is alſo full of oil. He adds in his account of the great mackaw tree, that the negroes ſay it is the tree which yields the true palm oil. In the pharmacopœia of the Edinb. coll. This ſpecies of tree is deſcribed as being the *palma* foliorum pediculis ſpinoſis, fructu pruniformi luteo oleoſo. Sloane Jamaic. and Adanſon Seneg. Mr. Curtis, in his Catalogue of Medicinal, &c. Plants in the London Botanical Garden, calls the tree *palma* oleoſa, Linn. The tree is tall and unbranched, with long reed-like leaves elegantly diſpoſed on the top. Several ſpecies of it are met with in the warmer countries. The fruit is preſſed, or firſt bruiſed, and then boiled in water, by either of theſe methods the oil is obtained, which is of the conſiſtence of butter, and is eaten as ſuch by the inhabitants in Guinea, and in the Cape Verde iſlands. It is of a ſtrong, but not diſagreeable ſmell, and hath but very little taſte. The colour, whilſt good, is of a deep yellow inclined to red, but by long keeping it becomes pale, and is then to be rejected. This oil is uſed when mixed with ſome warm penetrating ingredients, to rub on parts affected with old pains, and in ſome nervous diſorders.

PALMARIS BREVIS. Joannes Baptiſta Cannanus communicated this muſcle to Fallopius, and it was firſt publiſhed by Valverda, in his Anatomy written in Spaniſh. It riſes from the faſcia of the annular ligament, it runs acroſs the ball of the little finger, and is loſt in the ſkin to pull it inwards. Brown calls it caro muſculoſa quadrata.

PALMARIS CUTANEUS, i. e. Palmaris brevis.

PALMARIS LONGUS. This muſcle lies on the inſide of the extenſor carpi radialis, and riſing tendinous from the inner condyl of the os humeri, it runs under the annular ligament, makes a radiated expanſion on the palm, and is attached to the heads of the metacarpal bones, and the firſt joint of the fingers. It is alſo called ulnaris gracilis.

PALMATA. A name of ſeveral ſpecies of orchis.

PALMEIRA BRAVA. Ray ranks it as a palm-tree.

PALMOS. A palpitation of the heart, from πάλλω, *to beat*.

PALMULA. A date. Alſo a name for the broad and flat end of a rib.

PALPEBRÆ. The eye-lids. They are connected to the circumference of the ſocket by the tunica conjunctiva, ſee ADNATA. They are compoſed of the common teguments, a cartilage called tarſus, and an external membrane. They have two angles or corners, one the ſmall or external, the other the large or internal; theſe angles are called canthuſes. The form of each *eye-lid* is that of a ſegment of a circle, and in regard to the eye, is ſuch, that when both *eye-lids* are ſhut, they make an uniform arch, adapted to the convexity of the eye, and in contact with it; but in regard to one another when ſhut, their edges are ſo contrived, that they leave a ſort of groove, or channel between them, which is narrow toward the outer angle, and wider toward the inner, and ſerves to conduct the tears as they come from the upper part of the eye to what are called the lachrymal points. The margin, or baſis of each *eye-lid*, being a cartilage of a conſiderable thickneſs, is divided into the outer and inner edges; it is the outer edge only of each lid that is ſuppoſed to join when the *eye-lids* are ſhut, the inner edge being formed oblique or ſlanting, makes the groove, or channel, above mentioned, for the paſſage of the tears to the lachrymal points. This margin is the tarſus, and that in the upper *eye-lids* is the broadeſt. The cutis is very thin on the *eye-lids*. The outer edge of each eye-lid is furniſhed with a row of hairs called cilia. On the internal edge of each lid in the tarſus, is a row of ſmall holes, which are the excretory ducts of the ciliary glands. From the upper edge of the upper tarſus, and the inferior of the lower, is contained a membranous expanſion to the neighbouring edges of the orbit; each of thoſe membranes, together with its reſpective tarſus, has the form of the *eye-lid* to which it belongs, and is called ligamentum tarſi. The ligaments of the *eye-lids* are reckoned to be three; from the inner angle, to the naſal proceſs of the os maxillare ſuperius we ſee one, which is the tendon of the orbicularis; at the external angle we ſee another ligament, more diffuſed on the bony brim, blended with the cellular membrane; a third goes all round, proceeding out of the brim of the orbit from the perioſteum. The inſide of the *eye-lids* are lined by the ADNATA, which ſee. The muſcles which ſubſerve the motions of the *eye-lids*, are the orbicularis, and levator *palpebræ* ſuperioris. The *eye-lids*, and their muſcles are furniſhed with branches from the angular, temporal, and frontal arteries, and theſe communicate with thoſe ſent to the internal membrane of the *eye-lids*. The levator *palpebræ* receives a branch from the internal maxillary artery. The veins correſpond very nearly with the arteries, and carry their blood into external jugulars, by means of the veins in the temples and face. The nerves proceed from the opthalmic branch of the fifth pair, from the ſuperior maxillary branch of the fifth pair and from the portio dura of the ſeventh pair; the levator *palpebræ* ſuperioris receives a branch from the third pair. The *eye-lids* defend the eyes from the light during ſleep; they preſerve the eye from becoming dry by their frequent motion, which ſpreads the tears over the external ſurface of the globe. See LACRYMALES GLANDULÆ, LACRYMALIA PUNCTA, and LACRYMALIS SACCULUS.

PALPITATIO. So the Latins call the palpitation of the heart. The Greeks called it palmos, a vibration or trembling of the heart. Some confouud the *palpitatio* cordis with the cardialgia and cardiaca paſſio. Dr. Cullen places this genus of diſeaſe in the claſs neuroſes, and order ſpaſmi. The only one ſpecies he calls *palpitatio* cardiaca.

There is a morbid painful *palpitation* of the heart, which is chronical. There is a kind of this diſorder which happens to perſons otherwiſe healthy, and is occaſioned by ſtrong paſſions, ſurprize, ſtrong exerciſe, &c. Actuarius ſays there are two ſorts, one from plenitude or heat in the blood, and that this is the moſt frequent; the other is from vapours. In the firſt he ſays, there is an unequal pulſe; in the latter, the pulſe is unaffected.

Thoſe are the moſt ſubject to this diſorder who are of a firm habit, of a ſanguine, melancholy temperament, of delicate minds, and ſubject to frights; alſo the young, who abound in blood and juices, and thoſe whoſe evacuations of blood whether natural or artificial, are neglected or ſuppreſſed.

A *palpitation* of the heart may ariſe, either from a quick influx of the nervous fluid into the external ſurface of the heart about its baſis, or from a defect thereof into ſome of the nerves in this viſcus. The formal cauſe is always ſo violent a contraction and convulſion of the heart, that it is moved out of its natural ſtate: but the material or proximate cauſe is a certain ſtagnation of the blood, eſpecially in the right ventricle of the heart, and a too great congeſtion of it to the ſame part; on account of which there happens, an impetuous influx of the nervous kind into the cardiac nerves and fibres of the heart, and a preternatural contraction of them. The mediate cauſes are either in the heart, about it, or in parts remote from it. Among the firſt, the moſt frequent and conſiderable are polypous concretions, which are always fibrous and membranous, generated principally in the ventricles and auricles of the heart, then reaching into the veins, and thence frequently forced into the arteries; ſome fault in the fluids; a defect in the uſual evacuations of blood; tight ſtays are not an unfrequent cauſe of this diſorder in young women; coſtiveneſs; a difficult paſſage of the blood through the abdominal viſcera; a ſubtle acrid mat-

ter

ter in the blood; as when the itch, &c. is repelled; a defect of blood; great diſturbance in the mind; intenſe thought produces it in many hypocondriac patients, and particular odours have the ſame effect in hyſteric women; flatulent aliment; Hippocrates aſſerts, that all *palpitations* of the heart are accompanied with flatulencies, ſtrictures of the belly, thighs, and legs; too tight cloaths; hectic heats; aneuriſms, &c.

During this diſorder it often happens, that the arteries are every where affected with a violent pulſation, eſpecially thoſe above the clavicles; the diſeaſe frequently intermits eſpecially during the body's being at reſt; but after the occurrence of any of the cauſes it returns, the pulſations are ſo great that ſometimes its motions may be perceived on the outſide of the cloaths; it is ſometimes more violent, and ſometimes leſs ſo; ſometimes continues a longer, and at others a leſs time; ſometimes it attacks during ſleep, and awakes ſuddenly; ſometimes it only happens in the day, and is worſt after eating; ſometimes anxiety, or uneaſineſs in the præcordia, precedes; in the paroxyſm of *palpitation*, the breathing is difficult; though the pulſe is intermitting, it does not correſpond with the motion of the heart, but is languid and diminiſhed; in a violent paroxyſm, a great uneaſineſs is perceived in the region of the præcordia, and a conſiderable languor of the body, with a tremor of the joints remain after the *palpitation* is over. When polypous concretions in the heart are the cauſe, the following ſigns uſually attend: the *palpitation* is immediately increaſed after violent exerciſe, going up ſtairs, or the lighteſt commotions of the blood; great anxiety about the præcordia, with a weak, unequal, and ſometimes intermitting pulſe; the patient breathes with ſo much difficulty that ſometimes there is danger of ſuffocation; fainting frequently comes on, and ſometimes is fatal; the pulſe is ſometimes ſtrong, at others more feeble. When the polypous continues fixed, no *palpitation* happens; but when it is removed, it fluctuates in the ventricles of the heart, and partially or fully ſtopping the paſſages of the blood through ſome or other of the veſſels, a *palpitation*, or ſpeedy death is the conſequence. When a redundance of blood cauſes a *palpitation*, the ſigns are, the countenance is florid, the veſſels turgid with blood, and the pulſe is large: in a fit of very ſtrong *palpitation*, the diſtance between the pulſations is greater, and the longer the intervals, the more violent they are.

A *palpitation* of the heart ſhould be diſtinguiſhed from that which is perceived in women, about the laſt months of pregnancy, in the epigaſtric region, and which is only a pulſation of the cœliac arteries, in conſequence of too much blood being hurried through them.

One remarkable ſymptom attending a violent *palpitation* of the heart, is a pain which is acute and pungent, and ſeated immediately above the right orifice of the ſtomach. The third pair of cervical nerves paſs out between the third and fourth vertebræ, ſoon communicates with the ſecond, and ſending down a large branch, which being joined by another from the fourth, forms the phrenic nerve that runs along the pericardium to be loſt in the diaphragm; in this courſe the right phrenic is obliged to make a ſmall turn round that part of the pericardium which covers the apex of the heart; hence it is, that ſuch as have ſtrong *palpitations* have this kind of pain.

A *palpitation* of the heart, when it frequently returns, continues long, or is violent, is always to be feared, as it often ends in a fatal ſwooning, or a ſuffocation. An unequal pulſe, or a difficulty of breathing attending, are dangerous circumſtances. When the diſorder is idiopathic, there is very little dependence on any means made uſe of for relief; but when it is ſymptomatic, its cure is effected by the removal of the original diſorder. When it proceeds from terror, and returns often, it produces polypuſes, which again may prove a cauſe of the worſt kind. *Palpitations* attending various diſeaſes, increaſe the number of diſagreeable prognoſtics.

The indications of cure are, to allay the preternatural commotions of the nervous parts and fibres of the heart and veſſels; to hinder the ſtagnation of the blood about the heart and lungs, by deriving its afflux to theſe parts elſewhere, and rendering the circulation more free. And, thirdly, out of the paroxyſm, to remove the cauſes which excite the diſorder.

To prevent the returns of the diſorder, avoid every known occaſional cauſe, and carefully adhere to regularity reſpecting the non-naturals. If there are any ſymptoms of a polypus, all violent motions are to be avoided, leſt the polypus ſhould be looſened. All tight ligatures ſhould be made eaſy, and the cloaths ſhould be equally ſo; the patient ſhould never continue long in the cold; and when the fit approaches, a clyſter ſhould be inſtantly adminiſtered, and the extremities rubbed; as to the paſſions of the mind, endeavour to keep them free from every degree of exceſs.

During the paroxyſm, enquire for the cauſe. Bleeding is the principal remedy, except the cauſe be weak nerves, or lax habit, in which laſt caſe give the bark, with nervous and ferrugineous medicines. If the cauſe be in an ebullition, or ferment in the fluids, nitre, tart. emet. as a perſpirative. Hoffmann's mineral anodyne liquor &c. in a glaſs of water. If flatulence produces the fit, or when the patient is coſtive, ſkin dry, the feet cold, beſides the above medicines, give oily and carminative clyſters, rub the feet with warm cloths, and then put them into warm water. If hæmorrhages have preceded, to the above add analeptics and cordials; the eſſence of amber is particularly proper; bladders of warm water may be applied to the ſtomach. If an aſthma attends, bliſter, and give the volatile tincture of valerian at proper intervals. If gouty ſpaſms are the cauſe, bleed, bliſter, give volatiles, and put the feet into warm water.

Out of the fit, the whole intention of cure conſiſts in removing, or at leaſt diminiſhing the cauſe; thus, if there is a plethora, reduce it by proper evacuations; if a deficiency of good blood, endeavour to improve and increaſe it; if the *palpitation* is ſymptomatic, remove the original diſorder; if a bilious acrimony gives riſe to it, lemon juice, or other agreeable vegetable acids, will be proper; if the pulſe begins to be affected, bleed; opiates are often very uſeful; pedilaves ſhould not be uſed until the feet begin to grow warm by rubbing them, nor until the fit is going off.

See Actuarius, Hollerius, Sennertus, Lommius and Hoffmann.

PALUDAPIUM. Smallage.

PAMPINIFORME CORPUS, i. e. Spermatica corda.

PAMPINIFORMES. See Ductus Thoracicus.

PAMPINIFORMIA CORPORA, from pampinus, *a vine leaf*, and forma, *ſhape*, i. e. Spermatica Corda. The ſpermatic veſſels form a plexus, which from its ſimilitude to the tendrils of a vine, is called *pampiniformis*.

PANACEA, from παν, the neuter, of πας, *all*, and ακος, *a remedy*, παν, *all*, and ακος, whence is derived, πανακεια, i. e. remedium univerſale, *an univerſal medicine*, or it, comes from παν, *all*, and from the verb ακεομαι, *to heal*, quaſi omnia ſanans.

PANACEA DUPLICATA, i. e. Arcanum duplicatum.

There are many panaceas, as of antimony, mercury, &c. in moſt of the former diſpenſatories.

PANACEA VEGETABILIS. A name given to ſaffron.

PANACES HERACLEUM. A ſpecies of ſphondylium.

PANACES MOSCHATUM. i. e Herbatum Canadenſe.

PANACI HERACLEO, i. e. Tabaria.

PANARIS. The whitloe. See Paronychia.

PANARITIA. A whitloe with fever.

PANARITIUM. A whitloe.

PANATA, or Panatella. Panada.

PANAVA. The cataputia.

PANAX. See Pastinaca.

PANAX ASCLEPIUM. Eſculapius's all-heal.

PANAX ASCLEPIUM. Candy all-heal.

PANAX CHIRONEUM. Dwarf ciſtus.

PANAX COLONI, called alſo ſtachys paluſtris fœtida, galeopſis anguſtifolia fœtida, ſideritis anglica ſtrumoſa radice, galeopſis paluſtris betonicæ folio flore variegato, marrubium aquaticum acutum. Clown's woundwort, or all-heal. Boerhaave ranks it as a ſpecies of galeopſis, Cœſalpinus calls it tertiola, and commends it againſt the tertian ague.

PANAX COSTINUM. Opoponax-wort.

PANAX HERACLEUM. Opoponax-wort.

PANAX PASTINACEA. Opoponax-wort.

PANCASEOLUS, i. e. Bulbocaſtanum.

PANCHYMAGOGUM, from *παν, all. χυμος, humour*, and *αγω, to bring away*. The name of ſome cathartic extracts, which are ſaid to purge away all kinds of humours.

PANCRATIUM. A name for the ſcilla vulgaris radice rubra. It was alſo the name of an exerciſe which was uſed by the antients, and conſiſted of a mixture of wreſtling and boxing.

PANCREAS, from *παν, all*, and *κρεας, fleſh*. The ſweet-bread. See THYMUS. It is ſituated tranſverſely under the ſtomach, in the duplicature of the poſterior portion of the meſocolon, and reaches from the duodenum to the ſpleen. Its ſhape reſembles a dog's-tongue. It hath two edges, one anterior, the other poſterior; and two ſides, one ſuperior, and the other inferior. Its head lies in the firſt curvature of the duodenum, thence it runs acroſs the ſpine to the ſpleen behind and below the ſtomach. There is a natural cavity into the epiploon, between the lower ſide of the ſtomach, and the upper ſide of the meſocolon. It is here that the arteries, veins, and nerves enter, and the cyſtic and hepatic ducts come out to form the ductus communis cholidochus, which goes into the duodenum near the pancreatic duct. The veſſels of the *pancreas* come from thoſe of the ſpleen, which run along it. That head next the duodenum hath veſſels from the meſenterica and gaſtrica dextra. The ſubſtance of this viſcus is that of a conglomerate gland; in the whole length of it is a duct called ductus Wirtſungii, from its diſcoverer, but generally it is ſpoken of by the name of ductus pancreaticus: its beginning is towards the ſpleen, as it goes on it receives branches, grows larger, and proceeds into the duodenum, in the ſame canal as the biliary duct; the pancreatic duct is very thin, and without valves; it does not always go out jointly with the biliary duct, but it is ſeldom that we meet with it otherwiſe. Malpighi makes the *pancreas* a cluſter of veſiculæ; Ruyſch brings it out to be vaſcular, as injections prove it to be. The nerves come from the plexus hepaticus, plexus ſplenicus, plexus meſentericus, &c. The *pancratic* juice reſembles the ſaliva, but is leſs viſcid, and contains a larger proportion of the ſalts of the blood; it is probably a menſtruum for the ſolution of our aliment, but that it acts as a ferment, as ſome have aſſerted, is doubtful. All the *pancreatic* juice is ſent into the duodenum, and is ſecreted moſt when the ſtomach is fulleſt.

PANCREAS MINUS. Where the great extremity of the *pancreas* is connected to the duodenum, it ſends out an elongation, with a diſtinct duct in it, which open into the duodenum.

PANCREATICA. Inflammation of the pancreas.

PANCREATICÆ ARTERIÆ. The ſplenic artery runs from the cœliac artery, under the ſtomach and pancreas, to the ſpleen; it adheres to the lower poſterior part of the pancreas, to which it gives ſeveral branches called *pancreaticæ arteriæ*.

PANCREATICÆ VENÆ. They are ſeveral ſmall branches from the ſplenica, which run to the pancreas along its lower ſide. There are other ſmall pancreatic veins which do not ariſe from the ſplenica.

PANCRENE. The pancreas.

PANDALITIUM, i. e. Paronychia.

PANDEMIUS. Epidemical.

PANDICULATIO, Pandiculation, or Stretching. See OSCITATIO. It is that reſtleſs ſtretching and uneaſineſs that accompany the cold fit of an intermitting fever.

PANEM-PALKA. A ſpurious ſpecies of nut-meg tree.

PANICULA. A panicle. A ſtalk diffuſed into ſeveral pedicles, ſuſtaining the flowers or fruits. Of this kind are the oat, millet, &c. Panicula is alſo a diminutive of panus, a ſpecies of tubercle. It is a name for a ſort of crude bile.

PANICULA Minore, i. e. Panicum.

PANICUM. A plant ſo called from its panicle. Common panic. The ſpike conſiſts of innumerable thick ſeeds diſpoſed in leſſer ſpikes, ſo as to appear like a cluſter. It is cultivated in Germany. The ſeeds have been uſed as food, but are not regarded in medicine. There are ſeveral ſpecies. See Raii Hiſt.

PANIS, i. e. Phygethlon.

PANIS. Bread. From *παν, all in all.* Good *bread* ſhould be compoſed of flour well kneaded with the lighteſt water, ſeaſoned with a little ſalt, fermented with the fineſt yeaſt, and ſufficiently baked. Unfermented *bread* is viſcid and glutinous; fermentation deſtroys this viſcidity, and renders it more eaſily digeſtible, but at the ſame time inclines the ſubſtances fermented to acidity, whence unfermented *bread* only can be proper where viſcidity abounds in the ſtomach. That *bread* which is the lighteſt, and moſt eaſily diſſolved in water, is the moſt wholeſome, digeſted with the greated facility, and ſooneſt converted to laudable nutrition: the additions of lime, chalk, and alum, oppoſe diſſolution. The beſt *bread* for general uſe is made with good wheat, all ground down together (bran and all); to which one-ſixteenth part of barley-meal may be added. Bran conſiſts of the huſks of the grain, and a little of the farinaceous matter, and is ſuppoſed to have a laxative and detergent quality. *Bread* made with the whole of the grain, viz. the bran and flour was called by the ancients, autopyros.

PANIS ATER, and Panis Cibarius. Bread made of flour with all its bran.

PANIS CUCULI, i. e. Acetoſella.

PANIS PORCINUS, i. e. Cyclamen.

PANNICULUS. A piece of cloth.

PANNICULUS ADIPOSUS, i. e. Cellulosa membrana.

PANNICULUS CARNOSUS. Drake deſcribes this in the human ſubject; but Winſlow, Hunter, &c. deny its exiſtence, and ſay it is only in brutes. Some ſay its only in the face.

PANNUS. Woollen cloth. The name of a diſorder in the eye, called alſo unguis; and of a diſorder in the ſkin, as a ſpot or mark, from a veneral or other cauſe.

PANOPHOBIA. A kind of melancholy attended with groundleſs fear. See MELANCOLIA.

PANOCHIÆ. Bubos in the groin.

PANTHEÆ. Penſile beds.

PANTICES. The inteſtines.

PANULA, or Panus. A ſort of crude bile.

PANUS, i. e. Phygethlon.

PAO AGULA. So the Portugueſe call the agallochum.

PAPAGA & PAPAGALLI. Names for the ſeeds of baſtard-ſaffron. They are ſo called from the magpies eating them.

PAPAS. Potatoes.

PAPAVER, from *pappa*, that is pap; becauſe formerly nurſes mixed this plant with the children's pap-meat, as a remedy againſt the pains of the colic.

PAPAVER ALBUM, called alſo papaver hortenſe ſemine albo, ches boul. White garden poppy. *Papaver* ſomniferum album, or *papaver* calycibus capſuliſque glabris foliis amplexicaulibus inciſis, Linn.

This ſpecies is called white, becauſe its flower ſeeds are white.

PAPAVER NIGRUM, called alſo papaver hortenſis nigro ſemine. Black garden poppy.

This ſpecies is thus named becauſe its ſeeds are black.

Theſe plants are found wild in ſome parts of Europe, and ſeveral varieties, as to their flowers, are produced by culture in our gardens. The head, ſtalks, and leaves have an unpleaſant ſmell, and a bitteriſh biting taſte, of the ſame kind with thoſe of opium. This ſmell and taſte are lodged in a milky juice, which abounds chiefly in the cortical part of the heads, which may be collected in conſiderable quantities by ſlightly wounding them when almoſt ripe, and when the juice is run out, preſſing out what did not run, and which, on being expoſed for a little time to a warm air, thickens into a tenacious dark coloured maſs, ſimilar to the opium brought from Turkey, &c. it is weaker as a medicine, one grain of foreign opium is often equal to two of ours, yet is ſtronger in ſmell and taſte. The juices obtained from the white or the black poppy differ no other than in quantity afforded by each; the white affording the largeſt quantity. The ſeeds contain an inſipid oil, uſed for the ſame purpoſes as the olive oil; it is obtained by expreſſion, and is void of the narcotic quality of the poppy head.

As the white *poppy* affords the largeſt quantity of active powers, it is always cultivated when the intention is for medicinal uſes. See PAPAVER ALBUM, above. A decoction of the heads in water ſtrongly preſſed out, depurated by ſettling, then clarified with the white of an egg, and inſpiſſated, yields an extract amounting to 1-5th or 1-6th the weight of the heads. This extract is ſaid not to produce a nauſea or giddneſs, which generally follows the uſe of foreign opium. Its doſe is about double that of the opium from abroad; it checks a diarrhœa as well as any other opium, but does not ſo powerfully check expectoration.

A ſyrup is made from the white *poppy* heads. Themiſon firſt takes notice of it; he made it with the juice and decoction of theſe heads, and uſed honey for giving it the ſyrup conſiſtence. The London College directs the following:

Syrupus e Meconia ſive Diacodion.

Take of the heads of dried white *poppies*, without their ſeeds, three pounds and a half; of water, ſix gallons. Slice the heads, and boil them in the water, often ſtirring them, that they may not burn, till about a third only of the liquor is left, which will be almoſt all imbibed by the *poppy* heads: then take all from the fire, and preſs the liquor ſtrongly out from the heads: in the next place boil the liquor by itſelf to about two quarts, and ſtrain whilſt hot, firſt through a ſieve, and then through a thin flannel: ſet it by for a night, that the fæces may ſubſide; next morning pour off the clear liquor, and boil it with ſix pounds of double-refined ſugar, till the whole comes to the weight of nine pounds, or a little more, that it may become a ſyrup of a juſt conſiſtence.

This ſyrup is given to children in doſes of two drams, to adults an ounce and a half. In general an ounce of this ſyrup is equal to one grain of opium; but it is ſubject to great variation in point of ſtrength from the different degrees of maturity, and the ſoil and ſeaſons in which they are produced, the *poppy* heads varying according to theſe in the quantity they contain of the narcotic property.

PAPAVER RUBRUM, called alſo papaver rhœas, papaver erraticum. Corn roſe, wild poppy. It is the papaver rhœas, Linn. This plant hath deep red flowers, dark-coloured ſeeds, hairy leaves and ſtalks. It is common in corn-fields, and is ſometimes, like the others, made to vary its flowers by culture. The heads contain the ſame kind of narcotic juice with thoſe of the preceding, but in ſo ſmall a quantity that they are wholly neglected. The leaves of the flowers, on expreſſion, yield a deep red juice, and impart the ſame to watery liquors, and a bright though pale red to rectified ſpirit. A ſyrup is made by pouring ℔ iv. ſ. of boiling water on ℔ iv. of freſh gathered flowers; when all the flowers are emerged in the water, let them ſtand together all night: pour off the liquor in the morning, and with a ſufficient quantity of ſugar make it into ſyrup.

PAPAVER CORNICULATUM. Sea poppy, or yellow horned poppy. It is a name for ſeveral ſpecies of glaucium.

PAPAVER HERACLEUM, i. e. Cyanus ſegetum flore cœruleo.

PAPAVER SPINOSUM, called alſo argemone Mexicana. Purging thiſtle. Its juice is called glaucium, and is uſed as a cooling external medicine.

PAPAVER SPUMEUM, i. e. Lychnis ſylveſtris, or behen album.

Boerhaave enumerates thirty-four ſpecies. See Lewis's Mat. Med. Neumann's Chem. Works.

PAPAYA. A kind of tree, two ſpecies of which are deſcribed by Ray.

PAPAYA MAS, called alſomamœra mas. The male papa tree.

PAPAYA, called alſo papaya Peruvianis, papayamazum, platanus, mamœra fœmina. Female papa tree.

The fruit reſembles a melon; it is eaten raw or prepared with ſugar, and is ſaid to ſtrengthen the ſtomach.

PAPILIONACEA. Papilionaceous. Flowers are thus called from their reſemblance to the wings of a butterfly when expanded; they always conſiſt of theſe four parts, viz. the vexillum or ſtandard, the alæ or two wings, and the carina or keel. The keel is ſometimes entire, and ſometimes it conſiſts of two petals or ſegments adhering together. Of this tribe are peas, beans, kidney beans, vetches, and other leguminous plants. See Miller's Dict.

PAPILLA. The nipple, alſo called mamma and mamilla. Thus the little eminences on the breaſt, are called. In children of both ſexes, and in males of all ages, they are commonly no more than cutaneous tubercles. In females arrived at the age of puberty, the *nipple* begins to increaſe, in pregnant women and thoſe who give ſuck it is large, in old age it decreaſes and becomes flabby. The body of the *nipple* contains the terminations of the tubuli lactiferi, where they are tortuous, and act as valves; but as they are diſtenſible, as the *nipple* is handled they become ſtraight, and thus the milk hath a free paſſage.

PAPILLA. So Peyer calls the inteſtinal glands.

PAPILLÆ MEDULLARES. Small eminences on the medulla oblongata, called by Winſlow tubercula mamillaria.

PAPILLÆ PYRAMIDALES. On the ſurface of the ſkin theſe are obſerved. They are longer in ſome parts, as in the fingers, where they are called villi, and appear in rows, each having two ranks contiguous. They are the organs of touch, being the terminations of the cutaneous nerves, each of which are incloſed in two or three covers.

PAPILLARE OS, i. e. Os ſphenoides.

PAPILLARIS HERBA. Nipple wort.

PAPILLARES PROCESSUS. The extremities of the olfactory nerves inſerted into the mucous membrane of the noſe are thus named.

PAPPA. Paſteboard.

PAPPOS. The downy hairs upon the chin.

PAPPUS. Potatoes, alſo the down of the ſeeds of plants: hence plants, whoſe ſeeds, when ripe, are furniſhed with down, are called pappoſe or pappeſcent.

PAPULA. A pimple or ulcerous tubercle. Dr. Cullen places it as a variety of phlogoſis phlegmone. It ſuppurates with difficulty.

PAPYRUS. The paper-tree, called alſo papyrus Nilotica Alpina, Ægyptiaca, Cyperus Niloticus vel Syriacus. This tree afforded to the Egyptians food, furniture for beds, and other utenſils in houſes, ſails for ſhips, ſhoes for prieſts, and paper.

PAR. When applied to days it ſignifies even, when uſed in preſcriptions it ſignifies a pair or two. Some medicines are called fine pari, without an equal.

PAR CUCULLARE. So Caſſerius calls the muſcu'us crico-arytænoides.

PAR LINGUALE. The ninth pair of nerves from the head.

PAR MENTALE, i. e. Muſculus levatores labii inferiores.

PAR VAGUM. The eighth pair of nerves from the head, which are alſo called nervi vagi, nervi ſympathetici medii. This pair is made up of ſeveral ſmall chords which come from almoſt the whole length of the medulla oblongata, and being joined with the acceſſorius Williſii, which is a ſmall rope running up laterally from the medulla ſpinalis, paſſes through the foramen to join this eighth pair, which goes out by that common hole between the temporal and occipital bones, where likewiſe the internal jugular vein goes out of the cranium. The *par vagum* goes down the neck, by the ſide of the carotid arteries, and behind the internal jugular, and is accompanied by the intercoſtal nerve to the laſt cervical vertebræ, thence paſſes down into the thorax, gives branches to the pharynx, larynx, &c. and join many nerves. As they enter the thorax they go acroſs the ſubclavian arteries, and as the right trunk paſſes before the ſubclavian, it ſends off a twig, which bends backwards under the artery, and runs up the ſide of the aſpera arteria; this is called the recurrent nerve. Afterwards the *par vagum* runs down behind the lungs, to which they give a plexus, and then form two ropes, one anterior the other poſterior, which are called nervi ſtomachici, which paſs along with the œſophagus through the aperture in the diaphragm, and are diſperſed on the ſtomach, &c.

PARA. A Greek prepoſition which, when prefixed to the

the name of a diſorder denotes its ſlightneſs, as paraplexia, a ſlight apoplexy, &c.

PARACELSUS. His excellence conſiſted in being a practitioner in a very dark age, and in having obtained ſome knowledge of the uſe of mercury and opium. Indeed, he made ſome improvement in ſurgery, and began to throw off the idle notions of former times. About ninety years after him ſprang up Van Helmont. See Helmont.

PARACENTESIS, from παρακεντεω, *to make a perforation*. This operation is commonly called tapping, and is uſed for diſcharging water through the integuments of the belly from the cavity thereof. The place appointed for the perforation is about four fingers breadth from the navel, or rather in the middle betwixt the navel and the upper part of the os ilium. The left ſide is uſually preferred, on account of not injuring the liver. Mr. Sharp obſerves that, if the navel protuberates, and that not the inteſtines or omentum, but water is only lodged there, a ſmall puncture made there with a lancet will diſcharge the water, without endangering a rupture of the part.

In the young and robuſt, or if the conſtitution is not too much enfeebled, this operation may be performed; but when there is a fever, a ſcirrhus in any of the viſcera, an internal abſceſs, a conſumption, &c. refrain from this operation.

If the extravaſated fluid remains in the ſame ſtate for ſeveral years, particularly if the health in other reſpects is good, the evacuation is a radical cure, provided that the health is otherwiſe unaffected; but whilſt the bulk of the water increaſes, there is not that confidence of a radical cure.

Upon a ſudden evacuation of the waters in a hydrops pectoris, or in an aſcites, a violent deliquium enſues, becauſe the preſſure of the water is taken off from the arteries, whence they dilate, and the blood ruſhes into them from the upper parts of the body too ſuddenly.

In order to the eaſy and ſafe performance of this operation, it is proper to have in readineſs, 1. A roller of flannel, or a flannel that may be laced about the belly, after the evacuation of the water; whether a roller or the laced flannel are uſed, begin with faſtening them tight about the lower part of the belly, and continuing the ſame upwards, that the bowels may be duly preſſed againſt the diaphragm. 2. A piece of flannel, which, when doubled four-fold, will be about a foot ſquare. 3. A quart or thereabout of proof ſpirit, in which to dip the roller and flannel cloth before applying them to the belly. 4. A piece of ſticking plaſter about two inches ſquare, in the middle of which will be laid three pledgets of lint, one larger than the other, the leaſt being about the ſize of a ſix-pence. 5. The trochar with its canula, the point of which is dipped in oil; and a probe with which to thruſt back the inteſtines if they obſtruct the mouth of the canula when the water is nearly evacuated. 6. Two or three large baſons, to receive the water, and a pail to empty them into. 7. Four perſons beſides the operator, one on each ſide, to keep a proper preſſure on the patient's ſides, obſerving to preſs from behind rather forward, and continuing this preſſure during the time that the water is paſſing off, and alſo until the roller or the laced flannel are ſecurely applied. One aſſiſtant will be employed in taking the baſins away when full, and providing the operator with empty ones; and the fourth aſſiſtant will be ready to ſupply the patient with a little wine or other cordial if he faints.

When the water is drawn off, lay the pledgets upon the wound, and ſecure them with the plaſter; over them lay the flannel cloth, and then begin with the bandage or laced flannel, as already mentioned. See Heiſter's Surgery; Le Dran's Operations; Sharp's Operations.

PARACMASTICI. See Acmasticos.

PARACOE, from παρακουω, *difficult hearing*. Dullneſs of hearing.

PARACOPE. In Hippocrates it is a ſlight delirium.

PARACYNANCHE, from παρα, *de*, and κυων, *a dog*, and αγχω, *to ſtrangle*. A ſpecies of quinſy; it being a diſtemper to which dogs are ſubject.

PARACUSIS. Depraved or faulty hearing. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order dyſæſtheſiæ. He diſtinguiſhes two ſpecies. 1. *Paracuſis* imperfecta; in which ſounds are difficultly diſtinguiſhed. See Surditas. 2. *Paracuſis* imaginaria; as when the ſound perceived is not from without, but is excited within the ear. See Tinitus Aurium.

PARADISAICA ARBOR, i. e. Arbor vitæ.

PARADISI GRANA. Grains of Paradiſe. They have erroneouſly been ſuppoſed to be the ſeeds of the larger cardamoms, whence they are called by ſome cardamum maximum; by others, malagueta, malaguetta, melegeta, melleguetta, maniguetta, and cardamum piperatum. They are brought from Guinea and the Eaſt-Indies. They are angular, of a reddiſh brown colour without, and white within; ſmaller than pepper, in appearance ſomewhat reſembling cardamom ſeeds. They grow in pods, ſhaped like unripe figs, and about the ſize of one. This pod is divided internally into three cells, in each of which is contained two rows of ſeeds. They have the flavour of cardamoms, and the pungency of pepper: their pungency does not reſide like that of cardamoms in their eſſential oil, but in their reſin. The diſtilled oil poſſeſſes their ſmell, but is mild; the remaining decoction inſpiſſated to an extract retains all the pungency. In ſome parts, theſe grains are uſed inſtead of pepper. Dr. Trew thinks, that the ol. cajeput is extracted from them. See Lewis's Mat. Med. Neumann's Chem. Works.

PARAGLOSSA. A prolapſus of the tongue. A ſwelled tongue.

PARAGUA, i. e. Caſſine.

PARAKYNANCHE, from παρα, *de*, κυων, *a dog*, and αγχω, *to ſtrangle*. A ſpecies of angina.

PARALLELA. A ſort of ſcurf or leproſy, affecting only the palms of the hands; it happens ſometimes in the venereal diſeaſe.

PARALOPHIA, from παρα, *near*, and λοφια, *the eminence of the back*. Keil ſays it is the lower and lateral part of the neck.

PARALYSIS, from παραλυω, *to diſſolve* or *weaken*. A palſy; often it ſignifies a palſy of a particular part. Celſus and Cœlius Aurelianus ſay that the moſt antient writers give the name of attonitus morbus to that ſpecies which follows an apoplexy. Dr. Cullen places this genus of diſeaſe in the claſs neuroſes, and order comata. He diſtinguiſhes four ſpecies. 1. *Paralyſis* partialis; when ſome particular muſcles are affected. 2. *Paralyſis* hemiplegica; when one whole ſide is affected. 3. *Paralyſis* paraplegica; when one half of the body is affected, taking it tranſverſly, as both legs and thighs. 4. *Paralyſis* venenata; when too powerful ſedatives are applied externally, or taken internally.

The apoplexy, hemiplexy, and *palſy*, are ſo nearly connected, that they may be conſidered in one view. In the beginning, the *palſy*, which is cauſed by an exceſs of good blood, is acute; but it ſoon becomes chronical; the other *palſies* are all, and at all times, chronical.

A *palſy* is when there is an abolition of voluntary motion, or of feeling, or both. When all the parts below the head are affected, from any part of the body tranſverſly downwards, it is called paraplegia; if one whole ſide, or one ſide of the head and face, it is an hemiplegia, and when confined to a particular limb, it is a *paralyſis*, or a particular *palſy*; when both ſides are ſeized, and reaſon is loſt, it is then an apoplexy.

When the muſcles of the face are paralytic, the ſource of the diſorder is in the brain; but if theſe be free, the nerves only of the ſpine, or medulla oblongata, are affected. Dr. Cullen defines the *palſy* to be a loſs or diminution of the power of voluntary motion, but affecting certain parts of the body only; and it is often accompanied with ſleepineſs.

Dr. Shebbeare conſiders this diſorder as the effect either of too much vital heat or too little, and that as the ſame effect follows from oppoſite cauſes, ſo the ſame diſorder will require different remedies, according to the varieties of its origin. Occaſionally the *palſy* may proceed from an apoplexy, an epilepſy, violent pains, ſuppreſſion of uſual evacuations, a tranſlation of the morbific matter of acute diſeaſes, whatever diſtends, diſturbs, compreſſes, or contracts the nerves, ſtrong ligatures, luxations, fractures, wounds, gangrenes, inflammatory or other tumors in the coats of the nerves, extreme heat, violent cold, mineral effluvia, a too frequent uſe of hot water, &c. Dr. Cullen obſerves,

obſerves, that the power of voluntary motion may be owing either to a morbid affection of the muſcles, or organs of motion, by which they are rendered unfit for motion, or to an interruption of the influx of the nervous power into them, which is always neceſſary to the motion of thoſe that are under the power of the will. The diſeaſe, from the firſt of theſe cauſes, as conſiſting in an organic and local affection, is to be referred entirely to the claſs of local diſeaſes. As the *palſy*, that diſeaſe only, is to be conſidered, which depends upon the interrupted influx of the nervous power; and to this alone the appellation of *palſy* ſhould be given.

From anatomy we ſee that the nerves deſtined for the vital functions ariſe from the cerebellum, thoſe ſubſervient to the ſenſes from the baſe of the brain, and thoſe ſubſervient to the voluntary motions and the touch, principally from the ſpinal marrow; we may then readily infer, that in all apoplexies the cauſe compreſſing the nerves is within the brain; in a *palſy*, within the ſpinal marrow. The *palſy*, or loſs of motion thus named, Dr. Cullen obſerves, may be diſtinguiſhed into two kinds; one, depending upon an affection of the origin of the nerves in the brain, and the other depending upon an affection of the nerves in ſome part of their courſe between the brain and the organ of motion. He further adds, that whatever is neceſſary to be obſerved of the firſt, will readily apply to the latter, both in pathology and practice.

A *palſy* ſometimes attacks ſuddenly without any previous ſymptoms by which it might be expected; but ſometimes an hemiplexy ſucceeds an apoplectic fit, and begins with a refrigeration of the ſide to be affected, and a preceding vertigo, and gradually terminates in an abolition of ſenſation and motion; the ſound ſide is often racked with ſpaſmodic and convulſive motions; the mouth is frequently diſtorted like that of a dog, and as the diſorder proceeds, the functions of the mind, and eſpecially the memory, begins to be weakened. A particular *palſy* is ſometimes preceded by a ſenſation of weight in the part about to ſuffer, a ſlow motion, accompanied with ſtupor, paleneſs, and torpor; the part affected is lax, flaccid, ſoft to the touch, and cold, like as it is affected in an atrophy or an œdematous tumor. When the pharynx is affected with a *palſy*, the patient cannot ſwallow. A *palſy* in the eye-lids is attended with a diſcharge of tears. A *palſy* of the ſphincter ani is diſcovered by the deſcent of the rectum, and the involuntary diſcharge of the fæces. A *palſy* in the bladder is known by the involuntary emiſſion of urine. In moſt other caſes the eye diſcovers the nature of the diſorder; or, when it conſiſts of a loſs of ſenſe, the patient's complaint determines it. The parts affected ſometimes appear puffy, at others they are ſhrunk and ſhrivelled; in theſe reſpects, as well as in thoſe of ſenſe being loſt in ſome inſtances, and motion in others, Dr. Shebbeare ingeniouſly accounts for them as follows: He ſuppoſes theſe diſorders to have an exceſs of vital heat for their cauſe; in this caſe, as the body receives its heat from the earth in greater or leſs abundance, according to the quantity of red globes in the blood; and as this heat is conveyed by means of the nerves, as required for the reſpective motions, whether voluntary or involuntary; various circumſtances may occaſion a too ſudden and abundant heat to be conveyed to any part, or through the whole frame, in any inſtant of time; whence, by the return of the ſame from the brain, to and through the reſpective parts, the cellular membrane is ſo dilated as that many cells are ruptured into one, and in proportion as this accident is extenſive, ſo will the defect of motion be; or the exceſſive motion, as well as quantity of fire, may lacerate the parts of the brain, in which thoſe nerves take their riſe, and then paſſing down by thoſe nerves that are deſtined to motion, the action of the part or parts are at an end; or paſſing by thoſe deſtined for ſenſation, ſenſibility is leſſened or deſtroyed; and in this latter caſe, by the laceration of the cellular membrane, the nerves are ſeparated from contact with the ſkin, ſo that it is not as uſual confined, but riſes ſo far as to produce the appearance of unuſual fullneſs. Dr. Cullen obſerves, that in the *palſy*, the loſs of motion is often accompanied with a loſs of ſenſe; but, as this is not conſtantly the caſe, and as, therefore, the loſs of ſenſe is not an eſſential ſymptom of *palſy*, he does not take it into his definition. He further obſerves that, ſo far as it is in any caſe a part of the *paralytic* affection, it muſt depend upon the ſame cauſes, and will be cured by the ſame remedies.

The prognoſtics are generally to be cautiouſly pronounced, at leaſt when delivered with reſpect to a recovery. A ſpaſmodic apoplexy and ſanguineous hemiplegy are often removed, but they are apt to return and end in a fatal hæmorrhage in the brain: the other ſpecies of *palſies*, and a ſerous hemiplegy do not ſuddenly prove mortal; but the cure is more difficult and intricate, the more the ſenſes are injured, and theſe diſorders frequently continue during life. When infants become *paralytic*, they are ſometimes relieved at or about the years of puberty, but ſuch favourable changes rarely are obſerved in adults. A *palſy* in the belly and lower limbs is generally mortal, and often accompanied with a gangrene of the affected parts. If convulſions and great heat are perceived in the parts oppoſite to thoſe that are paralytic, the danger is great. When a *palſy* follows an apoplexy, or comes on in old age, it is rarely cured. If the ſeat is in the membranes of the medulla ſpinalis, the theca vertebrarum, &c. the caſe is out of the reach of art, death is unavoidable, but will only gradually approach. If the part affected is yet painful, capable of ſenſation, not too cold, nor extenuated, there are ſome hopes of a recovery, which is ſtill more to be expected, if there is a ſenſation of formication and puncture in it.

The indications are the ſame as in the apoplexy, (ſee HEMIPLEGIA,) and are

1. To remove the proximate and remote cauſes, which contribute to interrupt the influx of the nervous fluid into the nerves.

2. To ſtrengthen the parts affected, and the whole nervous ſyſtem.

When a ſanguine plethora is attendant, the principal cauſe is the exceſs of vital heat; bleed to reduce the heat, which muſt be brought and preſerved as near as may be to the ſtandard of health. And as, in this caſe, a laceration of the cellular membrane is the cauſe of motion being defective, as well as of the ſenſe of feeling being diminiſhed, a tight ſtocking, &c. according to the part affected, ſhould be applied, if poſſible, to aſſiſt the re-union of the parts that are torn aſunder. In this ſpecies of *palſy* the Bath waters, and all heating medicines, are quite contrary to the curative indication: inſtead of them, cooling medicines, ſubtepid baths, and lenient purges, ſhould be uſed. But though this method may be proper in a recent caſe; yet, if it is of long ſtanding, and the blood is impoveriſhed, though the cauſe was too much vital heat, the cure now will be the ſame when a defect of heat gave riſe to the diſorder.

When there is too little heat in the conſtitution, bleeding, and a cooling method, is evidently injurious: here the Bath water is uſeful both for bathing and inward uſe. The ſhrunk muſcle is reſtored and motion recovered, in curable caſes, by means of electricity. In this ſpecies of *palſy*, the cellular membrane not receiving its due degree of heat for keeping its cells diſtended, they gradually cling together, and thus deſtroy the power of action: warm bathing conduces much to the recovery of theſe patients. In the fit apply bottles or bladders filled with hot water to the feet; let the body be well rubbed with rectified ſpirit of wine: if the lungs have ceaſed to play, breathe warm breath forcibly into them, and as ſoon as the patient can ſwallow, give him cordial medicines. After recovery from the fit, attend to what affections may have agitated the patient, and then proceed with warm, nervous, corroborant medicines, not neglecting bliſters, and ſuch other evacuants as the kind of plethora may require.

In both the above ſpecies of *palſy*, a ſtimulating clyſter may be given with all convenient ſpeed; for thus the head will be in ſome meaſure relieved; the beſt ſtimulant is the ſal gem, or in want of it common ſalt.

Bliſters are not ſo well applied on the nape of the neck as on remoter parts; for in ſome inſtances they have produced convulſive twitchings when placed on the neck or back. In general *palſies*, bliſters are uſeful by their ſtimulus; but they are moſt ſo when only particular parts are affected, and then the propereſt place of application is where the nerves of the reſpective part have their origin;

or example, when a *palſy* ſeizes the upper extremities, bliſters ſhould be applied to the vertebræ of the neck, and obliquely towards the ſhoulders; if the lower extremities are affected, the region of the ſacrum is the propereſt part for bliſters. When in a *palſy* there is a plethoric ſtate of the ſyſtem, bliſters do not ſeem to be a ſafe means to be applied; but in all inſtances connected with, or that ſeem to depend upon a relaxed ſet of fibres, a moiſt atmoſphere, or the preſence of too much ſerum in the ſyſtem, bliſters are then the principal remedies to be depended on. They are alſo of ſervice in ſuch ſpecies of *palſy* as are produced by poiſons of different kinds, eſpecially thoſe of a metallic nature; but in theſe caſes, the uſe of ſtrong emetics and purgatives muſt always be premiſed.

After bleeding in the ſanguine ſpecies, ſpaſms of the internal parts, and a febrile ebullition, often remains; in which caſes nitre, Clutton's febrifuge ſpirit, &c. will be proper.

Diuretics of the warm and ſtimulating kind are proper in the ſerous kind of *palſy*; muſtard, horſe-radiſh, and ſuch like, prove highly beneficial.

If other diſorders attend, a due regard muſt be had to their removal.

Baths of rain water, or any other that is light, and in which aromatic ingredients are boiled or infuſed, may be uſed when circumſtances do not admit of the patient's going to Bath.

As to liniments, the linim. ſapon. perhaps equals any other in its efficacy and uſefulneſs.

When mineral exhalations have been the cauſe, the cure is difficult: lead particularly deſtroys ſenſation, whence often in *palſies*, purging medicines are required in very increaſed doſes.

A *palſy* from the colic requires perſpiratives inwardly, and warm applications outwardly. In this caſe, the Bath water is a ſpecific.

When a *palſy* follows an epilepſy, after proper evacuations, apply bliſters, and give aſſa fœtida with ſalt of amber.

A *palſy* in the belly is, in ſome meaſure, relieved by a fomentation of hot wine, in which aromatics have been boiled, and by drinking a little of the ſame when the pulſe will admit of it. When the tongue is affected, rub it with muſtard, or muſtard and brandy.

Dr. Cullen obſerves, that in the apoplexy, ſo in the *palſy*, the cauſes are, a compreſſion, preventing the flow of the nervous power from the brain into the organs of motion; or, the application of narcotic powers, which render the nervous power unfit to flow in the uſual and proper manner. Compreſſion may be from tumour, over diſtenſion, or effuſion. The ſame means that are uſeful in preventing apoplexy, are uſeful for the ſame end in caſes of *palſy*. The ſame may be ſaid reſpecting the cure; in the beginning. *palſy* proceeds as in the apoplexy. What is ſaid when the cauſe is from compreſſion, may be repeated reſpecting the application of narcotic powers being the cauſe. When the *palſy* hath continued for ſome time, be the cauſe what it may, ſome little deviations from the treatment of apoplexy may be proper. As to the uſe of ſtimulants, both in the apoplexy and *palſy*, ariſing from compreſſion, it is true, that they may, and often do, ſo excite the energy of the brain, as to overcome the compreſſion on the nerves; but then they ſo act on the ſanguiferous ſyſtem, and if this happens in a conſiderable degree, they may be productive of the cauſe which they were given to oppoſe: a circumſtance that calls for careful attention. As to externals, they have occaſionally been uſeful in ſlight caſes, but much cannot be expected from them. Heat, cold, and electricity, are the moſt powerful external applications for relieving general affections. Heat is employed in warm bathing, and thus is a powerful ſtimulant; but as it both ſtimulates the ſolids, and rarefies the fluids, it will be unſafe when compreſſion may be produced by the congeſtion in the brain, which may follow the uſe of warm bathing. Warm bathing is moſt proper, when the cauſe was the application of narcotic powers. Cold is a uſeful ſtimulant, if the power of reaction in the body is equal to the action of the cold upon it: if otherwiſe, cold is extremely hurtful to the paralytic. Electricity acts very powerfully on the nervous ſyſtem; but as it ſtimulates the ſanguiferous, as well as the nervous ſyſtem, it requires caution, for its uſe hath ſometimes been more injurious than beneficial. The efficacy of electricity is more from its repetition than from its force: it is alſo better adapted to relieve when the cauſe was from narcotic applications to the nerves. Exerciſe, ſuch as circumſtances will admit, are beneficial. Internally, the volatile alkaline ſalts and ſpirits, if given in repeated and ſmall doſes, inſtead of large ones, are uſeful and ſafe. In many inſtances of ſerous *palſies*, thoſe vegetables of the claſs of tetradynamia, are ſeveral of them very uſeful. Some reſinous ſubſtances, as guaiacum, &c. alſo ſome of the fœtid antiſpaſmodic medicines have been employed, but without that advantage that is often attributed to them.

See Archigenes, Ætius, Celſus, Cœlius Aurelianus, Arætæus, Bellonius, Trallian, Hoffmann, and Boerhaave; Shebbeare's Theory and Practice of Phyſic; Lond. Med. Obſ. and Inq. vol. iii. p. 160, &c. p. 257, &c. For many uſeful elegant forms of medicine; ſee Brooks's and the London Practice of Phyſic; ſee Cullen's Firſt Lines, vol. iii.

PARALYSIS, alſo called primula veris, Linn. Verbaſculum pratenſe odoratum, primula veris odorata, flore luteo ſimplici, primula veris major, paigles. Common cowſlips. This plant is ſufficiently known to need no deſcription. It is valued for its flowers, which have an agreeable ſmell, and are uſed to give flavour to a fermented liquor, known by the name of cowſlip wine. The flowers are gently anodyne and antiſpaſmodic.

Boerhaave enumerates twenty ſpecies of the primula veris, and of theſe are the two following:

Primula Veris Minor. The primroſe. It grows in hedges and woods; its flowers are weaker than thoſe of the cowſlip; the leaves and roots partake in ſome degree of the nature of aſarum, and are powerful errhines and emetics.

Primula Veris, called alſo herba petri, primula inodore lutea verbaſculum pratenſes. Orſlips, or great cowſlips. The flowers are diuretic.

None of theſe are now uſed in medicine.

PARANOIÆ. Delirium; alienation of mind; defective judgment.

PARAPHIMOSIS, from παρα, *de*, and φιμοω, *to tie with a bridle*. Φιμος ſignifies properly *a ſtricture*, ſuch as the neck of a purſe. It is when the prepuce is drawn back behind the glans penis, and cannot be drawn over it. See Lues Venerea. Dr. Cullen places it as a variety of the phlogoſis phlegmone.

PARAPHONIA. Depraved voice. Dr Cullen places this genus of diſeaſe in the claſs locales, and order dyſcineſiæ. He defines it to be a depravity of the ſound of the voice, and diſtinguiſhes ſix ſpecies. 1. *Paraphonia* puberum; it is that change of voice ſo remarkable in boys about foureen years of age, which from acute and agreeable, becomes grave and very diſagreeable. 2. *Paraphonia* rauca; when the voice becomes hoarſe and rough. See Raucedo. 3. *Paraphonia* reſonans; when from obſtruction in the noſtrils, the voice is rough, and the ſound ſeems to come whiſtling through them. 4. *Paraphonia* palatina; when from a defect of the lip, the palate, or uvula, the voice is rough, obſcure, and confuſed. See Asaphia. 5. *Paraphonia* clangens; when the ſound is ſhrill or ſqualling, or like that of geeſe. See Clangor. 6. *Paraphonia* comatoſa; when the voice is ſent out during inſpiration, and ſomewhat reſembles the ſnorting of people aſleep.

PARAPHRENESIS. A delirium; alſo the paraphrenitis.

PARAPHRENITIS. An inflammation of the diaphragm. Its cauſes are the ſame as thoſe of the pleuriſy.

The pain is very violent and deep ſeated in the lower part of the breaſt, or under the ſhort ribs, or ſtriking between them and the back; the fever is very acute, and the delirium is conſtant; the belly is drawn up, and kept as much at reſt as poſſible; the reſpiration is exceſſively quick, erect, ſmall, ſuffocating, and difficult, and performed principally by the muſcles of the breaſt; the patient is frequently affected with ſickneſs and hiccough, and often with involuntary laughter, convulſions, and madneſs; the pulſe is uſually very frequent and ſmall, often irregular; there is great anxiety; the ſymptoms of irritation

come on, and death frequently enſues: if this does not happen, the progreſs, termination, and manner of treatment are much the ſame as in the pleuriſy. The pain is greatly augmented during inſpiration, coughing, ſneezing, repletion of the ſtomach, nauſea, vomiting, and a compreſſion of the belly in diſcharging the fæces and urine. The riſus ſardonicus, convulſions, madneſs, and gangrene, often terminate the diſeaſe. Sometimes a purulent aſcites is a conſequence.

The cure is generally the ſame as in the pleuriſy. Emollient clyſters are peculiarly uſeful. See Boerhaave's Aphoriſms; Fordyce's Elem. part. ii.

PARAPHROSYNE. It is ſynonymous with mania. It is a tranſitory inſanity without a fever. A delirium. A ſymptomatic madneſs.

PARAPLEGIA, from παρα, ſignifying ſomething *injurious*, and πλησσω, *to ſtrike*. A paraplegy, or a palſy of all the parts below the neck, thus it is now underſtood; but in Hippocrates it ſeems to ſignify a palſy in any particular part, in conſequence of an apoplexy or epilepſy. Dr. Cullen makes it that ſpecies of palſy which divides the body horizontally, or tranſverſely, all allow ſuch a part being paralytic; the palſied part beginning below the neck.

PARAPLEXIA. The ſame as paraplegia. A partial apoplexy. Hippocrates calls a palſy from an apoplexy by this name, alſo by the name of paraplegia; which ſee.

PARAPOPLEXIA. A ſlight apoplexy.

PARATHREMA. A ſlight luxation. A tumor from protruſion; as an hernia.

PARASITICAL PLANTS. They are ſuch as are produced out of the trunk or branches of other plants, from whence they receive their nouriſhment, and will not grow upon the ground, as the miſleto, &c.

PARASPHAGIS. The part of the neck contiguous to the clavicles.

PARASTATA. It ſignifies any thing ſituated near another.

PARASTATÆ, from παριστημι, *to ſtand near*. In Hippocrates it ſignifies the epididymis. Herophilus and Galen called theſe the varicoſe *paraſtatæ*, to diſtinguiſh them from the glanduloſe *paraſtatæ*, now called proſtatæ. Rufus Epheſius called the tubæ Fallopianæ by the name of *paraſtatæ* varicoſæ.

PARASTREMMA, from παραστρεφω, *to diſtort* or *pervert*. A perverſion, or a convulſive diſtortion of the mouth, or any part of the face.

PARASYNANCHE. A ſpecies of quinſy.

PARATHENAR MAJOR. This muſcle in each foot is fixed backward by a fleſhy body, to the outer part of the lower ſide of the os calcis, from the ſmall poſterior external tuberoſity, all the way to the anterior tuberoſity; there it joins the metatarſus, and at the baſis of the fifth metatarſal bone, ſeparates from it again, and forms a tendon, which is inſerted in the outſide of the firſt phalanx of the little toe, near its baſis, and near the inſertion of the parathenar minor. It ſeparates the little toe from the reſt.

PARATHENAR MINOR. This muſcle in each foot is fixed along the poſterior half of the outer and lower ſide of the fifth bone of the metatarſus. It terminates under the head of the bone in a tendon, which is inſerted in the lower part of the baſis of the firſt phalanx of the little toe. Some call theſe muſcles, tranſverſales pedis.

PAREGORICUS, from παρηγορεω, *to conſole* or *mitigate*. An epithet for medicines which relieve pain.

PAREIRA BRAVA, alſo called pareyra, ambutua, butua, caapeba, convolvulus colubrinus. Wild vine. It is the ciſſampelos *pareira*, Linn.

It is the root of an American climbing plant. It is brought from Braſil, generally in crooked pieces of different ſizes, from that of a man's finger, up to that of a child's-arm; the outſide is browniſh, and variouſly wrinkled; the internal ſubſtance is of a pale, dull, yelloviſh hue, and interwoven, as it were, with woody fibres, ſo that on a tranſverſe ſection there appears a number of concentric circles, croſſed with ſtriæ, running from the centre to the circumference. There is a white ſpecies; the bark of the root of it is white, and the ſubſtance within appears like the root of liquorice.

This root is in high eſteem as an attenuant and diuretic, in ſuppreſſions of urine, in nephritic and calculous complaints, in ulcers of the kidnies and bladders where the urine is mucous and purulent, and can ſcarce be voided without pain; in aſthmatic caſes, when thick phlegm hath been very troubleſome, an infuſion of this root hath brought on expectoration. It gives out its virtue to water or to ſpirit. See Lewis's Mat. Med. Neumann's Chem. Works.

PARENCEPHALIS, from παρα, *near*, εγκεφαλος, *the brain*. The cerebellum.

PARENCHYMA, from παρεγχυω, *to pour into*. Eraſiſtratus is ſaid to have introduced this term to ſignify all that ſubſtance which is contained in the interſtices betwixt the blood-veſſels of the viſcera, which he imagined to be extravaſated and concreted blood. According to ſome, any of the viſcera through which the blood is ſtrained.

PARENCHYMATICI. Viſceral inflammations.

PARESIS. Aretæus ſays it is a palſy of the bladder, when the urine is either ſuppreſſed or diſcharged involuntarily. It is now generally underſtood to be an imperfect paralyſis.

PARIETARIA OSSA, from *paries*, *walls*; they defend the brain like walls. So the bones of the ſinciput are called.

PARIETARIA, alſo called helxine, muralis, perdicium, vitriaria, urceolaris. Common pellitory of the wall. It is the *parietaria* officinalis, or *parietaria* foliis lanceolato ovatis pedunculis dichotomis calycibus diphyllis, Linn. This plant is called *parietaria*, from *paries*, *walls*; muralis, from *murus*, *a wall*; helxine, from ελκω, *to draw* or *attract*, becauſe its rough leaves ſtick cloſe to what touches them; perdicium, from *perdix*, *a partridge*, becauſe partridges love to feed on it; vitriaria, and urceolaris, becauſe by its mucouſneſs it is of ſervice for ſcouring pots and glaſſes. This plant hath tender reddiſh ſtalks, rough, uncut, oblong leaves, pointed at both ends, and imperfect rough flowers growing in cluſters along the ſtalks, followed each by a ſmall ſhining ſeed. It is perennial, common on old walls, and amongſt rubbiſh. It flowers in May.

The leaves have been uſed externally for cooling; and internally as diuretic and emollient; but their efficacy hath not preſerved them a place in the preſent practice. See Raii Hiſt.

PARIN CHAKKA. Baſtard China.

PARISTHMIA, from παρα, *near*, and ισθμος, a part of the throat ſo called. The tonſils, or diſorders of the tonſils.

PARISTHMIOTOMUS. An inſtrument with which the tonſils were formerly ſcarified.

PARKINSONIA. Father Plumier diſcovered this plant in America, and named it thus in honour of Mr. John Parkinſon, an Engliſh botaniſt. See Miller's Dict.

PARNASSIA, called alſo hepatica alba; gramen Parnaſſi ciſtus humilis; pyrola rotundi folia. Graſs of Parnaſſus, or white liver-wort. The leaves are roundiſh, and diſpoſed in a circle; it grows in flowery marſhy places, and flowers in Auguſt. The whole plant is ſaid to be cooling and diuretic; but it is not in uſe at preſent. See Raii Hiſt.

PARONYCHIA. A whitelow, or whiteflaw, from παρα, *near*, and ονυξ, *a nail*. It is alſo called a felon. Le Dran calls it panaris. It is an abſceſs at the end of the fingers. It differs not from an abſceſs in any other part. According as it is ſituated more or leſs deep, it is differently denominated, or divided into ſpecies by ſome writers. Dr. Cullen places it as a variety of the phlogoſis phlegmone.

It begins with a ſlow heavy pain, attended with a ſlight pulſation without ſwelling, redneſs, or heat; but ſoon the pain, heat, and throbbing are intolerable; the part grows large and red, the adjoining fingers and the whole hand ſwells up; in ſome caſes, a kind of red and inflated ſuſe or ſtreak may be obſerved, which beginning at the affected part, is continued almoſt to the elbow; nor is it unuſual for the patient to complain of a very ſharp pain under the ſhoulder; and ſometimes the whole arm is exceſſively inflamed and ſwelled; the patient cannot ſleep, the fever, &c. increaſing, and ſometimes delirium or convulſions follow.

When it is ſeated in the ſkin or fat, in the back or the

fore part of the finger, or under or near the nail, the pain is ſevere, but ends well. When the perioſteum is inflamed or corroded, the pain is tormenting. When the nervous coats of the flexor tendons of the fingers or nerves near them are ſeized, the worſt ſymptoms attend. The ſecond ſpecies proves very troubleſome, and ſometimes ends in a caries of the ſubjacent bone. The third ſpecies is very tedious in the cure, and uſually the phalanx on which it is, is deſtroyed.

If the firſt kind ſuppurates, it muſt be opened and treated as abſceſſes in general; but the beſt method of treating the other two ſpecies, is, on the firſt, or at fartheſt, the ſecond day, to cut the part, where the pain is ſeated, quite to the bone; if this operation is longer deferred, a ſuppuration will come on; in which caſe, ſuppuration ſhould be ſpeedily promoted, and as early a diſcharge given to the matter as poſſible. As the pain is ſo conſiderable as to occaſion a fever, and ſometimes convulſions, the tinct. theb. may be added to the ſuppurating applications, and alſo given in a draught at bed-time.

See Le Dran's Operations, and Heiſter's Surgery.

PARONYCHIA, called alſo ſedum, ſaxifraga, rue, whitlow-graſs. It is ſaid to be emollient; but it is of too little efficacy to maintain a place in practice.

PARONYCHIA. A name for ſome ſpecies of adianthum and herniaria.

PAROPIÆ. The external angles of the eyes.

PAROPTESIS, from *ὀπτάω, to roaſt.* A provocation of ſweat, by making a patient approach a fire, or by placing him in a bagnio.

PARORASIS. An imbecility of ſight.

PARORCHIDIUM. A detention of the teſticles, as when they have not yet deſcended into the ſcrotum. The teſticles are ſometimes detained in the body; this caſe is called crypſorchis; or concealed teſticles. Sometimes the teſticles (one or both) are detained in the groin; uſually about the time of the child's birth they deſcend into the ſcrotum, in ſome inſtances a little before birth, in others ſoon after. But this is very uncertain with reſpect to different perſons; alſo in the ſame perſon the two teſticles will conſiderably vary as to the time of their deſcent. Sometimes one, at others both, are detained in the belly, or ſtick in paſſing through the groin. Theſe accidents happen and continue a longer or leſſer time after the birth; and in ſome inſtances never paſs down into the ſcortum. Mr. Pott takes notice of this caſe, and gives ſeveral inſtances of it in the quarto edition of his works; where he ſays, that he knows not of any particular inconvenience ariſing from the detention of a teſticle within the cavity of the belly; but the logdment of it in the groin, renders it liable to be hurt by accidental preſſure, &c. When it is ſo hurt, it may be miſtaken for a different diſeaſe, and thereby occaſion its being very improperly treated. To which conſiderations he adds, that there is no kind of diſeaſe to which the teſticle is liable in its natural ſituation, but what may alſo affect it, in any or all its unnatural ones. In the firſt caſe related by Mr. Pott, a teſticle being detained in the groin of a young healthy ſeaman, who hurt the part by hitting it againſt a piece of timber; the humour there became extremely painful, and was miſtaken for a bubonocele, from which it might have been more readily diſtinguiſhed by the following circumſtances, had not the extreme tenderneſs of the injured teſticle abſolutely prevented any examination there by the touch; and the very hard ſwelling of the ſcrotum, which prevented any certainty of a teſticle being there or not. But Mr. Pott here ſays, that the tumor in the groin did not, like the bubonocele, point obliquely from the ilium towards the pubes, but lay as it were acroſs the groin: alſo, as neceſſarily muſt happen, that when the ſcrotum became ſoft, no teſticle could be felt in it. Two ſtriking circumſtances by which to diſtinguiſh the detained teſticle from the bubonocele, and alſo to determine the nature of the caſe. In the earlier part of this young man's life, this detained teſticle had been miſtaken for a rupture, and a truſs had been applied to it. The ſecond caſe, the teſticle was detained in the groin; this patient had alſo been adviſed to wear a truſs on the ſuppoſition that the caſe was a rupture; but he could not wear it, becauſe of the pain it occaſioned. At length getting a clap, this detained teſticle inflamed, forming an hernia humoralis, which was miſtaken for a bubo. In this caſe, the humour was moveable, and the ſcrotum on that ſide had no teſticle in it: two circumſtances ſufficient for diſtinction and determination. Both the above caſes were cured as inflammations of the teſticles are, when their ſituation is in the ſcrotum.

PAROTIDÆA. The mumps.

PAROTIS, from *παρὰ, near,* and *οὖς, the ear,* or from *παρὰ,* and *ὠτός,* the genitive of *οὖς, the ear.* The parotid gland. It is ſeated, on each ſide, in a cavity below and before the ear, between the maxillary proceſs, the zygomatic proceſs, and the angle of the lower jaw; and the duct paſſes over the buccinator to pierce the membrane of the mouth, near the third dens molaris of the upper jaw. It is a conglomerate gland, and hath veſſels from the temporal artery. It hath an appendicle at the tendinous beginning of the maſſeter muſcle. It is one of the ſalival glands.

PAROTIS. An inflammation, or an abſceſs of the parotid gland. Dr. Cullen makes it ſynonymous with bubo.

PAROXYSMUS, from *παροξύνω, to irritate or render ſharp.* A paroxyſm; acceſs, or fit of a diſeaſe.

PARTEM (Pulv. ad.) See BORAX.

PARTHENIASTRUM. Baſtard feverfew.

Miller takes notice of two ſpecies, one of which grows in Jamaica, where it is called wild wormwood, and is uſed as a vulnerary. The other is found in the Spaniſh Weſt-Indies.

PARTHENIUM. A name for the tanacetum and matricaria.

PARTURIO, from *partus, a birth.* Labour, or the bringing forth of a child.

Women are generally delivered of their burden about the end of the ninth month, or very early in the tenth: inſtances have occurred of nature's deviating, and of healthy children, which became vigorous men, being brought forth at different periods, from ſeven to eleven months, after conception.

The cauſe and mechaniſm of labour is as follows: ſome days before the labour commences, the belly ſeems leſs; by its contents ſinking lower down; ſoon after this certain efforts are made by nature, which, from their exciting pain, are uſually called pains; in the beginning, theſe pains are ſlight, and the intervals conſiderable; after ſome of theſe efforts, the uterus begins to contract, and a mucus diſcharges from the vagina; after this, the pains become more ſevere, return more quick, and continue longer; the pulſe is now affected, the ſkin is hotter, the face reddens, and a general agitation follows; the mucus is tinged with blood; the os tincæ opens, its edges grow thin, the membranes protrude with the waters, dilate and widen the orifice; the child, at the inſtant of pain, is raiſed by the compreſſed waters from the os internum, towards the fundus, whilſt the uterus itſelf advances and deſcends by degrees into the inferior baſon. When the pain ceaſes each time, the womb riſes, but not ſo high as before; the tumor formed by the membranes diſappear; the os tincæ is relaxed, and the diameter diminiſhed; the child falls, by its gravity, upon the lower part of the womb; and may be eaſily diſtinguiſhed through the relaxed membranes, as alſo what part of its body preſents to the paſſage. Towards the end of labour, the ſucceſſion of pains are rapid, and the efforts violent: in the beginning the pains uſually begin in the ſmall of the back, and terminate about the pudenda; but now they begin in the regio umbilicalis, and die away toward the fundament, where, in moſt inſtances, they leave a ſenſibility of weight. The tumor formed by the waters diſtending the membranes below the mouth of the womb, dilates the parts, until at length it burſts, and diſcharges the waters. If the child's head preſents fairly, it ſtops the diſcharge of the remaining waters. Sometimes the ſame effort which burſts the membranes, expels the infant, and terminates labour; at others, the interval is long before the delivery of the child. The head of the child having paſſed the os internum, enters the vagina, which widens in proportion as it ſhortens; the perinæum is vaſtly ſtretched, and the frenulum ſometimes torn in the paſ-

ſage;

ſage; the nymphæ are obliterated, and the labia pudendi are turned inward, and confounded in the general diſtenſion. At length the head forces the os externum, and the body readily follows, with the reſt of the waters, mixed with blood. At this laſt period, the woman trembles and is convulſed, but is ſoon relieved by the expulſion of the child; after which there is a calm, until returning efforts are exerted for the excluſion of the placenta. Hence it appears, that parturition demands the concurrence of ſeveral agents. The cauſe and determination of labour is the firſt, and this is in the womb itſelf; the womb contracts, and compreſſes whatever it contains, in ſuch a manner, as forces it to eſcape by the part which makes the leaſt reſiſtance, which is conſequently by the vagina. The womb is muſcular, and reticulated; ſome of its fibres run uniformly parallel upon the inner ſurface of the womb, from the fundus to the neck; others diagonally croſſing upon theſe, and others again horizontally interlaced, and ſo cloſely wove towards the fundus, as to have been miſtaken for a muſcle deſtined for the ſeparation of the placenta. The uterus, in ſhort, is capable of dilatation and contraction, is analogous to the bladder, and acts in the ſame manner; the diaphragm and the abdominal muſcles co-operating to exclude the urine. The irritation which the womb ſuffers at the end of pregnancy, is what determines its action, and is the true cauſe of labours, as will thus appear. Before conception, the cavity of the womb is triangular and flattiſh; the ſides of the triangle are curved, with their convexity inward; this renders the angles very pointed, and leaves the uterus more thick in the middle, and at the fundus, where eminences are formed; the neck of the womb alſo is thick, and equals one third of its length, which, together with the above eminences, may be juſtly conſidered as the magazine or ſtore, in which nature hath ſhut up, and cloſely ſtowed the folded fibres, coiled and doubled, as it were, in reſerve, to expand with the gradual developement of this organ: as in the buds of trees are lodged the leaves and flowers, which to expand and blow, need only the juices of the circulating ſap. In the firſt months the retained menſes humect, and penetrate the tiſſue of the uterus, ſwell and diſtend the fibres, to the end of the fifth month, when, and rarely ſooner, the cervix begins to ſhorten, and diminiſhes daily. The expanſion once begun, continues with the growth of the fœtus, until the whole ſtock of fibres are unbent and exhauſted. At this period, the volume of the fœtus ſtill augmenting, the womb ſtretches beyond its limited dimenſions, becomes irritated, ſuſceptible of pain, and hence labour proceeds. The prelude to labour conſiſts of gentle efforts of ſhort duration; the womb eſſays her force, as it were, exactly filled, and meets with equal reſiſtance on every ſide, except towards the orifice, where the ſenſation of the firſt pain begins. The contraction of the womb acting on the orifice, diſtends its fibres, and cauſes pain; when the orifice is ſufficiently dilated to let the head paſs, the pain ceaſes, but it is renewed when the head enters the vagina, and ſtretches the fibres of theſe parts. Hence the degrees of pains may be accounted for, by the more or leſs extenſion of the orifice, &c. As the neck of the womb hath neither an equal length, nor equal thinkneſs in different women, and as the developement of its fibre may be retarded, or accelerated, by various circumſtances; in ſhort, as the operation goes on in proportion with the increaſe of the child, which may be faſter or ſlower, as well in the womb, as after its *birth*, it is obvious that ſome children may be protruded before the ordinary time of nine months, or their *birth* be protracted until after this term. However ſmall the dilatation of the os internum may be, it will occaſion a ſeparation of the chorion from the uterus, and break the communicating veſſels, ſo that the lymph, &c. that circulated between them, will tranſude, and become the ſource of that mucous diſcharge by the vagina in the beginning of labour: and this ſeparation, affected by gradation, will explain why the placenta retains its adherence until the laſt. If the membranes are ſtrong, their progreſſive ſeparation continues until it arrives at the borders of the placenta, where the ſubſtance, adheſion, and reſiſtance being greater, the bag generally burſts.

In a natural labour, the progreſs of the child's head through different parts, is as follows. The head of the child, if it hath not ſuffered much by preſſure, is near an inch narrower from ear to ear, than it is from the forehead to the vertex. The vertex is the part which preſents in a natural *birth*. The bones that are preſſed together at the preſentation, are the two parietal, and the occipital; ſometimes the frontal bones will be the ſuffering parts. When the vortex firſt preſents, one ear is to the pubis, the other to the ſacrum, ſo that the forehead muſt be to one ſide of the pelvis, and the hind head to the other; thus the wideſt part of the head is here in the wideſt part of the pelvis; ſo that being ſqueezed by labour pains, the vertex deſcends into the lower part of the iſchia, where the pelvis becomes narrower at the ſides, and here is the advantage of the ſacrum being concave; for the forehead now turns round into it, and the vertex toward the pubis, which ſtill takes the advantage of the width of the pelvis; it is then puſhed forwards, turning on as a fulcrum, until the forehead riſes gradually from under the perinæum.

With reſpect to preternatural preſentations, ſee PRÆSENTATIO.

Labours are uſually divided into natural, laborious, and preternatural.

Natural labours are, when the head preſents, and is delivered by common pains, requiring no other aſſiſtance than what is needful in ſaving the perinæum from being lacerated. Laborious labours, called alſo lingering, nonnatural, and difficult. They are when the head preſents, but labour pains being inſufficient, ſome ſafe contrivance becomes neceſſary to bring the head forward; and theſe are of two kinds; firſt, when delivery is effected without deſtroying the child; and ſecondly, when, in order to delivery, the head of the child muſt be opened, that its ſize may be leſſened, and the mother's life ſaved. Preternatural labours are when the legs or breech are delivered firſt, the body and head laſt.

Pains which come on about the time of labour, and ſuch as reſemble labour pains, are not always real labour pains, and therefore ſhould be diſtinguiſhed. Falſe pains, as they are uſually called, which are not the effect of labour, are cauſed by coſtiveneſs, a purging, or a plethora. If the os tincæ is ſhut during the pains, they are falſe, and if the woman is coſtive, give her a clyſter; if a purging attends, gentle opiates will relieve; and if ſhe is plethoric, bleed her. True labour pains are promoted by opium much more than by ſtimulating cordials. Giffard ſays, that clyſters to provoke too languid throws, an opiate to put away falſe pains, and a cordial after delivery (if the woman was low) were all the medicines he uſed. Falſe and true pains ſometimes attend at the ſame time; in this caſe an opiate ſhould be given.

Until the woman is likely to be ſoon delivered, ſhe may be up or in bed; but in order to delivery, the moſt convenient poſture for herſelf and her aſſiſtant is when laid on her left ſide upon a bed, with the knees drawn up towards the belly. Short breathed people may be laid high with their heads, or delivered in a ſitting poſture, with their knees raiſed towards their bellies.

The aſſiſting powers in a natural labour are all the body concurs to help. See Dr. Lowder's MS. Lecture xv. 4. 1ſt, 5th. But particularly we may conſider the diaphragm, abdominal muſcles, feet reſting againſt ſomething to keep the abdominal muſcles tenſe, holding ſomething by which to pull with the hands, that the muſcles of reſpiration may be tightened; a ſtrong inſpiration at the beginning of each pain, and a retention of the breath during its violence, and as the pain abates, a leiſurely paſſing out of the breath. The practice of crying out, and of drawing up the breath as the pain goes off, retracts the fœtus, and leſſens its force in diſtending the parts.

When the child's head preſſes againſt the perinæum, it ſhould be ſupported by gently preſſing with the hollow of the hand during the pain, to prevent its tearing.

Laborious labours may be cauſed by previous weakneſs, unſkilful management, convulſions, paſſions of the mind, rigidity of the os internum, eſpecially when an inflammation is brought on by dilating it with the fingers, and the head being got through, it contracts about the neck;

neck; narrowneſs of the pelvis, largeneſs of the head, a diſtorted pelvis, &c. Lingering labours will ſometimes exhauſt the woman's ſtrength, when the head is in a right poſition, notwithſtanding all our care. The head being long confined in the pelvis, is equally dangerous to the mother and the child; for by its preſſure againſt the ſoft parts it may ſtop the circulation, and bring on inflammation and gangrene, which would prove certain death to the mother, and to the child, by its affecting the brain; when danger of theſe kinds attend, the forceps are to be uſed.

Preternatural labours are more or leſs difficult, according to the poſition of the child and the contraction of the uterus; therefore are divided into three claſſes. 1. When the lower parts of the child, as the feet, knees, or breech, preſent. 2. When it is known that the preſentation is wrong, and we have the advantage of turning the child immediately on breaking the membranes, by means of the waters. 3. When the child preſents wrong, and the uterus is cloſely contracted, the advantage of the waters being loſt.

When it is known that the breaſt, belly, ſhoulders, or any part but the head, feet, knees or buttocks preſent, when the membranes have ſomewhat protruded, break them, and immediately introducing the hand, bring the feet into the paſſage, and ſo deliver, as when the feet preſent. See PRÆSENTATIO.

PARTURITIO. Laborious labour.

PARTUS. The birth.

PARULIS, from παρα, *near*, and ουλον, *a gum*. An inflammation. Boil, or abiceſs in the gums. Dr. Cullen places it as a variety of phlogoſis phlegmone.

PARVOS MEATOS. The cellular membrane of the ancients.

PASMA, i. e. Catapaſma.

PASSA. In Paracelſus it is a whitloe.

PASSERINA. Sparrow's toad flax. Some reckon it a ſpecies of linum, and others of lithoſpermon.

PASSIO. A paſſion, affection, or diſeaſe: hence paſſio hypochondriaca, &c.

PASSULÆ. Raiſins.

PASSUM. Raiſin wine.

PASTA REGIA. A lozenge.

PASTILLUS. A troch or paſtil.

PASTINACA. Parſnep. The root is thick, fleſhy, and juicy; the leaves are large and broad, and ſtrengthened by a thick rib; the ſeed is oval, large, thin, marginated, and caſts its huſk. Boerhaave enumerates eight ſpecies.

PASTINACA SYLVESTRIS, alſo called claphoboſcum, banica, and wild parſnep.

It hath dark green, indented leaves, and ſlender woody roots; it is common about the ſides of fields, flowers in June and July, and ripens its ſeeds in September. On eating the roots a heat is complained of in the mouth which is ſoon followed by thirſt; then the pupil gradually dilates, and the ſight is loſt; a delirium comes on; but on a diſcharge by vomit, theſe ſymptoms ſoon abate; the dilatation of the pupil is the laſt that diſappears. Among the garden ſort a faulty one is ſometimes met with, but wild parſneps are harder when boiled than the garden ſort, at leaſt than the good ones, and thus the bad may eaſily be known.

PASTINACA SATIVA, called alſo paſtinaca hortenſis. Garden parſnep. The leaves are paler coloured than the wild ſort; they are ſmooth and indented; the roots are ſweetiſh and nutritious; they yield with rectified ſpirit of wine a ſweetiſh extract, and in diſtillation with water they yield a ſmall portion of eſſential oil with the flavour of the root; the ſeeds are aromatic, but thoſe of the wild ſpecies are more ſo. Theſe roots are chiefly uſed as a part of diet.

PASTINACA OLUSATRA, called alſo panax heracleum majus, panax paſtinaceæ folio, ſphondylio vel paſtinacæ Germanicæ affinis panax, panax Herculeum, Hercules's all-heal, or wound wort. It hath uncut leaves, and heart-ſhaped, but with one of the ſides lower than the other; the middle ribs bearing the ſeveral ſetts of leaves, which ſtand in pairs along a larger rib. It is a native of the warm climes, and bears the cold of our's. The gum opoponax of the ſhops is the concreted juice of this plant. The ſeeds are much warmer than the wild or the garden parſnep. The roots and the ſtalks ſmell like opoponax. Boerhaave ſays, that on wounding the ſtalk of one of theſe plants, he obtained a juice, which, being inſpiſſated, agreed in all reſpects with the gum called opoponax.

PASTINACA, called alſo ſpondylium, branca urſina Germanica. Cow parſnep. It grows in meadows and the borders of fields; it flowers in July. It is chiefly noted as being a food moſt agreeable to rabbits.

PASTINACA. A name for a ſpecies of ſium, daucus, tordylium, and cuminum.

PATELLA. A dimin. of patina. The knee-pan, called alſo rotula, mola, genu, ſcutiforme os, cartilaginoſum, diſciforme, oculus genu, and cap of the knee. It a flattened bone, ſituated at the anterior part of the joint of the knee, with its broad part upwards, and the pointed part downwards. Its anterior ſurface is ſmooth; its poſterior ſurface is alſo ſmooth, and covered with a cartilage: it is divided internally by a longitudinal ridge, and tranſverſely likewiſe, ſo that there are four cavities, the two lower of which move upon the femur in the extenſion, the two upper in the flexion of the leg. The tendons of the extenſors are inſerted into the upper part of the patella, and a ligament runs from the lower part, to be connected to the tibia. The patella ſuffers the leg to have ſome degree of rotation, which if it had been a fixed proceſs like the olecranum, it would not: it likewiſe is leſs incident to fractures than if it had been one ſolid bone with the tibia. At the time of birth it is cartilaginous.

PATELLA DOCUMASTICA. A cupel or teſt.

PATETÆ UVÆ, or Patetheiſæ. Grapes that dry on the vines.

PATHECA. See JACE.

PATHEMA. An affection or diſorder. See AFFECTIO.

PATHETICI. Diſeaſes in which the appetites and paſſions are principally affected by exceſs or defect. Dr. Cullen places it as ſynonymous with his dyſorexiæ.

PATHETICUS, from παθος, *paſſion*. Becauſe they direct the eye to intimate the *paſſions* of the mind. An epithet of the fourth pair of nerves, ſo called becauſe they direct the eyes to intimate the *paſſions* of the mind. They are alſo called trochleares, and obliqui ſuperiores. They are the ſmalleſt pair in the body, and appear below the edge of the tranſverſe proceſſes; they paſs by the ſide of the ſella turcica, and go through the foramen lacerum orbitale ſuperius, to the ſuperior oblique muſcle.

PATHOGNOMONICUS, from παθος, *a diſeaſe*, and γινωσκω, *to know*. An epithet for a ſymptom or a courſe of ſymptoms that are inſeparable from a diſtemper, and are found in that only, and in no other. Quod convenit omni, ſoli, & ſemper.

PATHOLOGIA, from παθος, *a diſeaſe*, and λεγω, *to ſpeak* or *commemorate*. That part of medicine which explains the nature of diſeaſes, their cauſes, and ſymptoms. In order to underſtand a *diſeaſe*, we ſhould conſider the morbific cauſes, parts affected, ſymptoms, criſis, diagnoſis, and prognoſis: hence pathology is divided into all theſe parts.

PATRUM CORTEX, vel Pulvis, i. e. Cortex Peruvianus.

PATIENTIÆ MUSCULUS, i. e. Levator ſcapulæ; called alſo angularis.

PATOR NARIUM. The ſinus, cavity, or chaſm of the noſe.

PATRIMONIUM. A name for the genitals.

PATURSA. The venereal diſeaſe.

PAULADADUM, i. e. Terra militæ, alſo called terra ſigillata Sancti Pauli.

PAULINA [CONFECTIO]. The confection called paulina. This is a warm opiate. The London College gives a preſcription for it in their Diſpenſatory. It is the paulina of Ariſtarchus, which is the ſame with the confectio Archigenis.

PAVANA, i. e. Moluccenſe lignum.

PAVIA. See HIPPOCASTANUM.

PAVOR. Fear; but ſometimes it ſignifies the itch.

PAYES HERBA. A ſpecies of plantain in Peru. See Raii Hiſt.

PECHEDION. The perineum.

PECHYAGRA. The gout in the elbow.

PECHYS. The elbow.

PECHYTYRBE. An epithet for the ſcurvy.

PECTEN. The pubes, or ſhare-bone. In zoology it is a ſhell fiſh called a ſcallop.

PECTEN VENERIS. Shepherd's needle, or Venus's comb.

PECTINATIO. Combing. It is a ſpecies of friction.

PECTINÆUS vel PECTINALIS Muſc. From *pecten*, i. e. Os pubis. It riſes from the upper part of the os pubis, on the outſide of Poupart's ligament, runs downwards, backwards, and outwards, and is inſerted into the linea aſpera below the little trochanter. Brown ſays it is called pectinæus, becauſe it riſes from the os pectinis (i. e. pubis); it is alſo called lividus, from its colour.

PECTORALIS. Pectoral. An epithet for medicines which are appropriated to diſorders of the breaſts and lungs.

PECTORALIS MAJOR. This muſcle riſes in a radiated manner from the anterior and inferior part of the clavicle, then from the ſternum, and at the lower part from the third, fourth, and fifth ribs, from the cartilage, and partly from the bony portion of the ſixth rib; then paſſes towards the arm, with its upper edge contiguous to the deltoid, betwixt which two the cephalic vein has its courſe; near its inſertion the pectoralis doubles in, on its lower edge, and forms a poſterior and anterior lamella; then it runs to be inſerted into the anterior part of the biceps groove. This muſcle is partly a rotator of the arm, but its great uſe is to bring the arm forward, cloſe to the body.

PECTORALIS MINOR. Some call it ſerratus anticus minor: it lies beneath the pectoralis major. It riſes by three digitations from the third, fourth, and fifth ribs, then paſſes obliquely upwards and outwards, and joins with the ſhort head of the biceps, to be inſerted into the carotid proceſs of the ſcapula. Some make this a muſcle of the ſcapula, others of reſpiration, according as they make or one the other termination the fixed point.

PECTORALIS INTERNUS, i. e. Triangularis ſterni.

PECTORIS OS, i. e. Sternum.

PECTUS. The breaſt; alſo the metatarſus.

PECTUSCULUM. The metatarſus.

PEDECELLI, i. e. Phthiriaſis.

PEDIBUS BOVINUM (Oleum). Neat's foot oil. Is is prepared by boiling the joints of horned cattle in large veſſels.

PEDICULI INGUINALES. Crab-lice.

PEDICULARIA. Staves acre.

PEDICULARIS. A ſpecies of eye-bright; alſo the herb yellow rattle.

PEDICULATIO. The louſy evil.

PEDICULUS. A louſe; alſo a pedicle, or that part of a ſtalk which immediately ſuſtains a leaf, a flower, or a fruit, and is generally called a foot ſtalk.

PEDICUS, i. e. Extenſor digitorum brevis.

PEDILUVIUM. A bath for the feet. The feet are very ſenſible, and a bath of warm water removes their ſpaſm, and, by conſent, ſpaſms and pains in the belly. If the feet are cold, the belly is coſtive; pain, ſuch as the colic, affects it; the ſkin is rough, perſpiration defective, and the ſalutary evacuations from the uterus and hæmorrhoides checked; hence the pedilave is extenſively uſeful. Baths for the feet ſhould be uſed at bed-time, and thus a general perſpiration is produced. If uſed a few days before the menſtrual diſcharge, they promote them.

PEDION. The ſole of the foot.

PEDORA. The ſordes of the eyes, ears, and feet.

PEDUNCULUS. The ſame as pediculus, in both its ſignifications.

PEGANON. Rue.

PEGE. A fountain. The internal angles of the eyes are called pegæ.

PELADA. A ſhedding of the hair from a venereal cauſe.

PELECANUS. A pelecan. The name of an inſtrument for drawing the teeth; alſo a glaſs veſſel formerly uſed in chemiſtry for the digeſtion and circulation of liquors poured in at their narrow necks, which were afterwards hermetically ſealed: at preſent two matraſſes are uſed inſtead of a pelecan, the neck of one being entered into the neck of the other.

PELECINUS. The characters are, in all reſpects, like the aſtragalus, except that the pod is flat, long, bicapſular bivalve, and full of kidney-ſhaped ſeeds. It is alſo caled ſecuridaca peregrina.

PELIOMA. An ecchymoſis when livid coloured.

PELLICULA MEMBRANA. See Angina Membrana. It is alſo in general any thin membrane.

PELLIS. A ſkin of a beaſt. It is alſo called corium and tergus.

PELMA. The ſole of the foot, or a ſock adapted to the ſole of the foot.

PELTATIS CARTILAGO, from *pelta, a buckler*. The ſcutiform cartilage of the larynx.

PELVIS. A name for the inferior part of the cavity of the belly. It is bounded forward by the os pubis, backward by the os ſacrum above, and coccygis below, laterally by the illia above, and iſchia below.

In midwifery, the knowledge of the ſtructure, and peculiarities of the *pelvis*, is an important circumſtance. The brim of a well ſhaped *pelvis* repreſents an irregular oval, or ſomething that approaches to a triangle; if it is conſidered as an oval, its greateſt axis is from ſide to ſide; if we conſider it as a triangle, the poſterior part is far longer, and the oſſa pubis conſtitutes the other two ſides of the triangle; the lower circumference is formed behind by the ſacrum and os coccygis, on each ſide by the iſchium, and ſacro ſciatic ligaments, and before by the lower part of the pubis; when the body is reclined, or half-ſitting, as is were, the brim of the *pelvis* is horizontal, and a line would paſs from the navel through the middle of the cavity; but when a woman is in labour, or near her time, this imaginary line muſt take place higher, and accordingly we find, that the firſt of the external parts, which the head of the child preſſes againſt is behind the anus, and from thence it gradually advances up the perineum, until it comes to the lower part of the ſymphyſis of the oſſa pubis. The chief uſes we are to make of this ſuppoſed line, are, firſt, by it we place the woman in a good poſition during labour; for then ſhe can act more ſtrongly with her abdominal muſcles, and the child's head will fall directly into the middle of the *pelvis*; ſecondly, it will be a direction for us to introduce the forceps upon the child's head, and the hand into the uterus.

In conſidering the *pelvis*, we ſhould obſerve its width, the depth and form of its cavity, and the extent of its brim from the fore to the back part, which, in a well-formed *pelvis*, is an inch leſs than it is from ſide to ſide, four inches and a half from the fore to the back part, and five inches and a half from ſide to ſide.

The lower circumference of the *pelvis* is nearly equal, but when we allow for the os coccygis being moveable, it makes a quarter of an inch more in its longer direction from the os coccygis to the os pubis, than from iſchium to iſchium. The depth of the *pelvis*, from the upper-edge of the ſacrum, where it articulates with the vertebræ lumbarum, to the lower part of the coccygis, is about five inches in a ſtrait line. When the os coccygis is preſſed back, it is then ſix inches; from the brim of the *pelvis*, to the lower part of the ſymphiſis of the os pubis, is only two inches: whereas, from the under part of the iſchium, it is four inches. The brim is concave internally all round.

A ſtrait *pelvis* will cauſe a difficult labour; its ſtraitneſs is known as follows: introduce your finger up the vagina, and if you can feel the os ſacrum, the *pelvis* is ſtrait, or touch the oſſa pubis with your fore-finger, and ſtrive to touch the vertebræ of the loins with your middle finger; if you can reach them, it is narrow; if not, it will do.

PELVIS. It is the name for a cavity in the kidnies.

PELVIS AURIUM. The cochlea of the ear.

PELVIS CEREBRI. The infundibulum in the brain.

PEMPHIGO, i. e. Pemphigus.

PEMPHIGODES, or Pemphingodes. Fevers diſtinguiſhed by flatulencies, and inflations, in which we feel a ſort of aerial effluvia paſſing through the ſkin of the patient in the manner of an exhalation, and ſtriking upon the touch. Galen's Com. on 6 Epid. ſect. i. aph. xvii. Others ſay it is a fever, by the intenſeneſs of whoſe heat

puſtules are excited in the mouth, called aphonæ, or thruſh. Fœſius ſays, that ſome will have it to be a ſynochus, in which, by the heat, the blood veſſels are inflated, whence ſome call it an inflative fever.

PEMPHIGUS. The veſicular fever. Dr. Cullen places this genus of diſeaſe in the claſs pyrexiæ, and order exanthematæ. He defines it to be a contagious typhus. It is a rare diſeaſe in this country. On the firſt, ſecond, or third day of the diſeaſe, little veſicles, the ſize of oats, appear on different parts of the body; they continue a few days, and at laſt exude a thin ichor. See Acta Helvetica, vol. ii. p. 260.

PEMPTÆUS. An ague, the paroxyſm of which returns every fifth day.

PENICILLUS. A tent or pledgit.

PENIDIUM SACCHARUM. It is what the confectioners ſell under the name of barley-ſugar.

PENIS, from *pendo vel pendendo, to hang*, becauſe it hangs without the belly. It is compoſed of three parts, viz. the two corpora cavernoſa, and the corpus ſpongioſum urethræ. Its ſkin, which is thin, and without fat, hath a reduplication, which makes a hood to the glans, called preputium; the ſmall ligament, by which it is tied to the under-ſide of the glans, is called frænum; the uſe of the prepuce is to keep the glans ſoft and moiſt, and to preſerve its ſenſibility. The penis hath a ſmall ligament, which ariſes from its back, a little from its root, and which ties it to the upper part of the os pubis. It receives two branches of veins from the hypogaſtric veſſels, and its arteries from the hypogaſtric and pudicæ; the two veins unite towards its root, and make one trunk which runs on the back of the penis. It hath two nerves from the ſacrum, and ſeveral lymphatics, which empty themſelves into the inguinal glands. It hath three pair of muſcles, viz. the erectores, acceleratores, and tranſverſales. Cowper obſerves, that the cuticula on the glans penis is villous or downy, and that the cutis is thinner here, and, on the ſcrotum, than any where elſe. Regnerus de Graaf accurately deſcribes the penis. Ruyſch deſcribes the glans penis better than de Graaf. See alſo Cowper's Obſervations on the Penis.

PENNA. A feather. It alſo ſignifies a ſubmarine plant which grows on rocks, and reſembles a bird's-wing, which is alſo called mentula alata. If a feather is ſwallowed, it ſhould, if poſſible, be extracted. In the third vol. of the Lond. Med. Obſ. and Inq. p. 7, &c. is an account of a ſucceſsful attempt to recover a quill from the ſtomach, by means of a whalebone with a ſponge at each end, to each of which was a thread looſely connected, and by which the quill was entangled, and ſo brought up.

PENO-ABSOU. A tree in America, whoſe bark is very fragrant, and whoſe fruit, which is the ſize of an orange, contains from ſix to ten nuts, from which an oil is expreſſed. The fruit is poiſonous, but the oil is uſed to cure the wounds received by poiſoned arrows.

PENTADACTYLON. A name for the palma Chriſti.

PENTANEURON, i. e. Plantago anguſtifolia major.

PENTAPHARMACUM. A medicine conſiſting of five ingredients.

PENTAPHYLLOIDES. Barren ſtrawberry.

PENTAPHYLLUM. Cinquefoil. i. e. Potentilla reptans, Linn. A name alſo for ſeveral ſpecies of quinquefolium, and pentaphylloides, alſo a ſpecies of ſinapiſtrum, and of hermodactyls.

PENTAPLEURUM, i. e. Plantago anguſtifolia major.

PENTOROBUS. Peony.

PEPASTICA. Digeſtive medicines.

PEPITA NUX. Ignatius's bean.

PEPLION, or Peplos. They were purging medicines for evacuating bile and phlegm. Sometimes it is ſpoken of under the names of mecon, meconis, and meconium; alſo wild andrachne, chamæſyce, papaver ſpumeum, ſymphytum, and tithymalus.

PEPO. Common Pompion. Boerhaave enumerates fifteen ſpecies. They are not eaſily digeſted. By preſſure an oil is obtained from their pulp, which ſoftens the ſkin. See Raii Hiſt.

PEPTICOS. Digeſtive, or that promotes digeſtion.

PEQUETI RECEPTACULUM. Pecquet's receptacle, or reſervoir, i. e. receptaculum chyli.

PERAGU. A ſhrub in Malabar, whoſe juice kills worms, and its roots cure the tinetery, colic, &c. See Raii Hiſt.

PERCEPIER, alſo called chærophyllo, alchimilla montana minimæa, polygonum ſelinoides. Parſley breakſtone, or parſley piert. It is a low plant; it lies chiefly on the ground; its branches are hairy, full of ſmall leaves, ſet alternately at the points. It grows in dry places, and fallow fields, and alſo among corn. It is ſaid to be diuretic, but it is of too little efficacy to deſerve much notice. Raii Hiſt.

PERDETUM. In Paracelſus it is the root of ſkirret.

PERDICIUM, i. e. Parietaria.

PEREGRINUM LIGNUM, i. e. Nephriticum lignum.

PERESKIA. A plant with a roſe-ſhaped flower, which is met with in the Spaniſh Weſt Indies. In the Engliſh American ſettlements it is called a gooſeberry. The Dutch call it a blad apple. See Miller's Dict.

PERETERION, from *περαω, tranſfodio, to dig through.* The perforating part of the trepan.

PERFECTI MAGISTERII. Oil of bricks.

PERFOLIATA, called alſo bupleurum, thoroughwax. It is a plant with a ſmall fibrous ſticky root, from which ſprings ſmooth, and often reddiſh ſtalks. The leaves are oval-ſhaped, of a blue green colour; the flowers are of a yellow colour. It grows amongſt corn, is ſaid to be vulnerary, but is of little note in practice. See Raii Hiſt.

PERFOLIATA. Boor Cole.

PERFORANS MANUS, i. e. Flexor tertii internodii digitorum manus.

PERFORANS PEDIS, i. e. Flexor longus pedis.

PERFORATA. St. John's-wort.

PERFORATIO, Sometimes it ſignifies a ſeton.

PERFORATUS MANUS, i. e. Flexor internodii ſecundi digitorum manus.

PERFORATUS PEDIS, i. e. Flexor ſublimis pedis.

PERFORATUS CASSERII, i. e. Coraco-brachiæus muſculus.

PERFRICTIO. Shivering, or coldneſs. See HORROR.

PERIAMMA, i. e. Periapta.

PERIADYSMIA. Pain in the ſtomach.

PERIANTHIUM. It is the outermoſt part of a flower, which ſurrounds it before it is blown, and forms a kind of ſupport for it afterwards. Dr. Grew calls it the empalement, ſome improperly call it the calyx or cup, for the calyx is properly the hollow cup formed by the empalement, out of which the other parts of the flower grow. Some flowers, whoſe petals, or flower leaves, have a firm and ſtrong baſis, ſufficient to ſupport themſelves, therefore ſtand in need of an empalement, as the tulip, &c. which have none; theſe, however, have a calyx.

PERIAPTA. People on whom amulets were fixed for the removal of a diſeaſe. Blanchard ſays, it is a medicine which being tied about the neck, is believed to expel diſeaſes, eſpecially the plague.

PERIBLEPSIS, from *περιβλεπω, to ſtare about.* That kind of ſtaring look which is obſerved in delirious perſons.

PERIBOLE, from *περιβαλλω, to ſurround.* Sometimes it ſignifies the dreſs of a perſon; at other a tranſlation of the morbific humours to the ſurface of the body.

PERICARDIA ARTERIA. The artery of the pericardium. This ariſes from the anterior middle part of the common trunk of the ſubclavian, or the carotid; it runs down upon the pericardium all the way to the diaphragm, to which it ſends ſome branches.

PERICARDIA VENA. The vein of the pericardium. It ſometimes ſprings from the trunk of the ſuperior cava, at others from the origin of the right ſubclavian. The left vena pericardia comes ſometimes from the left ſubclavian before the mammaria, ſometimes from the mammaria or diaphragmatica ſuperior on the ſame ſide.

PERICARDITIS. Inflammation of the pericardium. Dr. Cullen places this diſeaſe in the genus carditis, which ſee.

PERI-

PERICARDIUM, from περι, *about*, and καρδια, *the heart*. The firſt membrane of the *pericardium* is formed by the pleura, which is connected to the *pericardium* by a cellular membrane, but this is only an occaſional covering, leaving the *pericardium*, where it adheres to the diaphragm. The ſubſtance of the *pericardium* is a ſtrong tough membrane, compoſed of two lamellæ, the external of which is by much the ſtronger; the internal is a complete bag, without perforation, being effected over the *heart* itſelf. This internal coat contains the fluid called liquor pericardii, which was ſuppoſed to be ſecreted by glands lodged there, but is certainly ſecerned by the ſmall continuations of the arteries. In ſound habits this liquor is found in a ſmall quantity; in unſound habits we find a larger quantity: its appearance is like ſerum, a little tinged with blood. The redneſs is owing to the tranſudation of the blood in the muſcular cavities of the *heart*; and the longer the body is kept, the redder the liquor grows. The uſe of the *pericardium* is to afford the liquor, and to confine the *heart*; and as it is connected by a great ſurface of the diaphragm, perhaps it keeps the *heart* unmoved by the motions of the diaphragm in inſpiration: but there is very little in this, as the middle of the diaphragm hath very little motion in inſpiration and expiration. The *pericardium* is much larger than the *heart*; it is not fixed to the baſis of the *heart*, but round the large veins above the auricles before they ſend off the ramifications, and round the large arteries before their diviſions.

PERICARDIO-DIAPHRAGMATICÆ VENÆ, i. e. Diaphragmaticæ ſuperiores.

PERICARPIUM, from περι, *about*, and καρπος, *the wriſt*. A topical medicine, applied to the *wriſts*.

PERICARPIUM, from περι, *about*, and καρπος, *fruit*. It is whatever ſurrounds the *fruit* of vegetables, whether membrane, huſk, or pulp. Some reſtrain it to the ſoft and moiſt pulp which covers the ſeeds, as in apples, &c.

PERICHONDRIUM. The *perichondrium* is ſaid to be only a continuation of the perioſteum. This Dr. Hunter ſays may be true of that ſort of cartilage which ſupplies the place of bone in an adult, as the trachea; or in ſuch as ſupplies the place of bone in infants, as epiphyſes; but on the cartilages that are expanded over the extremities of articulating joints, the *perichondrium* is the inner layer of the capſular ligament, reflected over the cartilage extremely fine. This is not diſcoverable in adults, but in young ſubjects, where the parts are ſeparable, it is eaſily diſcernable.

PERICHRISIS. A liniment.

PERICHRISTA. Any medicine with which the eyelids are anointed in an ophthalmia.

PERICLASIS, from περι, *about*, and κλαω, *to break*. A fracture with a great wound, wherein the bone is laid bare.

PERICLYMENUM. A name for ſeveral ſorts of caprifolium.

PERICLYMENUM PARVUM, i. e. Ipecacuanha.

PERICRANIUM, from περι, *about*, and κρανιον, *the head*. The membrane which immediately inveſts the bones of the ſkull, or under the hairy ſcalp. It is made up of two lamina, cloſely united; the external lamina parts from the internal at the ſemicircular plane ſurrounding the temples, and becomes a very ſtrong aponeurotic, or ligamentary expanſion, which covers the temporal muſcle, and is afterwards fixed in the external angular apophyſis of the os frontis, in the poſterior edge of the ſuperior apophyſis of the os malæ, and in the ſuperior edge of the zygomatic arch, as far as the root of the maſtoid apophyſis. At this place the aponeurotic coif ſeems to form the external lamina of the *pericranium*, and they both communicate with particular aponeurotic expanſions of the maſtoid, maſſeter, zygomatic, and other neighbouring muſcles.

PERIDESMICA (ISCHURRIA). A ſuppreſſion of urine from ſtricture in the urethra.

PERIDROMOS. The extreme circumference of the hairs of the head.

PERIESTECOS, from περιιστημι, *to ſurround*, or *guard*. An epithet for diſeaſes, ſigns, or ſymptoms, importing their being ſalutary, and that they prognoſticate the recovery of the patient.

PERIGRAPHE. An inaccurate deſcription or delineation. In Veſalius, *perigraphæ* are certain white lines and impreſſions, obſervable in the muſculus rectus of the abdomen.

PERIN. A teſticle. Some explain it the perinæum, others ſay it is the anus.

PERINÆOCELE. A rupture in the perinæum.

PERINÆUM, from περαω, *to flow round*. Becauſe that part is generally moiſt. It is the ſpace between the anus and the parts of generation; it is divided into two equal lateral portions by a diſtinct line, which is longer in males than in females.

In midwifery it is obſerved, that when the os externum is ſo much dilated by the head of the fœtus, as to allow the delivery of the ſame, it is generally ſtretched to the length of three, and ſometimes of four inches; whence at this time delivery ſhould not be precipitated, leaſt a laceration in this part ſhould be the conſequence. Inſtead of ſtretching back the *perinæum* with the finger, as is the practice of ſome, it ſhould be ſupported with the palm of the hand, and the head of the child, at the ſame time, moderately oppoſed in its force againſt it, until a ſufficient dilatation will render delivery ſafe. Inflammations, and lacerations of the *perinæum*, if they occaſion vomiting, they are fatal in a few days. If a laceration happens, keep the woman long in bed, and adviſe her to keep her knees cloſe, as conſtantly as poſſible; her bowels ſhould be kept ſoluble.

The puncture of the *perinæum*, is an operation which was uſed to be performed when the bladder was under ſuch a ſuppreſſion of urine as could not be relieved by any gentler method. The operation was performed by puſhing a trochar from the place where the external wound in the old way of cutting for the ſtone was made, into the cavity of the bladder, and ſo procuring the iſſue of the water through the canula. At preſent, inſtead of this method, the water is evacuated by puſhing the trochar into the bladder, from a little above the os pubis. This method of diſcharging the urine hath ſucceeded, but when the ſuppreſſion is of any conſiderable ſtanding, the operation is dangerous. See Le Dran's Operations; Sharp's Operations; and Sharp's Critical Enquiry.

PERINÆALIS (ISCHURIA). A ſuppreſſion of urine from a tumor in the perinæum.

PERIN-KARA. A wild olive-tree of vaſt growth in Malabar. See Raii Hiſt.

PERIN-NIROURI. A bacciferous ſhrub in Malabar. See Raii Hiſt.

PERIN-PANEL. A bacciferous Indian ſhrub, the leaves of which are uſed in ſuffumigations againſt hyſteric ſymptoms. See Raii Hiſt.

PERINYCTIDES. Puſtules, or pimples, which break out in the night.

PERIOSTEUM, from περι, *about*, and οστεον, *the bone*. It is that membrane which covers the bone. It is divided by authors into two layers; the internal layer (or *perioſteum* itſelf) lies cloſe to the bone, and appears furrowed, as the bone is: this is one of the fineſt, thinneſt membranes imaginable, and appears upon a ſucceſsful injection to be extremely vaſcular; the reaſon of which is, that the veſſels which run to the bone play a while upon the ſurface of this membrane, before they enter into the ſubſtance of the bone. The external layer is of a white gliſtening appearance. It is merely adventitious, being compoſed of the fibrous expanſions of membranes, ligaments, and tendons, wherefore it runs in various directions, according as theſe tendons, &c. are variouſly inſerted. The *perioſteum* is not elaſtic; Dr. Hunter thinks it is not very ſenſible, and adviſes in amputations not to ſcrape it, but only to paſs the knife about it, a little above the place where you intend to ſaw. The *perioſteum* is wanting on thoſe parts of a bone where ſtrong tendons enter, as in the trochanter. The uſes of the *perioſteum* are, to prevent the bad effect of friction on the bones, to protect the veſſels running into the bones; to connect epiphyſes; and to give origin to muſcles.

PERIPHIMOSIS, i. e. Paraphimoſis.

PERIPLEUMONIA, i. e. peripneumonia; periploca, i. e. Virginian ſilk.

PERIPLOCA. Italian and French ſcammony, called alſo ſcammonia Monſpeliaca rotundioribus, apocynum latifolium. Its concreted juice purges in ſomewhat larger doſes than the ſcammony of the ſhops. Boerhaave takes notice of four other ſpecies, but they are not purging.

PERIPNEUMONIA. A peripneumony, from περι, *about*, and πνευμων, *the lungs*. Dr. Cullen places it as a ſpecies of pneumonia, or inflammation of the contents of the

the thorax. Ruyſch ſays, it is an inflammation of the bronchial artery only. Hoffman ſays, that the ſeat is the bronchial and pulmonic arteries, and their lateral lymphatic veſſels.

Three kinds of *peripneumonies* are diſtinguiſhed, as follows: the true, or inflammation in the *lungs*; the ſpurious, or when a pituitous matter obſtructs the veſſels of the *lungs*; the catarrhous, or when a thin acrid defluxion on the *lungs* is the cauſe.

The true *peripneumony* is produced by cold applied to the ſkin, or mouth, or ſtomach; by an inflammatory diatheſis; an over diſtention of the *lungs*; or by any of the general cauſes of inflammation. Such cauſes as particularly affect the *lungs*, are a faulty air, cauſtic matter in the atmoſphere, or other faulty exhalations, violent exerciſe of the *lungs*, by running, wreſtling, &c. violent diſturbances of the mind, a quinſy, accompanied with an orthopnœa, a violent pleuriſy, or an exceſſive paraphrenitis. The diſorder excited, various effects will be produced, according to the diverſity of the part affected; for a bronchial inflammation by compreſſion and contagion inflames the contiguous extremities of the pulmonary artery. When the extremities of the pulmonary artery are inflamed, the blood becomes ſtagnant, the veſſel is extended, the thineſt part of the fluids is expreſſed, as it were, by tranſudation, and the thicker parts are accumulated: and all the blood, as yet capable of circulation, is collected between the right ventricle of the heart, and the extremities of the pulmonary arteries: hence the *lungs* become oppreſſed, incapable of expanding, and are livid, the left ventricle of the heart is deprived of blood, a great weakneſs is brought on, with a variety of other ſymptoms, as follow:

This fever is of the inflammatory kind, and begins with an obtuſe pain in the breaſt, which is rather tenſive and oppreſſive than acute; ſometimes this pain is felt in one, and ſometimes in both ſides; ſometimes it extends along the reins, at others it ſhoots to the back and to the ſcapulæ; the breathing is difficult, and affected with a kind of ſnoring; a cough uſually attends; it is ſometimes dry, at others the matter diſcharged is bloody, or chiefly blood; this cough is more acute than that which attends in the pleuriſy, the air from the *lungs* being particularly hot; the mouth, tongue, and ſkin, are very dry; there is a ſenſe of fulneſs in the thorax, anxiety about the præcordia, with reſtleſſneſs and toſſing in bed continually; this reſtleſſneſs never fails to attend, and that even in the beginning; ſleep becomes a ſtranger; the pulſe is commonly hard, always quick, but ſeldom ſtrong, or regularly full; it is ſometimes ſoft, ſlender, and intermitting; before bleeding it is hardly to be perceived in ſome caſes, but after bleeding it is ſtronger; the urine is often turbid; the difficuly of breathing, and the ſenſe of fulneſs increaſe; and a quantity of thick mucus being ſecreted, occaſions a ſound as the air paſſes through the branches of the trachea: if the ſymptoms are violent at the firſt, the patient is not able to lie down; when he does, it is only on his back, for he can hardly breathe if not erect, and the paſſage of the blood through the *lungs* is obſtructed, ſo that he fears ſuffocation; the veins of the neck ſwell, the pulſe becomes every way irregular; one arm is often affected as if with a palſy; the face ſwells, is of a dark colour, eſpecially about the cheeks and the eye-lids; and if the weather is ſultry, livid ſpots appear on the neck and breaſt, the tongue ſwells, and is of a dark red colour; the eyes are dull; a ſtupor, and a low delirium ſucceed, in which the patient raves, and ſeems neither aſleep nor awake; ſometimes there is a degree of paleneſs, and an air of aſtoniſhment at the beginning of the diſeaſe, the eyes ſtaring wildly, and this portends much danger. The beſt expectoration reſembles what is ſpit up with a cold, but rather more yellow and ſtreaked with blood, but becoming leſs ſo; inexpreſſible anguiſh is felt, and at laſt the patient is ſuffocated. If the ſymptoms do not ariſe to ſo great a height, and at the ſame time no means of reſolution have been applied before the fourth day, as if theſe means are not ſufficiently powerful, or if they are not continued until the diſeaſe is totally carried off, a ſuppuration takes place, and is indicated by ſlight and frequent ſhiverings; the pain at the ſame time going off gradually, the ſenſe of fulneſs, and the cough, with the other ſymptoms diminiſhing, and the patient being only able to lie on that ſide which was moſt affected.

This diſorder ſhould be diſtinguiſhed from a pleuriſy; from a difficulty of breathing in fevers; from the ſpurious peripneumony; inflammation in the mediaſtinum, or in the intercoſtal muſcles; from the catarrh, the aſthma, and other difficulties of breathing which happen in chronical diſeaſes.

A white ſediment in the urine, or a red ſediment changing to a white, promiſe a ſafe and ſpeedy recovery. If the *peripneumony* takes place after a cold fit of a fever, and the fever continues along with the inflammation, which hath been relieved either naturally or artificially, a criſis in the ſecond week ſometimes carries off both diſeaſes. If in the young and robuſt, a bloody ſpit appears on the fourth day, it is a good ſign; and if on the ſeventh day the ſame patient ſweats ſpontaneouſly, the diſeaſe is ended. If in phlegmatic and languid conſtitutions, when the diſorder hath a deep ſeat in the *lungs*, there is a termination of the diſeaſe on the eleventh or fourteenth day, partly by expectoration, and partly by ſweat, the pulſe becoming ſofter, the ſleep calmer, and the ſtrength being increaſed, the diſeaſe ends well. If the diſorder continues to the twenty-firſt day, an abſceſs will be the conſequence. It is moſt dangerous in flat-breaſted, and in aſthmatic perſons. Frequent ſtools, and urine without any ſediment, are bad ſigns. If the pulſe is ſmall, ſoft, and irregular, the danger is great. If the diſeaſe ruſhes on at once with a violent attack, if the horror, coldneſs, and ſhivering, laſts many hours, and are followed with nearly a ſcorching heat; if the brain is affected at the firſt onſet; if there is a ſmall purging with a teneſmus; if the patient abhors the bed; if either exceſſive ſweating, or exceſſive dryneſs of the ſkin attend; if the natural countenance is greatly changed, great danger attends. Suppuration generally proves fatal.

Avoid the extremes of heat and of cold where the patient lays. All the drink and medicines ſhould be milk warm.

Dr. Fordyce, in the ſecond part of his Elements, ſpeaks of a natural cure. He ſays, that this may happen by a ſecretion of mucus from the *lungs*, which at firſt is ſpit up thin, and with uneaſineſs, becoming gradually thicker, and of a yelloviſh or greeniſh caſt; it is often mixed with blood, relieving, and gradually diminiſhing the ſymptoms, ſo as to carry off the diſeaſe before the fourteenth day. Or, this diſorder may depart by an hæmorrhage, or by an inflammation ariſing in ſome other part of the body, as the noſe, &c.

The artificial cure, the ſame author obſerves, is effected by ſimple reſolution, or by evacuation from the mucous glands. The firſt method is to be purſued in the robuſt, the ſecond in the more infirm. Thus, in all caſes, on due bleeding, or expectoration, the cure chiefly depends.

When the cure is attempted by reſolution, the firſt ſtep will be to bleed freely. This operation muſt be uſed in point of frequency, according to the ſtrength of the pulſe, or its fulneſs and firm hardneſs. A large orifice ſhould be made by which to diſcharge the blood. The ſooner blood is taken away, the more beneficial its evacuation proves. When from the violence of the inflammation, the pulſe is ſmall, very frequent, and irregular, it often riſes, and becomes regular after the operation; and from the diſeaſe increaſing, or recurring, it is frequently neceſſary to repeat this evacuation two or three times. As ſoon as the preceding cold fit is over, take from a large orifice from ℥ xii. to ℥ xvi. of blood; this large bleeding gives more relief than twice the quantity taken at three times, and except ſymptoms promiſe well after the firſt bleeding, take from ℥ viii. to ℥ xii. more in four hours after; and, as required, repeat it in ſomewhat leſs quantities in ſix or eight hours after. If florid frothy blood is ſpit up, bleed as far as the patient's ſtrength will admit; but if the blood which is taken from a vein appears pale, and jelly-like, without the true buff; or if a ſpitting is already come on, bleeding will be injurious. The air in the room ſhould be kept moderately warm. The vin. antim. and ſal diuret. ſhould be given in the uſual doſes when given in inflammatory fevers; and if they are repeated every hour, or at leaſt every two hours, their efficacy will be more ſuited to the intention of giving them. Emollient clyſters,

in which nitre is diſſolved, ſhould be frequently injected. Nitre may be mixed in every draught of the patient's drink, or it may be rendered agreeably acid by the addition of Clutton's febrifuge ſpirit. Bliſter the back and ſides, eſpecially after bleeding, appears not a ſafe method to purſue: if in the courſe of the diſorder expectoration ſtops too ſuddenly, and is not immediately followed by ſome other evacuation, bliſter both the legs. A decoction of the rad. ſerpent. ſeneka, given in proper doſes, and at due intervals, is of ſingular advantage.

If expectoration is attempted as the means of relief, bleeding is rarely admitted of. If the expectorated matter be yelloviſh, or ſtreaked with blood, by keeping it up, the moſt deſirable ends will be anſwered. The gum ammoniacum is uſually preſcribed in this caſe, but the tart. emet. or the vin. antim. given in ſuch doſes as will keep up a nauſea, are of more extenſive efficacy. But expectorating medicines, as ſuch, muſt not be given before the matter to be diſcharged becomes fit for excretion, for otherwiſe a greater flow of humours will be invited to the lungs. Vapours from warm water, may be frequently received into the lungs with the breath. From the beginning give the decoct. rad. ſenekæ, beſides which but few other medicines will be required. If the diſeaſe ſeems to be of a mixed kind, or if the lungs are not ſo much inflamed, as they are loaded with a viſcid or pituitous matter, apply bliſters between the ſhoulders, and on the ſides. When the mucus that is ſpit up is very thin, opiates may be uſed in ſmall doſes, to moderate the pain; and, to eaſe the cough, let mucilages be frequently ſwallowed. A ſharp ſudden cold air, too hot an air, but medicines, exceſſive ſweating, imprudent purging, and diſturbed paſſions of the mind, may any of them check expectoration, in which caſe proceed as already directed. This diſorder, though generally carried off by expectoration, is ſometimes removed by urine, which on the ſeventh, ninth, or eleventh day, or ſometimes in the intermediate days begins to let fall a plentiful ſediment of a pale red colour, and ſometimes real pus; theſe diſcharges are ſucceeded by ſalutary ſweats, but are preceded by anguiſh, palpitations, an irregular pulſe, &c. If the pulſe flags, give a few grains of the ſal. c. c. with the conſ. cardiac. If when blood is taken away from a vein. it appears of a looſe or broken texture, immediately deſiſt from any diſcharge of it, and begin with the uſe of cooling antiputreſcents, as the acet. camphorat. the juice of oranges or lemons in the patient's drink, or let his drink be acidulated with Clutton's febrifuge ſpirit, joined with ſome proper cordial, &c.

A *peripneumony* is very apt to return on a little irregularity of diet. It terminates variouſly, as by a reſolution, a ſuppuration, a ſcirrhus, a copious ſpitting, a bilious flux, or by a copious thick urine, in which is either a ſediment of a pale red colour, or of a purulent quality. When the patient dies, he is carried off by a ſuffocation, from the difficulty of coughing up the matter which is lodged in the lungs.

PERIPNEUMONIA NOTHA. The ſpurious, or baſtard peripneumony. This diſorder may appear at any time in the year, but for the moſt part it approaches early in the ſpring, particularly after a very ſharp winter. This kind of *peripneumony* is chiefly diſtinguiſhed from a dry aſthma, by the degree of fever, and ſigns of inflammation which are manifeſt in it; in moſt ſymptoms, the ſpurious *peripneumony* alſo reſembles the true, but the heat, pain, and thirſt are not ſo conſiderable in the firſt as in the laſt.

Thoſe advanced in years, and thoſe of any age who have a groſs habit of body, and are addicted to ſpirituous liquors, alſo thoſe who are ſubject to catarrhs are moſt ſubject to this kind of diſorder.

It is often cauſed by cold north and north-eaſt winds. Bodies that are loaded in the winter with groſs and ſluggiſh humours, which at the approach of ſpring are rarefied, the lungs, becoming turgid therewith, a bad cough is produced, and then the *peripneumony* is ſoon introduced. A redundant viſcid ſerum, or even a putrid tendency in the juices may induce this diſeaſe. The drying up of an old ulcer or an iſſue, may, in ſome circumſtances, be a cauſe. A weakened ſtate of the lungs, as when an œdema forms itſelf there, may alſo occaſionally be productive of this diſeaſe.

Boerhaave obſerves, that the baſtard *peripneumony* ſteals upon the patient unawares with a ſlight wearineſs, weakneſs, a general proſtration of the faculties of the mind, thick and ſhort breathing, and an oppreſſion of the breaſt. The commotions it excites are ſo ſmall, that the heat and fever are ſcarce ſufficient to make the patient ſenſible of his diſorder, afterwards ſlight ſhiverings, which come on by fits, and the attacks of a gentle fever appear, whence difficulty of breathing, and weakneſs ſuddenly increaſing, bring on death, of which there was ſcarce any ſign by the pulſe or urine. Sydenham was one of the firſt who diſtinguiſhed this diſorder from a catarrh, and he gives the following account of its manner of invaſion, and its progreſs. The patient is hot and cold alternately, giddy, complains of an acute pain in the head, when the cough is moſt troubleſome; he vomits up all liquids, ſometimes with, and at others without coughing; the urine is turbid and intenſely red; the blood taken away reſembles pleuritic blood; the patient breathes quick and with difficulty; if he is adviſed to cough his head achs as if it would burſt; a pain is felt in the whole breaſt; a wheezing is obſerved by the attendants whenever the patient coughs. To what Sydenham hath ſaid it may be added, that the patient's cheeks and eyes often appear red and inflamed, the pulſe is ſmall, a low fever attends, and the urine is generally pale coloured.

If the ſtrength does not return after the diſeaſe is removed; if the pulſe is ſtill quick, though ſoft; if the breathing is difficult and oppreſſed; if there is at times a cold ſhivering, with flushing in the cheeks, the lips are dry, and the appetite defective, a phthiſis may be expected ſoon.

The indications of cure will be to expel the pituitous colluvies. 2dly. To ſtrengthen the habit in general, and the lungs in particular.

Attenuating ſtimulating expectorants, ſtomach purges, emetics, bliſters, both by their ſtimulus and diſcharge, and iſſues in the inſide and bottom of the knee, are all thought uſeful. For common drink, muſtard whey, or a decoction of madder-root, will be very convenient; bleeding, except in a ſmall quantity, when comatous ſymptoms appear, is not to be practiſed, but bliſters applied to the back, ſides, and arms, with gentle puking at proper intervals, and ſuitable expectorants may be much depended on. The decoct. rad. ſenek. is alſo uſeful in this diſorder.

If the cough is violent, opiates will be very uſeful, and may be given as ſoon as expectoration is become tolerably free; a mixture of the pil. e ſtyraci & pil. Rufi may be ſafely given in doſes, as circumſtances may require. To keep the bowels lax is a neceſſary point in order to relief, and the opiate may be given to any quantity, not to interfere wholly with the uſual efficacy of the purgative which it accompanies.

As expectoration is a principal means of relief, to the ſaline draughts made with the ſp. Minder. add as much of vin. antim. as will excite and keep up a nauſea, thus every uſeful ſecretion and excretion will be promoted.

When the breathing is eaſy, and expectoration free, begin to ſtrengthen the habit by means of the bark, to each ounce of which a dram, or more, of the balſam of Tolu may be added; mild chalybeates may alſo be uſed.

This diſorder terminates by a ſpitting, a bilious flux of the belly, or by plenty of thick urine, with a thick ſediment.

On inflammations of the lungs, ſee Trallian, Cœlius Aurelianus, and Aretæus; and on both the kinds of *peripneumony*, ſee Hoffmann, Boerhaave, Sydenham, Shebbeare's Theory and Practice of Phyſic; Fordyce's Elements, part ii. Brooks's Practice of Phyſic.

PERIPYEMA. A collection of matter ſurrounding any part.

PERIRRHOEA, from περιῤῥέω, *to flow from every part.* A copious flux of the humours, or morbific matter, from all parts of the body, to the proper emunctories, in order to their diſcharge, or rather the diſcharge itſelf.

PERIRRHEXIS. A ſpitting of blood from a rupture of the veins in the lungs.

PERISCYPHISMUS. It is an incision made acroſs the forehead, or from one temple to another, over the upper part of the os frontis, over the coronary ſuture. It

was formerly uſed when a conſiderable inflammation, or defluxion in the eyes attended. The lips of this wound are to be kept aſunder with lint, or when the diſorder abates, raſp the denudated bone, and proceed to healing. See P. Ægineta, lib. vi. c. 7.

PERISTALTICUS, from περιστελλω, *to compreſs*, or *contract*. The motion by which the inteſtines protrude the fæces, is called the periſtaltic motion. It is a worm-like motion.

PERISTOMA. The villous coat of the inteſtines.

PERISTAPHILO-PHARYNGÆI. Two ſmall muſcles inſerted between the uvula and lower extremity of the internal ala of the apophyſis pterigoidæus; they run obliquely backward on the ſides of the pharynx. They are difficult to find in very lean ſubjects, and ſeem to be what M. Santorini calls hypero-pharyngæi, or palato-pharyngæi.

PERISTAPHYLINUS EXTERNUS, i. e. Sphenoſalpingo-ſtaphylini.

PERISTAPHYLINI INTERNI, i. e. Petro-ſalpingo-ſtaphylini.

PERISYSTOLE. The interval of reſt betwixt the ſyſtole and diaſtole of the heart.

PERITERION. The perforating part of the trepan.

PERITONÆORIXIS. A burſting of the peritonæum, and conſequent hernia.

PERITONÆUM, from περιτεινω, *to extend round*. Dr. Douglas is the firſt who hath given us any true idea of this membrane which lines the belly, and inveſts all the viſcera contained therein. It is of a cloſe texture, and yet very pliable; it is capable of great extenſion, after which it can recover itſelf, and be contracted to its ordinary ſize, as appears in pregnancy, &c. It is connected to all the circumambient parts by a cellular membrane; it is this cellular membrane (which is generally called the external lamella of the *peritonæum*) which forms what we call the proceſſes of the *peritonæum*. The *peritonæum*, nevertheleſs, hath productions of its own; but they are different from thoſe of the cellular membrane, for they run from without inwards, and give an external covering to the contained parts.

PERITONITIS. Inflammation of the peritonæum, including the meſentery and omentum. Dr. Cullen defines it to be a fever, with pain in the belly, which is increaſed when the body is erect; but without other proper ſigns of abdominal inflammations, &c. places this genus of diſeaſe in the claſs pyrexiæ, and order phlegmaſiæ; and diſtinguiſhes three ſpecies. 1. *Peritonitis* propria; that is, when the peritonæum, ſtrictly ſo called, is inflamed. 2. *Peritonitis* omentalis. See PUERPERILIS FEBRIS. 3. *Peritonitis* meſenterica. See INFLAMMATION of the MESENTERY.

PERNIO, from πτερνα, *heel*. A kibe or chilblain. This diſorder attacks the hands, feet, heels, ears, noſe, and lips, all ages are ſubject to it; but children of a ſanguine habit, and a delicate complexion are the moſt ſo. Dr. Cullen places this diſorder as a variety of phlogoſis erythema.

When the parts ſubject to this complaint are ſuddenly expoſed to cold, or from being cold are too ſpeedily heated, they are ſomewhat inflated, afterwards come on heat, redneſs, pain, and itching. Theſe ſymptoms increaſing, ſmall bliſters are formed, which ſoon burſt, leaving a ſlight excoriation, which ſpeedily ulcerates; this ulcer ſoon becomes deep and obſtinate, diſcharging a ſharp ill-conditioned matter; in the laſt, and worſt degree, a gangrene is formed.

Beſides a fulneſs of the humours, and a tenderneſs in the ſkin, which are the moſt frequent cauſes diſpoſing to *chilblains*, the wearing of woollen gloves, or thoſe of furr and muffs, are too oft the productive cauſes; like the warm bath they render the ſkin more ſenſible, and increaſe the afflux of blood thereto.

The principal methods of prevention and relief are as follow: the ſkin is rendered leſs tender, and more firm; change of weather are guarded againſt; the vicious quality of the temperament is corrected; and according to the different degrees of the complaint when preſent, the ſubſequent applications are made uſe of.

When winter approaches, let the parts uſually affected be frequently put into cold water, avoiding every occaſion of ſubjecting them to warm. Iſſues, or frequent gentle purges, will drain off a redundancy of humours. As to a faulty quality in the blood, of whatever kind it may be, proper alteratives are not to be neglected; but when the diſorder is preſent, whilſt in its loweſt degree, dip the part into water that is cold, and as near to freezing as may be, and there continue it during a minute or two; or if the cold chills or benumbs the part very much, dip it in, and take it out two or three times, at ſhort intervals; after this it may be gently dried; the ſame proceſs being repeated, at leaſt every morning and evening, until all uneaſineſs is removed. The moſt troubleſome itching is removed by dipping the part in cold water, or by applying ſnow to it, though in ſome few inſtances the ſnow rather increaſes than diminiſhes the diſorder. When the patient cannot bear the cold, when a cough attends, or other circumſtances which forbid the application of cold to the extremities, the beſt ſubſtitute is, to wear dog-ſkin ſocks, or gloves, day and night, until the inflammation is removed. Linnæus recommends the diluted ſp. of ſea-ſalt for bathing the part affected with. In greater degrees, as when the part may be ſaid to be froſt bitten, the treatment will be as directed in the article CONGELATUS; in this caſe dog-ſkin gloves or ſocks, ſhould be worn. Vapours ſometimes agree better than baths, in which caſe the vapours from vinegar are the beſt; but as their vapour ſoftens the ſkin, it ſhould afterwards be often waſhed with a mixture, water two parts, and camphorated ſpirit of wine one part. If the parts are ulcerated, gentle purges may be uſed, the ſwelled parts expoſed to the ſteams of vinegar, and digeſtive ointments applied to the ſore. When a gangrene comes on, treat it as when the ſame happens from any other cauſe, attendance being given to the circumſtances of the conſtitution.

See Heiſter's Surgery; M. A. Severinus's Diſſ. de *Pernionibus*, in lib. de Abſceſſibus; Tiſſot's Advice to the People.

PERONÆA ARTERIA. The peroneal artery. It is the ſmaller diviſion of the poſterior tibialis; it paſſes down behind the fibula, between the ſoleus and the flexor pollicis, paſſes over the interoſſeous ligament, and about the upper and back part of the os calcis it forms an arch with the tibialis poſterior.

PERONÆUS MUSCULUS, from *perone*, the fibula. It riſes from the outer part of the fibula, it lies in a groove in the malleolus externus, and is inſerted in the baſis of the laſt metatarſal bone. i. e. that of the little toe.

PERONÆUS LONGUS. It riſes from the head of the fibula, its tendon is turned back under the tarſus, paſſing over the os cuboides (at which place it hath a ſeſamoid bone) and runs acroſs the ſole of the foot to be inſerted into the baſis of the firſt metatarſal bone, being an abductor.

PERONÆUS SECUNDUS. It riſes about the middle of the outward part of the fibula, and as it runs under the malleolus externus, it becomes tendinous, and is inſerted with the tendon of the peronæus brevis into the metatarſal bone of the little toe.

PERONÆA VENA. It it one of the diviſions of the poplitea; it runs nearly the ſame courſe with the artery of the ſame name.

PERONE. The fibula.

PERONEUS BREVIS, i. e. Extenſor digitorum longus.

PERSICA. The peach tree. Perſica from Perſia, whence they were firſt tranſplanted. It hath been called Rhodacinea, or Rhodacina, becauſe it was planted in Rhodes.

PERSICA NUX. The walnut.

PERSICARIA, called alſo hydropiper, culrage, lake-weed, water-pepper, and biting arſmart. It is the polygonum hydropiper, Linn. It is an annual plant, with oblong uncut leaves, pointed at both ends, and with imperfect flowers ſet in ſpikes on the tops of the ſtalks; the cup is thick and fleſhy, divided into five oval ſegments, which cloſing form a cover to an angular gloſſy ſeed. The leaves have a burning taſte, and ſeem nearly allied to the arum: their acrimony is diſſipated by diſtillation, and is deſtroyed in the proceſs: they are antiſeptic, diuretic, and aperient. It is called perſicaria becauſe the leaves reſemble peach leaves, and hydropiper becauſe it grows in water, and taſtes

like

like pepper. It is not uſed in the preſent practice. See Raii Hiſt.

PERSICARIA, alſo called maculata, perſicaria maculata, dead or ſpotted arſmart. Perſicaria mitis. It is the polygonum perſicaria, Linn. It is ſo called from moſt of the leaves having a blackiſh ſpot in the middle: it grows alſo in wet grounds. It is ſaid to be antiſeptic, but is not in uſe as a medicine. See Raii Hiſt.

PERSICARIA SILIQUOSA, alſo called balſamina lutea, noli me tangere, herba impatiens, mercurialis ſylveſtris, quick in hand, touch-me-not. This ſpecies is a forcible diuretic, but is rarely uſed. See Raii Hiſt.

PERSICON. The walnut.

PERSICUM BALS. i. e. Balſ. traumat.

PERSICUS IGNIS. A carbuncle. Avicenna ſays that *Perſicus ignis* is that ſpecies of carbuncle which is attended with puſtules and veſications.

PERSISTENS FEBRIS. A regular intermitting fever, the paroxyſms of which return at conſtant and ſtated hours.

PERSOLATA, or Perſonata. See BARDANA.

PERSPIRATIO. Perſpiration. Without a free *perſpiration* no animal nor plant can continue in a healthy ſtate. The matter of *perſpiration* is ſeparated through the ſkin, and alſo from the lungs; it is ſimply ſerum. This diſcharge is uſually leſs in women than in men; if in either women or men, the perſpiratory veſſels are obſtructed, the circulation of the blood meets with great reſiſtance.

Perſpiration is of two kinds, viz. that which is continually tranſuding and is called inſenſible; the other is the ſenſible, called ſweat. It hath been ſuppoſed that different veſſels threw off theſe diſcharges, but that is not the truth; the ſame veſſels which throw out the inſenſible, upon being more ſtrongly acted on, throw out the ſenſible *perſpiration*.

All animals have an abſorptive power, ſimilar to that of a ſponge, which is evident from the ſpeedy penetration of ſea-ſalt and ſalt petre into the moſt interior parts of the largeſt pieces of butcher's meat; it is moſt probable that the pores, &c. through which the ſalt paſſes, are thoſe through which the *perſpiration* is carried on in living animals. The pores are ſometimes ſo enlarged as to tranſmit particles of red blood, as happens in the muriatic ſcurvy; and ſometimes are ſo contracted that the neceſſary evacuation can no longer be continued, whence a variety of diſorders proceeds. The fat under the ſkin is ſuppoſed to prevent a too free exhalation of the ſerum from the body, and want of fat in the lungs, to be a reaſon why ſo free a diſcharge is made therefrom. The coats of all the veſſels are perforated by the pores through which the matter of *perſpiration* paſſes; hence, when morbid humours are attenuated they paſs through the ſkin, and are exhaled with the matter of *perſpiration*, or they may, and often are, abſorbed into the blood, and then excreted with the urine, &c.

PERTURBATIO ALVI. A diarrhœa.

PERTUSSIS. A hooping-cough, alſo called tuſſis ferina, the rheumatic cough, and convulſive cough. Dr. Butter ſays it is an epidemic, contagious, ſpaſmodic diſeaſe. It ſeems to be analogous to an intermittent fever in the periodic return of the fits; they both prevail in the ſame ſeaſons, ariſe from the ſame cauſe, and are cured by the ſame remedies. See Huxham de Aere, &c. Morb. Epid. p. 76, 77. Farther, the autumnal *hooping-cough* and intermittents are analogous, in that they renew their attacks in the returning ſpring, though ſeemingly cured, long before. The *hooping cough* reſembles the ſmall-pox, in not uſually returning, in being infectious to the prediſpoſed, and in that it muſt have its courſe.

It is originally ſymptomatic; is often a ſymptom in the aſthma. Sydenham ſays that the cough is excited by vapours which are thrown into the lungs from the blood. Dr. Butter ſays its ſeat is in the inteſtines; that neither the ſtomach nor the lungs are concerned in it; that the primary affection is a morbid irritability of the mucous glands; and that an infectious miaſma is the occaſional cauſe. Again, whilſt ſome aſſert that the diſorder is a convulſive one, occaſioned by irritating matter lodged about the bronchia trachea, and fauces; others ſay, and indeed with greater ſeeming probability, that it is a convulſion in the diaphragm, excited by ſharp humours in the primæ viæ, and which cauſe a ſpaſmodic ſtricture in the glottis. Walſchmeid ſays, it proceeds from a diſorder of the ſtomach. Dolæus ſays it is cauſed by tough viſcid matter lodged in the coats of the ſtomach. Hoffman attributes it to thin and acrid juices in the ducts deſtined to reſpiration, as the aſpera arteria, &c.

Dr. Cullen places this genus of diſeaſe in the claſs neuroſes, and order ſpaſmi.

This diſorder begins with a hoarſeneſs, but uſually with a dry cough, which continues about two weeks, and then becomes convulſive, and ſome phlegm is diſcharged; its increaſe and ſtate takes up about four weeks more, and in ſix weeks after it generally goes off, though ſometimes it continues eighteen or twenty weeks: ſometimes the phlegm is ropy, at others it is mixed with ſharp ſerum, but always is thrown up with difficulty: at the height the phlegm is more concocted, and as the cough declines the expectorated matter is whitiſh. After recovery a relapſe may eaſily happen from taking cold; but theſe relapſes are ſlight and ſhort. Some have only the antecedent ſhort dry cough: theſe get well in two or three weeks, but if phlegm begins to appear, the patient is not ſo ſoon quit of this diſorder. When the cough is in any degree violent, the blood is ſo obſtructed in the face as to occaſion blackneſs there, and, according as the veſſels of the noſe are more or leſs able to reſiſt, ſo an hæmorrhage from thence is more or leſs copious and frequent.

The *hooping-cough* is moſt fatal to children under two years of age. Older children uſually ſwallow the phlegm and then puke it. After three years of age it ſeldom proves fatal; though, in ſome inſtances wherein great weakneſs attends, and the bark hath been neglected, a conſumption follows, and the patient is carried off.

As opinions vary with reſpect to the ſeat, &c. of this complaint, ſo the methods of relief that are propoſed are alſo various; but, in general, gentle antimonial emetics adminiſtered about half an hour before the return of each fit, when the periods can be gueſſed at, are the principal aſſiſtants that hitherto have been obſerved. Particular ſymptoms are relieved by bleeding, bliſters, gentle laxatives, &c. In the beginning, if the face is very black during the fit, or if blood is diſcharged with the cough, bleed. If the breathing is difficult the lac. ammon. will be proper. To moderate the violence of the cough give, now and then the ſyr. e mecon. in ſmall doſes, or rather mix opiates with purgatives, and give them in ſuch doſes as whilſt the violence of the cough is moderated, the bowels may alſo be kept ſolative. Dr. Butter extols the uſe of hemlock as a cure. He directs to begin with a ſmall doſe, and gradually to increaſe until the ſymptoms of relief appear, and then continue that doſe as long as it produces good effects: when this medicine begins to loſe its effects, then augment the quantity gradually until its advantages are again manifeſt. For a child from ſix months to two years old he adviſes to begin with gr. j. which when diffuſed in an ounce and a half of water, may be given in the courſe of one day. From two years to four years of age two grains may be mixed in two ounces of water to be taken in the day. From four years upward to twenty the firſt daily doſe may be increaſed half a grain for each year. If a liquid form is diſliked, a pill or a bolus my be given. And Dr. Morris declares the moſt ſucceſsful efforts from caſtor one part, and the bark two parts; the doſe from ℈ i. to ʒ ſs. and repeated every four hours. If there is much fever, the bark is not convenient, expectorants ſometimes ſhould accompany this remedy, and often its efficacy is only advantageous in the decline of the diſeaſe: the fever is no objection to the cicuta. When there is little or no fever, cantharides have been uſed with advantage. Dr. Letſom, in his Medical Memoirs, from his own, as well as others experience, relates as follows in favour of the following preparation. "From the efficacy of this compoſion, the action of vomiting is leſs neceſſary to be frequently excited, as the diſeaſe uſually terminates in a few days after the exhibition of this remedy; hence (he adds) I have rarely had occaſion to give the antimonial powder more than two or three times." The compoſition is as follows, and was communicated to the Doctor by his friend Mr. Sutcliff, a ſurgeon and apothecary in Yorkſhire. ℞ Tr. cort. Peruv. ſi. ℥ i. ſs. elix. paregoric. ℥ ſs. Tr. cantharides. ʒ j. m. This is to be given in ſmall doſes three or four times a day, and to be gradually increaſed

until

until a ſlight ſtrangury is excited; and then the doſe muſt either be diminiſhed or repeated at longer intervals. It is then obſerved that, the ſtrangury uſually comes on above the third day, and the *hooping-cough* ſeldom continues above ſix days after giving of this medicine.

Dr. Cullen conſiders this diſeaſe under two periods: the firſt is when the contagion which cauſed it is recent, and continues to act; the ſecond is when the contagion ceaſes to act and the diſeaſe continues by the power of habit. The indication of cure under the firſt period is, to obviate the violent effects of the diſeaſe and its fatal tendency. To this end, in plethoric habits, or where the blood is difficultly tranſmitted through the lungs, bleeding will be neceſſary; but its repetition muſt be admitted with caution. The belly muſt be kept lax. If there is any inflammatory tendency in the lungs, bliſters ſhould be applied to the thorax, and repeated if required. Emetics ſhould be duly repeated, they interrupt the return of the ſpaſmodic affections; and by determining to the ſurface of the body, take off the determination to the lungs. The indication of cure under the ſecond period is effected by antiſpaſmodics or tonics. Of theſe, a variety have been propoſed, and occaſionally with ſucceſs, as caſtor, muſk, hemlock, cupmoſs, opium, Peruvian bark, &c. When neither fever nor difficulty of breathing forbid, opium is powerful in abating, but is not efficacious in removing the cough. In this laſt ſtage of the diſeaſe, the bark or ſome proper preparation of it, will be ſingularly uſeful.

The late Dr. Rutherford of Edinburgh, obſerves that when convulſions attend, the application of bliſters will be neceſſary, but as to their ſituation in this caſe, he prefers the ſide of the neck behind the ears, becauſe in that part there is the neareſt communication with the nerves of the glottis.

See Swan's Tranſlation of Sydenham, Huxham de Aer. & Morb. Epid. p. 76, 77. Lond. Med. Obſ. and Inq. vol. iii. p. 281—286, 319—325. a Treatiſe on the Kinkcough, by W. Butter, M. D. Dr. Cullen's Firſt Lines, vol. iii.

PERUVIANUM BALSAMUM. Peruvian balſam or balſam of Peru: it is alſo called Mexican balſam. Piſo deſcribes the trees which afford it, under the name of cabureiba. Peruifera, vel myroxylon peruiferum, Linn. There are three kinds of this balſam, viz. the white; it is of a pale yellowiſh colour (though called white); it is the native *balſam*, preſerved as it iſſues out from the tree: this is the beſt ſort, but is very rarely met with. The dry *balſam*; this is the white ſort inſpiſſated by the ſun's heat in gourd ſhells, in which it is ſometimes brought to Europe; it is of reddiſh colour, and a very agreeable ſmell; it is ſeldom to be met with. The common or black *Peruvian balſam*; this is artificially extracted from the bark, branches, and leaves of the tree, by cutting them in pieces and boiling them in water; it is of the conſiſtence of honey, of a dark black colour in the maſs; but, when ſpread thin, it is of a clear reddiſh or yellowiſh brown, of an agreeable ſtrong ſmell, ſomewhat approaching to that of a mixture of benjamin and ſtorax, and of a bitteriſh pungent taſte, eaſily inflammable, not in the leaſt miſcible with water, nor rendered white nor turbid on being agitated therewith. It is brought from Peru and Mexico.

Diſtilled in a retort with an open fire, it yields a butter like that of benzoine, and ſometimes a conſiderable quantity of concrete ſaline flowers ſimilar to thoſe from the ſame reſin. If this balſam is rubbed with ſugar, the white of an egg, or with the mucilage of gum arabic, it is rendered miſcible with water, but is longeſt ſuſpended with the laſt.

It is uſed for the cure of wounds in nervous and tendinous parts; it ſtrengthens the ſtomach, is uſeful in aſthmas, and as an antiſpaſmodic, though not ſo immediately uſeful or ſo powerful at preſent as opium, yet it is far more laſting in its efficacy.

See Tournefort's Mat. Med. Lewis's Mat. Med. Neumann's Chem. Works

PERUVIANUS GRISEUS, vel Spurius, i. e. Thuris cortex.

PERVIGILIUM. A want of ſleep, or rather intenſe watching. A ſymptom very common in fevers, and always a bad preſage.

PERVINCA. See VINCA PERVINCA.

PES. The foot. It is divided into the tarſus, metatarſus, and toes. The tarſus conſiſts of ſeven bones, viz. the aſtragalus; it is the ſuperior, and its upper head is received into the cavity of the tibia. The os calcis. The os naviculare. The os cuboides, which is the external of the four anterior. The os cuneiforme externum. The cuneiforme medium. And the cuneiforme internum. They follow in reckoning upwards. Theſe bones being convex above, and concave below, make the tread more ſecure, and from their number the ſhock is broke in jumping. A caries happening in theſe bones is dangerous, on account of their ſpongy ſubſtance, their ſize, and number.

When children's feet are diſtorted at their birth, or turned into a bad poſition, bring them as near as poſſible to a natural one, then with a roller dipped in flour and the white of an egg, roll them from near the knee to the toes, let them be held in a good poſition until the roller is dry, and change the bandage every fortnight.

PESSARIUM. A peſſary. Among other external remedies uſed by Hippocrates *peſſaries* were one; they were a kind of ſuppoſitories which they introduced into the exterior neck of the matrix: they were prepared of wool, lint, or linen, mixed with powders, oils, wax, &c. and made round like a finger. *Peſſaries* were in much uſe amongſt the ancients, and were formed of different ingredients, according as the different diſeaſes, &c. of the womb required them. See P. Æginet. lib. vii. c. 24. At preſent their uſe is chiefly confined to the ſupport of the falling vagina or uterus. They are uſeful to women who labour under an incontinence of urine. Sponges of ſuch a ſize as, when expanded, fill up the cavity of the vagina, are very good *peſſaries*; they may be dipped in any liquor that will aſſiſt in the intention of uſing them. They ſupport the uterus; at the ſame time, by putting a ſtring through them, the end of which is to be left hanging out of the os externum, the woman can take them away and apply them herſelf.

Commodious *peſſaries* are deſcribed in Heiſter's Surgery, in the article Procedentia Uteri; Dr. Simſon invented one, and deſcribed it in the Edinb. Med. Eſſays, vol. iii. p. 313.

Dr. Leake, in the fifth edition of his Medical Inſtructions, aſſerts that the uſe of *peſſaries*, by the pain and irritation they occaſion, are apt to produce the whites. He obſerves, that in caſes of bearing down and deſcent of the womb, to direct the curative method to the ſeat of the diſorder, is in every reſpect preferable to the application of thoſe painful and indelicate inſtruments, ſo often made uſe of with bad effect; for inſtead of ſtrengthening the weak part, they lay additional ſtreſs upon it, and conſequently are highly improper. It is evident that *peſſaries* only prevent the deſcent of the womb, by obſtructing the paſſage; therefore, ſo long as part is kept in a ſtate of continual diſtenſion, it never can be braced up or ſtrengthened by the power of art or nature. If the *peſſary* is introduced too ſmall, it will ſoon be forced away by the firſt fit of coughing, or ſtraining, &c. And if it is too large it will bring on the fluor albus in a high degree; beſide, it generally becomes ſo painful as not to be endured, and being a pernicious application, ought to be rejected from practice. It never can anſwer any good purpoſe; but, on the contrary, will always increaſe the diſeaſe, by overſtraining and weakening that part which was too weak before. As a further diſſuaſive from the uſe of theſe inſtruments, the Doctor gives the two follow caſes.

Firſt, A woman advanced in years, had worn a *peſſary* for ſome time; ſhe complained of great heat and inflammation at the lower region of the belly, attended with violent colic pains, and frequent but ineffectual endeavours to avoid her urine; ſhe had much fever, and at laſt became delirious, from want of ſleep and violence of pain, which threatened a mortification in the bowels. The *peſſary* was made of cork, was very large, and cloſely confined by means of the inflammation of the part, conſiderable force was required to extract it, which occaſioned much pain and diſcharge of blood; however, by proper care ſhe recovered and remained well.

Second, A *peſſary* was extracted from the fundament of a woman, after making its way through the vagina into the rectum, by a mortification of the parts.

PESTI-

PESTILENTIALIS. The plague.

PESTIS. The plague. Many writers have obſerved that the *plague* viſits England once in thirty or forty years; but happily for us this does not happen.

Dr. Cullen places this genus of diſeaſe in the claſs phyrexiæ, and order exanthemata.

The *plague* is the worſt degree of putrid fever, is moſt violent, rapid, and ſuddenly fatal. In the beginning it is ſometimes attended with inflammatory ſymptoms when it happens in cold climes; but it ſpeedily becomes moſt putrid. It is called peſtilential when the patient falls into ſudden weakneſs, and is affected with the worſt ſymptoms, and in the greateſt degrees at once. It is called *plague* when the worſt ſymptoms attend, but the loſs of ſtrength is not quite ſo ſudden; and all the other ſpecies are called putrid fevers; they are all of the ſame general nature, but denominated from their moſt remarkable ſymptoms, or other attending circumſtances.

Whatever be the nature of the peſtilential miaſmata, the effects are, immediately to diminiſh, and, according to the degree of its power, to extinguiſh the vital heat. It breaks the fibres of the blood, and diſſolves its texture, whence the purple ſpots.

The *plague* approaches with a chilline's and ſhivering, ſoon after, a violent vomiting, a painful oppreſſion of the breaſt, and a burning fever; all which continue till death changes the ſcene, or till the eruption of a bubo or a parotis diſcharges the morbific matter, and cures the patient. If the morbific matter is not thus thrown out upon the ſurface of the body, it proves mortal. Sometimes, though rarely, the diſeaſe is mortal before the ſigns of fever approach; the broad purple ſpots, which denote immediate death, coming out even whilſt the perſon is abroad about his buſineſs: theſe ſpots go in and out before death's approach. Sometimes ſwellings appear, without having been preceded by a fever, or any other conſiderable ſymptom. The breath and ſweat are very offenſive. The pathognomonic ſymptoms are, the buboes and carbuncles which appear in various parts of the body.

The *plague* and the eryſipelas ſo reſemble one another, that in time of *plague* they are not always duly diſtinguiſhed at the firſt.

The air does not ſeem capable of carrying infection far. Heat and moiſture aggravates, but cold deſtroys the infectious nature of the *plague*; ſo that in theſe northern climates the infection muſt be received at firſt from ſome perſon, or from ſome ſubject in which it is lodged. The peſtilential ſeminium readily adheres to ſpongy and porous bodies, and thus may be conveyed to a great diſtance, without any loſs of its pernicious quality.

From the general nature of the *plague*, bleeding ſeems to be an improper method for relief; yet it is ſtrongly adviſed by many practitioners of note, and amongſt the reſt Sydenham is one. Great circumſpection is doubtleſs neceſſary with reſpect to this operation; however, if ſymptoms of inflammation run high, by leſſening the quantity of blood, the propulſion of the virulent matter to the glands may perhaps be promoted; and this more particularly if the courſe of the blood to the external parts be afterwards aſſiſted by mild ſudorifics. One, two, or at moſt three days, will effect all that is propoſed by taking away blood, ſo that great difficulty will attend the determination, for depriving the patient of what he will ſo ſoon ſtand in the greateſt need of.

Mixtures with acids are peculiarly beneficial, and mild cordials ſhould accompany them. The juice of oranges may be ſqueezed in all the patient's drink, ſweet ſpirit of nitre, Clutton's ſeb. ſpt. are very powerful remedies. Perſpiration may alſo be promoted by means of antimonials; as ſoon as the pulſe will admit, the bark ſhould be given.

The air in the patient's room ſhould be as cool as is moſt agreeable to the ſenſations of the patient: his linen ſhould be often changed: his excrements immediately buried.

The earlier the tumors appear on the ſurface of the body the better; for thus all other ſymptoms are removed. Theſe tumors are BUBOES and CARBUNCLES, which ſee.

When the *plague* is fatal, ſome die of a fainting the firſt or ſecond day; others, in whom the poiſon is not thrown off upon the external ſurface, or, if thrown off, returning back, it brings on a mortification of the nervous coats of the noble parts, as the œſophagus, pleura, ſtomach, inteſtines, &c. whence the corpſe ſwell, and have an intolerable ſtench. Sometimes, when the tumors are too numerous, the patient dies of a ſymptomatic fever, from the inflammation, pain, and heat.

See Mindererus on the *Plague*, Johannes Langius, lib. i. epiſt. 18. Hoffmann, Lobb on the *Plague*, Fordyce's Elements, part ii.

PETALA. Petals. The tender fine-coloured leaves, which are generally the moſt conſpicuous parts of the flowers, are thus named, to diſtinguiſh them from the leaves of the plants. Flowers, with one leaf are called monopetalous flowers; with two, bipetalous; with three, tripetalous; with four, tetrapetalous; with five, pentapetalous with ſix, hexapetalous; with more than ſix, polypetalous.

PETALODES. An epithet for the ſediment of urine, importing that it is ſcaly or reſembling leaves. It is ſometimes obſerved when there is an ulcer in the bladder.

In botany petalodes is an epithet for thoſe plants which are furniſhed with flower-leaves or petala.

PETASITES, from πεταω, *to extend*, or from πετασος, *a hat* or *bonnet*; becauſe the leaves are large, have a hollow in the middle, and then extend horizontally round the hollow. It is alſo called tuſſilago major, galerita, peſtilent-wort, butter-bur. It is the tuſſilago petaſites, Linn. It is a perennial plant, found wild by the ſides of ditches and in meadows, producing, early in the ſpring, a thick naked roundiſh ſtalk, with a ſpike of ſmall naked purpliſh floſculous flowers on the top; the flowers and ſtalks ſoon wither, and are ſucceeded about May with very large roundiſh and heart-ſhaped leaves, ſtanding on long pedicles, ſomewhat hollowed in the middle, ſo as to reſemble a bonnet; the root is long, thick, of a dark brown or black colour on the outſide, and white within.

The roots are aperient, alexipharmic, and promiſe to be of conſiderable activity; they have a ſtrong ſmell and a bitteriſh acrid taſte, of the aromatic kind, but not agreeable, very durable and diffuſive, ſcarcely to be concealed by a large admixture of other ſubſtances. Their virtue is in a reſinous matter, diſtinguiſhed by the eye in the dried root, and which is readily extracted by ſpirit of wine. See Lewis's Mat. Med.

PETECHIÆ. Red or purple ſpots on the ſkin, which frequently appear in the ſmall-pox, &c. The Italians gave them this name from the word *petechio*, becauſe they reſemble the bites of fleas. The French call them purpuratæ; the Spaniards call them taberdillo; the Germans lenticulares.

PETECHIA. Dr. Schotte obſerves, that this word is not Latin but Italian, ſignifying a ſmall-pox of a purple colour. It originally ſignified ſuch appearances in the ſkin as elevated it, but cuſtom hath now eſtabliſhed its uſe to expreſs thoſe ſpots which are leſs or more diffuſed in the ſkin without ever raiſing its ſurface. Uſually they are reddiſh, purple, or blackiſh ſpots in the ſkin, like ſmall points, but ſoon ſpread and gradually grow broader. Theſe *petechiæ* go by various other names, ſome call them punctula, others lenticulæ, others call the diſeaſe in which they are one of the ſymptoms, morbus pulicaris. They cannot, with any propriety, be called lenticulæ, for in Celſus the lenticulæ were pimples or blotches, riſing above the ſkin: he compares the ſcales of the worſt ſort of impetigo with thoſe of the lenticulæ, lib. v. cap. 28. The term pulicaris, from their reſemblance to flea-bites, is not very applicable; for a flea-bite is not at all like a *petechia*; the flea-bite cauſes in moſt people, when recently inflicted, a little whitiſh tumor, encircled with red, which riſes above the ſkin; it hath a puncture in the middle, which only is perceptible when cloſely examined; this tumor ſubſides by degrees, and diſappears: the ſecond or third day a ſmall yellow or browniſh ſpot appears in its place, and this is not unlike a *petechia*.

PETECHIALIS FEBRIS. The petechial fever. In moſt writers it is treated of as a diſtinct ſpecies, but it is only the low or the putrid fever attended with purple ſpots. The purple ſpots are a ſymptom only, and are very common in putrid diſorders, whether of the acute or chronical kind. See PUTRID FEVER. See Hoffman, Pringle, and Huxham on *Petechial Fevers*.

PETICULAS, i. e. Petechialis febris.

PETIVERIA. Guinea hen-weed. Father Plumier called it Petiveria in honour of Mr. James Petiver, who was a curious botaniſt. It is common in the Weſt Indies, but is not noted for its medicinal qualities, though it gives the milk of cows a garlick ſmell if they eat it.

PETOLÆ. Crab-lice.

PETRA. In foſſilogy, an order of ſtones of a cloſe and ſolid ſtructure; and without the characters of the other orders of ſtones. Some of the genera of this order are, the pebble and jaſper.

PETRACORIUS LAPIS. The Perigord ſtone. It is a foſſile ferrugineous ſubſtance, black, hard, and heavy. It is dug up in the mountains of Dauphiny, and uſed in painting earthen veſſels and enamelling.

PETROLEUM. It is ſo called becauſe it is an oil which diſtils from rocks. It is the only liquid bitumen that is known: Neumann reckons the naphtha to be another liquid bitumen, and ſays that in conſiſtence next to the naphtha is the *petroleum*, which is groſſer and thicker than the naphtha, of a yelloviſh, reddiſh, or browniſh colour, but very light, ſo as to ſwim on ſpirit of wine; he alſo ſays that the *petroleum* in the ſhops is all fictitious. Mr. Edwards in his Elements of Foſſilogy, ranks it as a genus in the claſs of inflammables. He deſcribes it as being an inflammable, which when pure, is in a fluid form; very inflammable, and burning like oil; and generally of ſo little ſpecific gravity, as to ſwim almoſt in all fluids.

PETROLEUM FLAVUM, called naphtha Italica, Italian oil of petre, or rock oil, or yellow oil of petre It is of a clear yellow colour, leſs fluid than the white ſort, in ſmell leſs penetrating, leſs agreeable, and more nearly allied to that of the oil of amber. It is found in the duchy of Modena, but does not very materially differ from the white ſort.

PETROLEUM ALBUM. White petroleum. It is nearly colourleſs almoſt as fluid and limpid as water, of a ſtrong penetrating ſmell, not diſagreeble, ſomewhat reſembling that of the rectified oil of amber. It is found only in the duchy of Modena.

PETROLEUM VULGARE, called alſo oleum petræ, petroleum rubrum, petroleum gabianum, oleum gabianum, common rock oil, red petroleum. It is of a blackiſh red colour, of a thicker conſiſtence, and a leſs penetrating, and more diſagreeable ſmell than either the white or the yellow ſorts. It is found in Italy, and about the village Gabian in Languedoc.

PETROLEUM BARBADENSE, called alſo piſſelæum Indicum, bitumen Barbadenſe. Barbadoes tar. It is of a reddiſh black colour, and a thick conſiſtence, approaching to that of treacle or common tar; it is found in the American iſlands, particularly in Barbadoes, but we rarely have it genuine. It is a ſpecies of *petroleum*.

Theſe different kinds are met with, iſſuing from the cliſts of rocks, or are obtained by diſtillation from bituminous ſubſtances, but we rarely meet with any of them genuine Fine *petroleum* catches fire at the approach of a flame, even without the contact of one with the other, and it burns entirely away; concentrated acids make great conflict on being mixed with *petroleum*, but thus its conſiſtence is thickened, and its fragrance increaſed; it does not readily mix with the ſpirit of wine, but is readily united with the eſſential oil of vegetables.

The finer *petrola* are more agreeable than oil of amber, and more mild than oil of turpentine, they have been uſed in nervous complaints, and as diuretics, but chiefly in external applications againſt the rheumatiſm, palſy, chilblains, &c. In theſe intentions, the Britiſh oil, and ſuch other productions of our own, are equally efficacious. The Americans uſe the Barbadoes tar internally as a ſudorific, and externally as a diſcutient and antiparalytic. On diſtillation the Barbadoes tar yields an empyreumatic oil, which when placed betwixt the eye and the light, appears of an orange colour, but in other poſitions of a blue one; but by long keeping it appears yellow in all ſituations.

See Dict. of Chem. Neumann's Chem. Works, and Lewis's Mat Med.

PETRO PHARYNGÆI. Theſe muſcles riſe from the lower part of the extremity of the apophyſis petroſa, and run backwards, to be inſerted into the linea alba of the pharynx.

PETROSA APOPHYSIS. The rock or harder portion of the temple bones; in children it is eaſily ſeparable from the other parts, viz. the maſtoid, and ſquamous.

PETRO SALPINGO-STAPHYLINI. Each of theſe muſcles are fixed by one extremity, partly to the inner ſide of the bony portion of the Euſtachian tube, or to that next the apophyſis petroſa, partly along the cartilaginous portion of the ſame tube; thence it paſſes a little way under the ſoft membranous part, and then turns towards the ſeptum palati. See Winſlow's Anatomy.

PETROSELINUM. Parſley. See Apium.

PETROSILEX. In foſſilogy: it is a genus of ſtone, in the order petra; it characters are; petra, of a ſolid compact texture, in ſtructure reſembling flint, but coarſer, and not at all tranſparent; gloſſy, and not inveſted with an outward cruſt. Edward's Elements of Foſſilogy. It is alſo called chertz, ſemipellucidus, lapis corneus, and by the Germans hornſtein. Large quantities are found in beds of lime-ſtone, as flints are found in beds of chalk, with this difference, that flints conſiſt of looſe nodules, and chertz often forms large maſſes of the rock. Theſe ſtones are vitreſcible: are uſed as grinding ſtones for grinding calcined flints, and other hard ſubſtances, but have too ſmooth and cloſe a texture for the grinding of corn.

PETUM. Tobacco. The Indians call it petun.

PETUNTSE. The Chineſe name of a ſtone uſed in making the Oriental porcelain. It is whitiſh, fuſible by the fire, gives a phoſphoric light when rubbed, and poſſeſſes the properties of ſtones called fluors. See Dict. of Chem. and Dr. Lewis's note in Neumann's Chem. Works.

PEUCE The pine-tree.

PEUCEDANUM, from *peuce, a pine-tree*, which it reſembles in its leaves. It is alſo called fœniculum porcinum, cauda porcina, pinaſtellum, ſulphur-wort, and hog's-fennel. It is the *peucedanum* officinale, Linn.

Boerhaave mentions three ſpecies. See Lewis's Mat. Med.

PEYERI GLANDULÆ. Peyer's glands, i. e. Brunneiri glandulæ.

PEZA. The ſole of the foot or the ankle. According to ſome, it is all under the tibia.

PEZIZA. A ſpecies of fungus; ſometimes it is without pedicles, and ſometimes with them, having its edges divided ſo as to form a remarkable cavity between them. It is of an uniform ſubſtance like the fungoides, and neither diſtinguiſhed by lamellæ, nor pores

PHACE, or Phacos. A lentil.

PHACOIDES. Of the form of a lentil. An epithet for the cryſtalline humour of the eye.

PHACOSIS. A black ſpot in the eye reſembling a lentil.

PHAGEDÆNA, from φαγω, *to eat, feed upon.* It is an ulcer that corrodes, and ſo ſpreads. Sometimes it ſignifies a particular ſpecies of ulcer, as the herpes phagedæna. Some deſcribe it as only deſtroying the ſkin. It is alſo uſed to expreſs the canine appetite.

PHALACRA. In Hippocrates they are blunt and ſmooth ſurgical inſtruments, as a probe, or any other, with a button at the end.

PHALACROTIS. A decay of the hair.

PHALANGIUM. It is a plant, of which kind Boerhaave enumerates ſix ſpecies, but not in repute as a medicine.

PHALANGIUM. A name for ſeveral ſorts of ephemerum.

PHALANGIUM ALLOBROGICUM, i. e. Liliaſtrum Alpinum minus.

PHALANGOSIS. According to ſome it is when there are two more rows of hairs in the eye-lids. A diſeaſe of the eye-lid turns inwards, ſo that the hairs ſtimulate the eye, ſo ſays P. Æginet, lib. vi. c. 8. The eye-lid is tumefied or relaxed, ſo as to appear unſeemly or to offend the ſight; it proceeds either from a paralytic diſorder or the muſculus elevator palpebræ, or from the relaxation of the ſkin above; ſometimes an œdematous tumor is formed in the eye-lid, but it ſhould be diſtinguiſhed from that *phalangoſis*, which, when it proceeds from relaxation, requires an exciſion of the relaxed ſkin, though the

the diſorder ſometimes returns notwithſtanding the operation. See Hippocrat. lib. de Vict. Rat. in Oeul. & Celſus, lib. vii. c. 7. See Ptosis.

PHALANX. The bones of the fingers are called phalanges.

PHALARIS, alſo called Gramen Spicatum. Canarygraſs. Boerhaave takes notice of eight ſpecies. It grows amongſt corn, and is found in many places beſides the Canaries. The ſeeds are diuretic. See Raii Hiſt.

PHANTASMA. The ſame as pſeudoblepſis.

PHARMACEIA. Purgation of the belly by the exhibition of a cathartic.

PHARMACEUTICA. Pharmaceutics. That part of medicine which gives the deſcription of remedies, and teaches the method of rightly exhibiting them.

PHARMACEUTICE. φαρμακευτικη, *medicine*, (i. e. the art of healing) was carried on down to the time of Herophilus and Eraſiſtratus, in an union of all its branches; and then, Celſus informs us, medicine was divided into three parts; one cured by diet, another by medicaments, a third by manual operation. The firſt was named in Greek διαιτητικη, the ſecond φαρμακευτικη the third χειρουργικη; each deriving its appellation from the principal method taken to effect a cure; therefore, as that method which cures chiefly by diet, ſometimes admits medicaments, ſo that which chiefly oppoſes the diſeaſe by medicaments, ought alſo to attend to diet. Celſus's General Preface, and Preface to his Fifth Book. From whence it is evident, that it was a ſeparation in the different branches of medicine, and not in preſcribing diet and medicines, which was intended: for though they had different appellations, each ſect had the whole management in thoſe diſorders which fell properly under their cure. Accordingly, if we take a view of the ſeveral chapters in which each of theſe ſubjects are treated, we ſhall diſcover that one ſet of practitioners under took the cure of internal, and the other of external diſorders; and whether they were of that claſs which cure principally by diet, or principally by medicaments; yet each party took in every neceſſary for his purpoſe, both from diet and medicines. The firſt four books evince, that the dietetic branch were to have the entire management of all diſorders, which confined themſelves to the inward parts of the body, and originated internally. Aretæus and Celius Aurelianus, confined themſelves to this line. The fifth and ſixth books ſhew, that the pharmaceutiſts had the whole direction of diet and medicines in all the external diſorders, where the principal part was not conducted by the hand, whether ariſing from an external or an internal cauſe, being the ſect which are ſaid to have preſcribed medicines; and ſurgeons cured the wounds they had made, both by diet and medicine. Thoſe who cured internal, and thoſe who cured external diſorders, without manual operation, had the appellation of ietros among the Greeks, and medici among the Latins; nor was it intended that they ſhould interleſe with each other in their different departments. See Kirkland's Inquiry, vol. i. p. 64, &c.

PHARMACOCHYMIA. That part of the chemical art which teaches the preparation of chemical medicines, by way of diſtinction from the ſpagirical part, which treats of the tranſmutation of metals.

PHARMACOPŒIA, from φαρμακον, *a medicine*, ποιεω, *to make*. A *Pharmacopœia*, or Diſpenſatory. *Pharmacopœias* are compilations of medicines approved of by medical practitioners. About the middle, or the latter end of the fifteenth century, Nicolaus Præpoſitus of Tours wrote a general *Dispenſatory*, and it was the firſt. The compoſitions in it were principally taken from Meſue, and from Nicolaus de Salerno. The firſt *Pharmacopœia* which was ſet forth by public authority was that of Valerius Cordus, under the ſanction of the ſenate of Norimberg, anno 1542.

PHARYNGÆUM SAL. It is of uſe in quinſies, and thence ſo called. It is thus prepared: ℞ Crem. tart. ſal nitri ää ℥ i. alum. uſt. ℥ ſs. diſſolve in diſtilled vinegar, and coagulate the ſolution. This ſalt is diſſolved in water for gargariſms.

PHARYNGETHRON. The pharynx or fauces.

PHARYNGO-STAPHYLINI. They are two ſmall muſcles fixed to the lateral part of the muſculi thiro-pharyngæ, as if they were portions detached from theſe muſcles; thence they run up obliquely forward, along the two poſterior half arches of the ſeptum, and terminate in the ſeptum above the uvula, where they meet together; the thickneſs of the poſterior half arches is made up by theſe muſcles. See Winſlow's Anatomy.

PHARYNX. Thus the Greeks name what the Latins call *infundibulum*. It is a muſcular bag, fixed behind to the baſis of the ſkull, laterally to the bottom of the face, and below that to the larynx. See Œsophagus. The muſcles of this part are ſufficiently deſcribed by their names, they are the crico-pharyngæus, from the cricoid cartilage to the *pharynx*; thyro-pharyngæus, from the thyroid cartilage to the *pharynx*; hyo-pharyngæus, from the os hyoides to the *pharynx*; ſtylo-pharyngæus, from the ſtyloid proceſs to the *pharynx*; pterygo-pharyngæus, from the pterygoid proceſs to the *pharynx*; mylo-pharyngæus, from the dentes molares to the *pharynx*; ſalpingo-pharyngæus, from the Euſtachian tube to the *pharynx*; cephalo-pharyngæus, from the baſis of the ſkull to the *pharynx*; ſyndeſmo-pharyngæus, from the white ligament to the *pharynx*; chondro-pharyngæus, from the cartilaginous appendage of the os hyoides; gloſo-pharyngæus, from the root or upper part of the tongue laterally. Some have reckoned the muſcles of the *pharynx* to be but two or three, whilſt others have multiplied them to thirteen or fourteen on each ſide. Albinus divides them into ſix pair, viz. Stylo-pharyngæus, which is the ſame as deſcribed by Douglas under that name; conſtrictor Inferior, i. e. the crico-pharyngæus, and thyro-pharyngæus of Douglas; the conſtrictor medius, i. e. the hyo-pharyngæus, the chondro-pharyngæus, and cephalo-pharyngæus of Douglas; the conſtrictor ſuperior, i. e. the gloſſo-pharyngæus, mylo-pharyngæus, and pterigo-pharyngæus of Douglas; the palato-pharyngæus, i. e. thyreo ſtaphilinus of Douglas; and the ſalpingo-pharyngæus of Douglas. In their various actions they enlarge and compreſs the gullet, ſo as to forward the aliment into the ſtomach.

The ſpace is all the vacuity behind the velum pendulum palati.

The *pharynx* is made up partly of ſeveral diſtinct fleſhy portions, which are looked upon as ſo many diſtinct muſcles, ſo diſpoſed as to form a large cavity, and partly of a membrane which lines the inner ſurface of this whole cavity, and is a continuation of that of the nares and palate. This membrane is wholly glandular, and it is thicker on the ſuperior and middle portions of the *pharynx*, and on the bottom, or lower portion. Immediately above the firſt vertebræ, it forms ſeveral longitudinal rugæ, very thick, deep, and ſhort, and we generally find therein a collection of mucus, in dead bodies. In the great cavity there are no rugæ, the membrane there adhering, as well as in the upper part, very cloſely to the muſcles. At the lower part where it is the thinneſt, it covers the poſterior part of the larynx, and is very looſe, and formed into irregular folds.

In the Lond. Med. Obſ. and Inq. vol. iii. p. 85, &c. is a caſe, in which from a dilation of the *pharynx*, a difficulty of ſwallowing was occaſioned.

PHASEOLUS. The kidney-bean. It hath a long pod, full of kidney ſhaped or oval ſeeds; the plant, as to its outward appearance, is flexible, ſcandent, and moſtly trifoliated, or hath its leaves growing by threes. Botaniſts enumerate thirty ſpecies, or more.

PHASEOLUS. The kidney-bean tree. See Abrus.

PHASEOLUS, alſo called ſmilax hortenſis, *phaſeolus* major. French beans, or common kidney-beans. They are cultivated in gardens, they flower in July, the pods are uſed as aliment, they are opening, digeſtive, and provoke urine.

PHASEOLUS ZURRATENSIS, called alſo phaſeolus pruritus excitans, phaſeolus Braſilianus, cadjuct, cowhage, cow-itch, and ſtinking beans. The dolichos urens, vel dolichos pruriens, vel dolichos volubilis, leguminibus racemoſis hirtis, valvulis ſubcarinatis, pedunculis ternis, Linn. This is a ſpecies of the kidney-bean, it is brought from both the Indies. The hairy part upon the pods, if ſcraped off, and mixed with ſyrup to the conſiſtence of a ſoft electuary, may be given to children in doſes of a teaſpoonful, and two to adults, for deſtroying the long round worms. If ten or twelve pods are ſteeped in a quart of

beer, and ʒ iv. of the infuſion are taken every morning, it acts as a diuretic, and gives great relief in dropſies. See Raii Hiſt.

PHASEOLUS. See Indicum, Cajan, and Faba.

PHAUSINGES. Red circles in the legs, excited by fire. It ſometimes is uſed to ſignify other kinds of ſpots, as well as red ones cauſed by the fire.

PHELLANDRIUM AQUATICUM, Linn. Water-hemlock, fine-leaved. It is generally called *water-hemlock*, and thus is often confounded with the cicuta viroſa. See Cicuta Aquatica. Withering. in his Bot. Arrang. vol. i. p. 176, deſcribes the *phellandrium aquaticum* as follows: the rundle with many ſpokes; rundlets, the ſame; general fence, none; the empalement, a partial fence of ſeven leaves, ſharp, as long as the rundlet; cup, of five teeth, permanant; the bloſſoms general, nearly uniform; florets, all fertile, individually unequal; petals, five, tapering, heart-ſhaped, bent inwards; chives; threads; five, hair-like, longer than the petals; tips roundiſh; pointal; ſeed-bud beneath; ſhafts two, awl-ſhaped, upright, permanent; ſummits, blunt; ſeed-veſſels, none; fruit egg-ſhaped, ſmooth, crowned with the cup and the pointals, diviſible into two parts; ſeeds, two, egg ſhaped, and ſmooth. N. B. The florets in the center are ſmaller than the others. The branchings of the leaves are ſtraddling, the ſtem is very thick, hollow, ſcored, and the petals are white.

It is the *phellandrium aquaticum*, Linn. *Phellandrium*, vel cicutaria aquatica quorundum. Ray's Syn. 255. Cicutaria paluſtris. Gerard. 1063. Cicutaria paluſtris tenuifolia. B. p. 161. Skeleton waterwort; Withering's Bot. Arrang. which laſt author ſays, the ſeeds are recommended in intermittent fevers; the leaves are ſometimes added to diſcutient cataplaſms: the plant is generally eſteemed a fatal poiſon to horſes, occaſioning them to become paralytic; but this effect is owing to an inſect, (curculio paraplecticus) which generally inhabits within the ſtems: the uſual antidote is mio's dung.

PHELLODRYS. The laurel oak. It grows in Dalmatia and Greece. The leaves, bark, and acorns, agree in virtues with the common oak. See Raii Hiſt.

PHENGITES. A luminous ſtone, capable of acquiring light, and imparting it again.

PHIALA. A glaſs veſſel, with a big belly, and long neck. It is often uſed for chemical coagulations and ſolutions.

PHILADYNAMOS. An epithet of water, expreſſing the property of it, by which it diminiſhes the ſtrength.

PHILANTHROPOS. The name of a compound anti-nephritic medicine.

PHILANTHROPUS, i. e. Aparine.

PHILLYREA. Mock privet. See Ligustrum.

PHILONIUM. An opiate, ſo called from its inventor Philo. Galen ſays, that the antidote of Philo is one of the oldeſt of its kind; but the Mithridate is much older. The *philonium* Romanum is originally a preſcript of N. Myrepſus.

PHILTRON, from φιλεω, *to kiſs*. A love potion, or a medicine to excite love. It alſo ſignifies the cavity, or depreſſure on the upper-lip, which is ſituated immediately under the ſeptum of the noſe.

PHIMOSIS. It is when the prepuce cannot be drawn over the glans penis, ſo as to uncover it. Dr. Cullen places it as a variety of the phlogoſis phlegmone. See Lues Venerea.

PHLASMA. A contuſion or colliſion.

PHLEBOPALIE. The pulſation of an artery.

PHLEBORRHAGIA, from φλεψ, *a vein*, and ῥηγνυμι, *to break*. A rupture of a *vein*.

PHLEBOTOMIA, from φλεψ, *a vein*, and τεμνω, *to cut*. Phlebotomy. It is the ſame as venæ ſectio. The *cutting*, or opening a *vein*.

Bleeding, or the taking away blood, is only proper when there is too much craſſamentum in the veſſels, or when it is to avoid a worſe inconvenience than that of leſſening the already too little quantity of blood. In general, the pulſe is the beſt guide, both as to when to bleed, and the quantity to be taken away. When the pulſe is full, ſtrong, or tenſe, bleeding will always be proper, provided that a plethora be the cauſe, and not refraction; indeed, in old people, the pulſe ſeems hard from the rigidity of the coats of the arteries.

Bleeding is not only uſeful when actual inflammation attends, but alſo in ſanguine habits which tend to be plethoric. In the ſmall-pox, if the heat demands, and the pulſe will allow of bleeding, the operation may be performed at any period of the diſorder. In intermitting fevers, when the heat is great, and there is pain in the bowels, or if a delirium comes on, bleed in the interval of the fit, or on the acceſs of the hot fit. In the meaſles, blood for the moſt part ſhould be taken away, both in the beginning, and at the decline of the diſorder. In the bilious colic, blood is taken away in the beginning, to prevent an inflammation in the part where the pain is urgent. In the gout, when the fever runs high, bleeding is found uſeful; and if the patient is plethoric, or comatous, repeat the operation. In pregnancy, bleeding is generally required in the firſt three months, and its repetition in the laſt three. In the hæmorrhoids, where there is a fulneſs of the blood-veſſels, empty them by this operation. When the lochia are ſuppreſſed, bleeding is rarely to be omitted. In a concuſſion of the brain from a blow or a fall, bleeding is more frequently uſeful than the trepan. In apoplexies from a ſanguine plethora, bleeding is the principal means of relief. When bleeding is and is not convenient, would require a particular treatiſe to relate; but its proper uſe, or ill effects, are generally noted in theſe ſheets, in treating of each diſeaſe reſpectively. On the ſubject of *bloodletting*, ſee Galen de Sang. Miſſion. Borallus de *Venæſect.* M. A. Severinus on Bleeding, an Eſſay concerning *Blood-letting*, by R. Butler, M. D.

The firſt inſtance of bleeding on record, is that of Podalirius's; Hippocrates did not often direct this operation; Areteæus, Celſus, and Galen, uſed it more freely than Hippocrates; but at different periods, and by different profeſſors, it was encouraged, or nearly prohibited. Indeed until the circulation of the blood was demonſtrated, the principles for this practice did not ſeem ſo clear as they are at preſent; and even now, there is great diverſity of opinions reſpecting bleeding in many particulars.

PHLEBOTOMUS. A lancet, or a fleam for bleeding with.

PHLEGMA. Phlegm. Galen ſays, every humour that is cold comes under this denomination. In Hippocrates this word often ſignifies an inflammation.

In chemiſtry the word *phlegm* ſignifies the moſt watery part obtained from bodies by diſtillation or otherwiſe.

PHLEGMASIA. An inflammation.

PHLEGMATIA. A beginning anaſarca.

PHLEGMATITIA. The ſame as anaſarca.

PHLEGMATORRHAGIA. The name of a diſorder, in which a flux of thin phlegm was diſcharged from the noſtrils. See Salmuthus, obſ. 37.

PHLEGMONE, from φλεγω, *to burn*. A phlegmon or inflammation. See Inflammatio.

PHLEGMONE ARTICULI. See Arthropuosis.

PHLEPS. A vein. But among the ancients, it was both an artery, and a *vein*.

PHLOGISTICI. Inflammations, and fevers, with a hard pulſe and topical pain.

PHLOGOSIS. An inflammation, or an heat in any part without tumour; a flushing. See Inflammatio.

PHLOMIS. Yellow ſage.

PHLYCTÆNÆ, from φλυζω, *to be hot*, or *to boil*. Linnæus and Vogel uſe this term, as ſynonymous with hydatis; generally what is underſtood by it, are little watery puſtules, on any part of the body. Small eruptions of the ſkin, ariſing from an hot acrid and humour. Alſo puſtules which appear on the tunica cornea of the eye, of which there are two ſorts, viz. the unguis or puſtules, properly ſo called, and *phlyctænæ*. The puſtules are deep, and are filled with purulent matter; when they ariſe in the conjunctiva, they are reddiſh at the firſt, and afterwards white; but when on the tranſparent cornea, they are duſky at the firſt, and, in time, turn white. The *phlyctænæ* are ſmall veſicles, full of a tranſparent humour; they are ſeated on the cornea, and ſometimes on the conjunctiva; their ſeat is uſually under the external coat of the cornea, and hath been cured by taking off ſome of the cornea, and ſo removing the ſtagnating matter. A preceding inflammation is the cauſe of both puſtules and *phlyctænæ*. The only danger is, leſt they become ill-

conditioned

conditioned ulcers. Whether they are puſtules or phlyctænæ, dreſs them three or four times a-day with ſix or eight grains of ſac. ſat. in aq. roſ. ℥ iii. and when they give way, waſh them with equal parts of brandy and water; but if they neither diſperſe nor break ſpeedily, open with a lancet, and, when opened, dreſs with the aq. ſapharina.

PHLYXACION, or PHLYZACION. A puſtule, or veſication on the ſkin, excited by fire or heat. Sometimes it is the ſame as phlyctænæ.

PHŒNICIUS MORBUS. The elephantiaſis.

PHOS. Light. Alſo the black circle about the pupil of the eye.

PHOSPHORUS, from φως, *light*, and φερω, *to bring*. It is the name of a collyrium in Galen. It is alſo the name of ſome chemical preparations which ſhine in the dark. The *phoſphorus* igneus differs from other naturally ſhining bodies in this, that it is nothing but a kind of concealed fire, which diſcovers itſelf by light and ſmoak, but if it is rubbed, it breaks out into a flame. This diſcovery appeared about the year 1677; but was preceded by Baldwin's *phoſphorus*, which is an artificial Bolognian ſtone. After this diſcovery of Baldwin's, one Brand, a chemiſt in Hamburgh, made a *phoſphorus* of urine, which was firſt called *phoſphorus* igneus, then pyropus, then *phoſphorus*. The matter which fixes and increaſes the *phoſphorus* is alum, which of itſelf is prepared of urine, and yields the ſame acid which *phoſphorus* yields on burning; for upon analyſis, *phoſphorus* appears to be a compoſition of ſtrong acid, and an inflammable matter, exactly in the manner of common brimſtone, and may properly be called animal ſulphur. If *phoſphorus* is burnt under a bell, a ſp. ſulph. per camp. is produced. See Dict. of Chem. Neumann's Chem. Works.

PHOSPHORUS BONONIENSIS, i. e. Bononienſis lapis.

PHOSPHORUS KERCHERI, i. e. Bononienſis lapis.

PHOSPHORUS LIQUIDA. Liquid phoſphorus. Powder one grain of the *phoſphorus* of urine, and ten grains of camphor; then mix them well together by trituration. Theſe diſſolved in the ol. caryoph. make a liquid *phoſphorus*, with which any part may be rubbed without danger of inflammation.

PHOXOS. The ſugar loaf ſhaped head.

PHRAGMOS, from φραττω, *to incloſe as with an hedge*. An anatomical term for the double ſeries of teeth.

PHRASIUM VIRIDE, i. e. Flos æris.

PHRENES. A name by which Hippocrates, and the ancients, called the diaphragma.

PHRENESIS, or Phrenetiaſis, i. e. Phrenitis.

PHRENICÆ ARTERIÆ, i. e. Diaphragmaticæ arteriæ.

PHRENICÆ VENÆ, i. e. Diaphragmaticæ venæ.

PHRENISMUS, i. e. Phrenitis.

PHRENITICI NERVI. The nerves which run in the diaphragm.

PHRENITIS, from φρην, *the mind*. Phrenetic. The antients imagined that patients became phrenetic in conſequence of an inflammation of the diaphragm, and for this reaſon called the diaphragm by the name of *phrenes*, as though it were aſſiſtant to the intelligent parts.

PHRENITIS, from φρην, *the mind*. A phrenſy, or an inflammation in the brain, or its membrane, with a continual fierce delirium, and an acute coutinual fever. Dr. Cullen places this genus of diſeaſe in the claſs pyrexiæ, and order phlegmaſiæ.

It is idiopathic, as when the head is primarily affected; and ſymptomatic, as when the morbid affection is tranſlated to the head from ſome other part; thus, in a pleuriſy, the pain is ſometimes removed from the ſide to the head, whence the phrenſy that generally proves mortal. The idiopathic and ſymptomatic alſo differ thus; the former is inſeparably accompanied with an acute fever, the latter is followed by the fever.

The idiopathic rarely happens in temperate climes; the ſymptomatic is ſometimes met with, and moſt frequently appears about the criſis of other fevers, is attended with a rigor, a tremor of the joints, tenſion of the precordia, coldneſs of the extremities, thin urine, which is diſcharged either in too ſparing or too large a quantity; but becauſe of the weakneſs previouſly induced by the preceding diſeaſe, it proves almoſt always mortal.

Thoſe in the vigour of life, the paſſionate, the ſtudious, and thoſe with a weak nervous ſyſtem, are ſubject to this diſorder.

The cauſes are, a too great afflux of blood, from an increaſed action of the veſſels in the ſyſtem: the more remote cauſes are, exceſſive drinking, anger, an expoſure of the head to the ſun, an inflammatory diatheſis happening at the beginning of a fever, long watching, attention of the mind, any thing that forces the blood up into the head, a ſuppreſſion of natural periodical evacuations, &c.

According to Alex. Trallian, the ſigns of an approaching *phrenitis* are as follow: "Intenſe continual watchings, or if the patient ſleeps, his ſleep is interrupted and troubled, he ſtarts, and is affected with terrible dreams; he ſoon forgets what is ſaid to him; if at any time he returns an anſwer to a queſtion, he appears more fierce and angry than he ſeemed to be juſt before; the pulſe is ſmall and hard, and a pain is conſtantly felt in the occiput; as the diſorder increaſes, the eyes become more fixed and red, tears at the ſame time flowing from both of them." The ſigns of a preſent *phrenitis* are, according to Cœlius Aurelianus: An acute fever; a pulſe hardly perceptible on the ſurface of the body, or if it is, it is low and tenſe; the patient's face is inflated or full; blood drops from his noſtrils; continual watching, or diſturbed ſleep attend; he is ſeized with a kind of turbulent madneſs, a preternatural ſolicitude of mind, and a privation of reaſon; he frequently changes his poſture in bed, and his head is in a continual commotion; he is ſometimes chearful without any apparent cauſe; his eyes are red; he weeps gently, toſſes his arms about him, but hath no pain in his head; his joints are cold, but without any tremor; his urine is copious, yellow, aqueous, thin, and diſcharged by little and little. Some *phrenitic* patients are afflicted with a noiſe in their heads, a ringing in their ears, an inceſſant head-ach; their looks are fixed and ſtern, and their eyes frequently wink." Aretæus ſays, that theſe patients are rarely thirſty, and this is true, for though the tongue is black, drink is refuſed; an extraordinary throbbing is obſervable in the arteries of the temples and neck in many patients; and from ſullen ſilence, a ſudden outrage ariſes; except the inflammation ſoon abates, it proves fatal. Sometimes the inflammation ends in ſuppuration, eſpecially if the ſubſtance of the brain is affected; in this caſe, the ſymptoms abate, a ſtupor only being left; but in time, if the pus is not abſorbed, the whole brain is deſtroyed. The delirium always goes off ſlowly.

The *phrenitis* ſhould be diſtinguiſhed from a mania, and from the deliriums attendant on other acute fevers; alſo from that inconſtancy and fooliſhneſs obſervable after ſome fevers, and that is owing to weakneſs.

Green vomiting, frequent ſpitting, ſhiverings, crude aqueous pale urine, convulſions, and no thirſt, are bad ſigns. When external violence is the cauſe, the diſeaſe is uſually fatal. A conſtant trembling, ſtarting of the tendons, ſuppreſſion of urine, total want of ſleep, conſtant ſpitting, a grinding of the teeth when the inflammation is from the lungs or inteſtines, are generally fatal. The more favourable ſymptoms are, hæmorrhages, the piles coming on, a diarrhœa, a pain in the breaſt, or lower parts, a ſtrong cough, free perſpiration, a plentiful diſcharge of urine which drops a copious ſediment.

The indications of cure are, to remove the inflammation in the meninges; in order to which, it ſhould be known whether the antecedent cauſe is the repulſion of acrid matter from the ſkin, &c. or obſtructed blood, as in ſuppreſſion of the menſes, &c. or whatever other cauſe may have produced it.

An agreeable friend may be admitted, but, in general, every thing ſhould be guarded againſt by which the imagination can be affected; the room ſhould be kept dark as is convenient. The patient ſhould be as little contradicted as poſſible, and ſhould even be complied with, though in a ſmall degree to his hurt.

This inflammation only admits of one ſalutary termination, and that is by reſolution; therefore the moſt powerful means for that end are needful, and that without delay. Bleed as freely as the ſtrength will admit of, and repeat the

operation as it may appear needful; bleeding from a large orifice, and ſupporting the patient in a ſtanding poſture, that he may ſooner faint with the loſs of blood, will have their advantages. If the jugular vein can be opened, it is uſually preferred, and if obſtructed menſes or lochia were the cauſe, bleed in the foot, after having taken away a portion of blood as above directed.

As ſoon as the patient is bled, give him a briſk but cooling purge. An infuſion of tamarinds with the ſal Glaub. or manna with nitre, or cream of tartar; or if it can be had, the ol. ricini. Repeat the purging medicine, as well as the bleeding, at proper intervals, until the inflammation abates in its violence at leaſt.

In the intervals of purging, give the vin. antim. vel pulv. antim. every two hours, in ſuch doſes as the ſtomach will retain.

Nitre, crude ſal ammoniac, or Clutton's febrifuge ſpirit, may be freely mixed in all that the patient drinks.

Cooling laxative clyſters ſhould alſo be frequently injected, at leaſt let one be adminiſtered every night and morning.

The head may be ſhaved, and cloths dipped in vinegar and water may be laid thereon, as oft as they dry or grow warm.

When thus the ſtrength is ſomewhat reduced, let a large bliſter be applied to the ſhaved head. Sinapiſms may be applied to the feet before bliſters are admitted of.

When there is hope of a mild reſolution, opiates may be admitted to abate the watchfulneſs, and then omit the clyſters; indeed, if the patient is very outrageous, opiates muſt not be forborn.

Some uſe tepid water for putting the legs into twice a day, and others prefer a bath for the whole body. If a continual *phrenitis* comes on in conſequence of obſtructed menſes, piles, or lochia and ſpaſms are thereby produced, they are the beſt alleviated by baths.

If the hæmorrhoids ſwell, apply leeches to them

When the diſorder is ſymptomatic, if the pulſe will bear it, a vein may be opened; but if the patient is too low, leeches may be applied to the temples, bliſters to the head and arms, and ſinapiſms to the feet. Camphor and nitre well mixed by trituration, or diſſolved together in an emulſion, ſhould be often given; a dram of camphor, with from ſix to ten of nitre, may be the proportion.

The *phrenitis* goes off by reſolution, or ſuppuration. Sometimes a diarrhœa, or in women an exceſſive flow of the menſes, carries off the diſorder from the brain. By bad management it ſometimes ends in ſtupidity, or madneſs, which continues during life.

See Alex. Trallian, Cœlius Aurelianus, Ætius, Willis's Pathol. Cerebri, cap. x. Hoffmann, Boerhaave, Baglivi, Fordyce's Elements, part ii.

PHRENITIS APYRETA, i. e. Mania.

PHRENITIS. Vogelii, i. e. Synochus.

PHRENITIS INANITORUM, i. e. Mania corporea.

PHRICASMUS. Shivering.

PHRICODES. A ſort of fevers mentioned by the ancients, in which the patients trembled at the leaſt breath of air. According to ſome it is a kind of ſemitertian fever.

PHRYCTE. In Latin, *fricta*, ſimply, without its proper ſubſtantive, is reſina colophonia. Black reſin, ſo called in diſtinction from the liquid ſort, called hygra.

PHRYGIUS LAPIS. The Phrygian ſtone. It is ſo called becauſe the dyers in Phrygia uſed it much. It is produced in Cappadocia; the beſt is pale and ponderous. When calcined, it becomes reddiſh. Its uſes are the ſame as thoſe of the lapis calam.

PHTHARTICOS, from φθείρω, *to corrupt*. Deleterious, deadly.

PHTHEIRIASIS. See PHTHIRIASIS.

PHTHEIROCTONON. A name for the ſtaveſacre, ſo called from φθεὶρ, *a louſe*, and κτείνω, *to kill*, becauſe it deſtroys lice.

PHTHIRIASIS. The louſy evil. from φθεὶρ, *a louſe*. It is a louſy diſtemper, children are frequently its ſubjects, and adults are ſometimes troubled with it. The increaſe of *lice*, when in a warm moiſt ſituation, is very great, but a cold and dry one ſoon deſtroys them. On the human body four kinds of *lice* are diſtinguiſhed: 1. The pediculi, ſo called becauſe they are more troubleſome with their feet than by their bite. Theſe are in the heads of children, eſpecially if ſore or ſcabby: and often in thoſe of adults, if they are ſlothful and naſty. 2. Crab *lice*. See MORPIONES. 3. Body *lice*; theſe infeſt the body, and breed in the cloaths of the naſty and ſlothful. 4. A ſort which breed under the cuticle, and are found in the hands and feet; they are of a round form, and ſo minute as often to eſcape the ſight; by creeping under the ſcarf-ſkin they cauſe an intolerable itching; and when the ſkin burſts where they lodge, cluſters of them are found there; ſome authors call them acari, cyrones, and pedecelli.

A good diet and cleanlineſs conduce much to the deſtruction of *lice*. When they are in the head, comb it every day, and, after each combing, waſh it with the following: ℞ Staph. agr. vel coc. Ind. contuſ. ʒ i. aq. font. ℔ iſs. & colaturæ adde cinner clavel ʒ ſs. or, inſtead of this decoction, ſprinkle the pulv. ſem. ſtaph. agr. vel cocul. Ind. among the hairs every night, and confine it with a tight cap.

Codrochius, in his Treatiſe of Lice, ſays, that the powdered coc. Ind. exceeds all other means, and that it may be mixed in the pulp of apple, or in lard, and applied every night to the hair. Some writers aſſert, that if the pul. cort. rad. faſſafr. is ſprinkled on the head, and confined with a handkerchief, it deſtroys the *lice* in one night.

The body *lice* are deſtroyed by any bitter, ſour, ſalt, or mercurial medicine, if applied to the ſkin. See Turner's Diſeaſes of the Skin.

The black ſoap, and the flowers called cardamine, or lady's ſmock, are ſaid to be ſpecifics in all caſes of *lice* on the human body. See Sennertus, Codrochius, Mercurialis, and Turner, in his Diſeaſes of the Skin.

PHTHISIS, from φθίω, *to grow lean*. A conſumption. The Greek word, *phthiſis*, ſignifies corruption; but it is uſed only to expreſs that kind which cauſes a *conſumption* of the whole body; and generally only that *conſumption* of the body which hath for its cauſe an abſorption of purulent matter from the lungs; hence is diſtinguiſhed by the term, *phthiſis* pulmonalis.

This diſorder is chronical, yet inflammatory; and the only chronical diſeaſe that is ſo. Dr. Cullen does not rank the *phthiſis* as an original diſeaſe, but as a mode of ſome other diſeaſe being terminated; but he diſtinguiſhes two ſpecies, or at leaſt two ſtates. 1. *Phthiſis* incipiens. 2. *Phthiſis* confirmata; both theſe vary according to their remote cauſes, and, according to De Haen, the ſecond varies according to the ſource of the purulent diſcharge. But generally, if not always, the purulence is from the lungs only.

Conſumptions are reckoned phthiſical, when obſtructions of any kind are the cauſes; and atrophical, when produced by an exceſs in any kind of the natural ſecretions, or excretions; and when an ulcer in the lungs gives riſe to it, it is called the *conſumption* of the lungs. Dr. Reid obſerves, that *conſumptions* ariſing from various cauſes, have been differently denominated, ſymptomatic, ſcrophulous, ſcorbutic, aſthmatic, &c. But the *phthiſis* pulmonalis he defines to be, "an expectoration of purulent matter from the lungs, by means of frequent coughing, attended with a fever, having morning ſweats, and remiſſions in the forenoon, occaſioning a waſting of the fleſh and ſtrength.

The ſeat of the true *phthiſis* or *conſumption* is in the lungs; not in the blood veſſels there, but the air veſſels. Sometimes one lobe is affected, and ſometimes both.

Thoſe are moſt ſubject to a *conſumption* to whom any of the remote cauſes thereof belong.

The remote cauſes are, an hereditary diſpoſition, weak and flaccid lungs, laxity of the fibres, an ill conformation of the breaſt or its contained parts, a narrow depreſſed cheſt, with prominent ſcapulæ, protuberant ribs, long necks, crookedneſs, a too free uſe of ſpirituous liquors, obſtructed perſpiration and reſpiration, or the obſtruction of any natural ſecretion, cold winds, a vapid putrid air, a plethora, a defect of blood, exanthematous, &c. diſorders, grief, intenſe ſtudy, a ſedentary life, ſmall and tender blood-veſſels, &c.

The mediate cauſes are, congeſtions of humours to parts of the lungs already too weak to return by the veins what they received by the arteries; the humours there ſtagnating loſe their former quality, and become the beginning of tubercles.

It appears in perſons of every age: but moſt commonly from about the age of fifteen, up to that of thirty-five, the

ferror

fervor of the blood is the greateſt, and then an ill formation of the body, or of the breaſt in particular, and an acrimony in the juices, concurring with the mediate cauſes, the immediate cauſe, which is an ulcer in the lungs, hath every circumſtance favouring its appearance and progreſs. The ulcer is formed by the rupture of the ſuppurated cells in the lobes of the lungs, and the acrimony of the matter lodged there.

Cœlius Aurelianus in lib. ii. cap. 14. deſcribes a *conſumption* as follows: "A *phthiſis* is frequently produced by a previous ſpitting of blood, and ſometimes by a gentle, but long continued catarrh, or cough, by which the lungs are at firſt gently lacerated, and then ulcerated. It is accompanied by a latent fever, which begins in the evening, and is alleviated in the morning, and attended with a violent cough at thoſe times. At firſt a ſmall, but afterwards a large quantity of ſanious ſpit, is expectorated. Thoſe who fall into a *phthiſis*, in conſequence of an hæmorrhage, diſcharge, at firſt, a bloody ſpit, which becomes feculent, and then livid or green, and laſt of all white, and purulent, ſometimes ſalt, and at others ſweet; the voice is hoarſe and ſhrill, the breathing difficult, the cheeks red, and the reſt of the body of a cineritious colour. It is accompanied with a loathing of food, and a preternatural thirſt. Some patients have a ſenſe of a wound in their lungs, and even expectorate fibres of them. The pulſe is weak, hard, and formicular. A *phthiſis* is alſo accompanied with an inflammation of the feet. As the diſorder increaſes, a flux is brought on; and the phlegm diſcharged, when thrown upon a live coal, is of a fetid and diſagreeable ſmell. Dr. Reid deſcribes this diſeaſe as follows: the firſt ſtage of this diſeaſe begins with a cough, which is more or leſs troubleſome at night, uſually dry, cauſing pain and ſtitches in the breaſt, ſides, and head; ſlight rigors, and ſome degree of feveriſh heat, with pain in the back, joints, and limbs, the uſual effects of taking cold. Theſe ſymptoms increaſe; the cough becomes more violent, hard, dry, and inceſſant; reſtleſs at night; the pains in the thorax more lancinating and fixed; the difficulty and quickneſs of breathing conſiderable; expectoration little and frothy; the pulſe quick, hard, and ſometimes like a ſmall cord, at others full and laborious; the tongue white, and the back part tinged with yellow; the eyes dull; the countenance pale and ſickly. Some difficulty attends the fixing on ſymptoms that may be called ſigns of the firſt ſtage of a *conſumption*; the above ſymptoms, if not ſpeedily removed, may be ſaid to tend to, and too frequently end in it; and as the hard, dry cough, and dyſpnœa, indicate the exiſtence of tubercles, however ſmall, it may be called the inflammatory or firſt period. In a ſhort time the fever becomes more intenſe, with ſlight remiſſions in the morning; when a ſweat breaks out upon the breaſt and upper parts of the body, which ſenſibly relieves every ſymptom. The cough continues, and is aggravated in a recumbent poſture, keeping the patient from ſleep till towards morning. The expectoration increaſes in quantity, is frothy, ſometimes ſtreaked with blood. During the fever, the cheeks have a circumſcribed ſpot of pure florid red; the lips and tubercles in the canthus of the eyes are alſo brighter than when in health. The fever is augmented after eating, particularly ſolids, with flushing in the face, and burning heat in the palms of the hands and ſoles of the feet. As the diſeaſe advances, the fever comes on about the middle of the day, increaſes until the evening, and is violent moſt part of the night, until the ſweat breaks out, and the patient gets ſome reſt. In the morning they find themſelves relieved; but get up languid, pale, and unrefreſhed by their ſleep. Though the pulſe is always quicker than natural, yet there is a remiſſion of the fever for ſome hours in the forenoon. The expectoration becomes more copious, mixed with pus in ſmall globular maſſes; ſometimes diſagreeable to the taſte; yellow, greeniſh, and as the diſeaſe advances, of an aſh colour. The cough becomes leſs hard and looſe; the pains in the cheſt and head abate. At this period, when the hectic fever hath regular remiſſions, when the ſweats come on every morning, and when the patient ſpits up matter freely, the diſeaſe may be ſaid to be confirmed. The countenance now gives evident ſigns of waſting, the eyes are hollow and languid, the cheeks prominent, the noſe ſharp; the patient's fleſh wears away, and the ſtrength fails; the cough is more diſtreſſing in the firſt part of the night; the breathing ſhort, quick, and offenſive; their ſleep leſs, and diſturbed; morning ſweats more profuſe and melting; the interval from fever leſs diſtinct. The ſpitting is more loaded with matter, brought up more eaſily, and in greater quantity, ſometimes a pint in twenty-four hours: this is the ſecond period of the diſeaſe; in which there remains ſome degree of ſtrength, and the ſtomach is capable of digeſting food. From the beginning, the body is diſpoſed to be coſtive, particularly after the morning ſweats takes place. The menſes uſually ceaſe about this time. The third and laſt ſtage commences by the appearance of the looſeneſs. From being coſtive, there have frequent motions in a day, which ſoon become a confirmed diarrhœa; every thing taken into the ſtomach, quickly running off by the bowels. The fever, heat, and cough abate of their violence, and the morning ſweats become leſs profuſe. The diarrhœa increaſes; the ſtrength totally fails; frequent fainting comes on; ſometimes a ſlight delirium ſucceeds; the lower extremities ſwell; and, at laſt, death cloſes the ſcene. When the ſymptoms hurry the patient off quickly, the diſorder is commonly called a galloping *conſumption*. It ſhould not be unnoticed, that the above ſymptoms will be rarely met with exactly in the order above related.

The hectic fever attending the pulmonary *conſumption*, Dr. Reid thinks is different from that produced by ſuppurations, in or about any part of the body. See HECTICA.

The pulmonary *conſumption*, or true *phthiſis*, ſhould be diſtinguiſhed from all thoſe other diſorders which are denominated *conſumptions*, but in which the lungs are not remarkably affected; ſuch as the *conſumption* from a ſimple gonorrhœa, the fluor albus, the ſcurvy, ſcirrhous indurations in the meſentery, an abſceſs or ulcer in the meſentery, a chronical cough, &c.

It is remarkable that conſumptive patients are often chearful to the laſt, in the intervals of the fever, and flatter themſelves with the hopes of recovery. When the nerves are affected, as in the hypochondraic diſorder, there is always a ſinking redneſs; but, in conſumptions, the muſcular fleſhy parts decay, and ſuffer firſt; and that decay coming on gradually, ſcarce gives the ſoul notice of it, and thence the patient fancies himſelf in no great danger.

The matter expectorated engages the attention in this diſorder, particularly ſince Sydenham has ſaid, that if in a morning the patient ſpits out the phlegm into water, it will ſink if the lungs are ulcerated, but, if not, it will ſwim. But it may be obſerved, that if a ſmall quantity of mucus is mixed with the matter that is expectorated, it will always ſwim, let the lungs be in whatever ſtate they may. The moſt remarkable ſorts of ſpit are the bluiſh, the ruſt coloured, the blackiſh, and the cineritious; when any of the three firſt are thrown up, there is a taint in ſome of the viſcera, and the laſt indicates death's approach; it is the leaſt adheſive, and yet the heavieſt of any that ſuch patients excrete. The bluiſh ſpit is never thin, and is increaſed by things that cool the breaſt, as apples, &c. but leſſened by mercurials and ſudorifics.

The prognoſtics are rarely favourable, for it moſtly happens that the diſorder is too far advanced before the patient is ſo incommoded by it as to apply for relief; and often the firſt manifeſtation of the lungs being affected, uſhers in death. Aretæus ſays, that when pthiſical patients begin to grow better, the cough is leſs frequent, a larger quantity of ſanious and more moiſt ſpit is expectorated, much aqueous matter is evacuated by ſtool, the urine is copiouſly evacuated, though, as yet, it hath no ſediment, the voice becomes more clear and ſonorous, the ſleeps are ſufficiently long, the præcordia is much relieved, and the pain remitting, is ſometimes transferred to the ſcapulæ, the difficulty of breathing is gentle and leſs frequent, but accompanied with an aſperity of the voice, and when theſe things happen the patient recovers. Beſides the obſcurity of the diagnoſtics in ſome, and the late application of others, it is obſerved by Kirkringius, Willis, &c. that ſome have been thought to labour under a *conſumption* during thirty or forty years, without any evidence of the diſorder having any influence on their lives; but then the ſtate of the caſe hath not been rightly underſtood. Willis ſays that it ſometimes happens, that a cavity or two formed in the lungs, with callous ſides, ſo that matter collected in them is not conveyed to the maſs

of

of blood, but is every day totally expectorated, though its quantity is very large: perſons in this ſituation, have only, as it were, a fontanel in their lungs, and, although they ſhould every morning expectorate a large quantity of thick or yellow, and even, as it were, purulent ſpit, and a ſmall quantity of the ſame throughout the day, yet in other reſpects they enjoy ſufficient health, breathe eaſy, eat and ſleep well, have a due quantity of fleſh, or, at leaſt, have a good habit of body, and, at length, this diſcharge from the lungs abating, the patient is cured. So that on the whole, the favourable prognoſtics may only be conſidered as intimations that death is not ſo immediately to be expected, as when the more threatening ſymptoms attend. While the appetite is good, and the ſleep refreſhing, the diſorder does not appear to have made any dangerous progreſs; however in other inſtances this diſorder may be circumſtanced. It does not appear that a *conſumption* of the lungs is in its own nature ſo fatal as it uſually proves to be: wounds in the lungs are healed as ſoon as thoſe of any other of the viſcera; abſceſſes are formed in the lungs, which ſoon diſappear without inconvenience; and inſtances have occurred of patients recovering from all the ſtages of the pulmonary *conſumption*. To neglect, or miſmanagement, or both, for the moſt part, the uſual fatality is to be attributed. Dr. Geo. Fordyce obſerves, that there are two caſes in which an ulcer of the lungs is ſometimes cured: 1. From an abſceſs in a peripneumony. 2. From a wound in the lungs. But from any other cauſe he fears that it will ever prove fatal; for the ulcer is in the lungs, which are in conſtant motion, and have a quantity of air conſtantly taken into them, which prevents the ulcer from healing.

The origin of the genuine *phthiſis* pulmonalis may generally be traced from hæmoptyſis; from what is called taking cold; and ſometimes from external injuries. When the diſeaſe hath made a certain progreſs, the ſymptoms may have differed in their incipient ſtate. The general intentions of cure are, 1. To obviate the occaſional cauſes of fever. 2. To evacuate the purulent matter from the lungs. 3. To palliate the moſt urgent ſymptoms. 4. To regulate the air, exerciſe, diet, and paſſions of the mind.

The diet ſhould be light, nouriſhing, and aceſcent; a little may be often taken, but full meals ſhould never be allowed.

When ulcers are formed, and pus diſcharged, mild balſamics conveyed into the lungs with the breath, the bark taken freely into the ſtomach, a good air and proper exerciſe, are adapted for healing the ulcers. The bark, demulcent, and aceſcent diet and medicines, are uſeful to prevent putreſcency. The columbo root both mends the appetite, and blunts the acrimony of the juices; and may be uſed inſtead of the bark, when it does not agree with the patient: and as to particular ſymptoms, many of them are relieved as follows.

Dr. Fothergill obſerves, that the moſt benefit is obtained from medicine in the very beginning of the diſorder; a cough is firſt excited by acrid ſerum, or by an inflammation; the acrid ſerum, if not ſoon diverted, will cauſe an inflammation; and if this inflammation terminates any way than by a timely reſolution, though the immediate conſequences are ſeemingly ſmall, they prove inſurmountable, and proceed to a fatal iſſue. Tho' the inflammation ends in ſmall tubercles, which with much caution may not diſturb for many years, yet ſmall irregularities, and that want of care which is obſerved in moſt until too late, ſubject them to the worſt effects.

If inflammation and heat are conſiderable, bleeding is uſeful in the beginning, and may prove a principal means of cure; but, in the future ſtages, it only palliates for the preſent, and as it reduces the patient's ſtrength, the diſorder ſoon overcomes him.

Dr. Reid obſerves, that the recent effects of a cold are eaſily removed by bleeding, diluting drinks, abſtinences, and the uſual antiphlogiſtic plan. That when from a bad habit of body, or from neglect, the cough remains obſtinate and dry; with pain in the breaſt; ſtitches in different parts of the thorax, increaſed upon coughing, and attended with a conſiderable degree of heat and fever; bleeding ſhould be occaſionally repeated, in moderate quantities, according as the pulſe, &c. will permit, and until theſe ſymptoms abate. The bowels ſhould be kept lax by means of gentle ſaline purgatives; and if the cough prevents ſleeping, ſuitable doſes of the elix. pareg. may be given in the evening, and repeated in the night if required. But the remedy which he chiefly prefers in every kind of cough, and in every period of the pulmonary *conſumption*, is ſuch a doſe of pulv. ipecac. as will excite vomiting once or twice; this he repeats morning and evening, as the ſtrength of the patient and violence of the complaint may indicate. The Doctor obſerves, that the lungs are peculiarly affected by the ſtomach and its contents, and if the lungs are diſeaſed they will be the more influenced thereby; further, that if any of the hypochondriac viſcera are in a diſeaſed ſtate, the lungs, if inflamed, will be affected by them. It is well known, indeed, that when the lungs are ſound, acrid matter in the ſtomach and bowels hath cauſed and kept up an obſtinate cough. Hence the advantage of thoſe frequent but gentle emetics. By giving emetics as above recommended, not only the contents of the ſtomach are evacuated, accumulation of viſcid phlegm and acrid bilious matter prevented; but the lungs being compreſſed during the action of vomiting, whatever mucus and purulent matter are in the ramifications of the aſpera arteria, and air veſſicles, in tubercles or vomicæ, will be forced out and diſcharged; by which means an infinity of laborious coughing is prevented; the patient feels greatly relieved, and the tender lungs remain at reſt, till a freſh accumulation of matter is formed, which requires ſome time. By the univerſal concuſſion and agitation cauſed by vomiting, obſtructions in the liver, biliary veſſels, and in other hypochondriac viſcera, are attenuated and removed: and in all complaints ariſing from theſe cauſes, it is the moſt powerful and certain alterative that can be found in the whole materia medica. Puking once or twice does not fatigue even very enfeebled patients. Through every ſtage of the diſeaſe this method of puking with the ipecac. morning and evening, or every morning at leaſt, may be continued with great advantage. The ſtrength of the patient, and the urgency of the ſymptoms, will determine the frequency of the doſe. In the morning it ſhould be taken faſting, and if the patient is weak, it ſhould be taken in bed, but he muſt not ſleep after it, as that ſometimes prevents its action on the ſtomach. If it is required in the evening, its operation muſt be over before bed-time. Though emetics are ſo peculiarly inſiſted on, there are inſtances in which attention is required before they are adminiſtered, and indeed in which it will be proper to forbid their uſe; e. gr. ſome caſes of pregnancy in which abortion may be endangered; in ſchirrous affections of the ſtomach, they cannot be allowed of, with others that will occur to the attention of the judicious.

Vapours from demulcent balſamic medicines received into the lungs may be of uſe to moderate the cough, diſpoſe the ulcers for healing, and to aſſiſt expectoration; but the taking of balſamics into the ſtomach, rather counteracts than expedites the uſual intentions of preſcribing them. In applying vapours to the lungs by inſpiration, the ingredients ſhould be adapted to the ſtate of the diſeaſe, and it ſhould be obſerved whether the trachea or its branches are inflamed; whether or no there is an increaſed ſecretion of acrid mucus from the lungs; or whether or not they are ulcerated; in all theſe ſtates, whatever is conveyed into the lungs, muſt be aſſiſted by proper perſpiratives. Antiſeptics, or antiſpaſmodic, attenuant, and balſamic medicines, may all be conveyed by means of vapours into the lungs, and ſo applied immediately to the ſeat of the diſeaſe, and thus principally the attempts to cure ſhould be made. But if the cough is ſo troubleſome as to prevent ſleep, proper opiates will be neceſſary. See below. It is eſſentially requiſite to keep the lungs quiet, for the agitation of coughing fatigues the patient, increaſes the inflammation, and haſtens the ſuppuration of the tubercles. Repeated emetics greatly conduce to prevent theſe; but the additional aſſiſtance of anodynes are alſo ſometimes neceſſary. When the cough is prevented, or even conſiderably alleviated, the inflammation will readily diſperſe; the immediate cauſe of its continuance being removed.

Riding is indiſcriminately directed by Sydenham in all conſumptive caſes; and that the beſt phyſician in *conſumptions*

ſumptions is a horſe, and the beſt apothecary is an aſs, become a common-place witticiſm; but, if a patient is enfeebled, and rides in cold wet weather, he will be rather injured by it: if, in other more favourable ſeaſons, he is fatigued after riding, his breathing is thereby rendered more frequent and difficult, his ſkin parched and dry, the palms of his hands hot, his cheeks flushed, his tongue dry, and if he perceives a greater inclination to drink than to eat, a more gentle exerciſe muſt be uſed, riding on horſe-back muſt no longer be continued. In all caſes riding ſhould be over before dinner. Old people ſhould take longer journeys than young ones. In nervous *conſumptions* it is always uſeful. But in the true *phthiſis*, if in the beginning, eſpecially if the patient is plethoric, it endangers an hæmoptoe; and when there is a vomica, the briſk motion of a horſe may occaſion an inflammation. Again, *conſumptive* patients ſhould ride gently, only in a morning, and no longer than whilſt the pulſe continues calm. If after this exerciſe the patient's ſpirits are more gay, his appetite ſomewhat excited, his breathing is eaſy, his ſkin cool and ſoft, he may continue to ride whenever the weather will permit.

The bark is an important medicine after an ulcer is formed in the lungs, and an infuſion of it in cold water is an agreeable method of adminiſtering it. If it affects the breathing, three drams of the balſam of Tolu may be diſſolved with the mucilage of gum arabic, and added to each pint of the infuſion. The elixir of vitriol may be added to each doſe. Thus the hectic heats, night ſweats, and every ſymptom that can be attributed to the abſorption of purulent matter, are checked and kept moderate. It may here be remarked that, according to the experiences of different phyſicians, ſucceſs hath been various. Some extol the bark, the elix. vitrioli, &c. whilſt others declare them uſeleſs. It is well known to all, that diſeaſes of the ſame denomination are variouſly circumſtanced in different patients, and hence the ſeeming contradiction in the experiences related. If in one inſtance or more, the hectic fever attending, may be produced, as ſuppoſed by Dr. Reid, without the preſence of pus as an agent, in other inſtances the abſorption thereof may be an attendant; beſides, the various conſtitutions conſidered as natural, the different accidental diſorders in the habit, producing or accompanying the *phthiſis* pulmonalis, may ſufficiently reconcile the ſeeming different practices in this complaint, and render each an object not unworthy our attention. In many inſtances the merc. dulc. hath been the principal ſource of relief, according to the relations on this ſubject by Dr. Sims, who ſuſpecting a latent venereal cauſe, very happily proceeded on a mercurial plan, accompanied with ſuch other aids as his judgment in this, and ſagacity in that caſe, enabled him to diſcern as the needful.

Bliſters, when there is a fixed pain in the breaſts or ſides, increaſed by coughing that does not yield readily to bleeding, and the antiphlogiſtic medicines uſually given; good effects are often produced from ſmall bliſters applied upon the part, and repeated as ſoon as the ſkin is healed. This method is better than applying bliſtering ointment to continue the running, which is rarely ſufficiently effectual. But in ſome inſtances neither nitre, the bark, nor bliſters, can be complied with by the patient; in which caſes, ſuch other means as the ſagacity of the attending phyſician ſuggeſts, muſt be ſubſtituted.

Mercurials are extolled for their efficacy in diſſolving the tubercles which are formed as ſoon as the inflammation terminates that laid the foundation of the diſeaſe. The merc. alkalizat. given in ſmall doſes as an alterative, is preferred by ſome to all other preparations of this kind.

Milk hath been the diet propoſed in every age, at leaſt ever ſince Hippocrates's time. Women's milk, eſpecially if drawn from the breaſt by the patient, is to be preferred to all other; in want of it, aſſes milk is preferred, becauſe it abounds with ſweet ſerum, and poſſeſſes but little of the caſeous part with which more nouriſhing milks abound; next to the milk of aſſes, that of goats may be uſed; and if cows milk is drank, let it be mixed with an equal quantity of barley water. Milk affords a mild nouriſhment, and blunts the acrimony of the juices. Whey is alſo of ſingular advantage, and particular intentions might be carried on, by feeding the aſs, goat or cow, with ſuch vegetables as moſt conduce to effect the deſign of the preſcriber; or the milk may be mixed with infuſions of thoſe herbs.

Columbo root. It may be ſubſtituted for the bark, if it purges or otherwiſe offends.

Iſſues. Theſe ſhould never be omitted where there is a ſcrofulous diſpoſition, or a ſaline catarrh: they are moſt effectual if inſerted in the inſide of the lower part of the thigh.

A nauſea is often a troubleſome ſymptom, in which caſe two or three grains of ipecacuanha may be taken when required, and worked off with camomile tea.

Night ſweats are relieved by going early to bed, riſing ſoon in the morning, and taking the bark, as above directed. Frequently the elix. vitr. is a uſeful addition; it ſhould be given over night, and joined with the opiate when that is required. The ſp. vir. d. in the quantity of two or three drams to a pint of water, with a little of the ſyr. papav. rubr. is grateful and uſeful, if a glaſs of it is taken as often as is agreeable. As a ſalutary means of relief, in this inſtance, Dr. Sims recommends the wearing of a flannel ſhirt next the ſkin. He ſuppoſes that the morning perſpirations may ariſe, at leaſt in part, from that diſcharge being checked during the day, and nature making a puſh to relieve herſelf, and open the cloſed pores at night. Whatever therefore tends to keep up an equable diſcharge, prevents the neceſſity of a ſtruggle. He further adds, that the evening fever, and violent paroxyſm of coughing, which commences frequently on the patients going into bed, may alſo ariſe from the ſame cauſe; the latter however ſeems connected with the expoſure of the ſkin to the air, when the patient throws off his wearing apparel; as on cauſing a patient to make the experiment, he found that when he went into bed, without taking off his cloaths, he eſcaped the paroxyſm; whereas, whenever he put them off, although the bed was carefully warmed, he always had as violent a one as is ever obſerved in any.

The ſhortneſs of breath is relieved by proper vapours received with the breath, amongſt which thoſe from a mixture of wax and reſin are uſeful; the wax and reſin may be laid on an iron that is hot enough to ſend up vapours from them. Sterne's balſamic æther is much approved for this purpoſe.

Hectic heats are relieved by moderate bleedings, a free uſe of butter-milk, milk whey, and in the intervals the bark with elix. vitr. Two or three times a day give the following draught, and at bed-time add tinct. Theb. gt. vi. vel x. to the doſe: ℞ Mucil. e ſem. cydon. ℥ i. ſp. Minder. ʒ ii. ſyr. e mecon. ʒ ii. m. f. hauſt. Baths of ſoft water, with a little milk, and a ſmall quantity of nitre, are uſeful, and ſhould be daily uſed.

Spitting of blood. This ſymptom calls for repeated bleeding until it is overcome; and, to prevent returns, continue to bleed at proper intervals, and keep the mind free from all violent agitations.

A diarrhœa may be moderated, perhaps removed, by the decoct. vel extr. Campechenſis, or the pulv. e. bolo cum opio & pulv. trag. C. p. æq. If it is attended with griping pains and bloody ſtools, give the enem. amylo. cum opio. As this ſymptom uſually attends the laſt ſtages of a *conſumption*, when it is abated, the night ſweats and hectic heats will be increaſed, and vice verſa; ſo that little good is done by any means.

A vomiting may be generally relieved in the ſame manner as a nauſea; but, in caſe of failure, give the balſ. traumat. gt. xl. cum tinct. Theb. gut. v. in thea menthæ.

The cough, when attended with pain in the breaſt, requires repeated ſmall bleedings; the pil. Scillit. Ph. Edinb. or, when proceeding from ſcorbutic ulcers or ſcrofulous ones in the lungs, are much relieved with the pulv. hydrolapathum; but perhaps, in general, the beſt kind of remedy is ſuch doſes of a mixture of the pil. ſapon. and pil. Ruffi. as the urgency of this ſymptom may require; the proportions of each may be ſuch as while the cough is moderated by the opiate, the bowels may be moved by the purgative. In general their proportions may be from one to two parts of the pil. ſapon. to two parts of the pil. Ruffi. as a laxative, and almoſt a ſpecific for the cough, Dr. Sims recommends the uſe of ſulphur; he obſerves that it neither heats, nor checks perſpiration;

and is peculiarly efficacious in relieving, almoſt to the worſt ſtage of this diſeaſe.

PHTHISIS PUPILLÆ. A kind of amaurosis.

PHTHISIS HUMIDA, i. e. Phthiſis confirmata.

PHTHISIS SICCA, i. e Phthiſis incipiens.

PHU. A name for ſeveral ſpecies of valerian, but in general the garden valerian is underſtood by it.

PHYGETHLON, from φυω. It is repreſented variouſly: ſome deſcribe it as a broad, but not much elevated tumor, in which there is ſome reſemblance of a puſtule; it is attended with violent pain, ſo as ſometimes to excite a fever. It is ſlow in ripening, and is not much of it converted into pus. Its general ſeat is in the arm-pits, neck, and groins. Celſus ſays that ſome of his countrymen call it panus. Both Galen and Celſus ſay that an eryſipelatous inflammation is called phygethlon. Celſus, in ſome places, ranks it among glandular ſwellings. Some fix its ſeat in the glands under the jaw.

PHYMA, from φυομαι, *to grow*, or *to be generated from*, or from φυω, *to produce*. All kinds of preternatural tumors from any part of the body, and eſpecially ſuch as effect the ſuperficies of the ſkin, and ariſe without any external cauſe, and are generated, increaſed, inflamed, and ſuppurated in a ſhort time. See Galen's Com. in 6 Epid. Phymata are alſo inflammations of the glands, which ſuddenly break forth, and haſten to ſuppuration. Paulus, lib. iii. c. 22. Sometimes by phymata, a kind of ſcrofulous tumors met with in children, are thus called; and ſometimes this word ſignifies abſceſs in the inward parts, as when there is a vomica in the lungs, &c. It is ſometimes uſed to ſignify a tubercle, a caruncle, &c. According to ſome, *phyma* is a diminutive of phygethlon.

PHYMA. Græc. Celſ. φυμα. A little ſwelling like a boil, ſomewhat round and flatter.

PHYMATA. Inflammations.

PHYMATA. A kind of beaſt, which if a man looks at, he looks pale for ſome days after.

PHYMOSICA (ISCHURIA). A ſuppreſſion of urine from a phymoſis.

PHYSALUS. A road.

PHYSCONIA. A phyſcony. It is a hardiſh tumor, occupying a large portion of the abdominal cavities; it increaſes very gradually, is not ſonorous, nor yet is any fluctuation obſerved in it. Dr. Aitken defines it to be a ſchirrus of one or more of the abdominal organs. Dr. Cullen places this genus of diſeaſe in the claſs cachexiæ, and order intumeſcentiæ. Its ſpecies are various as the parts affected; e. g. the liver, kidneys, womb, ovaries, meſentery, inteſtines, omentum, &c. Other tumors on the ſkin, &c. are called by the name of phyſconia. This diſeaſe admits not of a cure.

PHYSOMETRA A tympany of the womb. Dr. Cullen places this genus of diſeaſe in the claſs cachexiæ, and order intumeſcentiæ. It is formed by air, &c. which diſtend the womb. It may be diſcharged by rendering the os uteri internum, pervious.

PHYSIOLOGIA, from φυσις, *nature*, and λεγω, *to treat of*. That branch of medicine which conſiders nature with reſpect to the cure of diſeaſes, particularly the human body, its parts, ſtructure, health, life, functions, and œconomy. *Phyſiology* depends much on the knowledge of anatomy. See Sauvage, Pemberton, or Haller, on this ſubject.

PHYSOCELE, from φυσα, *a flatus*, and κηλη, *a tumor*. A wind rupture. Or a windy tumor.

PHYTOLACCA, from φυτον, *a plant*, and *lacca*, becauſe it gives a red colour like lacca. The flowers are roſaceous and diſpoſed in bunches; the berry is ſoft, globular, and full of ſeeds, diſpoſed in an orbicular order.

Boerhaave mentions two ſpecies.

PHYTOLACCA AMERICANA, called alſo ſolanum magnum, Virginianum rubrum, ſolanum racemoſum Americanum, pork phyſic, pork-weed, poke-weed, red weed of Virginia, red nightſhade. It is found every where in North-America, from Virginia to New-York. It is a large plant, with a ſtrong ſtem: it ſends forth many branches. The leaves are large, ſmooth, juicy, oval, and entire, without indentations on the edge, and placed alternately. The root is large and perennial, runs deep into the ground, and divides into many branches. It is raiſed in our gardens.

The leaves are anodyne. The juice of the whole plant is ſharp and corroſive: it is not uſed inwardly; but inſpiſſated to the conſiſtence of an ointment, by ſetting it in the ſun, it is applied to cancers and to ulcers for removing their calloſity. The corroſive part is ſo volatile, that, if the juice is quite dry, it is inactive and uſeleſs. If the roots are roaſted and beat into a poultice, then applied to ulcers with hard tumors and calloſities, it diſſolves them. See Med. Muſ. vol. i. p. 85.

The other ſpecies is diſtinguiſhed by its having leſſer fruit, and is alſo called ſolanum Barbadenſe.

PIA MATER. Pia mater. Quia cerebrum accurate, ſicut mater infantem, involvit ſic ab arabibus dicta. The thin membrane which immediately involves the brain. It is ſo thin that it would be inviſible but for its veſſels; where they do not enter it is quite tranſparent. The brain is divided into lobes, which form convolutions, ſomething of the appearance of the inteſtines. The *pia mater* covers the whole external ſurface, and ſends proceſſes between the convolutions of the brain. The principal veſſels that go to the brain paſs on the *pia mater*: ſo that its uſe is to connect the lobuli of the brain, and to ſupport the veſſels. Some deſcribe a third covering of the brain, and call it arachnoides, and place it betwixt the *pia mater* and the dura mater; others make this the external lamella of the *pia mater*, but it is not of that ſignification which it is reckoned.

PICA, called alſo picatio, malacia. Longing. It is a preternatural appetite in pregnant women, and ſome ſick perſons when about to recover. It it called *pica* from the bird of that name, which is ſaid to be ſubject to the ſame diſorder. The diſorder conſiſts of both a deſire of unuſual things to eat and drink, and in being tired of one and wanting another, particularly things that are accidentally ſmelled. It is called malacia, from μαλακος, *weakneſs*. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order dyſorexiæ. In pregnant women it is ſomewhat relieved by bleeding, and in about the fourth month of their pregnancy it leaves them. Chlorotic girls, and men who labour under ſuppreſſed hæmorrhoides, are very ſubject to this complaint, and are relieved by promoting the reſpective evacuations. In general, whether this diſorder is obſerved in pregnant women, in perſons recovering from an acute fever, or in thoſe who labour under obſtructions of the natural evacuations, this craving of the appetite ſhould be indulged.

PICHROCHOLOS, from πικρος, *bitter* and χολη, *bile*. A perſon abounding with bitter bile, or a perſon ſubject to anger.

PICTONUM COLICA. See Colica.

PIEDRA DI COBRA, i. e. Cobra de capello. The pierres de cobras are diſcovered by Felix Fontana, to be artificial productions, and to conſiſt only of calcined hartſhorn.

PILA HYSTRICIS. The bezoar of the porcupine.

PILA MARINA. A ſpecies of alcyonium, or a round ſpherical ball found on ſea-coaſts amongſt wrack. Lemery deſcribes it as being about the ſize of a man's fiſt, ſometimes larger, ſometimes leſs: it is lanuginous, of a dark colour, formed by a collection of hairs, ſand, and other impurities of the ſea, united by means of ſome glutinous liquor. It is ſaid to kill worms. Zwelfer ſays that when it is calcined it is uſeful in ſcrofulas.

PILEUS, i. e. Cucupha. In anatomy it is the coif with which ſome children are born; it is called *pileus*, pileolus, galea, and vitta.

PILIOLUS. See Pileus.

PILMICTIO. A diſcharge of ſubſtances reſembling hairs with the urine.

PILOSELLA, i. e. Auricula muris. A ſpecies of pulmonaria, hieracium, gnaphalium, and turritis.

PILULA. A pill. *Pills* are a form well adapted for thoſe medicines that operate in ſmall doſes, and that are offenſive in taking. They diſſolve the moſt difficultly, and

and produce the moſt gradual and laſting effects of any other form; this, in ſome caſes, is a diſadvantage, in others an advantage. Emetics, if they are retained long in the ſtomach, uſually paſs off by ſtool; but ſtomachics are proper for this form.

Reſins ſhould be beat up with ſpirituous mixtures, ſuch as the ſyr. alb. ℥ viii. ſp. vini. R. ℥ i. m. gums with water, dry powders with the conſ. cynoſb. or mucilag. e gum arab.

Gold and ſilver leaf do not diſſolve in the ſtomach, and often hinder the pills from diſſolving, ſo ſhould never be uſed.

What cannot be included in four or five pills, for one doſe, is not fit for this form.

PILUS. A hair.

PIMENTA. All-ſpice or Jamaica pepper. See PIPERIS JAMAICENSIS.

PIMPILIM. Long pepper.

PIMPINELLA. Burnet or ſaxifrage, and Burnet ſaxifrage. It is called ſaxifraga becauſe it grows out of the rocks, as if it broke through them; and not becauſe of its efficacy in breaking the ſtone in the human bladder. Boerhaave reckons up eight ſpecies. The ſpecies ordered by the Edinburgh college, is the *pimpinella* ſaxifraga, or *pimpinella* ſanguiſorbæfolia, foliis pinnatis, foliolis radicalibus ſubrotundis, floribus umbellatis albis, Linn.

PIMPINELLA, called alſo ſanguiſorba, pimpinella minor, tragoſelinum. Smaller burnet ſaxifrage. It is a perennial umbelliferous plant: it grows in dry paſture grounds. It is the poterium ſanguiſorba, Linn.

PIMPINELLA ALBA GERMANORUM, called alſo pimpinella ſaxifrage major. Greater or white burnet, or ſaxifrage. Some of its leaves are deeply cut, the odd one into three ſections. It is common in Germany, but rarely met with in England.

All the ſpecies are joined into one by Linnæus: their qualities are alſo ſimilar. The roots have a hot pungent taſte, which is not durable; they have no particular taſte. When freſh they affect the eyes like as muſtard and horſeradiſh do. In drying they loſe all their ſubtil matter; water partially extracts their virtue, but ſpirit completely. When diſtilled with water they afford a ſmall portion of oil, which is acrid and fiery. Theſe roots are warm and ſtimulating, aperient and diuretic, and are uſeful when tenacious humours offend.

There is a ſpecies which is called nigra, from its being externally of a bright black colour, whilſt thoſe of others are whitiſh; it is remarkable for yielding a bluiſh oil: it grows wild in Germany and Switzerland.

PIMPINELLA. A name of the agrimoides, of ſeveral ſorts of tragoſelinum, and a ſpecies of melianthus.

PIMPINELLA ANISUM. Aniſe. The anniſeeds of the ſhops are the ſeeds of the *pimpinella aniſum*, or *pimpinella* Ægyptiaca, foliis radicalibus trifidis inciſis, floribus flaveſcentibus. Linn. See ANISUM, and ANISUM INDICUM.

PINEALIS GLANDULA, from *pinea*, *a pine apple*, to which it hath ſome reſemblance. The pineal gland. It is a ſoft greyiſh body, about the ſize of a pea; it is covered by the plexus choroides, and is ſituated on the cella turcica of the os ſphenoides. Its uſe, or that it is a gland, are alike uncertain.

PINGUEDINOSA MEMBRANA. The cellular membrane is ſo called, where the oily matter contained in it almoſt diſſolves ſpontaneouſly.

PINGUEDO. Fat. See ADEPS.

PINGUICULA. A plant ſo called by Geſner, becauſe its leaves are fat to the touch. See SANICULA.

PINHONES. The Barbadoes nut tree. See CATAPUTIA.

PINNA. A wing. The lateral and inferior parts of the noſe are called the *pinnæ* thereof; and the ſuperior broad parts of the ears are alſo ſo called.

PINNA, or Pinna Marina. A ſea-ſhell of a conical form, and of which there are many ſpecies. Large pearls are ſometimes found in them. See Lemery de Drogues.

PINNACULUM FORNICIS GUTTURALIS. The uvula.

PINO. The name of a ſpecies of nettle in Braſil.

PINUS. The pine-tree. It differs from the fir-tree in having its leaves ſtanding in pairs, thoſe of the firs being ſolitary. The *pine* abounds with the ſame kind of reſinous juice as does the fir-tree. The cones taſte agreeably, and are ſimilar in quality to the ſweet almonds. The reſin of the *pine-tree* is called frankincenſe. Some ſay it is the reſin of the pinaſter, which grows in Sweden, Norway, and Germany; others ſay it is only produced in Arabia. It is a ſolid brittle reſin, brought to us in globes of a browniſh colour on the outſide, internally whitiſh, or variegated with whitiſh ſpecks: it hath a bitteriſh acrid taſte, but no conſiderable ſmell: it totally diſſolves in rectified ſpirit of wine, but water ſcarcely affects it. It is a mild corroborant, though rarely uſed except in plaſters.

There are many ſpecies of *pine-trees*; among the reſt are the tæda, which grows in the country of the Griſons.

The bark of all the *pine-trees* is aſtringent, and the tops are antiſcorbutic. See Raii Hiſt.

PIPER. Pepper. It is the ſmall round aromatic fruit of a trailing plant, which grows in Sumatra, Java, and Malabar.

PIPER INDICUM, called alſo capſicum, capo molago, *piper* Hiſpanicum, *piper* Luſitanicum, ſolanum urens, ſiliquaſtrum Plinii, *piper* Braſilianum, *piper* Guineenſe, *piper* Calecuticum, Guinea pepper. It is the capſicum annuum. Or capſicum caule herbaceo, pedunculis ſolitariis, Linn. It is in long, roundiſh, taper pods, divided into two or three cells full of ſmall whitiſh ſeeds. It is a native of the Eaſt and Weſt-Indies. When this fruit is freſh it hath a penetrating acrid ſmell: to the taſte it is pungent and acrid; it produces a painful burning in the mouth, like that from arum root. Rectified ſpirit takes up its pungency, and if the tincture is evaporated, the remaining extract is exceſſively fiery. This kind of pepper is given in ſmall quantities, as one of the higheſt ſtimulants in cold, ſluggiſh, phlegmatic temperaments, in ſome paralytic caſes, in relaxations and inſenſibility of the ſtomach, and for promoting the efficacy of aloetic medicines, and the deobſtruent gums in uterine diſorders. A ſpecies of this is called in the Weſt-Indies bird-pepper, and is the baſis of a powder brought from thence under the name of Cayenne or Cayan pepper. There are four ſpecies of Guinea pepper, viz. the chilchotes, chilterpin, tenalchiles, and chilpelagua. There is a fifth ſpecies, which grows in Peru, and is called agy.

PIPER NIGRUM, called alſo molago-codi, melanſpiper, lada, molanga, *piper* aromaticum, ſpice, black pepper. It is the *piper nigrum*, or *piper* rotundum *nigrum*, foliis ovatis ſubſeptemnerviis glabris, petiolis ſimpliciſſimis Linn. The black pepper tree.

This is probably gathered before it is ripe; it is the fruit of a plant which grows in Java, Malabar, &c.

PIPER ALBUM, alſo called *piper* nigrum, maturum decorticatum, leucopiper, white pepper. The black pepper, when ripe, is macerated and decorticated, and then ſold as another ſpecies.

The black pepper is hotter and ſtronger than the white; they both ſeem to heat the conſtitution more than ſome other ſpices that are of equal pungency upon the palate; and from theſe ſpices they differ in this, that their pungency does not reſide in the volatile parts or eſſential oil, but in a ſubſtance of a more fixed kind, which does not ariſe in the heat of boiling water. Pepper infuſed in water impregnates it very ſtrongly with its flavour, but not with its taſte; by boiling a little while, a little more of its pungent matter is extracted, and its flavour diſſipated. Diſtilled with water, a thin, light, and limpid oil is obtained, which is very mild, for if a drop falls on the tongue, it only excites a grateful moderate warmth. Rectified ſpirit completely extracts the pungent part of the pepper; the tincture is hot and fiery, and when evaporated, a ſtill more fiery extract is left behind. The quantity of extract is nearly the ſame from both the ſorts of pepper, but that from the white is the weakeſt.

PIPER JAMAICENSIS, alſo called *piper* caryophyllatum, pimenta, *piper* odoratum *Jamaicenſe*, pimento, all-ſpice, and Jamaica pepper. The dried unripe aromatic berry of a large tree, growing in the mountainous parts of Jamaica, reckoned a ſpecies of myrtle, called by Linnæus myrtus pimenta, or myrtus *Jamaicenſis*, fol. oblongo-ovatis glabris alternis, racemis terminalibus & lateralibus, fructu orbiculari. This kind of pepper is moderately warm, of an agreeable flavour, ſomewhat reſembling a mixture of cloves, cinnamon, and nutmegs, whence its name

name of all-ſpice. Diſtilled with water it yields an elegant eſſential oil, which ſinks in water; it is moderately pungent, in ſmell and flavour approaching to oil of cloves, or rather a mixture of thoſe of cloves and nutmegs; the remaining decoction, inſpiſſated, leaves an extract ſomewhat ungrateful, but not pungent, and the berry itſelf is wholly deprived of its taſte as well as flavour, the warmth of this ſpice reſiding rather in the volatile than in the fixed part. Rectified ſpirit takes up all its virtue, but gives over little or nothing with it in diſtillation. The ſpirituous extract poſſeſſes the whole of the virtues of this pepper; it is very warm and pungent, but not fiery, like thoſe of the black and white peppers.

The Jamaica pepper is often ſubſtituted for the black and white ſorts.

Half a pound of this pepper is put into three gallons of proof ſpirit, and diſtilled. This water is ſubſtituted for the aq. aromatica, and the aqua mirabilis of former diſpenſatories.

The oil of Jamaica pepper is generally ſubſtituted for the oil of cloves, and is very little inferior to the oil of nutmegs.

PIPER LONGUM, called alſo macropiper. Long pepper. *Piper longum*, or *piper* indicum *longum*, fol. cordatis petiolatis ſeſſilibuſque. Linn. Indian long pepper tree. Of this there are three ſpecies. They are produced in the Eaſt Indies. The pods are round, about an inch long or rather more, with numerous minute grains within them. This is hotter and more pungent than any of the other ſorts of pepper; in its pharmaceutic properties it agrees with them entirely.

The black pepper is moſt agreeable to the palate, and is moſt uſed in food. The long is the ſtrongeſt and moſt uſed in medicine: the white is weakeſt, and ſeldom uſed in either. Their warmth and pungency reſide chiefly in their reſin; their aroma in an eſſential oil.

The general virtues of all the peppers, are, they are ſtomachic, carminative, and uſeful in low phlegmatic and leucophlegmatic habits; ten grains may be taken three times a day to aſſiſt digeſtion. When aſtringents have failed, a diarrhœa hath been cured by ℈ i. of pepper with ʒ ſs. of a diacodium, twice a day.

There are other ſpecies of peppers, but they are of but little note in medicine. See Neumann's Chem. Works; Lewis's Mat. Med.

PIPER CARYOPHYLLATUM. Jamaica pepper.

PIPER CAUDATUM. Cubebs.

PIPER CHIAPÆ. Jamaica pepper.

PIPER MURALE. See SEDUM.

PIPER TAVASCI, i. e. Caſſia caryophyllata.

PIPERITIS. Dittander.

PIRAMIDALIA CORPORA. The ſmall eminencies on the lower part of the medulla oblongata.

PISASPHALTUM. See AMBRA.

PISHAMIN VIRGINIANUM. A ſpecies of guajacana.

PISIFORME [Os], i. e. Lenticulare.

PISLOTHRA. Medicines which take off the hair.

PISONIA. It is a plant which is found in the Weſt-Indies; the natives call it ſingrigo. Father Plumier called it Piſonia, in honour of Dr. Wm. Piſo.

PISSÆUM INDICUM. See PETROLEUM.

PISSAGOUS, i. e. Bulbocaſtanum.

PISSASPHALTOS. Common foſſile pitch, or bitumen.

PISSELÆUM, from πίσσα, *pitch*, and ἔλαιον, *oil*. Oil of pitch. It is of the ſame nature as tar. It is prepared by boiling pitch; wool is ſaid to be ſpread over the boiling pitch, and when it is ſoaked with the riſing vapour it is wrung into a veſſel, and this is repeated as long as the pitch is boiling: but the common method of diſtilling to obtain eſſential oil is more probably uſed.

PISSELAION. Oil of cedar.

PISTACHIA, i. e. Terebinthus Indica Theophraſti.

PISTACIA, called alſo terebinthus Indica Theophraſti. The piſtic nut-tree, or the piſtachio nut-tree.

Piſtachio nuts are oblong and pointed, about the ſize and ſhape of a filbert, including a kernel of a pale greeniſh colour, covered with a yellow or a red ſkin. They are brought from the Levant. The kernels are agreeable to the taſte, are ſweetiſh and unctuous, and of the ſame general nature as almonds. See Raii Hiſt. Miller's Bot. Off.

PISTACIA SYLVESTRIS. See STAPHYLONDENDRON.

PISTACHIA, Jamaica birch.

PISTILLUM. The pointal or ſtyle. It is that column which occupies the center of the flower, riſing on the top of the embryo, and is generally ſurrounded with the chives. Theſe differ greatly in their form, for in ſome flowers they are roundiſh, in others triangular, oval, or ſquare.

PISTOLOCHIA, i. e. Ariſtolochia; alſo ſerpentaria Virginiana.

PISTOLOCHIA CONCAVA, i. e. Fumaria bulboſa.

PISUM. The pea. Of theſe there are various ſpecies, but they are not noted for their medical virtues. They are ſoftening and laxative.

PITHA. A name for the cereus ſcandens minor trigonus, &c.

PITTONIA. A plant mentioned by Miller. There are ſeven ſpecies in the warm parts of America.

PITUITA. So ſome call the water which comes from the ſtomach of ſome patients whilſt faſting in a morning.

PITUITA ALBA. The ſame as anaſarca.

PITUITARIA. It is that ſpecies of diarrhœa called diarrhœa mucoſa.

PITUITARIA GLANDULA. The pituitary gland. It is a ſmall ſpongy body, lodged in the ſella ſphenoidalis, between the ſphenoidal folds of the dura mater. It is of a ſingular ſubſtance, not appearing to be either medullary or glandular; on the outſide it is partly greyiſh and partly reddiſh, and white within. It is tranſverſely oval, and on the lower part, in ſome ſubjects, it is divided by a ſmall notch into two lobes, like a kidney bean. It is covered by the pia mater as by a bag, the opening of which is the extremity of the infundibulum, and it is ſurrounded by the ſmall circular ſinuſes, which communicate with the ſinus cavernoſi.

PITUITARIA MEMBRANA. The pituitary membrane. It is that which lines the whole internal nares, the cellular convolutions, the conchæ, the ſides of the ſeptum narium, and (by an uninterrupted continuation) the inner ſurface of the ſinus frontales and maxillares, and of the ductus lachrymales, palatini, and ſphenoidales. It is alſo continued down from the nares of the pharynx, ſeptum palati, &c. It is termed *pituitaria*, becauſe that through the greateſt part of its extent it ſeparates a mucilaginous lymph, called pituita by the ancients. This membrane is of different ſtructures in different parts; ſometimes it is thin, in other places it is thick and ſpongy; it is thickeſt on the ſeptum narium, the lower portion of the inner nares, and the conchæ; in the ſinuſes it is thinner; on the ſide next the perioſteum and perichondrium, it is plentifully ſtored with ſmall glands.

PITUITOSUS MORBUS. So the antients called the nervous fever.

PITYRIASIS. A ſcurvy diſorder of the head, chin, and eye-brows; called alſo porrigo.

PITYROIDES. An epithet for a ſort of ſediment in the urine, which reſembles bran.

PITYUSA. See TITHYMALUS.

PIX. Pitch.

PIX NIGRA, called alſo pix ſicca, pix arida, palimpiſſa Dioſcoridi. Common black pitch, dry or ſtone pitch.

It is tar dried by heat, or what remains of tar after diſtilling the eſſential oil from it; thus *pitch* is freed from the greateſt part of the eſſential oil, and the acid and aqueous parts of tar.

PIX BURGUNDICA. Burgundy pitch. It is the reſin of ſome turpentine trees, leſs diveſted of its oil than is the common reſin. Some ſay it is from the mountain pine. It is alſo called white pitch. It is from the pinus abies, or pinus foliis ſolitariis ſubulatis macronatis lævibus bifariam verſis. Linn.

PIX LIQUIDA. Tar. Dioſcorides calls it piſſæleon. It is the produce of all reſinous trees; it was firſt got from cedar, larch, fir, pitch, but now it is chiefly from pine trees. It is chiefly obtained from the pinus (ſylveſtris) foliis geminis: primordialibus ſolitariis glabris, Linn. & pinus

(abies)

(abies) foliis ſolitariis ſubulatis mucronatis lævibus bifariam verſis. Linn. The wood is incloſed in a large oven, which ſtands within another oven; the ſpace betwixt them receives the fire; from the bottom of the inner oven runs a gutter, by which the tar is conveyed off in proportion as it melts out from the wood.

Tar differs from turpentine in having received a diſagreeable empyreumatic impreſſion from the fire, and in containing along with the pungent, bitter, terebinthinate matter, a portion of the acid which is extricated from the wood by the heat, and likewiſe of its gummy or mucilaginous matter: by the mediation of theſe principles, a part of the terebinthinate oil and reſin becomes diſſolvable in watery liquors, which extract nothing from the purer turpentines.

Diſtilled in a common ſtill it affords the common black pitch, an eſſential oil, called from the name of the tree whence the *tar* is obtained ol. pini, or ol. tædæ, and an acid ſpirit. This oil hath the ſame general nature as the oil of turpentine, but is impregnated with the empyreumatic flavour of the *tar*.

Water in which *tar* hath been ſteeped is an uſeful remedy in many diſorders. It may be drank either warm or cold. In acute diſeaſes it is taken as freely as the thirſt may demand it; and in chronical diſorders from a pint to a quart may be taken every day, at three or four times, beginning with the firſt draught whilſt the ſtomach is empty. It is a good deobſtruent; it is warming and ſtimulating; it raiſes the pulſe, increaſes perſpiration, and the groſſer evacuations.

Tar water is made by putting two pounds of Norway *tar* to a gallon of water, ſtirring them well together for two or three minutes, and after ſettling two days, the clear liquor muſt be poured off. Of this a pint or more may be taken every day. Thoſe who are curious to ſee the variety of diſorders againſt which this water is ſaid to be a ſpecific, may conſult the biſhop of Cloyne's Treatiſe on *Tar* Water.

PLACEBO. A common place method or medicine.

PLACENTA, from πλακους, *a cake*. In botany it is that part of the pod or huſk of a plant to which the ſeeds are faſtened, and by which they are nouriſhed until they are ripe. In anatomy, it is a congeries of blood veſſels which adhere to the uterus during geſtation, which, together with the membranes and funis umbilicalis, is excluded generally after the fœtus; they are all together called the after-burden, the after-birth, and the ſecundines. The *placenta* is a round *cake*, thick in the middle, and thinner towards the edges; ſometimes it is oval, at others it is divided into two, as it were, adhering to each other by the membranes. It hath an internal convex ſurface, where the funis is inſerted, and an external concave ſurface, which ſeems compoſed of lobes. When there are two children there are two *placentæ*; and when they are but one to appearance, they are really two for the moſt part, for they have no communication of veſſels. The *placenta* hath generally been ſuppoſed to ſtick to the fundus, but that is uncertain; it adheres to that part of the uterus which it happens to fall upon. The *placenta* is made up of one vein, and of two arteries, which ramify together, the largeſt being on the internal ſurface; and even the parenchymatous ſubſtance appears by injections to be quite vaſcular. No nerves were ever found in the *placenta*.

In midwifery, many are in a hurry to bring away the *placenta*, and to that end introduce their hands into the uterus to ſeparate it therefrom; but, if left to itſelf a little while, freſh pains will ſeparate it, and during their action it is eaſily drawn away by gently pulling at the funis; and again, as by introducing the hand an inflammation in the uterus is ſometimes excited, patience is always to be exerciſed in this affair. It hath long ſince been obſerved, that haſtening the *placenta* was one cauſe of difficulty in delivering it. Many of the moſt eminent practitioners agree, that a flooding only can juſtify the ſpeedy ſeparation of the *placenta*. When neceſſity obliges the practitioner to introduce a hand into the uterus, the back of the hand ſhould be toward the uterus, and the hollow of the hand kept as cloſe to the *placenta* as poſſible in ſeparating it, that the womb may not be injured. Beſides the publications on the practice of midwifery, ſee Tolver's Preſent State of Midwifery in Paris.

PLADAROTIS. A fungous tubercle in the inſide of the eye-lid.

PLAGÆ. Solutions of continuity, wounds, ſtripes, blows, &c. It is ſynonimous with locales.

PLANCUS. See LEIOPODES.

PLANTA. A plant or vegetable. It is an organical body, deſtitute of ſenſe and ſpontaneous motions; it adheres to ſome other body ſo as to draw from it its nouriſhment, propagating itſelf by ſeed. Under this generical name are included trees, ſhrubs, under-ſhrubs, and herbs. Moſt *plants* are hermaphrodite, having the male and female parts in the ſame flower; others bear flowers on the ſame ſtem, ſome of which are male and others female; of this ſort are the melon and cucumber. Some whole *plants* bear flowers, which are never followed by any fruit; whilſt others of the ſame ſpecies bear fruit without flowers, and hence are diſtinguiſhed into male and female *plants*; of this ſort are the hop, hemp, poplar tree, &c. The female flowers are only followed by fruit; the hermaphrodites are reckoned among the female in this reſpect. Inſtances are well authenticated of the fœcundating farina, from the male flower, being carried to the female of the ſame ſpecies to the diſtance of fifteen leagues.

Plants can no more exiſt without nouriſhment and air, than animals can. Their nouriſhment is from oil rendered miſcible with water, by the intervention of alkaline ſalts, or alkaline earth: hence all good ſoils contain ſome proportion of one or the other of theſe: and the oily matter is attracted from the air, which is by putrefactions, exhalations, &c. abundantly ſupplied therewith. The radical fibres attract a part, and the leaves imbibe another portion of nouriſhment; the firſt from the earth, the latter from the air.

To a portion of iron in plants, their green colour is attributed; and this opinion is confirmed by all the accidents that happen to them from an excluſion of the ſun and air, or their free admiſſion, from putrefaction, &c.

On the ſtructure and nouriſhment of plants, ſee Dr. Grew; and on the ſleep of plants, ſee Dr. Hill.

PLANTAGO. Plantain. It is a ſmall perennial plant, common in fields, or by road-ſides; the leaves lie on the ground, have naked unbranched ſtalks, bearing on the top a ſpike of ſmall, imperfect, four leaved flowers, which are followed by little capſules, which opening horizontally, ſhed numerous crooked ſeeds.

PLANTAGO LATIFOLIA, called alſo ſeptinervia, arnogloſſum. Broad leaved plantain, common greater plantain, way-bread. *Plantago* major, or *plantago latifolia* major, foliis ovatis glabris, ſcapo tereti, ſpica floſculis imbricatis, Linn. It hath oval leaves, ſeven, ribs which are prominent on the lower ſide, running from end to end. It flowers in May.

PLANTAGO MINOR, called alſo anguſtifolia, quinque nervia. Rib-wort, the greater narrow-leaved plantain. It hath oblong, five ribbed leaves, and ſhort thick ſpikes.

The leaves of both theſe ſorts are ranked amongſt vulneraries, and are mildly aſtringent; they may be uſed indifferently, but they are rarely noticed in the preſent practice. Boerhaave enumerates ſeventeen ſpecies.

PLANTAGO. A name for a ſpecies of coronopus, and of pſyllium.

PLANTARES. Branches of the nerves called popliteus.

PLANTARES VENÆ. The tibialis poſterior having deſcended to the ſole of the foot, forms theſe veins, by dividing into ſeveral tranſverſe arches, which communicate with one another, and with the ſaphena, and ſend ramifications to the toes.

PLANTARIS ARTERIA EXTERNA. It is one of the diviſions of the poſterior tibial artery. It paſſes on the concave ſide of the os calcis obliquely under the ſole of the foot, to the baſis of the fifth metatarſal bone, and from thence it runs in a kind of arch toward the great toe, communicating there with the tibialis anterior, which perforates the interoſſeus muſcles. The convex ſide of this arch ſupplies both ſides of the laſt three toes, and the outſide of the ſecond toe, forming ſmall communicating arches at the end, and ſometimes at the middle of each toe, as in the hand. The concave ſide of the arch furniſhes the neighbouring parts.

PLANTARIS ARTERIA INTERNA. It is alſo a diviſion of the poſterior tibial artery. This inner *plantaris* having reached beyond the middle of the ſole of the foot, is divided into two, one of which goes to the great toe, communicating with the branch of the tibialis anterior; the other is diſtributed to the firſt phalanges of the other toes, communicating with the ramifications from the arch already mentioned.

PLANTARIS MUSCULUS. The muſcle whoſe tendon covers the planta, the ſole of the foot. It is alſo called tibialis gracilis. It riſes from the outer condyl; it paſſes down between the gaſtrocnemius and the ſoleus, and is united by a cellular membrane to the tendo Achillis. Winſlow thinks that as it is attached to the capſular ligament, it ſerves to keep it from being pinched in the motions of the joint. Dr. Hunter thinks it hath ſome action with which we are not acquainted, ſeeing it is always diſtinct.

PLANTULA MARILANDICA, i. e. Genſing.

PLANUM. The metatarſus.

PLANUM OS. It is the external lateral portion of the ethmoides. Its outſide, next the orbit of the eye (of which it is a part) is ſmooth; whence its name.

PLASTICUS, Plaſtic, from πλασσω, *to form*. Formative, or endued with a faculty of forming.

PLATÆ. The ſcapula.

PLATANUS. The plane tree. The leaves are large and laciniated; the flower is amentaceous, formed in a globular figure, and conſiſting of a multitude of ſtamina. The fruit, which is produced at a diſtance from the flower, is ſpherical, and contains vaſt numbers of long apiculated ſeeds, intermixed with much down. The Oriental ſpecies is called *platanus* latus, becauſe it extends its branches ſo as to cover an hundred men under its ſhade. The leaves cool and repel. See Raii Hiſt.

PLATANUS. It is a name for the female papaya, a ſpecies of maple, and the liquid amber-tree.

PLATINA. A Spaniſh word, and a diminutive of plata, which in that language ſignifies ſilver; ſo *platina* is little ſilver. The chemiſts call it white gold, for it reſembles gold more than any other two metals reſemble each other. It is a metallic body which does not melt in the fire, and is ſaid to be found in the gold mines in the Spaniſh Weſt Indies. It approaches the neareſt of all bodies to the weight of gold, being as 18¼ to 19. Margraaf thinks it is artificial, notwithſtanding what is ſaid of its being a natural production. Some think that it is a ſpecies of emery. See Dict. of Chem. Neumann's Chem. Works; Dr. Lewis's Philoſ. Comm. of Arts, vol. i.

PLATYSMA. Any thing which is flat and broad; thus a piece of cloth, of plaſter, or of metal, is called by this name.

PLATYSMA MYOIDES, alſo called muoides, quadratus genæ, detrahens quadratus, tetragonus, ſubcutaneus, quadratus.

This muſcle riſes from the ſkin inſenſibly below the claviculæ, and is inſerted into the baſis of the lower jaw; it then runs up, and joins the triangularis, and is inſerted into the angle of the mouth, and the ſkin of the cheek. It depreſſes the lower jaw.

PLAUTUS. See LEIOPODES.

PLECTANÆ. The cornua of the uterus.

PLECTRUM. A name for the ſtyloide proceſs of the os petroſum, for the uvula, and, in ſome authors, for the tongue.

PLETHORA, from πληθος, *plenitude*. A *plethora* is when the veſſels are too much loaded with fluids. The *plethora* may be ſanguine or ſerous; in the firſt, there is too much craſſamentum in the blood, in the latter, too little. In a ſanguine *plethora* there is danger of a fever, inflammation, apoplexy, rupture of the blood-veſſels, obſtructed ſecretions, &c. in a ſerous, a dropſy, &c. A rarefaction of the blood produces all the effects of a *plethora*; it may accompany a *plethora*, and ſhould be diſtinguiſhed therefrom. Mr. Bromfield obſerves, that a ſanguine *plethora* may thus be known to be preſent by the pulſe. An artery overcharged with blood is as incapable of producing a ſtrong full pulſe, as one that contains a deficient quantity; in both caſes there will be a low and weak pulſe; to diſtinguiſh rightly, the pulſe muſt not be felt with one or two fingers on the carpal artery; but if three or four fingers cover a conſiderable length of the artery, and we preſs hard for ſome time on it, and then ſuddenly raiſe all theſe fingers, except that which is neareſt to the patient's hand, the influx of the blood, if there is a *plethora*, will be ſo rapid, as to raiſe the other finger, and make us ſenſible of the fulneſs. See his Obſ. and Caſes, vol. i. Linnæus obſerves, that in the ſanguine *plethora* there is a redneſs of the ſkin from the fullneſs of blood, attended with a dyſpnœa. The ſanguine *plethora* is relieved by bleeding; the ſerous by purging, diuretics, and ſweating.

PLEURA, from πλευρα, the ſide. The breaſt is lined with a membrane thus called; it is ſmooth inwardly, but rough outwardly, where it is attached by a cellular membrane to the adjoining parts; it covers the diaphragm, as the peritoneum covers it on the under-ſide; where it goes to the ſpine, it covers the lungs, and makes a complete bag on each ſide, which duplicature forms the mediaſtinum. The uſe of the *pleura* is to give the contained viſcera a ſmooth ſurface, and to confine a lubricating juice, which is ſuppoſed to be ſecreted by the extremities of the arteries; and the mediaſtinum ſerves to keep the heart more fixed in the centre of the body, and prevent wounds of one ſide the thorax from affecting the other. The *pleura* is of a firm texture, and hath many blood veſſels and nerves running in it.

PLEURITICA. A pain in the ſide.

PLEURITIS, from πλευρα. A pleuriſy, or inflammation of the pleura.

Three kinds of *pleuriſies* are ſpoken of by different writers, viz. the true or inflammatory, the falſe, and the ſpaſmodic, or flatulent. Dr. Cullen places it as a ſpecies of pneumonia, or inflammation of the contents of the thorax: and diſtinguiſhes four ſpecies. 1. Pleuritides idiopathicæ ſimplices. 2. Pleuritides complicatæ. 3. Pleuritides ſymptomaticæ. 4. Pleuritides falſæ.

The true *pleuriſy* is when a pain and fever attends an inflammation of the *pleura*.

Some have diſputed whether the ſeat of this diſorder be the *pleura*, or the external coat of the lungs, but it is generally ſuppoſed to begin in the *pleura*, and ſo to extend to the lungs, as by diſſecting thoſe who die of *pleuriſies*, the outer coat of the lungs is found affected.

Its cauſes are whatever can excite internal inflammation in general; alſo ſuddenly drinking of cold water after being heated with exerciſe.

Arcteus gives the following ſhort, but excellent deſcription of a *pleuriſy*: "An acute pain accompanies it, which reaches to the throat, in ſome to the back, and in others to the ſhoulders; it is ſucceeded by a difficulty of breathing, watching, nauſea, redneſs of the cheeks, phlegm, and very yellow and bloody matter. It is worſe if the ſpit be not bloody, or a delirium, or a coma, comes on." The pulſe is remarkably hard, vibrating, and ſtrong; but the *pleuriſy* is principally known to be preſent by the pain in the ſide with a high fever, a difficulty of breathing, and a cough. The pain is uſually juſt above the ſhort ribs; it is increaſed by inſpiration, and leſſens on expiration; thence the breathing is difficult: if the pain ſhifts its ſeat, a favourable prognoſtic thence ariſes; the inſpirations are ſhort. The cough is ſhort, ſuppreſſed, and ſometimes dry; but at others, a mucus is ſpit up from the lungs; at firſt it is thin, but growing more like pus and bloody. The difficulty of breathing ſometimes ſo increaſes, as to check the blood in its paſſage through the lungs, and the patient is preſently ſuffocated. If a mortification takes place, the pain ceaſes ſuddenly, the pulſe as ſuddenly becomes weak and ſmall, though it be quick, and it is often irregular; a delirium and convulſions then preſently come on, and the patient is deſtroyed. If the diſorder does not prove fatal by any of theſe ways, nor yet is relieved by the ſpitting, or by ſome other natural or artificial method, a ſuppuration comes on, which is known by an irregular coldneſs and ſhiverings, and the pain becoming a dull one; if the ſuppurated part points externally, a fluctuation may be felt by preſſing it with the finger; and if the pus is emptied into the cavity of the thorax, an empyema is formed, and is known as remarked in that caſe. Sometimes this ſuppuration is twelve or fourteen days before it is formed; and whether it happens ſooner or latter, it is uſually fatal. There is no diſeaſe wherein the critical ſymptoms are more violent, and more ſtrongly marked than in this, and a perfect cure inſtantly follows, when death is often the moſt expected.

The *pleuriſy* ſhould be diſtinguiſhed from inflammation of the lungs, of the diaphragm, of the mediaſtinum, and

of

of the intercoſtal muſcles; from the baſtard *pleuriſy*, and peripneumony, and from rheumatic pains in the ſide.

If the fever is violent, the heat burning, the cough and tongue very dry, a gangrene may be ſoon expected, if a ſuppuration does not take place. If the ſtitch abates ſuddenly without any manifeſt cauſe, but at the ſame time the countenance changes, he grows pale and ſad, the eyes appear dull and heavy, and the pulſe feeble, it denotes a tranſlation to the brain, and is moſtly fatal. If purple ſpots appear, they are rarely other than fatal.

Let the air in the patient's room be cool, but not cold; and except the heat is very great, let all that is drank be tepid. A ſpoonful of linſeed not bruiſed, and half an ounce of liquorice root infuſed in a quart of boiling water, is an excellent common drink.

In this, as in all other inflammatory fevers, bleeding is a principal remedy. The quantity of blood which may be taken away, and the repetition of the operation, are beſt determined by the continued hardneſs of the pulſe. A free bleeding at the firſt is always more uſeful than ſeveral leſſer ones afterwards; therefore, as a repetition is not often convenient, bleed at the firſt until the patient faints, or till the pulſe is manifeſtly altered. If before aſſiſtance is called in, the expectorated matter is bloody, and ſomewhat digeſted, bleeding muſt be forborne.

Bliſters are rarely to be omitted; generally they are applied on the pained part, immediately after a free bleeding; but ſome prefer the application of them to the legs, and that when the violence of the fever is ſomewhat abated. Before a bliſter is applied, bladders of warm water may be tried by laying them over the part complained of, and the volatile liniment may be rubbed thereon. If the pain is obſtinate, when the bliſter on one ſide ceaſes to diſcharge freely, apply another to the other ſide.

Cooling clyſters frequently injected during the firſt three or four days, render the loſs of much blood leſs neceſſary.

Antimonial preparations given in ſuch doſes as will keep up a nauſea, are of ſingular advantage both with reſpect to the fever, and to expectoration.

Nitre and camphor, with ſmall quantities of opium to moderate the violence of the pain, are powerful aſſiſtants. If the opium ſeems to affect the head, add a little ſal C. C.

If what is ſpit up be yellow, or ſtreaked with blood, the gum ammon. will be a proper addition to the other medicines.

A cooling purge may be given as ſoon as the firſt bleeding is over, and if the heat and inflammation are violent, it may be repeated every ſecond day, notwithſtanding the clyſters; for, if poſſible, a reſolution of the inflammation muſt be aimed at.

If the menſes appear in female patients, they muſt not interfere with the neceſſary repeated bleeding, nor occaſion any alteration in the treatment of the diſeaſe.

If after taking away blood the pulſe ſinks, and becomes languid, the ſal C. C. in doſes of ſix or eight grains may be repeated every three or four hours.

In the very beginning of the diſorder, having premiſed due evacuations, the decoct. rad. ſenek. is almoſt a ſpecific. An ounce of the root may be boiled in water to a pint, and two or three ſpoonfuls may be given three or four times a day. If it excites a vomiting, give ſmaller doſes.

See Swann's Tranſlation of Sydenham's Works; Shebbeare's Theory and Practice of Phyſic; Hoffman's Med. Rat. Syſt. Fordyce's Elem. part ii.

The baſtard *pleuriſy* is an inflammation of the intercoſtal muſcles. The cauſes are nearly ſimilar to thoſe of the true *pleuriſy*. The ſymptoms and cure are alſo nearly alike. It differs from the true *pleuriſy* in that the pain is more external; where the pain is, there a ſwelling is perceived, and if the part is touched, the pain becomes very pungent, and he cannot lay on the pained ſide. There is leſs pain on inſpiration, and of conſequence not ſo great a difficulty of breathing. The cough is generally dry, the general inflammation is leſs violent, and the lungs are leſs apt to be affected; a mortification ſeldom takes place, and ſuppuration hath but little danger attending it.

In order to the cure, bleed in proportion to the hardneſs of the pulſe; purge at proper intervals; bladders of warm water may be applied to the part complained of, and it may alſo be rubbed with the volatile liniment: ſometimes when the pain is acute a bliſter is applied, and the decoction of rad. ſeneka given as in a true *pleuriſy*. If a ſuppuration threatens, encourage it by means of fomentations and poultices.

This diſorder ſometimes terminates in a ſweat, and rarely continues more than ſeven or eight days.

See Fordyce's Elements, part ii. Tiſſot's Advice to the People.

PLEURITIS HEPATICA. A variety of pleuriſy called a falſe pleuriſy, or an inflammation of the liver, with pleuritic ſymptoms.

PLEURITIS SPURIA. It is when the rheumatiſm is ſeated in the muſcles of the thorax.

PLEURITS SPLENICA. Inflammation of the ſpleen.

PLEURODYNE. Pains in the pleura.

PLEURODYNE RHEUMATICA. The rheumatiſm in the muſcles of the thorax, or baſtard pleuriſy.

PLEURON, i. e. Pleura.

PLEUROPNEUMONIA. A diſtemper conſiſting of a pleuriſy and peripneumony.

PLEURORTHOPNŒA. According to Blancard it is a pleuriſy, in which the patient cannot breathe without keeping his neck erect.

PLEUROSTHOTONOS, alſo called tetanus lateralis. It is when from a tetanus the body is bent to one ſide.

PLEXUS. In anatomy, is a kind of network, or complication of veſſels. A *plexus* of nerves, is an union of two or more nerves forming a ſort of ganglion or knot.

PLEXUS CARDIACUS, or Pulmonaris. It is formed of the reciprocal ramifications of both trunks of the eighth pair, and their mutual communications with the filaments of the intercoſtal or great ſympathetic nerve. It is ſituated above the lungs, on the foreſide of the bronchia, and it diſtributes filaments to the pericardium, &c.

PLEXUS CHOROIDES, alſo called plexus reticularis, or retiformis. The formix cut off, and removed, we ſee a vaſcular web, called the *plexus choroides*, with ſeveral eminences which it covers. The firſt two great eminences are called corpora ſtriata, and the other two are called thalami nervi opticorum. The firſt ſmall eminences are clearly united together, the anterior are called nates, and the poſterior teſtes. Le Dran explains it to be a folding of the carotid artery in the brain.

PLEXUS PAMPINIFORMIS. The ſpermatic veſſels.

PLICA, i. e. Plica Polonica.

PLICA POLONICA, or plaited hair. Dr. Cullen places this genus of diſeaſe under the name of trichoma, in the claſs cachexiæ, and order impetigines. This diſorder is only met with in Poland and Lithuania, and conſiſts of ſeveral blood veſſels running from the head into ſome of the *hairs*, which cleave together, and hang from the head in broad flat pieces, generally about an ell in length, but ſometimes they are five or ſix yards long; one patient hath more or leſs of theſe, up to twenty, and ſometimes thirty. They are painful to the wearer, and odious to every ſpectator. At the approach of winter, an eruptive fever happens to many in theſe countries; the eruptions principally infeſt the head, and when at the height an ichorous humour flows from them. In this ſtate they are too tender to admit of being touched, and the matter running down the *hairs* mats them together; the ſkin by degrees breaking, the ramifications of the capillary veſſels following the courſe of the *hair*, or prolonged out of the ſkin, at length are increaſed to a vaſt length.

No method of relief is known; for if the diſcharge is checked, or the veſſels cut off, the conſequence is an increaſe of more miſerable ſymptoms, and in the iſſue, death; though ſome aſſert that there is no danger in cutting them off. Sennertus ſays, when all the morbid matter is thrown out of the body, the *plicæ* fall off ſpontaneouſly. He further obſerves, that the only ſafe practice in this caſe is, to ſolicit the peccant matter to the hairs, to which it naturally tends, and that this is beſt anſwered by lotions of bear's breech. Some ſay that a decoction of the herb club-moſs, and its ſeeds, with which the head is to be waſhed, is ſpecific. See Sennertus, Hoffmann de Mob. cert. reg. propr. Gehema in epiſt. ad Bontokoe de *Plica Polonica*.

PLICATIO. A violent ſhock and bending of a long bone without breaking it.

PLUMBAGO. Plumbage. Called alſo Molybdæna. The beſt is like litharge, yellow, ſhining, and of a pale red under levigation, but boiled in oil it takes an aſh colour; that which is of a leaden colour is not good. It is generated in the refining furnace of gold and ſilver. There is a foſſil ſort They are of the ſame nature as litharge.

PLUMBAGO, called alſo dentaria, dentellaria, lepidium monſpeliacum, lead-wort, or French dittander. It is a plant whoſe root is fibrous, thick, fleſhy, hot, and perennial; the leaves are alternate and entire; the calyx is very hairy; the flower is monopetalous, and they are placed on ſpikes. Boerhaave mentions two ſpecies of them, and notes the whole plants as being hot and biting like the pellitory of Spain, and as proper ſubſtitutes for it.

PLUMBAGO. A name of the perſicaria.

PLUMBUM. Lead. Alſo called Saturnus. Greek writers often uſe the ſame name for *lead* and tin; and many of their Latin tranſlators interpret κασσιτερος both by *lead* and tin. Geo. Agricola mentions three kinds, viz. the white, by which he means tin; aſh-coloured, or biſmuth; and livid coloured, or *lead*.

Common *lead* is a pale, livid, ſoft, flexible metal, eaſily ductile, not at all elaſtic, or ſonorous, and if mixed with any metal, makes it not to ſound; it is about eleven times ſpecifically heavier than water, fuſible in a ſmall heat, it is ſoon calcined, and thereby increaſed in its weight; it does not ruſt; if continued in fuſion it contracts a various coloured pellicle on the ſurface, and, if kept ſtirring, ſo as that freſh ſurfaces may be expoſed to the air, it changes by degrees partly into a fume, and partly into a duſky coloured calx; when fuſed it paſſes through any veſſel yet made to hold it, and with it takes all mixtures except gold or ſilver, or it diſſipates them in vapour, or carries them with it as it is formed into ſcoria, and thrown off at the ſides of the cupel. If the calcination of *lead* is continued ſome time, and the heat is increaſed to different degrees, it becomes yellow, and is called maſticot, or painters yellow; afterwards it becomes red, and is called minium. Theſe calces haſtily heated to a conſiderable degree, melt into the appearance of oil, and, on cooling, form a ſoft flakey ſubſtance called litharge, which is yellow, or reddiſh, according as the *lead* was more or leſs calcined. If the calces are urged with a pretty ſtrong fire, they run into a yellowiſh glaſs, which whilſt in fuſion, corrodes the common crucibles until it hath ſaturated itſelf with their earth. Theſe ſeveral ſubſtances, by the addition of charcoal, iron filings, or any oily matter, becomes *lead* again. *Lead* diſſolves moſt in the weaker acids; ſuch as aqua fortis and water, vinegar, &c.

The ores of *lead*, in colour, commonly reſemble the *lead* itſelf, and are of a cubical, or parallelopipedal ſtructure. Sometimes the ore is black, red, yellow coloured, &c. Engliſh ores are reckoned of three claſſes; that which, affords of good metal betwixt thirty to forty pounds from every hundred weight; that which yields from forty-five to ſixty; and that which gives out from ſixty to eighty. The metal extracted from the ore by fuſion, often contains ſilver enough to pay for its ſeparation from the *lead*.

Ceruſſa. *White* Lead.

Put ſome vinegar into the bottom of an earthen veſſel, and ſuſpend over it very thin plates of *lead*, ſo that the aſcending vapour may circulate about the plates; ſet the containing veſſel in the heat of horſe dung for three weeks, then ſcrape off the white powder, and expoſe what remains of the plates to the ſteams of the vinegar again, until all the *lead* is corroded.

White *lead* is uſed as a coſmetic, but it ſpoils both the colour and the ſmoothneſs of the ſkin, injures the conſtitution, and makes the teeth carious. It is adulterated with chalk, lime, whiting, &c. The entire flakey maſſes, called flake *lead*, or white flake, ſhould be choſen. To diſcover adulterations, compare pieces of equal ſize; the genuine will be the heavieſt; or take an ounce of the ſuſpected ceruſe, of any fixed alkaline ſalt, half an ounce; of charcoal duſt, two drams; put them in a crucible, and in a heat ſtrong enough to fuſe the *lead*; thus the *lead* will be reduced to its metallic ſtate, which being weighed, diſcovers the proportion of the adulteration, one-tenth part being allowed for the corroding acid of the ceruſe.

Acetum Lithargirites. *Vinegar of Litharge.*

Take four ounces of litharge, and the ſtrongeſt vinegar a pint. Digeſt in a ſand heat for three days, ſhaking the mixture now and then.

This vinegar of *lead* is of the ſame nature as ſolutions of ſaccharum ſaturni. The calces of *lead* diſſolve more freely than *lead* in its metallic ſtate. When a ſaturate ſolution is required, the ceruſe is preferred to litharge. When this vinegar of *lead* is diluted with a large quantity of water, it abates external inflammations, the itching and other uneaſineſſes in cancerous ulcers; and before Mr. Goulard's practice, it was uſed for bathing inflammations in ſcirrhous tumors, to prevent their becoming cancerous. Inflammations, and inflammatory tumors in general, are diſperſed by it.

Plumbum Uſtum. *Burnt, or calcined Lead.*

Melt *lead* with a gentle fire, and keep it continually ſtirring with an iron ſpatula, until it changes into a powder.

Minium. *Red* Lead.

Melt any quantity of *lead* in an unglazed earthen veſſel, and keep ſtirring it with an iron ſpatula until it falls into a powder, at firſt blackiſh, then yellow, and at laſt red, taking care not to raiſe the fire ſo as to run the *lead* into a vitreous maſs.

The making of red *lead* is a diſtinct buſineſs, and its makers melt large quantities of *lead* at once upon the bottom of a reverberatoy furnace built for the purpoſe, and ſo contrived, that the flame acts upon a large ſurface of the metal, which is continually changed by raking it with an iron rake, drawn backward and forward until the fluidity of the *lead* is deſtroyed; after which, the calx is only now and then turned. The reverberation of the flame upon the ſurface is abſolutely neceſſary for this effect. Red *lead* is often adulterated with red oker, which is diſcovered by melting it as directed for diſcovering adulterations in white *lead*, only in this the ſalt may be omitted.

Saccharum Saturni. *Sugar of* Lead.

Gently boil ceruſe with diſtilled vinegar in a *lead* or glazed earthen veſſel, until the vinegar is ſweet; then pour off the clear vinegar, and evaporate to the conſiſtence of honey, and ſet it to cryſtallize in a cool place; exhale the remaining liquor, and ſet it to ſhoot again, &c. until no more ſalt will ſhoot. The ceruſe ſhould be freely powdered before the vinegar is put to it; and during the boiling, it ſhould every now and then be ſtirred with a wooden ſpatula. The ſtrong acid which remains after diſtilling the diſtilled vinegar, is the moſt proper for this uſe. If the heat is conſiderable in the boiling of the vinegar and *lead* together, the acid will be diſſipated before it can be fixed by its combination with the *lead*; the vinegar may be made hot, and that will ſuffice. When the ſolution is exhaled for cryſtallization, let a ſmall quantity of rectified ſpirit of wine be added to it, and the mixture ſuffered to cool gradually; the ſugar will then concrete into very large tranſparent cryſtals.

In all the intentions of the acetum lythargiritum, and the tinct. ſaturnina, the ſugar of *lead* may be uſed.

Tinctura Saturnina. *The Saturnine Tincture.*

Take ſugar of *lead* and green vitriol, of each two ounces; of rectified ſpirit of wine, a quart. Reduce the ſalts ſeparately to powder, and put them into the ſpirit, then digeſt without heat, and filtre the ſpirit through paper. The doſe is from ten to thirty drops; but as there is no internal occaſion for its uſe, but which is more ſafely anſwered by other methods, they ought to be preferred; and as the preparations of *lead* have a conſiderable uſe externally, and when ſo applied are not injurious, the moſt prudent practice is to confine them thereto. This tincture was called tinct. antiphthiſica, becauſe it was uſed for checking the immoderate ſweats in hectic complaints.

Extractum Saturni. *Extract of* Lead.

Take as many pounds of the litharge of gold as quarts of vinegar; ſimmer them together for an hour and a quarter, and often ſtir them during their ſimmering; then taking it from the fire, as ſoon as it is cool enough pour the

the clear liquor into bottles to be kept for uſe. If this liquor is made into the common conſiſtence of an extract, it muſt boil yet longer after its ſeparation from the maſs; it will then be of a reddiſh colour. This is Goulard's method of preparing it, on which the ſame things may be obſerved that are related of the acetum lithargirites. This extract is the baſis of all Mr. Goulard's preparations of *lead*.

Aqua Saturni. Water of Saturn.

Mr. Goulard alſo calls this by the name of vegeto-mineral water, and makes it by dropping into a quart of pure water, an hundred drops of the extract of Saturn, and then adding to them four tea-ſpoonfuls of brandy. This is his ſpecific in external inflammations, particularly of the eye, for waſhing ulcers, cancers, ſcrofulas, contuſions, phlegmons, eriſipelas, piles, chilblains, tetters, gangrenes, &c. A ſolution of the ſaccharum Saturni will have the ſame effect.

Lead is of ſo poiſonous a quality, that no dog nor cat will come near the place where the ore is waſhed; if they do, they ſoon die. *Lead* is ſo fatal, that all who work in mines, and other places where it is a principal ſubject of their operations, ſuffer much from it. If it is received into the conſtitution, it produces the colic, palſy, general diſorders of the nerves &c. but externally applied, it is not only ſafe, but powerfully diſcutient, aſtringent, antiſeptic, and ſedative.

Lead is ſometimes diſſolved in acid liquors to prevent or remove their too great acidity; but thoſe liquors are thereby rendered unfit for internal uſe: to diſcover when this is the caſe, drop into the ſuſpected liquor a few drops of a ſolution of orpiment, or of common ſulphur, in lime-water, and the liquor in which *lead* is diſſolved becomes brown; and if on droping into this a few drops of the ſpirit of ſalt, this brown colour does not diſappear, it is *lead*, and not any other ſubſtance that is diſſolved in the acid or aceſcent liquor.

See Dictionary of Chem. Neumann's Chem. Works. Lewis's Mat. Med. Goulard's Treatiſe on the Effects and various Preparations of *Lead*. Aitken's Obſervations on the external Uſe of Preparations of *Lead*.

PLUMBUM NIGRUM. Black lead. It is alſo called nigrica fabrilis; ochra nigra; wadt; kello; *black lead*. It hath none of the properties of common *lead*, except that of colouring in drawing lines. It will calcine, but not fuſe. It is not now uſed in medicine, though formerly it was reckoned drying and repellent. See Dict. of Chem.

PLUMMERI PILULÆ. Plummer's pills. Levigate calomel, and the precipitated ſulphur of antimony, of each two drams, together; when they are well levigated, add three drams of the gum-guaiacum, and one dram of the reſin; mix them well, and make them into a pill, with the balſam capivi, and of each dram make twelve pills.

Its uſes are the ſame as thoſe of the æthiopis antimonialis.

PNEUMA. Spirit, air, vapour, or the breath. Hippocrates often uſes the word *pneuma*, to ſignify a difficult or ſhort breath.

PNEUMATOCELE, from πνευμα, *wind*, and κηλη, *a tumor*. A flatulent hernia, or windy rupture. It is when wind only is the contents of a rupture; but it rarely if ever happens. In ſome putrid fevers, in the ſmall-pox, and gangrenes, ſome parts of the ſkin frequently crackle like parchment under the finger. When carcaſes begin to corrupt, air evidently begins to generate in the veſſels and cavities, from which it may be preſumed that, in a very corrupted ſtate of the fluids, the *pneumatocele* may be formed. Mr. Bell obſerves, that the term *pneumatocele*, is applied to ſignify a diſtenſion of the ſcrotum by a collection of air. This hath been deſcribed by moſt of the ancient writers as a very frequent occurrence; but there is much reaſon to think, that a great proportion of all the tumors they take notice of as containing air, were either formed by collections of water, or by a protruſion of ſome of the bowels. That ſpecies of hernia, to which young children are liable, is to this day by our common people termed a wind rupture; as are all thoſe collections of water in the ſcrotum, with which the new-born infants are affected: but we know well, that none of theſe tumors are formed merely by wind; their contents being of a very different nature. In wounds of the lungs, air is ſometimes extravaſated into the ſurrounding cellular ſubſtance, and in that way paſſes into the ſcrotum, as it does in particular inſtances over the whole body: and in high degrees of putrid diſeaſes, ſo much air may be ſeparated from the blood, as to diſtend the cellular ſubſtance of the ſcrotum, as well as of other parts; but a real *pneumatocele* has never, probably, exiſted as a mere local affection of the ſcrotum. In the caſe of air diffuſed into the cellular ſubſtance of theſe parts, in conſequence of a wound or any other affection of the lungs producing an extravaſation of it, the ſame method of cure will anſwer for its removal that is recommended for anaſarcous ſwellings formed by water, viz. ſmall punctures with the point of a lancet, which are found to be fully ſufficient for evacuating great quantities of air. But whenever the diſeaſe is induced by ſuch a great degree of putreſcency in the ſyſtem as is neceſſary for affecting a ſeparation of air from the blood, there can be little reaſon to expect any advantage to reſult from whatever means may be employed for relief; though when the putrid degeneracy of the humours is the cauſe, a plentiful uſe of antiſeptics and corroborants are indicated.

Mr. Pott poſitively aſſerts the *pneumatocele* to be a miſtake. He ſays, that there is no tumor of this kind, and in this ſituation, in a living animal: it is indeed particularly deſcribed by many writers, both ancient and modern, and ſaid to be a diſorder to which infants are particularly liable: but the complaint ſo deſcribed, and which nurſes, &c. do ſtill call a wind rupture, is not what they take it for; neither is it produced by wind; it is either a true inteſtinal hernia, or a ſpecies of hydrocele. There is no hernia produced by mere wind; the two diſeaſes which in new born children, and infants, are taken for, and called wind ruptures are, a tumor produced by a ſmall quantity of fluid remaining in the lower part of the tunica vaginalis, after its communication above with the cavity of the belly is cloſed; and a true, but ſmall inteſtinal hernia. The natural communication between the cavity of the tunica vaginalis and the belly not being ſhut until ſome ſpace of time after birth; it may become cloſe at its upper part, while there is a quantity of fluid on the lower, too large for the abſorbent veſſels to take up immediately; and conſequently that ſuch infant will, until that office be executed, labour under a true hydrocele of the tunica vaginalis teſtis; a caſe which is very frequent, though generally miſtaken for a wind rupture.

Some late writers miſtake the encyſted hydrocele of the tunica communis which connects the ſpermatic veſſels for the wind rupture; but it differs from the wind rupture in its ſituation; but unfortunately, the encyſted hydrocele of the tunica communis, may be accompanied with a hydrocele of the tunica vaginalis, or with a true hernia, and then the caſe is ſomewhat difficult to aſcertain.

See Bell's Syſtem of Surgery, vol. i. p. 496. Pott's Chirurgical Works, quarto edit.

PNEUMATOSIS, i. e. Emphyſema. Alſo a pain in the ſtomach from wind.

PNEUMATOMPHALOS, from πνευμα, *wind*, and ομφαλος, *the navel*. An umbilical flatulent rupture.

PNEUMONIA. In general, an inflammation in the thorax, and of the membrane that lines it: but in particular, an inflammation of the lungs. Dr. Cullen places this genus of diſeaſe in the claſs pyrexiæ, and order phlegmaſiæ. He diſtinguiſhes two ſpecies. 1. *Pneumonia* peripneumonia. See PERIPNEUMONIA. 2. *Pneumonia* pleuritis. See PLEURITIS.

PNEUMONICA. A ſenſe of weight, or a load on the cheſt.

PODAGRA, from πους, *a foot*, and αγρα, *a prey*. The gout in the feet. Dr. Cullen uſes this term for the gout as a genus. See ARTHRITIS.

PODALIRIUS. A ſon of the Grecian Æſculapius. In this ſon's line, medicine was improved down to Hippocrates, who was the ſeventeenth in lineal deſcent. *Podalirius* gives the firſt inſtance of bleeding; this inſtance obtained him the princeſs, whom he bled, for a wife, and a part of her father's kingdom for a dowry. Nothing remarkable is recorded of the hiſtory of phyſic from *Podalirius* to Hippocrates. See HIPPOCRATES.

POEGEREBA. An American root, uſed in Paris as an aſtringent in dyſenteries.

POERINSII. A name for the arbor ſaponaria.

POINCIANA. Flower fence. It is alſo called frutex pavoninus; criſta pavonis; acacia orbis Americani; erythroxylon, &c. It grows in the Spaniſh Weſt-Indies; its ſeed-pods, infuſed with galls, affords the beſt black ink. See Raii Hiſt.

POLEMONIUM, alſo called valeriana Græca; valeriana cœrulea; Greek valerian; and Jacob's ladder. It is difficult to aſcertain what plant this is. See Raii Hiſt. Plant.

POLIUM. Poley. Of this plant botaniſts enumerate twelve ſpecies: the London College directs the teucrium creticum, Linn. The two following have been noted in medicine.

POLIUM MONTANUM LUTEUM. Yellow mountain poley; it is alſo called ſmall upright poley mountain, and poley mountain of Montpelier. It is a ſmall ſhrubby plant, with ſquare ſtalks, oblong woolly leaves ſet in pairs, and with labiated flowers.

POLIUM CRETICUM, alſo called roſmarinum ſtæchadis facie; teucrium fruteſcens; tree germander; poley of Candia. The leaves are ſet on ſhort pedicles, and are not indented; the flowers ſtand in looſe cluſters, each on ſeparate foot-ſtalks.

Both theſe ſorts have the ſame qualities; the leaves and tops have a moderately ſtrong aromatic ſmell, and diſagreeable bitter taſte. Diſtilled with water, they yield a ſmall quantity of yellow eſſential oil; an extract from the remaining decoction is very bitter. The leaves and tops are corroborant, aperient, and antiſpaſmodic. See Lewis's Mat. Med.

POLLEX. The thumb of the hand.

POLLEX PEDIS. The great toe.

POLYCHRESTOS, from πολυς, *much*, and χρηστος, *uſeful*. An epithet of ſeveral medicines, denoting that they have many virtues.

POLYCHRESTUM SAL. Salt of many virtues. See NITRUM.

POLYCHRESTUM, from πολυ, *much*, and χρηστος, *virtues*, BALSAMUM. The balſamum. The balſam of guaiacum.

POLYDIPSIA. Exceſs of thirſt. Dr. Cullen places it as a genus in the claſs locales, and order dyſorexiæ: but he ſeems to think it is always ſymptomatic. See SITIS.

POLYGALA, alſo called flos ambarvalis; amarella; common blue milk-wort. It is a ſmall perennial plant, with the leaves alternate, uncut, and thoſe on the upper-parts of the ſtalk larger than thoſe on the lower; the flowers are irregular, tubulous, tripetalous, labiated, ſet in looſe ſpikes on the tops, the cup compoſed of five leaves, the two larger of which continue after the flower hath fallen, and embrace like wings, a flat bicellular ſeed-veſſel. The ſtalks of this common ſort are procumbent; the lower leaves are roundiſh, the upper are oblong, narrow, or pointed; the flowers are blue, purpliſh, or red; ſometimes white, with a kind of fringed appendix on the lower lip; the roots are ſlender and hard. It grows wild in dry paſtures, and flowers in July. The roots are ſomewhat ſimilar in taſte to the Senegal milk-wort, but much weaker; and in a leſs degree they have the ſame effect in pleuriſies.

POLYGALA. See SENEKA.

POLYGALA INDICA MINOR. See COLINIL.

POLYGALA VERA, called alſo polygala major maſſiliotica; polygala valentina maritima; colutea caule geniſta fungoſo; coronilla; aſtragalus. Milk vetch.

An infuſion of this herb hath been uſed for increaſing the milk in women's breaſts.

POLYGONATUM, alſo called ſigillum Solomonis; Solomon's ſeal. It is the convallaria *polygonatum*, or the convallaria foliis alternis, amplexicaulibus, caule ancipiti, pedunculis axillaribus ſubunifloris, Linn. It is a plant with unbranched ſtalks, oval narrow leaves, ribbed like thoſe of plantain, generally all on one ſide; on the other ſide hang oblong monopetalous white flowers, two or more together on long pedicles, followed each by a black berry; the root (the part uſed) is white, thick, fleſhy, with ſeveral joints, and ſome flat circular depreſſions, ſuppoſed to reſemble the ſtamp of a ſeal. It is perennial, grows in woods, and flowers in May. Boerhaave mentions ſeven ſpecies. The roots are reſtringent, incraſſant and corroborant; if bruiſed and applied by way of poultice, it diſſipates blackneſs from contuſions ſpeedily. See Raii Hiſt.

POLYGONUM. Knot-graſs. That uſed in medicine is the polygonum aviculare, Linn. The root is creeping and fibrous; the ſtalk and branches are full of joints; the ſtalks recline towards the earth, are ſmooth, finely channelled, ſlender, and branched, full of knots or joints, at which grow long oval ſharp-pointed leaves. The root is cooling and binding, and hath been uſed againſt hæmorrhages inwardly, and againſt inflammations outwardly. See Raii Hiſt.

POLYIDUS. The next phyſician on record after Thyodamas, the ſon of Melampus. Polyidus was either a nephew or a grandſon of Melampus. By the fabulous accounts given of him, we may conclude that he was eminent in practice. The next eminent phyſician was Chiron.

POLYMERISMA. Supernumerary limbs or parts.

POLYMORPHOS. Multiform. An epithet for the os ſphenoides.

POLYNEURON. Plantain.

POLYOSTEON. That part of the foot which conſiſts of many bones.

POLYPETALOUS. Many leaves. Thoſe plants are ſo called whoſe flowers have many leaves.

POLYPHARMACOS, i. e. Polychreſtos.

POLYPODES. Wood-lice.

POLYPODIUM. Polypody. It is generally called *polypody* of the oak. The ſpecies uſed in medicine is the *polypodium* vulgare, Linn. It is a plant with long leaves iſſuing from the root, divided on both ſides, down to the rib, into a number of oblong ſegments, broadeſt at the baſe: it hath no ſtalk or manifeſt flower; the ſeeds are a fine duſt lying on the backs of the leaves in roundiſh ſpecks, which are diſpoſed in rows parallel to the rib; the roots are long and ſlender, of a reddiſh brown colour on the outſide, greeniſh within, full of ſmall tubercles, which are reſembled to the feet of an inſect; whence the name of the plant. It grows in the clefts of old walls, rocks, and decayed trees. That produced on the oak is uſually preferred, though no better than the other ſorts. It is found green all the year. The leaves have a weak ungrateful ſmell, a nauſeous ſweet taſte, a roughneſs and a ſlight acrimony. Its virtues are the ſame as thoſe of fern.

POLYPODIUM TENERUM MINUS, alſo called dryopteris, filix querna repens. Oak fern. It grows in marſhy places. If the root is bruiſed and applied to the ſkin, when the body is in a ſweat, it takes off the hairs.

POLYPODIUM ANGUSTIFOLIUM, alſo called lonchitis, aſpera, filix foliis polypodii. Rough ſpleen-wort. It grows in rough uncultivated places. The root is aperient and diuretic.

POLYPUS, from πολυς, *many*, and πους, *feet*. Many feet. This name is generally applied to a large ſea-fiſh, which hath eight claws or legs which ſerve it to ſwim with, and to convey aliment to its mouth; the four middle claws are the largeſt; the other four are called brachia, crura, cirri, and barba. Its mouth is in the middle of its body. It is found in the Adriatic ſea. See Lemery Traité des Drogues.

POLYPUS. Coagulations and concretions of blood in the blood veſſels are thus called, becauſe they ſend off many ramifications into the adjacent veſſels. The true polypus is only ſuch a concretion of blood as conſiſts of a whitiſh fibrous, and pretty compact ſubſtance, and differs widely from grumous or coagulated blood, which, when found, is called the baſtard *polypus*; it is a ſolid fibrous concretion, formed of the more viſcid parts of the lymph.

Their ſeat is in the ſinuſes of the brain, the ventricles of the heart, the jugular veins, the veins in the uterus, and in any artery or vein. According to Dr. Hunter, in his lecture on the blood, this is no diſeaſe in the living body, for the *polypus* found in the blood veſſels are not found till the body is dying. Thoſe that are the ſubjects of manual operations, their ſeat is in the noſe, the uterus, and the vagina. Theſe are inſtances of the ſarcoma.

The matter of the *polypuſes* is the more weighty fixed viſcid particles of the chyle and lymph.

The remote cauſes of a *polypus* in the blood veſſels are various;

various; as, a redundance of the blood, or its deficiency, may alike be the occaſional cauſes of this diſorder; a tall ſtature, large draughts of cold water ſuddenly drank after being heated with exerciſe, a too free uſe of acids and of ſpirituous liquors, terror, ſudden frights, and long continued grief, the apoplexy, epilepſy, hyſteric fits, a peripneumony, a ſpaſmodic aſthma, a pleuriſy and other acute as well as ſeveral chronical diſorders.

If a *polypus* is in the præcordia, the principal ſign is a long continued palpitation of the heart, often excited by a ſlight cauſe; ſuch as the commotions of the mind, flatulent aliment, or ſuch as renders the patient coſtive; another ſign is, an unequal intermitting pulſe, which is often accompanied with fainting, and difficulty of breathing without any manifeſt cauſe, a compreſſion of the præcordia, and what moſt generally accompanies this is a fixt pain about the heart: each of theſe, if they are almoſt perpetual, are palpable ſigns, that the circulation of the blood is obſtructed by ſome foreign body.

The palpitation of the heart, ſo troubleſome and frequent, as alſo the anxiety which ſo often attends, are cauſed by paſſions of the mind, flatulent diet, coſtiveneſs, &c. which by diſturbing the equable circulation of the blood, produce a greater impetus thereof to the heart, where, being preternaturally congeſted and accumulated, on account of the obſtructing *polypus*, it cannot find a ſufficient ſpace for expanding itſelf; but violently diſtends the heart and its veſſels, ſo produces theſe ſymptoms. The inequality and intermiſſion of the pulſe is occaſioned by the bulk of the *polypus* intercepting or preventing the due conſtriction of the heart and other veſſels on which the circulation of the blood depends. The compreſſion complained of in the præcordia is owing to ſpaſms there. *Polypuſes* happen more frequently in the right auricle and ventricle than in the left, and oftener in the veins than in the arteries: for ſince the chyle, which by means of the ſubclavian vein is conveyed to the vena cava and the right ventricle of the heart, is full of groſs particles which move ſlowly, it eaſily depoſits its heavy parts, by which the columnæ of the heart, being embraced, one ſubſtance or body, as it were, is produced. Then the blood conveyed to the veins by means of their too weak contractile force, circulated more ſlowly, is of a thicker conſiſtence, and more weighty than the arterial blood; hence it eaſily depoſits its thick parts; but eſpecially when theſe, not being intimately mixed, cohere ſlightly, they, by the force of their gravity, tend moſt to the bottoms and ſides of the veſſels. But it is otherwiſe with the arterial blood, for its courſe is promoted more effectually by the force of the arteries, and by its paſſage through the lungs is freed from a part which was unfit for circulation, if it hath not received ſomething from the inſpired air to fit it more effectually for its progreſs.

Polypuſes, by intercepting the circulation, are often the cauſes of ſudden death; this may happen either from their bulk or from the force of the circulation ſeparating one of them from its ſeat, and forcing it into the mouth of ſome principal veſſel, and fixing it there. *Polypuſes* haſten ſome other diſeaſes to an unhappy termination, as is obſerved in peripneumonies, pleuriſies, aſthmas, ſuffocative catarrhs, conſumptions, &c.

The indications of cure, are, to prevent their increaſe, and to diſſolve that which is already formed. At beſt the cure is not leſs difficult than dubious; however, means being uſed, and ſucceſs having followed them, acquits from the charge of neglect, and juſtifies hope.

The patient ſhould avoid entering ſuddenly into vigorous exerciſe, but moderate degrees ſhould frequently be engaged in. Dilute the blood, and reduce its quantity, if redundant. If frights, or other great commotions of mind, ſhould occur, adminiſter ſuch medicines immediately as allay violent commotions, and as render the circulation equable, that are gently reſolvent, and promote perſpiration; let moderate exerciſe alſo be uſed, for thereby the heart is better enabled to free itſelf from the congeſted blood. The bowels muſt always be kept ſoluble. If the habit is robuſt, alcaline ſalts, either fixed or volatile, and bleeding in the foot, ſo as to reſolve the texture of the blood to the greateſt thinneſs that conſiſts with health. Spirituous liquors muſt be avoided; alſo all ſtrong exerciſe, and every diſturbance of mind.

POLYPUS NARIUM. A polypus in the noſe. It hath been called noli me tangere, ſarcoma, and hyperſarcoma; but the *polypus* is always ſoft, and hangs by one or more ſlender roots; the ſarcoma is ſometimes ſoft, but generally hard, and is fixed on a large immoveable baſis.

The *polypus* of the noſe is an excreſcence whoſe branches ſpread among the laminæ of the os ethmoides, and through the whole cavity of one or both noſtrils. All theſe *polypuſes* ſpread on the laminæ ſpongioſæ, pretty nearly in the ſame manner as the hydatids of the belly in one kind of dropſy do on the ſurface of the liver. They proceed from any part of the noſtrils, or thoſe ſinuſes of the cranium that are lined with the ſame membrane as that with which the noſtrils are; being no other than an enlargement of one or more of the glands thereof.

The cauſes may be external or internal; the external are chiefly ſome violence done to the pituitary membrane, the application of ſtimulating drugs thereto, and blows, ſcratches, &c. Internal cauſes are, acrid defluxions, frequent or profuſe hæmorrhages, &c.

Different *polypuſes*, and the ſame at different times, appear of different ſizes and conſiſtences; their elongation is ſometimes ſo quick that they appear below the noſtrils in two or three days; for the moſt part they are free from pain, yet ſometimes they are attended with both pain and hardneſs, and then they generally are diſpoſed to a cancer, in which caſe they are of a livid colour, and apt to bleed by the ſlighteſt touch.

When a *polypus* appears ſoft, and of a pale colour like the ſerum of the blood, being alſo free from pain, it then is the beſt kind, and in the moſt proper ſtate to extract; theſe have rarely more than one attachment, from which they hang, and it is very ſmall; this muſt be brought away with the *polypus*, which commonly happens in the extraction of it if the forceps take hold, high enough. If it is hard, and appears ſchirrus, it will in general be found to have a broad baſis, and be unfit in every reſpect to meddle with: but if it is of that innocent kind juſt mentioned, its attachment is uſually in the anterior parts of the noſe, let the *polypus* appear where it will, and will be beſt extracted anteriorly, for few can bear the introduction of the forceps up behind the uvula.

Mr. Sharp directs the following method of extracting a *polypus*: "Introduce a pair of forceps with a ſlit at their extremities (for the better hold), an inch and an half up the noſtril, to ſecure the *polypus* as near the roots as may be; then twiſt them a little from one ſide to the other, and continue this action while you pull gradually downwards; if it breaks, repeat the extraction as long as any remains, unleſs it is attended with a violent hæmorrhage, which is an accident that ſometimes happens, and rarely fails, if the *polypus* is become ſcirrhus; this hæmorrhage is ſoon abated by the contraction of the veſſels, or the application of lint dipped in ſome ſtyptic." It may be known that the *polypus*, is removed, 1ſt. By the ſight; 2dly, By the voice; and 3dly, By the freedom of reſpiration through the noſe. In introducing the forceps it is difficult to avoid the oſſa ſpongioſa; but to ſhun them, keep the beak of the forceps as near as poſſible to the os palati. When the operator draws away the *polypus*, he may generally bring it away whole, if he draws and moves it very gently. If any of the *polypus* remains, touch it with the lunar cauſtic.

See Poterius, Rulandus, Wedelius, Celſus, Ægineta, Albucaſis, Sennertus, Glendorp, Malpighi, Hoffmann, Levret, Le Dran, Sharp, and Heiſter.

POLYSARCIA, from πολυς, *much*, and σαρξ, *fleſh*. Corpulence. It may be called a ſpecies of cachexy, for many diſagreeable ſymptoms attend; ſuch as an exceſs of fleſh and fat, flowneſs of motion, oppreſſion, weakneſs, difficulty of breathing, ſweating on the leaſt exerciſe, and all the misfortunes that attend voracious animals, or thoſe fattened for uſe, ſuch as inflation, diſtenſion, &c. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order intumeſcentiæ. The beſt remedies in this caſe are, a ſpare thin diet, frequent and long continued exerciſe, little ſleep, and cloſe application of mind. See Cœlius Aurelianus Chron. lib. v. c. 11.

POLYURICA, (Iſchuria). A ſuppreſſion of urine from a long neglect to diſcharge it.

POMA ANARANTIA. The orange.

POMA SINENSES. China oranges.

POMA-

POMACEUM. Cyder. It is the juice preſſed from apples, which hath ſtood to ferment in hogſheads. The more harſh *cyders* are the ſtrongeſt, and keep longeſt. *Cyder* is a uſeful drink in ſcorbutic and melancholic habits; but if drank to exceſs, it occaſions drunkenneſs of a longer continuance, and more pernicious conſequences than is produced by wine. It does not intoxicate ſo ſoon as wine, for its ſpirit conveys along with it many viſcous particles, which hinder both its ſpeedy effect and ſudden diſſipation. Moderately uſed, *cyder* is more ſalutary than wine; and whey that is made by turning the milk with *cyder*, is a much more agreeable drink for patients who labour under fevers, than that which is made with wine.

POMAMBRA. Apples of amber. They are made of odoriferous powders, to which oils may be added, and theſe powders are made into balls, &c. with wax, or mucilage of gum arabic, &c. E. g. take of mace and cinnamon of each two drams; muſk, civet, and gum arabic of each one dram; gum tragacanth, two drams. Mix and make into balls. They are agreeable to ſmell to.

POMATUM. It is the unguentum ſimplex. It was formerly made with lard, ſuet, and a ſpecies of apples called pome-waters; but at preſent it is only lard beat up into a curd, with the addition of a little roſe-water, or other ſweet-water, to give it an agreeable ſcent.

POMPHOLYX, πομφολυξ. A bubble excited in a liquid ſubſtance by ſome flatulent ſpirit or air contained therein. This name is given to the matter which is found adhering to the covers of the crucibles, &c. in the form of thin cruſts or light downy powder, of a white or whitiſh yellow colour, and is the produce of zinc, which ſublimes from the lapis calaminaris in making of braſs. It is alſo called nihil album, and white tutty.

POMUM. An apple. It is any fleſhy veſſel, containing more ſeeds than one; ſo that all plants which produce ſuch fruit are termed pomiferous, that is, *apple*-bearing.

POMUM ADAMI. A name for the lemon, fructu Aurantii; alſo for the protuberance in the fore part of the neck formed by the thyroid cartilage.

PONDO, or Pondus. A weight. The medical or troy pound is leſs than the averdupoiſe, but the ounce and the dram are greater. The Troy pound contains 5760 grains, the avoirdupoiſe pound contains 7000 ſuch grains. The Troy ounce contains 480 grains; the avoirdupoiſe ounce contains only 437½ grains. The Troy dram contains 60, the avoirdupoiſe rather more than 27. So that attention hereto ſhould be had in the making up what is preſcribed with a view to the Troy *weights*.

The pound and the pint are called libra by the Latins. But there is not any known liquor, of which a pint in meaſure anſwers to a pound in *weight*.

Rectified ſpirit of wine, a pint in meaſure, exceeds a pound *weight*, by half an ounce.

PONS VAROLII. Varolius, an Italian anatomiſt, gave this name to a ſort of arch in the cerebellum. He firſt obſerved it.

PONTICA VINA. Acid, feculent, and tartarous wines.

PONTICUM MEL. A ſort of poiſonous honey.

POPLES. The ham or joint of the knee.

POPLITEA ARTERIA. The arteria cruralis, in paſſing the ham, takes the name of *poplitea*, which, whilſt in the ham, is covered only by the integuments. It ends by dividing into the tibialis anterior and tibialis poſterior. Surpriſing as it may appear, it is a fact, that though the artery in the middle of the thigh may be tied with impunity, and the blood be diſtributed as uſual to the leg and foot, yet the *popliteal* artery in the ham never can. An aneuriſm in this artery ſeldom laſts long enough to cauſe a caries in the adjacent bones. When this diſeaſe happens it admits of no relief, except from amputation of the limb. The artery in this part, when dilated, will increaſe, and at length preſs upon the parts below, ſo as to make them become œdomatous, painful, and hard; the conſequence of which will be the deſtruction of the patient by a mortification of the limb, if amputation is not complied with in time.

POPLITEA VENA. The crural vein takes this name, juſt above the ham, and at the lower part of the muſculus popliteus, it divides into the tibiales anterior, tibialis poſterior, and peronæa.

POPLITEUS. The ſciatic nerve having reached the ham, takes this name: it divides into two branches, which ſpread about the whole leg.

POPLITEUS MUSCULUS, from *ples, the ham*. The place of its ſituation. This muſcle riſes tendinous from the external condyl of the femur, within the capſular ligament; it paſſes tendinous under the ham inwards; it plays upon the head of the tibia, and is inſerted into the ſuperior, and inner part thereof, ſerving to turn the toes inwards.

POPULAGO. Marſh-marigold. The flower reſembles that of the ranunculus. The plant is ſo cauſtic, that cattle avoid it though graſs be ever ſo ſcarce. It is not noted for its medicinal qualities.

POPULARIS. Endemical or epidemical.

POPULUS. The poplar. Boerhaave takes notice of five ſpecies.

POPULUS NIGRA, Linn. Black poplar. It is a tall tree, with dark green, rhomboidal, acuminated leaves, producing imperfect flowers in catkins. In ſome of the individuals called male, the flowers are barren; in others, called female, they are followed by membranous pods, containing a number of ſeeds winged with down. It is indigenous in watery places, and quick of growth. The young buds of the leaves are made into an ointment; they abound with a yellow unctuous odorous juice, which they readily impart to rectified ſpirit of wine. The tincture yields a fragrant reſin, which approaches to the nature of ſtorax. See Raii Hiſt.

POPULUS ALBA. White poplar. It grows in moiſt places; a decoction of its bark is given to remove the ſtrangury and the ſciatica.

POPULUS TREMULA. The aſp, or aſpin-tree. Its qualities are ſimilar to thoſe of the black poplar. It grows in woods and marſhy places.

PORI. Pores. It is ſuppoſed that one grain of ſand will cover one hundred and twenty-five thouſand of the pores in our ſkin, and that each pore is the orifice of a diſtinct gland; but this is only a ſuppoſition founded on the authority of Lewenhoek, who with aged eyes, and bad glaſſes, ſaw what younger eyes, aſſiſted with better glaſſes than he ever poſſeſſed, could never diſcover. Plants perſpire as well as men; but notwithſtanding the great perſpiration of both, *pores* cannot be diſcovered either in the cuticle of a man, or in the fine membrane that covers the external ſurface of the leaves.

PORPHYRITES. Red marble, or porphyry. It is brought from Egypt, Ethiopia, &c. It is a genus in the order of ſtones called compound ſtones. The compound ſtones conſiſt of more than one kind of ſtone. The characters of the *porphyry* are, ſtone, conſiſting of a baſis, which is of a ſtrong compact texture, with detached pieces of felt ſpat embedded in it, and freely ſtriking fire with ſteel. Edwards's Elements of Foſſilogy.

PORRUM. Porret, or common leek. It differs from garlic only in being weaker. Botaniſts enumerate ſeven or eight ſpecies.

PORRUS, the ſame as ſarcoma.

PORTÆ VENA, vel Portarum Vena. The ſplenic, meſenteric, and meſocolic veins, uniting at the root of the meſentery, form the *vena portæ*. It may be conſidered as two veins joined endwiſe, and that ſend out branches in oppoſite directions to each other; that one of theſe veins is ramified in the liver, the other lying without the liver, and ſending its branches to the viſcera of the belly; that in the liver may be called *vena portæ* hepatica ſuperior, or minor; the other *vena portæ* ventralis inferior, or major. The particular trunk of the *vena portæ* hepatica, forms what is called the ſinus of the *vena portæ*; from this ſinus five principal branches go out, which are divided and ſpread through the whole ſubſtance of the liver; the extremities of theſe branches end in the pulpy friable corpuſcules, which ſeem to be thick villous folliculi. In theſe folliculi the bile is ſecreted, and collected by as many veſſels of another kind, which again unite in one common trunk; theſe ramifications are termed pori biliarii, and the trunk ductus hepaticus. The *vena portæ* ventralis is ſituated under the lower, or concave ſide of the

the liver, and joined by anaſtomoſis to the ſinus of the *vena portæ* hepatica, between the middle and right extremity of that ſinus, from thence it runs down from right to left under the trunk of the arteria hepatica, bending behind the beginning of the duodenum, and under the head of the pancreas, its length being about five fingers breadth. At the head of the pancreas it loſes its name, and divides into the meſaraica major and minor, and the ſplenica. See Winſlow's Anatomy.

PORTAGUILLE. See ACUTENACULUM.

PORTIO DURA. Winſlow calls it nervous ſympatheticus minor. It is one of the two diviſions of the ſeventh pair of nerves from the head, which run into the os petroſum, and there divides into the *portio dura* and *portio mollis*. The *portio dura* goes out between the ſtyloid and maſtoid proceſſes, paſſes through the parotid, becomes a cutaneous nerve upon the face, and communicates with the upper maxillary nerve.

PORTIO MOLLIS. The ſeventh pair of nerves go out from within the head, into the os petroſum, and there divides into two branches called *portio* dura, and *portio mollis*. The *portio mollis* is ſpent upon the labyrinth in the ear; it enters the meatus auditorius internus, and paſſes to the veſtibulum and cochlea.

PORTORARIUM. The duodenum, or the pylorus.

PORTULACA. Purpie, or garden-purſlane. It is chiefly uſed in the kitchen. Boerhaave enumerates ſix ſpecies; the leaves are cooling, antiſcorbutic, and moderately aſtringent. The ſeeds are the ſame.

PORTULACA MARITIMA. Alſo called halimus, atriplex maritima. Common ſea purſlane. It is found in ſalt marſhes; it flowers in July and Auguſt. It is a hot plant, and pickled in vinegar it helps the appetite.

PORUS. See POROS, *a paſſage*, and PORIS.

PORUS BILARIUS. The bile duct, from πορος, *a paſſage*.

PORUS OPTICUS. It is alſo called the blind point. It is the point on the retina where no object is ſeen.

PORUS RETICULATUS. A ſpecies of ſubmarine plant called eſchara.

POSCA. Vinegar and water mixed.

POSSETUM. Poſſet. This is by foreigners reckoned peculiar to the Engliſh. The ſerum of a *poſſet*, called *poſſet* drink, is like the whey of milk, only differing with reſpect to what the means were by which the curd and whey were made to ſeparate.

POSTBRACHIALE. The metacarpus.

POSTERIOR MUSCULUS AURIS, i. e. Abductor auris.

POSTHE. The prepuce.

POSTPOSITIO. Poſtpoſition. When the paroxyſm of a fever comes on later than it is expected, it is called the *poſtpoſition* of the paroxyſm. When it begins ſooner, it is called the anticipation.

POTAMOGEITON, from ποταμος, *river*, and γειτων, *adjacent*. Broad-leaved pondweed. It is alſo called millefolium, from the ſmallneſs of the leaves; and viola aquatica, from the colour of its flower.

This plant is found in ſtagnant waters; it flowers in June and July. Boerhaave enumerates eleven ſpecies, but they are not noted in medicine.

POTIO. A potion. It is a liquid form of medicine, calculated for one doſe or draught. *Potions* are diſtinguiſhed into cathartic, cardiac, and alterative.

PRÆCIPITANTIA. Precipitating medicines; that is, medicines which moderate the motion and heat of the blood, as was ſuppoſed, by abſorbing and correcting the acid contained therein.

PRÆCIPITANS MAGNUM. A name for the os ſepiæ.

PRÆCIPITATIO. Precipitation. It is the ſeparating of ſolid bodies from any fluid menſtruum wherein they are diſſolved, by the addition of a third body, which counteracting the power of the menſtruum, cauſes that which was diſſolved to regain its ſolid form, and to ſubſide in the ſtate of a powder. Or, by *precipitation*, bodies are recovered from their ſolutions, by means of the addition of ſome other ſubſtance, with which either the menſtruum, or the body diſſolved, hath a greater affinity than they have with one another.

Precipitation is of two kinds: firſt, where the ſubſtance ſuperadded, unites with the menſtruum, and occaſions that which was before diſſolved to be thrown down. Secondly, where the ſubſtance ſuperadded unites with the diſſolved body, and falls along with it to the bottom. Of the firſt we have an example in the *precipitation* of ſulphur from alkaline lixivia by the means of acids; of the ſecond, in the *precipitation* of mercury from aqua fortis by ſea-ſalt, or its acid.

When the matter to be precipitated is all at the bottom of the veſſel, the fluid being poured off, or filtered, what remains behind is all to be dried in the ſame manner as levigated powders are.

Precipitation may alſo be effected by dropping in a liquor ſpecifically lighter than the menſtruum by which the precipitated matter was diſſolved. Thus the ſpirit of ſal ammoniac precipitates plentifully the ſolutions of metals in acid menſtruums; the ſame is effected by rectified ſpirit of wine, which alſo precipitates all ſalts from water. Acids poured upon heavier acids will precipitate whatever ſwims in them; thus the ſpirit of ſalt precipitates lead, copper, and tin, diſſolved in oil of vitriol. *Precipitation* alſo ſucceeds, if an heavier body be added to the diſſolving menſtruum: thus acids, or water alone, will carry down all the ſolid corpuſcles which they meet with in tinctures of vegetables extracted by ſpirit of wine; and the ſame tinctures extracted by water, or wine, are precipitated by means of acid ſpirits.

When a third body is added to any ſolution, for precipitating one part thereof, it produces its effect by uniting with the diſſolving liquor, or with the matter which is diſſolved, and as one or the other happens. That which is precipitated is either ſimple or compound; if the precipitating matter joins with the diſſolving liquor, the precipitate is ſimple; if it unites with the precipitated matter, the precipitate is compound. This ſhould be obſerved, and the reſpective precipitates diſtinguiſhed by the words ſimple or compound.

Sometimes an advantage may be made of the liquor which remains after the *precipitation* is performed: thus, when fixt alkaline ſalt is diſſolved in water, and ſulphur is diſſolved in this lixivium, the addition of acids ſeparates and throws down the ſulphur, only in virtue of the acid uniting with, and neutralizing the alcali, by which the ſulphur was held diſſolved; conſequently, if the *precipitation* is made with the vitriolic acid, and the acid gradually dropt in till the alkali is completely ſatiated, that is, ſo long as it continues to occaſion any *precipitation*, or turbidneſs, the liquor will yield by proper evaporation and cryſtallization, a neutral ſalt, compoſed of the vitriolic acid and fixed alcali, that is, the vitriolated tartar; in like manner, if the *precipitation* is made with the nitrous acid, a true nitre may be recovered from the liquor; if with the marine, the ſalt called ſpiritus ſalis marini coagulatus; and if with the acid of vinegar, the ſal diureticus. See the Dict. of Chemiſtry.

PRÆCOCIA, or PRÆCOQUA. Apricots.

PRÆCORDIA. The diaphragm. Sometimes it ſignifies the hypochondria. Fernelius, in lib. iv. de Febr. comprehends under this term the region about the ſtomach, the *diaphragm*, the cavity of the liver and biliary ducts included therein, the pancreas, the ſtomach in particular, and its upper orifice, with whatever is contained under the inflections of the ſpurious ribs, towards the foreparts, and the ſternum. Some have given this name to the metatarſus.

PRÆPARANTIA MEDICAMENTA. Preparing medicines; that is, ſuch as prepare the morbid humours, and diſpoſe them to ſeparate from the healthy, and to paſs off by the help of evacuants.

PRÆPARANTIA VASA. It was formerly ſuppoſed that the ſeed was prepared in them; whence the name. The ſpermatic veſſels.

PRÆPARATA VENA. An ancient name for the frontal veins.

PRÆPUTIUM, from *præputo*. To lop off before. The prepuce or foreſkin.

PRÆSAGIA. Preſages. Fred. Hoffmann obſerves, that three things are requiſite to a right *preſage*, viz. 1ſt, That from due obſervation we are able to trace and inveſtigate the origins and cauſes of diſorders, in order to oppoſe them in the beginning, by proper remedies, or give

ſalutary directions. 2d, That we accurately know the various natures of diſeaſes, and their differences with reſpect to different conſtitutions, that we may the better be able to give medicines that are capable of removing them. 3d, That we be able to form a right judgment of the operation of medicines, and the event of diſorders This laſt, though it does not directly obtain the end of the healing art, yet it promotes the certainty of medicine and the reputation of the phyſician.

PRÆSENTATIO. A preſentation. In midwifery it is the manner in which a child offers itſelf in its paſſage into the world; and the different *preſentations* are denominated, according to that part of the child which is perceived at the mouth of the womb, when a woman begins to be in labour.

In a natural labour, the child preſents with its vertex. See PARTURIO.

The cauſe of wrong *preſentations* is not exactly known; but in different writers on midwifery, various opinions are given.

Preternatural *preſentations* are thus known. The membranes puſh out in a round form, in a right *preſentation*; but when any other part offers, the membranes protrude in a lengthened form; and when the pain is off, no part of the child can be perceived, but the membranes only, as in the beginning of labour; after ſome time indeed, from the quantity of water, the membranes have a round form, but then the orifice of the womb is but little opened thereby. If the head preſents, it is diſtinguiſhed by bringing the finger round, ſo as to take in a large ſpace of the head; we then feel an uniform hard ſubſtance, and often find a ſuture. When a ſhoulder, or a hip preſents, they have not that uniform hard feel which is obſerved when the head offers itſelf. If the back preſents, the vertebræ are felt. If the belly preſents, the funis umbilicalis diſcovers it. The breaſt preſenting, is known by feeling the ribs. When the breech offers itſelf, the private parts are eaſily perceived there, and the meconium is ſqueezed out at each pain. The hand, or foot preſenting, requires that we feel for the heel, that we may determine how to proceed.

Both feet preſenting. When this happens, the toes are generally towards the pubis, inclining a little to the right or to the left; draw the child gently downward whilſt the pains continue to increaſe, and are in their full force; and as you draw the child downwards gradually incline it to the ſide towards which its toes turn; for when the breech is delivered, the child muſt be turned with its face to the ſacrum of the mother. When the navel appears, draw down an inch or two of the funis, to prevent its being torn or too much ſtretched; when the body of the child is ſo far delivered, that its ſhoulders check its progreſs, introduce a finger to the elbow of the child; and gently draw the arm down, not perpendicularly, but by inclining it acroſs the breaſt of the child; this done, bring down the other arm with the ſame care. The arms brought down, place the fore and middle fingers of one hand, one on each ſide of the neck, with the thumb in one, and the fingers in the other axilla; then introduce the fore and middle fingers of the other hand into the mouth of the child to turn the face into the hollow of the ſacrum, and ſo finiſh the delivery.

One foot preſenting. In this caſe the toes are to the iſchium. If the leg is low in the vagina, ſo that the knee appears, it is too late to bring down the other foot, which may continue until the breech is delivered, and the child's face turned to the iſchium: then proceed as when the breech preſents.

Breech preſenting. When this is the preſenting part, if it is very high, and the os internum ſoft and open, break the membranes, and bring away the child by the feet; but if theſe circumſtances do not attend, leave the buſineſs a while to nature, the pains will puſh forward the preſenting part, and the labour will be as eaſy and ſafe as when the head preſents. In theſe caſes, the face of the child is uſually towards the belly of the mother, but ſometimes it is with its ſides towards her pubis and ſacrum, and as it inclines a little with its face to one or the other, in the courſe of the labour it will turn thereto. As it preſents, ſo let it deſcend, and keep the membranes whole as long as poſſible, for the more eaſy dilatation of the parts. When the hams of the child are from under the pubis, and the perineum freed from the breech preſſing on it, take hold of the child with both hands, and turn it with its face to the mother's back, and then bring down one leg after the other; if the child is very large, the legs muſt be brought down whilſt they are next the os pubis, and then the child's face is to be turned towards the mother's back. When the legs are free, proceed as when both feet preſent. When it is neceſſary to turn the child's face to the back of the mother, do it whilſt the pains are departing.

Back preſenting. When this ſituation is known, and the orifice of the womb is ſufficiently dilated, break the membranes, introduce the hand into the uterus, and carefully ſeek for the feet. When the child is in a lengthened form, and preſents with its back, neck, ſhoulders, or face, if at the ſame time the waters are gone, the caſe may prove a very difficult one. In tranſverſe ſituations of the child, the orifice of the womb does not open ſo ſoon as when the head preſents.

Belly preſenting. In this caſe the child is ſeldom living. The method of delivery is the ſame as when the back preſents. If the feet cannot be reached, get the knees to the belly, and then the feet are ſoon ſecured.

An arm preſenting in the vagina, and the membranes broke. This is one of the moſt difficult caſes that occurs in midwifery, eſpecially when the waters are gone, and the uterus contracts upon its burden forcibly. To proceed, puſh up the fore parts of the child towards the fundus uteri with one hand, whilſt with the other the feet are ſought for. Or, if the waters are all run off, begin with ſeeking for the feet; when they are found, draw them gently towards the vagina, at the ſame time puſh up the body of the child. When the feet are brought into the vagina, the caſe becomes the ſame as when the feet preſent. When the arm preſents, and the os internum is very rigid, before any attempts are made, wait for the dilatation of the part by the force of the pains.

In the London Medical Journal, vol. v. p. 64, &c. are related, by Dr. Denman, three caſes of the upper extremities preſenting, and the delivery being partly effected by the ſpontaneous evolutions of the child. In the firſt caſe, the woman had been in labour during the whole night, and one of the child's arms was the preſenting part; on attempting to turn the child, the pains were too violent to admit the introduction of the hand into the uterus. Imagining the child was ſmall, ſo that it might paſs, doubled, through the pelvis, farther endeavours to turn were omitted, and on waiting a little the breech preſented, and the head was the laſt part that was delivered. In the ſecond caſe, the *preſentation* was the ſame as in the firſt, and it was agreed on to turn the child; but the pains were ſtrong and frequent, ſo that the action of the uterus was ſuch as to forbid all endeavours that way. It was then agreed on to wait for the effect, which a continuance of the pains might produce, or till they were abated, when the child might be turned with leſs difficulty. The pains continued, and propelled the child lower into the pelvis, and in little more than an hour it was born; the breech being expelled, as in the firſt caſe. In the third caſe; the arm preſenting, and labour gone on for ſome time, after which attempts were made during ſeveral hours to turn the child, whoſe ſhoulder ſtrongly preſſed upon the perinæum; at length by the action of the uterus, the child was doubled, and the breech expelled; after which, the ſhoulders and head were extracted. In all theſe caſes the Doctor obſerves, that the women were at the full period of utero-geſtation, and the children were of the uſual ſize. More caſes might be related, but theſe ſufficiently prove the fact, that in caſes in which children preſent with the arm, women will not neceſſarily die undelivered, though they are not aſſiſted by art. With reſpect to the benefit we can in practice derive from the knowledge of this fact, it may be obſerved, that the cuſtom of turning and delivering by the feet in *preſentations* of the arm, will remain neceſſary and proper, in all caſes, in which the operation can be performed with ſafety to the mother, or give a chance of preſerving the life of the child. But when the child is dead, and when we have no other view but merely to extract the child, to remove the danger thence ariſing to the mother, it is of great importance to know that the child may be turned ſpontaneouſly, by the action of the uterus. If we avail ourſelves of that knowledge, the pain and danger which ſometimes attend the

operation

operation of turning a child, may be avoided. Nor would any perſon verſed in practice, fixing upon a caſe of preternatural *preſentation*, in which he might expect the child to be turned ſpontaneouſly, be involved in difficulty, if from a defect of the pains or any other cauſe, he ſhould be diſappointed in his expectations. Nor would the ſuffering or chance of danger to the patient be increaſed by ſuch proceeding. About thirty of theſe caſes have lately occurred, in two of which the children were born alive.

Some propoſe bleeding ad deliquium for abating the too ſtrong contraction of the uterus; and, at the moment of fainting, to attempt delivery.

The head locked faſt at the brim of the pelvis. In this caſe, and the ſeven next following, the membranes are broke, and the uterus is contracted about the body of the child. In this caſe, if the child be living, a tumor will be formed on its head, which will ſo increaſe, as to reach to the os externum; but when the child dies, this tumor becomes ſoft, and gradually diſappears. Whatever part of the head preſents, it may be locked faſt, though generally the face is towards the ſacrum; care is, however, required to know the part which preſents, and the ſituation of the child. In order to delivery, the curved forceps are neceſſary.

The middle of the ſagittal ſuture reſting on the pubes, and the face of the child turned up towards the fundus uteri. In this caſe the chin is preſſed upon the breaſt. Mr. Levret of Paris directs the following procedure in this caſe. "Before the firſt branch of the forceps is introduced, a fillet muſt be paſſed through the perforated blade, and likewiſe through the ſecond before it is paſſed; and after fixing the handles, tie the ends of the fillets together ſo as to hang down in a nooſe, about ſix or ſeven inches; then taking the forceps in the right hand, raiſe the handles, and bearing down at the ſame time with the left-hand in the garter, the forceps will be converted into a lever of the third kind, the moving power being between the point of ſupport (or the hand) and the point of reſiſtance (or the head of the child) which will be made to deſcend into the hollow of the ſacrum, and be delivered afterwards with eaſe.

The head preſenting with the ears to the pubes and os ſacrum. This is known by the ſagittal ſuture running from iſchium to iſchium, or oblique. And to know which way the face is turned, the ear ſhould be felt at the pubes. Sometimes the head may be removed from this poſition with our fingers; but when this cannot be done, the forceps muſt be uſed. If the face is to the left-ſide, turn the woman on her left-ſide; if to the right, lay her on her right ſide. In general, when the ears are to the ſides of the pelvis, and the forceps are to be applied, the woman ſhould be on her back, and her breech over the bed; but when the ears are to the pubes or groin, it is better to lay her on her ſide, and generally on the left. If the blade of the forceps cannot be introduced by the os pubis, the ear laying cloſe to it, introduce the blade a little to one ſide, then ſlip it over the ear under the pubis, and as the blade goes up, withdraw the hand. Over the ear is the beſt ſituation for the forceps, but if this cannot be, put one blade before one ear, and the other behind the other.

The forceps ſecured, pull gently when the pains are preſent, until the vertex is as low as the loweſt part of the iſchium; then turn the forehead into the concave part of the ſacrum, and give it a quarter turn more to bring the body into the ſame poſition, or, perhaps, the ſhoulders may catch againſt the pubis; then reverſe the quarter turn, and the forehead will be in its proper ſituation. The delivery will now be finiſhed, as when the head is low, and the pains gone.

The face preſenting with the chin to the pubes. In any faſe caſe, if the pains are ſtrong, uſe no forceps, but take time, and nature will do her own buſineſs. If the face preſents with the chin to the pubes, if the woman hath had children before, and the pelvis is good, the child will come forward very well by the force of the pains; for when it hath got below the pubis, the fore part of the neck will turn on it as on a fulcrum, and the vertex will riſe from under the perineum, and delivery will be effected without extraordinary difficulty, provided the perineum is well ſupported.

If called in time, and the os tincæ is dilated, it is uſually recommended to introduce the hand, and bring away the child by the feet; but if the pelvis is diſtorted, it is better to make the vertex preſent, by turning it with the hands. But be the pelvis as it will, if the face preſents with the chin to the pubes, if the waters are run off, the head low, and the pains very languid, apply the forceps. When the chin is cleared the difficulty is over. After the forceps are fixed, be careful to prevent the chin from catching againſt the os pubis.

The face preſenting with the chin to the os ſacrum. When the waters are run off, and the head is ſtrongly detained, delivery is extremely difficult. The head muſt be raiſed and turned with the chin to the pubis before delivery can be effected. In this caſe truſt to nature rather than begin too ſoon with the forceps; when the forceps are applied, force them upwards until you can turn the chin to the os pubis, and then proceed as when the chin at firſt preſented this way.

The face preſenting, and the chin to one ſide. If the woman is laid on her left-ſide, the child may often be turned ſo as for the chin to paſs under the pubis. If this cannot be done, introduce one blade of the forceps under the pubis, the other at the ſacrum; then bring the chin under the pubis, and proceed as in that caſe.

The face to the os pubis. When the fontanel preſents, the face is generally to the pubis. In this caſe, if the pelvis is good, and the parts dilated, the child will paſs by the force of pains; but if the parts are rigid, the perineum will be endangered. If the child is ſmall, and the pelvis large, pains may ſuffice to deliver the child; but if otherwiſe, as ſoon as the waters are broke, introduce the hand, and deliver by the feet. If this opportunity does not favour us, the forceps muſt be uſed. In order to feel the ear, puſh up the head, that the finger may paſs to the ear, and the forceps follow it; then fixing the other ſide of the forceps, and when the head is pulled ſufficiently low, turn the forehead into the cavity of the ſacrum, and deliver as when the head is low, but pains wanting.

The ſhoulders locked. In this caſe the head is moveable in the vagina; the face is on one ſide, one ſhoulder reſts on the upper and lateral part of the os ſacrum, the other paſſes over the ſides of the os pubis, ſo that the ſcapulæ and back of the child reſt in the pſoas and iliac muſcles on one ſide, and the knees and elbows preſs the ſame parts on the other ſide. The intention here is, to remove the ſhoulder on the ſide of the ſacrum, to bring them both to the wideſt part of the pelvis; to do this, ſlide a blade of the forceps under the ſhoulder of the child, and as with a lever raiſe that which reſts on the ſacrum, and carry it over the projection, which, when properly executed, the head will deſcend, and the delivery be almoſt ſpontaneous.

The head ſeparated and left in the uterus. In order to delivery, introduce a hand, and turn the chin to the os pubis, then, an aſſiſtant gently preſſing the belly to keep the head from rolling about, the operator muſt introduce the long curved forceps, and fix them on the head; having thus done, draw the head down until it is fixed in the pelvis; turn the handles up to the os pubis, and introduce a pair of ſciſſars; open the head, and deſtroy the ſtructure of the brain; after this, give the forceps a diagonal turn, then proceed as in any other caſe in which the head is ſo ſituated.

Twins. It is very difficult during pregnancy to know whether or no there will be twins at the birth. When there is but one child, the uterus rarely, if ever, riſes above the brim of the pelvis; ſo if on the third or fourth month it riſes up to the navel, it is very probable that there are twins. If after the delivery of one child the uterus is contracted into a firm hard ball above the os pubis, it is thereby known that there is not another; if, on the contrary, it is much diſtended, we ſhall find a child yet to come forth; and on examining there is another ſet of membranes. When one child delivered, tie the funis in two places, then wait for pains coming on, to deliver the next, except it preſents in a bad poſition, in which caſe bring it away by the feet. Except the placenta of the firſt child is looſe, and preſents itſelf for excluſion, leave it until the other child or children are delivered. The placentæ generally adhere to each other, but they are two diſtinct ones; though it ſometimes happens that ſome of their veſſels communicate; whence the neceſſity of tying the cut end of the funis when the firſt child is delivered.

Monſters. Theſe are when two children are ſo united

as to be one, or when one child hath, in ſome remarkable inſtances, the parts of two, and but one funis and placenta are found. When theſe are ſmall, they ſometimes paſs by the common methods of delivery, but when they are large they occaſion ſome difficulty. Rules cannot eaſily be laid down, becauſe of the variety of the ſubjects; the ſagacity and dexterity of the operator muſt here be wholly left to themſelves both in ſuggeſting the method, and in executing the plan for delivery.

The head low and right, but the pains have ceaſed. The head being long confined in the pelvis, is equally dangerous to the mother and the child, as a mortification may be induced in the firſt, whoſe influence will extend to the laſt, and prove fatal to both. To complete the delivery, the operator introduces one hand into the vagina, and puſhes them on until the ends of his fingers enter the orifice of the uterus; then with the other hand he paſſes one blade of the forceps between the introduced hand and the head of the child, withdrawing the hand, and holding the handle of the blade ſteady, he introduces the other hand in the ſame manner as the firſt, and after it he introduces the other blade of the forceps, then with both hands he puſhes them up until the locking part is within an inch of the child's head; he then locks and ties them ſo together that they may be ſteady, and proceeds by pulling them gradually from ſide to ſide, reſting a little now and then; when thus the head is brought ſo low as conſiderably to ſtretch the perineum, and to protrude from under the os pubis, the handles of the forceps muſt be raiſed gradually towards the woman's belly, and thus the head will be compleatly delivered: this done, and the forceps removed, the procedure will be as when the labour is natural.

The head too large, or the pelvis too ſmall. In theſe caſes the head being brought as low as the natural pains can force it, its ſize is leſſened by boring into it with a pair of ſciſſars contrived for that end, and diſcharging the brains; then with the curved crotchets ſecured on the head in the ſame manner as is directed for the forceps; or with a blunt hook introduced into the perforation made with the ſciſſars, the head of the child is brought forward. When the pelvis is diſtorted, the child muſt never be turned with a view of delivering it by the feet; but if it preſents by the feet, endeavours muſt be made to deliver it that way.

The occiput preſenting. When this happens, ſuppoſe the occiput lays over the os pubis with the face upwards, the operator muſt thruſt up the child, and preſs back the ſacrum, that the vertex may be brought to preſent; but if this cannot be done, fix one ſide of the forceps betwixt the os pubis and the occiput, ſo as that the point may be in the neck of the child, and ſtrive thus to move it; this done, fix the blades on the moſt convenient parts, and deliver. See the authors mentioned under the article OBSTETRICATIO.

PRAXAGORAS. The next celebrated phyſician to Diocles Caryſtius: he was of the Eſculapean family, born in the iſle of Cos, and is ſuppoſed to be the laſt of that family who had much repute. He adviſed in the iliac paſſion to cut the bowel open, and take out the excrement, and then to ſew it up; but in this he was never followed. A pupil of his was HEROPHILUS, whom ſee.

PREHENSIO. The catalepſy.

PREMNON. The extremity of the white of the eye.

PRESBYTÆ, from πρεσβυς, *old*, becauſe frequent in the aged. So thoſe are called whoſe eyes are too flat to refract the rays ſufficiently, ſo that unleſs the object is at ſome diſtance, the rays coming from it will paſs through the retina before their union, conſequently viſion is confuſed; old people are uſually the ſubjects of this diſeaſe. In order to remedy, or at leaſt to palliate this defect, the perſon ſhould firſt uſe glaſſes that do not magnify, and from them paſs gradually to more convex ſpectacles, which ſhorten the focus. It is a ſpecies of dyſopia, which ſee.

PRESSURA. Inflammation of the finger end from the effect of cold. It is an inſtance of the phlogoſis erythema of Cullen.

PRIAPISMUS, from *Priapus, the heathen god*, whoſe penis is always painted erect. A priapiſm. It is an erection of the penis without any concomitant pain, or the conſent of other parts. It is thus called, becauſe the perſon in this ſtate reſembles the lewd god *Priapus*. Cœlius Aurelianus ſays it is a palſy of the ſeminal veſſels, and other nerves diſtributed to the parts about the penis, by the diſtenſion of which this diſorder is produced.

PRIAPUS. A penis.

PRIMÆ VIÆ. The firſt paſſages; that is, the ſtomach and inteſtinal tube.

PRIMULA VERIS. The primroſe, i. e. primula vulgaris, Linn.

PRINCIPIA. The principles or elements of bodies. To know the virtues of *bodies*, or how mixed *bodies* ſtand related to the human *body*, either for preſerving, or for reſtoring it, we muſt know the principles of which they conſiſt; alſo the mixture and proportion of ſuch principles as their virtues conſiſt in: ſuch ſimple parts, therefore, as all mixed bodies can be reſolved into, are called *principles*, or *elements*.

In analyſing mixed *bodies*, a ſpirit, (or mercury as the ancients call it) ſulphur, that is oil, ſalt, water, and earth, are obtained. Modern chemiſts deny that either ſalt or oil are *principles*; for ſulphur and oil may be reduced to ſalt, earth, and water.

On this ſubject, what Beecher hath advanced, though very obſcure, is yet the ſource of many valuable diſcoveries in chemiſtry. Stahl hath improved on Beecher, and by the aid of theſe great men, it is demonſtrated, that fire, water, and earth, enter into the compoſition of *bodies*. Sir Robert Boyle and Dr. Hales have as clearly proved that air is a conſtituent of moſt *bodies*. Thus, as Ariſtotle taught long before chemiſtry furniſhed its aids for the eſtabliſhing this truth, the four *elements*, viz earth, air, fire, and water, are now ſaid to be the *principles* of all compound *bodies*. However *bodies* are decompoſed, theſe conſtituents are always obtained; and as theſe cannot be decompoſed any farther, they are conſidered as ſimple ſubſtances, and are called primary *principles*, or *elements*.

In decompoſing *bodies* that are much compounded they are not by a firſt analyſis reduced to their primary *principles*; but ſubſtances are obtained from them that are more ſimple than the original one was; and as theſe do the office of *principles* in the compoſition of *bodies* leſs ſimple than themſelves, they have been called *principiate principles*. Moſt chemical agents, as acids, alkalies, &c. are of this kind. *Principiate principles* have very different degrees of ſimplicity, and ſo are diſtinguiſhed into firſt, ſecond, &c. orders. See the Dict. of Chem.

PRIVATIVI. Diminution of the ſenſes. Defect of appetites. It is ſynonymous with dyſæſtheſiæ and dyſorexiæ in Cullen's Noſology, particularly in the inſtances of deficiency.

PROCARDION. The pit of the ſtomach.

PROCATARCTICA CAUSA. The procatarctic cauſes. See CAUSA. The pre-exiſtent cauſe, from προκαταρχω *antigredior*.

PROCESSUS. A proceſs, from *procedo, to ſtart out*. In chemiſtry, it is a ſeries of operations tending to the production of ſomething new.

In anatomy it is a *proceſs*, and is a protuberance or eminence of a bone. Many bones have *proceſſes* riſing out of them. If the *proceſs* ſtands out in a roundiſh ball, it is called caput, and the narrow part is called cervix; when the head is rather oblong, and unequally rounded, it acquires the name of a condyle; a rough, unequal protuberance is called a tuberoſity; ſuch *proceſſes* as terminate in a ſharp point, have the name of corone or coronoid; ſuch as form a longitudinal ridge are called ſpine, and ſometimes criſta, the labia are each ſide of a broad ſpine; ſuch as form brims of cavities are named ſupercilia. The uſe of *proceſſes* is to give bones their neceſſary ſhape, and to adapt them for motion; they ſometimes ſerve to give cavities, and generally are uſeful in allowing a greater ſurface for the origin, larger attachment, and more advantageous direction of muſcles. *Proceſſes* are of two kinds, viz. the APOPHYSIS, and the EPIPHYSIS, which ſee.

PROCESSUS CILIARES. See CILIARES LIGAMENTUM.

PROCESSUS MAMILLARES. So the olfactory nerves are called.

PROCIDENTIA. See PROLAPSUS.

PROCIDENTIA ANI, from *procido, to fall down*, called alſo prolapſus ani, exitus ani. The *falling down* of the

fundament. It is a relaxation of the ſphincter to ſuch a degree that the internal villous, or rugous coat of the inteſtine, turneth out, and beareth down, making a ſwelling proportionably.

The cauſes are, a weakneſs in the part, which is aggravated by coſtiveneſs, diarrhœas, and particularly a teneſmus: an acrid humour falling on this part, the hæmorrhoids, hard labour, a ſtone in the bladder, or whatever can occaſion a paralyſis of the levatores and ſphincter ani. Hoffman ſays the cauſe is not in a relaxation of the inteſtine, but of its ligaments.

Infants are the moſt frequent ſubjects of this diſorder, by reaſon of the tenderneſs of their frame and their frequent ſtraining, either from coſtiveneſs, or the *falling down* of a ſharp humour on theſe parts.

The ſigns are evident to the ſight; the inſide of the inteſtine is turned outward; the tumor is of a fleſhy colour, ſometimes it is wrinkled, at others it is ſmooth and ſhining, and is accompanied with an uneaſineſs, and an ineffectual deſire to go ſtool.

Sometimes this diſorder is miſtaken for the piles; indeed any tumour about the anus, when of a conſiderable ſize, may be miſtaken for the deſcent of the part, and vice verſa; therefore, attention is not unneceſſary. Through miſtake, a ligature hath been applied about the prolapſed anus, in order to extirpate it.

The cure is difficult, but leſs ſo in children than in grown people. When coſtiveneſs, a ſtone in the bladder, or labour, gives riſe to this complaint, the cure is ſometimes effected; when a diarrhœa follows it the cure is very difficult; if ſucceeded by the hæmorrhoids the difficulty is yet greater.

When acrid matter is obſerved to occaſion fruitleſs ſtraining, ſo as to force down the inner coat of the rectum, give a gentle doſe of rhubarb every third or fourth day; and in the intervals of purging give abſorbents and ſtrengtheners, ſuch as chalk, in frequent and ſmall doſes; if pain is conſiderable, give ſmall doſes of the tinct. Theb. at proper intervals. If the habit is coſtive, give laxatives in ſuch doſes as will procure a ſtool or two every day: if a diarrhœa attends, it ſhould be gradually checked; if there are ulcers in the inteſtines, or if by the ſharpneſs of the humours the mucus is abraded, the ſtarch clyſter, with a few drops of the tinct. Theb. ſhould be now and then injected. If a teneſmus comes on, let a clyſter be injected every night, or oftener, in which is the Venice turpentine diſſolved with the yolk of egg. If the prolapſed inteſtine is ſwelled, apply diſcutients; when the tumour gives way uſe gentle aſtringents; then, by gently preſſing the part with your fingers, the whole will return to its proper ſituation; after the reduction the part may be ſuſpended by the T bandage. It is the moſt eaſily reduced by the patient himſelf lying on his back, and writhing himſelf from one ſide to another, croſſing his legs, &c. But, as in all other caſes, let the cauſe be firſt attended to. If it goes up and down of its own accord, there is no occaſion for ſurgery; the beſt method will be to remove the irritation, and ſtrengthen the whole ſyſtem, which is generally in a relaxed ſtate. The irritation is frequently produced by an acrid mucus, which is generally relieved by alkaline medicines. Avoid aſtringents, even omit the bark, if it proves aſtringent. Sometimes the inteſtine is not only thruſt forth, but is ſo bound by the ſphincter ani above, that it cannot readily be returned; in ſuch caſe Mr. Pott adviſes to bleed, to give opium as required, to foment, and wrap up the part in an anodyne and emollient poultice; thus in a little time its ſtate is ſo altered, that it generally is returnable, until which time, the more we handle it the worſe it will be, but now having gently wiped it clean, it may be returned. If extirpation proves neceſſary, it is beſt performed by ligature; exciſion is not to be attempted, for fear of hæmorrhage, which ſhould it follow, it would be from veſſels that nature muſt ſtop, for art could not reach them. If the *prolapſus* is large, take a ſtrong needle, double threaded, and paſs it through the inteſtine, tie it above on one ſide, and then below on the other, or above and below properly. If the prolapſus is ſmall, paſs a double ligature round its whole diameter; in both caſes leave it to drop off. The pain is allayed by poultices, opium, &c. The ſphincter afterwards does its office, and this moſt troubleſome complaint is entirely got rid of.

When the *prolapſus ani* is cauſed by a ſtone in the bladder, or other diſeaſe, it will be reſtored when thoſe complaints are relieved on which it depends: therefore, great care ſhould be taken before extirpation is attempted, that the caſe is ſimply the relaxed *prolapſus*. If a gangrene affect the inteſtinal fold, ſlightly ſcarify the diſcoloured part, apply ſtupes wrung out of warm red wine, or other antiſeptics; repeat them every two or three hours, and betwixt the uſe of theſe continue the catapl. e cymino on the part. When the prolapſed part cannot eaſily be kept up in grown people, Cheſelden recommends to "take away a piece of the prolapſed gut lengthways, for after the cicatrix is formed, the gut will never deſcend." But on this Mr. Pott remarks, "I am ſorry for this, leſt Mr. Cheſelden's authority ſhould tempt any other perſon to make the ſame trial." Gooch, in his Caſes and Remarks, gives the draught of a convenient machine by which the parts may be ſupported. See Turner's, Wiſeman's, and Heiſter's Surgery.

PROCIDENTIA UTERI. The falling down of the womb. Different ſpecies of this diſorder are thus diſtinguiſhed: 1. Relaxatio, a bearing down or deſcent of the womb; it is when the womb deſcends down to the middle of the vagina, or even with the meatus urinarius. 2. Procidentia; the precipitation or falling out of the womb: it is when it deſcends to the labia pudenda. 3. The prolapſus; the precipitation, or falling out through the labiæ pudendæ. 4. Inverſio or peryerſio: and 5. Retroverſio.

In the leſſer degrees of theſe diſorders they are diſcovered by the touch, and the greater degrees by the eye. If the woman ſtands upright, and a finger is introduced into the vagina, the deſcent of the womb is diſcovered, and by meeting with the os tincæ the caſe is diſtinguiſhed from a deſcent of the vagina; though, in ſome inſtances, much difficulty attends the diſtinction of theſe accidents. If the woman is pregnant, ſhe finds a weight at the bottom of her belly, and the cervix uteri preſſes ſo low that ſhe cannot walk but with pain and ſtraddling; towards the latter end of pregnancy, the womb ſinks ſo low as to cauſe numbneſs in the hips and ſleepineſs in the thighs, a difficulty of urine and at going to ſtool, by preſſing the rectum and the neck of the bladder; a conſiderable pain is alſo felt in the loins, about the inſertions of the ligamenta lata. When there is a perverſio uteri, it appears like a piece of fleſh, and when this is the caſe, it is always attended with a *procidentia* veſicæ urinariæ.

Girls are ſometimes the ſubjects of this diſeaſe, but it moſt frequently happens to women who have had children, in whom it is generally cauſed by hard labour, or getting out of bed too ſoon after delivery, though ſometimes it is owing to a weak relaxed habit. A ſhort funis umbilicalis, and the placenta adhering, may be the cauſe, particularly if force is uſed in delivering them.

If any ſpecies of this diſorder is neglected, the woman ſuffers much pain, with a difficulty in voiding her urine, and ſometimes an inflammation, ulcers, or a cancer, will be formed in the womb.

In general the cure is only palliative, and conſiſts of introducing a peſſary into the vagina, by which the uterus is kept from falling down any lower; ſometimes this proves a means towards a radical cure, by giving the relaxed parts an opportunity of recovering their tone. Sometimes, when a leſſer degree of this diſorder hath happened, the uſual confinement in bed during the next lying in hath effected a cure; a peſſary ſhould be introduced as ſoon as it conveniently can, after delivery being completed, and worn for ſome time after the woman walks abroad. A round peſſary is the beſt, and ſhould be ſo large as to occaſion ſome uneaſineſs in paſſing it up, or it will be apt to fall down again. If a lacerated perineum is the cauſe of the womb bearing down, a peſſary will not be very uſeful; in this caſe a ſort of cuſhion may be placed with its convex ſide to the os externum, and ſecured there by the T bandage. If the prolapſus hath been long neglected, ſo that a ſwelling and inflammation is come on upon the part, bleed, keep the bowels open, and apply fomentations and poultices. If a mortification appears, give the bark, and uſe the juſt named applications, until the ſloughs ſeparate and the parts heal, after which apply a

peſſary, if the patient can bear it. Whenever a gangrene or a cancer appears, reduction increaſes the attending ſymptoms, or produces new and fatal ones; but if there are ulcers, the part ſhould be reſtored with all convenient ſpeed.

The inverſio is when the uterus not only deſcends, but is turned inſide outward. This never happens but immediately after delivery, the os tincæ then being nearly as large as the fundus; and, beſides this, ſome violence, ſuch as pulling the funis forcibly to bring away the placenta, is uſed, otherwiſe the contraction of the womb, after being freed from its principal burden, (the child) would abſolutely prevent all poſſibility of this kind of diſorder. Whatever be the cauſe, the part muſt immediately be reſtored, or the conſequence will ſoon be fatal, for its orifice will contract in this unnatural ſtate, and ſo prevent the needful relief. Firſt empty the bladder, if it contains much urine; then lay the patient on her back with her hips raiſed, then with the hand reſtore the uterus; gently return it into the vagina with three fingers, and then with the whole hand place it in the belly, after which, clench the fiſt, and retain it there, until the uterus contracts upon it; laſtly, ſupport it as in the caſe of a prolapſus.

The retroverſion of the uterus. This diſorder is not properly a ſpecies of *procidentia* as above deſcribed, but is when it ſo falls, from its natural poſition, that the urinary bladder is either preſſed by it, or drawn from its uſual place, and the fundus uteri preſſes upon the inteſtinum rectum; or it may be that the fundus uteri is thrown upon the os pubis, and its orifice towards the rectum. Moſt of theſe caſes happen in the early ſtages of pregnancy, ſeldom ſo late as the fourth month; they occaſion firſt a difficulty, then by degrees a ſuppreſſion of urine, and ſoon after, a ſuppreſſion of the inteſtinal diſcharge. For the moſt part the following treatment hath been ſucceſsful. Firſt, the urine is to be drawn off by means of the catheter, then a ſtimulating clyſter muſt be injected, that the inteſtines may be duly evacuated; theſe done, place the woman on her knees and elbows, with her head downwards, and by introducing one hand up the vagina, endeavour to draw it forwards, then with two fingers in the anus endeavour to puſh up the fundus uteri. See an account of ſome inſtances of this nature in the Lond. Med. Obſ. and Inq. vol. iv. p. 388, &c. and ſee Dr. Hunter's Tables of the gravid Uterus.

On the *procidentia uteri*, ſee Ruyſch's Obſ. No. 1, 7, 9, 10, and Saviard. Lond. Med. Obſ. and Inq. vol. iii. p. 8—6. Med. Muſeum, vol. i. p. 227—230. Heiſter's Surgery. Hamilton's Outlines. Edinb. Med. Comm. vol. iv.

PROCIDENTIA VAGINÆ. The degrees of this diſeaſe are different; but when a part of, or all the vagina appears through the pudenda, it may be called a prolapſus; when it deſcends to the labia pudenda, it may be termed a *procidentia*; and when not ſo far, a relaxation. Widemannus gives a caſe of a prolapſus vagina which had all the appearance of a prolapſus uteri, and which was not properly diſtinguiſhed until it was too late to afford any relief; but generally they are diſtinguiſhed by obſerving the os tincæ, which diſtinguiſhes the womb from all other caſes of a deſcent, and from the inverſio, by its only happening after labour. When the whole vagina is prolapſed, it appears like crude bloody fleſh. If the prolapſed vagina ſwells violently, and is attended with inflammation, there is immediate danger of a ſphacelus; if the prolapſed part be affected with little or no ſwelling, or if there is no inflammation, the tumor will be very little trouble, and without danger. This diſorder ſhould be diſtinguiſhed from a tumor, a fungus, a ſarcoma, &c. of the part.

The part may be reſtored with the fingers; which when done, the patient ſhould reſt in bed for ſome days, and uſe an injection of warm vinegar and water, or red wine and water; but if theſe fail, the T bandage muſt be worn. If inflammation, &c. attend, the ſame procedure will be proper, as when the like ſymptoms happen to the uterus. See Heiſter's Surgery.

PROCIDENTIA VESICÆ URINARIÆ. The inverſion of the uterus never happens without the bladder being diſplaced. They get down to the perinæum, and there make a protuberance. The bulb of the bladder being thus forced down, it is now no longer expoſed to the preſſure of the abdominal muſcles as before, and not having force enough in this poſture, to contract and preſs out the urine, the poor woman in this ſtate never makes any water, without firſt ſqueezing the bladder with her hands, or between her thighs. When the bladder is thus diſpoſed, if the catheter is to be introduced, it muſt not be thruſt inward, but downward, the bulb of the bladder being below the meatus urinarius.

PROCONDYLOS, from προ, *after*, and κονδυλος, *finger*. The firſt joint of each *finger* next the metacarpus, ante internodium.

PROCTALGIA. Inflammation of the anus, with pain. Dr. Cullen places it as a variety of phlogoſis phlegmone.

PROCTITIS. The ſame as PROCTALGIA.

PROCTOLEUCORRHŒA. The ſame as Proctorrhea, but thus named becauſe of the diſcharge reſembling that called the whites.

PROCTORRHŒA. A nervous flux, that is ſometimes yellowiſh, or ſtreaked with blood; probably from the external hæmorrhoidal veſſels, or perhaps in ſome inſtances from the internal ones; this diſcharge is accompanied with heat and itching about the anus.

PROEGUMENE. A precedent cauſe. Or an intercedent, internal cauſe of a diſeaſe, in the body, occaſioned by another cauſe.

PROFLUVIA. Fever, with an increaſe of ſome natural diſcharge.

PROFLUVIUM URINÆ, i. e. Diabetes.

PROFLUVIUM. A flux of any kind.

PROFUNDA BRACHII VENA, vel Profunda Superior. It is a branch from the baſilica vena, ſent off from it below the neck of the os humeri; and near the hollow of the axilla: it runs along the ſide of the brachial artery, and ſpreads in the adjacent muſcles.

PROFUNDUS MUSCULUS. A name for the perforans manus.

PROFUSIO. Paſſive hæmorrhages; ſuch as happen from wounds, &c. and not the effect of fever. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order apocenoſes.

PROGERMINUS ABSCESSUS. An abſceſs ariſing from a viſcid and almoſt corrupted phlegm.

PROGLOSSIS. The tip of the tongue.

PROGNOSIS, from προ, *before*, and γινωσκω, *to know*. The prognoſtic of a diſtemper. It is the knowledge of the ſigns by which we preſage thoſe circumſtances that will happen to the patient. In this Hippocrates excelled; his prognoſtics are at this day eſteemed; yet it muſt be allowed that ſome of them are fallacious from the difference of climes, and conſtitutions.

In forming prognoſtics, attend to, 1. What will be the future event of the diſeaſe. 2. From like diſeaſes having preceded in the ſame body. 3. And, from a knowledge of the preſent ſtate of the vital powers, and a compariſon thereof with the ſtrength of the morbific cauſe.

The ſigns of health, and death, are more fallacious in acute, than in chronical diſeaſes.

See the Engliſh tranſlations of Hippocrates's Prognoſtics in Acute Diſeaſes; and of Proſper Alpinus's Preſages on Life and Death.

PROHIBENS. The ſame as contraindicans.

PROJECTIO. Projection. In chymiſtry, it is the caſting of any ſubſtance to be calcined into a crucible, by a ſpoonful, or a ſmall quantity at a time. *Projection* is alſo an addition of a ſmall quantity of ſomething to a greater quantity of a metal, in order to meliorate the metal. See Wilſon's Chemiſtry.

PROJECTURA. An apophyſis.

PROLABIUM, *pro*, *before*, *labium*, *the lip*. The red part of the *lips*. Under the epidermis, which in this part is called epithelium, is a collection of fine long villous papillæ, cloſely connected together, and covered not only by the epidermis, but alſo that pellicle which covers the glandulous membrane of the cavity of the mouth: this villous ſubſtance is of exquiſite ſenſibility.

PROLAPSUS. See PROCIDENTIA. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order ectopiæ. A *prolapſus*, a procedence, or exany, is the miſplacing of a ſoft part, and ſo that it is generally obvious

to

to the ſight; or, it is a tumor ariſing from the diſlocation of a ſoft part, as a membraneous or fleſhy part, as is inſtanced in the bearing down of the rectum, an inteſtinal hernia, &c.

PRONATIO Pronation. When ſpoken of the hand, it is when the thumb is turned towards the thigh; ſo then, if the body is laid on its back, the palm of the hand will be downwards.

PRONATOR QUADRATUS. This muſcle is alſo called tranſverſus. It ariſes tendinous from the inner part of the ulna, and is inſerted into the inner part of the radius. One end of it is fixed to the lower part of the ulna, and by the other in the concave ſide of the lower extremity of the radius.

PRONATOR TERES. It riſes from the internal inferior part of the os humeri, and is inſerted into a line at the lower end of the radius. This muſcle is alſo called obliquus, and *pronator radii teres*.

PROPHYLACE, or Prophylactice, or Prophylaxis, from *προ, before*, and *φυλασσω, to preſerve*. The method of preſerving health, and averting diſeaſes.

PROPOLIS. Bee bread. It is a wax like a kind of glue, found in the entrance of bee hives. It ſoftens indurations; but it is not noticed in the preſent practice.

PROPRIETATIS, (Elixir,) i. e. elix. aloes.

PROPTOMA. A prolapſus or deſcent of a part.

PROPTOSIS, from *προπιπτω, to fall out*. The ſame as procidentia. It is to fall from its natural ſituation. When the eye is ſo enlarged that the eye-lids cannot cover it, it ſometimes burſts; and this diſorder is called *proptoſis* by the Greeks. If the eye is ſwelled with a watery humour, ſome call it hydrophthalmia; oculus bubulus; oculus bovinus; or oculus elephantinus, from its reſemblance to the eye of an ox, or an elephant. If the hydrophthalmia is recent, and the eye not altogether deformed, it may be reſolved by bleeding, purging, bliſtering, and diſcutient embrocations; if theſe fail, diſcharge the humour by tapping every two or three days, until there is no further need; dreſs the eye with lint dipped in the white of egg, and over it lay a thick compreſs dipped in ſpirit of wine, uſing at proper intervals, ſudorifics, diuretics, purges, &c. If the ſight is loſt, if a caries, a ſpina ventoſa, cut out the cornea, and proceed as in the ſtaphyloma. It is ſynonimous with ſtaphyloma in ſome writers.

PRORA. The occiput.

PRORÆ SUTURA. The lambdoidal ſuture.

PROSARTHROSIS, i. e. Adarticulatio.

PROSPER ALPINUS. A profeſſor at Padua. About the end of the ſixteenth, or the beginning of the ſeventeenth century, he revived the methodic ſect by his De Medicina Methodica. From the time of Myrepſus this ſect had been almoſt extinct.

PROSTATÆ, from *προ, before*, and *ιστημι, to ſtand*, from *προϊστασθαι, to be adjacent to*. The proſtrate glands. The *proſtatæ* are ſituated at the neck of the bladder, are ſhaped like an heart, the lower ſurface is the largeſt, and the upper ones are both flat. The membranous part of the urethra runs through it; it is about the ſize of a wal-nut. When cut open, the eminence called caput gallinaginis is ſeen. The vaſa deferentia paſs through its ſubſtance. When the *proſtate gland* is inflamed from a ſuppreſſed gonorrhœa, every means ſhould be uſed to reſtore the diſcharge; for, if this inflammation terminates in ſuppuration, whether the abſceſs breaks into the urethra, bladder, inteſtinum rectum, or perinæum, it will always be attended with diſagreeable conſequences. The ſymptoms of an inflammation or ſwelling of this gland are known from the pain and difficulty of making water; beſides, if we ſhould be doubtful whence they proceed, the finger will clearly teach us. If a ſuppuration has already taken place, we have only to obſerve, that mercury internally and externally will be neceſſary, and afterwards proper injections, the compoſitions of which muſt be left to the judgment of the practitioner. The remedies proper for indurated teſticles or buboes, will be ſuitable in this caſe; but eſpecially bliſters repeatedly applied to the perinæum, and internally hemlock in large doſes. If a total ſuppreſſion of urine is feared, bring on a ſuppuration to prevent worſe ill.

PROSTATA. A ſuppoſitory.

PRUNA. Prunes. Botaniſts enumerate nine ſpecies of prune trees. It is a name alſo for the carbuncle.

PRUNA GALLICA, called alſo pruna parva, prunus ſativa. Common or French prunes, called by our gardeners, the little black damaſk plum. The prunus domeſtica, Linn.

PRUNA BRIGNOLENSIA, called alſo pruna Brignolenſia, prunello, or Brignole plum. The prunus domeſtica, Linn. It is ſo called from Brignole in Provence. It is of a reddiſh yellow colour, and of a very grateful, ſweet, ſubacid taſte.

PRUNA DAMASCENA. The damaſk prune, called damſons. This ſpecies is generally ſupplied by the common prune. Their general qualities are to cool, quench thirſt, and render the bowels lax. The prunelloes quench thirſt more than the others; and the French prunes are moſt laxative.

PRUNELLA. See BRUNELLA.

PRUNUS SYLVESTRIS. The black thorn; or ſloe-buſh. The prunus communis, Linn. It is a prickly buſh, very common in hedges, produces an auſtere fruit, which is ſmaller than an ordinary cherry. This fruit is too harſh to be eaten before the froſts have ſoftened them. The juice expreſſed from them before they are ripe, or affected by the froſt, if inſpiſſated by a gentle heat, is called acacia Germanica, and is generally ſold for the acacia Egyptiaca, from which it differs in being harder, heavier, darker coloured, and of a ſharper taſte, and yet more remarkable in its giving out its aſtringence in a good meaſure to ſp. vini R. whereas the Egyptian acacia is not at all diſſoluble in ſpirit.

A conſerve is made of the ſloes by ſteeping them in hot water before they are affected with the froſt; and when they are ſoft enough to pulp, they are paſſed through an hair ſieve, and to one part of the pulp, three parts of lump-ſugar muſt be added. This is very aſtringent, and is alſo of uſe to brace up ſpongy gums. The flowers of the ſloe buſh are laxative. The bark is uſeful in intermittents. See Lewis's Mat. Med.

PRURIGO. A violent itching.

PRURITUS. A violent itching, or the itch. Dr. Cullen names this genus of diſeaſe pſora; he places it in the claſs locales, and order dyalyſes. Many are the appearances on the ſkin, and various the diſorders that are accompanied with, or manifeſted by an *itching* therein; but the *itch* is a ſkin diſeaſe, and hath for its cauſe a very ſmall kind of animalcula of a whitiſh colour, and ſhaped like a tortoiſe, each having ſix feet, and a ſharp head, with two ſmall horns on its point. They are very hard, ſo are not eaſily deſtroyed by rubbing them.

This diſorder uſually appears at firſt about the wriſts and fingers, then on the arms, legs, and thighs, but never affects the head. In the evening, when the patient approaches to the fire, or begins to grow warm in bed, the *itching* is moſt troubleſome; in ſome patients there are blotches here and there, in others there is a ſcurfy or ſcaly kind of eruption; this laſt is called the dry *itch*. The moiſt kind moſt frequently happens to children, and the drier ſort to adults. The humour in the moiſt ſort is ſanious and purulent, and an inflammation is obſervable about the baſis of each eruption; but in the dry kind, the puſtules are of a ſmall ſize, and are filled with a ſerous ichor, which by irritating the highly tender fibres under the cuticle occaſion both heat and *itching*.

The moiſt kind of *itch* is more eaſily cured than the dry ſort; this diſorder is obſtinate in old people, and ſtill more ſo in thoſe whoſe viſcera are unſound.

Whether the cauſe be a morbid ſerum in the blood, or the animalculæ abovementioned, ſulphur alone is to be depended on for a cure; it ſhould be taken inwardly, ſo as to keep the bowels lax; but if it agitates the blood, and occaſions eruptions to appear on the ſkin, it may be mixed with the cream of tartar. As to its external uſe, it need not be applied like other medicines to every part of the body; but if rubbed on the palms of the hands, and the ſoles of the feet, it ſuffices: and thus uſed there is leſs objection to the ſmell, and the uncleanlineſs complained of, than when the whole ſkin is anointed.

Dr. Pringle recommends the following ointment to be uſed at four times, each portion to be applied at bed-time; and to prevent any diſorder from too many pores being

ſtopped

ſtopped at once, he directs that one fourth part of the body only ſhould be rubbed at once.

℞ Flor. Sulp. ℥ i. p. rad. elleb. a ʒ ii. vel ſal ammon. crud. ʒ ii. axung. porc. ℥ ii. m.

During the uſe of ſulphureous applications, clean linen is neceſſary; it ſhould often be changed, but not worn again before being well waſhed and bleached.

Many other applications have been uſed, and ſtill are preferred by ſome. The following are recommended by eminent practitioners.

℞ Merc. cor. A. ʒ i. alum. rup. ʒ ii. ſal. prunel. ℥ ſs. aq. calcis ſi ℔ ſs. m. f. lotio.

℞ Merc. cor. A gr. x. merc. præcip. A. ʒ i. ung. pomat. ℥ iſs. m.

Dr. Turner prefers a ſolution of the ſalt of tartar in the proportion of a dram to an ounce of water: of this a teaſpoonful is to be taken two or three times a day in any ſmall drink. The body at the ſame time to be waſhed with a weak ley.

The extr. cicutæ hath been found uſeful in ſome obſtinate caſes, which reſiſted all other common methods.

Baths ſhould be uſed in the dry ſpecies particularly; and perſpiratives are uſeful in both ſorts of this complaint.

The venereal *itch* requires the uſe of mercurial alteratives, and the decoction of guaiacum. See Biſs's Eſſays; Turner on the Diſeaſes of the Skin; Barbette's Chirurgia, lib. i. c. viii. Wepfer's Obſ. 214. Philoſ. Tranſ. abr. vol. iv.

PSALLOIDES. So the ancients called the inner ſurface of the fornix, becauſe it appears as if ſtringed like a dulcimer.

PSELLISMUS. Stammering, or a faulty articulation of words. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order dyſcineſiæ. He diſtinguiſhes ſeven ſpecies. *Pſelliſmus* hæſitans; when there is difficulty to pronounce the firſt ſyllable or word, which is not effected before repeated trials are made. 2. *Pſelliſmus* ringens; when there is a fault in pronouncing the letter R. 3. *Pſelliſmus* lallans; when the letter L is ſounded improperly, or in the place of the letter R. 4. *Pſelliſmus* emolliens; when the hard letters are expreſſed too ſoft, as the letter S is too frequently ſounded. 5. *Pſelliſmus* balbutiens; when from a large tongue the labial letters are too much heared, and are often ſounded inſtead of others. 6. *Pſelliſmus* acheilos; when the labial letters are difficultly ſounded, or not at all. 7. *Pſelliſmus* lagoſtomatum; when, from a diviſion in the palate, the guttural letters are not well pronounced.

PSELLOTIS, i. e. Pſelliſmus, and pſelliſmus emolliens.

PSEUCROLUSIO. Pſeucroluſion. Bathing in ſalt-water.

PSEUDES. Falſe or baſtard. Hence is derived the word pſeudo, with which many names begin.

PSEUDIPECACUHANA. The white ſort of ipecacuanha. It hath no medical virtue.

PSEUDO ACACIA. Baſtard acacia. It is produced in America, and is raiſed in our gardens by the curious. Boerhaave takes notice of two ſpecies, but they are not noted as medicinal.

PSEUDO ACORUS. Yellow water-flag.

PSEUDO APIOS. A ſpecies of cataputia minor.

PSEUDO APOCYNUM. A name in Boerhaave for ſome ſpecies of bignonia.

PSEUDO ARISTOLOCHIA, i. e. Fumaria bulboſa.

PSEUDO ASPHODELUS. Baſtard aſphodel. Ray takes notice of three ſpecies, but they have little or no medical virtue.

PSEUDO ASTHMA. An aſthma excited by an abſceſs, or a vomica in the lungs.

PSEUDOBLEPSIS. Falſe ſight; as when a man ſees what does not exiſt, and the things that do exiſt are ſeen differently from what they are perceived by others, whoſe eyes are in a proper ſtate. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order dyſæſtheſiæ. He diſtinguiſhes two ſpecies. 1. *Pſeudoblepſis* imaginaria; in which things that do not exiſt are ſeen, as luminous appearance, ſuddenly paſſing by; various colours, &c. 2. *Pſeudoblepſis* mutans; as when any objects appear double, &c.

PSEUDO BUNIAS, i. e. Barbarea.

PSEUDO BUNIUM, i. e. Bunias.

PSEUDO CAPSICUM. Tree night-ſhade.

PSEUDO CASSIA, i. e. Folium, or Indian leaf.

PSEUDO CHAMÆBUXUS. A ſpecies of polygala.

PSEUDO CHINA. American China root.

PSEUDO COLOCYNTHIS, i. e. Pepo fructu ovato variegato.

PSEUDO CORALLIUM. Black coral.

PSEUDO COSTUS, i. e. Paſtinaca, oluſatri folio.

PSEUDO CYTISUS. A ſpecies of laburnum.

PSEUDO DICTAMNUS. Baſtard dittany. It is alſo called gnephalium veterum. It is a plant which reſembles the horehound in its virtues, but it is not uſed in the preſent practice. Boerhaave takes notice of ſeven other ſpecies, but they are of as little value in medicine as the juſt named.

PSEUDO DIGITALIS. The herb called American dragon's head.

PSEUDO FUMARIA. So Boerhaave calls the capnoides.

PSEUDO GNAPHALIUM, i. e. Gnaphalodes Luſitanica.

PSEUDO HELLEBORUS, i. e. Helleboro ranunculus.

PSEUDO IRIS, i. e. Acorus adulterinus.

PSEUDO LIEN. A name for ſome glands which Ruyſch obſerved near the ſpleen.

PSEUDO LOTUS, i. e. Guajacana.

PSEUDO LYSIMACHIUM. A name for a ſpecies of ſalicaria, and of a ſpecies of veronica.

PSEUDO MARRUBIUM. A name for two ſpecies of lycopus.

PSEUDO MELANTHIUM, i. e. Lychnis ſegetum major.

PSEUDO MOLA. A falſe mole; it is formed of a piece of the placenta, which hath been left in the uterus, after the delivery of a child.

PSEUDO NARDUS. So the narrow leaved, and broad leaved lavender is called.

PSEUDO PLATANUS. The great maple tree; a ſpecies of acer.

PSEUDO RHABARBARUM. A name for ſome ſpecies of thalictrum.

PSEUDO RUBIA, i. e. Rubeola.

PSEUDO SALVIA. A name for three kinds of phlomis.

PSEUDO SELINUM, i. e. A ſpecies of caucalis.

PSEUDO STACHYS. A name for two ſpecies of ſtachys, and one ſpecies of galeopſis.

PSEUDO STRUTHIUM, i. e. Luteola herba ſalicis folio.

PSEUDO VALERIANA. A name for ſeveral ſorts of valerianella.

PSIDA, or Pſidium. Pomegranate peel.

PSILOTHRA. Medicines which take off the hair.

PSILOTHRUM, i. e. Bryonia alba.

PSIMMYTHION. Ceruſs.

PSOÆ. The name of two pair of muſcles in the loins. According to Galen, Pollux, &c. the loins were called ψοαι.

PSOAS, alſo called lumbaris internus, pſoas magnus. It is placed obliquely on the ſides of the loins, and runs under Poupart's ligament to that thigh on which ſide it is. It riſes fleſhy from the ſides of the upper vertebræ lumborum; and from the roots of their tranſverſe proceſſes, paſſes down under Poupart's ligament, and is there joined by the iliacus internus, which lies upon the concave part of the ilium, and takes its origin from the anterior edge of the bone; it runs down before the *pſoas*, and makes one maſs with it; they then run over the head of the bone, and paſs upwards to be inſerted into (tendinous) the little trochanter, and fleſhy into the bone a little below that proceſs. Its office is to bend the femur, by bringing it forwards, partly to rotate it, and to turn the toes out. The kidnies often preſs upon this muſcle, over which runs a nerve; hence thoſe who have ſtones therein do often feel a numbneſs in the thigh of that ſide.

The *pſoa* abſceſs receives different names from different writers.

writers. Mr. Pott obſerves, that it receives this name from the matter of it ſliding in its fall upon the ſide of the *pſoas* muſcle, or betwixt that and the iliacus internus. Dr. G. Fordyce obſerves, that between the *pſoas* muſcle and the muſcle of the back, lies a quantity of looſe cellular membranes, from which an inflammation often takes place, which terminating in an abſceſs forms this diſorder.

Mr. Pott thinks this diſorder originates in the lymphatic glands, near the receptaculum chyli, the vertebræ about which are generally diſeaſed and carious in theſe caſes. Dr. Hunter again obſerves, that matter is ſometimes lodged in this part at the criſis of a fever, and he hath ſeen inſtances of matter proceeding from the liver into this ſituation, after making its way through the peritonæum. As there is a great quantity of cellular membrane over the *pſoa* muſcle, and a conſiderable way toward the ſkin, the matter ſeldom points outwardly on the back, where it is formed, but running down on the courſe of the muſcle, makes its way into the groin, thigh, ham, the inner condyle of the os femoris, &c. or when on the right ſide, it may penetrate the colon which lays upon it, and thereby occaſions a large diſcharge of matter per anum, and poſſibly a fiſtulous ſore.

The *pſoa* abſceſs often exiſts a conſiderable time before it is ſuſpected.

The eruptions in the beginning are ſimilar to thoſe of inflammation of the liver, excepting for the ſituation; its progreſs and termination is like that of the liver too. The pains are ſituated in the back, for the moſt part, rather lower than the region of the kidneys. The pain is but ſlight, and ſo moderate are the ſymptoms for a time, that frequently it hath not been attended to until ſuppuration had taken place. After the abſceſs is formed, the pain often becomes greater than before; for, the pus fermenting in the cellular membrane, ſpreads itſelf, and produces a great degree of general inflammation. This cellular membrane communicates itſelf with the cellular membrane in other parts, and the pus ſometimes makes its way through the peritonæum, into the cavity of the abdomen, whence ariſes hectic heats, and is fatal. The matter may alſo paſs down the *pſoas* muſcle, and make its exit externally a little further than the inguinal glands, or it may paſs further down the thigh, diſſect the muſcles, and form ſinuous abſceſſes. Sometimes the matter paſſes through the muſcles of the back, but may take its courſe into the cavity of the back part of the pelvis: thus it appears that the pus is capable of paſſing ſeveral different ways, and may communicate with all the parts at once, which makes it a dangerous abſceſs, not ſo much with regard to its ſize, as to the parts which it affects. Uſually the firſt ſymptoms that the patient feels in caſes of the *pſoa* abſceſs, is not where the diſeaſe originates, but a pain in the lower part of the thigh of the ſide affected; he ſtands on his toes, &c. and does not complain of the part for ſome time, but by attending to the circumſtances from the beginning, and laying the perſon affected on his back, lifting up his thigh, then between inſpiration and expiration, carefully examining the part, you will probably feel the tumor near, or in the region where the diſeaſe originates. The leg of the affected ſide ſeems to be ſhorter than the other, but it is not ſo. In ſome caſes the diſeaſe proceeds rapidly, in others very ſlowly, at length it appears in the groin, and the affected ſide; the muſcles of the thigh become exceedingly emaciated, and the whole body waſtes. When it proceeds thus far, the patient rarely, if ever, recovers; the ſymptomatic fever that generally attends cloſes the ſcene.

This diſeaſe is often confounded with the abſceſs of the hip joint, yet they are very diſtinct and different in their origin, ſeat, and progreſs. The *pſoa* abſceſs originates often in the lymphatic glands near the receptaculum chyli, the vertebræ about which are generally diſeaſed and carious; in other inſtances it originates in or about the loins, if not higher in the abdomen. The firſt ſymptom which the patient feels in this complaint is not where the diſeaſe originates, but a pain is felt in the lower part of the thigh of the ſide affected; he ſtands on his toes, &c. and does not complain of the part where the diſeaſe is ſeated for ſome time. At length it appears in the groin, the limbs waſte, and, indeed, the whole body alſo, &c. The hip-joint abſceſs originates in the hip-joint; when it attends, the leg of the affected ſide is ſhorter than the other; the pain begins in the part where the diſeaſe originates, and about the great trochanter. The *pſoa* abſceſs is a diſeaſe of the vertebræ of the loins, and of the parts adjacent; the hip-joint abſceſs is a diſtemper of the hip-joint, and its ligaments. To diſtinguiſh it from a local external abſceſs, lay the patient on his back, and ſqueeze the tumor; if it be a *pſoa* abſceſs, the matter will be preſſed into the cavity of the belly, but if it be in the part itſelf, no alteration takes place; and further, if there be two lumbar abſceſſes, by compreſſing one will fill the other. A ſtone in the kidneys hath been taken for this diſeaſe; but there is this difference between them, the ſtone in the kidney will ſometimes produce but ſlight inflammation, but at other times very conſiderable; beſides, the pain reaches from the kidneys down the groin to the bladder, paſſing ſtony concretions, and ſometimes blood with the urine; theſe ſymptoms do not exiſt in the *pſoa* abſceſs. See Abscess *in the Hip*.

If an abſorption takes place before the abſceſs hath burſt externally, the patient often dies. It is generally of the ſtrumous kind, but when not, it is often fatal. The matter is ſo deep ſeated, and the adjacent bones ſo injured by it, before a fluctuation can be diſcovered, that for want of aid the diſcharge is made internally, and then the patient dies. If a fetid ichor is diſcharged, or the bones are affected, little or nothing is to be hoped for. The matter of this abſceſs ſometimes makes its way from the region of the kidnies down to the bottom of the thigh of the affected ſide, but before this, the miſchief it hath done is not to be repaired; and if an opening is made, the patient is likely to be deſtroyed by the exceſs of the diſcharge.

A ſymptomatic fever generally attends this complaint, and cloſes the ſcene. But what is very remarkable, this fever does not come on during the time the matter is confined, nor to any great degree for forty-eight hours after the matter is let out; this circumſtance is extraordinary, as it cannot ariſe from the abſorption of matter, for that muſt have been greater before the opening; nor from a waſting in conſequence of the evacuation of the matter, as that was before extravaſated, and was an extraneous body with reſpect to the conſtitution; nor from the admiſſion of air, for that in other caſes does not produce ſuch effects; we are therefore at a loſs to know why the ſymptomatic fever does not occur till after the diſcharge of the matter.

This diſeaſe, whilſt in its inflammatory ſtate, is generally neglected or miſtaken; otherwiſe it probably would eaſily be cured, and that principally by bleeding. Dr. Fordyce obſerves, that this diſorder ſhould be treated in the ſame manner as inflammation of the liver, (except for the ſituation) both in the ſtate of inflammation and ſuppuration. He further adds, that in all internal ſuppurations, the lungs become affected; hence hectic heats, &c. are produced; thence it is neceſſary, that if the patient reſides in a large town, he ſhould remove into the country for the benefit of air. Correſpondent with this, Dr. Hunter obſerved in his Lectures, A. D. 1771, that the moſt likely means to prevent the fatal effects of this diſeaſe are, endeavours to keep up the patient's ſtrength ſufficiently to enable him to undergo the diſcharge, which is moſt likely to be accompliſhed by a nouriſhing diet, and clear air, the bark, elixir of vitriol, &c.

Elements of the Pract. of Phyſ. part ii. by G. Fordyce, M. D.

PSOAS PARVUS. When there is a little *pſoas*, it is on the anterior part of the great *pſoas*. It ariſes fleſhy from the upper vertebræ of the loins laterally; is inſerted by a long, flat, thin tendon, into that part of the os pubis, where it joins the ilium. Its uſe is to aſſiſt the recti abdominis in drawing the os pubis upwards, as in raiſing ourſelves from a decumbent poſture.

PSOPHOS. Crackling or rattling of the bones.

PSORA. A kind of itch. See Pruritus.

PSORIASIS. A ſpecies of itch which affects the ſcrotum, from ψωρα, *ſcabie labore*. The ſcrotum is alſo unuſually hard.

PSORICA. Medicines for the itch.

PSOROPHTHALMIA. An itchy or ſcurfy diſorder of the eye-lids, which renders them ſore, and ſometimes ſcabby. See Trachoma.

PSUCHAGOGICA. Medicines which recal life in an apoplexy or ſyncope.

PSYDRACIA. A ſpecies of puſtule, or of ſmall tubercles on the head, which reſemble puſtules, and corrode the ſkin. Trallian thus deſcribes them, in lib. i. c. 5. Phlyctenæ, or ſmall watery puſtules, when ſeated on the head, are called *pſydracium*. *Pſydracia*, a veſpis, ſignifies the humour, &c. from the ſtinging of waſps. Others deſcribe the *pſydracia* as hydatids, or ſanious puſtules.

PSYLLIUM. Flea-wort. It is alſo called pulicaris herba. It is the plantago *pſyllium*, Linn. It is an herb of the plantain kind, agreeing with it and the coronopus, only the ſtalks are leafy and ramous, or divided into a multitude of branches. It grows wild in the warmer parts of Europe, and is raiſed in our gardens. The ſeeds have formerly been brought from the ſouth of France; they are ſmall, ſmooth, ſlippery, of a ſhining brown colour, of an oblong flattiſh figure, ſuppoſed to reſemble that of a flea, whence the name of the plant.

A dram of the ſeeds renders a pint of water moderately ſlimy, and gently laxative. See Raii Hiſt. Lewis's Mat. Med.

PTARMICA, called alſo pſeudo-pyrethrum, dracunculus pratenſis, ſternutamentoria, ſneeze-wort, baſtard pellitory. It is the achillea *ptarmica*, of Linn. It is a plant with long, narrow, ſerrated leaves, and radiated diſcous flowers, ſet in form of umbels on the tops of the branches. It is perennial, grows in moiſt ſhady grounds, and flowers in June, &c. throughout the ſummer. The roots have a hot biting taſte, much like that of pyrethrum, with which they agree in their pharmaceutic and medical properties. See Lewis's Mat. Med.

PTARMICA, i. e. Xeranthemum, alſo ageratum, and a ſpecies of milleſolium.

PTERIS. Fern.

PTERNA, i. e. Os calcaneum.

PTERYGION. A film on the eye, called a web. In Celſus, lib. vi. cap. 19. it is a diſorder of the fingers, which he thus deſcribes: "In the nails there is a ſpecies of caruncle, accompanied with great pain, which the Greeks call *pterygion*." To theſe a mixture of alum and honey, in equal parts, is applied.

PTERYGIUM. See Albugo. It is alſo a name for the diſorder called unguis.

PTERYGODEES. So Hippocrates calls thoſe people whoſe cheſts are narrow and flat, ſo that their ſcapulæ are prominent, like wings. Such perſons are ſubject to conſumptions.

PTERYGOIDEUS EXTERNUS. Fallopius firſt deſcribed theſe muſcles. They riſe from the ala externa, and from the neighbouring parts of the os ſphenoides, and are inſerted into the neck of the condyle of the lower jaw, and likewiſe into the cartilage of the condyle, which cartilage is hollowed, to move upon the tuberoſity of the os temporis.

PTERYGOIDEUS INTERNUS. It riſes from the cavity between the lamellæ of the proceſſus *pterygoidæus*, and is inſerted into the inſide of the angle of the lower jaw. It lies on the inſide of the lower jaw, almoſt as the maſſeter does on the inſide, being of the ſame figure with it, only it is ſmaller and narrower.

PTERYGOIDEUS MAJOR, i. e. Pterygoideus internus.

PTERYGOIDEUS MINOR, i. e. Pterygoideus externus.

PTERYGOIDEUS PROCESSUS, from πτερυξ, *a wing*, and ειδος, *form*. See Sphenoides Os.

PTERYGOPALATINUS, i. e. Spheno-pterygopalatinus.

PTERYGOPHARYNGÆI, from πτερυξ, *a wing*, and φαρυγξ, *the palate*. It is a name of the cephalo-pharyngæus. In the edge of the internal alæ of the apophyſes pterygoidæi, theſe muſcles riſe, then run backward, and are inſerted into the linea alba of the pharynx.

PTERIGO-STAPHYLINUS SUPERIOR. The muſcles which bear this name are only the external portions of the ſpheno-ſalpingo ſtaphylini.

PTERYGO-STAPHYLINUS INFERIOR. Theſe muſcles are very ſmall. They are inſerted at one extremity into the uncus pterygoideus, and by the other into the ſeptum, near the uvula.

PTILOSIS, from πτιλος. A perſon who hath loſt his eye-laſhes. A baldneſs of the eye-laſhes, from a callous thickening of the edges of the eye-lids, ſo that it is a complication of a madaroſis, and a hard lipitude.

PTISANA, vel ptiſſana, from πτισσω, *to decorticate, bruiſe*, or *pound*. Ptiſan, or ptiſſan. Properly it is barley deprived of its hulls; or *pounded* barley, becauſe formerly the barley was *decorticated* by *pounding*, after having ſteeped it a little in water, and then it was dried. After this *pounded* barley was ground into meal, it was made into balls by firſt boiling, and then drying it to a due conſiſtence for this end.

Ptiſan was alſo made of other kind of grain; but then to *ptiſſana* was added the name of the grain from which it was made.

A quantity of theſe *ptiſans* was boiled in from ten to fifteen times their quantity of water, until the meal ſwelled very much; then they added a little vinegar, a little oil, and a ſprinkling of ſalt. The *ptiſan* thus boiled is called the cream, or ſoop of *ptiſan*; the broth, gruel, or juice of *ptiſan*.

PTOSES. Tumors cauſed by protruſion.

PTOSIS, from πιπτω, *to fall*. It is a diſorder conſiſting in the deſcent of the upper eye-lid, either on account of a palſy of the muſcles which ſhould elevate it, or a flux of humours which depreſs it.

PTYALISMOS, or Ptyaliſmus. A frequent and copious diſcharge of ſaliva; but at preſent it is generally underſtood to be a ſalivation excited by mercury. See Salivatio. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order apocenoſes. It is generally ſymptomatical. A ſingular caſe of a troubleſome *ptyaliſm* being cured, by chewing dry bread, and ſwallowing it, is related in the Lond. Med. Tranſ. vol. ii. p. 34, &c.

PUBIS INTEROSSEUM (Ligamentum). It is a ſtrong triangular membrane, fixed by two of its edges in the inferior branches of theſe bones, all the way up to their common ſymphyſis; the third edge, which is the loweſt, is looſe: and this whole membrane, the middle of which is perforated by a particular hole, is ſtretched very tight between the two bones, and under their cartilaginous arch, to which it adheres very cloſely.

PUBIS OSSA. They are ſituated in the middle, anterior, and internal part of the os innominatum. On their ſuperior part is a ridge, which runs on a continued line with another of the os ilium: it diſtinguiſhes the cavity of the belly from that of the pelvis. Betwixt the pubis and iſchium, is the foramen magnum ovale, which in the recent ſubject is filled up with a ligament. The ſymphiſis of the *os pubis* is a compoſition of two cartilages, and one ligament; the two cartilages cover the ſurface of each bone, and the ligament is betwixt them. On this ſymphiſis, ſee Dr. Hunter's Obſ. in the Lond. Med. Obſ. and Inq. vol. ii. p. 333.

As a ſubſtitute for the Cæſarean operation, the ſection of the ſymphyſis of the pubes is ſubſtituted by the French, and is thus directed to be performed: the inſtrument uſed on this occaſion, is a common diſſecting knife with a convex edge, a little blunt in the point, leſt it ſhould injure the bladder, and rather thin, becauſe it cuts the better. The proper ſituation for performing this operation, is to place the woman on her back at a height convenient to the accoucheur; the thighs being ſomewhat opened, and the mons veneris being ſhaved, introduce a catheter into the bladder. The inferior part of the integuments muſt be drawn down, and the inciſion begun about two or three lines above the pubes, and no higher. The firſt inciſion muſt not be carried further than the middle of the ſymphyſis. Another method may be uſed; viz. take the integuments between the fingers on each ſide the ſimphyſis, and make the inciſion in the middle: this way would be eaſier for the ſurgeon, and leſs painful for the patient; but the tenſion of the integuments makes it difficult. From this firſt inciſion you will have but little hæmorrhage, and the cartilage will be expoſed to the ſight, ſo that you may chuſe exactly where to proceed with the next inciſion. By cutting in the middle of the ſymphyſis, the ſuſpenſory ligament of the bladder will be divided, and in procuring the neceſſary ſeparation, it will be lacerated, which may occaſion an incontinence of urine. There are caſes, in which this complaint can be attributed to no other cauſe than

than the laceration or relaxation of the ligament of that viſcus; it will therefore be right to avoid cutting in the middle of the cartilage. There are ſeveral advantages from cutting on either ſide: 1ſt. Part of the ſuſpenſory ligament of the bladder will be preſerved, and it is likely by ſo doing, that the bone on that ſide will be touched; the ſhooting out from itwill procure a ſpeedy agglutination and reunion. 2dly, The left *pubes* appearing after the ſection to recede more than the right, there will be a greater opening on that ſide; beſides, 3dly, the neck of the bladder being rather more inclined to the right, and the fundus being ſo always, all theſe reaſons ought to determine us rather to chuſe the left ſide. The integuments being cut as far as the middle of the *pubes*, the ſuperior part of the cartilage will be expoſed; you muſt then begin the inciſion, and continue it as far as the ſymphyſis, taking care to direct the catheter to the ſide oppoſite that on which the operation is performed; then finiſh the ſection of the integuments, and afterwards that of the cartilage. As you are in moſt danger of wounding the bladder in dividing the upper part of the cartilage, it is very important not to be obſtructed by any hæmorrhage. This method, on account of its facility and readineſs, together with its ſucceſs, ſeems hitherto to be the beſt. The moment the ſymphyſis is divided, the *pubes* recedes, and this the more, according as the thighs are kept opened. If the ſeparation is very ſudden and conſiderable, as the poſterior articulations act in the nature of hinges, the interior ligaments which cover them will be diſtended too ſuddenly, which may be of bad conſequence; it is, therefore, adviſeable to keep the thighs moderately opened during the operation; and afterwards, upon raiſing them, to widen them gradually, until you have obtained the ſeparation neceſſary to finiſh the delivery.

With regard to the delivery, if the child preſents by the head, ſome adviſe to leave it to nature; I hope the following reaſons will induce to a different practice. After the ſection there is an arterial hæmorrhage, but however trifling it is, we ſhould not diſregard it. If, after the operation, we leave delivery entirely to nature, it would probably occaſion pains in the poſterior articulations, irritate and inflame the ſurrounding parts; hence, we ought not to leave the expulſion of the child to nature. As to the forceps, inaſmuch as they are ſuppoſed to diminiſh the ſize of the head, they appear to be of ſome uſe, but their preſſure is often of fatal conſequence.; the beſt way is, to turn the child, and deliver it footling; after which the woman's thighs are to be lowered and placed near one another. The integuments which were greatly diſtended during pregnancy, now will ſubſide, ſo as to cover the ſymphyſis. A bladder muſt be fitted to the end of the catheter, in order that the patient may not be obliged to ſtir when ſhe wants to diſcharge her urine, and alſo in caſe the bladder hath been injured, that the wounded part may heal without any inconvenience from urine.

As to the wound, nothing more is neceſſary than dry lint, moiſtened with brandy, beat up with the white of an egg, and diſcutient embrocations upon the poſterior articulations of the pelvis. A bandage muſt be applied to keep the parts in contact, to which there muſt be two tapes faſtened, to be conveyed between the legs, and tied before. The mother ſhould ſuckle the child for eight or ten days, to prevent bad conſequences from the milk; laxatives, with tonics, may then be directed, according to circumſtances. Care muſt be taken to keep the parts at reſt as much as poſſible, in order to favour a ſpeedy reunion. There is great reaſon to expect, that by obſerving the above directions, the cure may be effected in about three weeks in general, and that without any alarming ſymptoms.

Mr. Sigault, of Paris, is the firſt who propoſed and performed this operation, in which he was aſſiſted by M. le Roy, M. D. of the ſame place. They, with ſome others, obſerve, that the bones of the pelvis are connected by a ſubſtance which, during the latter period of pregnancy, ſwells and ſoftens, ſo that it may very eaſily be cut through; and that by ſuch an inciſion the two fore parts of the *pubes* recede from each other to the diſtance of from two inches to two inches and a half, more or leſs according to the ſwelling and ſoftneſs in the cartilaginous ſubſtance: thus the capacity of the pelvis is enlarged; for, in proportion to the ſeparation of the *pubes*, they alſo diverge forwards.

When the diameter of the brim of the pelvis from the ſacrum to the *pubes*, meaſures from two inches and a half to three inches and a quarter, this operation is recommended.

See Dr. Le Roy's Practical and Hiſtorical Enquiries, on the Section of the Symphyſis of the Pubes.

On this ſubject it may be proper to relate ſomething of what has been attempted in England, with a view to eſtabliſh the practice of it, particularly in ſuch caſes as have hitherto demanded the ſeverer operation called the Cæſarean ſection. To Dr. Leake we are indebted for a caſe, in which the requiſites are afforded, for an encouraging view of this new operation; alſo for anſwers to the objections advanced in oppoſition to it. The reaſons for preferring it are as follow: In December, 1778, a woman died in the Weſtminſter Lying-in Hoſpital about a fortnight after her delivery; after the neceſſary examinations for the cauſe of her death, the *ſection of the ſymphyſis pubis* was performed, in order to aſcertain *how much ſpace might be gained between the divided bones*. The cartilage being laid bare, it was cut through with great eaſe, and without wounding the neck of the bladder, or any of the contiguous parts. The *oſſa pubis* immediately receded from each other about one inch, and with very gentle force were ſeparated *two inches and an eighth*. The contents of the pelvis were afterwards removed, and on examination, the internal poſterior ligaments of the bones of the pelvis were neither lacerated, or in the leaſt injured.

The objections, with Dr. Leake's anſwers are, as follow: firſt, that the cartilage at the ſymphyſis of the *pubes* may happen to be oſſified, which would prevent its diviſion with the knife. It is anſwered, that cartilage being a ſubſtance eſſentially diſtinct from bone, is never found oſſified, except in a *præternatural ſtate*; or in *old age*, after the time of child-bearing is paſt, and where there could be no occaſion for the operation. Secondly, the neck of the bladder may be wounded. It is anſwered, the neck of the bladder being only ſlightly attached to the ſymphyſis of the *pubes*, by cellular membranes, and not in cloſe union with the cartilage, there *never can be the leaſt danger of wounding it*, except through ignorance of the ſtructure and ſituation of the parts. Thirdly, that the ſpace gained by the ſection of the *pubes*, may not, in a narrow pelvis, be ſufficient to allow the child's head to deſcend through the cavity. It is anſwered, in the caſe of Mrs. Braſier, M. Le Roy found a ſeparation of *two inches and a half*: and as the caſe at the Weſtminſter Lying-in hoſpital affords inconteſtible proof, that after the ſection of the cartilage, the bones of the *pubes*, without violence, receded from each other full *two inches and an eighth*; there can be no doubt but ſo much additional ſpace will, in general, be ſufficient to let the child's head paſs, even in a pelvis ſo preternaturally narrow, that no other means but the Cæſarean operation could be deviſed for its birth. It is generally allowed, even by the opponents of this operation, that the ſpace gained by the aperture between the divided bones, is nearly *two inches and a half*, even in the dead body, which is leſs yielding than the living one; and it may be added, that the ſpace gained from the ſacrum to the *pubes* will be equal to the enlargement of the pelvis from ſide to ſide. Fourthly, that the union of the cartilage may not be effected. It is anſwered, from obſervations and unqueſtionable authority of Petit and De la Faye, we are aſſured, that cartilages will as firmly unite after diviſion, as bones after a fracture. But to put this matter out of doubt, Camper, a Dutch phyſician, made experiment upon a quadruped, by cutting through the cartilage of the *pubes*, and after diſſecting the parts, he found they were firmly united. Fifthly, that the internal poſterior ligaments uniting the ſacrum and ilia, may be torn aſunder, by dividing the bones of the *pubes*. It is anſwered, reſpecting this, we may refer to the caſe above mentioned at the Weſtminſter hoſpital, where the ſection of the *pubes* was made in the preſence of ſixteen medical gentlemen, and where, notwithſtanding the ſpace gained was two inches aud an eighth, no laceration, or the leaſt mark of violence appeared, but, on the contrary, theſe ligaments were found perfectly firm, and in their natural ſtate.

If a comparative view is taken of the Cæſarean operation, and the ſection of the *pubes*, the advantages are conſiderably in favour of the latter. The ſection of the *pubes*, which allows the child to be born by the natural paſſage, carries not with it thoſe ideas of cruelty which attend the Cæſarean operation, where the patient is, as it were, embowelled alive. No formidable apparatus is neceſſary, the ſection being made with expedition, and without pain or danger; no blood-veſſel, nerve, or other parts, eſſential to life, are wounded: theſe divided, being only cutis, cellular membrane and inſenſible cartilage, from which neither hæmorrhage, or ſymptomatic fever are to be apprehended. Theſe are my reaſons for preferring the ſection of the *pubes*, by which the mother and the child may probably *both be ſaved*; but where the mother, at leaſt, to whoſe ſafety our principal attention ſhould be directed, would generally be loſt by the Cæſarean ſection.

See Practical Obſervations on the Child-bed Fever, by Dr. Leake, edit. 5. page 238—255. See alſo Comparatio inter Sectionam Cæſaream & Diſſectionem Cartilaginis & Ligamentorum Pubis in Partu, &c. Auctore, C. C. Siebold, M. D.

Dr. Hunter is leſs ſanguine with reſpect to this operation. He very early ſuggeſted its difficulties and diſadvantages; and ſince that, Dr. Walter, of Berlin, diſputes its uſefulneſs ſo much, as to preſer the Cæſarean operation to it. See his De Diſſectione Synchondroſeos Oſſium Pubis in Partu difficili.

PUDENDA ARTERIA, i. e. Pudica arteria.

PUDENDAGRA. So ſome have called the venereal diſeaſe; *pudenda*, from *pudor*, *ſhame*. Others define it to be, pain or uneaſineſs in the genital parts of men or of women, ſomewhat reſembling a diarrhœa, but without a dyſuria. But Dr. Berdoe aſſerts, in his Eſſay on the *Pudendagra*, that it is diſtinct from the venereal diſeaſe, and alſo that it is proper to women. It is an affection of the uterus alone in the beginning, however other parts may ſuffer in time. The prediſpoſing cauſe is a too rigid chaſtity, or a deprivation of the venereal act; the primary cauſe is a morbid affection in the nerves of the uterus; and the more immediate cauſe is an indulgence of the venereal appetite, at times when the uterus is ſo diſordered as to ſuffer thereby. An exceſſive flux of the menſes, and the fluor albus, aggravate the *pudendagra*, which is not properly confirmed until the uterine nerves having entirely loſt their ſenſibility, are no longer capable of diſtributing the menſtrual flux. Exceſſive venery haſtens the inſenſibility of the uterine nerves.

The *pudendagra* may affect the conſtitution many years without ſpreading its influence beyond the limits of the uterus.

In this diſorder there is a diſcharge of a purulent ichorous matter from the uterus, which may produce ſome inflammatory ſymptoms in the penis when a man cohabits with a woman who is thus affected; but though the woman is a great ſufferer, the infection which the man receives is ſoon removed by bleeding, and a few doſes of manna, or other more cooling laxatives.

On diſſecting thoſe who have died whilſt labouring under the *pudendagra*, it hath been obſerved, that the parts leading to the uterus were particularly relaxed, and that the uterus itſelf was enlarged by ſcirrhous and other tumors.

PUDICA ARTERIA. It comes out between the pyriform muſcle, and the ſpine of the iſchium; it runs downwards between the two ligaments (the one of which comes from the tuberoſity of the iſchium to the ſacrum, and the other from the ſpine of the iſchium to the ſacrum) on the inſide of the tuberoſity: as it goes on, it gives ramifications to the anus, which are called the external hæmorrhoidal, and then goes to the crura penis.

PUDICA EXTERNA ARTERIA. See Crural is.

PUDICÆ EXTERNÆ VENÆ. As the crural vein paſſes from under the ligamentum Fallopii, it ſends out branches to the inguinal glands, the muſculus pectineus, and the parts of generation; theſe are called *pudicæ externæ*, and they communicate with the *pudicæ internæ*.

PUDICÆ INTERNÆ VENÆ. The veins that ſpread about the parts of generation are thus called. They are branches from the venæ hypogaſtricæ.

PUERILIS MORBUS. The epilepſy.

PUERPERA. A lying-in-woman. Much care is uſually neceſſary when women are in this ſtate, for they are liable to many diſorders. As ſoon as delivery is effected, the woman ſhould have every thing that is wet removed; dry warm linen ſhould be in readineſs for her uſe; and as oft as they become very wet with the uſual diſcharges, freſh ones ſhould be ſupplied. If fainting fits come on after delivery, let the patient be laid with her hips higher than her head. It is generally neceſſary to keep the breaſts warm, by means of flannel cloths, until the milk flows freely. The air in the room ſhould be kept warm or cool, as is moſt agreeable to the ſenſations of the lying-in woman. During the firſt three or four days, the diet ſhould be thin, but yet not ſo as that the ſtrength is not duly ſupported by it. The common allowance is caudle, which is oatmeal boiled in water until it is of the conſiſtence of a thin jelly, and then rendered agreeable to the palate, by the addition of a little ſugar, and as much ale as will make it duly cordial; it is then called brown caudle; but if inſtead of ale a quantity of wine is added, it is named white caudle. If the ſtomach is ſubject to windineſs and acidity, the addition of a little brandy is to be preferred. Reſt muſt by every means be promoted; and, if required, opiates may be given for this end. Nor ſhould the neceſſary care to keep up a gentle perſpiration be wanting. Coſtiveneſs ſhould be guarded againſt, notwithſtanding that a diarrhœa at this time would be an unfavourable circumſtance. The child ſhould be applied to the breaſt in about ten or twelve hours after its birth, if the mother intends to ſuckle it; for the ſooner the ſecretion of milk can be promoted, the leſs danger will there be of the fever called a milk fever.

PUERPERILIS FEBRIS. The puerperal fever, or the child-bed fever. A fever happening from any diſeaſe in conſequence of pregnancy, or delivery of a child, and happening during the time of lying-in, may properly be called a *puerperal fever*. This is Dr. Cullen's ſpecies of peritonitis, which he diſtinguiſhes by the name of peritonitis omentalis. See Peritonitis.

The cauſes are various, and ſometimes the diſorder is inflammatory, but it ſoon tends to the putrid kind; it often is from the beginning a putrid fever. The omentum and peritonial coat of the inteſtines are generally the parts inflamed, but other of the abdominal viſcera may be alſo thus affected; but which ever of them is the ſeat of inflammation, a putrid matter is ſoon abſorbed therefrom, or there is an abſorption of putrid matter from without. But notwithſtanding that in many inſtances the womb hath been found, on diſſecting the deceaſed body, to be free from any appearance of a diſeaſe, it is moſt probable that the origin of this fever is in that viſcus. Conception is immediately followed with an increaſed ſpaſmodic irritability, which produces the ſymptoms of pregnancy; this irritability is increaſed by labour. In the pregnant ſtate the uterus is more irritable than uſual, and this circumſtance extends itſelf throughout the whole frame, whence pregnant women are violently affected by any cauſe that can increaſe their preſent preternatural ſtate, and hence the taking of cold, being kept too hot, or any other circumſtance that can excite a fever, may now be the cauſe of that which comes under this denomination. The occaſional cauſes may be a ſudden emptying of the womb, when there was a great quantity of water contained in the membranes; for then the blood ruſhing into the emptied parts with too much violence to be returned, excites inflammation there; coagulated blood lodged in the uterus, after delivery, and becoming putrid by the acceſs of air; obſtructed lochia, a putrid air, the coming of the milk, inflammation in the breaſts, the abſorption of acrid milk, and the retention of the excrements. Dr. Hulm and many others ſuppoſe, that an inflammation of the omentum and inteſtines, is always the cauſe of this fever, to which they are prediſpoſed by the preſſure of the gravid uterus.

In the *puerperal* ſtate, a quick pulſe, and a febrile heat, manifeſt the preſence of this fever, or at leaſt give us reaſon to ſuſpect its preſence, which is more certainly determined by the following diagnoſtics, which attend according as the cauſes are various.

If putrid blood inflame the uterus, and is abſorbed, the lochia will be diminiſhed or obſtructed; whilſt any of the

lochia

lochia is discharged it comes away in small lumps; thus the patient continues for three or four days; at length a fever comes on, being preceded by rigors, which are followed by a quick weak pulse, thirst, pain in the head, want of sleep, sighing, load at the præcordia, restlessness, great weakness, dejection of spirits, a wildness or else despair in the countenance, and often an inflammation in the eyes; sometimes there is a difficulty of breathing, pain in the side, the skin is dry, the tongue is of a glossy brown colour, and also very dry; sometimes in the advanced stage of the fever, if a hand is laid on the patient, one feels the same kind of prickling sensation in a less degree, as is felt after having the fingers in warm putrid blood. There is nothing to be learnt from the urine, as it is mixed with black putrid blood, which is constantly drained through the vagina. A diarrhœa soon follows the feverish symptoms, the stools are fetid, liquid, and blackish; the tongue is brownish, or of a reddish colour; the skin is very dry and hot; often there are aphthæ in the mouth; the breasts are flaccid, and upon drawing them, blood, instead of milk, is frequently discharged. Milk may indeed appear in the breasts when the putrefaction is several days before it takes place, yet they soon become perfectly flaccid. Sometimes the belly swells during the course of the disease, but a soreness and tenderness of it is a never failing attendant soon after the fever begins. Dr Hulme observes, that as the child seems chiefly supported in the abdomen, by resting upon the brim of the pelvis, the greatest pressure will commonly be upon the small intestines, either on the right or left iliac region, or directly in the middle above the os pubis; and from this circumstance he accounts for the pain and tenderness of the hypogastric region, which is the constant and inseparable companion of this disease, and therefore constitutes the chief pathognomonic symptom: a delirium is common through a great part of the disorder.

It may be observed that a tenderness and soreness in the belly, or flaccidness of the breasts, are not to be feared if there is not a fever at the same time.

When an inflammation of the uterus is the cause, the pulse is quick, a fever attends, pains resembling after-pains, and which shoot from the loins and belly into the groin and thighs, without any perfect intermissions; soon after these symptoms the anus and the neck of the bladder sometimes becomes very sensible; the tongue is white and moist; the belly costive; the lochia are suppressed, or only a brown ichor is discharged from the uterus. The breasts are flaccid.

When this fever is produced by inflammation of the abdominal viscera, a dull weight and pain at first is felt in the belly, the pulse is not very quick, nor the heat very considerable; the patient is generally costive; but sometimes the fever runs higher, and a diarrhœa comes on, and in general the patient is affected as those are who die of bruises in the belly.

If putrid effluvia from without are the causes, they at the first occasion symptoms of local inflammation, yet the disorder may be distinguished from an original disorder of the uterus, (unless the patient is seized with an epidemic disease previous to, or during labour) by the lochia being at first regular, and the after-pains, if there are any at the same time, unaccompanied with symptoms of inflammation.

These symptoms are generally more or less of them in all these fevers, be the cause what it will. They vary also according to the time of seizure, as well as from the difference of causes. The pulse is commonly more quick in *puerperal* than in other fevers, because of the extraordinary irritability attendant on those patients; and in consequence of the discharges during delivery, it will be generally very weak.

The *puerperal fever* should be distinguished from the milk fever, from after-pains, and from colic pains.

A small degree of fever in lying-in women is more dangerous than in any other state. That state of increased irritability, &c. which renders lying-in women liable to so many accidents, seems to be much abated after the discharge of the lochia and the coming of the milk; whence, after these, whatever disorders attend, their danger will be considerably lessened.

In order to the cure, if the patient did not lose much blood in the time of delivery, and the pulse is full and quick, take away a little; but if the evacuation when delivered was sufficiently large, though the pulse is hard, defer bleeding, and proceed with such medicines as the case requires. If the patient is costive, a glyster may be given, and after it, a dram of sal Glaub. ver. every three or four hours, or at greater intervals, according to the effect produced by each dose; if the salt runs too fast through the bowels, a few drops of the tinct. theb. will restrain it. If the salt is rejected, give two or three grains of calomel, with half a grain of the tart. emet. After a few stools, antiphlogistics and sudorifics may be used, e. g ℞ Sal diuret. ʒ ss. vin. antim. gut. xxx. vel tart. emet. gr. ½ m. f. haust. 4ta vel 5ta quaq. hora. If these run off too freely by stool, add to each dose two or three drops of the tinct. theb. If a sweat comes on, continue these draughts: if not, when there seems to be no farther need of evacuating the intestines, give the following bolus and draught every four or five hours.

℞ Sal ammon. crud. gr. xv. vel ℈ i. sp. cæti & pulv. e chel. c. ää gr. x. conf. lujulæ q. s. f. bol.

℞ Spt. Minder. & aq. menth. sim. ää ʒ i. m. f. haust. these produce a sweat.

The patient's drink may be tepid or cold water, in which toasted bread is steeped.

A mixture of sal volatile and water, in equal parts may be rubbed on the belly.

Hitherto the disorder is considered in its first or inflammatory state; but if a diarrhœa comes on, the putrid or second stage is commenced. The diarrhœa is not to be immediately or suddenly checked, but nature must be assisted by rendering the matter less active which irritates the intestines, by correcting the whole state of the fluids, by lessening the irritability of the habit, that the materia morbi may have the less effect, by giving antiseptic diuretics, and by defending the nerves of the primæ viæ against irritation, so that, whatever putrid matter gets into the intestines, it may pass off without acting as a violent purge. The columbo root with rhubarb may be given as a cordial, to lessen irritability, and carry off putrid matter from the primæ viæ; and the above purposes are answered where the pulse is full, and the heat great, by giving a powder composed of the pulv. flor. chamomil. and amylum; this may be repeated every four or five hours with a little sp. nitri d. vel sp. sal marin. in any thing that the patient drinks. But in this second stage of the fever the bark is most to be depended on: as soon as the pulse sinks, and the heat is lessened, or that the stomach will bear it, it hath relieved both the fever and the diarrhœa, by going off in two or three stools, and a sweat; but whilst the heat is considerable, always join a little of the sp. nitri d. with every dose of the bark, and if two or three drops of the tinct. theb. are also added, the heat is more effectually abated, provided it does not wholly suppress the purging. If the diarrhœa goes off without the fever abating, instead of laudanum, give rhubarb with the bark. If the pulse sinks, and the nervous oppression comes on, the julep e camph. will lessen preternatural irritability, keep the diarrhœa within bounds, and by its immediate action on the nerves, it revives and supports the spirits; an ounce is a sufficient dose, and may be repeated every four or five hours. What the patient drinks may be acidulated with the sp. sal. marin. When blood pent up in the uterus corrupts there, and gives rise to this disorder, however inflammatory the first symptoms may appear to be, bleeding must be omitted; purging and saline medicines are also alike improper; the absorbed matter is more than sufficiently attenuating, and often causes greater discharges by stool than the patient can bear; in this case give a dose or two of rhubarb with the columbo root to evacuate the bowels, and then supply the patient with antiseptics as above, of which the chief is the bark. If the patient is weak, join the rad. serp. V. with the bark. If the fever is caused by obstructed lochia, from inflammation, give antiphlogistics, but, if the lochia is obstructed from the coagulated blood choaking up the os uteri, internal medicines are useless. If a putrid air produced this fever, the mucus, the bile, &c. in the primæ viæ will be contaminated, and, unless removed, will be a constant fomes to the disease: in this case begin with an emetic, keep the room filled with pure cool air: the emetic should be given be-

fore the inflammation of the viſcera comes on. If it does not give way to this treatment, the diſeaſe is deeply ſeated, and an abſorption of putrid matter from the uterus may be ſuſpected to contribute to the diſorder, or that the blood is contaminated, and then the above antiſeptics will be required. See Kirkland, Denman, Hulme, Leake, and White, on the *Puerperal*, or Child-bed Fever.

PUGILLUS. A pugil. The eighth part of an handful.

PULEGIUM. Pennyroyal. It is a plant of the mint kind, differing from the mints ſtrictly ſo called, in the flowers being diſpoſed, not in ſpikes on the tops, but in thick cluſters at diſtances round the joints of the ſtalks, and the upper ſegment of the flower not being nipped at the extremity.

PULEGIUM VULGARE, called alſo pulegium regale, pulegium latifolium, mentha aquatica. Pudding-graſs, common pennyroyal. It hath oval obtuſe leaves, and trailing ſtalks, which ſtrike root at the joints. It grows wild on moiſt commons, and flowers in June. It is the mentha *pulegium* vel mentha floribus verticillatis, foliis ovatis obtuſis ſubcrenatis caulibus ſubteretibus repentibus, ſtaminibus corolla longioribus, Linn.

All the *pennyroyals* are warm and pungent, ſomewhat ſimilar to mint, but more acrid, and leſs agreeable, both in ſmell and taſte. They are leſs proper than mint in the common naufeas, but more efficacious as warm carminatives and deobſtruents in hyſteric caſes and diſorders of the breaſt. This ſpecies is the ſtrongeſt, though the leaſt ungrateful.

The active principle of the *pennyroyals* is their eſſential oil, which is more valuable than that of mint. It comes over at the beginning of the diſtillation with water, and riſes in great part with ſpirit of wine; it taſtes and ſmells ſtrongly of the plant. Its doſe is from gr. i. to v.

The London College directs a ſimple and a ſpirituous water to be diſtilled from *pennyroyal*; but an infuſion of it is equal, if not ſuperior: and the whole virtue of the herb may be thus extracted, either by water or by ſpirit. See Lewis's Mat. Med.

PULEGIUM CERVINUM, i. e. Mentha cervina, Linn.

PULMONARIA MACULOSA, alſo called pulmonaria ſymphytum maculoſum, ſage of Jeruſalem, Jeruſalem cowſlips, and ſpotted lungwort. *Pulmonaria* officinalis, Linn. It is an hairy ſcabrous plant, with leaves of a dark browniſh green colour on the upper ſide, and ſpotted for the moſt part with white, underneath it is of a paler green; the lower leaves are oval, and ſet on broad pedicles; thoſe on the ſtalks are narrower, long pointed, ſet alternately without pedicles: the flowers are monopetalous, of a purple or blue colour, and ſometimes white, followed each by four ſeeds incloſed in the cup. It is perennial; it grows wild in many parts of Europe, and flowers in April or May. Their virtues are ſimilar to thoſe of the herb trichomenas.

PULMONARIA AUREA, alſo called pulmonaria Gallica, hieracium murorum, piloſella major. French or golden lungwort. It grows on old walls, in woods, and in ſhady places. Its virtues are the ſame as the above ſpecies.

PULMONARIA ANGUSTIFOLIA. Sage of Bethlehem. It is cultivated in gardens; it flowers in May, and is of the ſame virtue as the ſage of Jeruſalem. See Lewis's Mat. Med.

PULMONARIA. A name for the muſcus pulmonarius, and for a ſpecies of hieracium.

PULMONARIS ARTERIA. See PULMONES.

PULMONARIÆ VENÆ. See PULMONES.

PULMONES. The lungs. They are two ſpongy bodies, which are reddiſh in children, greyiſh in adults, and bluiſh in the aged. They are divided into two principal lobes, which are incloſed in two diſtinct bags, formed of the pleura; ſo that the right and the left lobes have not the leaſt communication. On the right ſide the lobe is divided into three leſſer ones, one inferior, one ſuperior, and one anterior, the loweſt lying upon the diaphragm. On the left ſide there are two lobes divided by a fiſſure. The ſpace betwixt the *lungs* is filled up by the heart below; above by the thymus and trachea; behind by the œſophagus and ſpine. The *lungs* are narrow above, and broad below, correſpondent to the ſhape of the thorax. The *lungs* are univerſally covered on their external ſurface by the pleura, and an inner lamella of it runs into their ſubſtance, as we find in infants.

The whole maſs of the *lungs* is compoſed of air-veſſels, blood-veſſels, lymphatics, nerves, and cellular membranes.

The air-veſſels are very ſmall branches continued from the wind-pipe, with which in a ſound ſtate they have a free communication, ſo as at every inſpiration to be filled with air. See BRONCHIA. The blood-veſſels are the pulmonary and the bronchial arteries and veins. The pulmonary artery riſes from the right ventricle, runs upwards to the left of the aorta; on the curvature it divides into two branches, which diviſion lies before that of the trachea, the right branch is longer than the left, for the ſame reaſon as the trachea is ſo; juſt as it is plunging into the *lungs* it divides into two or three branches. When this artery hath divided into very ſmall branches, they do not anaſtomoſe like the ſmall branches of the aorta, but they join again, and form veins, which uniting together go to the left auricle of the heart, commonly in four or five trunks. The bronchial arteries. See ARTERIÆ BRONCHIALES. The large veſſels run in the large interſtices, and in the ſmall parts the branches ſtill run on in the interſtices of ſmaller lobuli, and are connected by a cellular membrane, as in the other parts of the body; at laſt the arterial ramifications terminate in a fine net-work, upon the cells called rete Malpighi, where it is ſuppoſed that the blood undergoes the alteration, as there it is neareſt to the air; from this net-work the veins begin, and carry the blood back. The pulmonary artery receives and returns the whole maſs of blood which circulates through the *lungs* before it paſſes to the reſt of the body, to the end that ſuch parts of this fluid ſhould be ſeparated, and carried off by reſpiration as were unfit to be circulated, or unneceſſary in the œconomy of nature. The bronchial arteries are deſtined to the nouriſhment of the *lungs*. The lymphatic veſſels are diſtributed on the ſurface of the *lungs*, and convey the lymph which they imbibe to a certain duct, whence it is returned to the maſs of blood. The nerves are from the eighth pair chiefly; they are very ſmall branches. The cellular membrane fills up the intermediate ſpaces between the veſſels. See ASPERA ARTERIA, and BRONCHIA.

As to the uſe of the *lungs*, Dr. Rutherford, of Edinburgh, ſays, that the good ſtate of them ſeems to have an influence on ſanguification; he ſays, that they are of more conſequence than any other viſcus for making good blood, and that, whenever their action is weakened, the blood grows thinner in proportion. Many other conjectures are made on this ſubject, among which the moſt important are, that from the air received by inſpiration, a neceſſary principle is imbibed in order to life and health; and that with the air carried out from the *lungs*, a quantity of matter is alſo carried from the blood, which, if retained, would either be a redundant load, or otherways injurious. Dr. Prieſtley aſſerts, that a principal uſe of the *lungs*, is to carry off redundant phlogiſton from the blood.

The *lungs* differ from every other part of the body in many other reſpects, particularly in the following: their ſubſtance is more vaſcular, and a greater quantity of blood paſſes through them in a given time. The aſpera arteria minutely ramifying through every part of their ſubſtance, terminating in air veſicles, is peculiar to them, and by reſpiration they are kept in a perpetual motion; theſe differences ſubſiſt through life, in ſickneſs and in health. When the *lungs* are diſeaſed, their motion is not only increaſed by the reſpiration being quickened, but they ſuffer, for the moſt part, violent concuſſions by means of coughing. This circumſtance attending no other viſcus, renders ſuch diſorders more difficult to cure; for all authors agree in this, that reſt is abſolutely neceſſary to parts when inflamed. If by any means the cough could be prevented, it is moſt probable that diſeaſes of the *lungs* would be nearly in the ſame ſtate, and admit of a cure as readily as any other internal part, equally inflamed. The increaſed frequency of reſpiration does not appear to be in theſe caſes of great importance, becauſe it is natural and familiar, as it takes place upon any exertion or quick motion of the body.

PULMONIA, i. e. Peripneumonia.

PULPA. Pulp. It is the ſoft part of fruits which ſurrounds the ſeeds.

PULPEZIA. An apoplexy.

PULSATILLA. Nigricans. Stoerck, Ph. Edinb. It is the *pulſatilla* flore minore *nigricante*, C. B. Anemone pretenſis, vel anemone pedunculo involucrato, petalis apice reflexis, foliis bipinnatis, Linn. It is a ſpecies of anemone, much reſembling the *pulſatilla* vulgaris, or paſque flower, but its flower is leſs, and of a darker hue. It is a native of the South of Germany, and other neighbouring countries. All the anemonies have a conſiderable degree of acrimony; but this ſeems to poſſeſs the largeſt ſhare. The whole plant when chewed impreſſes the tongue with a ſharp, burning, durable taſte; the root is milder than the other parts. On diſtilling the plant with water, the liquor which comes over is ſtrongly impregnated with its virtues; and the remaining extract is alſo conſiderably active. From numerous trials, Dr. Stoerck, of Vienna, celebrates the efficacy of this plant in various chronic diſeaſes of the eye; in venereal nodes and nocturnal pains, in foul ulcers with caries, in ſerpigo, and ſuppreſſed menſes; he relates inſtances of its curing blindneſs of many years continuance, by diſſipating and diſſolving films and obſcurities of the cornea. In theſe caſes its good effects were firſt indicated by conſiderable pain excited in the eye. The ſenſible operation of the medicine was nauſea and vomiting, particularly when the diſtilled water was uſed; an increaſed flow of urine, and ſometimes gripes and looſeneſs, with increaſed pain at firſt in the affected parts. From all theſe circumſtances, the *pulſatilla* ſeems to be endued with very active and penetrating powers, yet ſuch as may be employed with perfect ſafety, if proper caution be uſed. The doſes of the diſtilled water to adults is about half an ounce twice or thrice a day; of the extract, reduced to powder, with the addition of ſugar, five or ſix grains. Bergius ſpeaks, in his Materia Medica, p. 491, of having given the extract copiouſly, eſpecially in diſeaſes of the eyes, but without any effect. The Edinb. College had adopted the diſtilled water of *pulſatilla*, but has now changed it for the extract. See Lewis's Mat. Med. ed. 3.

PULSUS. The pulſe. *Pulſes* were not attended to before the time of Hippocrates, ſince whom what have been called improvements thereon being more than any one can retain in his memory, they cannot be applied to uſefulneſs in practice: Celſus calls the *pulſe* res fallaciſſima: moſt publications on this ſubject are in truth to be arranged in the ſame order. To the different degrees of irritability in conſtitutions is owing the variety of *pulſes*, with reſpect to their being quick or ſlow; every accident that happens to the body, and every affection in the mind hath an influence on them; ſo that very little can be determined from them whence concluſions may be made in practice. The hard and the ſoft *pulſe* are very often owing to a quantity of fat, or of a cellular membrane being ſituated betwixt the artery and the finger, or from the almoſt total abſence of theſe in this ſituation. The full and the ſmall *pulſes* are owing chiefly to the different diameters of the arteries; and, except the quick, the ſlow, and the irregular *pulſes*, there are none of the kinds which are ſo ingeniouſly diſtinguiſhed by authors, but what will, on proper enquiry, be found to be fallacious.

There are adults in health, whoſe *pulſe* exceeds not thirty or forty ſtrokes in a minute; others, while they are at reſt, have a *pulſe* ſo quick that it may be counted to 120, and during the preſence of a fever, the *pulſe* hath been obſerved in ſome inſtances to beat 220 times in the ſame ſhort period.

Schwalbius, of Prague, contented himſelf with three *pulſes*, viz. the equal and unequal, the quick and ſlow, and the ſtrong and the weak. Sylvius reduces *pulſes* to three kinds, viz. the ſtrong and weak, the large and ſmall, and the quick and ſlow. Fernelius obſerves, that "the ordinary affections of the body change the *pulſe*; ſo that without duly adverting to theſe affections, the *pulſe* cannot be certainly underſtood, nor can it be determined how far it recedes from a natural ſtate in conſequence of diſeaſe."

In the Lond. Med. Tranſ. vol. ii. p. 18, &c. Dr. Heberden hath inſerted ſome obſervations on the *pulſe*, in which it appears how little it is to be depended on alone, or without the conjunction of other ſymptoms; in how few caſes an attention to the *pulſe* is of any ſignificancy; and as to various diſtinctions concerning *pulſes*, how groundleſs they are. The quick and the ſlow *pulſes* he fixes on, as thoſe on which uſefulneſs and certainty attend, when they are the ſubjects of our remarks, and leaves for our notice the following obſervations, viz. That the *pulſe* of a child under two years old ſhould be felt whilſt it is aſleep, becauſe it is ſo eaſily quickened by every new ſenſation; that the *pulſe* of an healthy infant on the day of its birth, and when it is aſleep, is between 130 and 140 in a minute, the mean rate during the firſt month is 120, and rarely, if ever, below 108. During the firſt year the limits may be from 108 to 120, the ſecond year at 90 and 100, the third year at 80 and 108, the fourth, fifth, and ſixth nearly the ſame as the third, the ſeventh year it is ſometimes at 72, but generally more; the twelfth about 70; in adults it is uſually from a little below 60 to a little above 80.

A full meal quickens the *pulſe* to about 10 or 12 in a minute more than its number of *pulſations* were before the advantage of refreſhment.

If the *pulſe* is quickened, ſo as to exceed the healthy ſtandard by ten *pulſations* in a minute, there is ſome diſorder; but the irritability of a child is ſuch, that a very ſlight fever will make the artery beat 140, or even 160, when no danger attends: and as there is much difficulty in counting the *pulſe* when it is at 180 and upwards, we are better enabled to judge of the danger of fevers in children by the thirſt, quickneſs of breathing, averſion to food, and want of ſleep, than by the *pulſe*.

A child of two years old will die of an inflammatory fever, though the artery beats only 144 in a minute; yet children of four years ſometimes recover from fevers when the *pulſe* is at 156.

If the *pulſe* of a child be 15 or 20 below the healthy ſtandard at its loweſt limits, and there be at the ſame time the ſigns of conſiderable illneſs, it is a certain indication that the brain is affected, conſequently ſuch a quiet *pulſe* ſhould alarm us with the probability of danger.

In adults labouring under an inflammatory fever, the danger is generally not very great, where the beats are fewer than one hundred. An hundred and twenty ſhew the beginning of danger, and they ſeldom exceed this number, unattended with delirioufneſs, and where the caſe does not prove fatal. To this there are two exceptions: Firſt, before ſome critical ſwelling begins to ſhew itſelf in fevers, then the *pulſe* hath riſen to 150. Secondly, in acute rheumatiſms, the *pulſe* riſes to 120, without danger; but in both theſe caſes the appetite, the ſenſes, ſleep, and ſtrength, deviate leſs from their natural ſtate than when the life of the patient is in danger.

When aſthmatic patients are ſeized with a ſudden fit, the *pulſe* ſometimes beats 120 times in a minute, in which caſe danger is great, but if this is exceeded, they rarely recover.

When the *pulſe* from being very quick, ſuddenly becomes quiet, all other ill ſymptoms continuing, it ſhews that the patient is become irritable: that the diſeaſe is tranſlated to the brain, and that a palſy, an apoplexy, or death, will be the conſequence.

In an inflamed ſcirrhus ſeated in any of the viſcera, in a cancer, ulcers in the internal parts, a quick *pulſe* is a more certain ſign of danger than a quiet *pulſe* is of ſafety. In hectic and rheumatic patients, the appetite continues, and an ability to take ſmall journies, when the *pulſe* is ſo quick that in an acute fever, with ſuch a quickneſs in the *pulſe*, they would be forced to keep in bed.

A good *pulſe*, with a loſs of appetite, ſtrength, and ſleep, with thirſt, and a quickneſs of breathing, is a dangerous ſituation; on the contrary, a bad *pulſe*, the appetite, ſleep, and ſtrength not much affected, with moderate thirſt, and the breathing but little affected, is ſafe.

PULVINARIA. Cuſhions made with chaff, in which is mixed ſome medical ingredients coarſely powdered.

PULVIS. A powder. This form receives ſuch materials only as may be reduced and kept in this ſtate a ſufficient time without any loſs of their virtues, and yet do not poſſeſs ſuch qualities as render them ſo bulky for a ſufficient quantity to be taken in each doſe, or to render them very diſguſtful to the taſte. Bitters, fetids, acrid medicines, alkaline ſalts, gums, emollients, and muci-

laginous

laginous ſubſtances, are generally improper for keeping and giving in this form. The doſe of *powders* are from ℈ i. to ʒ ſs.

Compound *powders* are called ſpecies.

PUMEX, alſo called lapis bibulus, lapis ſcyrus. Pumice ſtone. It is found in volcanos. It hath been uſed as a dentifrice, but, if freely uſed, it wears away the enamel. It is a ſpongy maſs of a ſtony nature, but light and brittle: the beſt is of a white or greyiſh colour.

PUNCTA LACHRYMALIA. Lachrymal points. They are two ſmall holes, one on each upper and one on each lower eye-lid, on their inner edge, near the internal angles, where may be ſeen a ſmall eminence. Theſe orifices are ſituated oppoſite to each other. They convey away the tears when they have anſwered their purpoſe on the anterior ſurface of the eye, and carry them into the *lachrymal* ſac, and ſo into the noſe.

PUNCTICULA, vel Punctilaris, i. e. Petechialis febris.

PUNCTUM AUREUM. It is when an hernia of the inteſtines is reduced, an inciſion is made through the ſkin and membrana adipoſa, quite down to the upper part of the ſpermatic veſſels; then a golden wire is to be fixed and twiſted ſo as to prevent the deſcent of any thing down the tunica vaginalis.

PUNCTURA. A puncture. Synonymous with vulnus.

PUNCTURA AUREA, i. e. Punctum aureum.

PUNICA. The Pomegranate. See GRANATA MALA.

PUORRHŒA. A purulent diſcharge from the belly.

PUOTURIA. White, mucous, or purulent urine.

PUPILLA. The pupil. Becauſe it repreſents your image when looked into no bigger than the *pupilla, a puppet*. The choroides is continued on the inſide of the cornea tranſparens of the eye, and forms the iris; but it is perforated in the middle, and ſo forms the *pupilla*; as the iris contracts or expands, the *pupil* is larger or leſs. The uſe of the *pupil* is, to tranſmit the rays of light to the humours of the eye.

PUPILLARIS MEMBRANA. In the fœtus of five, ſix, and ſeven months, there is no pupil, but a fine vaſcular membrane, with large arteries going quite acroſs the part where the pupil is afterwards ſeen. It cannot be ſeen without injecting it; nor is it known what becomes of it after the birth. It is alſo called velum pupillæ.

PURGAMENTUM STELLARUM, i. e. Cœlifolium.

PURGANTIA. Purgative medicines. The firſt purge on record is Melampus's giving hellebore to the daughter of the king of Argos. *Purging medicines* are thoſe that facilitate, or increaſe the natural diſcharge of the alvine fæces. Thoſe which facilitate the natural diſcharge are called lenients, laxatives, or ſolutives, and by the Greeks eccoprotics; their action is from a fine ſaline ſtimulant quality, which is ſoon loſt in boiling. When theſe medicines increaſe the natural diſcharges, they are called *purgatives*, or cathartics, &c. They are of different degrees of ſtrength and action: the more rugged are called draſtic.

Eccoprotics are ſuch as give no diſturbance to the body, and expel but little from it; of this kind are ſoft oils, or they are ſuch as are now called lenitives, but by the ancients were called minoratives; they do not evacuate much fæces at once, but by degrees: of this ſort is the ol. ricini, which, whilſt it ſtimulates, it alſo lubricates, and its conſiſtence is ſuch as hinders its eaſy paſſage into the lacteals.

Draſtic purges act by a fine cauſtic inflammatory ſalt, which operates much in the ſame manner as poiſons do. The reſinous extracts of *purging* vegetables cauſe vomiting, convulſions, and death; and, on opening the ſtomach and bowels after their uſe, they are found inflamed, and marked with red ſpots, as when arſenic is taken.

For the milder kind of *purgatives*, we are indebted to the Arabians.

Eccoprotics ſhould be uſed in caſe of coſtiveneſs; when women are pregnant; and, in all very irritable habits, for in general *purges* are unfriendly to the ſtomach, and to thoſe whoſe nervous ſyſtem is ſubject to diſorderly motions. But in dropſies, and when there is a torpid ſtate of the inteſtinal fibres, draſtic purges are neceſſary; they ſhould be confined to the hydropic, lethargic, paralytic, apoplectic, and ſuch like.

Purgatives are excellent alteratives. In order to their uſefulneſs when given in this character, let ſuch a quantity as would ſuffice for a *purging* doſe, be divided into leſſer doſes; all which muſt be taken at proper periods, in the ſpace of twenty-four hours.

Diluting drinks are taken during the operation of *purging medicines*, to aſſiſt the increaſed ſecretion of the inteſtinal juice, in waſhing off the ſtimulus, alſo to ſoften the fæces. See Quinſey's Pharmaceutic Lectures, ſect. iii. and iv. Tournefort's Mat. Med.

PURGATORIUM. In Paracelſus it is a name for any diſeaſe.

PURPURA. The purple fiſh. It is found in the Mediterranean ſea. Its ſhell is ſtriated, furrowed, rough, ſtrong, and with ſhort tubercles. The juice of this fiſh, as well as that of many others, dyes linen of a *purple* colour, which fades not, though frequently waſhed.

PURPURA. A name for the miliary fever; alſo the ſpotted fever. The ſpots are ſymptomatic only.

PURPURA ALBA. A ſpecies of eruption to which men with a phlegmatic plethora are inclined.

PURPURA SCORBUTICA. It is the herpes of Vogel; the *purpura* of Hoffmann; and the true ſerpigo of ſome other writers. Hoffmann ſays, it is to be conſidered as entirely the progeny of a *ſcorbutic* diſpoſition. It is diſtinguiſhed by the eruption of exanthemata, of a very peculiar kind on the ſurface. Sometimes it is accompanied with an acute, and even a malignant fever; on other occaſions, it runs its courſe without fever, continuing for a greater length of time, and diſturbing the functions in a more gentle manner. In this diſeaſe, the ſmall papulæ which appear on the ſurface, are ſometimes of a red, ſometimes of a white colour. In the former caſe, there are veſicles more or leſs broad, containing a fluid; but the latter conſiſts of ſmall knots, fixed as it were deep in the ſkin; theſe are about the ſize and figure of millet ſeed, rough to the touch, and filled with a thick purulent matter. When the eruption firſt appears, it is attended with corrugation, roughneſs and dryneſs of the ſkin; none of the exanthemata are in their nature apt ſo ſuddenly to diſappear and return again. This return of the eruption is in general attended with a ſenſe of heat or coldneſs, of itching or pricking in the part; while other exanthemata appear on every part of the body, the *purpura* is chiefly obſervable on the neck, breaſt, back, and arms, very rarely affecting the inferior extremities.

To prevent this diſeaſe, it is recommended to avoid all kinds of malt liquors. Patients diſpoſed to it are adviſed to uſe for their common drink, either mineral water, or pure water, with a mixture of wine. Exerciſe, change of air, tranquility of mind, and amuſement, are of great ſervice in their prevention. Avoid all that produces coſtiveneſs, or that leſſens perſpiration. High ſeaſoned animal food, and pork, are to be avoided. Milk and whey are very ſerviceable. After the diſeaſe hath taken place, the patient ſhould ſleep in a large bed-chamber, of a moderate temperature. He ſhould ſhun great heat in bed, and not lie in it very long together: thus exceſſive ſweats, which aggravate the diſeaſe, are avoided; but though exceſſive ſweating is injurious, a moderate perſpiration is beneficial. The mineral anodyne liquor is here of ſingular efficacy. See Lewis's Tranſlation of Hoffmann.

PURPURATÆ, i. e. Petechialis febris.

PURULENTIA. Purulence, or ſuppuration.

PURPURA URTICATA. The acute nettle raſh.

PUS. Matter. The *matter* which appears on the ſurface of wounds that are healing; alſo what is met with on opening well digeſted abſceſſes, is called *pus*. It is unctuous, yelloviſh, nearly of the conſiſtence of freſh cream, without any particular ſmell, and of a mild taſte, which reſembles that of chyle. See Dr. Gaber's Experiments with reſpect to the Nature and Formation of *Pus*, in the Med. Muſeum, vol. iii. p. 269, &c.

When mucus is detained in the lungs for a time, and then ſpit up, it often reſembles *pus*; to diſtinguiſh rightly, if *pus* (or *matter*) is mixed with water, and ſlightly agitated with a whiſk, it is eaſily diffuſed, and after ſtanding a few hours falls to the bottom of the veſſel. Mucus is with difficulty diffuſed in water, requiring ſtrong agitation, and

then forms with it a permanent ropy fluid. When the *matter* ſpit up by conſumptive patients is agitated in water, it mixes without difficulty; and on ſtanding a ſhort time, a *matter* falls to the bottom, reſembling *pus*; and the fluid above remains ropy, reſembling the mucus and water.

PUSTULA. A puſtule, or little pimple, from *pus*, *corruption*. Theſe particularly appear in the ſpring, and are of various kinds; for ſometimes a certain roughneſs appears all over the body, reſembling that which is produced by the application of a nettle, or the obſtruction of ſweat, and are called by the Greeks exanthema. They are red and white, and of different ſizes. There are alſo *puſtules* of a black, livid, or any other colour; they are produced by cold, fire, or medicine, as the epynictis, &c. Celſus recommends, as the cure of all *puſtules*, a due proportion of exerciſe, and to leſſen the quantity of aliment.

PUSTULA ORIS. The thruſh. See APHTHÆ.

PUTREDO, vel Putrefactio. Putrefaction. *Putrefaction* is a ſpecies of fermentation, in which the phlogiſton and the fixed air of the putrefying ſubject, are ſeparated, and by which a diſſolution of the parts of the ſame body are not only effected, but a fetor is always induced in it. In order to *putrefaction* taking place, it is neceſſary that there ſhould be a degree of heat, moiſture, and of atmoſpheric air; but whenever a ſmall portion of matter is become putrid, it eaſily diffuſes itſelf through a large quantity, like as leaven does in paſte; this is in nothing more manifeſt than in the human body, wherein a ſmall portion of putrid matter being abſorbed, eaſily and ſoon contaminates the whole.

From *putrefaction* it is that the plague, the ſpotted fever, the true ſcurvy, and other diſorders of the like kind, take place. In all theſe diſorders the ſtrength is diminiſhed, and ſo is the vital heat. In general, if a recovery is within the power of medicine, the bark, acids, fixed air, warm perſpiratives, camphor, &c. are the moſt powerful antiputreſcents, and are the moſt ſucceſsful means for removing theſe diſorders.

On this ſubject, ſee the Appendix to Sir John Pringle's Obſervations on the Diſeaſes of the Army; Biſs's Eſſays; Macbride's Eſſays.

PUTRID FEVER. See SYNOCHUS. Under this general name may be included the plague, ſpotted or petechial fevers, peſtilential, malignant, camp, jail fever, &c. The more mild inſtances are of the typhus kind. Dr. Cullen obſerves, in the firſt volume of his Firſt Lines, that the ſynochus ſeems not ſo properly a genus, as a variety of typhus; that the typhus ſeems to be a genus comprehending ſeveral ſpecies, but that theſe are not well aſcertained by obſervation; and in the mean time we can perceive, that many of the different caſes obſerved do not imply any ſpecific difference, ſeeming to be merely varieties, ariſing from a different degree of power in the cauſe, from different circumſtances of the climate, or ſeaſon in which they happen, or from different circumſtances in the conſtitution of the perſons afflicted. One effect ariſing from theſe circumſtances is, a putreſcent ſtate of the fluids. From the diſſolved ſtate of the blood, as it appears when drawn out of the veins; or as it appears from the red blood's being diſpoſed to be effuſed, and run off by various outlets, and ſeveral other ſymptoms, we have no doubt that real *putreſcency* of the fluids takes place in *fevers*. This *putreſcency*, however, often attends intermittent, as well as continued *fevers*; and of the continued kind, both the ſynochus and typhus, and all of them in very different degrees, ſo that whatever attention it may require in practice, there is no fixing ſuch limits to it as to admit of eſtabliſhing a ſpecies under the title of *putrid*.

Theſe *fevers* are often inflammatory in their beginning, but they ſoon become *putrid*, and they are all of the continued kind. Indeed in ſome caſes, diſorders of a very oppoſite nature, by continuance, degenerate into putrid ones.

Thoſe who are weakly, who live poorly, and labour hard, the luxurious, thoſe who ſit up late, people of cold, of phlegmatic, or of irritable conſtitutions, the penſive, and thoſe who are oppreſſed with grief, are moſt ſubject to *putrid fevers*.

The ſame cauſes which produce the plague, if applied in a leſs degree, produce the other ſorts of *putrid fevers*. The remote cauſes are improper diet, and ſuch as are *putrid* when eaten; corrupted grain, as well as corrupted animal diet, is productive of *putrid* diſorders; a too free uſe of alkaline ſalts, and ſuch other medicines as diſſolve the blood; a moiſt ſouth wind long continued, eſpecially if much heat attends it; putrid effluvia; warm, calm, ſultry weather, with a moiſt atmoſphere. The proximate cauſe is a diſſolution of the blood, which is ſoon produced by *putrid* miaſmata, received either into the lungs by inſpiration, into the ſtomach with the food, or being generated in ſome part, is abſorbed, as from *putrid* ulcers, &c. According to the quantity of *putrid* matter received into the conſtitution, and the different parts which it firſt impreſſed, the ſymptoms excited will be ſomewhat various; if received from the atmoſphere by the lungs, as when *putrid* vapours are diffuſed in a country where theſe diſorders are epidemical, or in cloſe confined places, ſuch as ſhips, jails, &c. in this caſe nervous ſymptoms are firſt produced. If the ſtomach is firſt diſordered thereby, a ſickneſs, vomiting, or great anxiety, are brought on; when it enters into the blood by abſorption, the blood is at firſt diſſolved, then proceed heat, delirium, a diarrhœa, high coloured fetid urine, &c.

Putrid fevers attack with more violence than the nervous. And Dr. Huxham obſerves, that "the rigors are greater, the heats ſharper and more permanent, yet, at the firſt, they are ſudden, tranſient, and remitting; the pulſe is more tenſe and hard, though ſometimes quick and ſmall, and at others ſlow and regular, then fluttering and unequal." In the beginning it generally happens, that during the firſt twenty-four hours, the alternate heat and cold are conſiderable, and ſymptoms of ardency are attendant, but theſe ſoon vaniſh; the *fever* increaſes every evening, and in the ſecond week the patient becomes delirious, and the ſymptoms, which at firſt came on, increaſing, deſtroy the patient; or gradually decreaſing, about the end of the ſecond week, the delirium changes to a ſtupor, and other ſymptoms taking place, the patient, from the end of the ſecond, or the beginning of the third week, grows better; but in ſome caſes and under ſome kinds of management, the *putrid* ſymptoms increaſe from the ſecond week, both in their number and degree, and the patient ſinks under them. In the beginning, the head-ach and vomiting are violent; there is often a pain in the temples, or over the eyes, and in the bottom of the orbit; the eyes are full and heavy, yelloviſh, a little inflamed, then the countenance becomes bloated; the temporal arteries throb, though at the ſame time the pulſe at the wriſt is ſmall; there is a ringing in the ears, great dejection of ſpirits and faintneſs, reſpiration is difficult, mixed with ſighing, and the breath is hot and offenſive; pains are complained of in the loins and limbs, an univerſal wearineſs, and often a load at the ſtomach, attended with pain and heat there, alſo a naufea, and often a diſcharge of blackiſh or bilious matter. In the beginning the tongue is white, then grows drier and darker coloured: in ſome it is livid, in others black, or of a dark pomegranate colour. In the increaſe of the *fever*, the thirſt is the greateſt, but no liquor pleaſes; moſt things are mawkiſh and bitteriſh to the taſte, but often the ſenſe of thirſt is little or none during the whole of the diſeaſe; the lips and teeth are furred with a black tenacious ſordes; in the beginning the urine is pale and vapid, high coloured in the advance, and at laſt grows very brown and blackiſh, and hath more or leſs of an offenſive ſmell; the ſtools are blackiſh and very offenſive; they often run off inſenſibly; after profuſe evacuations by ſtool, the belly becomes ſwollen and tenſe; livid ſpots appear on the ſkin; hæmorrhages, and cold clammy ſweats appear in ſome inſtances on the fourth or fifth day, in others not till the eleventh, but generally they uſher in death.

Putrid fevers ſhould be diſtinguiſhed from thoſe of the ardent kind, the nervous and inflammatory, particularly from the peripneumony.

The vital heat, and the adheſion and quantity of the craſſamentum of the blood, mutually depend on each other; and as the *putrid* infection both diſſolves the craſſamentum, and repels the vital heat, from thoſe circumſtances, moſt, if not all the ſymptoms that are obſerved in *putrid* diſorders, may be accounted for, whether they attack the ſanguine or the ſerous habit.

The prognoſtics are generally very uncertain. A red raſh, or an inflamed ſcab below the noſe, or about the

lips, are favourable for the moſt part; deafneſs at the decline is generally eſteemed a promiſing ſymptom; but amongſt the unfavourable ones are, a change of voice, wild ſtaring eyes, difficulty of ſwallowing, inability to put out the tongue, a conſtant inclination to uncover the breaſt, urine that depoſits a dark or blackiſh ſediment, no thirſt, inflamed fauces, a diarrhœa with a ſwelled belly, bloody ſaliva, purple or livid ſpots on the ſkin, black aphthæ, laborious reſpiration, ichorous and fetid ſtools, cold ſweats, convulſions, &c.

The indications of cure are, to check the *putrefaction*, and to recal the vital heat. In order to which, the air in the patient's room, and the linen which is worn by the patient, ſhould be often changed; the ſtools and urine ſhould be immediately conveyed under ground, to prevent their diffuſing their morbid qualities in the air. Acid vapours may be diffuſed in the apartments of the ſick, or fumigations of myrrh and other aromatic and antiſeptic ingredients may be uſed. In the adminiſtration of medicines, the doſes ſhould be ſo repeated as to ſupport the heat of the patient in as equal a degree as is poſſible; the medicines and diet may be given in ſmall doſes, and proportionably frequent, and endeavour to ſupport the heat of the patient as near to that of health as may be.

The diet ſhould be acid or aceſcent. The drink ſhould be acidulated, and often mixed with red wine; whey made with muſtard is both agreeable to ſome and uſeful to moſt. The elixir of vitriol, or Ciutton's febrif. ſpt. may be uſed for acidulating what the patient drinks. Beef broth that is boiled long enough to extract the finer parts of the meat, is an excellent part of diet in theſe caſes; but it ſhould not be continued boiling until the groſſer parts of the meats are drawn out.

As to medicines, in many caſes, the bark and ſpirit of vitriol, accompanied with the julep of camphor, ſucceed without any other aids.

Bleeding is rarely, if ever, to be admitted of, for the *putrefaction* ſoon produces all that can be effected by it. Some bleed if the pulſe is quick and tenſe; the pain in the head and back is violent, the breathing difficult, and other ſymptoms of ſtrength appear; but, as the *putrid* miaſmata ſoon produce all that bleeding can effect, and as the greateſt point is to ſupport or to recover the vital heat, bleeding, as a leſſer ill, may probably be ſometimes admitted of, but much caution is required before the operation is determined on.

In general, an antimonial emetic ſhould begin the cure; or the pulv. ipec. may be given with the tart. emet. and a cordial draught, or a doſe of the julep. e camph. may immediately ſucceed its operation.

After the emetic and the ſucceeding draught have been taken, give frequent ſmall doſes of the vin. antim. or of the tart. emet. with proper antiſeptics and cordials. Neutral ſalts are generally hurtful, and even the ſp. Mindereri is better omitted.

The bark is a principal means of relief, and ſhould be given very early in the diſorder; at the lateſt it ſhould be begun with as ſoon as ſymptoms of inflammation or of ardency diſappear; and, if theſe do not attend, begin with it immediately after the operation of the emetic. The bark may be given in ſubſtance, in a cold infuſion with water, and in conjunction with ſaffron, ſnake-root, or other ſuch like medicines, according to the intention of the preſcriber.

Whilſt the pulſe is quick and full, bliſters are not adviſable; but generally they are uſeful in the early ſtages of theſe *fevers*, and if one is applied as a former one begins to dry, the advantage will be conſiderable in every ſtage. If a delirium approaches, the head or back may be bliſtered, as alſo if the patient is comatous. If in the earlier ſtage of a *putrid fever*, the patient is delirious, and other ſymptoms ſeem to forbid the uſe of bliſters, ſinapiſms may be applied to the feet.

Clyſters are convenient, both for carrying off *putrid* matter from the inteſtines, and for conveying antiputreſcents there. Though, for ſimply regulating the ſtools, perhaps a little tart. emet. and rhub. may be the moſt proper; and when any purging medicine is uſed for carrying off the contents of the bowels, the patient ſhould be ſupported during their operation with cordial liquors.

Camphor is both uſeful as an antiſpaſmodic and antiſeptic, but is moſt eminently ſerviceable in the beginning of the diſeaſe.

Amongſt the antiſeptics fixed air is found to be peculiarly uſeful, and may be commodiouſly adminiſtered in clyſters.

The vis vitæ muſt be carefully ſupported; the principal means of which are, acids, the bark, red wine, and a ſupine poſture.

If a diarrhœa comes on, give gentle opiates, ſuch as the ſpec. e ſcord. cum op. or the conf. Democrat. &c. Aſtringents are uſeful, but acids are the moſt ſo in theſe kinds of looſeneſſes, eſpecially if accompanied with perſpiratives.

If the petechiæ ſuddenly diſappear, a delirium will come on, and the pulſe ſink; in this caſe bliſter the head or the inſides of the thighs, or apply ſinapiſms to the feet. Bliſters remarkably relieve the nervous ſymptoms attendant on theſe diſorders.

However deſirable a general diaphoreſis may be, it ſhould never be forced by the uſe of medicines; to promote it, when there is the leaſt degree of tendency thereto, and to ſupport it when preſent, ſub-acid diluents, with cordials, may be freely uſed.

When petechiæ appear, give ſtrong red wine negus, well acidulated.

Sometimes a vomiting continues to afflict the patient, after having emptied the ſtomach by means of an emetic: if in this caſe the theriaca Andromach. given with the ſaline draught fail to relieve, apply a cataplaſm of the theriac Andromach. well charged with aromatic ſpices.

If a grain or two of the tart. emet. with a ſmall quantity of rhubarb is given, whenever a diſagreeable taſte is perceived in the mouth, or even without this indication, if it is repeated every two or three days, much putrid colluvies will be carried off, which would otherwiſe prove a pabulum to ſupport the violence of the diſorder.

See Huxham and Sir John Pringle on *Putrid Fevers*; Fordyce's Elements (part the 2d); An Enquiry into the Cauſes, Symptoms, and Cure of *Putrid Fevers*, by W. Fordyce, M D.

PYCNOTICA. Incraſſating medicines.

PYGÆ. The buttocks.

PYLORICA ARTERIA. It is a branch of the hepatic artery, which runs, and is ramified on the pylorus, and from thence to the cardia, and anaſtamoſes with the arteria gaſtrica dextra, and terminates on the pylorus by an anaſtomoſes with the coronary artery of the ſtomach.

PYLORICA VENA. It is a branch from the venæ portæ ventralis. Sometimes it is only a branch of the gaſtrica recta; it paſſes over the pylorus to the ſhort arch of the ſtomach, where it anaſtomoſes with the coronary vein thereof.

PYLORUS, from πυλη, *a door*, and ουρος, *to guard*. The word ſignifies a porter, and thus the Greeks called the right orifice of the ſtomach.

PYOSIS, i. e. Hypopyon.

PYRAMIDALE CORPUS. The ſpermatic cord.

PYRAMIDALES MUSCULI. The pyramidal muſcles of the belly, alſo called ſuccenturiati. They preſent themſelves next to the aſcending and deſcending oblique muſcles. They were firſt diſcovered by Fallopius. They are ſituated before the extremities of the recti, ariſing from the fore part of the os pubis, cloſe to the ſymphiſis. They grow ſmaller as they proceed; they end in a point, and are loſt in the linea alba. Their figure gives them their name. They pull down the linea alba. Fallopius called them ſuccenturiati, or auxiliary muſcles, from a ſuppoſition that they are only ſupplemental to the recti in their action, the order of their fibres in both agreeing; and theſe being always abſent when the recti are continued fleſhy to the juncture of the oſſa pubis.

PYRAMIDALIA CORPORA. A name of two protuberances from the medulla oblongata, and alſo a name for the ſpermatic veſſels.

PYRAMIDALIS NASI [Muſc.] It is alſo called recti and triangularis. One extremity is inſerted in the ſynarthroſis of the os frontis, and oſſa naſi; it runs down the ſide of the noſe, and is again inſerted into the cartilage there.

PYRE-

PYRETHRUM, from πυρ, *fire*, becauſe of the fiery heat of the root. It is alſo called buphthalmum Creticum. Pellitory of Spain. It is the anthemis *pyrethrum*, or anthemis caulibus ſimplicibus unifloris decumbentibus, foliis pinnato-multifidis, radice longe ſervida, flore bellidis, Linn. It is a trailing perennial plant, with finely divided leaves, like thoſe of fennel or chamomile, and naked thick ſtalks, bearing each a large flower, with a yellow diſk, ſurrounded with petals of a pure white colour on the upper ſide, and of a fine purple underneath. The root ſinks deep in the ground like a carrot, is of a browniſh colour on the outſide, and white within. It is a native of the warmer climes, and is brought to us from Italy, but bears the cold of our climate. It flowers from January to May. The roots which grow in England are larger than thoſe from abroad.

The roots are hot and pungent to the taſte, but have little or no ſmell. Its pungency is in its reſin, which is of a fixed kind. Water extracts but little of the reſin, ſpirit of wine takes up the whole of it. In diſtillation, neither water nor ſpirit takes up any thing with them. The watery extract is the moſt in quantity, but the ſpirituous contains moſt of the active parts.

It is chiefly uſed as a maſticatory. Dr. Lewis recommends a decoction of theſe roots with the tinct. ſacra in cliſters for the ſaturnine colic. It is not certain that the pellitory of the moderns is the ſame with that of the antients. See Newmann's Chem. Works; Lewis's Mat. Med.

PYREXIÆ, πυρετικες, from πυρετος, *febris* vel *fervis*. Febrile diſeaſes.

PYRIFORMIS MUSCULUS. It riſes from the lower part of the os ſacrum, where it is joined to the os ilium; it paſſes through the ſciatic notch, and is inſerted into inſide of the tip of the trochanter major, ſerving as a rotator, an extenſor, or an abductor, according to the direction of the thigh. It is called *pyriformis* from its figure, and iliacus externus from its ſituation.

PYRITES. Fire-ſtones. They are alſo called marchaſita. They are called *fire-ſtones*, becauſe they ſtrike fire with ſteel. By expoſing them to the air they become vitriolic; ſome are calcined, and then expoſed to the air. They vary much in their appearances, being of different colours, ſhapes, and internal ſtructure. In moſt parts they are found near the ſurface of the earth. They conſiſt chiefly of ſulphur, iron, and unmetallic earth; in ſome there is a little copper; in the yellow ſort there is much ſulphur; in the white there is but little.

When *pyrites* are expoſed to the air, the inflammable part of their ſulphur is diſſipated, the ſtones become powdery, and acquire a vitriolic taſte; the rain now falling on them, waſhes away the remaining acid of the ſulphurous contents, and veſſels are placed underneath to receive it; and from this the green vitriol is generally made.

Pyrites are not uſed medicinally in ſubſtance, but in Saxony they obtain the common ſulphur therefrom; artificial vitriols are prepared from them; and it is ſuppoſed that the chalybeate ſprings receive their impregnation from them. See Lewis's Mat. Med. Dict. of Chem. Neumann's Chem. Works.

PYRMONT WATER. It is one of the principal of the chalybeate kind.

PYROSIS. In Scotland this is called the water-braſh. Dr. Cullen places it as a genus of diſeaſe in the claſs neuroſes, and order ſpaſmi. This diſorder is named *pyroſis* ſuecica by Sauvages, but Linnæus calls it cardialgia ſputatoria. Dr. Cullen conſiders the *pyroſis* as an idiopathic diſeaſe, and ſeems to be the firſt who hath treated of it in a ſyſtem. He obſerves, that it is a diſeaſe frequent among people in lower life, but occurs alſo, though more rarely, in people of better condition. It appears (he ſays) moſt frequently in perſons under middle age, but ſeldom in any perſons before the age of puberty. When it has once taken place, it is ready to recur occaſionally for a long time after, but it ſeldom appears in perſons conſiderably advanced in life. It affects both ſexes, but more frequently the female; it ſometimes attacks pregnant women, and ſome women only when they are in that condition. Of other women, it more frequently affects the unmarried, and of the married, moſt frequently the barren; it frequently happens to women labouring under the fluor albus. The fits of this diſeaſe uſually come on in the morning and forenoon, when the ſtomach is empty. The firſt ſymptoms of it is a pain at the pit of the ſtomach, with a ſenſe of conſtriction, and as if the ſtomach was drawn towards the back; the pain is increaſed by raiſing the body into an erect poſture, and, therefore, the body is bended forward. This pain is often very ſevere; and after continuing for ſome time, it brings on an eructation of a thin watery fluid in conſiderable quantity: this fluid hath ſometimes an acid taſte, but very often is without this, and abſolutely inſipid. The eructation is for ſome time frequently repeated, and does not immediately give relief to the pain which preceded it, but does ſo at length, and puts an end to the fit. The fits come on without any evident exciting cauſe; they attack perſons uſing animal food, but more frequently thoſe who live on milk and farinacea. Cold applied to the lower extremities ſeems often to be an exciting cauſe, and ſo is every conſiderable emotion of mind. The doctor goes on to obſerve, that the nature of this affection is not very obvious, but he thinks it may be explained as follows: it ſeems to begin by a ſpaſm of the muſcular fibres of the ſtomach, which is afterwards, in a certain manner, communicated to the blood-veſſels and exhalents, ſo as to increaſe the impetus of the fluids in the veſſels, while a conſtriction takes place on their extremities. The increaſed impetus pours out a larger quantity of fluid than uſual, while the conſtriction upon their extremities allows only the pure watery parts to be poured out, analogous, as I judge, in every reſpect to what happens in the diabetes hyſtericus. As to the cure, little can be done. Opium relieves the paroxyſm. The vitriolic æther, volatile alkali, &c. are ſometimes of ſervice. Linnæus ſpeaks of the nux vomica being uſeful, but to prevent the returns of this diſorder is not eaſy. See Cullen's Firſt Lines, vol. iii.

PYROSIS. It is the name of a diſeaſe in the ear, which affects the patient as if a heat was excited there by a burning coal.

PYROTECHNIA, from πυρ, *fire*, and τεχνη, *art*. Chemiſtry.

PYRUS. The pear-tree. The tree and fruit are ſufficiently known not to need any deſcription. From pears the liquor called perry is obtained by expreſſion.

PYULCON, from πυον, *pus*, and ελκω, *to draw*. An inſtrument to fetch out the matter from the cavity of the breaſt, or any ſinuous ulcer.

PYURIA. The ſame as Dyſuria mucoſa.

PYURIA ARTHRITICA. The ſame as dyſuria mucoſa.

PYURIA VISCIDA. The ſame as dyſuria mucoſa.

PYURIA MUCOSA. The ſame as dyſuria mucoſa.

Q.

QUADRAGESIMUS DIES. The fortieth day. The antients fixed on this day as the laſt to which acute diſtempers could extend, calling all thoſe chronical which continued longer. But Dr. James obſerves, that he hath ſeen an acute diſeaſe which continued ſixty days

QUADRANS. A three ounce meaſure was formerly thus named

QUADRATI MUSCULI. Four-ſquared muſcles. See OCCIPITALIS MUSCULUS.

QUADRATUS FEMORIS. This muſcle riſes from the outſide of the tuberoſity of the iſchium, and it is inſerted into the line between the trochanter major and minor, ſerving to rotate the thigh.

QUADRATUS GENÆ, i. e. Platyſma myoides.

QUADRATUS LUMBORUM. This muſcle riſes from the ſpine of the ilium, whence it goes to the tranſverſe proceſſes of the four upper lumbar vertebræ, and partly from theſe tranſverſe proceſſes, which part goes to the laſt rib. This muſcle lies between the contained parts of the belly, and the erectors of the back, and ſerve to pull the body to one ſide, by bringing the laſt rib down. This muſcle is alſo called quadrigeminus, and lumbaris externus; underneath it a troubleſome abſceſs is ſometimes formed. See ABSCESS of the LOINS.

QUADRIFOLIUM. A name for the trifolium, *quadrifolium*, hortenſe album.

QUADRIGA, alſo Cataphracta. A bandage for the ſternum and ribs. It is twenty-four feet long, three or four fingers broad, with two heads; it binds upon the thorax and ſternum more firmly when the ribs are fractured. The middle is placed on one ſide of the body; the two heads are carried ſo as to interſect on the oppoſite ſhoulder; they are brought back to where they begin, and then paſs circularly round the body.

QUADRIGEMINI. A name for the following four muſcles taken together, viz. pyriformis, gemellus ſuperior, gemellus inferior, and the quadratus femoris.

QUADRIGEMINUS, i. e. Quadratus lumborum.

QUARTANA CONTINUA. Continued quartan. The paroxyſm returns every fourth day, after previous pandiculations and horripilations, but does not very exactly obſerve its period; nor when the paroxyſm abates does it totally intermit, but is only milder on the intermediate days than in that in which the paroxyſm happens. The heat is alſo preternaturally intenſe, the pulſe increaſed, the appetite languid, the ſtrength low, the mouth dry, the head giddy, the ſleep reſtleſs, the urine red, thick, and with a high coloured ſediment.

QUARTANA DUPLEX. A double quartan. It is when within four days two ſucceeding paroxyſms happen, in ſuch a manner, that each preſerves its proper type, and peculiar time of acceſſion, alternately correſponding to the preceding paroxyſm, and the third day only being totally free from the fever.

QUARTANA FEBRIS. An ague, or quartan fever. It hath two fits in four days, or two days free from the fit, ſo on the firſt and the fourth the fever attends, and on the ſecond and third it is free; the acceſſion of the fit is in the afternoon. Dr. Cullen places this genus of diſeaſe in the claſs pyrexiæ, and order febres. It is uſually both more violent and obſtinate than a tertian. Sometimes a *quartan fever* is double, that is, when the fits come on every other time at different hours, and ſo that the third day only is free from *fever*. It is called ſpurious when the fit begins at any other time of the day than about four or five o'clock in the evening.

The fits return with greater regularity generally than is obſerved in other ſpecies of *fevers*.

The cure is as related for intermitting fevers.

QUARTANA LEGITIMA. The ſame as quartana. It obſerves its periods in its proper returns, which is in the afternoon, more exactly than in any other ſpecies of fevers.

QUARTANA SPURIA. Spurious Quartan. It hath no certain period for its returns, which, however, is in the forenoon generally; the heat alſo is greater, and affects the patient more than the cold fit does.

QUARTARIUS. A meaſure which contains about four ounces.

QUARTATIO. Quartation. It is an operation in chemiſtry, by which the quantity of one thing is made equal to a fourth part of the quantity of another thing. Thus when gold, allayed with ſilver, is to be parted, we are obliged to facilitate the action of the aqua fortis by reducing the quantity of the former of theſe metals to one fourth part of the whole maſs, which is done by ſufficiently encreaſing the quantity of the ſilver, if it be neceſſary. Some extend this name to the operation of parting.

QUARTURA, i. e. Quartatio.

QUARTZ. It is a hard vitrifiable ſtone, called alſo quartzoſe ſtone. It is found both with ores and without them. According to Cronſtedt, it always forms hexagonal priſms, pointed at one, or both ends, when there has been no interruption to its cryſtallization; and this cryſtallized *quartz* is rock cryſtal, which, like the uncryſtallized *quartz*, is colourleſs or coloured, tranſparent or opake. See Dict. of Chemiſtry, edit. 2. In Foſſilogy, the *quartzoſe ſtone* is an order in the claſs of ſtones; the characters of this order are, that it is a foſſil body, ſtriking fire with ſteel, and either tranſparent or figured, and of a ſolid ſtructure.

Of the tranſparent *quartz*, called *quartzoſe* cryſtal, are the various precious ſtones, as the diamond, ruby, &c.

According to Mr. Edwards, the characters of *quartzoſe* cryſtal are, that it is a *quartzoſe ſtone*, which is well diſtinguiſhed from the other foſſil bodies of the order of *quartz*, being never properly inveſted with an outward cruſt, clearer than flint and agate, frequently figured; agate and flint never or ſeldom having proper figures; not breaking in ringlets like flint, and wanting the delicate appearance of agate, and being by the character of the order diſtinguiſhed from all other foſſil bodies.

Different ſorts of *quartzoſe* cryſtal frequently are called precious ſtones; the reaſon for this diſtinction being chiefly on account of their beauty and hardneſs, for they have great luſtre; and many of them are ſo hard, that they cannot be touched by the file, yet, upon this or any other diſtinction, to conſider precious ſtones as different bodies from *quartzoſe* cryſtal, and to arrange them accordingly, is contrary to nature, and all the laws of arrangement. *Quartzoſe* cryſtal, poſſeſſing an eminent degree of beauty and hardneſs, is called ruby, when it hath a fine red colour, and preſerves it in the fire; ſaphire, when it hath a bright blue colour; topaz, when it has a beautiful golden yellow colour; emerald, when it hath a fine green colour; chryſolite, when it hath a duſky green colour, with a caſt of yellow; amethyſt, when it hath a violet colour; garnet, when it hath a deep red colour; hyacinth, when it hath rather a deep red colour, approaching to a flame colour; beryl, or aqua marina, when it hath a ſea or bluiſh green colour. The *quartzoſe* cryſtal, which is ſuperior to all other precious ſtones in its pellucidity, luſtre, beauty, and hardneſs, and which attracts its foil, is called diamond, and is of various colours. See Elements of Foſſilogy. The precious ſtones (ſee GEMMA) have been extolled in medicine, but their abſolute inſolubility in the human ſtomach renders them incapable of uſefulneſs, and the preſent practice rejects them.

QUASSI LIGNUM. Quaſſi wood. This wood is ſo called from a negro who was named Quaſſi; he lived at Surinam,

Surinam, and uſed it medicinally. He had great ſucceſs by giving it in fevers of the intermittent, malignant, and putrid kinds. It is the *quaſſia* amara, or the *quaſſia* floribus hermaphroditis, foliis imparipinnatis, foliolis oppoſitis ſeſſilibus, petiolo articulato alato, floribus racemoſis, Linn. The wood hath no ſmell, is very bitter, and ſtronger and more concentrated than that of any one medicament yet known; it is totally void of ſtypticity. As a bitter, it may be uſed as is common with bitters in general; it may be given in the form of pills, powders, or infuſion. *Quaſſi* made a tincture with it in brandy, but an infuſion of it in boiling water ſeems to be the beſt preparation. A dram may be infuſed in a pint of boiling water, and an ounce may be given for one doſe. When the bark could not be taken, in the intermiſſion of fevers, the *quaſſi* with an equal quantity of rad. ſerpent. V. infuſed in boiling water, anſwered every end that was expected from the bark; it allayed vomiting, and appeared powerfully to reſiſt putrefaction.

QUATRIO. The aſtragalus.

QUERCERA, i. e. Epialos.

QUERCUS. The oak tree. It is the *quercus* robur, or *quercus* foliis deciduis oblongis ſuperne latioribus, ſinubus acutioribus, angulis obtuſis, Linn. The common Engliſh oak tree. It is a common foreſt tree, and is known in all parts of Europe. The bark is a ſtrong aſtringent, moderately bitter, having no particular ſmell; with a ferruginous ſolution it ſtrikes an inky blackneſs. It hath been uſed with ſucceſs in intermitting fevers, and in gleeting gangrenous wounds and ulcers, in which caſes, ſome ſay, its extract is as good as the extract of the bark. Both water, and rectified ſpirit, take up its virtues. The bark is more uſed for tanning, than as a medicine.

QUERCUS MARINA. See KALI.

QUIETALES. Diſeaſes in which the voluntary and involuntary motions, and the ſenſes are diminiſhed.

QUINA QUINA. The Peruvian bark.

QUINCUNX, a five ounce meaſure.

QUINQUEFOLIUM, alſo called pentaphyllon. Common cinquefoil, five-fingers, or five-leaved graſs. It is a trailing plant, with ſerrated leaves, ſet five together, on long pedicles. It is perennial, grows wild on clayey grounds, and flowers in June. The roots are aſtringent, they give out their virtue to water and to ſpirit. The leaves are of the ſame nature as the roots. See Raii Hiſt.

QUINQUEFOLIUM. A name for a ſpecies of tormentilla, of a ſpecies of argentina, and a ſpecies of ſinapiſtrum.

QUINQUINA. The Peruvian bark.

QUINQUE NERVIA, i. e. Plantago.

QUINTA ESSENTIA. Quinteſſences. They are made by adding to any eſſential oil twelve times its quantity of pure alcohol of wine, and ſhaking them ſo together, that the oil may not appear. If theſe are diſtilled in a cloſe veſſel, with a fire of 90 deg. by Farenh. therm. the alcohol will riſe with only the preſiding ſpirit of the oil; and if with care the thinner part is ſeveral times ſeparated from the thicker, by repeated gentle cohobation, the alcohol will at length be ſo impregnated with thoſe oily ſpirits, as to appear to be almoſt pure ſpirit itſelf, leaving a groſs exhauſted oil behind.

Dry *quinteſſences* are made by diſſolving an aromatic oil in alcohol of wine, then adding to them ten times their weight of ſugar finely powdered, then placing them in a proper place and veſſel for exhaling the ſpirit from the ſugar, but preſerving it from being loſt. Thus the ſugar will remain dry, but with the virtues of the aromatic oil in it. ℈ i. in a glaſs of wine is a good cordial.

QUINTANA. An ague, the paroxyſm of which returneth every fifth day; the ſecond, third, and fourth are free from fever.

QUISQUILIUM. A grain of chermes.

QUOTIDIANA CONTINUA. The continued quotidian of Vogel, is the continued quartan of Cullen.

QUOTIDIANA FEBRIS. A quotidian fever. It intermits, but returns every day, and that generally early in the morning: when the fit approaches at any other time of the day, it is called ſpurious or anomalous. Dr. Cullen places this genus of diſeaſe in the claſs pyrexiæ, and order febres. The blood is more denſe in this ſpecies of intermittents than of any other. For the general method of cure, ſee INTERMITTENT FEVER.

QUOTIDIANA SOPOROSA, i. e. Tertiana Carotica.

R.

RABDOIDES. See RHABDOIDES.

RABIES, i. e. Hydrophobia. When from the bite of a mad dog, the patient hath a deſire of biting, the canine madneſs is called *rabies*.

RACEMUS. A cluſter, ſuch as a bunch of grapes, or of ivy berries, or other fruit which grows in cluſters; or rather a ſtalk divided into ſeveral branches, ſuſtaining each a flower or fruit, ſet thick together, as is ſeen in grapes, &c.

RACHIALGIA, i. e. Colic, particularly the colica Pictonum.

RACHIALGIA PICTONUM, i. e. Colica Pictonum.

RACHIALGIA METALLICA, i. e. Colica Pictonum.

RACHIALGIA ab ADIAPNEUSTIA, i. e. Colica Pictonum.

RACHIALGIA TRAUMATICA, i. e. Colica Pictonum.

RACHITÆ, or Rachiæi. The muſcles belonging to the back.

RACHITIS, ſo Dr. Gliſſon called it, from ῥαχις, *the ſpine of the back*, becauſe he ſuppoſes a fault in the ſpinal marrow produces it. The rickets. This diſorder is alſo called cyrtonoſus. In ſome countries it is called the Engliſh diſeaſe, though it is much more frequent elſewhere: it did not appear in England until about the middle of the ſeventeenth century, from whence it is ſaid to have ſpread all over Europe, and whence it obtained the name of Engliſh. Dr. Gliſſon ſays, that it was firſt obſerved in the Weſt of England, in the counties of Dorſet and Somerſet, betwixt the years 1600 and 1620, and that afterwards it ſpread.

It is a chronical diſeaſe, and a ſpecies of cachexy. Dr. Cullen places this genus of diſeaſe in the claſs cachexiæ, and the order intumeſcentiæ. He diſtinguiſhes two varieties. 1. *Rachitis* ſimplex; when there is no other diſeaſe. 2. *Rachitis* cum aliis morbis conjuncta. The whole habit is affected, but more particularly the heads of the bones or joints, with their ligaments and cartilages; and alſo the whole cranium. Bodies that have been diſſected after the death of ricketty patients, were found to have pale and flaccid muſcles, ſwelled lungs, enlarged livers, indurated meſenteric glands, ſpongy bones, the nodes on them were ſoft, and the marrow within them like bloody

ſerum. Some obſerve, that the top of the ſpinal marrow is uncommonly hard and obſtructed, that water is lodged between the dura and pia mater, and that the brain is large.

Uſually the ſubjects are children from ſix months to ſix years of age, though ſometimes its attack is not before the ſixth year, or even after. Mr. Bromfield gives an inſtance of a woman being afflicted with, and at length dying under this diſorder. See his Chirurg. Obſ. vol. ii. c. 2 Children who cut their teeth late are diſpoſed to this complaint.

The remote cauſes are, whatever hinders digeſtion, generates a viſcid chyle, or in general leſſens the vis vitæ. A cold moiſt atmoſphere diſpoſes to the *rickets*, whence the greater frequency thereof in marſhy countries. In Holland, and at Halle in Saxony, this diſorder prevails very much, on account of their atmoſphere being filled with moiſt and otherways unſalutary exhalations. Bad nurſing, a too acefcent diet, &c. are alſo cauſes of this kind. The immediate cauſes are, ſuch an indiſpoſition of the ſpinal marrow as prevents a due paſſage of the vital heat along it, whence all thoſe parts which receive nerves therefrom are but poorly nouriſhed; whilſt a redundance of this neceſſary principle is conveyed to the head, whence its extraordinary increaſe, and the florid complexion uſually obſerved in patients thus afflicted; and, as Dr. Hunter obſerves, a deficiency of the oſſeous or of the earthy matter of the bones.

The chief differences in this diſorder are from the greater or leſſer number of the following ſymptoms being attendant in one and the ſame patient; and from the different degrees of their violence. Uſually the firſt appearance of this kind is in the eighth or ninth month of the child's age; by degrees ſeveral parts of the body become diſproportioned, the ſkin grows lax, the belly becomes flaccid, the muſcles wear away, particularly thoſe of the neck, the joints of the hands, arms, knees, and feet grow large, ſo that there ſeems to be excreſcencies on the bones of the wriſts and ankles; the bones at length are too weak to ſupport the body, and, as well as the ſpine, they grow crooked; the child walks with more and more difficulty, until it entirely loſes the uſe of its feet; the carotids and jugulars ſwell, but the other blood-veſſels ſeem leſs: the head grows large; the ſutures are viſible; the fontanel is often membranous; the neck is too weak to ſupport the head ſteadily; the countenance is lively; the child is more ſenſible than is common to children of the ſame age; the breaſt is ſtrait, and compreſſed on its ſide. The ſternum riſes up ſharp, and in a point, and the extremities of the ribs are knotty; the diſeaſe at length increaſing, a fever comes on, which is followed by a cough, a difficulty of breathing, and other ſymptoms which continue during life; the wriſts are knotty and diſtorted, ſo are the ankles; the ribs protuberate and grow crooked; the hypochondres ſwell; other ſymptoms reſembling the conſumption come on, and at length deſtroy the patient. Children who are old enough to walk go tottering and waddling along; but they like beſt to ſit ſtill, and as their diſorder increaſes, they would always lay down; the teeth come forward very ſlowly, and with much uneaſineſs, ſoon decay and fall out: and it is remarkable that moſt of this time the appetite fails not, nor does the patient ſeem to digeſt with difficulty what he eats.

The *rickets* do not often prove fatal; but when an hectic fever, conſumptive ſymptoms, or an aſthma, &c. ſucceed, the patient is carried off by them. If the diſorder continues after the fifth year of the child's age, it proves difficult of cure, and the body uſually continues weakly and deformed for ſome years after. When a faulty air or a bad diet are the cauſe, or if it is ſucceeded by the ſmall-pox, the itch, or other cutaneous eruptions, and is not accompanied with conſiderable incurvation of the bones, and inability to motion, the cure is not very difficult. The bones of the legs, though very crooked, will become nearly and often quite ſtraight during the growth of the child, if it becomes ſtrong and healthy.

The intentions of cure are, to diſſolve the viſcidity of the juices, open obſtructions, and promote a free circulation, and then to increaſe the vital heat and ſtrengthen the ſolids.

The diet ſhould be light, cordial, and nutritious; be of broth, in which cray-fiſhes are boiled, is excellent, or beef broth alone; ſpiced meats are uſeful; rice with wine and a little cinnamon mixed with it will be a proper change. The air ſhould be dry and warm; exerciſe, according to the ability of the child, ſhould be regular, gentle, and frequent. To keep the child dry and clean conduces much to relief.

Gentle emetics and lenient purges ſhould begin the cure, particularly the tinct. ſacr. and tinct. rhab. mixed in equal parts; theſe may be repeated two or three times: or equal parts of calomel and rhubarb may be given, and repeated to as not to ſalivate: after theſe, when the children's bellies are ſwelled, give pills of the gall of eels, or pikes as deobſtruents; or, if the patient is emaciated, or the viſcera are not ſound, ſaponaceous medicines ſhould be given, particularly the ſal diureticus.

Liniments may be uſeful both by their efficacy as medicines, and by the friction uſed in the proper application of them. R ol. Palmæ ʒ ii. balſ. Peruv. and ſp. ſal. ammon. āā ʒ ii. ol. n. m. per expr. ʒ i. ol. carioph. & ſuccin. āā gut, xxm. with this or even with ſp. vini. c. let the ſpine and any of the affected joints be rubbed twice a day. If before the uſe of the liniment, &c. the parts are rubbed before the fire with a large flannel cloth, their efficacy will be more increaſed. Dry frictions alone are peculiarly uſeful.

If on trial cold bathing is found to excite a glowing warmth, it may be continued with advantage; if on the firſt uſing the cold bath the child ſhivers, put it between blankets until it grows warm or ſweats a little; afterwards uſe warm water, and gradually proceed to the uſe of colder.

To warm the conſtitution and ſtrengthen it, nothing excels the cort. Peruv. and flor. mart. The firſt may be given in powder, or in the form of an infuſion, and the latter alſo may be given in ſubſtance or tincture. Inſtead of theſe the unruſted fine filings of iron may be mixed with mild aromatics, and waſhed down with any bitter infuſion. Dr. Zaviani gives the flor. mart. gr. v. more or leſs, every day for two weeks, interpoſing the pulv. rhab. gr. v. once in four or five days; he then omits the medicines during two weeks, after which he repeats them as before. But if the patient is feveriſh, give him the infuſ. cort. Peru. cum elix. vitr. inſtead of the iron or any of its preparations.

The ſal tart. is highly extolled in this diſeaſe. In the fourth vol. of the Edinb. Med. Comm. is the following account of its efficacy: A boy of ſeven years old, who laboured under *rickets* to a great degree; his inferior extremities were become ſtiff and immoveable; the abdomen flaccid; he was emaciated with a diarrhœa and conſtant ſweatings, and had five fiſtulous ulcers all running at the ſame time. The following was preſcribed: R decoct. cort. Peruv. ℥ viii. ſalis tartari ʒ ſs. m. Half of this mixture was taken every day. In the courſe of one month, the patient was ſo far recovered as to be able to riſe from his bed, and to walk with ſome ſupport. At that time the bark was changed for the rubia tinctorum; and in leſs than four months, the boy was ſo recovered as to walk with a crutch, and the ulcers by that time were nearly healed. Many *ricketty* people have been cured by a watery ſolution of the ſalt of tartar, without any other means being uſed.

The oſmunda regalis, or flowering fern, if given in decoction, powder, or extract, is recommended as of great efficacy in this diſorder.

A glaſs of claret, with a morſel of bread ſhould be given to the child, an hour before dinner every day, and again in the evening.

See Boerhaave's Aphoriſms; F. Hoffmann's Oper. tom. iii. p. 487, &c. Swan's Tranſlation of Sydenham's Works, ſecond edit. p. 64, 65, 384, 604, note k. Med. Muſ. vol. i. p. 66, 71. Shaw's Practice of Phyſic. Zaviani's Treatiſe on the *Rickets*. Petit's Diſeaſes of the Bones.

RACHOSIS. Excoriation of the relaxed ſcrotum.

RADIÆUS MUSCULUS, i. e. Radialis.

RADIÆUS EXTERNUS, i. e. Extenſor Carpi Radialis.

RADIALIS ARTERIA. It is a branch of the humeral artery. It runs down the ſide of the radius, covered by the ſupinator longus; at the wriſt it divides into two, one

one of which paſſing over the palm of the hand, is loſt in the fleſhy part of the thumb; the other paſſes on, and between the metacarpel bone of the fore-finger, and the firſt bone of the thumb, plunges into the palm, and forms a ſort of arch there. In its courſe, it ſends off branches which run on both ſides of the hand, communicate with the cubital branches, and is loſt among the metacarpal bones.

RADIALIS MUSCULUS. See the extenſor and the flexor muſcles.

RADIALIS. The nerve ſo called. See CERVICALES.

RADIALIS EXTERNA [VENA.] When the cephalica hath reached the bend of the arm, it divides into two principal branches, one is called the *radialis externa*; it ſpreads about, and along the fore-arm.

RADIALIS INTERNA VENA. It is a long branch from the mediana cephalica.

RADICULA. A name for the raphanus.

RADIUS. Radius, a ſtaff or beam. It is one of the bones of the fore-arm, which is ſo called from the reſemblance it bears to the ſpoke of a wheel. Its upper extremity is formed into a ſmall circular head, which is hollowed for an articulation by arthrodia, with the tubercle of the os humeri at the ſide of the trochlea; and the half of the round circumference of the head, next to the ulna is ſmooth, to be received into the ſemilunated cavity of that bone. The lower extremity of the *radius* is much larger than the ſuperior; it is flattened before, and grooved backwards by the tendons of the muſcles. The extremity of the *radius* is hollowed for the reception of the bones of the wriſt. The reaſon why the fibres of the interoſſeus ligament run obliquely upwards from the ulna to the *radius* is, that as this laſt is very ſlightly articulated to the os humeri, in a fall the force of it would be communicated to its upper extremity, and eaſily diſlocate it if this ligament was not to take off the force of the fall.

RADIX. A root. It is that part of a plant by which it naturally receives its nouriſhment. Some roots are fleſhy, others are fibrous, and others again are woody.

Roots are divided into different ſpecies. Linnæus divides them into fibrous, bulbous, and tuberous, which are again ſubdivided by other diſtinctions, the chief of which are the following:

RADIX ASPHODELI. Aſphodel root. It is that which is compoſed of ſeveral oblong fleſhy knobs. Of this kind are the king's-ſpear, and the day-lily.

RADIX BULBOSA. The bulbous root. It is that which conſiſts of ſeveral coats, involving one another, or of ſeveral ſcales lying one over another. The firſt of theſe is called a tunicated root. Of this ſort are onions, &c. The laſt is called a ſquamous, or ſcaly root. Of this ſort are the lily, &c.

RADIX FIBROSA. A fibrous root. It is one which conſiſts only of ſmall fibres like hairs. Of this ſort, ſee GRASS and CORN.

RADIX GRANULOSA. A granulous root. It is a kind of granulous root, conſiſting of many ſmall fleſhy knobs, which reſemble grains of corn. Of this kind is the white ſaxifrage.

RADIX GRUMOSA. A grumous root. It is one which conſiſts in many oblong fleſhy knobs, joined to one centre at the top. Of this ſort is the ranunculus.

RADIX PALMATA. A handed root. It is a tuberous root, divided, as it were, into ſeveral fingers, ſo as to reſemble a hand. Of this ſort is the handed orchis.

RADIX TESTICULATA. A teſticulated root. It is a double tuberous *root*, for it conſiſts of two knobs, reſembling a pair of teſticles. Of this ſort are ſome of the orchis ſpecies.

RADIX TUBEROSA. A tuberous root. It conſiſts of an uniform fleſhy ſubſtance, and is generally roundiſh. Of this kind is the ſow-bread.

RAIS DI JUAN LOPEZ LUSITANIS. It is the radix Indica Lopeziana, Pharm. Edinb. Radix Indica, a Joanne Lopez, denominata Gaubii Adverſar. cap. vi. The root of an unknown tree, growing, as ſome ſay, at Goa, others ſuppoſe in Malacca, from whence it is ſometimes brought to Batavia. It is met with in pieces of different thickneſs, ſome, at leaſt, of two inches diameter. The woody part is whitiſh and very light; ſofter, more ſpongy, and whiter next the bark, including a denſer, ſomewhat reddiſh medullary part. The bark is rough, wrinkled, brown, ſoft, and as it were woolly, pretty thick, covered with a thin, paler cuticle; neither the woody nor cortical part hath any remarkable ſmell or taſte, nor any appearance of reſinous matter. On boiling in water, no odour is emitted, and the ſtrained liquor, which is of a yellow hue, is almoſt inſipid, only impreſſing the tongue with a very light, obſcure bitteriſhneſs, and without viſcidity. The extract obtained by evaporating the decoction, is equally void of ſenſible activity. Rectified ſpirit is tinged by the *root* of a brown colour, but acquires no particular taſte. After drawing off the ſpirit from the tincture, a matter remains reſembling balſam, which bubbles and inflames in the fire, and has a bitteriſh taſte, like that of opium.

This *root* is regarded in the Eaſt Indies as a medicine of extraordinary efficacy in diarrhœas. Gaubius, in his Adverſaria, ſtates ſome experiments made with it, which, in ſome degree, confirm its reputation; it appeared remarkably effectual in abating colliquative diarrhœas, which had reſiſted the uſual remedies, and thoſe attending the laſt ſtage of conſumptions were particularly relieved by its uſe. It ſeems not to act by an aſtringent power, but by a faculty of reſtraining and appeaſing ſpaſmodic and inordinate motions in the inteſtines. Gaubius compares its action to that of ſimarouba, but thinks it more efficacious than this medicine. The powder is given with any proper vehicle, in doſes from fifteen to thirty grains, repeated three or four times a day. A tincture made with common ſpirit is ſaid to be equally effectual with the *root*; of this tincture the doſe was a tea-ſpoonful three times a day. Lewis's Mat. Med. edit. 3.

RAMALIS VENA. The vena portæ.

RAMEX. An hernia.

RAMEX VARICOSUS, i. e. Hernia varicoſa.

RAMUS. A branch. It is the diviſion of a ſtalk, or a tree; it is called a bough.

RAMUS INFERIOR. A name of the third maxillary branch of the nerves, which proceed from the fifth pair.

RAMUS SUPERIOR, i. e. Frontalis nervus.

RANA. The frog, or paddock. The ſpawn of *frogs* was formerly uſed for cooling, but now it is wholly neglected.

RANINÆ ARTERIÆ & VENÆ, vel RANULÆ. See SUBLINGUALIS. Quia nigræ ſunt inſtar ranularum.

RANULA. The name of a tumor which is ſeated under the tongue; it hath been brought to reſemble a little frog, whence the name of *ranula*; though ſome ſay that it is thus named, becauſe it alters the voice of the patient, ſo as to make him croak like a frog. This tumor is formed in the ſalivary glands under the tongue, and is ſeated on either ſide of the frænum; it is generally of the ſcrofulous kind. The matter varies much in different inſtances of this diſorder, being ſometimes like the white of an egg, at others it is more ſolid; in ſome inſtances it is purulent, in others it differs from all theſe. It ſometimes grows ſuddenly, impedes both the ſpeech and ſwallowing, and alſo cauſes much pain; but generally its growth is more gradual, and its effects not ſo violent. Inſtances have occurred of their having degenerated into cancers. They are all of the encyſted kind, and are with great difficulty either diſperſed or brought to ſuppuration, generally requiring the knife for their removal. If a tumor of this kind is ſeated where the ſalival ducts enter into the mouth, inciſions muſt never be attempted, becauſe of the danger of wounding theſe ducts, with the nerves or blood-veſſels; in this caſe wait until nature opens a paſſage for the contents: if it is ſeated on either ſide, great care is required, leſt the nerves or the bloody-veſſels there, ſhould be injured: however, in ſuch caſes, hold up the tongue of the patient, and make an inciſion tranſverſely into the tumor, the matter being diſcharged, dreſs with the honey of roſes acidulated with the ſpirit of vitriol, that the cyſt may alſo be deſtroyed. See Heiſter's Surgery.

RANUNCULUS. Crowfoot. It is a plant with pentapetalous flowers, that are alſo roſaceous; they are ſet in five-leaved cups; they are followed each by a round cluſter of naked ſeeds, and are perennial. Boerhaave enumerates ſixty-nine ſpecies, ſome of which are inert, and others are very cauſtic.

RANUNCULUS BULBOSUS, called alſo ranunculus tuberoſus major, round-rooted, or bulbous crowfoot. It hath a round tuberous root, the ſize of an olive; the leaves are divided commonly into three ſegments, and theſe are further ſubdivided; the ſtalks are erect; the flowers are of a bright gloſſy yellow, their cups turned downwards. It is common in paſture grounds, and flowers in May. This is one of the cauſtic ſpecies.

RANUNCULUS LONGIFOLIUS PALUSTRIS MINOR, called alſo flammula, ſpearwort, or ſmaller water crowfoot, with fibrous roots, long, narrow leaves, acuminated at both ends, and leaning on procumbent ſtalks; it grows in watery places, or moiſt meadows, and flowers in June. The roots and leaves have no ſmell, but have an acrid fiery taſte. Taken internally, they appear to be deleterious, even when ſo far freed from the cauſtic matter by boiling in water as to diſcover no ill quality to the palate. The effluvia of the leſs acrid ſpecies, or varieties, cultivated in gardens, when freely inſpired, have occaſioned head-achs, anxieties, vomitings, and ſpaſms. The leaves applied externally bliſter the part, the roots do ſo too, and as ſuch have been uſed; their pungency is diminiſhed by drying, and deſtroyed by long keeping. See Raii Hiſt. Lewis's Mat. Med.

RANUNCULUS VIRIDIS. The name of a ſpecies of frog.

RAPA. The turnip, commonly called the round rooted turnip. It is a plant with a round root, with jagged leaves, yellow flowers, with ſmall round, ſmooth, reddiſh, or blackiſh ſeeds, lodged in long pods. The garden *turnip* is ſuppoſed to be a variety produced by culture from the ſmaller ſort, which grows wild in ſandy grounds in ſome parts of England. It is biennial. Botaniſts enumerate ten ſpecies.

Turnips are uſeful and agreeable food; they are detergent, laxative, and diuretic, but in weak ſtomachs they produce flatulencies, and are ſometimes not eaſily digeſted. The liquor preſſed from them, after boiling, is taken medicinally in coughs and diſorders of the breaſt; the ſeeds are alexipharmic and diaphoretic; they have no ſmell, but to the taſte they are mildly acrid. The female ſpecies, which are longiſh, are thought the beſt; the male ſpecies is round. See Raii Hiſt. Lewis's Mat. Med.

RAPHANIA. Raphany. It is a nervous affection, of the ſpaſmodic kind, in which there is a violent contraction of the joints, with convulſive agitations, and great pain at various periods. Linnæus giveth this name to this diſeaſe, from its ſuppoſed cauſe, viz. the ſeeds of the raphanus raphaniſtrum, Linn. i. e. the baſtard radiſh, or charlock. Dr. Rothman, who wrote on this diſeaſe, ſuppoſes it to be cauſed by the raphanus above named, becauſe of its prevalence when the ſeeds of that plant abounded amongſt the corn. Linnæus alſo having fed ſome birds with the ſeeds of the raphaniſtrum, and finding that they died convulſed, he gave this diſeaſe the name of *raphania*. The Germans call this diſorder, kriebel krankheit. Sauvage names it, eclampſia typhodes; alſo convulſio *raphania*, vel convulſio ab uſtilagine.

It is defined to be, "A ſpaſtic contraction of the limbs or joints, attended with convulſions, and excruciating periodical pains." Dr. Cullen places it in the claſs neuroſes, and order ſpaſmi, in his Noſology.

In the ſixth volume of Amœnitat. Academicæ, Dr. Rothman gives the hiſtory of this diſeaſe, and a full deſcription of it. He obſerves, that it had been frequently epidemical in Sweden, notwithſtanding that many phyſicians think it is a new diſtemper: he has traced it in the writings of many authors, from the year 1596 to 1727, by which it appears to have been common in other parts of Europe; he adds that, this dreadful diſtemper ſometimes held the ſick for three or four weeks, and thoſe who periſhed, generally ſunk under a diarrhœa, or died in convulſions. The poorer people were the chief ſubjects of this complaint; they were uſually attacked in autumn, ſoon after eating bread made of new corn.

In order to its relief, valerian, caſtor, camphor, and other ſimilar antiſpaſmodics were given with ſome advantage. See Pulteney's View of Linnæus; Memoirs of the Royal Med. Society, at Paris, A. D. 1779, but particularly Dr. E. Roſen, and Dr. Rothman's Diſſertatio *Raphaniæ*.

RAPHANISTRUM. This plant is ſo called from its likeneſs to the raphanus minor, with which it alſo agrees in its medical virtues.

RAPHANISTRUM. A name for ſome ſpecies of eruccago, of rapiſtrum, and of the miagrum.

RAPHANUS HORTENSIS, called alſo radicula, raifort. Common garden radiſh. It is ſufficiently known not to need a deſcription. Its virtues are ſimilar to thoſe of the cochlearia. The root is attenuating, and occaſionally is both flatulent or carminative; all the parts of the plant are antiſcorbutic. The roots are more acrid after drying than they are whilſt freſh, but this acrimony is ſoon diſſipated by boiling.

RAPHANUS RUSTICANUS, alſo called raphanus ſylveſtris, raphanus marinus, armoracia, horſe-radiſh. It is the cochlearia armoracia, or cochlearia foliis radicalibus lanceolatis crenatis, caulinis inciſis floribus albis, Linn. Its flowers and ſeeds reſemble thoſe of ſcurvy-graſs, the leaves are large and long, and are indented about the edges. It is found wild about the ſides of ditches and rivulets, but for medicinal and culinary purpoſes it is cultivated in gardens. It is perennial, and flowers in June. It rarely perfects its ſeeds, but is propagated by traniverſe cuttings of the roots.

The roots impreſs both the noſe and the palate with a quick penetrating pungency; they alſo contain in certain veſſels a ſweet juice, which ſometimes exudes in little drops upon the ſurface. Its pungent matter is a very volatile ſalt, which is all diſſipated in drying, and is carried off in diſtillation, both by water and by ſpirit of wine. As the pungency exhales, the ſweet matter becomes more ſenſible, though this alſo is in a great meaſure diſſipated. It impregnates both water and ſpirit by infuſion or diſtillation very richly with its active matter; in diſtillation with water it yields a ſmall quantity of eſſential oil, exceedingly penetrating and pungent. This root agrees with creſſes and ſcurvy-graſs, and differs from muſtard-ſeed (though reſembled to it by ſome) in the volatility of its pungent matter, and its ſolubility in ſpirit. It is ſtimulating, aperient, attenuant, and antiſeptic; it promotes urine and perſpiration, the expectoration of viſcid phlegm, and excites an appetite in weak relaxed ſtomachs, without producing immoderate heat, or inflammatory ſymptoms. It is uſed in paralytic and rheumatic complaints, in ſcurvies and ſcorbutic impurities, in dropſies that follow intermitting fevers. If this root is chewed in the mouth, it produces the ſame effects as the pelitory root hath, in producing a diſcharge of ſaliva, in a want of taſte, and in a palſy of the tongue.

When an infuſion of *horſe-radiſh* root is uſed, wine is the beſt menſtruum. Infuſions thus made excite a kindly glow in the ſtomach, and in the habit in general, an advantage which does not uſually attend thoſe made with water, or with ale.

If the root is kept in a cool place, and buried in dry ſand, its virtues are retained a long time. Dr. Alſton ſays, that it may be ſo dried as to powder, and ſtill to retain an uſeful portion of its virtue.

The London College directs a compound water, in which this root is the principal ingredient, and from which it takes its name. See Neumann's Chem. Works; Lewis's Mat. Med.

RAPISTRUM, called alſo lampſana, ſinapi arvenſe præcox, ſemine nigro, charlock, chadlock, kedlock, or wild muſtard. This plant is called rapa, becauſe its leaves reſemble thoſe of the rapa. All the ſpecies, of which ſix are reckoned by Boerhaave, are antiſcorbutic, but their efficacy is too inſignificant to obtain a place in practice.

RAPUNCULUS. A plant ſo called from the reſemblance of its root to that of rapum; in other reſpects, it reſembles the campanula. It is not noted for its medical virtues.

RAPUNCULUS. A name for the cervicaria, for a ſpecies of rapuntium, and for ſeveral ſpecies of campanula.

RAPUNTIUM. It is a plant which much reſembles the

the campanula in its external appearance. One ſpecies of it bears the flower which is known by the name of cardinal flower; but they are not remarkable for their medicinal qualities.

RAPUNTIUM. Small rampions. Alſo a ſpecies of rapunculus.

RASPATORIUM, from *rado, to ſcrape.*

RAUCEDO. An hoarſeneſs. It is a diminution of the voice, ſometimes attended with a preternatural aſperity or roughneſs thereof: the parts affected are, the aſpera arteria, and particularly the larynx. Dr. Cullen obſerves, that it is generally a ſymptom of catarrh, but ſometimes it is a ſpecies of paraphonia; which ſee.

Its cauſes are, a ſort of catarrh, which ariſes from too great acrimony and viſcidity of the lymph: in which caſe a ſmall quantity of horſe-radiſh juice, mixed with honey, may be ſwallowed every morning, with a draught of new milk whey. 2. A copious effuſion of thin lymph upon the larynx and parts adjacent; and when from this cauſe, relief may be expected from the pulv. e trag. c. amylum, terr. Japon. &c. 3. In the ſmall-pox, puſtules in the membranes of the larynx, &c. produce an *hoarſeneſs*, which is relieved by the uſe of attenuants and lubricants, which aſſiſt the variolous matter in its paſſage through the ſkin. 4. A tumour, or inflammation, in or about the larynx; to remove the complaint from this cauſe, let vapours of warm water be received into the throat, or frequently uſe the following gargle: ℞ decoct. fol. vel rad. althaeæ ℔ i. ſp. ſal ammon. vol. gt. 60 m. 5. A dryneſs about the larynx and the muſcles ſubſervient to ſpeech. Here nitrous and acid attenuants, mixed with diluents, are very uſeful. 6. The ſpittle becoming thick or acrid, hence a viſcid tough matter ſticks to, and renders the ſurface of the larynx, &c. unequal, and conſequently the voice *hoarſe*; to remove which cauſe, things that attenuate and dilute the lymph, that render the ſpittle thin, ſoft, and copious, and empty the glands, will be the proper means; ſuch are emollients and expectorants.

In many inſtances the moſt ſpeedy relief is obtained from continuing the feet in warm water, for the ſpace of half an hour, about bed-time.

RAUCITAS, i. e. RAUCEDO.

REALGAR. A compoſition of ſulphur, orpiment, or yellow arſenic, and unquenched lime. It is alſo a name for the white arſenic. Mr. Edwards, in his Elements of Foſſilogy, places the *realgar*, or ſandarach, amongſt the cryptometallines, as a ſpecies of arſenic flos. It is of a red colour, always gloſſy, but not always tranſparent.

RECEPTACULUM CHYLI. The receptacle of the chyle. It is alſo called *receptaculum* Pecqueti, becauſe Pecquet firſt demonſtrated it. Euſtachius and Aſellius, were in ſome degree acquainted with it. It lies on the right ſide of the aorta, at the union of the laſt vertebra of the back with the firſt of the loins. It is a ſort of membranous veſicle, of various ſhapes in human ſubjects. Sometimes it ſurrounds the aorta like a collar. Its coats are very thin. The upper portion is contracted between the aorta and the vena azygos, and forms a particular canal which runs up through the thorax, and is called the DUCTUS THORACICUS, which ſee.

RECIPE. Take. It is uſually placed at the beginning of preſcriptions, and is generally wrote thus, ℞, or with the character for tin ♃, over which metal Jupiter was ſuppoſed to preſide, and ſo is uſed to denote the invocation of Jupiter, before preſcribing.

RECTI MUSCULUS NASI, i. e. Pyramidalis naſi.

RECTIFICATIO. See DEPURATIO.

RECTUM INTESTINUM. The laſt of the large inteſtines, called the *rectum*, or the ſtrait gut, is every where covered by longitudinal muſcular fibres, and hath ſtrong circular ones for expelling the fæces. It is not furniſhed with bands as the colon is, nor is it covered with the peritoneum, as are the other inteſtines. At the lower extremity of the *rectum* are certain cryptæ, which are ſuppoſed to be the ſeat of worms, and certain vaſcular ridges between the cryptæ where the piles are ſituated, which are external or internal, according to their ſituation. This gut is a continuation of the laſt convolution of the colon, which having paſſed below the laſt vertebra of the loins to the inſide of the os ſacrum, is bent backward in the concave ſide, to which it is connected, and having reached the os coccygis, it runs in the direction thereof, and bends a little forward, terminating beyond the extremity of the os coccygis. The inner coat is furniſhed with many glands, which ſeparate a mucus with which to keep it ſupple. The arteries are from the hæmorrhoidalis interna, the laſt branch of the meſenterica inferior, which communicate with the hypogaſtrica, and particularly with the hæmorrhoidalis externa. The veins are branches from the meſaraica minor, or hæmorrhoidalis interna, which communicate with the hypogaſtrica. The nerves are from the plexus meſentericus inferior, and the plexus hypogaſtricus.

Sometimes, there are hard, ſcirrhous lumps, without pain, ſeated at the bottom of the *rectum* or near the anus; theſe are thruſt out at every effort to void the ſtool, and then indeed is perceived a degree of uneaſineſs, but at no other time, except after handling them. If they have a ſmall baſis, Mr. Pott adviſes to remove them as ſpeedily as poſſible, for if they continue, they certainly prove fatal. In the inſtances that cannot be removed, the beginning ſymptoms do not give any light into their nature; the firſt ſymptom is a feel as if the patient wanted to void a large ſtool; on making the attempt, nothing is voided; this unavailing needing is frequently returning; at length he trieth a glyſter, but when the pipe is about to be introduced into the gut, it is obſtructed by a lump there; thus he is alarmed. The judicious ſurgeon, on introducing a finger, ſoon perceives the nature of the caſe, but he only offers a palliative remedy.

Another diſeaſe of this gut, is a fungous or general relaxed ſtate of its whole ſubſtance. When it is extruded through the anus, it is bound by the ſphincter muſcle, and puts on the appearance of a fungus with a narrow baſis; the mere fungus is uniform, and may be got round; it is ſoft to the touch, yet from the irritation of the part this may be as painful as a cancerous one. It is therefore proper juſtly to diſtinguiſh them, as the firſt may be cured, but the latter cannot. The cancerous fungus within the *rectum* is ſeldom uniform, but generally unequal, ſpreading from a large baſis, and diſcharges an offenſive ichor or gleet.

RECTUS. The name of ſeveral muſcles as follow; they are ſo called from the recti linear direction of their fibres.

RECTUS ABDOMINIS. The recti muſcles of the belly ariſe from the os pubis, are inſerted into the ſternum, and are expanded upon the cartilages of the fifth, ſixth, ſeventh, and ſometimes of the eighth ribs. In their courſe they are divided into four or five portions, by three or four tendinous interſections. They lay on the fore-part of the belly, immediately under the integuments, betwixt the linea alba and the linea ſemilunares. The veſſels which paſs underneath the upper parts are the mammary artery deſcending, and its vein aſcending; thoſe of the lower part are the epigaſtric artery aſcending, and its vein deſcending.

RECTUS DEPRIMENS OCULI. See DEPRESSOR OCULI.

RECTUS INFERIOR OCULI. See DEPRESSOR OCULI.

RECTUS CRURIS. Some call it rectus ſemoris, and others call it rectus anterior. It riſes by a ſtrong tendon from the anterior and ſuperior proceſs of the ileum, and from the cartilaginous tip of the acetabulum, and is inſerted into the upper part of the patella.

RECTUS INTERIOR. See GRACILIS INTERIOR.

RECTUS MAJOR. It riſes from the upper part of the ſpinal proceſs of the dentata; it runs upwards and outwards, and is inſerted near where the os occipitis is joined to the os temporis, ſerving to bring the head backwards. It is alſo partly a rotator of the head.

RECTUS MINOR. This riſes from the knob which anſwers to the ſpinal proceſs of the atlas, and paſſes thence to the head. It can only move the head upon the atlas.

RECTUS LATERALIS. It riſes from the tranſverſe proceſs of the atlas, and is inſerted into the os occipitis and os temporis, near the maſtoid proceſs. It bends the head to one ſide.

RECTUS INTERNUS MAJOR. It lies before the rectus internus minor. It riſes commonly by ſo many tendons from the tranſverſe proceſſes of the fifth, fourth, third, and ſecond cervicle vertebræ, and is inſerted in-

to the cuneiform proceſs of the os occipitis, and bends the neck forward. Winſlow calls it, rectus anticus longus.

RECTUS INTERNUS MINOR. Winſlow calls it rectus anticus brevis. It riſes from the root of the tranſverſe proceſs of the atlas, and is inſerted into the cuneiform proceſs of the os occipitis, juſt behind the groove where the lateral ſinus forms the beginning of the internal jugular. This muſcle gives the head a lateral jerk upon the atlas.

RECTUS ANTERIOR, i. e. Gracilis anterior.

RECTUS ATTOLLENS, i. e. Genio-hyoidæus.

RECTUS EXTERNUS OCULI. See ABDUCTOR OCULI.

RECTUS INTERNUS OCULI. Muſculus interior. It riſes from the bottom of the ſocket near the hole by which the optic nerve paſſes into the orbit, paſſes on the ſide of the globe next the noſe, and is inſerted into the ſclerotica. It draws the eye towards the noſe.

RECTUS SUPERIOR OCULI. See ELEVATOR OCULI.

RECURRENS. The recurrent nerve. See PAR VAGUM.

REDUC. Alſo called redux, or a flux. It is a powder by which calcined metals, or minerals, are reduced to a reguline form. *Fluxes* are generally either of the vitreous, or of the ſaline kind; by the vitreous is meant, all thoſe that are of themſelves, or that readily aſſume a gloſſy form in the fire; the chief of which are the glaſs of lead, glaſs of antimony, and borax; by the ſaline is meant all thoſe that are compoſed of ſalt, whether of nitre, or tartar, or the like. There are *fluxes* of a yet cheaper kind; ſuch are dried wine lees, dried cow dung, dried horſe dung, dried river mud; fuller's earth, iron filings, pot-aſh, &c. There are a variety of compound *fluxes*, ſome of which are better adapted for ſome ores than others are, and, indeed, almoſt every operator hath his favourite kind. The common black *flux*, ſee in the article CALCINATIO.

REFRIGERATORIUM. A refrigeratory. It is the veſſel filled with water, through which the worm paſſes in diſtillations: its uſe is, to condenſe the vapours as they paſs through the worm.

REGIMEN. The *regimen*, or the regulation of the diet, with a view to preſerve, or to reſtore health. In chemiſtry it is the regulation of fires.

REGINA PRATI, i. e. Ulmaria.

REGIONALIS MORBUS. An epidemical diſeaſe.

REGISTERES. Regiſters. They are openings in different parts of furnaces, which are to be ſhut occaſionally with ſtoppers or burnt clay. By means of theſe *regiſters* the fire may be governed as we pleaſe, for their heat is increaſed or diminiſhed by the cloſing, or opening of theſe holes. Theſe holes ſhould be from two to four inches wide, if the diameter of the furnace is a foot within.

REGULUS. Thus the chemiſts have called metallic matters when ſeparated from other ſubſtances by fuſion. The alchemiſts firſt invented this name, becauſe they expected to find gold in the metal. At preſent the word is confined to the metallic part of certain ſemi-metals which have no proper name, as the *regulus* of antimony, the *regulus* of cobalt, the *regulus* of arſenic, &c.

REMITTENTES. Remitting diſeaſes. They are when a diſtemper abates, but does not go quite off before it returns again. This moſt frequently happens in thoſe fevers which only go near to a diſtinct intermiſſion, without completely effecting it.

RENALES ARTERIÆ. They are commonly called emulgents, are generally two in number, and go out laterally from the lower deſcending aorta, immediately under the meſenterica ſuperior, one to the right hand, the other to the left. The right is ſituated more backward, and is longer than the left, becauſe of the vena cava which lies on the right ſide, between the aorta and the kidney; they run commonly without diviſion, and almoſt horizontally to the kidnies, into the depreſſions of which they enter by ſeveral branches, which form arches in the inner ſubſtance of the viſcera. From theſe arches many ſmall branches go out toward the circumference, or ſurface of the kidnies. Sometimes two arteries go into one kidney. Generally the right renal artery paſſes behind the vena cava, and the renal vein in the other ſide; and the left artery firſt behind, and then before the vein. Sometimes they ſend branches to the glandulæ renales, membrana adipoſa of the kidnies, and even to the diaphragm.

RENALES GLANDULÆ. See CAPSULÆ ATRABILARIÆ.

RENALES VENÆ, alſo called emulgentes venæ. Theſe ſpring from the inferior vena cava, when it arrives at the kidnies, into which theſe branches are ſent. Theſe are the largeſt veins that go from the vena cava, betwixt the liver and the biſurcation. The right emulgent is the ſhorteſt, becauſe of the ſituation of the kidney; the left is longer, becauſe it hath to croſs the trunk of the aorta. Uſually the left emulgent vein furniſhes the left ſpermatic vein.

RENELIUS. Snorting. Snoring.

RENES. The kidnies. They are two oblong flattened bodies, extending from the eleventh and twelfth ribs, to the fourth lumbar vertebra. The right *kidney* lies under the great lobe of the liver, and is lower than the left, which is ſituated under the ſpleen. The *kidnies* are ſhaped like a large bean; their circumference is concave on the ſide next the vertebræ, and convex on the oppoſite ſide. The aorta deſcendens, and the vena cava inferior, lie between the *kidnies*, pretty cloſe to the bodies of the vertebræ, and each of them commonly ſend off one capital branch, ſometimes two or three, which enter into the ſinuous part of the *kidney*, and dividing into two or three branches before it enters, ramifies through the whole. With theſe veſſels the nerves enter. The *kidnies* are covered on one ſide by the peritoneum, and the whole ſubſtance is inveſted by a capſula, compoſed of two laminæ connected together by a cellular ſubſtance. The external lamina is thin and ſmooth, and makes the *kidney* uniform. In children we may obſerve this convex ſubſtance is divided into little lobules, and we ſometimes find it ſo in adults. There are two ſubſtances obſervable in the *kidney*, the external or cortical, and the internal, which is called tubular or mammillary, which laſt is made up of a number of pyramidal portions (about twelve in each *kidney*), whoſe points are received into the pelvis, ſo that the cortical part not only lays round the outer ſurface of the *kidney*, but throws proceſſes into the interſtices. The cortical part is quite vaſcular; in minute injections are obſerved certain appendages, called by ſome corpora loboſæ, but which are naturally cryptæ, or cells, where the ſmall arteries ſeem to be expanded. Ruyſch ſays they are arteries coiled up in a little ſpace. The veins have none of theſe cryptæ; whence it is plain that they are not extravaſations; beſides, they are uniform, and only in the cortical part. Each mammilla lies in a kind of membranous calix, or infundibulum, which opens into a common cavity, called the pelvis, which is membranous like the infundibula, of which it is a continuation. After the infundibula have contracted into a conical form round the apices of the mammillæ, each of them forms a ſmall ſhort tube, which uniting at different diſtances along the bottom of the ſinus of the *kidney*, form three large tubes, which go out from the ſinus in an oblique direction from above downwards, and, immediately after, unite into one trunk, which is called

The URETER, and runs down obliquely, with a ſmall degree of inflexion, to the lateral parts of the inner-ſide of the os ſacrum, and paſſing between the rectum and bladder, it terminates in the latter in its inferior part, near the veſiculæ ſeminales; they perforate each coat diſtinctly in a ſlanting manner, ſo that their oblique inſertion anſwers the ſame end as a valve. The internal ligamentary membrane of the uterus does not end with their inſertion into the bladder, but is continued toward the proſtrate gland, where it ſeems to be inſerted; this ligament keeps the lower part of the bladder from ſtretching, and keeps the *ureters* fixed. The ſituation of the *ureter*, with reſpect to the renal artery and vein, is thus: the artery is in the upper part of the ſinus of the *kidney*, and partly before the vein; the vein is about the middle and between the artery and the *ureter*, which is in the lower part, ſomething behind the vein, and partly ſurrounded by a branch of the artery, whence appears the impoſſibility of nephrotomy, and that the operation, however repreſented, is no other than opening an abſceſs in the loin, through which opening the ſtone paſſes.

RENES SUCCENTURIATI, i. e. Renales glandulæ.

RENOVATIO. Renovation. In chemiſtry it is the reſtoration of a mineral body to a perfect ſtate, from one which is imperfect.

RENUANS MUSCULUS. A name for the *rectus anticus brevis*.

REPELLENTIA. Repellent medicines. By theſe are meant ſuch as prevent ſuch an afflux of a fluid to any part as would raiſe it into a tumour. Whatever other medicines may occaſionally produce the effects of repellents, thoſe only are properly of this tribe, which cool, dry, aſtringe, and ſtrengthen the parts, and enable them to reſiſt the afflux of ſuch matter as is lodged there.

REPULSIO. Repulſion. The cauſe which oppoſes itſelf to abſolute attraction hath been acknowledged by all who were converſant in phyſics, with reſpect to the celeſtial bodies; and it hath been termed *repulſion*, that is, a power as real as attraction, which repels bodies after they have approached each other to a certain point, and prevents their uniting together. This repulſion, though a ſecond cauſe, and ſubject to the laws of attraction, is properly inherent in matter; this property acts conjointly with attraction in the elements of bodies, and in all the operations of chemiſtry. It appears that it is from theſe two effects reunited, and from their different degrees of action, that the variety reſults, which is obſerved in the hardneſs and denſity of bodies. Many have rejected this repulſion, which Sir Iſaac Newton had allowed in ſublunary things; but if we juſt glance on many of the operations of chemiſtry, it is impoſſible to help admitting a retropulſive property in bodies.

RES NATURALES. The naturals. According to Boerhaave, theſe are life, the cauſe of life, and its effects. Theſe, he ſays, remain in ſome degree, however diſordered a perſon may be.

RESINA. Reſin. All ſorts of exudations, from evergreens, as turpentine, tar, &c. are in a general acceptation included under the name of *reſin*. Eſſential oils, indurated by age, or by acids, are called *reſins*. When the eſſential oil of the exudations from ever-green trees is exhaled, the remaining maſs is called *reſin*. As *reſin* conſiſts of oil and acid, it is artificially produced by the admixture of ſpirit of vitriol and ſpirit of wine, or the ſpirit of turpentine. The *reſina* alba of the Pharm. Edinb. Coll. is from the pinus ſylveſtris, and the pinus abies. The *reſina* flava is alſo from the ſame.

Reſins in general diſſolve in ſp. vin. R. It is chiefly by this means that they are extracted from the ſubjects in which they are contained. They alſo diſſolve in expreſſed oils, and in eſſential ones; and may be united with water by means of the ſame intermedia which render fluid oils miſcible with water. In a heat leſs than that of boiling water, they melt into an oily fluid, and in this ſtate they may be incorporated one with another. In their reſolution by fire, in cloſe veſſels, they yield a manifeſt acid, and a large quantity of empyreumatic oil.

The acrid *reſins* exhibited by themſelves tenaciouſly adhere to the coats of the inteſtines: by their ſtimulating power they irritate and inflame them, and thus produce ſpaſms, inflammations, &c. Theſe inconveniences are remedied by alcaline ſalts, by ſoap, and in a good meaſure by ſugar, if they are triturated with the *reſin*, before the patient takes it. Some rub eſſential oils with *reſins* to correct them, but the oil is ſoon ſeparated therefrom in the ſtomach, and the *reſin* is rendered more active, and ſo becomes more virulent, or, at leaſt, the ſame effects being produced in a degree by the oil which is obtained from the *reſin*, the *reſin* will act with more advantage.

Reſins act principally by irritating the ſtomach and bowels, and by attenuating the fluids; if the irritation is quick, they prove emetic; if not ſo ſudden, they paſs off by ſtool. They operate more violently in robuſt conſtitutions than on thoſe of a contrary habit; the veſſels of the former being more tenſe, ſo leſs capable of bearing irritation. The action of theſe medicines is extended beyond the primæ viæ, as is evident from the children being purged by the milk of thoſe nurſes who take them. See Neumann's Chem. Works; Dict. of Chem.

RESPIRATIO. Breathing. It is the action of taking in and of diſcharging the air from the lungs. As ſoon as the child is born, the air ruſhes into its lungs and diſtends them, and as heat rareſies the air, its force is ſo increaſed, that by expanding the lungs the whole breaſt is diſtended: thus the rareſying air, diſtending the lungs every way by its natural ſpring, increaſed by heat, may be conſidered as the firſt mover in the action of reſpiration. By this firſt diſtenſion of the lungs it happens that the blood which had hitherto paſſed by the foramen ovale, whilſt the fetus continued in the womb, is now obliged to take a different way, and paſs by the pulmonary artery and veins; and the former paſſage, by this means, is rendered uſeleſs. This makes it neceſſary that *reſpiration* be continued for ever after during life.

As the ſpring of the air is increaſed by the heat of the lungs, ſo the ſame air, when rarefied by the heat it meets with, becomes lighter than the external air, is made to reaſcend by the contraction of the diaphragm and intercoſtal muſcles, which are antagoniſt powers to the dilating one of rarefied air.

After the firſt expiration, a portion of the inſpired air remains, which is rarefied by the heat to which it is ſubjected; thus the external or atmoſpherical air again deſcends into the lungs; and as in the firſt inſtance of *reſpiration* the ſame circumſtances follow, ſo inſpiration and expiration continue to ſucceed, until with the laſt expiration death is uſhered in.

Reſpiration is partly voluntary and partly involuntary; but, as we determine this or the other muſcle to action by the influence which our wills have on them, ſo we exert a ſimilar power on the organs of *reſpiration* by the ſame means.

Some aſſert that the elevation of the breaſt by means of the intercoſtal muſcles is neceſſary to inſpiration; but perhaps a due attention to theſe muſcles will diſcover to us that their action is only during expiration, and if ſo their theory falls to nothing.

On particular occaſions, as in a difficulty of breathing, other powers are aſſiſtant in *reſpiration* beſides the air, the intercoſtal muſcles, and the diaphragm: and during ſleep, the air and the diaphragm are alone, or very nearly the whole, that are active herein.

The uſes of *reſpiration* are many, ſome of which are as follow: by *reſpuration* air is duly received into the lungs, in order to the exerting of our voices: by expiration the defect of perſpiration through the ſkin is in a good degree regulated; for much of the perſpirable matter is carried off from the body with the air which is expired; and in cold weather, &c. when the diſcharge is leſſened through the ſkin, there is a proportionable increaſe of the ſame from the lungs. Again, as the pulſe, ſo the action of the lungs is accelerated by heat; whence an advantage of inſpiration is, the cooling of the blood by the application of cold to that portion of it which is paſſing through the lungs, as well as by expiration, to carry off a portion of redundant heat along with the matter perſpired. Laſtly, by the action of the parts ſubſervient to *reſpiration*, the progreſs of the aliment through the ſtomach, &c. as alſo of the fæces through the inteſtines, are facilitated and haſtened.

See Haller's Phyſiology, ſect. 10; Hoadley on *Reſpiration*; Shebbeare's Theory and Practice of Phyſic.

RESTA BOVIS. Reſt-harrow.

RESUMPTIVA. Reſtoratives. They differ not much from agglutinant corroboratives, and their manner of operation in the ſame way may be accounted for, only that *reſtoratives* are more adheſive and ſubtil, whereby they enter into the nouriſhment of the remoteſt parts. All under this claſs are rather nutrimental than medicinal, and repair the waſtes of the conſtitution more than alter and rectify its diſorders. Cordials are known by this name.

RETE MALPIGHI. See PULMONES.

RETE MIRABILE. It is the name of a congeries of blood-veſſels in the brain.

RETE MUCOSUM. The true ſkin on its whole ſurface is covered with two lamellæ, one is the *rete mucoſum*, the other is the cuticula. The *rete mucoſum* is the principal ſeat of colour in man; in Europeans it is tranſparent, in mulattoes it is brown, and in negroes it is black. One uſe of the *rete mucoſum* is, to keep the papillæ moiſt, which would otherwiſe grow rough and unfit for ſenſation. The *rete mucoſum* is alſo called *corpus mucoſum*,

mucoſum, and *corpus reticulare*. Mr. Sheldon thinks that the colour of the *rete mucoſum* depends on the blood, which he ſays is darker in the Africans than in the Europeans: he was informed by a phyſician, on whoſe veracity he had the greateſt dependence, that the bile and ſemen of the Africans are darker than in Europeans. This obſervation contributes in favour of Mr. Sheldon's opinion. Wherever the cuticle thickens, the *rete mucoſum* thickens in proportion; as is exemplified by thoſe laminæ of integuments in the hands and feet of Africans. It is alſo obſerved, that in the fœtus of nine months, the *rete mucoſum* is yellower than the cuticle. In Africans the *rete mucoſum* is more eaſily ſeparated from the cuticle than in Europeans.

RETINA. Thus the expanſion of the optic nerve on the inner ſurface of the eye is called. Though this expanſion is ſuppoſed to be a production of the medullary ſubſtance of the optic nerve, which is ſpread like a membrane, and from its reſemblance to a net, is called *retina*; yet by laying open the coats of the nerve, its medullary ſubſtance cannot be clearly traced, as continuing on to form it. This inner coat of the eye is moſt probably the ſeat of viſion, notwithſtanding the objections lately made to this opinion.

RETROVERSIO UTERI. See PROCEDENTIA.

RHABARBARUM. *Rhubarb*, alſo called *rheum*; *lapathum Orientale*; *lapathum Chinenſe*; *rhubarb*. The Greeks called it *rhabarbarum*, from its growing on the banks of the river Rha (i. e. Wolga) in the barbarous country of Ruſſia. But the later Greeks are ſaid to have called it *barbaricum*, becauſe it was brought to Barbaria, a country lying on the Sinus Barbaricus, whence it was ſent to other countries.

Rhubarb is a plant of the dock kind. It is the *rheum* palmatum, or *rheum* Chinenſe, foliis palmatis acuminatis ſcabriuſculis, foliorum laciniis oblongis acutiuſculis, Linn. The leaves are ſomewhat heart-ſhaped, acuminated, and ſlightly hairy. The root is the only part in uſe; it is brought from China, and from Siberia, by way of Ruſſia. As good *rhubarb* plants have been raiſed in our phyſic gardens as any that are met with abroad; they grow with vigour in open ground.

Two ſorts of the roots are met with in our ſhops, viz. one from Turkey, or perhaps much of this is from Ruſſia; for in the Ruſſian territories the fineſt *rhubarb* grows in large quantities. The Turkey *rhubarb* is generally in flattiſh pieces, more compact and hard than the Ruſſian; that which grows in Tartary and Siberia is in round lumps, leſs weighty than the Chineſe, but of a finer grain, and always perforated; the reaſon of this difference in weight and form, is owing to the different methods of curing them. In China they cut their *rhubarb* into ſlices, and preſs it cloſe before drying; in Ruſſia they hang it up to dry without cutting it into ſlices or preſſing it. The Chineſe pieces are externally of a yellow colour, and within there is a mixture of bright reddiſh ſtreaks with the yellow. The ſecond ſort is brought from the Eaſt Indies; it is in longiſh pieces, harder, heavier, and more compact than that from Turkey. Dr. Alſton thinks this as good as the Turkey ſort. The firſt ſorts muſt be kept dry, or they grow mouldy, or are deſtroyed by worms. The Indian *rhubarb* is not ſo ſubject to theſe inconveniences, and the finer pieces, after being rubbed with the powder of Turkey *rhubarb*, are ſold for it.

Whether *rhubarb* is of the Turkey or of the Eaſt-India kind, chuſe that which is of a lively colour when cut, that is firm and ſolid, but not hard, that is eaſily powdered, and when powdered is of a bright yellow colour; that on being chewed imparts to the ſpittle a yellow colour, but that does not grow ſlimy whilſt in the mouth; to the taſte it ſhould be ſub-acrid, bitteriſh, and ſtyptic, and its ſmell lightly aromatic.

Rhubarb gives out its purgative quality moſt freely to water; after digeſting it with water it becomes inactive, but after ſeveral digeſtions with ſpirit of wine it retains ſome of its purgative virtue. The powder purges the moſt; the next to it is an infuſion in water; the ſpirituous tincture purges the leaſt, but hath more of the aroma and of the aſtringency of this root. The watery infuſion, when reduced to an extract, hath its virtue much diminiſhed; the ſpirituous loſes leſs, ſo that ʒ ſs. of it will operate moderately, but not more ſo than an equal quantity of the powder.

The London college directs a tincture to be made with wine, and another with proof ſpirit. Theſe are intended for ſtomachics and ſtrengtheners, as well as for purgatives. Spirituous liquors excellently extract that part of the *rhubarb* in which the two firſt qualities reſide. When given in the firſt intentions a ſpoonful or two is a doſe; but, when they are intended as purgatives, from two to three ounces muſt be given.

The Edinburgh college directs an infuſion in water as follows:

℞ Rad rhab. inciſ. ʒ i. aq. bullient. ℔ i. infund. per noct. & colaturæ adde aq. cinnam. ſp. ʒ i. When *rhubarb* is given as a purge, this is one of the beſt preparations.

Whether *rhubarb* is taken in powder or infuſed in water, if the doſe is mixed with a diſh of coffee, the patient will rarely object to its taſte.

The practice of toaſting *rhubarb* is attended with no real advantage; but if it is not removed from the fire as ſoon as it is fit for powdering, it will be injured. If inſtead of toaſting it, a ſmall quantity of any thing aſtringent is added, the end of toaſting would be better anſwered.

Rhubarb is a mild cathartic, and alſo a mild aſtringent; it ſtrengthens the inteſtines, leaves the belly coſtive, and is hence preferred in diarrhœas and dyſenteries. It is often given more with a view to its ſtrengthening, than to its purgative quality. That which is bright, of a light texture, moſt fragrant and ſound, contains leſs reſin in proportion to its earthy and ſaline parts, than that which is heavy, tenacious and fetid; and therefore we find it milder in its operation, more grateful to the ſtomach, and better to anſwer the intention of an aſtringent, a diuretic or an alterant: and the other more to nauſeate the ſtomach, and to operate more ſtrongly as a purge in the firſt paſſages. *Rhubarb* changes the urine to a yellow colour before it operates as a purge: it is a good ſubſtitute for aloes when they are productive of the piles, which are ſeldom occaſioned by *rhubarb*; at the ſame time, as an attenuant, it is very little inferior to aloes. In acute fevers, when there is apprehenſion of producing a diarrhœa by purging medicines, *rhubarb* is ſafe. In diarrhœas and dyſenteries, *rhubarb* is doubly uſeful; 1ſt, by carrying off the peccant matter; 2dly, by ſtrengthening the bowels againſt a further afflux. A peculiar excellency in *rhubarb* is, its evacuating viſcid bile when lodged in the bile ducts; in this caſe, next to aloes, it is the beſt amongſt purging medicines; and it hath this advantage over aloes, viz. that it may be given where inflammation is attendant, provided bleeding be premiſed. In groſs habits, *rhubarb* is an uſeful aſſiſtant to ſecure the efficacy of the bark, if joined with it. See Lewis's Mat. Med. Neumann's Chem. Works.

RHABARBARUM ALBUM. i. e. Mechoachana.

RHABARBARUM ANTIQUORUM. i e. Rapontic.

RHABDOIDES, from *ῥαβδος a ſtrait twig*, and *ειδος, form*. A name for the ſagittal ſuture.

RHACHIS. The ſpine of the back,

RHACHISAGRA, from *ραχις, the ſpine of the back*, and *αγρα, a prey*. A ſpecies of gout fixed in the ſpine of the back.

RHACHLÆI, or RHACHITAE. The muſcles belonging to the ſpine of the back. From *ῥαχις, the ſpine of the back*.

RHACOSIS. Excoriation of the relaxed ſcrotum.

RHAEI. Rhubarb.

RHAGADES, from *ῥηγνυμι, to break off*. Chaps, clefts, or fiſſures in the ſkin. If ſeated in the anus, and recent, the patient muſt ſit ſtill, and ſit over the ſteam of warm water. The cerat. epulot. may alſo be applied. If the lips of theſe fiſſures are callous, cut them, or otherwiſe treat them, as that they may become new ulcerations. See Turner's, Wiſeman's, and Heiſter's Surgery. *Rhagadia* may be cauſed by extenſion, contraction, or acrimony; are amongſt equivocal ſigns or productions of the firſt infection of the pox. They are ſeated about the anus and various parts of the pudendum muliebre, the anus, corners of the mouth, noſtrils, eye-lids, nipples, &c. Theſe chaps iſſue ſometimes a thin, ſharp ichor, which

is

is either venereal, or of other kinds of acrimony; and at times are very painful. If they are freſh contracted, they are not difficult, but if their lips are deep, callous, and inflamed, they are more difficult to remove. See a Treatiſe on the Venereal Diſeaſe, by N. D. Falck, M. D. edit. 2. 1774.

Different from the *rhagadia*, in appearance, are the chaps in the palms of the hands, and ſoles of the feet; both proceed from the acrimony of the virus, ſearching as it were for the cuticula, by which it is ſhrunk together.

RHAMNUS, alſo called ſpina cervina, *rhamnus* catharticus, ſpina ſolutiva, ſpina infectoria, cervi ſpina. Buckthorn, and purging thorn. It is the *rhamnus* catharticus, or rhamnus catharticus, foliis, ovatis, ſpinis terminalibus, floribus, quadrifidis dioicis, baccis nigris, Linn. It is a prickly buſh, or a low tree, common in hedges, having pointed leaves; in June it produces ſmall green flowers, and in the beginning of October it ripens into black berries, which contain a dark green juice, with four ſeeds in each.

It is uſual to find theſe berries mixed when brought to the markets, with the berries of the black alder, and alſo of the dog berry tree; but they are thus diſtinguiſhed; the juice of the buckthorn berries is green, that of the others not ſo, the buckthorn berry hath four ſeeds, that of the alder hath but two, and the dog berry hath but one.

Buckthorn berries have a faint unpleaſant ſmell, and a bitteriſh, acrid, nauſeous taſte; they operate briſkly by ſtool; at theſame time they occaſion dryneſs in the mouth and throat, with thirſt, and griping in the bowels; but if plenty of warm ſmall liquor is drank during the operation, theſe effects are not ſo much obſerved.

A ſyrup is uſually kept in the ſhops, which is made by boiling the juice of theſe berries with ſugar, to a proper conſiſtence. From one to two ounces are given for a doſe, but it is rarely uſed, on account of its nauſeous taſte and churliſh operation.

Thoſe who ſell the juice often mix it with water. See Lewis's Mat. Med. Neumann's Chem. Works.

RHAMNUS. A name for the paliurus, the rhamnoides, and the hippophæs.

RHAPONTICUM. The true rhapontic. It is alſo called rheum; rheum ponticum; rha verum antiquorum; rheum Dioſcoridis; rhaponticum Alpini; rhabarbarum Dioſcorides; rhab. forte Dioſcoridis; Engliſh rhubarb. It is as the true rhubarb, a ſpecies of dock, with ſmooth, roundiſh leaves, ſomewhat channeled pedicles: it grows wild on the mountains of Thrace, whence Alpinus brought it into Europe about the year 1610. It bears the hardeſt winters in our climate. The roots are often mixed with thoſe of the true rhubarb, but are detected by their mucilaginous taſte when chewed, and by their not tinging the ſaliva of ſo bright a yellow as the true rhubarb does; when the *rhapontic* is cut through, it appears regularly marbled in a radiated manner; it is duſky on its ſurface, and of a looſe ſpongy texture, more aſtringent than the modern true rhubarb, and leſs purgative; as a purge, two or three drams are required, but it is a better ſtomachic than the true rhubarb. See Raii Hiſt. Tournefort's Mat. Med.

RHAPONTICUM VULGARE, called alſo rhapontic cum folio heleni incano, centaurium majus, centaurium magnum, great centaury. Common rhapontic. It is the centaurea centaurium, Linn. It is a large plant, with leaves, compoſed of oblong, ſerrated ſegments, ſet in pairs on a middle rib, edged in the intermediate ſpaces with a ſerrated margin; the ſtalk divides towards the upper part into ſeveral branches, which bear on their tops round, ſoft, ſcaly heads, from which come forth bluiſh floſculi, followed by down, incloſing the ſeeds. It is perennial, a native of the ſouthern parts of Europe, and raiſed with us in gardens. The root is of a dark black colour on the outſide, it is internally reddiſh, and yields, when freſh, a juice of a deep red. It hath a ſlight ſmell, which is not diſagreeable, and in chewing it diſcovers a viſcous ſweetneſs, and roughneſs, with ſome degree of acrimony. It is reckoned to be an aperient and corroborant, and is ſuppoſed to be particularly uſeful in alvine fluxes. It is very much inferior to the true *rhapontic*. See Raii Hiſt. Tournefort's Mat. Med.

RHENCHOS. Snoring. This affection is otherwiſe called ſtertor, which is found like that of the cerchnon, but greater and more manifeſt. A *ſtertor* is that ſound which is ſuppoſed to be made betwixt the palate and noſtrils, by perſons aſleep: cerchon, or cerchnon, is that bubbling noiſe which is made in reſpiration, from the larynx, or the aſpera arteria. Theſe affections are owing to a weakneſs of nature.

RHEON, and Rheum. Names for the rhapontic, and alſo the rhubarb.

RHENOPHONIA, i. e. Paraphonia reſonans.

RHEUMA, from *ῥέω, to flow*. A flux, or fluxion. The ſame as catarrh, which ſee.

RHEUMA CATARRHALE, i. e. from cold.

RHEUMA EPIDEMICUM, i. e. from contagion.

RHEUMATICA. The rheumatic fever.

RHEUMATISMUS. The rheumatiſm, from *ῥέω, to flow*. It is a painful diſeaſe, affecting the intermediate ſpaces between the joints and muſcles in different parts of the body; ſometimes the viſcera are alſo attacked. It is with or without a fever; when a fever attends, it is called the acute, and where there is no fever, it is called the chronical *rheumatiſm*. The ancients called all kinds of pains affecting the external parts or joints, by the common name of arthritis; but about the end of the ſixteenth, or beginning of the ſeventeenth century, ſome celebrated French phyſicians called thoſe that were ſituated any where but in the joints, that is in their tendinous and nervous ligaments, by the name of *rheumatiſm*. Dr. Cullen places the acute *rheumatiſm* as a genus in the claſs pyrexiæ, and order phlegmaſiæ. The varieties of the one ſpecies take their name from the parts affected; as 1. Myoſitis; when the pain is ſeated more in the muſcles that proceed from the joints. 2. Lumbago; when the muſcles of the loins are the ſeat of the complaint. 3. Ichias; when the muſcles of the hips are the ſuffering parts. 4. Pleurodyne, and pleuritis ſpuria; when the muſcles of the thorax are attacked.

The chronical *rheumatiſm* is conſidered by Dr. Cullen as generally the mode of an acute *rheumatiſm* terminating.

Whatever part of the body the *rheumatiſm* affects, or whatever ſpecies of this diſorder is complained of, the cellular membrane is the immediate ſeat thereof.

Perſons of any age may be afflicted with the *rheumatiſm*, but uſually thoſe in the prime of life are its ſubjects, and particularly thoſe of an active diſpoſition.

The cauſes of the acute *rheumatiſm* are, whatever may conduce to the production of an inflammation in the part affected. The chronic *rheumatiſm* hath for its principal cauſes, an irritating acrimony in the juices ſecerned into the parts complained of.

The acute or inflammatory *rheumatiſm* is attended with a fever, pains in the limbs, which are generally in the joints, preventing their motion, and are accompanied with heat, redneſs, and ſwelling of the part. When the pain is fixed, the fever abates, though with ſome it continues many days, always increaſing in the evening. After ſome days, the pain commonly quits one part and affects another, as from the knee to the foot, from thence to the hip, &c. The feet, ankles, knees, hips, loins, nape of the neck, ſhoulders, ſhoulder blades, arms, elbows, and wriſts, are the uſual ſeats of the pain. So great is the tenderneſs of the parts affected, that the patient complains of the leaſt motion, as when violence is uſed. The parts in which the pain is uſually moſt afflictive, are, the neck, the loins, and the hips. The violence of the acute *rheumatiſm* ſeldom continues above fourteen days, though a weakneſs and puffneſs, &c. will remain long, or many months, eſpecially if the diſeaſe attacks the patient in autumn. Some, after the pains are gone off, complain of a laſſitude, which does not leave them till an eruption of ſome kind appears on the ſkin.

The chronical *rheumatiſm* is known by the pains, and the abſence of fevers, by the long continuance of the pain, and by a few parts only being attacked at once. Generally there is no viſible alteration in the affected part, though ſometimes it is hot, red, and ſwelled.

When the pain is in the hip, and extends down the thigh, it is called ſciatica.

When the ſymptoms of a ſcorbutic habit attend theſe pains, the diſorder is called a ſcorbutic *rheumatiſm*.

When a violent pain is fixed on the loins, reaching

ſometimes to the os ſacrum, attended with nephritic ſymptoms, it is called a *rheumatic* lumbago; in this caſe the patient is forced to ſit upright, and to keep his body perpetually forward.

When the *rheumatiſm* is unattended with a fever, it muſt be diſtinguiſhed from the gout; when the loins are the ſeat of the diſorder, care is required to diſtinguiſh it from the gravel, from a ſtone in the kidneys, and from an inflammation in the ureter; alſo from an abſceſs in the parts about the loins. A *rheumatiſm* in the muſcles of the belly muſt be diſtinguiſhed from the colic. One ſpecies of *rheumatiſm* ſhould alſo be diſtinguiſhed from another.

Whilſt the ſeat of the pain is in the external parts there is no great danger; but if the internal organs are the ſeat thereof, the danger is great. If the brain is attacked, and delirium is the conſequence; if the lungs are affected, a ſuffocation diſturbs the patient; if the ſtomach or the bowels are the ſeat of the diſorder, an inflammation there may be ſoon expected. If the pain continues long in any joint, its motion will be impaired for life; a wry neck hath ſometimes been the conſequence of preceding *rheumatic* pains. Dr. Rutherford, of Edinburgh, obſerves, that wherever a *rheumatiſm* is ſeated, that part never ſweats, and that as ſoon as a ſweat can be raiſed in the pained part, the diſorder will be conquered; it may alſo be obſerved, that when in either the acute or chronical *rheumatiſm* the ſymptoms vaniſh, and at the ſame time a free perſpiration comes on, and the ſame is obſerved on the parts affected, and the urine is turbid and copious, a cure may certainly be expected.

The indications of cure will be, to diminiſh the fever, when attendant, and to moderate the pain; to diſſolve and eliminate the morbid matter, and to ſtrengthen the weak parts.

As to the acute *rheumatiſm*, an obſtructed perſpiration and an inflammatory diatheſis conſtitute the moſt general cauſes. This laſt concurring cauſe muſt be immediately removed; for whilſt it ſubſiſts, a perſpiration is not to be expected, and hence, as in other inflammatory diſorders, we are in general to proceed in this.

Bleed. By this operation the hardneſs of the pulſe is abated, and though the pains ſtill continue, the patient is not ſo reſtleſs, the tenſion of the veſſels is removed, the fever is reduced, and makes room for attenuants and diluents. But, as ſizy blood is no rule for bleeding in this diſorder, ſo very free diſcharges this way do but lay a foundation for the chronic *rheumatiſm*. When weakly people are attacked with the acute *rheumatiſm*, much care is required before bleeding is preſcribed; for, if imprudently admitted of, it produces diſorders in them that are not removed but with the greateſt difficulty; in ſuch patients, a cooling but moderately nouriſhing diet ſhould be uſed; whey, for inſtance, may be ſubſtituted inſtead of bleeding. Bleeding is ſafe and uſeful when the ſymptoms are violent and threatening, as when the fever is violent; when the wandering pains ſhift ſuddenly from the extremities to the internal parts, and affect the ſides or the breath.

Clyſters or purges. A laxative clyſter may be given, and, if the head is uneaſy, repeat the clyſter every night and morning: but, in general, a cooling purge, given every other day, or as may ſeem neceſſary, is preferable to clyſters; when bleeding is required, a purge ſhould be given after each time the blood is taken away. Clyſters with nitre, for moderating the fever, are uſeful; but, for purging, give medicines by the mouth. If purges are duly adminiſtered, leſs blood may be taken away, and opiates can be more freely uſed. Indeed, in conſtitutions that are rather ſerous than ſanguine, purging is more the proper evacuant than bleeding is.

Nitre. In the inflammatory *rheumatiſm* this ſalt is peculiarly uſeful; it may be diſſolved in every draught of the patient's drink, and given as freely as the ſtomach will admit it. In the decline of acute, and in every ſtage of chronical *rheumatiſms*, it may be given to advantage in conjunction with the ſal. vol. c. c. Imperial is an agreeable liquor for common drink, and may be freely taken.

Opium. The pains are moſtly increaſed in the night, whence opiates are given, but bleeding ſhould be premiſed, and purges adminiſtered as above mentioned; otherwiſe the advantages from opium will not equal the inconveniences they often occaſion. When this medicine is allowed of, it ſhould be given rather to moderate the pain than to cauſe ſleepineſs.

Guaiacum. The volatile tincture of this gum may be given from ʒ ii. to ℥ ſs. twice a day in any thing that the patient drinks; if it paſſes off too freely by ſtool, add a few drops of the tinct. Thebaic. to each doſe.

Antimony. The preparations from this drug which paſs off by perſpiration are never to be omitted; they may be given at proper intervals, betwixt the doſes of ſuch other medicines, as circumſtances may require.

The bark. In old chronic *rheumatiſms*, when the blood is poor, the bark is the principal remedy, if given when free from febrile ſymptoms. And in the acute *rheumatiſm*, as ſoon as it puts on the appearance of an intermittent, the bark is neceſſary; and whether it intermits or not, as ſoon as plentiful ſweats break out, and the urine depoſits a copious ſediment, the bark will ſhorten the diſeaſe.

Warm baths. They may be made of pure ſoft water, and heated ſo as juſt to produce an agreeable ſenſation in the ſkin. In theſe the patient may be placed for a quarter of an hour, more or leſs, as circumſtances indicate; and then being preſerved from cold, he muſt be rubbed dry, and put between blankets, if poſſible to excite a perſpiration.

Bliſters. If placed on the part affected are ſometimes uſeful. Dr Cullen ſays, that they ſeldom fail of ſucceſs if applied before the ſwelling comes on. In chronic *rheumatiſms* their efficacy is more frequently uſeful.

After the cure, the cold bath is uſeful in preventing returns; and the ſtrength ſhould be confirmed by the uſe of bitters, aromatics, and chalybeates.

In chronical *rheumatiſms*, mild mercurials given in ſuch doſes as not to ſolicit the excretions too much; daily frictions, with a flannel cloth, particularly on the parts that are, or were pained; bliſters on or near the ſuffering part; iſſues in the inſide of the lower part of the thigh; and a decoction of the rad. ſeneka, which is called a ſpecific, are chiefly to be depended on. The tinct. guaiac. vol. in large doſes, is alſo of ſingular efficacy.

If with *rheumatic* diſorders, there is a ſcorbutic habit, the ſulphureous water at Harrowgate, &c. ſhould be both drank and bathed in.

In the lumbago, apply iſſues and bliſters on the thigh, and then having premiſed proper evacuations, opiates, and mercurial alteratives if properly perſiſted in, will moſt effectually anſwer the expectations of the patient. See Swan's Tranſlation of Sydenham's Works; Shebbeare's Theory and Practice of Phyſic; Tiſſot's Advice to the People; Cheſhyre on the *Rheumatiſm*; Lobb on painful Diſtempers; Brooks's and the London Practice of Phyſic.

RHICHNOSIS. Lean and wrinkled.

RHIGOS. Rigor. When any ſenſible part of the body is affected with ſpaſms, all the other parts are readily drawn into conſent with it; hence the horror and *rigor* on the ſurface of the body, the coldneſs, &c. Irritation in the primæ viæ is often the cauſe. Galen ſays, a *rigor* is a ſtrong and urgent ſenſe of a refrigeration of the natural heat. *Rigor* ſometimes ſignifies an inflexible hardneſs and tenſion of the nervous and muſcular parts, but theſe are better expreſſed by the word *rigiditas*. Others define a *rigor*, as being a general chillyneſs, with a ſenſe of coldneſs inwardly, and a contraction of the lower jaw.

RHOCAS. The watery eye.

RHOCHMOS. Snoring, or ſnorting through the fauces.

RHODIA, alſo called rhodia radix, anacampſeros, rhodiola, telephium, luteum minus. Roſe-root, or roſe-wort. It is a ſpecies of orpine; its dried root ſmells like the damaſk roſe.

RHODODENDRON. The dwarf roſe bay.

RHODODENDRON (CHRYSANTHEMUM). Foliis oblongis impunctatis ſupraſcabris venoſiſſimis, corolla rotata irregulari, gemma floriſera ferrugineo-tomentoſa, Linn.

This ſpecies of dwarf roſe bay hath been recommended in rheumatic pains, particularly the chronic kind. Dr. Kolpin, of Alten-ſtetin, uſed an infuſion of it in water,

kept twenty-four hours in nearly a boiling heat. The proportion was, from two drams of the leaves and tops of the plant to half an ounce, to ten ounces of water; the dose two ounces, to be repeated after a few hours, and continued as required. Dr. Home observes, in his Clinical Experiments, &c. that it is astringent, and powerfully sedative; he directs it in infusion, from half a dram to three drams for a dose. Dr. Kolpin observes, with respect to the infusion of this vegetable, that when taken internally, it produces a feverish heat, a kind of intoxication, and sometimes a stupor and loss of the senses; at the same time the patient feels a singular pricking sensation in his limbs, or other parts of his body; the intoxication soon goes off, leaving behind it neither head-ach nor nausea. During the heat produced by this remedy, the patient complains of intense thirst, and if cold water is drank in this state, there ensues a violent but salutary vomiting, especially in complaints of the bowels. Besides the vomiting and purging, this medicine produces a sweat on the parts affected with the rheumatism or gout. Large doses produce a stupor and anxiety. In some instances the pains grow worse on the first use of the infusion; but this increase of disease is soon followed by a remarkable degree of relief; instead of quickening the pulse, it renders it weaker and slower. In the instances of venereal rheumatism, its effects are very considerable. Many who drank this infusion, complained of a heat and constriction in the fauces; a proof that the plant possesses a little acrimony; but this effect speedily passes off. In robust habits, it operates quickly, and with a degree of violence; in the infirm and feeble, it is very slow in its effects, hence in such instances the patient should not be uneasy to increase the dose.

RHOMBOIDES MUSCULUS, from ῥομβος, *a four-square figure*, and εἶδος, *form*. It rises from the ligamentum colli, the spinal processes of the third, fourth, fifth, sixth, and seventh cervical vertebræ; and the first, second, third, and fourth dorsal; and is likewise attached below to some of the ribs: it runs beneath the latissimus dorsi, and is inserted into the whole length of the basis of the scapula, to bring it upwards and backwards. Some divide the *rhomboides* into the major and minor; and, if so, the minor is above the major below.

RHOPALOSIS, i. e. Plica Polonica.

RHUS, from ῥεω, *to flow*, because it stops fluxes. It is also called *rhus* obsoniorum, and coriariorum. Common sumach.

It is a shrub, or low tree, with oval, pointed, serrated leaves, and clusters of yellowish or greenish flowers, each of which is followed by a small, red, flattish berry, including a roundish, reddish, brown seed. It is a native of the south of Europe, and is cultivated in our gardens. The berries have an acid, austere taste, are cooling and restringent. The leaves and young twigs are restringent; but it is chiefly used by dyers. See Tournefort's Mat. Med. Neumanns' Chem Works.

RHYSSEMETA. A wrinkled face.

RIBES. The common red currants, called also ribesium, grossularia non spinosa. The different sorts have a cool acidulous sweet taste, agreeable both to the palate and the stomach; they agree in general with the summer fruits in their medicinal qualities.

RICÆ, ῥικος. A covering on the heads of the Roman and other women during the time of sacrifices; hence *rica*, the kerchief.

Kerchief (the great). The French call it, *le grand couvre chef*. It is used after trepanning, &c. It is made of a square cloth, and, when dexterously applied, it keeps the dressings on. As to the method of applying it, seeing and practising only can obtain a dexterity therein.

Kerchief (the triangular). The French call it, *couvre chef en triangle*. It is a square cloth, folded in the form of a triangle. The middle of the longest side of which is applied to the forehead, the two ends of the same tied behind the head, and the angle, which falls behind the head, secured there to the confined ends of this kerchief. Its use, in general, is to secure the dressings on the face and head.

RICINI, (Ol). See Cataputia.

RIGOR. See Rhigos.

RIGOR NERVOSUM, i. e. Tetanus.

RISUS SARDONICUS. See Spasmus Cynicus.

RIVINIANÆ GLANDULÆ, i. e. Sublinguales glandulæ.

ROB. See Extractio.

ROBINIA. False acacia.

RODATIO. Too short eye-lashes.

RONCHUS. Snorting or snoring through the fauces.

ROSA. The rose. Miller enumerates no less than forty-nine species of this flower, amongst which the white, the damask, and the red, are in use.

White *roses* are the weakest, so that when the damask (*rosa* pallida) vel (*rosa* centifolia, Linn.) can be had in sufficient quantities, they only are used. They give out their agreeable scent both to water and to spirit, but most so to the latter. They do not lose much by drying, if carefully managed, nor do they soon lose their qualities by keeping. On distilling large quantities, a small portion of a fragrant butyraceous oil, of a yellowish colour, is obtained; it concretes in a slight degree of cold: both the water and the oil are chiefly used as perfumes. On distilling the damask *roses*, a liquor is left in the still which purges gently. This is made into a syrup, and given to children. If the liquor which remains after distillation is evaporated to an extract, it purges adults, if given in a dose from ℈ i. to ʒ i.

The red *roses* have but little of the fine flavour of the pale sort; to the taste they are bitterish and somewhat astringent. They are the *rosa* Gallica, or *rosa* Germanibus ovatis pedunculisque Hispidis, caule petiolisque Hispido-accileatis, flore rubro multiplici, Linn. The astringency is the greatest before the flower opens, and this quality is improved by hasty drying in a gentle heat, but by slow drying, both the colour and astringency are impaired. They give out their virtues to water and to spirit. Water they tinge with a deep red, and spirit with a pale one. The extract from a watery infusion is austere, bitter, and subsaline; that from spirit more so in each of these instances. See Lewis's Mat. Med.

ROSMARINUS, called also libanotis coronaria. Common rosemary. *Rosmarinus* (officinalis) latifolia, Linn. The flowers are called anthos in the Edinburgh Dispensatory. Rosemary is a large shrubby plant, with long, narrow, stiff leaves set in pairs, of a dark green colour above, and hoary beneath, with flowers of a pale bluish colour. It is a native of the southern parts of Europe, where it grows wild in dry gravelly ground. It is common in our gardens, where it smells stronger in proportion as the soil is dry and gravelly.

Rosemary hath a warm, pungent, aromatic, bitter taste, and a fragrant smell, approaching to those of lavender, but more of a camphorated kind; the leaves and tender tops are the strongest; next to these the cup and the flowers. The flowers by themselves are much the weakest, but most pleasant; it is chiefly in the cup that the active matter of the flowers reside; for the bluish petalum, carefully separated, hath but little either of smell or taste.

A conserve is made of the flowers, by beating them, but their virtue is destroyed in a great measure; the tender tops and leaves are the best for this form.

The leaves and tops give out their virtue completely to rectified spirit, which, when distilled from them, becomes considerably impregnated with their fragrance, leaving, however, in the extract, the greatest share of both their flavour and pungency.

The active matter of the flowers is more volatile than that of the leaves, the greatest part of it arising with spirit; the Hungary water is a strong spirit distilled from the flowers.

Spiritus Rorismarinæ. *Spirit of* Rosemary.

Take two pounds of fresh *rosemary* flowers; rectified spirit of wine a gallon; distil to dryness in a vapour bath. This is the Hungary water, and to make it in perfection the spirit must be very pure, the leaves at their full growth, gathered without bruising, and committed to distillation. If the flowers were hung in the still, or retort, in a wicker basket, the spirit being first put therein, and a gentle heat applied just sufficient to make the spirit rise, the vapour lightly percolating through the flowers, will imbibe their fine parts, and leave their grosser behind.

Pure spirit extracts in great perfection all the aroma of the

the *rofemary*; but in diſtillation, it leaves ſo much behind, as that the reſinous maſs left upon abſtracting the ſpirit, proves an elegant aromatic, and very rich in the peculiar qualities of the plant.

Aqueous liquors extract a uſeful portion of the virtues of *roſemary* by infuſion, and elevate them by diſtillation. Along with the water ariſes a conſiderable quantity of eſſential oil, which is light, thin, pale, and almoſt colourleſs; it hath a caſt of a green and yellow.

See Tournefort's Mat. Med. Lewis's Mat. Med. Neumann's Chem. Works.

ROS SOLIS, alſo called roſa ſolis, rorella, ſponſa ſolis, rorida. Red rot, Sun dew. It is a ſmall low plant, with a little fibrous root, from which ſpring ſmall, round, hollowiſh leaves, on foot-ſtalks of about an inch long, covered with ſhort red hairs, which makes the whole leaf appear red. It grows in boggy ground, and flowers in June and July. Some commend it as a cordial, but it is injurious to cattle if they happen to eat it, and is very cauſtic, ſo it hitherto hath not obtained a place in practice. See Raii Hiſt.

ROSTRUM LEPORINUM. The piece of fleſh which hangs betwixt the diviſion of the hare-lip. The hare's-lip is alſo thus named.

ROTATOR MINOR. The leſſer trochanter.

ROTATOR MAJOR. The greater trochanter.

ROTATOR NATIS. The great trochanter.

ROTULA In anatomy it is the knee-pan. In pharmacy it is a troche. It ſignifies a little wheel.

ROTUNDA LIGAMENTA. The round ligaments. On each ſide of the womb there is one; they are two vaſcular ropes, compoſed of arteries and veins, lymphatics, and nerves, and ariſing from the fundus uteri, run under the duplicature of the broad ligaments to the rings of the abdominal muſcles, and paſſing under Poupart's ligament, are loſt on the crural veſſels &c. or vice verſa, ariſing from the crural veſſels, &c. are loſt on the fundus uteri. They run in a contorted form, and thus are capable of being lengthened. It is probable that the nerves of theſe ligaments being compreſſed in time of labour between the uterus and abdominal muſcles, cauſe the pain which the patient feels and complains of in the inſide of her thighs.

ROTUNDUS MUSCULUS. The round muſcle.

RUBEOLA. The meaſles. See MORBILLI.

RUBIA, alſo called rubia tinctorum, Linn. Erythrodanum, rubia major. Madder. Rubia foliis annuis, caule aculeato, Linn. The root is called radix rubra.

It is a rough procumbent plant, with ſquare jointed ſtalks, and five or ſix oblong pointed leaves, ſet in form of a ſtar at every joint; on the tops come forth greeniſh yellow flowers, which are followed by two black berries. The root is long, ſlender, juicy, of a red colour both externally and internally, with a whitiſh woody pith in the middle. It is perennial, and cultivated in different parts of Europe for the uſe of dyers.

The roots are bitteriſh, and ſomewhat auſtere; they have but very little ſmell. They impart to water a dark red tincture; to rectified ſpirit and diſtilled oils a bright red. Both the watery and the ſpirituous tinctures taſte ſtrongly of the madder. Taken internally it tinges the urine red; and if fowls, &c. have it mixed with their food, their bones becomes red and brittle, but the fleſh and the cartilages are no way affected by it. The bones thus tinged preſerve their colour, though boiled in water, or ſteeped in ſpirit of wine. The ſubtil parts of which this root is poſſeſſed, render it eminently uſeful as a reſolvent and aperient in obſtructions of the viſcera, particularly the urinary organs; in coagulations of blood from falls; in the jaundice, and in the dropſy. It paſſes freely by urine.

RUBIA SYLVATICA LÆVIS, alſo called gallium, mollugo, and mountain wild madder. Its virtues are ſimilar to the above kind.

RUBIA SYNANCHICA, called alſo rubeola, ſynanchica Lugdunenſis, aſperula, ſaxifraga, and ſquinancywort. It hath a black, thick, woody root, which runs deep into the earth, with many capillary fibrils, divided into a multitude of heads, and ſhoots up many ſmooth, ſlender, ungulous ſtalks, a ſpan long or more; at every joint of the ſtalk are four leaves, which are ſhort and broad; the flowers are on the top of the ſtalks and branches, and form umbels of a red colour, and agreeable ſmell, like that of the jaſmine; each flower is followed by two ſeeds, which are rough, and when dry of a yellow colour.

It is found on chalky grounds, and is ſaid to be of uſe in quincies, but the preſent practice does not own it.

RUBIA. A name of the rubiola, for a ſpecies of croſswort, and a ſpecies of horſe-tail.

RUBRICA FABRILIS. Red oker, ruddle, marking ſtone. See OCHRA.

RUBUS IDÆUS. The raſberry.

RUBUS VULGARIS. The common bramble or black berry-buſh. Rubus fruticoſus, Linn. It grows wild in hedges and in woods. The berries have a faint taſte, with an agreeable flavour. The leaves are moderately aſtringent. The flowers appear in July, and the fruit is ripe in Auguſt and September; but no part of this buſh, or its productions, are under the preſent practice.

RUCTATIO, or Ructus. A diſcharging of wind upwards. When a diſeaſe it is an inſtance of diſpepſia, and is better relieved by means that help digeſtion, than by ſpirituous liquors, and warm carminatives.

RUDII EXTRACTUM, i. e. Extr. cathartieum.

RUPELLENSIS SAL. It is alſo called ſel de ſeignette, and Rochel ſalt. It is a ſoluble tartar, made with the mineral fixed alkaline ſalt after its being melted by the heat of the fire, by which it forms more eaſily into cryſtals. ʒ vi. of this ſalt is a gentle cooling purge.

RUPTURA. A rupture. The word hernia is tranſlated by the Engliſh word rupture, (ſee HERNIA;) but this tranſlation was in conſequence of the idea that the peritoneum was ruptured when the abdominal contents protruded through the teguments. The word *ruptura* or *rupture*, is moſt properly ſpoken of a cartilage, a ligament, or a tendon; when they are divided by violence, then a ſpecies of wound is produced, viz. the lacerated.

RUSCUS, alſo called bruſcus, oxymyrſine, myrtacantha, myacantha, ſcopa regia. Wild myrtle, knee holly, butcher's broom. It is the ruſcus aculeatus, Linn. It is a low woody plant, with oblong ſtiff prickly leaves joined immediately to the ſtalks; from the middle ribs of the leaves on the upper ſide iſſue ſmall yellowiſh flowers, which are ſucceeded by red berries. The root is pretty thick, knotty, furniſhed with long fibres matted together, of a pale browniſh colour on the outſide, and white within. It grows wild in woods and heaths, is perennial and ever-green; it flowers in May, and its berries open in Auguſt. The root taſtes ſweet, and is ſlightly bitter; it is aperient and diuretic; its virtues are extracted by water and ſpirit; and on inſpiſſating the tincture, they remain entire behind. The young ſhoots are moſt powerful, and are eaten inſtead of aſparagus. See Miller's Bot. Off.

RUSCUS LATIFOLIUS, called alſo laurus Alexandrina, Alexandrina genuina, hippogloſſum. Laurel of Alexandria.

The root of this plant is knotted at the head; the ſtalks are tough and pliant; the leaves are placed alternately; on the middle of the back part of each grows a ſmall moſſy flower, which is ſucceeded by a red berry. This plant grows on the mountainous parts of Italy and Hungary. It is diuretic. See Miller's Bot. Off.

RUTA. Rue. Ruta graveolens, or ruta ſylveſtris major, fol. decompoſitis, petalis laceris, floribus lateralibus quadrifidis, Linn. Large wild rue. It is a ſmall ſhrubby plant, with thick bluiſh green leaves, divided into numerous roundiſh ſegments; on the tops of the branches come forth yellowiſh flowers, followed each by a capſule, which is divided into four partitions full of ſmall, blackiſh, rough ſeeds. It is cultivated in gardens, flowers in June, and holds its leaves all the winter.

Rue hath a ſtrong unpleaſant ſmell, and a penetrating pungent bitter taſte; if much handled it is apt to inflame and exulcerate the ſkin. It is commended as a powerful ſtimulant, aperient, antiſeptic, and as being in ſome degree antiſpaſmodic. In crudities and indigeſtion, for preſerving againſt contagious diſeaſes, and the ill effects of corrupted air, in uterine obſtructions, and hyſteric diſeaſes, its efficacy is conſiderable. It is uſeful in cold phlegmatic habits, for it quickens the circulation, diſſolves tenacious juices, and promotes the fluid ſecretions.

A conſerve

Externally it is discutient and antiseptic, if applied by way of fomentation.

A conserve is made of the young leaves, and this is the most agreeable method of giving it inwardly.

Its virtues are extracted by water and by spirit of wine, but most perfectly by the latter. On inspissating the spirituous tincture, very little of its flavour arises with the menstruum, nearly all the active parts of the *rue* remaining in the extract, which impresses the palate with a warm, subtil, durable pungency, and in smell it is rather less unpleasant than the herb in substance. Next to the conserve this is the best preparation of *rue*. Though the principal virtues reside in the essential oil, yet this oil not being very volatile, it resides in the extract.

Distilled with water, a yellowish, or brownish essential oil is obtained: and if the liquor which remains in the still is inspissated by evaporation, a warm, pungent, bitterish extract is obtained.

When *rue* leaves are distilled for their essential oil, they should be used whilst fresh, should be gathered when the flowers are ready to fall off, and as the seeds and their capsules contain more oil than the leaves, they should be gathered and distilled also. They all require to be macerated some time before they are distilled.

See Tournefort's Mat. Med. Neumann's Chem. Works, Lewis's Mat. Med.

RUYSCHIANA TUNICA. See CHOROIDES.

RYTHMUS, from *ῥυθμος*, *measure*, a term used by musicians. A term used by musicians with respect to time in music; but since Herophilus applied it to the pulse, it is used to express the time, motion, or modulation of the pulse.

S.

SABADILLA, i. e. Cevadilla.

SABINA, also called savina, sabina sterilis, common or barren savine. It is the juniperus sabina, or juniperus fol. oppositis erectis decurrentibus oppositinibus pyxidatis, ramis serratulis, Linn. Common savin. It is an evergreen shrub, with short narrow leaves, which are so stiff as to be prickly: when old, and not till then, it bears blackish berries, like those of the juniper. It is a native of the southern parts of Europe, and is raised with us in gardens. The leaves and tops have a strong smell of a disagreeable kind; of a hot, bitter, acrid taste. They give out great part of their active matter to watery liquors, and the whole to rectified spirit. Distilled with water they yield much essential oil, which smells strongly and tastes moderately of the savin: its dose is from two to four drops.

The decoction which remains after distilling for the oil, yields an extract, which retains much of the pungency, warmth, and bitterness of the plant. On inspissating the spirituous tincture there remains an extract consisting of two distinct substances; one is yellow, unctuous, or oily, bitterish, and pungent; the other is black, resinous, tenacious, less pungent, and sub-astringent.

Savin is stimulant and aperient, useful in uterine obstructions which proceed from a sluggishness of the humours and a laxity of the vessels. The oil impregnates the urine with its smell. *Savin* promotes all the glandular secretions. See Lewis's Mat. Med.

SABINA. A name for some species of cedar.

SACCHARUM. Sugar. The Arabians call it suchar, succhar, sutter, zuchar, zuccara, and zozar; the Greeks called it sakchar, sakchari, salcharion, and spodion. It is the saccharum officinarum. Linn.

Sugar is the essential salt of the sugar cane, or of whatever vegetable it is obtained from. It is chiefly the produce of the arundo saccharifera C. B. which grows spontaneously in the East Indies and some of the warmer parts of the West, and is cultivated in many of the American islands: the best canes grow in the Canary and Madeira islands. The expressed juice of the cane is clarified with the addition of lime-water, &c. and boiled down to a thick consistence; it is then removed from the fire, and then the saccharine part concretes into brown coloured masses: this is the saccharum rubrum of the Pharm. Lond. and Edinb. It leaves an unctuous liquor, called melazzo or molasses, from its being of an honey-like consistence, and with us it is called treacle. This red sugar is clarified in conical moulds, by spreading on the upper broad surface some moist clay, whose watery part gently percolating through the mass, carries with it a large portion of the treacly matter. This is further refined by dissolving it in water and mixing it with the whites of eggs, then draining off the water, and covering it with clay again in the moulds: this is the sacchar. alb. Ph. Edinb. This process again repeated, it is the sacchar. purissim. Ph. Lond. Brown sugar boiled to a proper consistence, is placed in a hot room to shoot into crystals upon sticks placed for the purpose, and it is then called saccharum candidum in the Pharm. Edinb.

By the assistance of heat *sugar* dissolves in rectified spirit of wine, but the greatest part separates when cold, and concretes into a crystalline form. On this foundation saccharine concretions are obtained from saturated spirituous tinctures of several of the sweet plants of our own growth, the saccharine part separating when the tincture is set in the cold, whilst the resinous and other matter separated from the plant remains in the spirit.

On all trials hitherto made, *sugar* appears to be perfectly neutral, and unites with most kinds of humid bodies without altering their native qualities. It serves as an intermedium for uniting together some bodies naturally repugnant; in consequence of this property it is supposed to unite the unctuous part of our food with our juices. Hence some conclude that it increases fatness, whilst others say it hath the contrary effect, by preventing the separation of the oily matter from the blood. Neumann observes, that he hath known very lean people who have eaten great quantities of sugar. Some say that it thickens the juices, and makes them sluggish; that it retards the circulation, obstructs the natural secretions, and thus occasions or aggravates scorbutic, cachectic, hypochondriac, and other disorders; but general experience does not manifest that *sugar* produces any of these effects in a remarkable degree. Its moderate use is innocent, and perhaps, of all others, it is the most inoffensive of the sweets.

Sugar preserves both animal and vegetable substances from putrefaction, and appears to possess this power in a much greater degree than the common alimentary salt. Animal flesh hath been preserved by sugar more than three years from every degree of being tainted or putrified. The impure brown *sugars* are most laxative, in consequence of their oily or treacly matter. The candied sugar dissolving with difficulty, renders it more fit for gradually melting in the mouth to moderate coughs. In other respects, its principal use is to render other medicines more palatable, or to give them a proper form. See Neumann's Chem. Works; Lewis's Mat. Med.

SACCULI ADIPOSI. The cells of the cellular membrane filled with fat.

SACCULUS CHYLIFERUS, i. e. Receptaculum chyli.

SACCULUS CORDIS, i. e. Pericardium.

SACCULUS LACHRYMALIS. The lachrymal ſac is an oblong membranous bag, by which the tears are conveyed from the ſurface of the eye to the noſtril, on each ſide reſpectively. It receives the tears at the lachrymal points, from whence it conveys them to the os turbinatum inferius, where it opens into the noſtril. The body of the bag is in the grooves of the os unguis, and os maxillare, which form the paſſage.

SACCUS. The inteſtinum cæcum.

SACER IGNIS. The eryſipelas.

SACER MORBUS. The epilepſy.

SACER MUSCULUS. Winſlow calls this muſcle tranſverſo ſpinalis lumborum. It is compoſed of ſeveral oblique, converging, or tranſverſo ſpinal muſcles; and it lies between the ſpinal and oblique apophyſes of the loins, reaching to the os ſacrum. The loweſt is fixed to the upper lateral parts of the os ſacrum, and to the poſterior ſuperior ſpine of the os ilium; the reſt are fixed to the three loweſt tranſverſe apophyſes, and to the four loweſt oblique apophyſes of the loins, and their lateral tuberoſities, from thence they run up to all the ſpinal apophyſes of the vertebræ.

SACRA HERBA, i. e. Verbena.

SACRA VASA. The veſſels which belong to the os ſacrum and the adjacent parts, as the arteries and veins.

SACRA ARTERIA. It goes out from the back part of the aorta, at the bifurcation, on each ſide reſpectively. Sometimes they take their riſe ſomewhat higher from the lumbares, or from the iliacæ. Sometimes there are three or four of them, and ſometimes but one. They are ramified on the os ſacrum and the neighbouring parts of the peritoneum, rectum, fat, &c. and alſo penetrate into the ſubſtance of the bone.

SACRA VENA. It ſometimes proceeds from the bifurcation of the vena cava, at others from the origin of the left iliaca, and accompanies the artery of the ſame name.

SACRO LUMBARIS, called alſo ſacro lumbalis. This muſcle is one with the longiſſimus dorſi at its origin, but ſoon divides, and is inſerted by digitations into the angle of every rib. The uppermoſt tendon is inſerted into the tranſverſe proceſs of the laſt cervical vertebra.

SACRO LUMBARIS, (Accessorius) called alſo acceſſorius ad ſacro lumbalem, acceſſorius ad ſacro lumbares, cervicales deſcendens, and cervicalis dorſi. It is a continuation of the cervicalis dorſi; it lies on the outſide of the complexus, and coming down from the tranſverſe proceſſes of the lower vertebræ colli, is continued down under the ſacro lumbaris to the ribs, which it depreſſes, as well as the ſacro lumbaris.

SACRI NERVI. Five or ſix branches of nerves from the ſpine paſs through the os ſacrum, whence their name. The three firſt join the fourth and fifth lumbar nerves to form the ſciatic nerve. The third ſacral nerve gives ſome branches to the pelvis.

SACRO COCCYGÆUS, i. e. Coccygæus poſterior.

SACRUM OS. This bone is thus named from its having been offered in ſacrifices. Some call it os baſillare, from its being, as it were, the ſupport of the whole ſpine. This bone is of a ſomewhat triangular ſhape, broad above, narrow below, convex behind, and concave before. In the fœtus ſtate it conſiſts of five diſtinct bones, but in adults they are united into one. On the outſide there is a ridge, which is called the ſpine. On the fore part there are four pair of holes for the tranſmiſſion of the nerves. This bone is connected with the oſſa innominata by ſynchondroſis, and forms the poſterior part of the pelvis. Below, the os ſacrum is connected with the os coccygis.

SAGAPENUM, alſo called ſerapinum, gum ſagapen. It is the gummy reſinous juice of an oriental plant, ſuppoſed to be a ſpecies of ferula. It is brought from Alexandria either in diſtinct tears, or run together in large maſſes; outwardly it is of a yellow colour, internally it is paler, and clear like horn. It grows ſoft on being handled, ſo as to ſtick to the fingers. Sometimes pieces of bdellium are ſold for it, but they may be diſtinguiſhed by their weaker ſmell. The ſmell of *ſagapenum* is ſtrong and diſagreeable, like that of the leek, or of a mixture of aſſafetida and galbanum. To the taſte it is moderately hot and biting. It is one of the ſtrongeſt of the deobſtruent gums. As an alterative it may be given from gr. iii. to 3 ſs. and a purge 3 i. muſt be given for a doſe. It is generally uſed as an aperient, an expectorant, or a deobſtruent. Neumann ſays it is uſed in the ſame caſes as is the ammoniacum. Boiling water diſſolves about 3-4ths of this gummy reſin. Rectified ſpirit takes up about one half. Water brings over with it in diſtillation much of the flavour of the ſagapenum, and a ſmall portion of eſſential oil, but the diſtilled ſpirit is moſt flavourleſs. See Lewis's Mat. Med. Neumann's Chem. Works; Tournefort's Mat. Med.

SAGITTA. Arrow-head. At firſt the leaves of this plant reſemble thoſe of plantane, but afterwards the bearded head of an arrow; the fruit conſiſts of a collection of ſeeds like the ſtrawberry. It is ſaid to poſſeſs ſimilar virtues with the plantane, but it is rarely uſed.

SAGITTALIS SUTURA. The ſagittal future. It runs from the os frontis to the os occipitis, betwixt the parietal bones.

SAGITTARIA. A ſpecies of ſagitta.

SAGITTARIA ALEXIPHARMICA, alſo called canna Indica, arundo Indica, arrow root, dart wort. The root is alexipharmic, and is uſed by the Indians to remove the poiſon which they receive from darts when wounded by them. It is found in the Weſt-Indian iſlands, and is two or three inches long, as thick as a man's thumb, jointed and white. See Raii Hiſt.

SAGO. See Palma.

SAL. Salt. It is a body that is more or leſs hard, having a remarkable ſavoury taſte, is entirely ſoluble in water, and does not precipitate, unleſs there is more than the water can diſſolve; or, as Geoffroy defines it, "It is a ſolid, friable, pellucid, ſapid, mineral body, ſoluble in water, fuſible by fire, and concreſcible into the form of cryſtals." This definition agrees with ſea-ſalt, nitre, vitriol, alum, borax, and ſal ammoniac. Salts are natural or ſimple, and artificial or compound. The ſimple are the acid and alkaline; the compound the neutral, metallic, and earthy; of the acid kind there are the vitriolic, nitrous, muriatic, vegetable, animal, &c. of the alkaline there are the fixed, both vegetable and foſſil; and the volatile, which laſt are chiefly from animal ſubſtances; they are very rarely found in the mineral kingdom. See Tournefort's Mat. Med. Lewis's Mat. Med. Dict. of Chem. Neumann's Chem. Works; and ſee Chrystallizatio.

SALEP. See Orchis.

SALICARIA. Spiked willow. Boerhaave mentions four ſpecies, which are admired for the beauty of their flowers, but are not noticed in medicine.

SALIVA, from *σιαλος*. It is that fluid by which the mouth and tongue are continually moiſtened in their natural ſtate, and is ſupplied by glands which form it, that are called ſalivary glands. This humour is thin and pellucid, incapable of being concreted by the fire, almoſt without taſte and ſmell. By chewing, it is expreſſed from the glands which ſeparate it from the blood, and is intimately mixed with our food, the digeſtion of which it greatly promotes. In hungry perſons it is acrid and copiouſly diſcharged; and in thoſe who have faſted long it is highly acrid, penetrating, and reſolvent. A too copious evacuation of it produces thirſt, loſs of appetite, bad digeſtion, and an atrophy. See Haller's Phyſiology in the article of Maſtication; Boerhaave's Inſtitutes; Fordyce's Elements, part 1, p. 23.

SALIVALES GLANDULÆ. The ſalivary glands. They are commonly reckoned three pair, viz. the parotid, the maxillary, and the ſublingual; but Dr. Hunter would reckon the ſublingual of another kind.

SALIVALIS DUCTUS STENONIS. Steno's ſalival duct. It is alſo called the upper ſalival duct. It is the duct which carries the ſaliva from the protid gland into the mouth.

SALIVANTIA. Medicines which excite a ſalivation.

SALIVARIS HERBA. The pellitory of Spain.

SALIVATIO. A ſalivation. It is that extraordinary diſcharge of ſpitting which is excited by the uſe of mercury; a practice which is now rarely directed, becauſe all the advantages of mercury are obtained by uſing it as an alterative; and that without the trouble and danger which attends this method of promoting an evacuation by it. However, as occaſionally it may be needful to excite a gentle ſpitting, in general it is beſt done by rubbing a proper quantity of the ungt. cœrul. every or every other night on the thighs. Mr. Clare recommends the application of merc. dulc. gr. iii. vel iv. to the inſide of the cheek; he directs the patient to moiſten his finger with ſaliva, then therewith to take up the merc. dulc. and rub it on and around that place where the parotid (ſalivary) duct opens into the mouth. He adds that, a grain or two of the merc. dulc. applied behind the præputium, or to the labia, will, when accompanying the application of it to the inſide of the cheek, greatly advance the cure. This muſt be repeated every or every other day as its efficacy is more or leſs. This mode, he obſerves, is leſs diſagreeable than the uſual one of rubbing the ungt. cœrul. as is commonly directed. Before the uſe of the merc. dulc. it is proper to waſh the mouth well with warm water, that the mucus ſpread about on the cheeks may not prevent its abſorption. See an Eſſay on the Cure of Abſceſſes, &c. by P. Clare, Surgeon. Mr. Cruikſhank hath added an Appendix to Mr. Clare's publication, well deſerving the attention of every practitioner. The following are ſome of the many valuable inſtances of information communicated in a few pages. He obſerves, that there is no doubt of abſorption taking place on the inſide of the mouth, of the præputium, of the labia, &c. and that any fine powder, capable of being abſorbed there, will be more readily taken up when mixed with a watery fluid, as ſaliva —The particles of the blood, ſeen in the ſimple microſcope, are at leaſt ten times larger than thoſe of the levigated calomel, yet I have often ſeen the abſorbents turgid with red blood. The particles of quickſilver, in the beſt prepared mercurial ointment, are, in the ſame microſcope, as diſtant as the particles of the blood; and it is well known, they are very readily taken up by the abſorbents of the ſkin.—The particles of levigated calomel are not much coarſer than thoſe of its precipitate by the volatile alkali; but this precipitate, we are certain, may be abſorbed from the external ſurface of the body; why then may not calomel be abſorbed from the inſide of the mouth? Mr. Hunter hath frequently directed merc. dulc. to be rubbed on the ſkin along with the volatile liniment; and ſeen it have the effects of the ungt. cœrul. It is very probable that the merc. dulc. mixed with ſaliva might make a good mercurial ointment. The ſurface on the inſide of the cheek, is a better abſorbing ſurface, than perhaps any other acceſſible to friction in the body. Though every ſurface abſorbs, they do not all abſorb equally. Merc. dulc. taken into the ſtomach frequently gripes, &c. but this effect is not obſerved when it is abſorbed by the inſide of the cheek: probably it becomes milder in its operation this way, as it is known that the divided quickſilver becomes milder when abſorbed by the ſkin. Friction with merc. dulc. on the inſide of the cheek, is a leſs tedious, leſs laborious proceſs, than the common one of rubbing the ungt. cœrul. To rub half a dram of the ungt. cœrul. every night on the inſide of the thighs for half an hour, is almoſt intolerable; but what then muſt it be to rub on a larger quantity? The proceſs always tires the patient before it is half performed, and often on this account he omits it. From this circumſtance a cure is often miſſed of. Let us ſuppoſe fifteen grains of the ungt. cœrul. equal to one grain of merc. dulc. and that we can go on with the merc. dulc. for twelve or fifteen days with ſenſible advantage: we muſt acknowledge that when the ungt. is uſed, it becomes neceſſary long before the end of this period to increaſe the doſe, in order to keep up the effects. Beſides, the ungt. being more viſcid than the merc. dulc. mixed with ſaliva, will require a larger ſurface and a longer time before it can be ſufficiently rubbed in. The merc dulc. is ſufficiently rubbed in in a quarter of an hour. The friction of the ungt. cœrul. on the thighs and arms makes the ſkin look dirty. It hath an offenſive odour whilſt it is rubbed; as it is greaſy, it does not rub in ſo as to be dry, and thence the ſkin is clammy, and ſticks to every thing about it; many ſkins are inflamed by it, which retards the cure this way, by being a cauſe for its omiſſion. Some ſkins are diſagreeably affected with oil, ſo when the merc. dulc. is not admitted as above recommended, the quickſilver may be divided with the ſynovia of cows or ſheep inſtead of oil or lard, which in ſome ſkins produce eryſipelatous inflammation, &c. It is probable that affecting the glands on the mouth with mercury conduces more to cure the venereal diſeaſe, than a large quantity conveyed into the circulation. A warm bath may be entered into two or three times before anointing with the ungt. cœrul. after which, the patient being kept in a warm room, and having on a flannel ſhirt, the principal care is not to raiſe the *ſalivation* ſuddenly, or to any conſiderable height. A *ſalivation* ſhould riſe very gradually, and ſhould ſubſide as ſlowly; inattention to this hath been productive of many inconveniences. The body ſhould be prepared by a ſpare diet for a few days, and bleeding as well as uſing the warm bath. Except in ſtrong conſtitutions, from a pint to a quart is a ſufficient diſcharge of the ſaliva in twenty-four hours. Support the patient's ſtrength with plenty of light but nouriſhing diet; give him a pint of gruel, or of a decoction of mallows and liquorice in milk and water, almond emulſion, and barley-water, with gum arabic diſſolved in it, &c. repeat the above quantity every two or at the moſt every three hours; and if he is faint with it, give now and then a little wine whey, maced ale, or mulled wine. If the patient is a woman, and expects her menſes, defer the procedure until they ſettle. If the neceſſary precautions are taken to raiſe and to carry the *ſalivation* on gently, the many bad accidents mentioned by writers on this ſubject will be prevented; and as to avoid inconveniences is better than to remove them, it may here ſuffice to have put the practitioner on his guard againſt ills which otherwiſe muſt occaſion him much trouble and anxiety.

SALIX. The common white or the Dutch willow tree. It is not noticed in general practice; but ſome who have uſed it in agues have ſucceeded by giving a dram of its bark in powder, and repeating it every four hours during the intermiſſions. This ſpecies is diſtinguiſhed from the other by its oblong, pointed, ſerrated leaves, being hoary on both ſides, though moſt ſo on the lower, and in the branches being tough. See Raii Hiſt. Plant. Philoſ. Tranſ 1763. It is the *ſalix* fragilis, Linn.

SALPINGO PHARYNGÆUS. It ariſes from about the tuba Euſtachiana, and is inſerted into the pharynx. Valſalva and Douglas ſay it is one of the origins of the muſcle of the pharynx.

SALPINGO STAPHYLINUS. This muſcle ariſes fleſhy from the bony part of the tube of the ear, and is inſerted into the baſis of the uvula with its partner muſcle on the other ſide. They draw the uvula upward and backward.

SALPINGO STAPHYLINI INTERNI. See PETRO SALPINGO STAPHYLINI.

SALSAPARILLA, i. e. Sarſaparilla.

SALVATELLA VENA, from *ſalus*, *health*, becauſe it hath been thought that to open this vein, melancholy was cured. This vein runs on the back of the hand; it comes from the little finger and that next to it; or, according to ſome, it proceeds from betwixt the thumb and the fore finger, and runs up to the ulna.

SALVIA, from *ſalvus*, *ſound* or *healthy*. Sage. Botaniſts enumerate more than twenty ſpecies. It is a low ſhrubby plant, with ſquare ſtalks, obtuſe, wrinkled, dry leaves, and large bluiſh flowers, which are on looſe ſpikes on the tops of the branches. It is a native of the ſouthern parts of Europe, but bears the cold of our clime. It flowers in May and June.

SALVIA MAJOR. Greater or common garden ſage. It is the *ſalvia* officinalis, or *ſalvia major*, foliis lanceolato-ovatis integris crenulatis, floribus ſpicatis cœruleis, calycibus acutis, Linn. Common green *ſage*. The leaves are nearly oval, but pointed; ſome are green, others red, but both ſorts are on the ſame plant. The leaves and tops are moderately aromatic and corroborant, and are uſed in debilities and relaxations both of the nervous and vaſcular ſyſtem. From 3 ſs. to 3 i of a conſerve made with them cures weak ſtomachs, if repeated twice a day. Their ſmell is ſtrong, but not diſagreeable; their taſte is warm, biteriſh, and ſub-aſtringent; with a ſolution of chalybeate vitriol

vitriol they ſtrike an inky blackneſs. This ſpecies is more agreeable, but not ſo ſtrong as the leſſer *ſage*. The flowers of both are weaker but more agreeable than their leaves. The beſt preparations are, the watery infuſion, and a tincture or extract, made with rectified ſpirit of wine; theſe contain the whole virtue of the *ſage*. The watery infuſion, acidulated with the juice of lemon or of orange, is an agreeable common drink in fevers. By diſtillation with water a ſmall quantity of eſſential oil is obtained, which only poſſeſſeth the aromatic part of the herb. See Tournefort's Mat. Med. Lewis's Mat. Med.

SALVIA MINOR, alſo called ſalvia virtutis. Leſſer ſage, or ſage of virtue. *Salvia* auriculata, or *ſalvia minor* aurita, & non aurita, Linn. *Sage of virtue*. Its leaves are narrower than thoſe of the greater *ſage*, whitiſh, and never red: they are ſtronger, but not ſo agreeable as the above ſpecies, but in other reſpects their qualities are the ſame.

SALVIA SYLVESTRIS, alſo called ſcorodonia, ſcordium, ſcordotis. Germander ſage. Wood ſage. Teucrium *ſcorodonia*, or teucrium *ſylveſtre*, foliis cordatis ſerratis petiolatis racemis lateralibus ſecundis, floribus herbaceis, Linn. It grows in woods and hedges. In ſmell, taſte, and medical virtues, it comes nearer to *ſcordium* than to *ſage*; it is leſs diſagreeable than the former, and more ſo than the latter.

Among the ſpecies of *ſage* is the phlomis, or yellow *ſage*. Boerhaave reckons up eight ſpecies of it. It is aſtringent and vulnerary.

SALVIA VITÆ, i. e. Ruta muraria.

SAMBUCUS, alſo called acte. Common elder. *Sambucus* nigra, or *ſambucus* cymis quinque partitis, floribus umbellatis, fructu in umbella nigra, caule arboreo. Linn. Common black berried *elder*. It is a tree or ſhrub whoſe branches are full of fungus; it is covered with an aſh-coloured chapt bark, under which lies a thinner green one, and under it a white one. It flowers in May, and ripens its berries in September.

The young leaves, when budding, are ſaid to purge. The bark is recommended as a ſtrong hydragogue. Sydenham directs three hands full of the inner bark to be boiled in a quart of milk and water to a pint, half of which is to be drank every night and morning: he ſays it operates upward and downward. Some confine theſe effects to the ebulus or dwarf *elder*; but they have both been uſed without any remarkable advantage. An infuſion of the freſh flowers is gently laxative, and of the dried ones is perſpirative. The juice of the berries, when inſpiſſated to a rob, is a good diſſolvent and aperient; in colds juſt received, it gently looſens the belly and promotes urine, or perſpiration, or both. See Lewis's Mat. Med. Anatomia Sambuci per M. Blockwitz.

SANCTÆ HELENÆ [RAD.] It is a long knotted root, black without and white within; to the taſte it is like the galangal root. It is brought from St. Helena in the province of Florida. It is there uſed againſt pains in the ſtomach and in nephritic diſorders.

SANDARACHA. Sandarach. A name for a ſort of arſenic; alſo a gummy reſin, of a yellowiſh white colour, ſaid to flow from the cedrus Lycia major Dodon. It is in ſmall lumps, dry, brittle, of a pleaſant ſmell, of a reſinous and gently acrid taſte: it is brought from Africa. The gum of the juniper tree is generally ſold for it. See REALGAR.

SANGUIFLUXUS, i. e. hæmorrhagia.

SANGUINIS INOPIA. A tabes from loſs of blood. An inſtance of the atrophia inanitorum of Cullen.

SANGUIS. Blood. The fluid which is contained in the arteries and veins is called the *blood*. On a ſlight examination it may appear homogeneous, but it conſiſts of very diſſimilar parts. When *blood* is taken from the body immediately it loſes its volatile part, which flies off in the form of a vapour, and is of the nature of ſal ammoniac. When this vapour is diſſipated the remaining *blood* quickly congeals into a trembling maſs. The principal part of this coagulated maſs is in the craſſamentum, which hath the red colour to itſelf, and gives it to the other parts; when this craſſamentum is freed from its watery part, it is wholly inflammable. In a maſs of healthy human *blood* about one half is craſſamentum; in ſtrong laborious people the ſerum is not much more than one third part. The next part of the *blood* is the ſerum; from this is formed what is called the pleuritic cruſt on the ſurface of the *blood*, after taking it from a vein by the uſual method of bleeding; of this polypuſes and artificial membranes are alſo formed. In this ſerum, beſides the albumen, which hardens like the white of an egg, there is much water, and a ſmall quantity of ropy mucus. Beſides theſe parts, a portion of ſea-ſalt is found in the *blood*, and is manifeſt to the taſte, and oftentimes to the microſcope. By a chemical analyſis, a fine chalky earth is alſo found to exiſt in the moſt fluid parts of the *blood*; a portion of fixed air, to the amount of half a ſcruple in every ounce; and alſo a ſmall quantity of iron, which the loadſtone will attract. To theſe may be added the elementary fire.

The natural elements of the *blood* formed by the animal œconomy are, the albumen, and the globules. The albumen is the immediate matter of growth and nutrition. The globules never paſs the emunctories, except by exceſs or diſeaſe; as for the ſaline, acid, morbid, bilious, and other particles that are found in the circulating *blood*, they are rather heterogeneous than elementary parts of it.

In an healthy ſtate the *blood* is mild and gelatinous, but by ſome diſorders it is rendered very acrid.

On viewing the *blood* with a microſcope, whilſt it circulates in the veins, the globules are obſerved to be elaſtic, ſo as to change and recover their figure. Mr. Hewſon ſays that they are not ſpherical, but almoſt flat.

The uſe of the globules in the *blood* ſeems chiefly to be for the preſervation of heat in the body; and that of the ſerum for nutrition, and by the various ſecretions from it to moiſten the ſeveral ſurfaces in the body, to preſerve the flexibility of the ſolids, &c. A due proportion of the reſpective parts of the *blood* is neceſſary to health; a redundance of the globules diſpoſes to acute fevers, inflammations, &c. and their deficiency, to many chronical diſorders.

As to the red colour of the *blood*, Dr. Hunter thinks it is chiefly owing to the degree to which it is condenſed; but moſt writers attribute it to the acid to which it receives from the air in the lungs.

That life is a property of the *blood*, ſee what Mr. J. Hunter hath taught concerning it. And for an enlargement on what is ſaid above, beſides many other particulars reſpecting the *blood*, ſee Mr. Hewſon on the Properties of the *Blood*; Berdoe on the Nature and Circulation of the *Blood*; Fordyce's Elements, part 1; Haller's Phyſiology, in lect. vii.

SANGUIS DRACONIS, called alſo cinnabaris Græcorum. Dragon's blood. It is a reſin of a red colour, obtained from certain trees like palm-trees in the Eaſt-Indies. The Calamus var. Palmijuneus *Draco*. Rumph. Amb. lib. 7. t. 58. f. 1. & Linn. Sp. Pl. 463. The Calamus Rotang. Curtis's Cat. of the Lond. Bot. Garden. One ſort is in oval drops, wrapped up in flag leaves; another ſort is in large maſſes, which are often impure, but ſometimes as good as the firſt.

This reſin is of a deep red colour, and on being powdered is of a crimſon caſt. It readily melts, and catches a flame from a candle. It almoſt totally diſſolves by the help of heat in rectified ſpirit of wine, tinging a large quantity of this menſtrum of a deep red colour: it is ſoluble in expreſſed oils; but it gives out little or nothing to water. The beſt pieces break ſmooth, and free from viſible appearances; they have no remarkable ſmell or taſte, except when diſſolved, and then they ſeem to be ſomewhat acrid. The Dutch often adulterated this reſin with mixtures of gum arabic, Braſil wood, alum, &c. but theſe are diſcovered by their diſſolving in water, or by their crackling and not burning in the fire. It is not much uſed as a medicine, though it is recommended as a gentle incraſſant, deficcative, and reſtringent. See Lewis's Mat. Med.

SANICULA. Sanicle. It is ſo called from *ſanando*, *healing*.

SANICULA MAS, alſo called diapenſia, ſanicle, ſelf-heal. It is the *ſanicula* Europæa. Linn. It is an umbelliferous plant, with ſhining dark green, roundiſh, ſerrated leaves; the ſeeds are rough and ſtick to one's cloaths. It is perennial and ever-green: it grows wild in woods, on hilly grounds, and flowers in May. It is mildly aſtringent, taſtes roughiſh and bitter; and it hath an acrimony which

which chiefly affects the throat. Both the watery and ſpirituous extracts poſſeſs the virtues of this plant.

SANICULA EBORACENSIS, called alſo pinguicula, ſanicula montana flore calcari donato, viola paluſtris. Butter-wort, Yorkſhire ſanicle. It is the *pinguicula* vulgaris. Linn. It is a ſmall plant, with a few gloſſy unctuous leaves which lie on the ground. It is perennial, grows in elevated marſhy grounds, and flowers in ſpring. Its unctuous glutinous juice is uſed by ſome as a liniment for chaps, and as a pomatum for the hair: it is alſo purgative, but none of the *ſanicles* are much noted in general practice

SANIDODES, alſo, but improperly, Saniodes. Where the breaſt is ſtraitened or flattened like (σανίδος, the genitive caſe of σανις) *a table*. Flat cheſted.

SANTALUM. Saunders. There are three ſorts brought from the Eaſt Indies.

SANTALUM CITRINUM, alſo called ſantalum palidum. Yellow Saunders. *Santalum* album. Linn. It is a pale yellowiſh, or browniſh coloured wood, with a cloſe even grain, an agreeable ſmell, and a bitteriſh aromatic taſte, accompanied with a kind of pungency. Diſtilled with water, it affords an oil which thickens into the conſiſtence of a balſam, and ſmells like ambergriſe; the remaining decoction is bitteriſh. Rectified ſpirit extracts by digeſtion more than water does; and an extract from this tincture is ſix times ſtronger than the wood itſelf. Hoffman ſays its virtues are ſimilar to thoſe of ambergriſe. See SANTALUM ALBUM.

SANTALUM ALBUM. White Saunders. It is of the ſame nature as the yellow, but ſo weak that it is now neglected. The *ſantalum* citrinum, called *ſantalum album*, by Linnæus, is the medullary part of the ſame tree, of which the *ſantalum album* is the alburnum, or outward ſappy part.

SANTALUM RUBRUM. Red Saunders. Pterocarpus ſantolinus, vel pterocarpus foliis ternatis ſubrotundis retuſis glaberrimis petalis crenatis undulatis. Linn. This is of a dull red colour; it is ſaid to be aſtringent; it hath little or no ſmell, and as little taſte. It is chiefly uſed as a colouring drug; it tinges water with a yellowiſh hue, and rectified ſpirit with a deep red; but it does not diſſolve in expreſſed oil. See Lewis's Mat. Med.

SANTERNA. Borax.

SANTONICUM, alſo called ſem. cinæ, ſem. lumbricorum, ſemen ſanctum; ſem. zedoarie, ſementina, ſantolina, xantolina. Worm-ſeed. The plant from which theſe ſeeds are obtained is the artemiſia *ſantonicum*, or artemiſia abſinthium Siberienſis fruticoſa incana ramoſiſſima, linearibus breviſſimis obtuſiuſculis. Linn. In the Flora Auſtriaca, it is called artemiſia Auſtriaca. In Curtis Cat. of the Lond. Bot. Garden, it is called artemiſia Judaica. It is a ſmall, light, oval kind of *ſeed*, of a yellowiſh green colour, with a caſt of brown, eaſily friable. They are generally mixed with ſmall bits of ſticks and leaves. They are brought from the Levant, and are ſuppoſed to be the produce of a ſpecies of artemiſia. Miller ſays it is a ſpecies of wormwood. They have a ſtrong, and rather diſagreeable ſmell, and a bitter ſubacrid taſte, and are uſually employed for deſtroying worms in children. They give out their virtue to water and to ſpirit; the ſpirituous infuſion is the moſt agreeable. In evaporating the watery infuſion, all the ill-flavour is carried off, and only a ſimple bitter remains. As a bitter the watery extract is the beſt preparation; as an anthelmintic, the ſpirituous extract ſhould be preferred. Theſe *ſeeds* are ſeldom met with genuine; they are mixed with the *ſeeds* of ſouthern-wood. The marks of goodneſs are, their full body, their greeniſh colour, ſtrong ſmell, their bitter and aromatic taſte. See Lewis's Mat. Med. Neumann's Chem. Works.

SAPA, alſo called apochyliſma, ſuccago, robub. & rob. It is the juice of ſome vegetable boiled up with ſugar, or honey, into the conſiſtence of honey.

SAPHENA VENA MAJOR, ſo called becauſe it is almoſt σαφὴς, i. e. *viſible*. About an inch below the paſſage of the cruralis from out of the abdomen, it ſends off a large branch, called ſaphena; in all its courſe down to the foot, it is only covered with the integuments. It follows the direction of the Sartorius muſcle, until it arrives at the inner condyle of the thigh-bone; it then runs on the inſide of the tibia, ſending off branches as it paſſes along; at the lower part of the tibia it ſends off a branch, which runs over the joint of the tarſus to the outer ankle. The extremity of the ſaphena paſſes on the foreſide of the inner ankle, and runs betwixt the firſt two metatarſal bones, towards the great toe.

SAPHENA MINOR VENA. It is a branch from the ſaphena major, and ſeparates from it ſoon after its paſſing from the inguen; it runs down below the ham, and communicates with ſaphena major. Another branch, which proceeds from the cruralis, a little above the ham is thus named; it runs to the outer ankle. Some call it *ſaphena* externa.

SAPHERA. Zaffer.

SAPIENTIÆ DENTES. The laſt of the molares are thus called; they do not appear until after puberty, and ſometimes not before the twenty-ſixth year.

SAPIENTIÆ OLEUM. Oil of bricks.

SAPO. Soap. It is a compoſition of oils and fats, with alkaline ſalts, ſo incorporated as to diſſolve together in water, into a milky ſemi-tranſparent liquid. *Soap* may alſo be formed by a combination of oil and acids.

SAPO ALBUS, alſo called ſapo Hiſpanicus. Hard, or Spaniſh ſoap. It is made in Spain, with olive oil and the Spaniſh barilla, by a like proceſs as is directed for the *ſoap* of almonds. *Soap* is an uſeful mixture with reſinous pills, for it renders them more eaſily ſoluble, and more perfectly miſcible with our fluids; it diſſolves mucous matter in the body, and ſo is uſeful to reſolve obſtructions. It acts in the primæ viæ, as well as in the remote and minute veſſels, and by diſlodging viſcid phlegm from the bowels. It alſo carries off and deſtroys worms, for which end it may be given either by the mouth or clyſter-wiſe. The aſcarides are ſometimes rooted by clyſters in which are a dram or two of *ſoap*. By the diſſolving quality of *ſoap* it alſo proves diuretic, and is uſeful in gravelly complaints by lubricating, as well as by its gentle ſtimulus.

The common ſoft *ſoaps* are ſo acrid, that they are only fit for external uſes. The whiteſt of them are made with tallow, fat, or coarſe oils, the blacker, or greener ſorts, are made of whale oil.

All theſe *ſoaps* diſſolve in water, but more plentifully in proof ſpirit; but thoſe ſpirits have a degree of acidity in them which occaſions a milky hue in the ſolutions of *ſoap*. This may be corrected, as obſerved by Geoffroy, who ſays, that twenty-eight parts of good proof ſpirit, with the addition of one part of ſalt of kali, will diſſolve ten parts of good *hard ſoap* into a perfect limpid liquor.

SAPO VOLATILIS. Volatile ſoap. Of this there are three kinds; one is compoſed of fixed alkalies and *volatile* oils; another of *volatile* alkalies and groſs oils; the third of ſalt and oil that are both *volatile*: but none of theſe compoſitions, in which either the alkali or the oil is *volatile*, are ſo ſaponaceous as thoſe in which they are both of the fixed kind. See Dict. of Chem. Neumann's Chem. Works; Lewis's Mat. Med.

SAPO VITRI, i. e. Magalaize.

SAPONACEÆ PILULÆ. See OPIUM.

SAPONACEUM LINIMENTUM. Saponaceus liniment. Take of the ſpirit of roſemary, a pint; of hard Spaniſh ſoap, three ounces; of camphor, one ounce. Digeſt the ſoap with the ſpirit until it is diſſolved; then add the camphor. This hath been called opodeldoc. It is in much eſteem for rubbing on parts affected with old pains, the rheumatiſm, &c.

SAPONARIA, alſo called ſtruthium, lanaria, lychnis ſylveſtris. Bruiſe-wort, ſoap wort. It is the *ſaponaria* officinalis. Linn.

It is a ſmooth herb, with plantane like leaves, and cluſters of red, purple, and whitiſh flowers; the root is long, ſlender, ſpreading to a great diſtance, of a browniſh colour on the outſide, and white within, with a yellowiſh fibre in the middle. It grows in moiſt grounds, and flowers in July.

This plant is called *ſaponaria*, becauſe its juice takes out greaſe from cloaths. The roots and leaves are glutinous and ſweet to the taſte, but in the roots there is alſo a ſlight pungency, and in the leaves a bitteriſhneſs. The ſoapy matter diſſolves either in water or in ſpirit of wine. The Germans uſe the root, and ſay it is preferable to the ſarſaparilla. M. Andry, M. D. of Paris, gives the inſpiſſated juice of the *ſaponaria* officinalis, with great ſuc-

teſs, in caſes of gonorrhœa. The patients take about half an ounce of this medicine daily; and in general a cure is effected in about a fortnight, without the aſſiſtance of any other remedy. And —— Segey, M. D. of Paris, hath ſucceeded with this plant in the moſt obſtinate caſes of lues venerea. He directs it in the following manner: R. rad. ſaponaria offic. ſicc. ℥ iſs. ſol. ejuſdem ſicc. ℥ ſs. coque in aq. pur. ℔ vj. ad iv. From two to four pints of this decoction are to be daily taken; and in bad caſes, the patient is to take at the ſame time the plant in powder, or in the form of an extract. This plant is alſo ſaid to be uſeful when applied externally to venereal ulcers, either in fomentation, or in a dry form, by ſprinkling it in powder over the ſores. See Lewis's Mat. Med. Neumann's Chem. Works.

SAPONARIÆ NUCULÆ, alſo called baccæ Bermudenſes. Soap berries, Bermudas berries. This is a ſpherical fruit about the ſize of a cherry. Its cortical part is yellow, gloſſy, and ſo tranſparent as to ſhew the ſpherical black part which rattles within, and which includes a white kernel. It is the produce of a ſmall tree in Jamaica, and other parts of the Weſt Indies. The kernel when ſteeped in water, raiſes a froth like ſoap ſuds.

Theſe *berries* are powerful in removing obſtructions in the liver and ſpleen; they mend an ill habit of body, and are a ſpecific in the chlorоſis; they help digeſtion. The beſt preparations are, a tincture made with white wine, a tincture in ſpirit, and the extract from the ſpirituous tincture. See Lewis's Mat. Med. Med. Muſ. vol. iii. p. 538.

SAPPHIRUS. The ſapphire. It is one of the precious ſtones, and is of a fine blue colour; but there are ſpecies that are white, &c. The beſt come near to diamonds in ſplendor, tranſparency, and hardneſs.

SARCOCELE, from *σαρξ*, *fleſh*, and *κηλη*, *a tumor*. It is a firm, fleſhy kind of enlargement of the teſticle, or the ſcirrhous teſticle. The *ſarcocele*, or hernia carnoſa, Mr Pott ſays, taken in a general ſenſe, means any induration or diſeaſed *fleſh*, though here confined to the teſticle; and further obſerves that the *ſarcocele*, which is diſtinguiſhed by the ancient writers into the *ſarcocele*, the hydro-*ſarcocele*, the ſcirrhus, the cancer, the caro adnata ad teſtam, and the caro adnata ad vata, are really little more than deſcriptions of different ſtates and circumſtances of the ſame diſeaſe. The caro adnata ad teſtam is a ſcirrhus begun in the epididymis. The caro adnata ad vaſa, is a ſcirrhus of the epididymis ſomewhat increaſed, when it ſeems as if it ſprung from the ſpermatic veſſels. The hydro-*ſarcocele* is when the teſticle is enlarged or hardened; there is alſo a palpable accumulation of fluid in the vaginal coat. The *ſarcocele* is a diſeaſe of the body of the teſticle; and, as the term implies, conſiſts, in general, in ſuch an alteration, made in the ſtructure of it, as produces a reſemblance to a hard fleſhy ſubſtance, inſtead of that fine ſoft, vaſcular texture, of which it is, in a natural and healthy ſtate, compoſed. Many paſs ſeveral years with this diſeaſe, under its moſt favourable appearances, and without encountering any of its worſt; but, on the other hand, there are many who, in a very ſhort time, run through all its ſtages. Sometimes the firſt appearance is a mere ſimple enlargement and induration of the body of the teſticle; void of pain, without inequality of ſurface, and producing no uneaſineſs, nor inconvenience, except what is occaſioned by its mere weight. And in ſome few inſtances it remains thus for a conſiderable time, without viſible or material alteration; but, in other inſtances, very ſoon after its appearance in this mild manner, it ſuddenly becomes unequal and knotty; and is attended with very acute pains, darting up to the loins and back; but ſtill remains entire; that is, it does not burſt through the integuments. In ſhort, ſuch is the variety of the appearances of this diſeaſe, that deſcription can hardly afford an adequate idea of it. Sometimes the diſorder ſeems to be merely local, that is, confined to the teſticle; at other times there is a pallid or leaden countenance, indigeſtion, nauſea, colic pains, ſudden purgings, &c. ſufficiently indicating a vitiated habit and diſeaſed viſcera. The progreſs alſo which it makes from the teſtis upward, is very uncertain; the diſeaſe affecting the ſpermatic proceſs, in ſome ſubjects, for a great length of time; while, in others, it totally ſpoils the teſticle very ſoon, and almoſt as ſoon ſeizes the ſpermatic cord.

Amongſt the miſtaken cauſes of a ſcirrhous teſticle, Mr. Pott reckons the hernia humoralis. He does not ſay that a *ſarcocele* never follows an hernia humoralis, but that it does not at any time neceſſarily cauſe or produce it. Mr. Bell, in his Syſtem of Surgery, ſays, that a hardened ſtate of the teſtis and epididymis, produced originally by a venereal taint, does in ſome inſtances degenerate into the worſt ſpecies of *ſarcocele*. However, in general, the hernia humoralis is one of the diſeaſes which ſhould be diſtinguiſhed from the *ſarcocele*. A quantity of water is ſometimes collected in the vaginal coat of a ſcirrhous teſtis, and ſome have ſuppoſed that this water renders the teſtis ſcirrhous; but this not being true, the hydrocele and the ſcirrhous teſticle ſhould alſo be diſtinguiſhed.

The only remedy from which any advantage is expected, is, the removal of the diſeaſed parts by extirpation. But before the operation is attempted, a conſideration of the manner of the *ſarcocele's* having been formed, and the ſtate of the ſpermatic cord from the ring to the teſticle, are objects of neceſſary conſideration. When it proceeds from a blow on the part, ſucceſs is more likely to follow, than when it is cauſed by a cancerous or ſtrumous acrimony attending on that gland; when theſe laſt are cauſes, they will generally be found to exiſt on other parts alſo; therefore though the diſeaſed teſticle be removed, yet from the ſame cauſe exiſting in the habit, other parts ſoon after become diſeaſed in the ſame manner. In ſtrumous habits the glands of the meſentery, the lymphatics, &c. are generally obſtructed; therefore external applications ſignify very little; but ſuch medicines muſt be uſed as firſt act on the primæ viæ, and then on the lymphatics; for in children they are ſeldom ſeen with this diſorder without an enlarged belly, which before any further attempts are made muſt be leſſened.

Mr. Pott obſerves, that ſome writers direct with reſpect to the ſpermatic cord as follows: firſt, if it is ſoft, and of its natural ſize, caſtration may be ſafely performed; which is right. Secondly, if it is much enlarged, the operation is not vindicable. But this is going too far; for though it may be conſiderably enlarged, yet if it has no unequal feel, is not painful, or manifeſts no tendency to ſcirrhus; its being enlarged is of no conſequence, for obſtruction in a diſeaſed gland will frequently occaſion an enlarged varicous ſtate of its veſſels. Lymphatics alſo, from the ſame cauſe, may be dilated or ruptured, which muſt conſequently occaſion an extravaſation in the cells of the ſpermatic proceſs, both which frequently happen in the *ſarcocele*, and muſt certainly give the ſpermatic cord an enlarged feel; but it is not either of them that can be the leaſt objection to the operation; the ſpermatic cord not being diſeaſed, only enlarged, which is a circumſtance worth regarding; for when it is only enlarged, the operation may be of uſe; but, when in an enlarged, ſcirrhous, painful ſtate, too high to be able to make a ligature fairly above the part diſeaſed, the operation can be of no uſe, but is moſt likely to prove fatal. Many adviſe to defer the operation until ſuch ſymptoms come on, as darting pains in the teſticles, pains in the loins, &c. which, in truth, inſtead of being a proper time, is too late, the ſpermatic proceſs becoming affected, when a teſticle is become truly ſcirrhous, ſo as never poſſibly after to be of any uſe to the patient. By carrying ſcirrhi too long, though at firſt the diſorder be local, a ſcirrhous habit will be brought on; for before the ſpermatic proceſs becomes affected with ſcirrhous teſticles, the patient's habit is often found affected, and he is attended with colicky pains, and other conſequent ſymptoms.

After a venereal gonorrhœa, Dr. Swediar obſerves, that from improper treatment it ſometimes happens that one or both teſticles grow hard, i. e. become ſcirrhous. In ſome of theſe inſtances the diſorder is accompanied with a ſenſation of a painful preſſure; but frequently without any pain at all. He adds, that, in theſe caſes, mercury given internally, or rubbed in externally, into the perinæum and ſcrotum, twice a day, with the conſtant application of a warm poultice made of the root of atropa mandragora, Linn. are often uſeful. Alſo that the cicuta, applied internally and externally, may be tried, with

proſpect

proſpect of advantage. An emetic has been ſometimes found effectual. The decoction of the bark of the root of Daphne Mezereum, Linn. internally, and a poultice of it externally, has lately been very much recommended; but whatever means are uſed, it too generally happens that theſe ſwellings remain unaffected, except we can bring on the running again from the urethra; one method of effecting which, is to inoculate the venereal virus by means of a bougie introduced a little way into the urethra. However the ſingularity of this laſt propoſition may ſtrike, Dr. Swediar aſſures us, that ſucceſs hath followed ſuch practice: and we have only to conſider, that an undoubted authority bids us to chuſe the leaſt evil of two that preſent or attend. Mr. Bell ſays that, when a hardneſs of the teſticle does not yield to the means commonly employed, ſuch as moderate evacuations of blood, when theſe are indicated; a ſoft eaſy diet; a lax belly; the uſe of a ſuſpenſory bandage; and eſpecially when mercury, which, on the chance of the diſorder being venereal, is very commonly tried, are all uſed without any effect; we may in ſuch circumſtances always have great cauſe to ſuſpect that the diſeaſe is of a real bad nature; and when to this is joined an acceſſion of more inveterate ſymptoms, and if the diſorder, from the ſtate of an indolent hard tumour, becomes painful, &c. no farther delay ought then to be adviſed. Caſtration muſt be proceeded to. See Sharp's Operations; Pott's Chirurgical Works; Bell's Syſtem of Surgery.

SARCOCOLLA. Sarcocol, or fleſh glue. It was thus called, becauſe of its ſuppoſed power of conglutinating wounds. It is a gummy reſinous juice, from the penæa mucronata, Linn. according to Curtis, in his Catalogue of the London Botanic Garden: and from the penæa *ſarcocolla*, according to Weſton in his Univ. Bot. and is brought from Perſia and Arabia, in ſmall ſpongy grains, of a whitiſh yellow colour, and a few of a reddiſh, and ſometimes of a deep red colour; theſe grains, when entire, are about the ſize of a pea. The whiteſt and moſt bitter is preferred as being the beſt. Its bitteriſh ſubacrid taſte is followed by a ſweetiſhneſs; it ſoftens in the mouth, bubbles and catches flame from a candle: it diſſolves freely in water, and a great part of it diſſolves in ſpirit of wine. Its medical qualities are not much known. See Lewis's Mat. Med. Neumann's Chem. Works.

SARCOEPIPLOCELE. A kind of compound rupture, conſiſting of a deſcent of the epiploon, and a ſarcocele. Or a rupture of the indurated epiploon, either umbilical or ſcrotal.

SARCOLOGIA. Sarcology. It includes myology, ſplanchnology, angiology, neurology, and the doctrine of the integuments.

SARCOMA, from σαρξ, *fleſh*. Thus a fleſhy tumour on any part of the body is named. It is occaſioned by an effuſion of the nutritious juices out of their tubuli. Theſe tumours have no cyſtis; they do not yield to the impreſſion of a finger, nor are they moveable. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order tumores. Extirpation is the only remedy; and if the baſis is narrow, a ligature may be uſed, but if it is broad, the knife will be neceſſary. See Turner's Surgery, vol. i. p. 201.

SARCOMA. A name for a polypus of the noſe.

SARCOMPHALON, from σαρξ, *fleſh*, and ομφαλος, the navel. A fleſhy excreſcence at the navel.

SARCOPHYIA. A ſarcoma.

SARCOTICA. Sarcotics. Medicines which generate fleſh in wounds. From σαρκοω, *to heal*.

SARDA, or Sardius. The cornelian ſtone.

SARDIASIS. Involuntary convulſive laughter; or rather the cynic ſpaſm.

SARDONIUS RISUS. Sardonian laughter. A convulſive involuntary laughter, and is thus named from the herba Sardonia, which is a ſpecies of ranunculus, and is ſaid to produce ſuch convulſive motions in the cheeks as reſemble thoſe motions which are obſerved in the face during a fit of laughter. This complaint is ſometimes ſpeedily fatal. If the ranunculus happens to be the cauſe, the cure muſt be attempted by means of a vomit, and frequent draughts of hydromel with milk. See Ætius Tetrab iv. ſerm. i. cap. 66.

SARDONYX. It is a precious ſtone, of a nature betwixt the ſardius and onyx. The cornelian is alſo thus named: alſo the onyx, when its colours are red and white. The *Sardonyx* is of the agate kind, and an individual of the ſpecies of agate, called onyx.

SARSA, i. e. Sarſaparilla.

SARSAPARILLA, alſo called zarza, zarzaparilla, ſmilax aſpera Peruviana, ſalſaparilla, zarcaparilla. It is called ſarſaparilla from the Spaniſh words zarſa, a bramble, and parilla, a little vine. This plant is a ſmall kind of vine, which reſembles a bramble. Some call it a ſpecies of bind-weed. It is brought from the Spaniſh Weſt Indies; the ſlenderer pale ſort comes from New Spain, the dark and thick from Honduras, the darkeſt and thickeſt from Quito. The ſort moſt eſteemed is the ſmilax aſpera Peruviana, C. B. the ſmilax ſarſaparilla, or ſmilax Virginiana hederæfolia, foliis inermibus ovatis retuſo mucronatis trinerviis, Linn. Virginian ivy-leaved rough bind-weed. It is light, white within, but is not eaſily powdered. The root conſiſts of a number of ſtrings, which are as thick as a gooſe-quill, flexible, free from knots, and compoſed of fibres which run their whole length, ſo that they may be ſlipped from one end to the other. On their outſide is a thin, brown, or yellowiſh aſh-coloured ſkin; under this is a thicker, white, friable ſubſtance, and in the middle is a woody pith.

Theſe roots have a farinaceous bitteriſh taſte, and no ſmell. In 1563, the Spaniards brought a parcel of them into Europe, as a ſpecific in the lues venerea, and, indeed, a decoction of them in water is an excellent auxiliary to mercury. When children are infected with the pox from their parents or nurſes, the powder of this root may be put into their food. It is reſolvent, attenuant, reſtores the appetite and digeſtion, even when the patient is hectic from a venereal cauſe. It promotes perſpiration, attenuates viſcid humours; it relieves venereal head-achs and nocturnal pains; it is peculiarly uſeful when the bones are carious, or any way diſordered from the venereal diſeaſe.

The beſt preparation is a decoction as follows; ℞ Rad. ſarſaparil. ℥ iii. aq. fluv. ℔ vi. coq. ad. ℔ ii. & cola. If a little liquorice root is added at the end of the boiling, the decoction will be more palatable. The doſe is half a pint four times in twenty-four hours, or ſo as that two pints are taken in at that time; it muſt be made freſh every ſecond day. It is the long ſtringy part only that is uſeful. See Lewis's Mat. Med. Neumann's Chem. Works; Lond. Med. Obſ. and Inq. vol. i. p. 149, &c.

SARTORIUS. Some call this muſcle faſcialis. It is called *ſartorius*, or the taylor's muſcle, becauſe taylors croſs their legs with it. It riſes from the anterior ſuperior part of the os ileum, runs inwards contiguous to the blood veſſels, and is inſerted into the inner condyle of the thigh bone. It partly rotates the thigh.

SASSAFRAS. It is the root of a large tree of the bay kind, the laurus ſaſſafras, or laurus fol. integris trilobiſque. floribus flavis, baccis cœruleis, Linn. The ſaſſafras tree. It is light, and covered with a rough and ſungous bark, outwardly of an aſh colour, and inwardly of the colour of ruſty iron. It is brought from Virginia and other parts of America. It hath a fragrant ſmell, a ſweetiſh ſub-aſtringent aromatic taſte; the bark is ſtronger than the internal woody part, and the ſmall twigs than the larger pieces. Spirit of wine takes up all its virtues, and water extracts a large portion of them. Diſtilled with water it affords an eſſential oil, which is limpid at the firſt, but afterwards grows yellow, or of a reddiſh brown; the remaining decoction when evaporated, affords a bitteriſh ſubaſtringent extract; but an extract made from a ſpirituous tincture poſſeſſes all the virtues of the root.

Saſſafras is uſed chiefly in infuſion as a mild diaphoretic and corroborant in ſcorbutic, catarrhal, and cachectic diſorders; but for theſe purpoſes the ſpirituous extract is the beſt preparation See Tournefort's Mat. Med. Lewis's Mat. Med. Newmann's Chem. Works.

SATUREIA SATIVA, alſo called cunila ſativa, thymbra, and ſummer's ſavory. It is the ſatureia hortenſis, Linn. It is a low ſhrubby plant, ſomewhat hairy, with ſmall oblong narrow leaves ſet in pairs. Its flowers are in cluſters in the boſoms of the leaves, and are of a purpliſh colour. It grows wild in the ſouth of Europe, and

is ſown annually in our gardens. The leaves are warm, aromatic, and to the ſmell are like thyme, but much milder. Rectified ſpirit takes up all their active matter. Water takes up the ſmell but not the taſte. By diſtillation with water, a ſmall quantity of eſſential oil is obtained. They are heating, ſomewhat diuretic, and promote the menſes.

SATUREIA MONTANA, alſo called thymbra, winter ſavory. Its virtues are much the ſame as thoſe of the above ſpecies. See Raii Hiſt.

SATURNUS. Lead. Sometimes antimony is thus named.

SATYRIASIS. It is a violent deſire of venery, even ſo that reaſon is depraved by it. Dr. Cullen places it as a genus of diſeaſe in the claſs locales, and order dyſorexiæ. He diſtinguiſhes two ſpecies. 1. Satyriaſis juvenilis, when beſide the exceſs of deſire, the body is otherwiſe but little diſturbed. 2. Satyriaſis furens, when with the exceſs of venereal appetite, the body is much diſturbed, as with fever, &c. The pulſe is quick, the breathing ſhort, the patient is ſleepleſs, thirſty, and loathes his food; the urine is evacuated with difficulty, and a fever ſoon comes on. The nature and cure are much the ſame as are thoſe of the furor uterinus. See Cœlius Aurelianus, lib. iii. c. 18, acut.

SATYRION. A name for ſeveral ſpecies of orchis, which ſee.

SATYRISMUS. The ſame as ſatyriaſis.

SAURURUS. A plant called the lizard's tail. Boerhaave mentions four ſpecies. Their virtues are ſimilar to thoſe of arum.

SAXIFRAGA ALBA, alſo called ſanicula ſedum. White ſaxifrage. It is the ſaxifraga granulata, Linn. It is a plant with kidney-ſhaped, yelloviſh green leaves, round, purpliſh, branched ſtalks, on the tops of which are ſhort looſe ſpikes of white flowers. The root is compoſed of ſmall fibres, intermixed with little tubercles. It is perennial, grows wild in ſandy paſtures, and flowers in May. The tubercles of the roots have a ſweetiſh and lightly acrid taſte, and they are aperient and diuretic. See Lewis's Mat. Med.

SAXIFRAGA ANGLICA. Engliſh, or meadow ſaxifrage. It is the pucedanum ſilaus, Linn. It is an umbelliferous plant with winged leaves; the flowers are of a yelloviſh white colour; the root is long, and about as thick as a finger, brown or blackiſh on the outſide, and white within. It is common in meadows and paſture ground, and flowers in June. The root, leaf, and ſeeds, are diuretic, aperient, and carminative, and are far preferable to thoſe of the white *ſaxifrage*. See Lewis's Mat. Med.

SAXIFRAGA. It is a name for a ſpecies of paronychia, filipendula, apium, &c.

SAXIFRAGA, from *ſaxum a ſtone*, and *frango, to break*. An epithet for medicines which diſſolve or break the ſtone in the bladder.

SAXUM. In foſſilogy, it is an order in the claſs of ſtones. The characters are, ſtone of a granulated ſtructure; and wanting the characters of the other orders of this claſs. Edwards's Elements of Foſſilogy.

SCABIES. The itch; alſo a diſorder of the bladder mentioned by Ætius. If after a painful diſcharge of the urine, branny ſcales appear in it, with plenty of ſlender filaments, which ſubſide, the ancients call it a *ſcabies*, becauſe it indicates a corroſion of the mucous and villous membranes thereof. In order to the cure, Ætius orders an abſtinence from heating things, and recommends milk, broth, &c. In Linnæus's noſology, it is an order in the claſs of vitia, and ſignifies cutaneous diſeaſes.

SCABIOSA. Common field ſcabius. Scabioſa arvenſis, Linn. It is a rough hairy plant; it grows wild in paſture ground; it is of a nauſeous bitter taſte; it flowers in June. It is aperient, ſudorific, and expectorant. Externally it hath been uſed as a cure for the itch, whence its name ſcabioſa. Boerhaave enumerates forty-eight ſpecies, but they are not noted for medicinal qualities.

SCABIOSA. It is a name for ſeveral other plants.

SCALENUS MUSCULUS, (σκαληνος, a figure with three unequal ſides.) Some call it triangularis. It takes its origin from the tranſverſe proceſſes of the vertebræ colli; it grows larger as it deſcends, and is then collected into two maſſes, the anterior and poſterior; the anterior is inſerted into the inner edge of the firſt rib; on each ſide of this portion, the ſubclavian vein and artery, and the bronchial nerve paſs out; the poſterior part is attached to the poſterior part of the firſt rib, and partly runs to the ſecond; its office is to raiſe thoſe two ribs, and to move the vertebræ colli to one ſide.

SCALPO. To ſcalp. To lay the ſkull bare is called ſcalping. The operation is performed by making an inciſion through the integuments and pericranium equally and at once: in doing this, uſe the edge of the knife rather than the point, eſpecially if a fracture is ſuſpected. After making the inciſion, raiſe the pericranium a little from the bone with the edge of the knife, and to clear the bone uſe the ſcalprum.

In purſuing a fiſſure, a rectilinear inciſion is the beſt; and in moſt other caſes, an oval one is to be preferred. Arnaud and Gooch both give inſtances of their having made a crucial inciſion upon the temporal muſcle with good ſucceſs, the muſcle ſtill continuing its action. See Gooch's Treatiſe of Wounds, p. 253.

SCALPRUM, from *ſcalpo, to raſp or raiſe*. A denticular, or raſpatory; it is alſo called a rugine. It is any kind of iron inſtrument with which you may raſp or ſcrape a rotten bone, &c. Sometimes the word *ſcalprum* means a little chiſſel for amputating the fingers with.

SCAMMONIUM. Scammony. The natives of Aleppo call it mahmoody. The beſt is brought from Aleppo, an inferior ſort from Smyrna. It is the produce of the convolvulus foliis ſagittalis poſtice truncatis, pedunculis biſloris. Roy. Lugd. b. 427, Mat. Med. Convolvulus ſcammonia vel Syriacus, or convolvulus Syriacus, ſeu ſcammonia Syriaca, foliis ſagittatis poſtice truncatis, pedunculis teretibus ſubtriſloris, floribus pallidi luteis, Linn. Syrian bind-weed, or *ſcammony*. The root is very long, and about three or four inches thick. In the month of June they cut the tops of the roots, as they are in the ground, and from this inciſion there flows a milky liquor, which is received in ſhells, &c. and which growing hard by its thinner parts being exhaled in the warm air, is the gummy reſin, called *ſcammony*.

The gummy reſin is brought to us in light ſpongy maſſes, gloſſy, of different ſhades from a grey or yellow white, almoſt to a black; when broken it appears bright and ſhining; it eaſily crumbles between the fingers; if it is touched with a wetted finger it becomes milky; and if it is broken, and put into a glaſs of water, it diſſolves into a milky liquor of a greeniſh caſt. An inferior ſort is brought from Smyrna, which burns the mouth more than that from Aleppo does. Though different parcels of *ſcammony* vary ſo much in their colour whilſt in the lump, when powdered they are all of them of a browniſh white colour.

Chuſe ſuch as eaſily crumbles between the fingers, is pellucid, grows inſtantly white on being wetted, and that leaves but little feces when diſſolved.

It is adulterated with wheat flour, ſand, aſhes, &c. to diſcover which, the beſt method is to diſſolve it in water, and let it ſtand a while; thus the *ſcammony* will be ſuſpended in the water, and the impurities will ſink. The ſooner it diſſolves, and the leſs there is of ſediment, the purer it is.

It loſes its virtue by being carcleſsly kept.

It is a very briſk purge, and uſually given to carry off redundant ſerous humours in cold phlegmatic conſtitutions. Like aloes, it ſeems to act more by ſuſing the humours, than by a ſtimulus in the firſt paſſages.

Inflammatory diſorders are increaſed, and very irritable habits are injured by it. It is given from gr. iii. to ʒ i. for a doſe. It needs no corrector, though ſome expoſe it to the fumes of burning ſulphur, but thus they render it inert. It conſiſts of about equal parts, reſin and gum; whence it diſſolves equally in water and in ſpirit.

The London college directs a compound powder, and an electary, in which *ſcammony* is the principal ingredient; it is called e electo ſcammonio, but formerly it was named electo. caryocoſtinum. See Lewis's Mat. Med. Neumann's Chem. Works. Lond. Med. Obſ. and Inq. vol. i. p. 13, &c.

SCAPHA. In anatomy it is the external circumference of the ear, oppoſite to the helix.

SCAPHA. It is a double headed roller, of about two fingers breadth, for ſecuring the compreſs after bleeding any part of the head.

SCAPHOIDES. (Os). from σκαφη, a *ſkiff*, or *little veſſel*, and εἶδος, *form*. The firſt bone of the firſt row in the wriſt is thus called by the Greeks; the Latins call it naviculare. It is articulated to the thumb. In infants it is wholly cartilaginous; ſome call it os cymbæ, and os cymbiforme; alſo the third bone of the tarſus.

SCAPULA. The ſhoulder-blade. It is a triangular bone, ſituated on the outſide of the ribs, extending from the ſecond to the ſeventh; its ſides are unequal; the poſterior ſide or baſis is the longeſt, the inferior coſta is ſhorter, and the ſuperior coſta is the ſhorteſt. The body of this bone is concave towards the ribs, and convex behind, where it is called dorſum. Three proceſſes proceed from the ſcapula, 1. The Corocoid, which ſee. 2. The ſpine; it ariſes from the poſterior convex ſurface, and divides it unequally; it riſes ſmall at the baſe, and becomes higher and broader as it advances. The extremities of it are broad and flat, and hang over the cavity of the os humeri. To this part of the ſpine, which is called acromion, the clavicle is articulated. 3. The third proceſs is produced from the neck of the bone; this is hollowed on its anterior part by a glenoid cavity, which hath an acute extremity above, and an acute one below.

SCAPULARIA. The ſcapulary. See Deligatio.

SCAPULARIÆ ARTERIÆ. The ſcapulary arteries. The external *ſcapulary artery* paſſes through the notch in the ſuperior coſta of the ſcapula, to the muſculus ſupra ſpinatus & infra ſpinatus, teres major & minor, alſo to the articulation of the ſcapula with the humerus.

The internal *ſcapulary artery* ariſes from the axillary, near the axilla, and runs backward to be diſtributed to the ſubſcapularis, giving branches to the ſerratus major, the axillary glands, the teres major, &c.

The ſuperior *ſcapulary artery* is a branch from the ſubclavian; it runs downwards to the inſide of the clavicle; it follows the tract of that bone, and goes to the adjacent muſcles.

SCARIFICATIO, from σκαριφος, a *little knife*. Scarification. The word generally ſignifies thoſe inciſions that are made with the inſtrument, called a ſcarificator, and which is uſed in the operation called cupping. See Cucurbitula, and Anasarca.

SCARLATINA ANGINOSA. A ſymptomatic kind of quinſy. By different writers it is named angina mucoſa, the mucous quinſy, febris *anginoſa*, cynanche exanthematica, angina eryſipelatoſa, amphimerina *anginoſa*, &c.

It chiefly affects young people, and women; ſometimes it attacks the aged of both ſexes. In large families and ſchools, when it begins, it ſeldom paſſes any one there except the robuſt.

In this kind of *quinſy* the tumour is leſs than in the inflammatory *quinſy*; there is great redneſs in the part; when ulcers appear they are very ſlight and free from all the malignant ſymptoms of the putrid ſore throat; it is more of the inflammatory kind than of the putrid, and the inflammation is of the erythematous ſpecies. Dr. Grant obſerves, that uſually the pain in the throat is a very early ſymptom, attending before the rigor, though now and then inſtead of pain in the throat there is perhaps a foreneſs of the tongue, or a degree of ſalivation in the courſe of the diſeaſe; an efflorescence often appears on the arms, but ſometimes they ſwell without the efflorescence. For the moſt part the appearance of ulcerous ſloughs, is no more than an inflammatory exudation on the parts about the fauces, and may eaſily be waſhed off. The tongue often appears as if glazed, and is tender, ſwelled, and affected with pain. Uſually it arrives at its height in about ſeven days, and in a fortnight the patient is perfectly recovered.

It ſhould be diſtinguiſhed from a catarrh; from the inflammatory *quinſy*; from the putrid *quinſy*, and from the thruſh.

If the pulſe is large, ſoft, and not above one hundred in a minute, the danger is not conſiderable. The ſalivation is very ſalutary; as ſoon as it is well eſtabliſhed, the danger is over.

This fever is cauſed and kept up by contagious particles; to attempt their expulſion by opening all the natural emunctories is the principal curative intention.

When the habit is good and ſymptoms ſlight, a few doſes of R. rhab. and cr. tart. with a draught now and then of weak wine whey, is all that can be uſeful. The degree of the diſtemper demands the firſt attention. If inflammation is conſiderable, bleed, more or leſs freely as circumſtances determine; and this at any period of the diſeaſe. Emetics and purgatives are of principal uſe, when the ſeaſon is favourable to bilious and putrid diſeaſes. In the early part of the diſeaſe, a kindly perſpiration is peculiarly ſalutary, which ſhould if poſſible be kept up at leaſt to the fifth day, when it uſually is convenient to open the bowels a little. When the ſalivation commences, improve the diet; a little wine ſhould be added to the ſuppings. Mild antiſeptics are often now required, which may be accompanied with ſome light preparation of the bark; it may be proper to be cautious of an early uſe of the bark, as it checks thoſe diſcharges that are obſerved to be ſo ſalutary, and rather increaſes the ſwelling of the parts affected. At any period of the diſeaſe, if the ſwallowing is difficult, apply a bliſter round the throat.

Sometimes bleeding is improper; when warm ſuppings, moderate diaphoretics, and gentle purgatives are to be preferred. Sometimes the parotid and maxillary glands ſwell, and are hard; if bleeding can be admitted, it may be recommended; if not, repeat proper purging once in two or three days. Sometimes the noſe bleeds; in which caſe, if the head is much affected with pains, the ſkin hot and dry, the breathing difficult, the pulſe hard, and not immoderately quick, bleeding will be a moſt neceſſary ſtep.

When from the ſeaſon, &c. bleeding cannot be prudently encouraged, the tart. emet. is ſingularly uſeful, given ſo as to vomit and purge. When the pulſe is ſmall and ſoft, the rigor great at the firſt attack, the conſequent heat conſiderable, be careful early to clear the primæ viæ; thus, the pulſe riſes, a kindly perſpiration comes on, which may be ſupported to thirty-ſix or forty-eight hours, or as required; then give a gentle purge as above noticed, when the ſalivation appears.

A relapſe ſometimes approaches with pain in the feet and hands; in which caſe wrap the parts pained in flannels, and promote a gentle perſpiration. Antimonials are efficacious when perſpiratives are required in any period of this diſeaſe: but the ſp. Mind. ſeems generally to deſerve the preference.

Emollient and gently detergent gargles are valuable aids for relieving the uneaſineſs, &c. in the throat.

Bliſters on the throat are often objected to on account of the mark they leave in the ſkin; in thoſe caſes firſt apply a bliſter between the ſhoulders, and when its diſcharge begins to decline, apply one behind each ear, and down the ſides of the neck.

Huxham treats on this diſeaſe, under the name of Febris *anginoſa*. See alſo Dr. Wm. Fordyce's New Enquiry into the Cauſe of Fevers; Dr. Wm. Grant's Obſervations on the *Angina* maligna Ulceroſa.

SCARLATINA, vel SCARLATINA FEBRIS. The ſcarlet fever. It is ſo called from the colour of the patient's ſkin, which appears as if tinged with red wine. Dr. Cullen places this genus of diſeaſe in the claſs pyrexiæ, and order exanthemata. He diſtinguiſhes two ſpecies. 1. *Scarlatina* ſimplex; that is when not accompanied with any ſpecies of quinſy. 2. *Scarlatina* cynanchia; when accompanied with the ulcerated quinſy. Sydenham obſerves, that children are its moſt frequent ſubjects, and that when it is epidemical, it is uſually ſo at the cloſe of the ſummer. It begins with a chilline ſs and ſhivering; after which the whole ſkin is covered with red ſpots, which are more numerous, larger, and redder, but not ſo uniform as thoſe of the meaſles. Theſe ſpots continue two or three days, and after they vaniſh, and the ſkin is ſcaled off, there remains a kind of branny ſcales diſperſed over the body, which fall off, and come again, two or three times ſucceſſively.

It ſeldom requires much aſſiſtance from art, except there is an approach to that putrid ſtate to which it inclines in the advanced degrees. Bleeding is rarely required. The patient may be kept in his room, but not much in bed; his drink may be acidulated with the ſpirit of vitriol, or with Clutton's febrifuge ſpirit; and if a ſtool is required, rhubarb will be the moſt convenient; when the ſkin peels off a more active purge may be given.

Sometimes a coma, or an epilepſy, happens in the beginning of the diſeaſe, in which caſe apply a bliſter to the back. When it is attended with more malignant ſymptoms, its tendency is to the putrid kind of fever, with ulcers, &c. in the throat. Here bliſters, which may be applied to the back and throat, with the bark, are the chief dependencies, and, as in the putrid ſore thrort, acids and cordial perſpiratives may accompany the bark. Antimonial preparations, which are ſo generally uſeful in fevers, in this caſe are apt to occaſion a purging.

See Swan's Tranſlation of Sydenham's Works; Obſ. on a late particular Scarlet Fever, by N. Cotton, M. D.

SCARLATINA URTICATA Acute nettle raſh.

SCELETOS, from *σκέλλω, to make dry.* A ſkeleton. All the bones of an animal freed from the teguments, veſſels, muſcles &c. and properly connected, have the general name of ſkeleton. There are two ſorts, viz. the natural, and the artificial; the firſt of theſe is when the bones are kept together by their own ligaments; the ſecond is when they are joined with wire.

SCELOTYRBE. It ſignifies thoſe pains in the legs that generally attend ſcorbutic habits; whence it is frequently uſed for the ſcurvy itſelf; and alſo applied to ſome medicines contrived againſt ſuch diſorders. It is often expreſſive of the chorea ſancti viti.

SCELOTYRBE FESTINANS. Idiopathic convulſion.

SCELOTYRBE VERMINOSA. A kind of ſymptomatic convulſion.

SCIRRUS. See SCIRRHUS.

SCIATICA. See RHEUMATISMUS. It is the rheumatiſm when ſeated in the hip.

SCIATICA ARTERIA. It is a branch of the hypogaſtrica; it runs under, and gives branches to the muſculus pyriformis, quadrigemini, and the os ſacrum, and to the inner ſide of the os iſchium; it paſſes obliquely over the ſciatic nerve; and as they both go through the great poſterior ſinus of the os ileum, it detaches ſmall arteries, which are diſtributed to the inner ſubſtances of the nerve: afterwards it runs up in a radiated manner, on the outſide of the os ilium, and is diſtributed to the inner ſubſtance of that bone, and to the muſculi glutæi, eſpecially to the medius and minimus.

SCIATICA VENA. When the crural vein hath deſcended to about the upper extremity of the muſculus vaſtus internus, it produces a branch which runs down on the ſide of the trunk, covering the crural artery almoſt down to the ham, where it is again united to the trunk by an anaſtomoſis; and ſometimes it is continued a little way down on the leg. It is called the ſciatic vein, from accompanying the ſciatic nerve.

SCIATICUS NERVUS. See LUMBARES.

SCILLA. The ſquill, or ſea onion. Scilla maritima, or ſcilla Hiſpanica, foliis lanceolatis ſtrictis, ſcapo longiſſimo multiflоro, floribus albis & nudis, bracteis refractis. radice alba, Linn. It is a plant with a large bulbous root, like that of an onion, which is very acrid. The leaves are broad, the flowers are like thoſe of the ornithogalus, and grow in a ſpike before the leaves appear. There are two ſpecies which are uſed indifferently, viz. the red and the white, Boerhaave mentions a third ſort.

Epimenides taught Pythagoras the uſe of *ſquills*, and the vinegar prepared with them; and Pythagoras made the vinegar into an oxymel.

This plant grows on ſandy ſhores in Spain and the Levant, from whence we have them. Chuſe ſuch roots as are large, plump, freſh, and of a clammy juice. To the taſte they are naufeous, bitter, and acrid; if much handled they exulcerate the ſkin. Internally they are a powerful attenuant and aperient; in doſes of a few grains they promote expectoration and urine; indeed when ſquills are given as a diuretic, the doſe is a true one that will ſit eaſy on the ſtomach, but ſmall doſes excite expectoration moſt effectually; in larger doſes it is purgative or emetic. They powerfully diſſolve tough phlegm, and promote its diſcharge; whence their ſingular uſefulneſs in the humoural aſthma; but if the lungs are inflamed, the ſquills muſt be omitted until after bleeding and cooling antiphlogiſtics are uſed. In dropſies, begin with a ſmall doſe, and gradually increaſe it, but ſo as not to paſs off by ſtool.

On account of their offenſive taſte, the beſt form is pills; and to prevent the naufea which they excite, when not intended either as an emetic or an expectorant, a few grains of ſome agreeable aromatic may be added to each doſe, or it may be made up with the freſh root of elecampane.

Water, wine, proof ſpirit, rectified ſpirit, and vinegar, extract the virtues both of the freſh and the dry *ſquills*; but none of them carry any thing with them by diſtillation; ſo that in the extract made from the decoction, the whole of the active parts are retained. Alcalies abate both their bitterneſs and acrimony; vegetable acids make very little alteration in either, but they improve their expectorating quality.

The London college directs the two following preparations: Acetum ſcilliticum, and the oxymel ſcilliticum. See Lewis's Mat. Med.

SCINCUS. The ſcink or ſkink. It is a ſmall amphibious animal of the lizard kind; it is caught about the Nile. The fleſh of this animal hath been in much eſteem as a diuretic, alexipharmic, &c. but it is now neglected.

SCIRRHUS, from *σκίρρος*, to harden. A *ſcirrhus* is a hard tumor, with little or no ſenſation remaining in it. Galen Comment in Aph. xxxiv. ſect iv. Dr. Cullen places this genus of diſeaſe in the claſs locales and order tumores. Dr. Aitkin reckons the phyſconia (a genus in Dr. Cullen's ſyſtem) a ſpecies of *ſcirrhus*. The ſarcocele he includes as another ſpecies. The ſeat of this kind of tumor is uſually ſome glandular part; not but ſome other may alſo, and ſometimes is thus diſordered. Dr. Cullen defines a *ſcirrhus* to be a hard tumor, of a part for the moſt part of a gland, not painful, and difficultly ſuppurating. The fluids in the glands being inſpiſſated, increaſe in hardneſs, and form a *ſcirrhus*; or the contents of the lymphatic veſſels in the liver, or other parts coagulating, gradually harden, and form the like. It is probable that *ſcirrhuſes* are formed by too free bleeding; for thus the circulation may be ſo diminiſhed in its force as not duly to affect the ſmaller veſſels, and thus obſtructions may be formed, which end in *ſcirrhuſes*.

All perſons, and at any age, may be the ſubjects of this diſorder; but the ſedentary, and more particularly women, when their menſes decline, and ſometimes indeed at their approach, are moſt frequently thus diſordered.

From the moſt attentive examination, it appears that the matter of theſe tumors is inſpiſſated lymph. They often ariſe without any previous inflammation from the proper fluid ſtagnating in the gland, or extravaſation from contuſion, &c. Sometimes it happens when a gland is the ſeat of an inflammation, and the inflammation terminates without coming to ſuppuration.

Externally they are perceived by the touch. Internally the evidences are obſcure, but if the cauſes of a *ſcirrhus* have occurred, and if ſome defects attends to which we may impute a *ſcirrhus* as the cauſe, the exiſtence of one may be ſuſpected.

Though a *ſcirrhus* does not always become cancerous, yet cancers are moſt frequently only *ſcirrhuſes* in their beginnings. The effects of a *ſcirrhus* will be various, and very different, according to the part it affects, and the functions which it injures. By preſſing on the vena cava, a mortification in the legs has been produced; by preſſing on certain nerves, epileptic fits have been produced. If all the glands in the neck are indurated, thoſe of the meſentery will be ſo too, in which caſe a cure is not to be expected. A *ſcirrhus* in the liver produces a jaundice, which is difficult, and often impoſſible to cure, and this jaundice is followed by a dropſy. A *ſcirrhus* may ſo preſs upon the thoracic duct as to occaſion a fatal atrophy. Whether a *ſcirrhus* is ſeated internally or externally, if it is affected by acrid humours, or inflammation, being thereby heated, it becomes cancerous.

If an attempt is made towards the cure of a *ſcirrhus*, we ſhould be certain that it is recent and not yet quite hardened, and that it is in its benign ſtate, i. e. that it is free from itching, heat, or pain; for, after the appearance of any of theſe circumſtances, nothing but a palliative cure can be admitted of, except the knife can be prudently uſed. In the earlier ſtate of an external *ſcirrhus*, gentle

mercurials

mercurials are uſed internally, but with caution not to irritate; externally, cooling and anodyne applications only are to be employed; ſuch as the aq. ſaturn. of Goulard; the *ſcirrhous* part ſhould be covered with ſoft leather to prevent the cloaths from irritating it; whatever heats, ſoftens, or can tend to produce a ſuppuration muſt be carefully avoided; a ſolution of ſal ammoniac in vinegar is applied externally as a reſolvent; ſome apply the vapours of vinegar to the tumid part. If a *ſcirrhus* is ſmall, and continues of the ſame ſize, do nothing; if it ſuppurates, increaſes, and is detached, extirpate it with the knife. Some good practitioners adviſe to extirpate theſe tumors as ſoon as they ſeem to reſiſt the effect of gentle means made uſe of for reſolving them, and that before any ſymptoms of their becoming cancerous appear. For correcting the faulty ſtate of the fluids, and for reſolving *ſcirrhous* obſtructions, the merc. cor. A. given ſo as not to ſalivate, contributes much, if the bark, and the extr. cicutæ, accompany it; their united efficacy is ſometimes ſuch as cannot be produced by any two of them without the third.

What is here ſaid of a *ſcirrhus* in general is applicable to a *ſcirrhus* in any external part; however, as there are ſome peculiarities from their ſituation, it may be proper to take notice of ſome of them.

A *ſcirrhus* may affect the ſebaceous glands of the ſkin, particularly about the face and lips, where it is ſo very irritable, that whatever is applied occaſions great pain, and therefore is called noli me tangere. Here Mr. Plunket's medicine (ſee CANCER) may do well if the caſe be recent; but it ſhould never be uſed unleſs we can remove the whole tumor. If we cannot affect this, we are at firſt flattered with the hopes of a cure, but the diſeaſe ſoon re-appears in another ſtate, which carries off the patient. In ſhort, whilſt *ſcirrhous* tumors are looſe, entirely free from pain, and the figure of the tumid gland is unchanged, whether the cauſtic or the knife are uſed, ſucceſs may reaſonably be expected, whether the ſituation of the diſordered gland is in the face, or any where elſe in the reach of thoſe means of relief.

A *ſcirrhus* in the breaſt. Whether the breaſts of women are glandular or not, their ſtructure is ſuch, that indurated tumors are formed in them. Some tumors in the breaſt reſemble a true *ſcirrhus*; but in time they inflame, ſuppurate, and end favourably; and it is not eaſy to give the diſcriminating ſigns with preciſion enough to be depended on in the beginning. It may be obſerved that a genuine *ſcirrhus* ſeldom occaſions uneaſineſs, except it becomes cancerous; and when an inveterate *ſcirrhus* ſeizes the breaſt, the ſubaxillary glands are generally indurated too. The breaſts are ſometimes rendered *ſcirrhous* by the imprudent application of the ſpirit of wine to them; about the ceſſation of the menſes, the breaſts of many women are thus affected.

A *ſcirrhus* in the inteſtines. After an inflammation in theſe parts, a *ſcirrhous* may be formed, in which caſe there will be a ſtupor, a ſenſe of weight, and a conſtant diſtraction perceived where it is ſeated. There will be a leſſening of the cavity of the inteſtines as the bulk of the tumor increaſes; the chyle and the fæces ſtagnate there; at length the iliac paſſion, or ſome other violent ſymptom, puts an end to the patient's miſery. In ſuch a caſe, if any palliative remedy moderates the uneaſineſs and retards the growth of the tumor, that will be all that medicine can effect.

A *ſcirrhus* liver. A part of the liver, or its whole ſyſtem, may become *ſcirrhous*. Theſe tumors in this part generally are ſmall in their beginning, and are gradually increaſed; when they inflame they occaſion feveriſhneſs, and the general health is much diſordered; but theſe ſymptoms vaniſh, and for a time the health ſeems to be reſtored; the intervals of theſe inflammations become ſhorter, and then the appetite and fleſh fail, a little cough comes on, and a hiccough, ſometimes with, ſometimes without, bring on death; in ſome all this happens in a few months; in others it takes up ſeveral years. If the inflammation is in the internal parts of the liver, the pain is ſometimes too little to be regarded; but happening on the external parts, it extends to the diaphragms, or other adjacent parts, and in this caſe the patient generally lies on his right ſide. In the advanced ſtate of theſe *ſcirrhi*, the blood will guſh out freely from the noſe, ſtomach, navel, and with the ſtools; in the worſt of theſe caſes, though the countenance is of a leaden colour, yet ſometimes there will not be any ſigns of a jaundice; for this ſymptom does not happen except the ducts are compreſſed by the *ſcirrhus*, ſo as to hinder the paſſage of the ſecreted gall through the common gall duct. An indurated liver is often very evidently diſtinguiſhable by applying the hand to the region of it. As to other ſigns that attend a *ſcirrhus* liver, they alſo accompany other diſorders, ſo determine nothing in this caſe.

But whether it happens that a *ſcirrhus* is ſeated in the liver, ſpleen, or the pancreas, certainly to diſtinguiſh them ſeems to be but of little moment, as little or nothing more can be done towards relief than what the common cure of the hectic fever requires, whether it ariſes from this, or from any other cauſe. In the beginning, and whilſt the diſorder is ſlight, perhaps a free uſe of graſs roots, endive, ſuccory, and whey, uſed as a diet, might be of ſome uſe; but in the more advanced degree, no cures are performed, except by an inflammation ending in ſuppuration, and the abſceſs burſting where the matter can be carried directly out of the body, as when the matter is emptied into the hæpatic duct, or through the ſide of the belly, which laſt may happen when the liver adheres thereto.

A *ſcirrhus* in the tongue. A tumor of this kind ſometimes happens in this part, and remains many years indolent; in which caſe avoid all attempts to remove it, as it may eaſily be made to become cancerous. If it ſhould become painful, and is moveable, diſſect it out; but if immoveable, cut away a part of the ſound fleſh with it; dreſs the wound with the honey of roſes and balſam of Peru.

A *ſcirrhous* tonſil. This can no way be managed with advantage, except by means of the ligature, as recommended by Mr. Sharp. See his Operations and his Critical Enquiry.

A *ſcirrhous* womb. This is one of the opprobriums of medicine; it always degenerates into a cancer, and deſtroys the patient.

SCLEROPHTHALMIA. See XEROPHTHALMIA EROPHTHALMIA.

SCLEROTICA, from *σκληρος, hard*. Of the proper coats of the eye, the tunica *ſclerotica* is the outermoſt. This, in the poſterior and far greater part of its circumference, is white and opake; but in the anterior is tranſparent, and takes the name of cornea. The remarkable whiteneſs which this coat appears to have, is from the expanſion of the tendons of the muſcles, which move the eye over its fore part; this tendinous expanſion, though called tunica albuginea, is not properly a coat of the eye; for it, like the conjunctive, is only partially ſpread over its forepart. See CORNEA.

SCLOPETOPLAGA, from *ſclopetum, a gun*, and *plaga, a wound*. It is a ſpecies of vulnus, though ſome writers make it a genus of diſeaſe. This kind of *wound* is a contuſed *wound* in the higheſt degree. The ancients ſuppoſed theſe to be of a malignant, poiſonous nature from gunpowder; hence warm antiſeptics, &c. were uſed; but the ill effects of *gun*-ſhot *wounds*, are owing to contuſion, laceration, &c. and require the moſt lenient methods to be purſued; ſuch as relaxing the parts by an emollient cataplaſm; and if there is but one ſmall opening, to enlarge it for a free diſcharge of matter, or to be able to extract foreign bodies, if it can be done eaſily; but, if by endeavours to remove them, you are likely to irritate, or give great pain, it will be beſt to wait until the inflammation, &c. is gone, and ſuppuration eſtabliſhed; by which means you will have a larger opening, and extract any extraneous body more eaſily; for, at firſt, the orifice of a *wound* through which a ball hath entered by its contraction, is always exceeding ſmall before ſuppuration commences.

Amongſt the many peculiarities from *gun*-ſhot *wounds*, ſee a remarkable one in the article FRACTURA, and the diviſion, a fractured leg.

Moſt limbs are taken off in the field of battle, and few

of them recover. It is beſt to perform as few operations as poſſible in theſe caſes; and, if you can, leave thoſe few until ſome time after they have been wounded, as moſt of theſe, where amputation is performed immediately, die of the operation, as indeed they do in all caſes where it is performed in high health. Limbs ſhould not be amputated in the field if they can poſſibly be avoided. The inflammation ſhould firſt be allowed to go off; and if ever from the nature of the *wound*, the inflammation that we ſuppoſe ſhould attend it, ſhould be imagined to hazard the patient's life, this ſhould not be a ſufficient reaſon for amputation, becauſe the operation will more than hazard his life in ſuch a ſituation, and in ſuch a ſtate, as experience evinces.

The joints having been maſhed by external force, or a ball having paſſed through them, ſeldom do well without amputation, eſpecially if there is a great laceration of the ligaments, and a diſcharge of the ſynovia, with the admiſſion of the external air; for the violent inflammation, ſloughing, and diſcharge, bring on a hectic fever, which with colliquative ſweats, from the abſorption of matter, will carry him off.

It may be further obſerved, that injuries from ſmall ſhot are rarely ſo prejudicial to the bones, as thoſe from larger ſhot; from theſe laſt, the bones are generally ſplit or ſplintered, and require that amputation be performed above the joint of the part where the injury is received, if poſſible.

Thoſe who aſſert, that amputation ſhould be quickly performed, when rendered neceſſary from *gun-ſhot wounds*, advance the following reaſons: 1. When the injury is from large ſhot. 2. When violent ſymptoms comes on. 3. When violent ſymptoms are overcome by medicines, yet there is ſtill a neceſſity for amputation; theſe form the three ſtages from this kind of injury: and when it happens that a patient paſſes through the firſt and ſecond, except perhaps one in one hundred, he is taken off in the third ſtage.

SCOLOPENDRIUM, alſo called lingua cervina. Harts tongue. It is the aſplenium *ſcolopendrium*, or aſplenium frondibus ſimplicibus cordato-lingulatis integerimis, ſtipitibus hirſutis. Linn. See LINGUA CERVINA.

SCOPULA. A bruſh. The fleſh *bruſh* promotes a briſk circulation, and free perſpiration. Perſons with weak nerves, the ſedentary and paralytic, ſhould ſupply the want of exerciſe with half an hour's rubbing every night and morning.

SCORBUTUS. The ſcurvy. By the ancients it is called ſtomacace, and ſcelotyrbe, becauſe of theſe ſymptoms that attend it. Hippocrates deſcribes it under the name of the diſeaſes of the ſpleen, in his De Intern. Affect. Dr. Cullen places this genus of diſeaſe in the claſs cachexiæ, and order impetigines.

The *ſcurvy* is a chronical diſorder of the putrid kind, and when a fever attends it, is called the putrid fever, which ſee.

The immediate cauſe is the ſame wtih thoſe that produce the putrid fever, that is, putreſcence. The mediate and more remote cauſes are whatever leſſen the vis vitæ, too little or an improper kind of food, a damp air, living in marſhy countries, various kinds of acrid matter in the blood, a long uſe of mercury; in the navy, a ſolution of copper from want of care to clean the veſſels in which their food is boiled; animal diet which is not well preſerved with ſalt; infection, &c.

The preſence of this diſorder is known by a pale, or a yellowiſh complexion, which gradually grows darker; a melancholy dejection of ſpirit, a laſſitude, a ſtiffneſs in the joints, a feebleneſs in the knees, and on uſing the leaſt exerciſe there is great weakneſs, with a difficulty of breathing; the gums ſoon after begin to itch, ſwell, and bleed, on gently being rubbed, and have an unuſual livid redneſs; they are ſoft, ſpongy, putrid and fungous; this change in the gums, Dr. Lind ſeems to think, is the pathognomonic ſymptom of the diſeaſe. Hæmorrhages alſo happen in other parts: the ſkin feels dry, except in the laſt ſtage of the diſeaſe, when a cold clammy moiſture may be obſerved on the ſkin. In ſome the ſkin is rough, but generally it is ſmooth and ſhining, and covered with many ſpots, as if bruiſed; theſe are of a yellow or reddiſh colour, and as the diſeaſe increaſes they become blacker. In ſome the ankles ſwell towards the evening, and are ſettled again in the morning. Many other ſymptoms occur, but they are accidental. If a ſcorbutic diarrhœa comes on, and there is a pain in the breaſt, it is generally fatal. Ulcerated lungs are a frequent conſequence of the *ſcurvy*: the ſtools are very offenſive: the urine ſpeedily becomes putrid. In the ſecond ſtage, the patient ſometimes loſes the uſe of his limbs, the flexor tendons in the hams are contracted, the patient frequently faints upon the leaſt motion; and on being ſuddenly moved into the freſh air, it ſometimes happens that he expires. Hæmorrhages from the lungs, inteſtines, &c. now are frequently happening: but the appetite is often good, though the ſpirits are low. The third ſtage hath many violent, and uſually fatal ſymptoms.

The *ſcurvy* ſhould be diſtinguiſhed from the ileum cruentum, the black jaundice, hypochondriac and melancholic diſorders, ſome ſymptoms of the lues venerea, and ſcorbutic cachexy.

The indications of cure are, to ſtop the progreſs of putrefaction, and totally to remove it; ſecondly, to ſtrengthen the habit in general.

If bad waters are the cauſe, or improper food, they muſt be changed for that which is more ſalutary; the air in the patient's room muſt be regulated by ſuch methods as will render it dry and warm. Fixed air communicated to the water which the patient drinks; an infuſion of malt, as recommended by Dr. Mac Bride; the bark in doſes as large as will be eaſy in the ſtomach, and repeat them two or three times a day. The elixir of vitriol may be given frequently in the patient's drink; theſe and other antiputrefcents, or ſuch means as are uſed in the putrid fever, will be the principal ones here.

If the patient is cold, pale faced, and hath ſwelled legs; if his thirſt is not great, he may take four or ſix ſpoonfuls of the following three or four times a day: ℞ rad. raph. hort. ʒ iv. fol. cochl. trifol. palud. ā m. ii. ſalvia. m. i. vin. alb. ℔ vi. m.

If, on the contrary, there is a feveriſh heat, thirſt, ſome difficulty in breathing, and the gums are putrid: ℞ rad. lapath. acut. ʒ i. crem. tart. ʒ iii. coq. per hora ſs. in lact. vac. ℔ iii. & colaturæ adde mel. brit. ℥ i. m. cap. ʒ iii. ter. die.

The roots of the herba Britannica, or the great water-dock, is much extolled in this diſorder.

Particular care is required to promote the diſcharges through the ſkin, and by the kidnies. And as to particular ſymptoms, ſome of the chief of which are as follow, they may be managed by theſe or ſuch like methods: the ſpongy gums may be waſhed with a decoction of the bark acidulated with the ſp. ſal. marin. and ulcers ſpread in the mouth, touch them now and then with the mel roſar. acidulated with the ſp. ſal. marin. If a ſalivation comes on, divert it by bliſters on different part of the body, ſinapiſms to the ſoles of the feet and hams, and, if poſſible, excite a perſpiration; for the ſtricture of the ſkin is the chief cauſe of this ſymptom, and here boluſes of camphor and theriaca may be repeated every four or ſix hours. If the legs are œdematous, uſe gentle frictions. Ulcers in the legs, &c. may be treated as thoſe in the mouth are. In caſe of hæmorrhages, the mineral acids may be given at proper intervals. When a fever attends, the dulcified mineral acids, or Clutton's febrifuge ſpirit, may be joined with ſuch other medicines as the peculiarity of the caſe requires. But though ſome advantage may be obtained by theſe particular adminiſtrations and applications, yet all theſe and the reſt of the ſymptoms diſappear in proportion as ſucceſs follows the general method of cure.

Dr. George Fordyce obſerves, that the *ſcurvy* is taken off or prevented by ſuch food as is capable of being digeſted properly. Putrefaction of the fluid never produces a diſeaſe of itſelf, but only ſymptoms depending upon this; for when theſe ſymptoms are taken off, the patient recovers; and we ſometimes ſee in putrid fevers, where the patient is conſiderably weakened, ſo that in all probability he could not ſurvive many hours, yet there hath been a ſudden alteration take place: the ſymptoms of putrefaction immediately ſubſide, and the patient recovers; if then we could give proper food, we might be able to prevent it, and could always cure it, when it hath taken place. In order to the cure, any ſuch looſe food that hath no medical pro-

perty is of great ſervice; and the moſt powerful are thoſe of the tetradynamia claſs, ſuch as cabbages, turneps, &c. for, firſt, they produce a fermentation in the ſtomach, and become acid. Secondly, they contain a quantity of eſſential oil, which makes the matter ſoon evacuated out of the body. We ſhould then make choice of ſuch food as this. Beſides theſe, there are native vegetable acids or aceſcent fruits to be got, which likewiſe prove uſeful; but then the difficulty is to find out any vegetable food, that will give a tendency to become acid, that may be kept on board of a ſhip for the uſe of ſailors: there are but few which we can preſerve, and theſe are oranges, lemons, limes, &c. any of theſe, given with animal food, will be of uſe. Sugar is an antiputreſcent, though not ſo powerful as the vegetables; but it was much uſed with food, &c. before vegetables came into uſe. Theſe then are the methods to prevent and to cure putrefaction. Many have uſed remedies as antiputreſcents, to ſtop putrefaction, hence they have given acids, &c. for that purpoſe, but they will not produce that effect. They have a tendency to prevent the peculiar fermentation taking place in the ſtomach, as well as to check putrefactive fermentation; hence vegetable food will not ſtop fermentation, but only tend to alter the mode of the fermentation, and rather tend to convert the ſubſtance into an acid than ſuffer it to putreſy. Another method to relieve from the *ſcurvy*, is to keep up the ſtrength of the ſtomach, which has been of conſiderable ſervice; hence, bark, &c. have been uſed, which are powerful remedies for that purpoſe.

Sir John Pringle, in his Diſcourſe on the Improvements for preſerving the Health of Mariners, ſays, that to know the nature and cauſe of the *ſcurvy*, is an eſſential ſtep to the knowledge of the cure. He ſays, that on examining all the articles which of old have been uſed, and approved of, as well as thoſe which of late have been introduced into the navy, however they vary in their mode of operating, they all ſome way contribute towards preventing or correcting putrefaction. He directs that the men be put to watch at three watches inſtead of two; to this end divide the crew into three companies, and put each company upon the watch by turns, four hours at a time; thus every man hath eight hours free, for four of duty: whereas, when half the men take watch every four hours by turns, they can have but broken ſleep; and when expoſed to wet, they cannot get dry before they lay down. 2dly, To preſerve the men from the injuries of the weather, in hot climes defend them by an awning over the deck; in cold ones, allow extraordinary jackets with a hood; and in wet weather, proper means for drying and ſhifting themſelves. 3dly, Make a point of cleanlineſs; this guards from putrefactions: keep the men's perſons, cloaths, bedding, and births, clean; review the men, and all things belonging to them, and the ſhip, and ſee that all is as clean as can well be. 4thly, Ships ſhould have the means of a conſtant ſupply of freſh water to waſh the men's linen, for ſalt water neither mixes well with ſoap nor dries readily. 5thly, Dry and air the hammocks, bedding, and all bundles, every day that is fair: by the perſpiration of many men, every thing below deck will in twenty-four hours contract an offenſive ſmell. 6thly, Purify the ſhip; ſcrape and waſh the decks; purify the holds, and wells of the pumps; and where the bilge-water is, with fire as follows: light a good quantity of wood, and put it into a proper grate, then carry it ſucceſſively to every part of the ſhip below deck. Wherever fire is, the air neareſt it being heated, becomes ſpecifically lighter; and, by being lighter, riſes and paſſes through the hatch ways into the atmoſphere. The vacant ſpace is filled with the cold air around, and that being heated in its turn, in like manner aſcends, and is replaced by other air as before. Thus by continuing the fire for ſome time in any of the lower apartments, the foul air is in a good meaſure driven out, and the freſh admitted. And probably the acid ſteams of the wood in burning act here as an antiſeptic, and correct the putrid remains of the air. When fire cannot be put down into the well, and carried in other places, it, and the ſhips may be fumigated by gunpowder to remedy the corruption of the air; or burning tar, or other reſinous ſubſtances.

Dr. Hulme communicates fixed air to the ſtomach, &c. as follows: ℞ ſal tart. gr. xv. aq. puræ ℥ iij. f. hauſt. As ſoon as this is ſwallowed, mix and take the following: ℞ aq. puræ ℥ iij. ſpt. vitr. q. ſ. ad ſaturat. ſalis ut in hauſt. precedent. Repeat this four times a day.

The *ſcorbutic* ulcer is alſo called the putrid ulcer. Its diſtinguiſhing characteriſtics are: it affords no good digeſtion, but a thin, fetid, ſanious ſtuff, mixed with blood, which at length hath the true appearance of coagulated gore, lying caked on the ſurface of the ulcer, and is with difficulty wiped off. The fleſh underneath the ſlough is ſoft and ſpongy: if theſe ſloughs are removed by eſcharotics, or the knife, they ſoon return; the edges are generally of a livid colour, and puffed up with excreſcences of proud fleſh, ariſing from below under the ſkin. From compreſſion, the fungus is apt to mortify; and the member always becomes œdematous, painful, and for the moſt part ſpotted. As the *ſcurvy* increaſes in the general habit, the ulcer ſhoots out a ſoft, bloody fungus, which the ſailors call by the name of bullock's liver, which indeed it much reſembles when boiled; it often riſes in a night's time to a great ſize, and, if deſtroyed, will be re-produced to the ſame ſize in twenty-four hours. Theſe ulcers do not ſpeedily affect the bones. The ſlighteſt wounds or bruiſes in ſcorbutic patients degenerate into ſuch ulcers. By their remarkable putridity, they are eaſily diſtinguiſhed from all other kinds of ſores. In ſome inſtances theſe ulcers are attended with ſoft, ſpongy gums.

As an internal medicine when *ſcorbutic* ulcers attend, Dr. Kirkland highly recommends the ſp. ſal. marin. given in water, or mixed with the bark.

Mr. Bell, in his treatiſe on ulcers, obſerves, that the cure of the *ſcorbutic* kind depend much upon the correction of the putrid diatheſis in the ſyſtem: for which purpoſe, vegetables, particularly the aceſcent ones, with milk and whey, are almoſt certain remedies. The different ſecretions, particularly thoſe of the ſkin and bladder, ſhould be gently promoted. In the *ſcurvy*, perſpiration is almoſt quite checked. Gentle laxatives are of uſe, particularly tamarinds, cream of tartar, &c. The beſt external applications are the ungt. Ægyptiac. vel, mel roſar. cum paucul. ſp. vitriol. In the milder inſtances, ſuch as uſually happen in England, the cauſe is more frequently from the want of due nouriſhment; hence what is called the antiſcorbutic courſe will not be required; but in its ſtead, better food and greater plenty of it; a little good wine is a powerful aid. The bark is more uſeful in this than in any other kind of ulcer; it ſhould be given as freely as the ſtomach will admit it. As a dreſſing, pledgits of lint dipped in a ſtrong decoction of the bark will be uſeful in correcting the fætor of the diſcharge, &c. though doubtleſs the carrot poultice by far excels this decoction as a dreſſing. When the fætor from the diſcharge is removed, and the ſloughs only are to be removed, the ungt. Baſil. flav. with merc. cor. rubr. will be the moſt convenient. Generally the cure is finiſhed by means of gentle preſſure. Sometimes an iſſue becomes uſeful. What is ſaid with regard to the treatment of *ſcorbutic* ulcers, is applicable to all ſuch ſores as are in the leaſt connected with a putreſcency of the fluids, from whatever cauſe: thus ſuch as remain after critical abſceſſes that ſucceed to putrid fevers, require the ſame general method of treatment.

SCORDIUM, alſo called Triſſago Paluſtris, chamædrys paluſtris caneſcens, water germander. Teucrium ſcordium, or teucrium foliis oblongis ſeſſilibus dentato ſerratis floribus geminis axillaribus pedunculatis, caule diffuſo, odore allii. Linn. Water germander. The flowers are like thoſe of the chamædrys, one or two proceeding from the ala of each leaf. The calyx is tubulated, and the ſmell is like that of garlic. The plant is a trailing one; the leaves are hoary. If the leaves are rubbed betwixt the fingers they yield a moderately ſtrong ſmell of the garlick kind; they are bitter to the taſte; by keeping the herb for ſome

panded fibres of the cremaſter muſcle on each ſide. Betwixt the cuticle and the cutis is the rete mucoſum, as in other parts of the body. Adjoining to the internal ſurface of the ſkin, is a thin covering of a looſe, hollow texture, void of fat, and is the cellular membrane: next, within this cellular ſubſtance is, an apparently thin, muſcular or fleſhy body, called by the Greeks, dartos: a name which it derives from its raw, or excoriated appearance, and not from its uſe of contracting the *ſcrotum*. Immediately within the dartos, is a ſecond cellular ſubſtance, which is more conſiderable than the firſt named portion. The membrana cellularis externa *ſcroti* admits of a paſſage to the fleſhy fibres of the dartos muſcle; which fibres are attached to, or connected with, the internal ſurface of the cutis; the dartos likewiſe admits of a paſſage to the filaments of the internal cellular membrane; ſo that the two cellular membranes are obſerved to communicate. Upon the external ſurface of the *ſcrotum* is a prominent line or ridge, termed raphe. The direction, or courſe of the raphe is perpendicular or longitudinal, and it is continued from the anus to the extremity of the penis on its inferior part. The raphe divides the external ſurface of the *ſcrotum*; pretty nearly into two equal portions. The *ſcrotum* forms two diſtinct bags; one for each teſticle, and its immediate tunics, or coats. Theſe bags are formed by a duplicature of the part called the dartos; and they are ſituated on each ſide of the raphe of the *ſcrotum*. The bags being thus formed, are laterally connected to each other, by the intervention of a cellular membrane. This union or connection of the ſides of the dartos conſtitutes that partition, which by anatomiſts is denominated ſeptum *ſcroti*. The ſeptum *ſcroti*, on its inferior part, is connected to the internal ſurface of the cutis, immediately under the raphe; on its ſuperior part, this ſeptum is connected to the inferior and external ſurface of the urethra, after having been expanded upwards betwixt the tunica vaginalis of each teſticle. Upon a removal of the ſeveral parts which unite in forming the *ſcrotum*, the tunics or proper coats of the teſticles, next preſent themſelves to view.

The *ſcrotum* is liable to inflammation and abſceſs, which ſometimes are attended with a conſiderable degree of fever, and that not without danger of life. If poſſible endeavour to remove the inflammation without permitting ſuppuration to take place: to this end, bleeding and other antiphlogiſtics muſt be directed; diſcutient cataplaſms applied cold, and renewed as often as they become warm; and if poſſible, confine the patient to his bed. The *ſcrotum* ſhould be ſuſpended in a bag-truſs, ſo as that it may be kept near the belly; and if it is thought proper to encourage a ſuppuration, let a fomentation be uſed warm, at leaſt twice a day, and after each time of fomenting, a poultice applied warm, and renewed as often as it becomes cool. In this caſe the patient muſt be ſupported with a generous diet and proper cordials, ſuch as the cort. Peruv. rad. ſerp. rad contray. in ſubſtance or in form of decoction as may ſeem moſt eligible, the conſ. card. is alſo to be added, and if pain requires it an opiate occaſionally.

When by the ſize and prominence of the ſwelling, the ſoftneſs of the integuments, their ſhining red colour, the peeling off of the cuticle from the cutis, the mitigation of pain in the part itſelf; an œdemetous appearance of the integuments upon being preſſed; but above all, the fluctuation of matter under the fingers, it appears that maturation is perfected, then open the tumor on its moſt depending part. If the tumor be large, and the integuments thin and much diſcoloured, remove an oval piece; thus you will be able more effectually to apply thence the full dreſſings. As ſoon as the matter is diſcharged, fill the wound with ſoft lint, and over it apply the poultice, or apply a pledgit of ſoft tow with ſome emollient ointment ſpread on it. The future dreſſings may be the ungt. Baſil. or other digeſtive. At the end of the two firſt days, the dreſſing ſhould be renewed twice in twenty-four hours, and thus continue on account of the acrimony and quantity of the diſcharge, ſo long as may be thought neceſſary, not forgeting to uſe an emollient fomentation, for the ſpace of ten or fifteen minutes previous to each dreſſing. If the diſcharge is thin, ſanious, or corroſive, ſprinkle ſome brandy or camphorated ſpirit of wine upon each fomentation cloth. If after the operation any conſiderable hardneſs of the integuments ſhould ſtill remain, continue to apply the ſuppurating poultice, at each time of dreſſing over the pledgits of digeſtive, until the hardneſs is removed. The uſe of the bark alone, or with the rad. ſerp. V. or rad. contray. or a decoction of theſe; as alſo the elix. vitr. in the patient's drink will generally greatly ſupport the patient's ſtrength, and alter the matter in its quality.

Another afflictive diſeaſe is too often met with in the *ſcrotum*, viz. the cancer. It ſeems peculiar to chimney-ſweepers; hence is called the chimney-ſweepers cancer, the chimney-ſweepers wart, and the ſoot wart. From whatever cauſe it may be, it is evident beyond a doubt that chimney-ſweepers are peculiarly liable to this diſeaſe in this part. Mr. Pott ſeems to be the firſt writer who hath noticed it; he thinks it may be owing to a lodgment of ſoot in the rugæ of the *ſcrotum*, and at firſt not be a diſeaſe of the habit.

He further obſerves, that it always makes its firſt attack on, and its appearance in, the inferior part of the *ſcrotum*; when it produces a ſuperficial, painful, ragged, ill-looking ſore, with hard and riſing edges. It does not uſually appear before, whence it is often taken both by the patient and the ſurgeon for venereal; and being heated with mercurials, is ſoon and much exaſperated: in no great length of time, it pervades the ſkin, dartos, and membranes of the *ſcrotum*, and ſeizes the teſticle, which it enlarges, hardens, and renders truly and thoroughly diſtempered; from whence it makes its way up the ſpermatic proceſs into the abdomen, moſt frequently indurating and ſpoiling the inguinal glands: when arrived within the abdomen, it affects ſome of the viſcera, and then very ſoon becomes painfully deſtructive.

The only chance of putting a ſtop to, or of preventing this miſchief, is immediately to remove the part afflicted, i. e that part of the *ſcrotum* where the ſore is. If it be ſuffered to remain until the virus hath ſeized the teſticle, it is generally too late, even for caſtration. If ever extirpation bids fair for the cure of a cancer, it ſeems to be in this caſe; but then the operation ſhould be immediate, and before the habit is tainted. When it reaches the teſticle, it is rapid in its progreſs, and moſt certainly deſtructive in its event: ſo, early to extirpate is the only cure.

Fiſtulous ulcers are ſometimes met with in the *ſcrotum*; if theſe communicate with the urethra, a particular attention thereto will be required in attempting to relieve. The cauſes may be an abſceſs in the *ſcrotum*; a wound made through the *ſcrotum* into the urethra; the venereal diſeaſe firſt affecting the urethra, and from thence producing the ulcer in the *ſcrotum*, &c. The external ſore is generally very ſmall and ſinous; the lips grow callous; the diſcharge is thin, copious, and almoſt continual; and if there is a communication with the urethra, the urine will more or leſs eſcape through the external wound at the times of making water; it will alſo inſinuate itſelf into the cellular membrane of the *ſcrotum*, and its neighbouring parts, and be therein confined; whence many inconveniences ariſe that cannot be removed until the orifice made through the urethra is healed.

When this diſorder originated in the urethra, it may be known by introducing a catheter or bougie; for an obſtruction will be met with there: when it is cauſed by an abſceſs forming itſelf within the cellular membrane near the urethra, or in the corpus cavernoſum urethræ, there will be little or no reſiſtance met with from the bougie. As to fiſtulous ſores, calloſities, enlargements, and diſtenſions in theſe parts; it is worth remembering, that although the diſeaſe ſhould appear to be not confined to the *ſcrotum*, but that it extends to the perinæum and nates, and there be many external fiſtulous openings through the integuments of theſe parts, yet theſe ſhall in ſome inſtances be diſcoverable only on opening into the urethra; to remove which ſhould be the primary attempt of the ſurgeon, as the cure of the whole very much depends, if not altogether, upon this very circumſtance; and of this be aſſured, that the permanency of the cure of every wound, however circumſtanced, depends upon the roundneſs and firmneſs of its foundation at the bottom.

When a venereal cauſe gave riſe to this diſorder, the judicious

judicious introduction and uſe of bougies, made of a proper compoſition, ſize, and ſtiffneſs, joined with mercurial frictions, applied near to, or immediately upon, the diſeaſed parts, in proper quantities, at proper intervals, and continued for a due length of time, joined with ſoft, oily purges, occaſionally adminiſtered, and ſoft, diluting drinks, will often render every ſevere operation unneceſſary; though the circumſtances attendant upon the complaint be of a bad and complicated kind.

See Pott's Chirurgical Works; Warner's Caſes in Surgery; Warner on the Teſticles.

SCRUPULUS. A ſcruple. A weight with us, which is equal to twenty grains; but in France, Germany, &c. it contains twenty-four grains. Three ſcruples, however, is a dram, and eight drams an ounce, in all theſe countries.

SCYTHICUS LATEX, alſo called *ὑπνῶμα, a divine water.*

SEBACÆ GLANDULÆ. Many of theſe are about the noſe, where their contents are often hardened, and at the extremities of their ducts there appear black ſpots, and when the matter is ſqueezed out it reſembles a worm with a black head. Theſe glands are ſeated in the cellular membrane, under the ſkin, and in various parts of the body they are enlarged and form encyſted tumors. Theſe glands are called the miliary glands by ſome. But as to miliary glands, diſtinct from theſe, the moderns deny their exiſtence, not being able to diſcover them.

SEBACEOUS HUMOUR. The *ſebaceous humour* is ſupplied by the ſebaceous glands, to preſerve the ſenſibility of the ſkin, and to keep it moiſt by preventing too copious a perſpiration. When this glutinous *humour* is wanting, as in eryſipelas, the ſkin is dry and parched, and little or no ſwelling can be brought on there by inflammation, becauſe the erethyſm of the veſſels is but ſmall, and the morbific *humours* having nothing in their way to retard their egreſs, they exhale through the expiring veſſels of the ſkin. All the inner membranes of the body are ſupplied with an *humour* ſimilar to this.

SEBESTEN, alſo called myxa, myxara, ſebeſtina, vidamaram, ſebeſten. That uſed in medicine is the cordia *ſebeſtina*, Linn. It is a fruit the ſhape of a plum, black on the outſide, with a flattiſh wrinkled ſtone. It is produced in Egypt and Aſſyria. It is cooling and moiſtening; but is not uſed as a medicine, though it is ſaid to obtund ſharp humours which fall on the lungs.

SECALE, alſo called ſiligo, rogga. Rie. It is a kind of grain: it nouriſhes leſs than wheat, and ſome people find that the bread made of it gripes and gently purges them. Sometimes this grain is corrupted, and then it occaſions painful and convulſive diſorders, and death.

SECRETIO, from *ſecerno, to ſeparate.* Secretion. The various *ſecretions* are all from the blood, but how it happens that each *ſecretory* veſſel at firſt ſeparated a particular part from the general maſs, and always continues to do the the ſame, is perhaps not ſo clearly underſtood as is ſuppoſed. See Haller's Phyſiology, ſect. 8. Pemberton's Phyſiology, ſect. 7.

SEDANTIA. Sedative medicines. In general, by *ſedatives* are underſtood ſuch as ſoothe, compoſe, check, or allay any irregular motion in the ſolids or fluids. They ſeem to ſtand oppoſed to what irritates, and are the loweſt claſs of antiſpaſmodics, as anodynes are of the moſt powerful claſs.

SEDATIVA SAL. Sedative ſalt. The acid of borax hath, until very lately, been unknown as to its peculiar nature and origin. Mr. Hœffer found it in an uncombined ſtate, but diſſolved in the laguni, or lakes of hot mineral water near Monte Rotundo, Berchiaio, and Caſtelnuovo, in Tuſcany, in the proportion of nine grains in one hundred of water. Mr. Maſcagni hath found it adhering to ſhiſtus on the borders of the lakes, of a dirty white, yellow, or greeniſh colour, and cryſtallized in the form of needles. This acid, i. e. the acid of borax is called *ſedative ſalt.* See Borax and Tincal. Kirwan's Elem. of Mineralogy.

SEDENTARIA OSSA. So Daventer calls the protuberances of the os coxendicis upon which we ſit.

SEDUM. So called from *ſedendo*, ſitting, becauſe of its poſture on walls, &c. where it grows; or from *ſedando*, becauſe it allays when applied to parts that are inflamed. It is alſo called ſempervivum, becauſe, as its name expreſſes, it is always green; and vermicularis, becauſe its leaves reſemble worms. In Engliſh it is called ſengreen and houſe-leek. Boerhaave mentions twenty-eight ſpecies. The ſort uſed in medicine is the *ſempervivum* tectorum, Linn. The greater houſe-leek. They are ſmall plants, whoſe ſhort and thick ſtalks are covered with little fleſhy conical leaves, ſet thick together in the manner of ſcales; on the tops appear pentapetalous flowers, which are followed by a pod full of ſmall ſeeds. They are annual, grow on old walls and dry ſtony grounds. They flower in June and July.

The leaves have an acrid taſte, but no remarkable ſmell: applied externally ſome of them veſicate the parts, and if taken internally, in no great quantity, they are ſtrongly emetic; whilſt the common ſort, and ſome other ſpecies abate external inflammation, and if taken inwardly, are emollient and laxative, and have ſomething of acrid, auſtere and aſtringent; but they are not of any note in the preſent practice.

SEDUM. It is a name for ſeveral ſorts of cotyledon and ſaxifraga.

SEIGNETTE [Sal. de]. See Rupeliænsis Sal. It is thus named from Dr. Seignette, of Rochelle, who invented it.

SELENITES. It ſometimes reſembles the lapis ſpecularis, and ſometimes cryſtal; but it wants the leafy ſtructure of the one and the leafy hardneſs of the other. It is tranſparent, but not always free from cloudineſs. It calcines into gypſum or plaſter of Paris. This name is given to a combination of the vitrolic acid with calcareous earth. See the Dict. of Chem. Neumann's Chem. Works.

SELINUM, i. e. Apium.

SELLA TURCICA. It is a depreſſion between the clinoid apophyſes of the ſphenoid bone.

SELTZER WATER. It is a mineral water which ſprings up at Lower Seltzer, a village in the electorate of Triers, about ten miles from Frankfort on the Mayne. It is a very uſeful medicinal water: it contains a very ſmall portion of calcareous earth, of a native mineral alcali, and an acid; but of theſe the quantity is too ſmall to attribute any medicinal virtues to; but it contains alſo near 1-7th of its bulk of fixed air, which is more than is found in any other mineral water, and to this it owes its principal virtues. See Dr. Brockleſby's Experiments on *Seltzer Water*, in the Lond. Med. Obſ. and Inq. vol. iv.

SEMEIOTICE. That part of medicine which treats of the ſigns of health and diſeaſes. See Dr. Wynter's Tranſlation of Lommius's Obſ.

SEMEN. Seed. In botany it is a body perfected by the mutual operation of both ſexes, containing the rudiment of ſuch plant as that from which it was taken, ſo may properly be judged to be analogous to the egg of an animal.

SEMIFIBULÆUS, i. e. Peronæus ſecundus.

SEMILUNARES [Cartilagines]. They are placed upon the upper part of the tibia; they are thick on the outſide, and ſerve to deepen the cavity; they likewiſe ſerve to give ſome degree of rotation to the joint, being moveable and variable, to adapt themſelves to the condyls in the various motion of the joint.

SEMIMEMBRANOSUS MUSCULUS. It riſes tendinous from the poſterior part of the tuberoſity of the iſchium, cloſe to the origin of the muſculus quadratus femoris, and is inſerted into the back part of the internal condyle of the tibia.

SEMINERVOSUS MUSCULUS. It is alſo called ſemitendinoſus. It lies upon the outſide of the ſemimembranoſus: at its origin it is one maſs with the head of the biceps; when they have run together a little way they part, and the *ſemitendinoſus* runs to the internal condyl and upper part of the tibia, making conjointly with the ſartorius and the gracilis, a ſort of faſcia.

SEMI-ORBICULARES. The orbicular muſcle of the lips, if conſidered as two, are called ſemi-orbiculares ſuperior and inferior.

SEMISPINALIS. See Multifidus Spinæ.

SEMITENDINOSUS, i. e. Seminervoſus.

SEMITERTIANA FEBRIS. The Greeks call it hemitritæus. It is a kind of fever, compounded of an intermitting tertian and a continual quotidian. Some call

it a continual tertian. It is one of thofe tertians which return every day. Some rank it as a remittent fever.

There is nothing peculiar in the management of this diforder which the practitioner will not naturally fuggeft from his acquaintance with the nature and general methods of relief in fevers. See Spigelius and Hoffman on the Semitertian Fever, and Lommius's Med. Obf.

SENEGAL [GUM], i. e. Gum rubrum aftringens.

SENEKA, alfo called fenega, polygala Marilandica, fenegaw, American milk-wort, and fenekka, rattle-fnake root. *Polygala fenega*, or *polygala Marilandica*, floribus imbetibus fpicatis albis, caule erecto fimpliciffimo, foliis lato-lanceo-latis. Linn. *Senega, rattle-fnake root.* The leaves are pointed and fomewhat oval; the ftalks are upright and branched; the flowers are white: the root is variouſly bent and jointed; it is about the thickneſs of a little-finger, and refembles the tail of a rattle-fnake; it hath a membranous margin, which runs its whole length on each fide; outwardly it is of a yellowifh or a pale browniſh colour, internally white. It is a native of Virginia, Penſylvania, and Maryland, and is cultivated in our gardens. This root is a ſpecific againſt the poiſon of the rattle-fnake: the powdered root, or the freſh root beat into a cataplaſm, is applied outwardly, and a decoction is taken inwardly. In inflammatory fevers it promotes perſpiration, and it aſſiſts the expectoration in pleuriſies and peripneumonies; it is cathartic, and often proves emetic, to prevent which it is given in weak cinnamon water. In pleuriſies, whether inflammatory or ſpurious, in the rheumatiſm, gout, gouty rheumatiſm, and the humoral aſthma, it is ſingularly uſeful. The powder is preferred to any other preparation, and the doſe is from ℈ i. to ʒ i. but a decoction of three ounces of the root in water enough to ſtrain off a pint, is uſually given from two to four ſpoons full three or four times a day. See Lewis's Mat. Med.

SENNA. It is a ſhrub with a roſaceous flower, which is followed with a pod with ſeeds like grape-ſtones. Botaniſts enumerate nine ſorts, but the following is that which is preferred in practice.

SENNA ALEXANDRINA, alſo called folia Orientalia. Alexandrian ſenna. Caſſia ſenna, or caſſia Alexandrina, foliis trijugis quadrijugiſive acutis, floribus luteis. Linn. Alexandrian acute, ſix leaved ſenna. It is called *Alexandrian* not becauſe it grows there, but becauſe it is from thence chiefly that it is ſent into Europe. The leaves, which are the parts in uſe, are of a lively yellow green colour, an oblong ſomewhat oval figure, ſharp pointed at the end, about a quarter of an inch broad, and not an inch long. Chooſe thoſe which appear bright, freſh, free from ſtalks and ſpots, that are well and ſtrongly ſcented, that are ſmooth and ſoft to the touch, thoroughly dry, ſharp pointed, bitteriſh and ſomewhat naufeous to the taſte. There are inferior ſorts, but they are generally diſtinguiſhed by their not being pointed, but more or leſs broad at the end.

The Arabians firſt brought theſe leaves into uſe; they are moderately ſtrong, and in general a ſafe cathartic; they enter the blood and attenuate it. Dr. Aiſton preſcribed it in ardent fevers, and frequent experience manifeſts its ſafety and advantage even in the moſt delicate habits, and the moſt robuſt it operates on ſufficiently. Largely diluted, as when a dram of theſe leaves are infuſed in four ounces of ſoft cold water, is the moſt agreeable method of taking it; the addition of acids takes off the naufea which it excites, and as the griping quality depends upon its reſin, the dilute infuſions will be the freeſt from this effect. From ʒ i. to ʒ iii. are uſually ſufficient for one doſe.

Senna gives out its virtues both to water and to ſpirit. Long boiling deſtroys the purgative quality. If the *ſenna* is infuſed in an infuſion of bohea tea, its naufeous quality is as well covered as though the famed fig-wort was uſed, and if it is infuſed in a decoction of guaiacum its purging quality will be increaſed, and the griping which it generally occaſions will be prevented.

The London college directs ſeveral elegant preparations from this article. See Tournefort's Mat. Med. Neumann's Chem. Works; Lewis's Mat. Med.

SENSIBILIS. Senſible. It is applied to whatever is capable of making an impreſſion on the ſenſes.

SENSIBILITAS. Senſibility. The quality of being ſenſible, or the perceiving of any viſible thing, affecting or cauſing ſome alteration in the organ of ſenſe. The brain is the only ſenſible part of the body; all other parts are ſaid to be ſenſible, becauſe a portion of the medullary part of the brain is diffuſed over them, but they loſe this quality as ſoon as it is rubbed off or becomes dry. As the brain is the only ſenſible part, ſo it is alſo the only irritable part, the muſcular fibres contracting in conſequence of the irritation received by that portion of brain which covers them; theſe fibres are the only parts which perform their office by ſhortening themſelves, and thus it happens that they are the only parts which contract, and which have tremulous motions upon involuntary irritations. Every part of the body is capable of ſenſation in a ſound or in a morbid ſtate. See IRRITABILITY. See alſo Fordyce's Elements, part i. Medical Commentaries by Dr. Hunter.

SENSUS EXTERNI. The external ſenſes. Theſe are generally reckoned to be the ſenſe of ſeeing, hearing, taſting, ſmelling, and feeling, each of which ſee. Theſe five ſenſes agree in the following particular; viz. that nothing is perceived until it firſt makes an impreſſion upon the organ of ſenſe; but they differ as to our conſciouſneſs of that impreſſion: in touching, taſting, and ſmelling, we are conſcious of the impreſſion, but not ſo in hearing and ſeeing; on which account theſe latter are conſidered as more refined; the former ſeeming to exiſt externally at the organ of ſenſe, are conceived to be merely corporeal. See Haller's Phyſiology; Shebbeare's Theory and Practice of Phyſic.

SENSUS INTERNUS. The internal ſenſes are thoſe affections of the mind which are excited in it by its perception of ideas; theſe are generally reduced under theſe four heads, viz. imagination, memory, attention, and the paſſions of the mind. Their influence on health is noted in many particulars taken notice of in the different parts of this work. See Haller's Phyſiology.

SEPARATORIUM. A ſeparatory. The name of an inſtrument for ſeparating the pericranium from the cranium; alſo a chemical veſſel for ſeparating liquors, but particularly for the ſeparation of the eſſential oil of any vegetable ſubject from the water that is diſtilled therefrom.

SEPIUM OS, alſo called ſepia os, ſepiæ os. Cuttle-fiſh bone. The *cuttle-fiſh* is a kind of polypus. It hath two *bones*, one which is like a knife, the other is like a quill; the latter of theſe, when calcined in the ſun, is uſed as a dentifrice ſometimes, but the preſent practice rarely notices it.

SEPTANA. A ſeptinary fever, that is, a fever which performs its period in ſeven days. Alſo an erratic intermitting fever which returns every ſeventh day.

SEPTICA. Septics. Medicines which promote putrefaction; alſo corroſive ones.

SEPTICUS LAPIS, i. e. Cauterium potentiale.

SEPTIMANA. It is a kind of febris erratica.

SEPTUM CORDIS. The partition between the two ventricles of the heart. *Septum*, i. e. *an incloſure*, from *ſepes, a hedge.*

SEPTUM LUCIDUM. The thin partition which divides the two lateral ventricles of the brain. It is a kind of duplicature of a continuation of the corpus callofum. It is united on its lower part with the fornix.

SEPTUM NARIUM. The partition betwixt the noſtrils. It is formed by the deſcending laminæ of the os ethmoides, and by the vomer, and it is placed in the groove framed by the criſtæ of the oſſa maxillaria, and riſing edges of the oſſa palati. The cartilage which forms the lower part of this *ſeptum*, is joined to the anterior edge of the middle portion of the os ethmoides, to the anterior edge of the vomer, and to the anterior part of the groove formed by the oſſa maxillaria, as far as the naſal ſpines of theſe bones.

SEPTUM PALATI, i. e. Palatum Molle.

SEPTUM TRANSVERSUM, i. e. Diaphragma.

SERAPION. A phyſician of Alexandria. He, and Philinus, of the iſle of Cos, were both ſcholars of Herophilus, and were founders of the empiric ſect, which happened about two hundred and eighty-ſeven years before Chriſt. One of the moſt eminent among the followers of this ſect, was Heraclides Tarentinus, whom ſee.

SERICUM. Silk. Raw *ſilk* prepared in the manner of ſponge when it is calcined, excels the ſponge in its medical effects; it alſo yields more volatile ſalt than any other animal ſubſtance yet tried. In Switzerland, the volatile ſalt of raw ſilk is called the Engliſh ſalt: they alſo give the ſame name to the volatile ſalt of vipers.

SERIFLUXUS. A ſerous diſcharge, or flux of ſerum.

SERPENTARIA VIRGINIANA, called alſo ariſtolochia, piſtolochia, viperina, colubrina, Virginiana, contrayerva Virginiana. Virgin ſnake-weed. It is the *ariſtolochia ſerpentaria*, or *ariſtolochia Virginiana* foliis cordato-oblongis planis, caulibus infirmis ſuperne flexuoſis teretibus, floribus recurvis ſolitariis, fructu parvo pentangulari. Linn. It is brought from Virginia and Carolina; it is ſmall, light, buſhy, and compoſed of a number of ſtrings or fibres iſſuing from one head, and matted together, of a browniſh colour on the outſide, and pale or yelloviſh within. It hath an aromatic ſmell, ſomewhat like that of valerian, but more agreeable, and warm, bitteriſh, pungent taſte, not eaſily covered by a mixture with other ſubjects.

Snake-root gives out its active matter to water or to ſpirit. The greateſt part of its flavour is carried of either by water or by ſpirit in diſtillation; and if the quantity diſtilled be large, there ariſes with water a pale coloured eſſential oil, of a ſtrong ſmell, but not a ſtrong taſte, the greateſt part of the camphorated pungency and bitterneſs of the root remains in the inſpiſſated extract. The ſpirituous extract is ſtronger than the watery, not from its having loſt leſs by evaporation, but from its containing the active parts of the root concentrated in a ſmaller volume, its quantity amounting only to one half of the other.

The Virginian *ſnake-root* is a warm diaphoretic, of excellent uſe in low and putrid fevers; it raiſes the pulſe, promotes perſpiration, reſiſts putrefaction, and corrects a putrid diſpoſition which is already begun. Dr. Alſton ſays it reſembles the ariſtolochia in virtues, but that he prefers the ariſtolochia tenuis to the ſerpentaria on all accounts. The doſe may be from gr. iii. to ʒ ſs.

The Virginian aſarum is ſometimes ſold for the *ſnake-root*, but the aſarum is blacker.

The London College directs a tincture of *ſnake-root* which is made with proof ſpirit. In this tincture, if the *ſnake-root* with which it is made be powdered fine, is the whole virtue of the root. It may be taken from two teaſpoonfuls, to a table ſpoonful, three times a day. See Lewis's Mat. Med.

SERPIGO. This word is uſed both for the herpes and impetigo. Linnæus ſignifies by it tettars and ringworms.

SERPYLLUM. Boerhaave takes notice of ſix ſpecies of this plant.

SERPYLLUM VULGARE MINUS. Common mother of thyme, or wild thyme. Thymus ſerpyllus, or thymus ſerpyllum vulgaris minor, foliis planis obtuſis baſi ciliatis, floribus capitatis caulibus repentibus, Linn. Common ſmall wild thyme. It grows wild on heaths and dry paſture ground; it flowers in June and July; it is an agreeable aromatic, ſimilar to that of the other ſpecies, but milder, and in flavour it is rather more grateful. Its eſſential oil is both in ſmaller quantity, and leſs acrid, and its ſpirituous extract comes ſhort of the penetrating warmth and pungency of that of the common thyme.

SERPYLLUM CITRATUM, alſo called thymus citratus. Lemon thyme. It differs but little from the mother of thyme in its appearance, except that it is upright and buſhy. It is a native of dry mountainous places, common in gardens, and flowers in July. It is leſs pungent than the common thyme, and more ſo than the mother of thyme, and more grateful than either. Its ſmell is like that of lemon peel; diſtilled with water, it yields a larger quantity of eſſential oil than the other ſorts do. This oil contains nearly all the medicinal parts of the plant. Spirit of wine alſo takes up the finer parts.

SERRATUS ANTICUS MAJOR, (from *ſerra*, a *ſaw*.) The fore, or greater ſaw-like muſcle. It riſes by digitations from the nine ſuperior ribs, then paſſes backwards, and is inſerted into the whole length of the ſcapula. Its largeſt portion is inſerted into the lower angle of the ſcapula, which it rotates and brings forwards. Between every portion of this muſcle, there is a quantity of cellular membrane interpoſed, eſpecially about the middle, where it ſeems to divide it into two diſtinct muſcles. If the pectoralis minor is called ſerratus anticus minor, this muſcle is called major, otherwiſe it is ſimply called ſerratus anticus.

SERRATUS ANTICUS MINOR. See SERRATUS ANTICUS MAJOR.

SERRATUS POSTICUS SUPERIOR. It riſes by a thin broad tendon, from the two upper vertebræ of the back, and the two lower of the neck, and runs to be inſerted into the ſecond, third, and fourth ribs.

SERRATUS POSTICUS INFERIOR. It riſes from the faſcia of the loins, and is inſerted into the three laſt ribs, ſerving to bring them down.

SERTULA CAMPANA, i. e. Melilotus.

SERUM. Whey. The thin part of the blood is alſo called its ſerum. The ſerum of the blood contains a coagulable matter, which forms what is called the buff upon the blood after taking it from a vein. Dr. Fordyce obſerves, in the firſt part of his Elements, that the ſerum is fluid in any degree of heat between thirty and one hundred and ſixty of Farenheit's thermometer; that it conſiſts chemically of a coagulable matter and water, in which common ſal ammoniac, phoſphoric ammoniac, and generally common ſalt, and frequently ſelenites, and fixed ammoniac ſalt are diſſolved; that it contains a ſuperfluous water, which may be ſeparated from it by filtration in the body, but that water which is chemically combined with the other parts cannot; that the ſeparation, or addition of ſuperfluous water, does not affect its viſcidity ſo far as it is of any conſequence in the circulation, but the ſeparation of that water which is in chemical combination may render it more viſcid; that the water which is chemically combined with it is never ſeparated whilſt it is contained in the blood veſſels, conſequently this part of the blood is always equally viſcid, ſo far, at leaſt, as its viſcidity can effect the circulation, or the ſecretions; and that it may be coagulated by a juice ſecreted in the ſtomach, or by injections thrown into the blood veſſels.

SESAMOIDEA, from σησαμον, and ειδος (Ossa.) The ſeſamoid bones. Theſe are the little bones moſt frequently found at the articulations of the toes and fingers; thoſe two at the firſt joint of the great toe are much larger than any other, and allow the flexors to ſend their tendons along this joint ſecure from compreſſion, and, beſides, giving them an angle at their inſertion, the force of the muſcles is augmented. They have their name from their ſuppoſed reſemblance to the ſeed of the ſeſamum, yet they are of very different figures and magnitudes. They are generally moſt numerous in old people, and Winſlow thinks they are often formed of the ligaments, or tendons, about the articulations where there is much ſtrong compreſſion on them. Cheſelden obſerves, that the *ſeſamoid bones* are reckoned to be forty-eight in number; but that there is commonly found, but two under the ball of each great toe, two at the middle joint of each thumb; and ſometimes one at the lower end of each thigh bone, at the beginning of the plantaris muſcle. He adds that, he found in ſome bodies, the little cartilages at the receiving ends of the bones of the fingers oſſified; and concludes, that thoſe who enumerate forty-eight *ſeſamoid bones*, have miſtaken theſe oſſifications for them.

The great toe hath the largeſt *ſeſamoidea*; the inner one is the largeſt; the Arabians call it albadara, and ſay that, of this bone, as it were of ſeed, a man receiveth the new body wherewith he riſeth at the reſurrection.

Dr. James, in his Med. Dict. art. Albadara, relates a caſe of frequent fits troubling a young lady, which after reſiſting various means of relief, were effectually cured by amputating the great toe: this operation was propoſed on a ſuppoſition that the *ſeſamoid bone* there, was diſlocated; and from thence the fits were produced. He further adds a caſe that ſeems to have been the object of his own attention, and which he apprehends aroſe from an injury done to the *ſeſamoid bone* of the great toe. On the patient's firſt reception of the hurt, he was ſeized with a fit, and whenever he moved that toe, he fell into another. Theſe fits much reſembled the epileptic kind, except that no froth was diſcharged at the mouth: the injured foot firſt began to be convulſed, then the leg, and from thence a very uneaſy ſenſation aſcended to his head, and

and then the convulſions began to be univerſal. This caſe proved fatal.

SESAMUM VERUM, alſo called ſeſamum veterum, digitalis Orientalis. Oily purging grain. The ſeſamum Orientale, Linn. It is an Egyptian plant, the ſeeds of which afford a great quantity of oil by expreſſion, but hath no right to the title of purging.

SESELI VULGARE, alſo called ſiler montanum, liguſticum, ſermountain. Common hartwort. That which is ordered by the London College is the laſerpitium ſiler. It is a ſmall umbelliferous plant, with large leaves ſet in pairs; the root is large, thick, and branched. It is perennial, grows wild in the ſouth of Europe, is raiſed in our gardens, and flowers in June.

All the parts of this plant are aromatic, of an agreeable ſmell, and warm ſweetiſh taſte; the roots are the moſt warm and pungent, the ſeeds are moſt pleaſant and ſweet. A ſpirituous extract of the ſeeds is an elegant aromatic ſweet. See Lewis's Mat. Med.

SESELI MASSILIENSE, called alſo fœniculum tortuoſum, Italian hartwort, French hartwort, hartwort of Marſeilles. It is the ſeſeli tortuoſum, Linn. It is perennial, and a native of the ſouth of Europe, from whence the ſeeds are brought.

The ſeeds are aromatic, warm, and biting to the taſte, more pungent than thoſe of the common hartwort, but want their ſweetneſs. See Lewis's Mat. Med.

SESELI ETHIOPICUM, alſo called bupleurum arboreſcens ſalicis folio. Shrub hartwort of Ethiopia. This ſpecies is met with in the gardens of the curious; it flowers in Auguſt; its ſeeds are ſomewhat acrid.

SETACEUM. A ſeton, ſo called from ſetæ equinæ, horſes hairs, becauſe horſes hairs were firſt uſed for keeping the wound open; but now thread is uſed, becauſe it is leſs painful. Camanuſali, a phyſician of Bagdat, who lived before that city was taken by the Tartars in 1258, mentions a *ſeton* in the cure of a diſorder of the eye. Rhazes alſo ſpeaks very particularly about *ſetons*. Originally, an actual cautery was uſed for making a ſeton with. Hollerius firſt made it with a needle unheated.

This operation is performed by elevating the ſkin with the finger and thumb, an aſſiſtant doing the ſame at about an inch from where the operator holds it, and having armed a large broad crooked needle with as many threads as the operator thinks needful, paſs the needle through the ſtretched ſkin, and bring the threads a little way through, and there leave them; rub a little of the thread, as much as will paſs into the *ſeton* at each time of dreſſing, with the ung. baſil. flav. move the thread backward and forward every morning and evening, and thus the diſcharge will be promoted, and may be continued at pleaſure.

Setons are commended in diſorders of the head and eyes; but iſſues, or perpetual bliſters, are more agreeable, and equally uſeful methods. See Heiſter's Surgery.

SEXTANA. Erratic, intermitting fevers, which return every ſixth day.

SIALOGOGA, medicines which excite a ſalivation. Of this kind, mercury is the moſt powerful, and next to it is the metallic part of antimony.

SIBBENS. This name is given to the venereal diſeaſe in ſome parts of Great Britain. In the year 1773, Mr. Hill, a ſurgeon in Dumfries, publiſhed his Caſes in Surgery; to which he hath added an account of this diſorder, and that with a view to the confutation of a theſis which had been publiſhed, and erroneouſly aſſerted the *ſibbens* to be different from the pox.

SICYEDON. A tranſverſe fracture.

SIDERATIO. An apoplexy, a ſphacelus, alſo a ſpecies of eryſipelas, which is vulgarly called a blaſt.

SIGILLATA TERRA, ſealed earths. Theſe take no place amongſt foſſils, being artificial. Their virtue and uſes the ſame as the terra Lemnia, and other bolar earths.

SIGILLUM HERMETICUM. An hermetic ſeal. A glaſs veſſel is ſaid to be hermetically ſealed, when the glaſs is melted, and the veſſel by this means is cloſed.

SIGILLUM SOLOMONIS. See POLYGONATUM.

SIGMOIDES PROCESSUS, i. e. Proceſſus Coracoides. It is called ſigmoides from its reſemblance to the Greek letter ſigma. Three valves of the heart have this epithet, viz. of arteriæ pulmonalis, and aorta. The ſemicircular cavity of the cubit, at the articulation of the fore-arm with the humerus, is ſometimes called the ſigmoidal cavity; and the cartilages of the aſpera arteria have the epithet ſigmoidal applied to them by ſome authors.

SIGNUM. Signum, a ſign. Signs are univerſal; univocal or pathognomonic; equivocal or doubtful; commemorative. Galen defines it to be, "that which diſcovers, or makes known, what was formerly unknown."

Signs are thoſe appearances which manifeſt the loſs of health, or the preſence of diſeaſe, and relate to the general cauſes thereof. Symptoms are thoſe diſorders which are produced by the continuance, or other circumſtances of a preceding diſorder. *Signs* ſhew the nature of the diſtemper, and ſymptoms point out its effects, or what may be expected as to health, life, or death. *Signs* always attend a diſeaſe, but ſymptoms do not. Some divide *ſigns* into diagnoſtic, prognoſtic, commemorative, equivocal, and pathognomonic.

SIGNETTE, (SAL DE) i. e. Sal Rupellenſis.

SILEX. Flint. Many have been the pretences to preparations of an extraordinary medical efficacy from flints, but experience hath not ſupported their credit; ſo that at preſent their uſe is chiefly confined to the making of glaſs, and of artificial gems, in which they are preferred to all other materials which have been uſed for thoſe ends. See Neumann's Chem. Works; Dict. of Chem. In Foſſilogy, *flint* is a genus in the order of quartzoze ſtones; its characters are, quartzoſe ſtone, very hard and compact; of a ſolid ſtructure; always inveſted with an outward cruſt; and either tranſparent, or ſemitranſparent. Edwards's Elements of Foſſilogy.

SILIQUA. An ancient weight equal to three grains and one-twenty-eighth. The carob-tree, alſo a pod, which is a membranaceous veſſel, containing the ſeeds of ſome plants, and a name of ſeveral different plants.

SILIQUA HIRSUTA. The cowhage.

SILIQUA DULCIS, alſo called caroba, ceratia, ceratonia, ſiliqua edulis. The carob-tree. It grows in Sicily and Naples; the fruit is cooling, and moderately laxative. At Venice they are much uſed.

SILIQUA PURGATRIX. It is a large tree, a native of Guinea; its pod is much more purgative than that of the common carob. See Raii Hiſt.

SILPHIUM. Aſſafœtida, alſo the ſtalk of the plant which affords it.

SIMAROUBA, alſo called euonymus, and the bark, which is the part in uſe, is called ſimarouba, ſima ruba, and Guiana bark. It is the bark of an unknown tree in Guiana. Some think it to be the bark of the piſtachia terebinthus, Linn. The Edinburgh College, in their Pharmacopœia, ſay, that it is the quaſſia ſimaruba, vel quaſſia floribus monoicis, foliis abrupte pinnatis: foliolis alternis ſubpetiolatis, petiolo nudo, floribus paniculatis. Linn. Suppl. 234. Curtis, in his Catalogue of the Medicinal Plants in the London Botanic Garden, calls it quaſſia dioica. It is brought to us in long pieces, of a yellow white colour, light, tough, and fibrous. It reſembles that which the ancients deſcribe under the name of macer. It was brought into Europe in the year 1713. Dr. James ſays, in his Medicinal Dictionary, that it is the bark of a Weſt Indian tree, viz. of the tree from which we have the Cayan wood. It is a ſpecific in dyſenteries, particularly the feroſo-bilious, bloody, and mucous kinds; it removes theſe diſorders when there is no fever, and when the ſtomach is unhurt, without the uſual inconveniencies of aſtringents; it abates ſpaſms, and hyſteric affections. If any ſymptom ſeems to require an emetic, let it precede the uſe of this bark.

The beſt preparation is the following decoction, four table ſpoonfuls of which may be given every three, four, or ſix hours. ℞ Cort. ſimaroub. craſſ. contuſ. ʒ ii. coq. in aq. font. ℔ i. ℥ iv. ad ℔ i. & cola.

It hath been obſerved, that if this decoction is made ſtronger it excites ſickneſs, but in proportion thereto it fails as an antidyſenteric. See Lewis's Mat. Med. Mem. de l'Acad. des Sciences 1729, par M. de Juſſieu.

SIMPLEX OCULUS. It is a bandage for the eye, being only a ſingle headed roller applied to the cheek, then paſſed over the eye, and the offa parietalia running down behind the head, and paſſing by the nape of the neck, it riſes to the place it began at, and ſo is continued till the whole is taken up. It is called ſimplex oculus for

both eyes, when it is a little longer, and made to pafs over both eyes; for both eyes it is rolled up into two heads, and the middle is applied to the nape of the neck.

SINANCHICÆ. Italian ruſhy horſe-tail.

SINAPELŒON. Oil of muſtard-ſeed.

SINAPI. Muſtard. It is an annual plant, with long rough leaves, divided to the rib into irregular ſegments, of which the extreme one is the largeſt, producing at the tops of the branches tetrapetalous yellow flowers, followed each by a ſhort, ſmooth, quadrangular pod, divided longitudinally by a membrane, which projects at the ends, containing ſmall roundiſh ſeeds, of a reddiſh brown colour. Both the colleges of London and Edinburgh, order, in their Pharmacopœias, the *ſinapis* alba, or *ſinapis* floribus luteis, ſiliquis hiſpidis, roſtro obliquo longiſſimo, ſeminibus albis, Linn. White muſtard-ſeed. That with the dark brown ſeeds, is the *ſinapis* arvenſis, or *ſinapis* floribus luteis, ſiliquis multanguiis toroſoturgidis roſtro longioribus, Linn. Commonly called Durham *muſtard*, and *ſinapis* nigra, Linn. It is a native of England, but commonly cultivated for dietetic and medicinal uſes. Botaniſts enumerate fifteen ſpecies.

Muſtard-ſeed yields upon expreſſion much oil; this oil is as inſipid as that from olives, the pungency remaining entire in the cake which is left after the expreſſion. For table *muſtard*, this cake is better than the whole *muſtard*. Spirit of wine takes up but very little of the pungency of *muſtard*; but water takes up from the bruiſed ſeeds nearly the whole of their active matter. If *muſtard* is added to boiling milk, the whey will be ſeparated from the curd, and poſſeſs much of the virtue of the ſeeds. Diſtilled with water, they yield a limpid eſſential oil, which is extremely pungent and penetrating both to the ſmell and taſte, and ſo ponderous as to ſink in water. The remaining decoction, on being inſpiſſated, becomes a ſweetiſh, brisk, mucilaginous extract.

Muſtard is one of the ſtrongeſt of the pungent ſtimulating diuretics, that operates without exciting much heat. In paralytic, cachectic, and ſerous diſorders, a large ſpoonful of the unbruiſed ſeeds have been taken two or three times a day. The bruiſed ſeeds prepared as for the table is rubbed with advantage on parts affected with numbneſs, or with rheumatic diſorders. In all diſeaſes where an acid in the primæ viæ attends, *muſtard* ſhould be freely uſed; if eaten plentifully with the victuals it aſſiſts digeſtion; mixed with horſe-radiſh, it is infuſed in wine as a ſtimulant and diuretic in languid conſtitutions; and when beaten up with vinegar into a cataplaſm, it is applied to the feet to remove deliriums in fevers, and to bring down the gout from the head or the lungs to the feet. Theſe cataplaſms act more quickly than bliſters; they are alſo uſeful applications to the feet for raiſing the pulſe in low fevers, and for relieving the head in thoſe diſorders. If *muſtard* is mixed as for the table, and of this mixture a table ſpoonful or two is added to a pint of tepid water, and drank on an empty ſtomach, it operates as an emetic; and, if repeated once or twice in a week, is of ſervice in nervous diſorders. *Muſtard*-whey is a uſeful drink in all low fevers. Lewis's Mat. Med.

SINAPI. A name of the turritis, rapiſtrum, erucago, and ſiſymbrium.

SINAPISMUS. A ſinapiſm. It is the ſecond degree of irritating external applications. See EPISPASTICS. It is ſo called becauſe of the muſtard, which is generally a part of the compoſition, and which produces a redneſs, itching, heat, and tumor in the part to which it is applied.

SINCIPUT, i. e. Bregma.

SINE PARI. The vein ſo called, ſee AZYGOS. The empl. ſine pari, or matchleſs plaſter. A pompous name for a plaſter, which is now not noticed.

SINGULTUS. The hiccup. It is a ſpaſmodic affection in the ſtomach, œſophagus, and muſcles ſubſervient to deglutition. Hippocrates ſays, that the ſtomach is its alone ſeat; Hoffmann ſays, that the diaphragm is that part principally affected; but others ſince him, aſſert the ſtomach to be the principal ſeat. The diſorder is primary, or ſymptomatic. The immediate cauſe is generally allowed to be an irritation in the ſtomach. When attending acute diſorders, it is called the acute; and when a companion of chronical diſorders, it is called the chronical *hiccup*. The occaſional cauſes are errors in diet, a wound or other injury done to the ſtomach, an inflammation there, acrid poiſon, inflammation in the diaphragm, or any of the abdominal viſcera, ſour juices, and flatulence in the ſtomach, &c.

The ſymptomatic kinds are attended with flatulence, and are uſually relieved by the ſp. vol. fœtid. to which a ſmall quantity of the tinct. Theb. may be added. The julap. e moſch. is of excellent ſervice. And when this diſorder is obſtinate, muſk ſhould be given in doſes from gr. ten to twenty, made up into the form of a bolus. The ſp. nitri D. may be often given in ſmall doſes.

When it happens in weak ſtomachs from a full meal, or hard flatulent aliment, relief is generally obtained by a glaſs of good wine, or of tepid water, with an equal quantity of ſome ſpirituous liquor.

If acid crudities in the ſtomach are the cauſe, give abſorbents and the bark, with warm bitters.

When irritating poiſons are the cauſe, beſides emetics, plenty of warm milk, and frequent doſes of ſweet oil, will be uſeful.

If indigeſted aliment is the cauſe, a table ſpoonful of ſharp vinegar will often relieve.

Emetics and ſternutatories often effect a cure.

When the diſorder is idiopathic, purgatives mixt with opiates, ſo that a moderate doſe of the compoſition may looſen the belly, are the moſt efficacious.

SINUS. A *ſinus* in a bone is a cavity which receives the head of another bone. In ſurgery, it is a collection of matter with only a ſmall orifice for its diſcharge; and this orifice is not callous. See FISTULA. In anatomy, the vagina is called ſinus muliebris, or *ſinus* pudoris.

SINUS COXÆ, i. e. Acetabulum coxendicis.

SINUS MAXILLARIS, i. e. Antrum Highmorianum.

SINUS VENÆ PORTARUM. The trunk of the vena portæ hepaticæ ſuperior vel minor.

SIPHILIS. The pox.

SIRENES. A ſort of worms. See BOVINA AFFECTIO.

SIRIASIS. A diſtemper to which children are ſubject; it conſiſts of an inflammation of the brain and its membranes, attended with a depreſſure of the fontanella, a cavity of the eyes, a burning fever, a paleneſs and dryneſs of the whole body, and a loſs of appetite. Dr. Cullen ranks it as ſynonymous with phrenitis.

SISARUM. Skirrets, or their worts. They are well known in our gardens, and are chiefly cultivated for culinary purpoſes. If plentifully eaten they are diuretic. Raii Hiſt. Plant.

SISYMBRIUM. It is a plant with thin pods, of which Boerhaave reckons up thirteen ſpecies, one of which is the

SISYMBRIUM AQUATICUM, alſo called raphanus aquaticus. Water radiſh. It grows in marſhy ditches, flowers in June and July, and is ſuppoſed to agree with the horſe radiſh in its virtues

SISYMBRIUM. A name of ſeveral ſpecies of mint, of water-creſſes, and ſome other plants.

SITIOLOGICE, from σῖτος, *aliment*, and λέγω, *to ſpeak*. That part of medicine which treats of aliments.

SITIS. Thirſt. It is excited by a defect of moiſture; a thickneſs of the humours; redundant heat; muriatic, alcaline, ammoniacal ſalts; aromatic, oleous, and rancid acrimony; or from poiſons. See POLYDIPSIA.

Thirſt is beſt allayed by acids; water kept a while in the mouth, then ſpit out, and repeated as required; a bit of bread chewed with a little water, which latter may be gradually ſwallowed; if the perſon is very hot, brandy is the beſt for holding in the mouth, but ſhould be ſpit out again: except in fevers, large draughts of cold water are hurtful.

SIUM. The root is like that of colewort, fibrous and ligneous; the leaves are pinnated, growing by pairs to one rib, and ending with an odd one; the petals of the flowers are bifid, the ſeeds are roundiſh, gibbous, and ſtriated.

SIUM LATIFOLIUM, alſo called paſtinaca aquatica. Great water parſnep. It grows in rivers and marſhy places, it flowers in July. The leaves are ſaid to break the ſtone in the bladder, and have other virtues attributed to them, but they are not noticed in the preſent practice.

SIUM ANGUSTIFOLIUM, alſo called berula Gallica, laver verum Matth. apium paluſtre foliis oblongis. Common upright water-parſnep. It grows in moiſt wet places, and flowers in June. Its leaves are ſaid to have the ſame effect as thoſe of the great water-parſnep.

SMALTUM. Smalt. It is made of flints and potaſh, which are melted into an imperfect kind of glaſs, coloured with cobalt, and when cold, is reduced to a powder.

SMARAGDUS. The ſmaragd, or emerald. It is a precious ſtone, of a green colour. The fineſt are brought from Abyſſinia. They are the fourth in hardneſs from diamonds.

SMILAX ASPERA. Rough bind-weed. It is cultivated in gardens, and flowers in ſummer. The leaves, tendrils, berries, and roots, are uſed as perſpiratives, to cure ſkin diſeaſes and pains in the joints. It is a ſuccedanum for ſarſaparilla, and is celebrated againſt venereal diſorders. See Raii Hiſt.

SMIRIS, or Smyris. Emery. It is a hard mineral, which contains a ſmall portion of iron. It is uſed for poliſhing of metals, glaſs, and hard ſtones. There are three kinds, the firſt is blackiſh; the ſecond is hard, uneven, reddiſh, and does not, like the other, ſtain the hands; the third is of a blackiſh red colour, with gold veins: it is found in the gold mines. Some reckon it amongſt the iron ores.

SODA. A burning uneaſineſs in the throat, with rancid or hot eructations It is ſynonymous with dyſpepſia, and pyroſis. It is uſed to expreſs the heart-burn; and by ſome a ſort of head-ach. It is a name for pot-aſh, and for the mineral fixt alkaline ſalt.

SOLANOIDES. Baſtard night-ſhade. It hath a roſe ſhaped flower, which is followed by a ſort of berry. Miller takes notice of two ſpecies, but they are not noted in medicine.

SOLANUM. Night-ſhade. It is a plant with a monopetalous flower, divided into five ſegments, having its cup divided in the ſame manner, with the ſame number of ſtamina in the middle, and followed by a juicy berry.

SOLANUM LETHALE, called alſo ſolanum maniacum, belladona, ſolanum ſomniferum, ſolanum furioſum. Deadly night-ſhade. It is the atropa belladonna of Linnæus.

It is one of the poiſonous plants that are indigenous in Great Britain; it is poiſonous in all its parts.

The root is long, large, and creeping. The ſtalks are purpliſh, upright, firm, numerous, branched, and herbaceous. The leaves are egg-ſhaped, entire, very large, ſmooth at the edges, pointed a little at the extremities, and of a beautiful green colour, hairy and ſoft. The flowers ſtand on ſingle foot-ſtalks: they are formed of one petal; bell-ſhaped, and very lightly divided into five ſegments at the edge. Their colour is a dark dead purple. The berries which ſucceed the flowers are globular; they are firſt of a red colour, and afterwards become black. This plant flowers in July, and its fruit is ripe about Michaelmas.

It is found in woods and hedges, amongſt lime-ſtone and rubbiſh; and alſo where the ground is rich from manure. The plant hath a faint ſmell, ſomewhat of the poppy kind, which is loſt when it is dry; whether freſh or dry there is no peculiar ſenſation conveyed, when the leaves are applied to the organs of taſte.

The ſymptoms produced by this plant are, giddineſs as if intoxicated, great thirſt, pain in and tightneſs acroſs the breaſt, difficulty of breathing, raving but with ſhort intervals of relief, at times faintneſs, and inſtead of raving, a kind of fooliſhneſs is obſerved to take place, ſtaring, flabbering, and giving anſwers foreign to the queſtions aſked In ſome a violent ſtrangury comes on. When adults have been injured with this poiſon, they have related that they had felt themſelves as if drunk, but ſaw and underſtood all that was doing, even when they gave the wildeſt anſwers. Some are ſaid to have continued in a ſtate of madneſs for ſome days; others loſe their ſight for a time, the iris being ſo much relaxed as to become paralytic, and dilated to a very conſiderable ſize. In children the belly ſwells, and convulſions ſometimes follow. To children it is generally fatal. When adults die of this poiſon, it uſually proves fatal in leſs than twenty-four hours. Theophraſtus called this plant ſtrychnos, and the ſymptoms produced by it were called ſtrychnomania.

In caſe of injury from this plant, uſe the ſame means as are recommended in the article AMANITA, which ſee.

Notwithſtanding the above effects of this *nightſhade*, a prudent uſe of it has been recommended as follows: the leaves applied in the form of a cataplaſm are uſeful for relieving cancers; an infuſion of the leaves is extolled as an internal medicine in cancerous caſes; but on trial it does not appear to deſerve the encomiums that have been paſſed in its favour. The doſes are very ſmall, and their effects various and uncertain; ſometimes it purges, at others runs off by the kidnies, or through the ſkin, and often no evacuation of any kind is obſerved. Thoſe who took the infuſion ſuffered by giddineſs, throbbing pain in the eyes, a diſcharge of tears, and in all there was a dilatation of the pupil. Mr. Gataker obſerves that it is a medicine not ſo much calculated for general uſe, as for particular caſes where the common remedies have failed, and where this ſeems upon trial, to be free from the principal inconveniences which ſo often attend the uſe of it.

See Gataker's Eſſays; Bromfield on *Nightſhade*; Wilmer's Obſ. on Poiſonous Vegetables; Withering's Bot. Arrang.

SOLANUM HORTENSE, alſo called ſolatrum, ſolanum vulgare, ſolanum officinarum, ſolanum nigrum, Linn. Common, or garden night-ſhade. Its leaves are oval, pointed, and irregularly indented; the flowers are white, and in cluſters; the berries are black. It is annual, grows in uncultivated grounds, and flowers in Auguſt.

Either of theſe two ſpecies may be indifferently uſed; their leaves have been found to be uſeful in cancerous diſorders, foul ulcers accompanied with pain, obſtinate pains in particular parts, ſcorbutic and ſcrophulous diſorders. It is ſaid to be particularly purgative of the bile; in theſe caſes it is taken in the form of an infuſion. Its uſefulneſs hath been alſo obſerved as an external application; beat into a poultice, or mixed with the white bread poultice, it hath abated the violence of inflammations in the eyes, head-achs, pains in the ears, acrid defluxions, inflammations of the venereal kind, pains from ſcirrhous tumors, and thus applied on ſcrophulous and cancerous tumors, it hath been followed with conſiderable advantages.

The moſt common effects obſerved on taking the infuſion of the leaves are, a warmth diffuſed in a few hours over the body, a plentiful ſweat ſucceeding this heat, and a lax belly the next day; if a ſweat did not break out, a conſiderable diſcharge of urine, or looſe ſtools, was the conſequence. One or other of the excretions are uſually increaſed by it; if this does not happen, it ſeldom is of ſervice, and if benefit is not obſerved ſoon, its further uſe will not avail much. In ſanguine habits, bleeding and purging ſhould precede its uſe, and if the ſtomach ſeems affected with crudities, an emetic ſhould be given before the *night-ſhade* is uſed. Feveriſhneſs is no objection to its uſe.

The leaves may be uſed either freſh or dry. Infuſe half a grain in an ounce of boiling water to be taken at bedtime; gradually increaſe the doſe, which may be repeated every night, and continue that quantity, which produces giddineſs, or ſickneſs, or a lax belly, or ſome other ſenſible effect; ſometimes one doſe is enough in two or three days. The doſe hath been gradually increaſed to twelve grains. See Storck on the *Solanum*.

SOLANUM LIGNOSUM, alſo called dulcamara, amara dulcis, ſolanum ſcandens. Bitter-ſweet, woody night-ſhade. It is called bitter-ſweet, becauſe it is firſt ſweet then bitter. It is the *ſolanum* dulcamara, or *ſolanum* caule inermi fruteſcente flexuoſo, foliis ſuperioribus haſtatis, racemis cymoſis, Linn. Purple flowering, woody *night-ſhade*. Many of its leaves are deeply cut, or are furniſhed with two ſmall appendages at the bottom. The flowers are in cluſters of a blue colour; the berries are red. It grows on the ſides of ditches, and in moiſt hedges, climbing upon the buſhes with winding, woody, but brittle ſtalks. It is perennial, and flowers in June and July.

Their ſenſible operation as a medicine is by ſweat, urine,

urine, or ſtool. A tincture may be made by digeſting four ounces of the twigs in two pints of white wine, and of this the doſe will be from ʒ ii. to ʒ vi.

This ſpecies is not ſo deleterious as the above two, and it acts more uniformly.

Dr. Hulſe ſays it is one of the moſt powerful diſcutients; he directs four handfuls of the leaves, and four ounces of linſeed, to be boiled together in wine, or in hog's fat, to a cataplaſm, and to be applied warm.

Boerhaave enumerates twenty-four ſpecies of *ſolanums*, but theſe are the moſt noted.

SOLEN, σωλην, *a cradle for a broken limb.* Any tube or channel.

SOLIDA. A ſolid. Haller obſerves in his Phiſiology, that the *ſolid* elementary parts of our fibres (and fibres conſtitute all our *ſolids*) are a calcareous earth kept together by a gluten. That in a natural ſtate when bones loſe their gluten, this earth falls into powder; and that in this earth there is a portion of iron. In a fœtus the gluten forms about two thirds of the ſubſtance of the bones; and in an adult, nearly half of the bone is gluten. The *ſolids* contain much air, and the more *ſolid* a part is, the more air it contains. The bones contain a quantity, which, when ſet at liberty, is two hundred times the bulk of the bone. Air ſeems to be the primary band of the elements, for until the air is expelled, the other parts do not ſeparate.

SOLEUS. A muſcle ſo called from its likeneſs to a ſole fiſh. This muſcle is a biceps, riſing on the outſide from the upper part of the tibia, internally from the outſide of the fibula, it leaves a notch for the paſſage of the veſſels, it joins the gaſtrocnemius to form the tendo Achillis. Brown calls it gaſtrocnemius internus.

SOLITARII, diſeaſes affecting only one part of the body.

SOLUTIO. Solution. It is the dividing of a ſolid body into particles ſmall enough to ſwim in the menſtruum, without being viſible. The diſſolving fluid is called a menſtruum, or ſolvent.

Solution is alſo defined to be an union formed by the integrant parts of one body with the integrant parts of another body of a different nature. Thus, as a new compound is the reſult of this union, we hence ſee that *ſolution* is nothing elſe than the act of combination.

Solution is an uſeful operation in chemiſtry, and in that art hath various intentions; it is neceſſary for the producing of new combinations, and thereby obtaining new kinds of medicines, as is inſtanced in the union of acid with alkaline ſalt, in making the ſal diureticus, the ſp. Mindereri, &c. it is uſeful for the purifying and cryſtallizing of ſalts, &c.

As the nature of ſolvents and things to be diſſolved are different, ſo the manner of effecting *ſolutions* differ. In ſome caſes it is effected by ſimple commixture, and frequent agitation; ſometimes the aſſiſtance of heat is required. There is a kind of *ſolution*, called *ſolutio* per deliquium; it is performed by expoſing the matter to the air, from which attracting water, it collects, in time, enough to diſſolve itſelf; ſome ſubſtances not ſoluble in water will diſſolve when expoſed to the air, and in thoſe inſtances, the proceſs is called deliquation. See Dict. of Chym.

SOLUTIONES. In Sagar's Noſology, it ſignifies freſh wounds, whilſt as yet bleeding.

SOLUTIVA. Laxatives.

SOMNAMBULISMUS, i. e. Somnambulo.

SOMNAMBULO. One who walks in his ſleep. It is a ſpecies of oneirodynia.

SOMNIUM, i. e. ſomnambulo. More properly dreams and viſions in ſleep; ſo an inſtance of oneirodynia

SOMNUS. Sleep. Action is deſtructive of our frame, and reſt repairs its decays. During *ſleep*, the nouriſhment received from food in our waking hours is applied to the decayed parts, the blood is recruited, and the ſecretions perfected; whence the impropriety of diſturbing the order of nature by employing the functions with any other work: and hence the neceſſity of ſome time for digeſtion to be performed before going to reſt.

See Cheyne on Health, alſo on Regimen; Fordyce's Elements, part the firſt; Haller's Phyſiology; Med. Muſ. vol. i. p. 11—14.

SONUS. Sound. That air, though concerned in propagating *ſound*, is not *ſound* itſelf, is evident from ſound running almoſt as faſt againſt the wind as with it.

As the diverſity of *ſounds* depends on the different natures and colliſions of ſonorous bodies, an acute tone proceeding from a body whoſe parts are ſo diſpoſed as to render them fit for producing only the moſt inſtantaneous vibrations, which they convey to the ambient air; and a grave tone proceeding from a body which is only capable of ſlow and protracted vibrations, it muſt of courſe follow, that the membrana tympani does, in its various degrees of tenſion and relaxation, adapt itſelf to the ſeveral natures and ſtates of ſonorous bodies; for inſtance, it becomes tenſe for the reception of acute *ſounds*, becauſe, in ſuch a ſtate, it is ſuſceptible of quick, and inſtantaneous tremulous motions; on the contrary, it is relaxed for the admiſſion of grave *ſounds*, becauſe, during ſuch relaxation, it is qualified, and diſpoſed, for the reception of the more ſlow and languid undulations of the air.

The external air impreſſes the membrana tympani, moves it with the malleus, which moves the incus, and this the ſtapes which impreſſes the auditory nerve.

Further, in order to *ſound* being perceived, the ſpiral laminæ in the cochlea, being compoſed of fibres of various lengths and ſizes, each receives the particles ſhaken off from ſounding bodies, which anſwer in uniſon to theſe fibres in the ſpiral laminæ, and the motions in the fibres of theſe laminæ ſhake off the ſame particles which are ſent to them, and thence they paſs to the ſenſorium by the nerves. It is probable that all the different organization of the ear was originally deſigned to put theſe fibres of the ſpiral laminæ in due tenſion, and in tune; and from the different degrees of perfection in the formation of this organ, ariſes the different accuracy which one ear hath above another, in diſtinguiſhing the concord of different inſtruments, or ſtrings of the ſame inſtrument.

SOPHIA, called alſo ſophia chirurgorum, thalictrum, naſturtium ſylveſtre, ſeriphium Germanicum, eryſimum, ſiſymbrium. Flix-weed. It is the ſiſymbrium ſophia, Linn. It is a plant with a hard woody root, full of ſmall fibres at the bottom; the leaves are long, winged, neatly divided, reſembling thoſe of Roman wormwood, and beſet with ſhort hairs; the flowers are at the ends of the branches, and are of a yellow colour; they are ſucceeded by ſlender ſeed veſſels, of about one inch long; the ſeeds are red. It grows in ſandy ground, and amongſt rubbiſh, and bears flowers in June.

The ſeeds only are uſed; in Paris they are ſold under the name of talitron. Boerhaave ſays, that their inward uſe aſſiſts the healing of ill-conditioned ulcers. Their taſte is ſomewhat aſtringent, but acrid like that of muſtard; they are alſo ſaponaceous and diuretic. See Miller's Bot. Off.

SOPOR, i. e. Caros.

SOPORALIS. The ſleepy vein. So the ancients called the jugular vein.

SOPORARIÆ ARTERIÆ. The carotid arteies.

SOPOROSI. Soporoſe affections, or diminution of ſenſe and motion.

SORA, i. e. Effere.

SORANUS. He was the moſt ſkilful of the methodic ſect, and he put the laſt hand to its improvement. He lived under Trajan and Adrian. Cœlius Aurelianus contains ſome of the works of Soranus. There were other Soranus's; this was born at Epheſus, he ſettled at laſt at Rome. The next celebrated phyſician, after Soranus, was Cœlius Aurelianus.

SORBUS. The ſervice tree. That uſed in medicine is the *ſorbus* aucuparia. Linn. It reſembles the pear and the cratægus in all reſpects, except that the leaves are pinnated, as in the fraxinus. The fruit is reſtringent before it is ripe; but when ripe, it is very agreeable. Raii Hiſt.

SORDES AURIUM. Ear wax.

SORY. It is a mineral that is blackiſh, hard, heavy, of a cavernous ſpongy texture, a diſagreeable ſmell, a nauſeous vitriolic taſte; it is compoſed of vitriol, ſulphur, and an earth. It is found in the mines in Devonſhire. It contains a cupreous vitriol; hence it is emetic. The Greeks uſed it as a depilatory.

SOUDE, alſo called ſoude blanche. See KALI.

SPA WATER. It is one of the beſt of the chalybeate kind in Europe.

SPANOPOGON. Thinly bearded.

SPARGONOSIS. A milk abſceſs.

SPASMA, from *σπάω, to draw.* A ſpaſm, a convulſion, a ſtrain. A *ſpaſm* may be ſaid to be preſent when any part of the human body, by the influence of the muſcular, membranous, or nervous fibres is contracted involuntarily. This ſpaſtic affection particularly affects the nervous and membranous parts, ſuch as the ſtomach, and the whole volume of the inteſtines: whence proceed the hyſteric and hypochondriac paſſions. A *ſpaſm* is alſo preſent when there is an hæmorrhage, a congeſtion of blood, unequal flux of the fluids, anxieties, and ſuppreſſed excretions. A *ſpaſm* affecting the dura mater conſiderably occaſions contractions of the whole nervous and membranous ſyſtem, whence an epilepſy, or univerſal convulſion. *Spaſms* in the medulla ſpinalis produce convulſions in particular parts. Many diſorders are the effects of *ſpaſms*, viz. obſtructed perſpiration, hæmorrhages, coſtiveneſs, ſtrangury, aſthma, &c. See SPASMI below.

SPASMI. Spaſmodic diſeaſe. In Dr. Cullen's Noſology, this is an order in the claſs neuroſes. The term *ſpaſm* hath been variouſly uſed; in the moſt common ſenſe, it hath ſignified any preternatural contraction of any particular part of the body, either without any ſtimulus immediately applied to the part, or which remains after its cauſe is removed. More properly ſpaſms are thoſe preternatural contractions, which are attended with conſiderable mobility of the ſyſtem. Dr. Cullen defines *ſpaſm* to be preternatural motions of the muſcles, or of the muſcular fibres; and under the title of *ſpaſmodic* affections, he includes all the diſeaſes which conſiſt in the preternatural ſtate of the contraction and motion of the muſcular or moving fibres in any part of the body. The *ſpaſmi* have generally been divided into the tonici and clonici, ſpaſtici and agitorii, or motorii, and *ſpaſms*, ſtrictly ſo called, and convulſions. But moſt of the *diſeaſes* called *ſpaſmodic*, are in reſpect to tonic or clonic, of ſo mixed a nature, that it ſeems preferable to arrange *ſpaſmodic* diſorders according as they effect the ſeveral functions, animal, vital, or natural. Cullen's Firſt Lines, v. iii.

SPASMUS. A ſpaſm, the cramp, or convulſion, from *σπαω, to draw.*

SPASMUS CLONICUS. Clonic ſpaſm. In a morbid ſtate, the contraction of the muſcles, or of the muſcular fibres, are involuntary, and are excited by unuſual and unnatural cauſes. When the contractions are ſucceeded by a relaxation, but at the ſame time, are repeated without the concurrence of the will, or the repetition of the natural cauſes, and are, at the ſame time, repeated more frequently, and commonly more violently, than in a healthy ſtate; this ſtate of morbid contraction hath been named *clonic ſpaſm*, and is what Dr. Cullen, in his Noſology, names *convulſion*. See Cullen's Firſt Lines, v. iii.

SPASMUS CYNICUS, alſo called riſus ſardonicus. See SARDONICUS RISUS.

SPASMUS TONICUS. Tonic ſpaſm. In a morbid ſtate, the contraction of the muſcles, or of the muſcular fibres, are involuntary, and are excited by unuſual and unnatural cauſes. When the contractions are to a violent degree, and are neither ſucceeded by a ſpontaneous relaxation, nor readily yield to an extenſion, either from the action of antagoniſt muſcles, or from other extending powers applied; this ſtate of contractions is what hath been called a *tonic ſpaſm*, and what Dr. Cullen names ſtrictly and ſimply, a *ſpaſm*. See Cullen's Firſt Lines, v. iii.

SPECIFICA. Specifics. By *ſpecifics* is not meant ſuch as infallibly and in all patients produce ſalutary effects. Such medicines are not to be expected, becauſe the operations and effects of remedies are not formally inherent in them, but depend upon the mutual action and reaction of the body and medicine upon each other; hence the various effects of the ſame medicine in the ſame kind of diſorders in different patients, and in the ſame patient at different times. By *ſpecific* medicines we underſtand ſuch medicines as are more infallible than any other in any particular diſorder.

SPECILLUM. A probe. Æſculapius is ſaid to have been the firſt who invented its uſe. Quo aliquid ſpecimus, i. e. obſervamus.

SPECULARIS LAPIS, alſo called glacies Mariæ. Muſcovy glaſs. It is a tranſparent concrete, commonly found in pretty large maſſes, which may be eaſily ſplit into a number of thin plates or leaves. Sometimes theſe plates are ſo broad as to be uſed for lanterns. Neumann ſays it is erroneouſly taken for the *glacies Mariæ*, and that it is not, as is generally ſaid, a ſpecies of talc.

SPECULUM. A probe, or an inſtrument for dilating the natural paſſages, or cavities with, of which there are the *ſpeculum* ani, *ſpeculum* oculi, *ſpeculum* oris, *ſpeculum* uteri. *Speculum* is alſo a name for the tunica aranæ of the eye.

SPERMA CETI, improperly called parmy citty. Indeed the name *ſperma* is not a juſt one, for this ſubſtance is a kind of fat, taken from the head of a ſpecies of whale, and which is artificially purified by long boiling with alkaline ley. This fat is found in other parts of this kind of whale, but the beſt is in the head. It differs from other animal fats in not being diſſoluble by alkalies, or combinable with them into a ſoap, and in riſing almoſt totally in diſtillation, not in form of a fluid oil, but in that of a butyraceous matter, reſembling the butter of wax. By long keeping it becomes yellow, or rancid; this rancid part, like other fats, diſſolves in alkaline ley, and the remainder is left ſweet and white.

This concrete is without any remarkable ſmell, and hath a butyraceous taſte. It is much uſed in coughs, dyſenteries, eroſions of the bowels, and in ſuch caſes in general as require that the ſolids ſhould be relaxed or ſoftened, alſo in which acrid humours are to be obtunded. It readily diſſolves in oils, and unites with wax by the aſſiſtance of heat, and thus it is uſed externally. For internal uſe, it may be diſſolved with water, and ſo formed into an emulſion, by the intervention of the mucilage of gum arabic, or by the help of almonds, which are to be rubbed with it.

Sperma ceti is an admirable ſubſtitute for oils, when they do not reſt eaſy on the ſtomach. Sir Richard Manningham extols the mixture of *ſperma ceti* with diaphoretics in the cure of internal inflammations; and he ſays that when bleeding cannot be prudently ventured on in inflammatory fevers, the *ſperma ceti* mixed with contrayerva root, and the volatile ſalt of hartſhorn, may be depended on, if means can be expected to produce any good effect. See Lewis's Mat. Med. Neumann's Chem. Works.

SPERMATICA ARTERIA. The ſpermatic artery. There is one in each ſide. Each of theſe *arteries* riſe from the aorta, but are not, as ſome aſſert, ſmall at their origin, and larger in their proceſs, nor do they anaſtomoſe with the *ſpermatic* veins. For the moſt part theſe *arteries* riſe from the anterior part of the aorta, between the emulgent and the inferior meſenteric *arteries*; their courſe is obliquely downwards and outwards, they run upon the ſoas muſcle to the brim of the pelvis, and then through the aperture in the external oblique muſcle; they run behind and contiguous to the peritoneum, and do not lie in the cavity of the belly. They are connected by the cellular membrane to each other, and to their coreſponding veins, all which run in a ſerpentine manner, and form the *ſpermatic* cord.

SPERMATICA CORDA. The ſpermatic cord. It is compoſed of the *ſpermatic* artery and vein, of nerves, lymphatics, the vas deferens, the cremaſter muſcle, and aponeurotic membrane, derived from the opening of the external oblique muſcle of the belly; they are all connected by the cellular membrane.

This *cord* is alſo called corpus varicoſum, corpus pyramidale, corpus pampiniforme, vaſa ſpermaticæ, vaſa preparantia, and capreolaris.

SPERMATICÆ VENÆ. Spermatic veins. A little below the emulgent *veins* the vena cava ſends out the right *vena ſpermatica*. The left *ſpermatic vein* commonly ſprings from the left emulgent *vein*, the reaſon of which is ſaid to be, the avoiding the aorta in its paſſage, by which the motion thereof might be retarded. But this does not ſeem to be the cauſe, as the ſame caution is not obſerved with reſpect to the emulgent.

SPERMATOCELE, from *σπερμα, ſemen,* and *κηλη, a tumor.*

tumor. It is a morbid diſtenſion of the epididymis and vas deferens, produced by a ſtagnation of *ſemen*. This may be produced by *tumors*, ſtricture, or inflammation, about the caput gallinaginis, or in the courſe of the vas deferens; but there is reaſon to think that it is more frequently induced by the laſt, viz. by inflammation, than by either of the other two.

When an inflammatory affection of the parts is diſcovered to be the cauſe of the diſeaſe, general and topical bloodletting, gentle laxatives, a low cooling diet, and reſt of body, will commonly be found the moſt effectual remedies. And again, when *tumors* are diſcovered to preſs upon the vas deferens, they ought either to be brought to ſuppurate, or their extirpation ſhould be attempted when that can be done with propriety. At other times theſe *tumors* are found to depend on a venereal cauſe; and in ſuch inſtances a well directed courſe of mercury hath been known to remove them.

On ſome occaſions, it is ſaid, that all the other means having failed, caſtration has at laſt been found requiſite. But this cannot be ſuppoſed to be a very neceſſary ſtep. See Bell's Syſtem of Surgery, vol. i. p. 495.

SPHACELUS. A mortification. See MORTIFICATIO.

SPHACELUS OSSIS, i. e. Spina Ventoſa.

SPHACELISMUS, the ſame as phrenitis.

SPHÆNOIDES OS. The ſphenoid bone, from σφὴν, a *wedge*. It is alſo called os cuneiforme. See SPHENOIDES OS.

SPHENOIDES OS. The ſphenoid bone. It is an irregular *bone* which runs into the baſis of the ſkull, from one temple to the other. Externally it hath five proceſſes, which are all ſubdivided. The firſt and ſecond are the two lateral apophyſes, the upper part of each of which is called the temporal proceſs; that part of them which jets out towards the inſide, lower than the temporal, and which makes up part of the orbit, is called the orbitar proceſs; the loweſt and back part of theſe proceſſes is called the ſpinous proceſs. The two external proceſſes which get out nearly perpendicular to the baſe of the cranium, with each a foſſa behind, are called the pterygoid proceſſes. The azygous proceſs is that ſharp middle ridge which is in the baſe of the bone.

SPHENO-MAXILLARIS ARTERIA. It is the firſt branch of the *maxillaria* interna *arteria*; it goes to the inferior orbitary, or *ſpheno maxillary* fiſſure, and to the orbit, through the foramen *ſpheno* palatinum.

SPHENO-MAXILLARIA FISSURA. So Winſlow calls the inferior orbitary fiſſures formed by the edges of the maxillary notches in the os ſphenoides. They are continued in the maxilla ſuperior, and are there called the inferior orbitary fiſſures.

SPHENO-PALATINUS. Theſe muſcles riſe (one on each ſide) from the os ſphenoides, and are inſerted into the ſides of the glandula palati, and back part of the uvula.

SPHENO-PALATINUS. It is the name of a branch from the upper maxillary branch of the fifth pair of nerves. It is diſtributed to the muſculus pterygoideus internus, to the back part of the nares, to the ſinus ſphenoidales, and to the tuba Euſtachiana.

SPHENO-PHARYNGÆUS. This muſcles riſes (one on each ſide) from the alary proceſſes of the ſphenoid bone, and runs to the ſides of the pharynx.

SPHENO-PTERYGO-PALATINUS. Valſalva diſcovered that this muſcle does not belong to the uvula, but to the tuba Euſtachiana. It riſes from the os ſphenoides, and is inſerted into the fore-part of the palate.

SPHENO-SALPINGO-PHARYNGÆI. Theſe muſcles are fixed by one extremity partly to the ſphenoidal ſide of the bony portion of the Euſtachian tube, partly to the neareſt ſoft portion of the ſame tube; thence it runs towards the external wing of the apophyſis pterygoides, into which one portion of the muſcle is inſerted; the other portion runs to the end of the wing, and turns round to the forked extremity thereof as over a pully, and is afterwards inſerted in the ſeptum palati near the uvula.

SPHENO-SALPINGO-STAPHILINUS, i. e. circumflexus palati.

SPHINCTER ANI. The ſphincter of the anus, from σφίγω, *conſtringo*, *to ſhut*. The extremity of the *anus* is ſurrounded by the *ſphincter* which ariſes from the bottom of the os coccygis, and its fibres ſeparating, ſurrounds the *anus*, and terminates in the lower part of the bulb of the urethra.

SPHINCTER GULÆ, i. e. Sphincter œſophagi.

SPHINCTER LABIORUM. The ſphincter of the lips. This muſcle ſurrounds the *lips* with orbicular fibres, and when it acts it corrugates them. It is an antagoniſt to all the other muſcles of the *lips*, keeping them in order, and allowing them an equal balance.

SPHINCTER ŒSOPHAGI. The ſphincter of the œſophagus. See ŒSOPHAGUS.

SPHINCTER VAGINÆ. The ſphincter of the vagina. Juſt within the *vagina* we obſerve this *ſphincter* muſcle; it is two planes of circular fibres that come partly from the perinæum and partly from the *ſphincter* ani; they ſurround the *vagina*, and are loſt in the fibres of the crura clitoridis. Its office is to bring the perinæum cloſer to the bones, and ſo embrace the penis in coitu.

SPHINCTER VESSICÆ. The ſphincter of the bladder is a ſeries of tranſverſe fibres running croſs-wiſe under the ſtraight fibres of the neck of the bladder in a circular manner.

SPICA. A ſpike. It is a part of a ſtalk thick ſet with flowers or fruit, ſo as to form an acute cone. *Spica* is the name of a bandage, which is of three kinds; and ſo called from their reſemblance to an ear of corn.

SPICA INGUINALIS. It is a bandage uſed for the cure of an inteſtinal hernia, a diſlocation of the thigh, and a fracture of the os ilei. It is either ſingle or double headed; the ſingle is twenty-four feet in length and three fingers broad; the end is placed on the os ilei of the ſound ſide; hence the head of the roller paſſes round the bottom of the belly and the hip, then to the back part of the thigh, comes up between the thighs, and is conveyed to the groin, and ſo over the back where it begun; pin the bandage to the compreſs on the groin, and finiſh by a turn or two round the belly. When applied to one groin only it is called *ſpica inguinalis* ſimplex. When the ſimple *ſpica* hath two heads, place the middle part at the perinæum, from whence the heads aſcend obliquely to the hip, from whence they paſs behind and before to the other hip.

SPICA INGUINALIS DUPLEX. The double inguinal ſpica. It is uſed when a rupture, &c. is in both groins. It is *double* headed, twenty-four feet long, and three inches broad. Its middle is fixed on the loins, and brought round the belly, where the ends are changed; then they go round the outſide of the thighs, paſs under the buttocks, and aſcend on each groin; there, having ſecured the dreſſings, they aſcend over the oſſa ilia to their beginning, where the heads are again changed and brought round to the belly, where they are again changed, and then they deſcend on each ſide of the ſcrotum, and go round the buttocks to each groin, and ſo to the belly, where they are again changed, and then they aſcend to the oſſa ilia. This direction muſt be repeated often.

SPICA SIMPLEX. It is a bandage, ſo called from its reſemblance to an ear of a grain. Some call it geranium. It is a common roller, about five ells long, and three fingers breadth broad, rolled up with one head. When it is rolled up with two heads it is called *ſpica duplex*.

SPIGELIA, i. e. anthelmia.

SPINA. The ſpine. It is divided into true and falſe vertebræ. The true are twenty-four in number, viz. ſeven of the neck, twelve of the back, and five of the loins. Each vertebra is compoſed of its body and proceſſes. The body is the thick anterior part, which is convex before and concave behind, and moſt horizontal and plain both above and below. The ſurfaces of two contiguous vertebræ are covered with a cartilage. There is a ligament, compoſed of concentrical curved fibres, which is firmly attached to the horizontal ſurface of the vertebræ, beſides which there is a ſtrong ligament, which lies between the edges of the vertebræ, whoſe fibres decuſſate each other in the form of an X. From each ſide of the body of each vertebra, a bony ridge is produced backwards and to a ſide, from the poſterior extremity of which one ſlanting proceſs ariſes, and another deſcends: the ſmooth ſide of each of theſe four proceſſes (which are

called the oblique) is covered with a cartilage, and the two inferior oblique proceſſes of each vertebra are aticulated with the two ſuperior oblique proceſſes of the vertebra below. From between the ſuperior and inferior oblique proceſſes of each ſide the vertebra is ſtretched out laterally, and forms a proceſs called tranſverſe. From the poſterior root of the two oblique and of the tranſverſe proceſs, on each ſide, a broad oblique bony plate is extended backward; where theſe meet, the *ſpinal* proceſs riſes, and ſtands out backwards. Theſe ſeven proceſſes form the poſterior parts of the vertebræ, and are hollow at their anterior middle part, which cavity joined with that on the back part of the bodies, make a great canal which anſwers to another in the vertebra above and below, for the medulla *ſpinalis*. There are two ſemicircular notches belonging to each vertebra, which coincide with two ſimilar notches in the adjoining vertebra; through theſe foramina, (which are placed immediately behind the body of the vertebræ) the *ſpinal* nerves paſs out.

The cervical vertebræ are concave above and convex below; they are flat forward and behind. Their *ſpinal* proceſſes are bifid to allow a more convenient inſertion for the muſcles. The tranſverſe proceſſes are ſhort and generally bifid, the root having a hole for the ſecure paſſage of the vertebral artery and vein. The oblique proceſſes are quite horizontal. The rotatory motions of the head are not entirely performed by the firſt and ſecond vertebræ (as is moſtly imagined), but they are greatly aſſiſted by the reſt of the *ſpine*; for the rotation of any two vertebræ is inconſiderable, yet it is not ſo when we conſider them all together; beſides, if this rotation was betwixt the firſt and ſecond only, as we are capable of rotating the head a quarter of a circle, ſo great a degree of motion would have deſtroyed the *ſpinal* marrow of that part.

The dorſal vertebræ are of a middle ſize betwixt the cervical and lumbal, and are flattened laterally by the preſſure of the ribs, which are inſerted into ſmall cavities in the ſides of theſe vertebræ. The ribs are articulated betwixt two vertebræ, except in the firſt, eleventh, and twelfth, where the cavity for their reception is entirely formed in the ſaid vertebræ.

The lumbar vertebræ are larger than the others; the cartilages between them are thicker, and the *ſpinal* and oblique proceſſes ſtronger, which is neceſſary, as they have a greater quantity of motion, and are the moſt expoſed in injuries offered to the *ſpine*.

The falſe vertebræ are divided into two bones, viz. the os ſacrum and os coccygis.

Upon the *ſpine*, particularly in the cavities of the thorax and abdomen, are found a number of lymphatic veſſels and glands.

SPINA ALBA. The white thorn tree, alſo called oxyacantha, meſpilus apii folio ſylveſtris ſpinoſa. Hawthorn. It is the cratægus oxyacantha, Linn. It is common in hedges: its flowers have an agreeable fragrance, and have been uſeful in ſtrengthening weak ſtomachs by uſing them in the manner of tea or an infuſion.

SPINA ÆGYPTIACA, i. e. Acacia.

SPINA ARABICA. The Arabian thiſtle.

SPINA BIFIDA, alſo called hydrops medullæ ſpinalis. Sagar ſays that it is a true dropſy of the thecæ *ſpinalis*. It is a tumor of the colour of the ſkin, and is ſeated upon the vertebræ of the neck, back or loins, or on the ſutures of the ſkull. It receives its name from the proceſſes of the ſpine being wanting, where it is. It is known by its ſituation, its being always there at the birth of the patient, its watery contents, and the palſy, which uſually attends it. Dr. Cullen names it HYDRORACHITIS, which ſee.

This diſorder is incurable. For the moſt part thoſe children on whom theſe tumors are found, die in a day or two. If this tumor is opened, death is ſpeedily the conſequence. Dr. Mackenzie, profeſſor of midwifery in London, gave a drawing which was a caſe of this kind, and with which the child lived four months, but at length died in convulſions. Mr. Warner gives an inſtance of this diſorder in a young man of twenty years old. See his Caſes in Surgery.

SPINA CERVINA, i. e. rhamnus cathartieus, Linn.

SPINA VENTOSA, ſee HYDARTHRUS. Called alſo ſpinæ ventoſitas, ſideratio oſſis, cancer oſſis, gangræna oſſis, ſphacelus oſſis, teredo, and by ſome French authors exoſtoſis. When children are the ſubjects of this diſeaſe, M. Severinus calls it pædarthrocace. With us it is often called a white ſwelling. *Spina* ſeems to have been a term applied by the Arabians to this diſorder, becauſe it occaſions a pricking in the fleſh like the puncture of thorns, and the epithet *ventoſa* is added, becauſe that, upon touching the tumor, it ſeems to be filled with wind, though this is not the cauſe of the diſtenſion. The late Mr. Sharp ſays, that the *ſpina ventoſa* is a caries of a bone, attended with an internal corruption of its whole ſubſtance, and generally ariſing from a putrefaction of the marrow, by which the periofteum and ligaments, as well as the bone, are wholly deſtroyed.

Mr. Pott divides this diſorder into the hydrops articuli, the fungus articuli, or thickening of the ligaments of the joint, and the enlargement of the bone. The firſt of theſe, or the hydrops articuli, very often comes on ſuddenly, is of ſhort duration, and goes off as ſuddenly; it often happens in relaxed habits from a want of lymphatic abſorption, from relaxation, from an obſtruction in the lymphatic circulation in the joint; it ſometimes happens in rheumatic habits. The ſecond is generally known by the uniform ſwelling of the parts growing very hard, ſo as to deſtroy all diſtinction; and laſtly, by an inflexibility: this uſually ends in amputation.

There is a diſeaſe in the *ſpine* to which no name ſeems to be fixed; it is manifeſt by its becoming more or leſs curved, and by a loſs of the uſe (generally) of the lower limbs. It is ſometimes called the *curved ſpine*. Mr. Pott is the firſt who hath favoured the world with any juſt idea either of its nature or cure. In one of his publications he calls it a kind of palſy in the lower limbs; in another he ſpeaks of it as a uſeleſs ſtate of them. From his account of this diſorder, it hath a ſcrophulous origin; but as its moſt ſtriking ſymptoms are from the caries, which takes place in the bodies of ſome of the vertebræ, may it not be properly termed the *ſtrumous ſpinal caries*?

In this diſeaſe, there is a total or partial abolition of the power of uſing, and ſometimes of even moving the limbs, generally only the lower, but ſometimes the upper, or both, in conſequence of a diſeaſe in the *ſpine*, which is firſt manifeſted by a curvature taking place in ſome part of it. To this diſtemper, both ſexes, and all ages, are equally liable, though the majority of theſe patients are infants or young children.

When the attack is made on an infant of only one or two years old, the true cauſe is rarely diſcovered until ſome time after the effect has taken place; the nurſe or parents ſuppoſe that the child is weakly, or hath been hurt at its birth. When on the attack the patient hath been uſed to walk, the loſs of the uſe of his legs is gradual, though not in general very ſlow. At firſt he ſhews ſigns of being ſoon tired, he is languid, liſtleſs, and unwilling to move much, or at all briſkly; ſoon after this he is obſerved frequently to trip and ſtumble, although there is no impediment in his way; whenever he attempts to move quickly, he finds that his legs involuntary croſs each other, by which he is frequently thrown down ſuddenly, and that without ſtumbling; upon endeavouring to ſtand ſtill and erect, even for a few minutes, his knees give way, and bear forward. When the diſtemper is a little further advanced, it will be found that he cannot, without much difficulty, direct either of his feet preciſely to any exact point; on attempting to do ſo, they ſuddenly interſect, and very ſoon after, both thighs and legs loſe much of their natural ſenſibility, and become perfectly uſeleſs. When an adult is thus affected, the progreſs of the diſtemper is much the ſame, but rather quicker. Arrived at this ſtate, whatever be the age or ſex of the patient, complaint is made of twitching and frequent pains in the thighs, particulary when in bed, and of uneaſy ſenſation at the pit of the ſtomach; when he ſits on a chair or a ſtool his legs are almoſt always found acroſs each other, and drawn up under the ſeat; in a little time after theſe particulars have been obſerved, the power of walking is totally loſt.

The true curvature is invariably uniform in being from within outwards. This curve of the *ſpine* varies in ſituation, extent and degree, being either in the neck, back, or (more rarely) in the upper part of the loins; ſometimes comprehending one vertebra only, ſometimes two, three or more; by which the curve becomes neceſſarily more or

leſs

leſs extenſive; but whatever variety theſe circumſtances may admit, the lower limbs moſt frequently feel the effect; ſometimes the arms only are paralytic (as it is called,) and a few inſtances have occurred in which both legs and arms were alike affected. The effect is alſo different in different ſubjects; ſome are rendered totally and abſolutely incapable of walking in any manner, or with any help, and that very early in the courſe of the diſeaſe, that is, ſoon after the appearance of the curvature; others can move with the help of crutches, or by graſping their thighs juſt above their knees with their hands; ſome can ſit in an erect poſture or in a chair, without much trouble or fatigue, whilſt others are incapable of doing ſo, at leaſt for any length of time; ſome have ſuch a degree of motion in their legs or thighs, as to enable them to turn and move for their own convenience in bed; others have not that benefit, and are obliged to lie until they are moved by another.

When a naturally weak infant is the ſubject, the curvature is in the vertebræ of the back; it is not unfrequently productive of additional deformity, by gradually rendering the whole back what is vulgarly called humped; and by alterations which all the bones of the thorax ſometimes undergo in reſpect to ſituation, in conſequence of the flexure and weakneſs of the *ſpine*, by which, ſuch perſons are juſtly ſaid to be ſhortened in their ſtature; but in all caſes, where this effect has been gradually produced, to whatever degree the deformity may extend, or however the alteration made in the diſpoſition of the ribs and ſternum, may contribute to ſuch deformity, yet I think that it will always be found, that the curvature of the *ſpine* appeared firſt, and, if I may ſo ſay, ſingly, and that all the reſt was conſequential.

The general health of the patient does not ſeem, at firſt, to be materially, if at all, affected; but when the diſeaſe has been ſome time, and the curvature thereby increaſed, many inconveniences and complaints come on, ſuch as, when the incurvation is in the neck, and to a conſiderable degree, by affecting ſeveral vertebræ, the child finds it inconvenient and painful to ſupport its head, and is always deſirous of laying it on a table or pillow, or any thing to take off the weight. When in the dorſal vertebræ, there is a difficulty of breathing, loſs of appetite, indigeſtion, dry cough, quick pulſe, a diſpoſition early to an hectic pain, and what they all call tightneſs at the ſtomach, obſtinate conſtipations, or purgings, involuntary flux of urine and fæces, &c. with the addition of what are called nervous complaints, ſome of which are cauſed by the alterations made in the form of the cavity of the thorax, others ſeem to ariſe from impreſſions made on the abdominal viſcera.

An adult in a caſe where no violence hath been committed, or received, uſually complains, that his firſt intimation was a ſenſe of weakneſs in his back bone, accompanied with what he calls a heavy dull kind of pain, attended with ſuch a laſſitude as rendered a ſmall degree of exerciſe fatiguing; that this is ſoon followed by an unuſual ſenſe of coldneſs in his thighs, not accountable for from the weather, or any cauſe that can produce a diminution of their ſenſibility. That in a little time more, his limbs were affected with an unuſual ſenſibility, alſo were frequently convulſed by involuntary twitchings, particularly troubleſome in the night; that ſoon after this, he not only became incapable of walking, but that his power either of retaining or diſcharging his urine or fæces was conſiderably impaired, and his penis became incapable of erection. The adult as well as the child complains conſtantly of a tightneſs and pain at his ſtomach, and he finds all the offices of his digeſtive and reſpiratory organs much impeded.

The loſs of motion in the limbs, which generally accompanies a diſtorted *ſpine*, is ſuppoſed to proceed from the ſaid diſtortion. Until the curvature is diſcovered, it generally paſſes for a nervous complaint; but when the ſtate of the vertebræ hath been adverted to, recourſe is almoſt always had to ſome previous violence to account for it; ſome blow, fall, or other accident, which are ſuppoſed to have hurt the back, or derange the *ſpine*. In ſome few inſtances, theſe exertions may have been ſuch, as might be allowed to have been equal to the effect; but in the majority, theſe are ſo far from being the caſe, that if they are admitted to have any ſhare at all in it, ſome prediſpoſing cauſe, at leaſt, muſt be looked for, in which conſiſts the very eſſence of the diſeaſe. From many conſiderations reſpecting this ſubject, it appears, that when we attribute the whole of this miſchief to the mere accidental curvature of the *ſpine*, in conſequence of violence, we miſtake an effect for a cauſe; and that previous both to the paralytic ſtate of the legs, and to the alteration of the figure of the back-bone, there is a prediſpoſing cauſe of both, conſiſting in a diſtempered ſtate of the ligaments and bones, where the curve ſoon after makes its appearance. The primary and ſole cauſe of the miſchief, is a diſtempered ſtate of the parts compoſing, or in immediate connection with the *ſpine*, tending to, and moſt frequently ending in a caries of the body or bodies, of one or more of the vertebræ; from this proceed all the ills, whether general or local, apparent or concealed; this cauſes the ill health of the patient, and in time the curvature. The helpleſs ſtate of the limbs is only one conſequence of ſeveral proceeding from the ſame cauſe.

It has been ſuppoſed that there is a diſlocation of the vertebræ, but there is no diſplacement of them with regard to each other; the *ſpine* bends forwards only, becauſe the rotten bone or bones intervening between the ſound ones give way, being unable in ſuch a ſtate to bear the parts above. From every circumſtance in the living, and appearance in the dead, it is evident, that the complaint ariſes from what is commonly called a ſcrofulous indiſpoſition affecting the parts that compoſe the *ſpine*, or thoſe in its immediate vicinity: this morbid affection ſhews itſelf in a variety of forms, but they are always ſuch as ſooner or later determine the true nature of the diſtemper. Sometimes each of the diſtempered ſtates of theſe parts, is accompanied by a greater or leſſer degree of deformity and crookedneſs of the *ſpine*, without any apparent diſeaſe of the bones compoſing it; ſometimes the deformity is attended with eroſion or caries of the body or bodies of ſome of the vertebræ; and ſometimes the ſame bones are found to be carious, without any crookedneſs or alteration of figure. It may not be amiſs to remark, that ſtrumous tubercles in the lungs, and a diſtempered ſtate of ſome of the abdominal viſcera, often make a part of the attendants.

It is further to be obſerved, that when theſe complaints are not attended with an alteration of the figure of the back-bone, neither the real ſeat, nor true nature of the diſtemper are pointed out by the general ſymptoms, and conſequently that they frequently are unknown, at leaſt while the patient lives. When the ligaments and cartilages of the *ſpine* become the ſeat of the diſorder, without any affection of the vertebræ, it ſometimes happens that the whole *ſpine*, from the loweſt vertebra of the neck downwards, gives way laterally, forming one great curve to one ſide; and ſometimes a more irregular figure, and attended with many marks of ill health. The attack is ſometimes on the bodies of ſome of the vertebræ, and when this is the caſe, ulceration and eroſion of the bones is the conſequence; this eroſion or caries of the bones often produces the curvature peculiar to this diſeaſe, by waſting the body of each vertebra that is affected, and then the ſpinal proceſſes of the diſtempered vertebræ protuberate behind in conſequence of their fore parts falling down as above noticed. When the attack is made upon the dorſal vertebræ, the ſternum and ribs, for want of proper ſupport, neceſſarily give way, and other deformity, additional to the curve, is produced. As to the caſes of carious *ſpine* without curvature, it ſometimes happens that internal abſceſſes and collections of matter are formed near the *ſpine*; this matter affecting the *ſpine*, and alſo making its way outward, produce what are called pſoa abſceſſes, &c. and deſtroy the patient; the real and immediate cauſe of death in theſe inſtances are rarely known until the body is examined. The uſeleſs ſtate of the limbs is by no means a conſequence of the altered figure of the *ſpine*, or of the diſpoſition of the bones with regard to each other, but merely of the caries: of this truth there needs no other proof, than what may be drawn from the cure of a large and extenſive curvature, in which three or more vertebræ were concerned; in this, the deformity always remains unaltered and unalterable, notwithſtanding the patient recovers both health and limbs.

On

On diſſecting ſeveral of the patients who died under this diſeaſe, whoſe ſpines were curved in various degrees, and whoſe limbs were become uſeleſs, appearances as follow were obſerved: in infants and young children, alſo thoſe who had been afflicted but a ſhort time, whatever their age was, the ligaments connecting the vertebræ, which formed the curve, were in ſome degree altered from a natural ſtate, being ſomewhat thickened, relaxed and altered, and the cartilages between the bodies of the vertebræ much compreſſed and leſſened in ſize. Thoſe who had ſo long laboured under the diſeaſe as to have been deſtroyed by it, or by its conſequences, the corpora vertebrarum were completely carious, the intervening cartilages totally deſtroyed, and a quantity of ſanies lodged between the rotten bones, and the membrane inveſting the *ſpinal marrow*. In the body of one man who died of this diſorder, in its laſt and worſt ſtate, the bodies of three of the vertebræ were not only quite carious, but completely ſeparated from all connection with the other parts of the ſame vertebræ. The bodies of the vertebræ concerned are often affected, while the ligaments bear but little marks of diſtemper; but whether the ligaments be affected or not, the bodies of the vertebræ are always diſeaſed, and this diſeaſe erodes them (or renders them carious:) the ſtate alſo of the intervertebral cartilages are ſubject to great variety, they being ſometimes totally deſtroyed, while the caries is ſmall in degree, ſometimes apparently but little injured, where the caries has done conſiderable miſchief, and ſometimes totally deſtroyed or annihilated.

Mr. Pott obſerves that, in compliance with cuſtom, he hath called this diſeaſe a palſy; but that notwithſtanding the limbs be rendered almoſt totally uſeleſs, yet there are ſome eſſential circumſtances in which this affection differs from a common nervous palſy: the legs and thighs are rendered unfit for all the purpoſes of locomotion, and have loſt much of their natural ſenſibility; but notwithſtanding this, they have neither the flabby feel which a truly paralytic limb has, nor have they that ſeeming looſeneſs at the joints, nor that total incapacity of reſiſtance which allows the latter to be twiſted in almoſt all directions; on the contrary, in this diſeaſe, the joints have frequently a conſiderable degree of ſtiffneſs, particularly the ancles, by which ſtiffneſs the feet of children are generally pointed downwards; and they are prevented from ſetting them flat on the ground. In the true paralyſis, from whatever cauſe, the muſcles of the affected limb are ſoft, flabby, and unreſiſting, and incapable of being put into even a tonic ſtate; the limb itſelf may be placed in almoſt any poſition or poſture; and if it be lifted up, and then let go, it falls down, and it is not in the power of the patient to prevent, or even to retard its fall: the joints are perfectly and eaſily moveable in any direction; if the affection be of the lower limbs, neither hips, nor knees, nor ankles, have any degree of rigidity or ſtiffneſs, but permit the limb to be turned or twiſted in almoſt any manner. But, in caſes of uſeleſs limbs from the ſame cauſe as that of the curved *ſpine*, the muſcles are extenuated and leſſened in ſize; but they are rigid, and always in a tonic ſtate, by which the knees and ancles acquire a ſtiffneſs not very eaſy to overcome; by means of this ſtiffneſs, mixed with a kind of ſpaſm, the legs of the patient are either conſtantly kept ſtretched out ſtrait, in which caſe, conſiderable force is required to bend the knees, or they are by the action of the ſtronger muſcles drawn acroſs each other, in ſuch a manner as to require as much to ſeparate them. When the leg is in a ſtraight poſition, the extentor muſcles act ſo powerfully as to require a conſiderable degree of force to bend the joints of the knees; and when they have been bent, the legs are immediately and ſtrongly drawn up, with the heels towards the buttocks: by the rigidity of the ancle joints, joined to the ſpaſmodic action of the gaſtrocnemii muſcles, the patients toes are pointed downwards in ſuch a manner as to render it impoſſible for him to put his feet flat on the ground, which makes one of the deciſive characters of this diſtemper. Thus the marks of diſtinction between this diſeaſe and the palſy, are ſufficiently ſtrong to ſhew the impropriety of confounding them.

The reſtoration of the *ſpine* to its natural figure, depends much on the early adminiſtration of the help propoſed; though the diſtemper may be ſo far cured, as that the patient may recover the uſe of his limbs, yet ſuch an alteration may have taken place in the bodies of the vertebræ, as to render it impoſſible for the *ſpine* to become ſtraight again; and, if from inattention, from length of time, or from any other circumſtances, it happens that the bodies of the vertebræ become completely carious, and the intervening cartilages are deſtroyed, no aſſiſtance is to be expected from the propoſed remedies. According to the obſervations made on the uſual effect of the diſcharge produced by art for the removal of this diſorder, after the diſcharge hath continued for ſome time, the patient begins to feel better health, he gradually recovers his appetite, gets refreſhing ſleep, hath a more quiet and leſs hectical pulſe; but the chief relief is from having got rid of that diſtreſſing ſenſation of tightneſs about the ſtomach; in a little time more, a degree of warmth and a ſenſibility is felt in the thighs, to which the patient hath been a ſtranger for ſome time; and generally much about the ſame time the power of retaining and diſcharging the urine and fæces begins to be in ſome degree exerted. The firſt return of the power of motion in the limbs is rather diſagreeable, the motions being involuntary and of the ſpaſmodic kind, principally in the night, and generally attended with a ſenſe of pain in all the muſcles concerned. At this point of amendment, if it may be ſo called, it is no uncommon thing, eſpecially in bad caſes, for the patient to ſtand ſome time without making any farther progreſs; this in adults occaſions impatience, and in parents deſpair; but in the milder kind of caſes, the power of voluntary motion generally ſoon follows the involuntary. The knees and ancles by degrees loſe their ſtiffneſs, and the relaxation of the latter enables the patient to ſet his feet flat upon the ground, a certain mark that the power of walking will ſoon follow; but thoſe joints having loſt their rigidity, become exceeding weak, and are not for ſome time capable of ſerving the purpoſe of progreſſion. The firſt voluntary motions are weak, not conſtantly performable, nor even every day, and liable to great variation, from a number of accidental circumſtances, both external and internal. The firſt attempts to walk are feeble, irregular and unſteady, and bear every mark of nervous and muſcular debility. The patient requires much help, and his ſteps, with the beſt ſupport, will be irregular and unſteady; but when they have arrived at this, no inſtance hath occurred in which the full power of walking was not ſoon attained. When the patient can juſt walk, either with crutches, or between two ſupporters, he is generally troubled to reſiſt or overcome the more powerful action of the ſtronger muſcles of the thighs over the weaker, by which his legs are frequently brought involuntarily acroſs each other, and he is ſuddenly thrown down. Adults find aſſiſtance in crutches, by laying hold of the chairs, tables, &c. but for children, a go-cart is the beſt; it ſhould reach up to the arm-pit, and ſhould encloſe the whole body; this takes off all inconvenient weight from the legs, at the ſame time enables the child to move them as much as it pleaſes.

While the curvature of the *ſpine* remains undiſcovered or unattended to, the caſe is generally ſuppoſed to be nervous, and nervous medicines, ſo called, are as generally adminiſtered; but without any advantage. When the caſe is known, recourſe is too frequently had to ſteel ſtays, ſwings, ſcrew chairs, &c. to reſtore the *ſpine* to its natural figure; but ſtill the patient grows unhealthy, and languiſhing under a variety of complaints, dies in an exhauſted emaciated ſtate. The remedy for this dreadful diſeaſe conſiſts merely in procuring a large diſcharge of matter by ſuppuration, from underneath the membrana adipoſa on each ſide of the curvature, and in maintaining ſuch diſchage until the patient ſhall have perfectly recovered the uſe of his legs. They who have been experimentally acquainted with the very wonderful effects of purulent drains, made from the immediate neighbourhood of diſeaſed parts, will not be much ſurprized at this particular one; and will immediately ſee how ſuch kind of diſcharge, made and continued from the diſtempered part, checks the further progreſs of the caries, gives nature an opportunity of exerting her own powers of throwing off the diſeaſed parts, and of producing by incarnation an union of the bones, (now rendered ſound) and thereby eſtabliſhing a cure. It matters not by what means the diſcharge is procured, provided it be large, and from a ſufficient depth.

With

With a cauſtic an eſchar is to be made on each ſide of the curved part of the *ſpine*; the eſchar ſhould be of an oval ſhape, about an inch and a quarter in length, and three quarters of an inch in breadth, at the broadeſt part. Apply each cauſtic near the ſide of the curvature, ſo as to leave the portion of the ſkin covering the ſpinal proceſſes of the protruded bones, entire and unhurt, and ſo large that the ſores upon the ſeparation of the eſchars may eaſily hold each three or four peas in the caſe of the ſmalleſt curvature, but in large curves, at leaſt as many more. A few days after applying the cauſtics, the ſloughs begin to looſen, it is then proper to cut out all the middle, and put into each a large kidney-bean; when the bottoms of the ſores are become clean by ſuppuration, ſprinkle now and then a ſmall quantity of finely powdered cantharides on them, by which the ſores are prevented from contracting, the diſcharge is increaſed, and poſſibly other benefit is obtained. The iſſues ſhould be kept open until the cure is compleat; that is, until the patient has not only the perfect uſe of the limbs, but alſo the general health. By means of this diſcharge, the eroding caries is firſt checked, then ſtopped, in conſequence of which an incarnation takes place, and the cartilages between the bodies of the vertebræ having been previouſly deſtroyed, the bones become united with each other, and form a kind of anchyloſis. No degree of benefit or relief, nor any the ſmalleſt tendency towards a cure is to be expected, until the caries be ſtopped, and the rotten bones have begun to incarn; the larger the quantity of bones concerned, and the greater the degree of waſte committed by the caries, the greater muſt be the length of time required for the correction of it, and for reſtoring to a ſound ſtate ſo large a quantity of diſtempered parts. And vice verſa. Nothing can be more uncertain than the time required to accompliſh a cure: ſometimes it is perfected in two months, and at others it requires two years; and in this laſt, two thirds of the time hath paſſed without any ſenſible amendment.

The diſcharge by means of the iſſues is all that is requiſite for the cure; but yet, this is no reaſon why every aſſiſting means ſhould not be applied at the ſame time in order to expedite, ſuch as the bark, cold bathing, frictions, &c.

In the courſe of lecturing in the year 1781, Mr. Pott obſerved, that it ſeems to be one of the few things that one may reaſon upon à priori, viz. that the whole train of the various ſymptoms of this diſeaſe are derived originally from a conſtitutional prediſpoſing cauſe; for, whenever in a curvature of the *ſpine* the diſcharge begins to have any effect, the leſſer ſymptoms (if they may be ſo called) as pain in the ſtomach, tightneſs acroſs the breaſt, incapacity of holding the urine or fæces, all give way before the removal of the lameneſs from the curve (as it is called) begins to take place.

Laſtly. If it is conſidered, that the primary cauſe of the curved *ſpine* and all its ſymptoms, preceding, attending, and conſequent, is a morbid ſtate of the *ſpine* and of the parts connected with it, the following inference will be allowed, viz. by an early and proper attention, the temporary lameneſs, permanent deformity, and fatality, may be prevented. It is found that iſſues are capable of affecting a perfect curve, even after a caries hath taken place, and that to a conſiderable degree, which is alſo true; is it not reaſonable to conclude, that the ſame means made uſe of in due time might prove preventive? In many habits iſſues would be beneficial, independent of this diſorder; infants and young children of ſtrumous habits, are the ſubjects who are moſt liable to this diſtemper; and they are in general more ſerved by artificial drains than any other perſons whatever.

N. B. A curvature of the *ſpine* may take place from the mollities oſſium, the rickets, and from the various cauſes of caries. An aneuriſm often produces a caries in the bones; ſo an aneuriſm near a vertebra may render it carious; the venereal diſeaſe ſometimes attacks the vertebræ, and renders them carious. The ſcrofula attacking the lymphatics and glands about the *ſpine*, is ſaid to be the conſtant cauſe of the curved *ſpine* above noticed, in which the curvature is angular; the angular protuberance ariſes immediately from the caries of the vertebra or vertebræ, and is attended with a uſeleſs ſtate of one or more of the extremities; but may not any cauſe, that produces a caries in the vertebræ, occaſion the angular inſtead of the curved appearance of the *ſpine*? and when the carious vertebra happens, ſo as that it is nearly deſtroyed, may not all the ſame ſymptoms proceed from ſuch deſtruction of the vertebra or vertebræ, though the cauſes of the caries were various?

See Remarks on that Kind of Palſy of the lower Limbs, which is frequently found to accompany a Curvature of the *Spine*, and is ſuppoſed to be cauſed by it, by Percival Pott, F. R. S. &c. 1779. Farther Remarks on the uſeleſs State of the lower Limbs, in conſequence of a Curvature of the *Spine*, &c. by Percival Pott, F. R. S. &c. 1782. Select Caſes of the Diſorder commonly called the Paralyſis of the lower Extremities, by John Jebb, M. D. &c. Edit. 2.

SPINACHIA, alſo called ſpinacia, olus Hiſpanicum, lapathum hortenſe. Common ſpinage. It is only uſed at the table, but if freely eaten it is laxative, diuretic, and cooling. See Raii Hiſt.

SPINALES COLLI MINORES, i. e. Interſpinales muſc.

SPINALIS ARTERIA. There are two *ſpinal arteries*, one anterior and one poſterior, both produced by the vertebrales; each of which, as ſoon as it enters into the cranium, ſends out a ſmall branch, by the union of which the poſterior *ſpinales* is formed. Afterwards the vertebrales advancing to the apophyſis baſilaris, of the os occipitis, detach backward two other ſmall branches, which likewiſe meet, and by their union form the *ſpinalis* anterior. Theſe *ſpinal arteries* run down on the fore and back ſides of the medulla *ſpinalis*, and by ſmall tranſverſe ramifications communicate with thoſe which the intercoſtal and lumbar *arteries* ſend to the ſame part.

SPINALIS COLLI. This muſcle riſes (one on each ſide) from the ſpines of the ſeven uppermoſt vertebræ of the back, and is inſerted into the ſpines of the five lower vertebræ of the neck.

SPINALIS DORSI MAJOR. It is a long ſlender muſcle lying on the lateral part of the extremities of the ſpinal apophyſes of the back. It is commonly called ſemiſpinales.

SPINALIS DORSI MINOR. Theſe muſcles are of two kinds; ſome go laterally from the extremity of one ſpinal apophyſis to another, being often mixed with the ſhort faſciculi of the *ſpinalis* major: the reſt lie directly between the extremities of two neighbouring ſpinal apophyſes, being ſeparated from their fellows on the other ſide by the ſpinal ligament.

SPINALES LUMBORUM. Theſe are ſome faſciculi which run up from the ſuperior falſe *ſpines* of the os ſacrum to the lower ſpinal apophyſes of the loins, which may be looked upon as ſo many *ſpinales lumborum* majores. There are alſo ſome *ſpinales* minores between the ſpinal apophyſes of the loins, and tranſverſales minores between the tranſverſe apophyſes, which are ſometimes of a conſiderable breadth.

SPINALIS MUSCULUS. This muſcle (and its fellow on the oppoſite ſide) riſes tendinous from the ſpinal proceſſes, and run to be inſerted into the tranſverſe proceſſes. It is diſtinguiſhed into *ſpinalis* colli, and *ſpinalis* dorſi. It goes in this manner as high as the ſpinal proceſs of the ſecond vertebra.

SPINOLA, i. e. ſpina bifida.

SPIRITUS. Spirit. Any fine volatile ſubſtance which exhales from bodies in a given degree of heat is called *ſpirit*; hence, by a ſort of imaginary analogy, the nervous fluid hath been called *ſpirit*, and is generally termed the animal *ſpirit*. *Spirit* in the human body is ſpoken of under the different characters of natural, vital, and animal. The firſt are ſaid to preſide over the digeſtion of the aliment, and the elaboration of chyle, or the natural actions. The ſecond is ſaid to preſide over the motion of the lungs and heart, or the vital actions. The third over the animal actions, as ſenſation, voluntary motion, &c.

In botany it is that volatile part in the eſſential oil of plants to which their peculiar ſmell and taſte is owing. It is alſo called *ſpiritus* rector.

In pharmacy there are many different ſubjects to which the name of *ſpirit* is given; but they are chiefly the *ſpirits* obtained by fermentation, which ſeem to be the only proper ones; thoſe that are formed of a ſaturate ſolution of volatile alkaline ſalts in water are more properly ſolutions than *ſpirits*. The fermented vegetable *ſpirit*, commonly called vinous *ſpirit*, is water ſo impregnated with the oilineſs of a vegetable, that it will burn all away. See VINUM ADUSTUM.

SPIRITUS MINDERERI. Mindererus's ſpirit. Take any quantity of the volatile *ſpirit* of ſal ammoniac; gradually pour upon it the pureſt diſtilled vinegar, until the effervescence ceaſes, occaſionally ſtirring it, to promote the action of the vinegar on the ſalt; or it may be gently heated, by which it will effervesce, if it is not neutral. To hit the neutralized point is difficult; but the beſt way of trying it is to ſtain a thick writing paper on one ſide with the blue called lachmus or archil, and on the other ſide with red, by mixing as much diluted *ſpirit* of ſalt in the lachmus as will redden it; then dip this paper into the mixture which is to be neutral, and if the alcali is predominant, the red ſide will turn blue; if the acid prevails the blue ſide will become red, and no change is produced if the mixture is neutral. The *ſpiritus Mindereri* is analagous to the crude ſal ammoniac in its medicinal qualities, but is ſomewhat more penetrating. From ʒ ii. to ℥ ſs. is the uſual doſe when perſpiration is to be excited.

SPLANCHNICA, from *σπλάγχνον, an entrail or bowel.* Medicines appropriated to the diſeaſes of the bowels or viſcera.

SPLANCHNOLOGIA. Splanchnology. It treats of all the viſcera in the head, breaſt, or belly.

SPLEN. The ſpleen, or milt. Hippocrates calls it the left liver. Ariſtotle calls it the left or baſtard liver. Some of the ancients called it fomes ventriculi, i. e. fuel to the ſtomach; becauſe they ſay its office and ſituation is to the ſtomach as a furnace to a copper, i. e. that it warms the ſtomach. The *ſpleen* is ſituated in the hypochondrium laterally, in the cavity between the falſe ribs and the ſpine. It is of a long oval figure, about ſeven fingers breadth in length, and four or five in breadth. It is generally of a livid or a black red colour, and very lax. It is compoſed of three ſides, the convex is next the diaphragm, the concave is divided by a longitudinal ſulcus where the ſplenic veſſels enter, and divide the *ſpleen* into an under anterior and upper poſterior part. It receives the great extremity of the ſtomach on its concave part. It receives a coat from the peritoneum. At the fiſſure in the inferior edge the veſſels enter variouſly, ſome in the middle and others in the extremities; theſe veſſels ſend branches to the ſtomach, they are called vaſa brevia. Haller ſays that it is compoſed wholly of arteries and veins, and that its uſe is to ſupply the liver with due ſupplies of blood. See Haller's Phyſiology, ſect. 26. Caſſerius, Ruyſch and Winſlow.

SPLENALGIA. Pain in the ſpleen, or its region.

SPLENALGIA SUPPURATORIA. Inflammation of the ſpleen, tending to or ending in a ſuppuration.

SPLENIA. Compreſſes. The antients called them ſplenia, becauſe they often reſembled the ſpleen in ſhape. And they are called compreſſes, becauſe they keep other dreſſings tight and firm. They are made of lint, tow, and folded rags. Their principal uſes are, to cheriſh the natural heat of the part, or to keep out the cold: to ſecure the dreſſings under them; to convey liquid remedies to the diſordered part, and to continue them longer thereon; to fill up inequalities and depreſſions, ſo that the dreſſings may be ſecured: and, laſtly, to prevent the ſkin from being irritated by the ſtricture of the bandages.

SPLENICA, i. e. ſplenalgia.

SPLENICA ARTERIA. The ſplenic artery paſſes downwards and to the left ſide, behind the upper edge of the pancreas, to which it gives branches; afterwards it divides into ſeveral branches, which enter the fiſſure in the inſide of the ſpleen. Before they enter the ſpleen they give off the vaſa brevia, and the gaſtrica ſiniſtra, which is the largeſt of the vaſa brevia.

SPLENICA VENA. The ſplenic vein is one of the diviſions of the vena portæ ventralis. It runs tranſverſely from the right to the left, firſt under the duodenum, and then along the lower ſide of the pancreas near the poſterior edge; in its courſe it gives off ſeveral branches. It terminates afterwards by a winding courſe, in which it ſends branches to the ſpleen. Laſtly, it reaches the fiſſure of the ſpleen, which it enters, and runs through its whole length by ſeveral branches, much in the ſame manner as the ſplenic artery.

SPLENITIS, from *σπλὴν, the ſpleen.* An inflammation or a tumor of the ſpleen. *Splenitis* is alſo a name for the vein in the left hand which is called ſalvatella, the fellow to which in the right hand is called jecoraria. Dr. Cullen places the *ſplenitis*, or inflammation of the ſpleen, as a genus in the claſs pyrexiæ, and order phlegmaſiæ.

SPLENIUM, i. e. Aſplenium.

SPLENIUS, called alſo triangularis, and maſtoidæus ſuperior. It riſes from the ligamentum colli, a little below the firſt tranſverſe line of the os occipitis, from the lower vertebræ of the neck, and five upper dorſal vertebræ, and is inſerted into the poſterior part and whole length of the maſtoid proceſs, and into the tranſverſe proceſs of the atlas and dentata, ſerving to bend the neck backwards. Albinus divides this into two muſcles, viz. the *ſplenius* capitis, and the *ſplenius* colli: but this diviſion is quite unneceſſary.

SPLENOCELE. A rupture of the ſpleen.

SPODIUM ARABUM. Burnt ivory. Ivory is the tuſks of elephants, which often grow to ſeven feet in length, and at their baſis are as thick as a man's thigh; one of them will ſometimes weigh one hundred and ſixty pounds. The African ivory turns yellow with keeping; the Ceylon ivory keeps its whiteneſs longeſt. The ſhavings are boiled in water, and thus a jelly is formed, which hath the ſame effects as the jelly of hartſhorn; the African ivory abounds moſt with oil and ſalt, the qualities of which are not different from thoſe obtained from hartſhorn. When ivory is burnt to blackneſs, it is called ivory black and velvet black.

SPONGIA. Sponge. It is ſomewhat like a fungus; it is a plant which grows in the ſea; it is very bibulous, of a ſoft ſubſtance, full of perforations, and elaſtic. It is brought from Smyrna and Aleppo: the beſt is ſaid to be got in the Archipelago. Thoſe pieces which are full of fine perforations are called males, and of theſe the hardeſt are called tragi; the contrary are called female.

It is uſed inſtead of flannels, for applying fomentations, for it keeps the heat longer; for tents to dilate wounds with, in which caſe it is dipped in hot bees-wax, then ſqueezed hard until it is cold, after which it is cut into proper ſizes; for pledgits to be applied over the lint which is laid on the ſtump after amputating a limb; and in ſcrofulous diſorders, and cutaneous foulneſſes, for which end it is reduced, by lightly burning it, to a black powder, which is given in doſes from gr. x. to ϑ i. two or three times a day: its virtues, which render it uſeful in theſe diſorders, depend on a volatile, animal, alkaline ſalt, (with which it abounds) and the oil of the *ſponge* united.

When *ſponge* is cut in ſmall pieces, and freed from the ſtony matters which are lodged in it, it is burnt in a cloſe earthen veſſel until it is black and friable, and when being powdered in a ſtone or a glaſs mortar, it is kept in a cloſe vial for uſe. The burning ſhould be diſcontinued as ſoon as the matter becomes thoroughly black; as the outſide of a large quantity will be ſufficiently burnt, before the middle is much affected, the beſt method is, to cut it in ſmall pieces, and keep it continually ſtirring in ſuch a machine as coffee is roaſted in.

Except raw ſilk, more volatile alkaline ſalt is obtained from *ſponge* than from any other matter. By boiling the *ſponge* in water, it gives out a portion of ſea-ſalt; by burning it to aſhes, it yields a large quantity of fixed alkaline ſalt, the ſame as is obtained from the ſea-ſalt. See Lewis's Mat. Med. Neumann's Chem. Works.

SPONGIOSUM OS. A name for the os ethmoides. The oſſa ſpongioſa inferiora are two oblong bones lying looſe between the anterior and poſterior noſtrils; they are glewed to the upper maxillary bones, and are convex towards the ſeptum naſi, while on the oppoſite ſide, which faces the ſinus maxillaris, they are concave. They have each

each two proceſſes on their upper edge; the poſterior covers part of the maxillary ſinus; the inferior joining with the os unguis, compoſes part of the ductus lachrymalis. The offa ſpongioſa ſuperiora, ſee ETHMOIDES Os.

SPORADICI. Sporadic diſeaſes. Such diſeaſes as reign in the ſame places and time; here and there one or a very few perſons only being their ſubjects. Such diſeaſes are neither endemic, epidemic, or contagious.

SPUTUM. Spit. This name is given to whatever comes from the mouth; but it is properly confined to what is excreted by coughing. Bloody *ſpit* is when the blood-veſſels in the lungs are eroded, and in this caſe a cough attends. Salt acrid *ſpit* endangers an eroſion in the lungs. Bitter, or ſalt *ſpit*, is from a mixture of bile. Sweet *ſpit* is from concocted phlegm; fetid *ſpit* is from a putrefaction of the humours of which it is compoſed; purulent *ſpit* is from a phthiſis approaching or begun. See Proſper Alpinus's Præſages.

STAGMA. A liquor expoſed to diſtillation; alſo a name for the oil of vitriol.

STAMINA. Alſo called chives; they are thoſe ſlender threads which encompaſs the ſtyle in the centre of flowers, and ſupport the apices or ſummits which contain the male duſt.

STANNUM. Tin. Alſo called plumbum candidum; Jupiter. It is the lighteſt of all the metals; the leaſt ſimple, being mixed with various heterogene particles, particularly ſulphurous or arſenical, whence the inconveniences to which its eſſayers are ſubjected; it is leſs fixed in the fire than any other of the metals; it is ſoft, flexible, and malleable, yet it increaſes the elaſticity of ſome elaſtic bodies; it is not ſonorous, yet when mixed with other metals their ſound is encreaſed; it melts long before ignition, even with a heat not much exceeding boiling water; in melting it hath this peculiarity, in which it differs from all other metals, that it crackles as it melts; when crude, it diſſolves only in aqua regia; but when freed from its ſulphur, &c. by calcination, it diſſolves even in vinegar. Its ore is found in many parts of the world, but the beſt is the Malacca *tin*, and the next is the Engliſh.

Tin hath been extolled as a ſpecific in diſorders of the uterus and lungs, and particularly as an antihectic, but experience does not ſupport its character, ſo that it is almoſt thrown out of the preſent practice. The London college continues the preparation called aurum muſivum; and Dr. Alſton hath given the filings of *tin* a degree of reputation for deſtroying worms, particularly the flat one; he directs it to be given in treacle, in doſes of from ʒ ſs. to ʒ i. the patient takes it in the morning faſting; the day after three doſes are taken, a purging draught ſhould be taken. Some have obſerved that *tin* hath been effectual in epilepſies from worms and from frights, and in the chorea Sancti Viti; though not in any other nervous diſorder. In nervous diſorders it ſhould be finely powdered; but, as a deſtroyer of worms, the filings are moſt effectual.

If *tin* is heated, it becomes ſo brittle, that by agitation, when juſt ready to melt, it falls into a fine powder; but the *tin* is more eaſily powdered by rubbing three parts with one of coralline, and pounding them together. See Lewis's Mat. Med. Neumann's Chem. Works.

STAPEDIS MUSCULUS. It lies in a little cavity of the os petroſum, and is inſerted into the head of the ſtapes.

STAPES. The ſtirrup. It is one of the bones in the ear, and is thus named becauſe it is exactly like a *ſtirrup*. It ſtands with its baſis upwards and inwards upon the feneſtra ovalis, and at its narrower part is articulated with the inſide of the long proceſs of the incus.

STAPHISAGRIA, called alſo pedicularis, ſtaves acre, and louſe-wort. It is the Delphinium *ſtaphiſagria*. Linn. It is a plant with large leaves, and blue flowers, which are followed by pods, containing large, rough, triangular, dark coloured ſeeds. It is a native of the ſouth parts of Europe, from whence the ſeeds are brought to us; but they are moſt plentiful in Dalmatia and Iſtria.

The ſeeds have a diſagreeable ſmell, a nauſeous, bitter, burning taſte. If taken in doſes from ten grains to a ſcruple, they purge and vomit ruggedly, and inflame the throat and ſtomach; but they are chiefly uſed to deſtroy lice. Their acrimony is partially extracted by water, totally by rectified ſpirit, but not raiſed by either in diſtillation. The beſt method of uſing them for deſtroying lice, &c. is to ſtrew the fine powder on the part, and to ſecure it with an handkerchief, or other proper bandage; or if a decoction is more convenient, boil an ounce in a pint of water for a few minutes. The powder may be mixed with oatmeal to kill mice and rats. See Neumann's Chem. Works; Lewis's Mat. Med.

STAPHYLINI. Winſlow calls by the names ſtaphylini and epiſtaphylini, two fleſhy ropes cloſely united together, as if they were but one muſcle; but in ſome ſubjects they are diſtinguiſhed by a very fine white line. They are fixed by one extremity in the common point of the poſterior edges of the offa palati, and from thence they run downwards and backwards along the middle of the ſeptum, and alſo along the middle of almoſt the whole uvula. Morgagni diſcovered them, and they are called by ſome azygos Morgagnii.

STAPHYLINUS EXTERNUS, i. e. Circumflexus palati.

STAPHYLOMA. This term comprehends two diſorders of the eye; one when the tunica cornea is gradually rendered protuberant; the other, when the pupilla breaks forth upon the tunica cornea, and deforms the eye with the tumor, like σταφυλη, a *grape*, by which the ſight is deſtroyed. Theſe tumors, from their different forms and ſizes, aſſume different names; as margarita, myocephalon, clavus, mylon, pomum, uva, or acinus; according to the reſemblance they bear to the things whence they are named. Sauvage ſignifies by this word a dropſy of the cornea. Not only the cornea, but alſo the ſclerotica, is alſo ſometimes ſwelled, and occaſions great pain and violent inflammation, which ſometimes ends in a ſuppuration, or a cancer. Monſ. St. Yves propoſes to extirpate the tumor, and then dreſs with lint dipped in brandy and water; after which the artificial eye may be fixed. If the caſe is ſlight, compreſſes of alum-water may be laid on, and the patient may lay continually on his back. If a wound is the cauſe, try to puſh back the tumor with a probe.

For the moſt part, the cure is not undertaken to recover the ſight, but only to remove the deformity and the bad ſymptoms.

STAPHYLOSIS. A protuberance or protuſion of the choroides of the eye.

STATIONARIA FEBRIS. A ſtationary fever. So Sydenham calls thoſe fevers which happen when there are certain general conſtitutions of the years, which owe their origin neither to heat, cold, dryneſs, nor moiſture, but rather depend upon a certain ſecret, and inexplicable alteration in the bowels of the earth, whence the air becomes impregnated with ſuch kinds of effluvia, as ſubject the body to particular diſtempers, ſo long as that kind of conſtitution prevails, which after a certain courſe of years declines, and gives way to another. Each of theſe general conſtitutions is attended with its own proper and peculiar kind of *fever*, which never appears in any other.

STEATITES. Soap-rock. It is an earth found in Cornwall: it hath the aſpect of marble, and is conſiderably hard: it is white, variegated with red, blue, or green: it is ſmooth to the touch, and gloſſy on the ſurface. Its chief uſe is in the porcelain manufactory.

In foſſilogy, it is a genus of earth; its characteriſtics are, that it is gloſſy; very ſmooth, unctuous, and reſembling hard ſoap; and readily falling down in water, when it poſſeſſes no kind of ductility, nor any grittyneſs. See Edwards's Elements of Foſſilogy. By fire it is hardened ſo as to ſtrike fire with ſteel. It hath the property of fullers earth, in cleanſing cloaths from greaſe. It is ſo ſoft as to be cut with a knife, or with a tool turned by a lathe; accordingly it is, in ſome places, made into pots for the uſe of the kitchen, and hence named lapis ollaris. The ſerpentine ſtone, the nephritic ſtone, the ſubſtances called French chalk, are ſo many kinds of *ſteatites*. See Dict. of Chemiſtry, edit. 2d. Vogel uſes the word to ſignify corpulency.

STEATOCELE, from στεαρ, *ſuet*, and κηλη, an *hernia*. A ſpecies of *hernia* cauſed by a collection of *ſuety* matter in the ſcrotum.

STEATOMA, from στεαρ, *ſuet*. A ſpecies of tumor,

commonly called a wen, of which it is a ſpecies. Its contents appear like *ſuet*: it does not yield to eſcharotics; but when convenient, is to be removed with a knife. See NÆVUS.

STELLA. The name of a bandage uſed in arteriotomy: it is ſo called from its many croſſings on the temples, or from its reſemblance to a ſtar: it ſhould be twenty or twenty-four feet in length, two fingers broad, and double-headed. When this bandage is uſed, cover it with proper compreſſes, then place the middle of the roller on the ſound temple, and bring one head round the occiput, and the other round the forehead, until they meet at the part affected; and there croſſing each other, form a kind of knot; carry one end over the vertex, the other under the chin; croſſing again, over the ſound temple, whence they are carried round the forehead and occiput, to the compreſſes on the wound, &c. until all the bandage is taken up.

STERILITAS. Barrenneſs. In this caſe, if medicines prove uſeful, it is only by reſtoring the general health. But the cauſe is ſo frequently a ſcirrhus in the uterus, or other parts ſubſervient to generation, that it rarely happens that the complaint is removed. It is ſynonymous with dyſpermatiſmus.

STERNO-CLEIDO-HYOIDÆUS, i. e. Sterno-Hyoides.

STERNO COSTALES. See TRIANGULARES STERNI.

STERNO-HYOIDES. This muſcle riſes from the inſide of the ſternum and the clavicle, and running over the thyroid cartilage, is inſerted into the baſe of the os hyoides to pull it down. Some call it ſterno maſtoideus, but very improperly.

STERNO-MASTOIDÆUS. See MASTOIDÆUS, and STERNO-HYOIDES.

STERNO-THYROIDÆI. The muſcles thus named, riſe between the cartilages of the firſt and ſecond rib; run before, and cloſe to the *thyroid* gland and the trachæa, and are inſerted into the knobs of the *thyroid* cartilage, pulling the whole larynx down.

STERNUM, from στηθος, the *breaſt* or *breaſt-bone*. It is the broad, flat *bone*, at the anterior part of the thorax. In adults of a middle age, it is compoſed of three *bones*, but frequently the two lower *bones* are ultimately united. The firſt *bone* is the thickeſt; to this the clavicles and the firſt ribs are articulated, and half the cavity for the reception of the ſecond rib. The ſecond bone is longer, narrower, and thinner than the firſt; in the ſides of it are complete cavities for the third, fourth, fifth, and ſixth ribs, and half pits for the ſecond and the ſeventh. The third *bone* is the leaſt, and hath only half of the cavity for the ſeventh rib. It is called cartilago enſiformis, and in young ſubjects is always cartilaginous.

STERNUTATIO. Sneezing.

STERNUTATORIUM. A ſternutatory. See ERRHINES.

STERTOR. Snoring, or what is called a rattling in the throat. See RHENCHOS. It is a noiſy reſpiration, as in an apoplexy, in which the mucus from the fauces is forced through the noſtrils.

STIBIUM. Antimony; alſo the glaſs of antimony.

STIGMA. Scarlet coloured ſpots, ſuch as happen after a blow: alſo particular marks in the face, or any part of the body, commonly called moles. The ſpots called vibices are ſometimes thus named.

STILLICIDIUM. In pathology, it ſignifies the ſame as ſtrangury. In pharmacy, it ſignifies an inſtillation of liquor upon ſome part of the body: the French call it la Douche; and we commonly expreſs it by, pumping upon.

In pumping upon a diſeaſed part, three things act at the ſame time upon the inſpiſſated and ſtagnating fluids: firſt, the falling fluid, which abrades and comminutes the inſpiſſated juices by its force and compreſſion; ſecondly, the nature of the water may contribute to this effect, and the fall of it may help it to penetrate; thirdly, the heat of the water, which inſinuates itſelf, and warms the part quite through, it aſſiſts and quickens the motion of the fluids; hence it follows, that a part is tranſpired through the ſkin, and the reſt aſſiſted in its circulation.

Le Dran, in his 93d and 94th Obſ. gives ſome account of this operation in the anchyloſis, and attempts to account for the action of the pumping; but his reaſoning is rather ſpecious than ſatisfactory.

STILLICIDIUM URINÆ, i. e. Dyſuria.

STOECHAS. French lavender. It is called *ſtœchas* from the iſland Stœchades; and *ſtœchas* Arabica, becauſe much commended by the Arabian phyſicians; it is alſo called ſpica hortulana, ſticadore, and caſſidony. It is the lavandula *ſtœchas*. It is a low, ſhrubby plant, with ſmall, oblong, narrow leaves, bearing on the tops of the branches ſhort thick ſpikes, or ſcaly heads, from which iſſue ſeveral ſmall purple labiated flowers, followed each by four ſeeds, incloſed in the cup: it is a native of the ſouthern part of Europe, common in our gardens, where, with a little ſhelter, it bears the hardeſt weather; it flowers in May and June. The flowers which are brought from France and Italy are rarely ſo good as thoſe of our own growth. The heads ſhould be gathered when firm and hard, which is about the end of July.

Diſtilled with water, it yields a conſiderable quantity of a pale-coloured fragrant eſſential oil; but with rectified ſpirit of wine, it yields but little. Its virtues agree with thoſe of our *lavender*, but are inferior. See Neumann's Chem. Works; Lewis's Mat. Med.

STOECHAS. A name for ſome ſpecies of elichryſon.

STOLONES. The ſuckers of plants, that is, ſuch ſhoots as ariſe from the roots of plants, and may be taken off with fibres to them, ſo as to propagate the ſpecies thereby.

STOMACACE, from στομα, the *mouth*, and κακος, *evil*. A ſymptom of the ſcurvy, conſiſting of a fetor of the mouth, and an roſion and ſpontaneous hæmorrhage of the gums. It is alſo a name for the ſcurvy. The bleeding of the gums is always ſymptomatic.

STOMACHICA PASSIO. In this diſorder there is an averſion to food; even the thought of it begets a nauſea, anxiety, cardialgia, an effuſion of ſaliva, and often a vomiting; faſting is more tolerable than eating: if the patient is obliged to eat, he muſt endure a pain that is worſe to him than hunger itſelf; he is troubled to chew, but more ſo to ſwallow his food; there is an averſion to common food, and a deſire to what is unuſual; often, a pain is complained of between the ſhoulders, and it is increaſed after eating; reſtleſſneſs, dimneſs of ſight, a noiſe in the ears, a heavineſs in the head, numbneſs in the limbs, a palpitation in the hypochondria, and a ſpitting of cold watery phlegm; the patient imagines that the ſpine of his back moves towards his legs, and whether ſtanding, or lying, he ſeems to be moved like a reed that is ſhaken by the wind; though not thirſty, he deſires to drink after eating; though drowſy, he keeps walking; is lean, pale, feeble, faint, timid, ſilent, but ſoon angry; he is much diſturbed with black bile, and falls into fits of melancholy; the ſymptoms during a fit, are fainting, a cold numbneſs of the joints, an unuſual heat which runs through the members, and moſt perceived in the palms of the hands, with a dewy ſweat, reſtleſſneſs, jactitation, anxiety, deſpondency, a change of colour, a ſmall, ſwift, weak pulſe, a waſting of the body, or, on the contrary, an immoderate appetite, with indigeſtion, and an acrid, acid, or nidorous quality in the contents of the ſtomach; ſometimes the patient is ſpeechleſs, grinds and clenches his teeth; there is always a cold in the head, with a ringing in the ears; ſometimes, though rarely, there is great thirſt; a pain in the precordia, which extends to between the ſcapulæ; and when the inflammation is conſiderable, there is a difficulty of ſwallowing, and a ſtrangulation, which ſome have called a ſtomachic quinſy; an hardneſs of the ſtomach, without pain, with other ſymptoms, as a windineſs, inflation, borborygmi, &c.

The cauſes are a diſcharge of pus from the belly upon the ſtomach, intenſe thinking, a neglect of proper nouriſhment and reſt, ſorrow, taking cold, continual indigeſtion, vomiting, &c.

In order to the cure, the patient's inclinations muſt be complied with; the juice of quinces are recommended; warm ſtimulants, ſuch as pepper and ginger, with aloes, and other ſuch like bitters, are found to be uſeful. See Aretæus de Cauſ. Sign. diutin. Morb. lib. ii. cap. vi. Cœ-

lius Aurelianus Morb. Chron. lib. iii. cap. ii. Aretæus de Curat. Chron. Morb. lib. ii. cap. vi.

STOMACHICI NERVI. See PAR VAGUM.

STOMACHUS, from στομα, *a mouth*, and χεω, *to pour*. Becauſe it ſends the food into the orifice of the guts. The word *ſtomachus* properly belongs only to the upper orifice of the *ſtomach*, though given to the whole viſcus. The ſtomach is ſituated under the left ſide of the diaphragm, juſt below the leſſer lobe of the liver, paſſing down a little way, and then turning over the ſpine to the right ſide. In ſhape it much reſembles the pouch of a bagpipe; it lies in an oblique direction from left to right, and hath a ſubſtance called meſogaſtrion in its concave part, between the orifices attaching it to the ſubjacent parts; its ſuperior orifice is called the cardiac orifice; it is on the left ſide; the inferior orifice is toward the right ſide, and is called pylorus. The outward coat of the ſtomach is from the peritoneum; the ſecond coat is muſcular; the inner or villous coat appears like a pile of velvet, but ſhort and flat, and it is extremely vaſcular; betwixt theſe coats the cellular membrane runs, and, according to ſome, is reckoned diſtinct coats; to that betwixt the muſcular and the villous coat, ſome have given the name of nervoſa. The muſcular coat of the ſtomach can contract it to a very ſmall ſize, as in vomiting. Dr. Hunter thinks, that the cavity is contracted ſo as not to be larger than the ſize of a nutmeg, when all the contents are thrown out. The arteries are principally the coronaria ventriculi, and the two gaſtricæ; the veins are ramifications from the venæ portæ in general, and, in particular, from the meſeraica major, ſplenica, and hæmorrhoidalis interna; the nerves are from the eighth pair. See DEGLUTITIO.

STORAX RUBRA, i. e. Thuris Cortex.

STRABILISMUS, from στραβιζω, and that from στρεφω, *to turn*. Strabiſmus, and ſtraboſitas. Squinting. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order dyſcineſiæ. He diſtinguiſhes three ſpecies. 1. *Strabiſmus* habitualis. When from a cuſtom of uſing one eye. 2. *Strabiſmus* commodus. When one eye in compariſon with the other, from greater weakneſs or mobility, cannot accommodate itſelf to the other. 3. *Strabiſmus* neceſſarius. When ſome change takes place in the ſituation or figure of the eye or a part of it. It may be cauſed from habit contracted by mocking thoſe who *ſquint*; by viewing many agreeable objects at once; by placing the eye of an infant obliquely to a candle, or a window, &c. or this diſorder may proceed from a fault in the firſt conformation of the eye, or ſome particular part of it; or the weakneſs of one eye may produce this defect in the other; the muſcles of the eye may be too long, or too ſhort, preternaturally relaxed or contracted; a tumor in the orbit, or an adheſion of the eye to ſome part of the eye-lid, may alſo be a cauſe; ſpaſm, or an apoplexy, may alſo produce it.

Thoſe who *ſquint* from ſome accident after they are grown up, ſee double; but when they *ſquint* from their infancy they do not.

Some attempt to remove this defect in children, by ſetting them to look at their faces in a looking-glaſs, and repeat this attempt for a quarter of an hour, night and morning; and while this method is in uſe, the eyes ſhould be waſhed with Hungary water; to ſtrengthen the muſcles waſh the temples and the forehead three times a-day. See St. Yves on the Diſorders of the Eyes.

STRAMEN CAMELORUM. Camel's hay.

STRAMONIUM. Thorny apple. It is the datura *ſtramonium*, or datura fœtida pericarpiis ſpinoſis erectis ovatis, foliis ovatis glabris of Linnæus. The *ſtramonium* ſpinoſum of Gerard; and the ſolanum maniacum of Diaſcorides.

The root is long, large, and fibrous. The ſtalk is of a pale green, ſtrong, and near three feet high. The leaves are large, of a lively green, placed on ſtrong peduncles; they are broad, pointed at the extremity, beautifully indented, and are placed without any regular arrangement. At night, the leaves, particularly the upper ones, riſe up and incloſe the flowers. The flower appears in Auguſt, conſiſts of one petal, funnel-ſhaped, tubular, and folded at the border in five parts; they grow at the bifurcation of the branches, are large, and of a milk white colour, though ſometimes they have a tinge of purple or velvet. The ſeed veſſel is oval, large, and covered with ſhort, ſharp, and ſtrong thorns. The ſeeds are brown.

It is a native of America.

The ſeeds and leaves received into the human ſtomach produce a vertigo, and afterwards madneſs. Boerhaave relates that ſome boys who had eaten ſome ſeeds of *thorn apples*, were ſeized with giddineſs, horrible imaginations, terrors, and delirium: and that thoſe who did not ſoon vomit, died. Some ſay it cauſes convulſions.

This plant hath a diſagreeable, naufeous ſmell, when rubbed between the fingers. According to the relations of ſome, the leaves are ſaid to be cooling, and the ſeeds narcotic; others obſerve, that the ſeeds produce a ſtrange kind of delirium, which continues twenty-four hours; and that the root occaſions uneaſy ſleep and troubleſome dreams.

In caſe of injury from the ſeeds or any other part of this ſpecies of datura, proceed as in caſes of poiſon by muſhrooms. See AMANITA and VENENUM.

Dr. Storck took *ſtramonium* offic. datura pericarpus ſpinoſis erectis ovatis, Linn. He preſſed out the juice from the freſh plant, and inſpiſſated it to an extract, and, in different caſes, gave it in doſes from gr. ſs. to ʒ i. in twenty-four hours. In epileptic diſorders, convulſions, and madneſs, it proved to be a medicine of ſingular efficacy; he cured ſeveral patients whoſe diſorders were violent, and of long continuance, with it. See Miller's Bot. Off. Dr. Storck on the *Stramonium*; Withering's Bot. Arrang. Med. Muſ. vol. i. p. 448. &c. Wilmer's Obſ. on Poiſonous Vegetables.

STRANGALIDES. Hard tumors in the breaſts from milk.

STRANGURIA, from στραγξ, the genitive caſe of στραξ, a *drop*, and ουρον, *urine*. A ſtrangury. It is a diſcharge of *urine* by *drops*, attended with pain. See DYSURIA.

STREMMA, from στρεφω, *to turn*. A ſtrain. When a membranous, or tendinous part is ſtretched beyond its proper limits, it is ſaid to be ſtrained. This accident happens chiefly about the joints, occaſions weakneſs and pain there, with ſwelling, and often a total inability to move. A *ſtrain* approaches very nearly to the nature of a contuſion, and, as in contuſions, reſt, with the application of warm vinegar, three or four times a day, will be proper; and when the ſymptoms abate, in proportion thereto let a little ſpirit be added to the vinegar, which now may be uſed cold, and a bandage may be made uſe of to ſupport the weakened part, until the natural degree of ſtrength returns. Dr. Lobb adviſes the uſe of vinegar, and of rectified ſpirit of wine alternately, firſt rubbing in the vinegar, then two or three hours after rub in the ſpirit.

Cold water is uſed by ſome; but if the *ſtrain* is deep, it does no ſervice; if there is inflammation, it does harm, ſo that it is only in ſlight, and ſuperficial, and theſe muſt be recent caſes too, in which it can be of ſervice.

STRIDOR. Grinding of the teeth. Hippocrates obſerves, that in acute diſeaſes this ſymptom is uſually fatal if the patient has not been accuſtomed to it in his childhood.

STRIGIL, or Strigilis. An inſtrument with which to ſcrape off the ſweat during the gymnaſtic exerciſes of the ancients; and, in their baths, ſtrigils were made of metals, horn, ivory, and were curved: ſome were made of linen.

STRIGMENTUM. The ſtrigments, filth, or ſordes, ſcraped from the ſkin in baths, and places of exerciſe; ſome of theſe *ſtrigments* were only the ſweat, others were the ſweat mixed with the duſt raiſed in the place of exerciſe, or purpoſely ſtrewed on the bodies of them who were there engaged. *Strigments* were of three ſorts: 1. Sweat. 2. Sweat with the duſt and oil, which was rubbed on the bodies of the men. 3. Oils and duſt ſcraped from ſtatues, and which often partook of verdegriſe, from the oil diſſolving the copper.

STRONGYLUS. Round worms. See VERMES.

STRUMA. The *ſtruma* of the ancients were thoſe ſcrofulous tumors that were encyſted. See SCROFULA.

STRYCHNOMANIA. So the ancients called the diſorder produced by eating the deadly night-ſhade.

STRYCHNOS. So Theophraſtus called the deadly night-

night-ſhade. In Linnæus's Syſtem of Vegetables, it is a genus of plants in the claſs pentandria, and order monogynia. Its two ſpecies are the *ſtrychnos* nux vomica, and *ſtrychnos* colubrina.

STUM. It is muſt, whoſe fermentation hath been prevented, or prematurely ſuppreſſed, by fumigation with ſulphur.

STUPOR. Loſs of feeling. The ſame as anaſthæſia. Or it is a tranſitory numbneſs, ſuch as is occaſioned by accidental preſſure, &c.

STUPOR DENTIUM. An affection of the teeth, in which a certain pain is felt in the membrane which ſurrounds them, and by which ſenſation is in a degree deſtroyed. It is produced by taking acid and auſtere ſubſtances into the mouth.

STUPA, or Stuppa. A ſtupe. It is a piece of cloth uſually of flannel, dipped in ſome proper liquor, and applied to an affected part.

STYLIFORMIS, i. e. Gr. phoides.

STYLOCERATOHYOIDEUS, Stylo, from the *ſtyloid proceſs*, and κέρατα, *horns of the hyoides*. Stylo-ſtyloid proceſs, i. e. Stylohyoides.

STYLO-CHONDRO-HYOIDÆUS. So Douglas names one of the muſcles called ſtylohyoidæus, becauſe it is inſerted into the cartilaginous appendix of the os hyoides.

STYLO-GLOSSI. From *ſtilus*, a *pencil*, and *gloſſa*, a *tongue*. Theſe muſcles riſe from the inner-part of the ſtyloid proceſs, and go the whole length of the tongue, ſerving to expand it.

STYLO-HYOIDES. It riſes from the proceſſus ſtyloides, and runs to the cornu and baſis of the os *hyoides*. Generally its fibres paſs on each ſide of the tendon of the digaſtric muſcle.

STYLOIDES PROCESSUS, from στῦλος, a *pencil*, and εἶδος, *form*. See Temporum Ossa.

STYLOIDES RADIALIS [Ligamentum]. It is fixed round the neighbouring tuberoſity of the os ſcaphoides.

STYLOIDES ULNÆ [Ligamentum]. It is fixed in the os cuneiforme, and then in the os unciforme, from whence it is a little ſtretched over the fourth bone of the metacarpus.

STYLO MASTOIDEUS FORAMEN. This hole is the orifice of the paſſage for the portio dura of the auditory nerve, which runs behind the tympanum.

STYLO PHARYNGÆI. Theſe muſcles riſe from the beginning of the ſtyloid proceſſes, and are inſerted into the pharynx, and into the thyroid cartilage.

STYMATOSIS. A bloody diſcharge from the penis.

STYPTICA, from στύφω, to *aſtringe*. Styptics, or medicines which ſtop hæmorrhages. Of *ſtyptics* for ſtopping hæmorrhages there are few to be depended on; their uſefulneſs is only in very ſlight caſes, and the beſt of them is the lycoperdon.

STYRAX, alſo called ſtorax; and becauſe it was formerly brought to us in reeds or canes, it was named *ſtyrax* calamita. Caſper Bauhine calls the tree that affords it *ſtyrax* folio mali cotonei, becauſe its leaves are like thoſe of the quince-tree. Ray calls the tree from which the liquid *ſtyrax* is obtained, *ſtyrax* aceris folio, becauſe its leaves reſemble thoſe of the maple. It is the *ſtyrax* officinale, or *ſtyrax* Syriacum, foliis mali cotonei, floribus albis, Linn. The Syrian *ſtorax* tree.

Storax is the moſt fragrant of the ſolid reſins, and, indeed, of all the vegetable ſubſtances. There are three kinds: 1. The fine ſort, called the red *ſtorax*; it is the pure native juice which flows from inciſions made into the trunk of the tree; it is not in tears, but in maſſes, ſometimes compoſed of whitiſh, and pale reddiſh brown lumps; ſometimes it is of an uniform reddiſh yellow, or browniſh appearance, unctuous and ſoft like wax, and free from viſible impurities. With this kind we rarely meet. 2. The common *ſtorax*: this is ſuppoſed to be the thinner juice thickened with ſaw-duſt, for it is more fragrant than the pure ſort, both whilſt mixed with the ſaw-duſt, and when ſeparated therefrom by means of rectified ſpirit of wine; its flavour is alſo of the ſame kind. It is now brought in large pieces, of a reddiſh brown colour, ſoftiſh, and, as it were, unctuous to the touch, yet brittle and friable. This is the only ſort that is generally met with, and that which is ordered by the London college. 3. *Storax* in the lump: it is in maſſes of an uniform texture, and of a yellowiſh red, or browniſh colour, ſometimes interſperſed with whitiſh grains. This is called *ſtorax* in the tear.

It is the produce of Syria, Cilicia, and Pamphylia; ſome ſay that true *ſtorax* is alſo a produce of Italy. There is a ſort in America, but it differs much from the above. It exudes from the leaves of the trees in the warm climes where it is produced; but is moſt abundantly obtained by making inciſions through the bark thereof.

Neumann ſays, that an ounce of common *ſtorax*, gave out to rectified ſpirit of wine, ſix drams of reſinous matter, then to water half a dram of gummy, and the reſt was ſaw-duſt; and that on heating another ounce with water firſt, he obtained two drams of gummy, then with ſpirit half an ounce of reſin. Pure ſpirit raiſes but little from the *ſtorax* by diſtillation, but water takes up much of its flavour; and when it is almoſt all drawn off, a fine ſubtil eſſential oil riſes, in the proportion of about ℈ ii. from ℥ xvi. The reſiduum on being urged with a due degree of heat, afforded ʒ ix. of an empyreumatic liquor, then ʒ ii. ℈ i. of thick butyraceous oil; afterwards ℥ ii. ʒ i. of an empyreumatic oil, which had nothing of the ſmell of the *ſtorax*, along with ʒ v. of an acid ſpirit. On waſhing the butyraceous oil with warm water, then ſetting the water in a cool place, a ſmall portion of ſaline matter ſeparated, which appeared like the flowers of benjamin. The ſame ſaline matter is obtained from the pure reſin, by boiling it in water. This ſpirit carries but little from the *ſtorax* in diſtillation; yet if twice its weight of the ſalt of tartar is added, a ſpirit is obtained which is ſtrongly impregnated with both the taſte and ſmell of this reſin. The ſtrongeſt, and the moſt fragrant principle, ſeparable from *ſtorax*, is the ſubtile, ſlightly empyreumatic oil which ariſes firſt in diſtilling of it.

It is chiefly uſed as a perfume, but is ſometimes uſed as a medicine, and that both externally and internally; its qualities are to reſolve and ſtrengthen. See Lewis's Mat. Med. Neumann's Chem. Works.

STYRAX LIQUIDA. Liquid ſtorax. It is a reſinous juice obtained from a tree in Virginia and Mexico, which Ray calls *ſtyrax* aceris folio. The juice called liquid amber, is ſaid to exude from the leaves of this tree ſpontaneouſly, but more freely from inciſions made in the trunk of it; and the *liquid ſtorax* is ſaid to be obtained by boiling the bark and the ſmall branches in water. Two ſorts of *liquid ſtorax* are diſtinguiſhed, but the ſort which is commonly met with, is of a weak ſmell, a grey colour, and is ſuppoſed to be artificial. It is not in preſent uſe. See Neumann's Chem. Works; Philoſ. Tranſ. No. 323; Lewis's Mat. Med.

STYRAX ALBA. The white Peruvian balſam.

SUBALARIS VENA, from *ſub*, *under*, and *ala*, the *armpit*. The axillary vein.

SUBCLAVIÆ ARTERIÆ, from *ſub*, *under*, and *clavicula*, the *channel-bone*. The ſubclavian arteries. They are ſo called from their ſituation being under the clavicles. They ariſe from the arch of the aorta, on each ſide of the left carotid, which commonly lie in the middle between them. The origin of the left *ſubclavian artery* uſually terminates the aorta aſcendens. Theſe *arteries* on each ſide terminate at the upper edge of the firſt rib between the lower inſertions of the firſt ſcalenus muſcle, and there, as they go out of the thorax, they take the name of the *arteriæ* axillares.

SUBCLAVIUS MUSCULUS. It riſes by a ſmall tendon from the anterior part of the cartilage of the firſt rib, cloſe to the ſtrong ligament which connects this rib to the clavicle, runs along the whole under ſide of the clavicle into the coracoid proceſs, where it is articulated to the clavicle. Its uſe is to bring the clavicle upwards and forwards.

SUBCOSTALES. Theſe muſcles are ſituated more or leſs obliquely on the inſides of the ribs near their bony angles, and running in the ſame direction with the external intercoſtals. They are fixed by both extremities in the ribs; the inferior being always at a greater diſtance from the vertebræ than the ſuperior, and ſeveral ribs lying between the two inſertions.

SUBCUTANEUS, i. e. Platyſma Myoides.

SUBER. The cork-tree. It is a kind of evergreen oak;

oak; it is a native of Italy, France, Spain, and other warm parts of Europe. The bark ſeparates ſpontaneouſly from the tree, and a new one ſollows it. It is this bark that is cut into corks for ſtopping of bottles.

SUBHUMERALIS VENA, i. e. Articularis vena.

SUBLIMATIO. Sublimation. It is the condenſing and collecting in a ſolid form, by means of veſſels aptly conſtructed, the fumes of bodies raiſed from them by the application of a proper heat. Fluids are ſaid to diſtil, and ſolids to ſublime. If the ſubliming matter concretes into a maſs, it is commonly called a ſublimate; if into a powdery form, it is called flowers. See the Dict. of Chem.

SUBLIMATIONES URINÆ, i. e. Enæoremata.

SUBLIMATUM. Sublimate. i. e. Merc. coroſ. alb.

SUBLIMIS. A name for the perforatus digitorum, and of the flexor muſcles of the feet.

SUBLINGUALIS ARTERIA. The ſublingual artery is the ſecond branch from the external carotid; it riſes a little above the ſuperior guttural artery; it runs inwards, upwards, and over the cornu of the os hyoides, and ſinks into the tongue to ſupply all the adjacent muſcles. It is alſo called the ranine artery.

SUBLINGUALES GLANDULÆ. The ſublingual glands. They lie between the mylo-hyoidæi and the genio gloſſi muſcles, and almoſt always diſcharge their ſaliva in the ſame place with the ſubmaxillary glands under the tongue.

SUBLUXATIO. Subluxation. It is where the head of a bone is not quite out of its ſocket, but reſts upon the brim.

SUBMERSIO. Drowning. In Dr. Cullen's Noſology, it is a variety of the apoplexia ſuffocata. Sauvage terms it aſphyxia immerſorum. Inſtances have occurred of perſons lying under water for ſix hours, and afterwards to have been reſtored to life and health; two hours have been employed in the recovery of thoſe who had lain long under water, before any advantage was obſerved from endeavours, and at length ſucceſs hath followed. Strange are the reports on this ſubject. Some modern phyſiologiſts aſſert, that no terreſtrial animal can be recovered, if it continues ſix minutes under water at one time, without breathing. Very little water is ever ſwallowed by drowned perſons; they do not attempt to breathe until they are inſenſible, and then on attempting, a little water is ſucked in, and a ſmall portion of it paſſes into the lungs. On taking the body out of the water, it muſt not be laid on the cold earth, but on a warm bed, the cloaths that are wet being firſt ſtripped off; or it may be laid in the hot ſun, or any warm place, there to be rubbed with coarſe cloths until a glow is perceived in the ſkin; a ſtrong healthy perſon may blow his warm breath into the patient's mouth to diſtend the lungs; or better and more certainly will air be directed into the lungs, if an opening was made into the trachea, as propoſed in the article tracheotomy; becauſe the air blown into the mouth may paſs only by the œſophagus into the ſtomach; or the ſmoke of tobacco may be conveyed into the patient's mouth, or his throat may be tickled with a feather to excite a vomiting; after which let him be laid before a warm fire, or on any other warm place, until life appears. The jugular veins may be opened to ſet the circulation forward again, the veins in other parts will rarely bleed; the fumes of tobacco may be thrown up the inteſtines; volatiles and ſtimulants may be applied to the noſe and the tongue; theſe are moſt uſeful after bleeding. If theſe fail, bronchotomy may be performed, and warm breath may be blown in at the aperture, until ſigns of life appear; not any thing ſhould be forced down the throat, but as ſoon as the patient can attempt to ſwallow, give him a draught of warm water, with a table-ſpoonful of muſtard in it, to drink. Continue theſe means until life ſeems to be confirmed. Generally, after recovery, an oppreſſion, a cough, and a fever, follows. In the firſt volume of Dr. Fothergill's Works, Dr. Lettſom hath inſerted the following method of treatment, found by the Humane Society to be moſt ſucceſsful on theſe occaſions.

I. The body ſhould not be rolled on the ground, or over a barrel, nor lifted up by the heels, or be any other way roughly handled, or violently ſhook; but be removed to a convenient place, lying as on a bed, with the head a little raiſed, in as natural a poſition as poſſible.

II. The body, well wiped with a cloth, ſhould be placed in a warm bed or blanket; but not too near a large fire. Bottles of hot water ſhould be laid to the bottoms of the feet, joints of the knees, and under the arm pits. A warming-pan moderately heated, or hot bricks wrapped in cloths, ſhould be rubbed over the body, particularly along the back. The natural warmth of a healthy perſon, eſpecially a child, lying cloſe to the body, hath been found very efficacious. The room ſhould be kept open and airy, with few perſons in it. The ſhirt of an attendant, or ſkin of a ſheep freſh killed and warm, may be uſed to advantage. Should the accident happen in the neighbourhood of a warm bath, brew-houſe, bake-houſe, glaſs-houſe, ſaltern, ſoap manufactory, or any fabric where warm lees, aſhes, embers, grains, ſand, water, &c. can be eaſily procured, it will be very proper to place the body in any of theſe, moderated to a degree of heat, very little exceeding that of a healthy perſon.

III. The body being placed in one or other of the above advantageous ſituations, various ſtimulating means ſhould be immediately employed. The moſt efficacious are, blowing with force into the lungs, by applying the mouth to that of the patient, cloſing at the ſame time his noſtrils; throwing the ſmoke of tobacco up the fundament into the bowels, by means of a clyſter-pipe or fumigator; a pair of bellows may be employed until the others can be procured; rubbing the belly, cheſt, back and arms, with a coarſe cloth, or dry ſalt, ſo as not to rub off the ſkin, or with a flannel dipped in brandy, rum, or gin; applying ſpirit of hartſhorn, volatile ſalts, or the like, to the noſtrils, and rubbing them on the temples frequently; tickling the throat with a feather, to excite a propenſity to vomit; and the noſtrils alſo with a feather or ſnuff to provoke ſneezing. The body ſhould at intervals be ſhaken, and varied in its poſition.

IV. If there be any ſigns of returning life, ſuch as ſighing, gaſping, twitching, beating of the heart, return of natural warmth or colour, a ſpoonful of water may be adminiſtered, to try if the power of ſwallowing be returned; if it be, a ſpoonful or two of warm wine, or of brandy and water, may be given to advantage, but not before.

Early bleeding has been found pernicious, and even fatal; it is not always applicable, though it may ſometimes be employed by a perſon of ſkill, to remove or prevent ſymptoms of inflammation.

N. B. The above methods of reſtoring life are applicable to various other caſes of apparent ſudden death, whether from hanging, apoplectic and convulſive fits, cold, ſuffocation by damps or noxious vapours, proceeding from coal mines, confined air of wells, caves, ciſterns, or from the muſt of fermenting liquors.

See Tiſſot's Advice to the People; Med. Muſæum, vol. iii p. 376, &c.

SUBOCCIPITALES NERVI. So the tenth pair of nerves are called which proceed from the head. They are ſmall; they paſs out at the foramen magnum, between the baſis of the ſkull, and the tranſverſe proceſs of the atlas, where they form a ganglion, and give branches to the adjacent muſcles; after which, forming a ſort of arch with an aſcending twig of the firſt cervical pair, a branch is ſent off, which is called the occipital nerve.

SUBORBITARIUS. A branch of the upper maxillary branch of the fifth pair of nerves; it runs on the lower part of the orbit of the eye, &c.

SUBPOPLITEUS, i. e. Popliteus.

SUBSCAPULARIS. It riſes from the whole inner ſurface of the ſcapula; it paſſes under the coracoid proceſs, and is inſerted into the external tubercle of the os humeri, juſt below its head.

SUBSULTUS, from *ſub*, under and *ſalio*, *to leap*; is the ſame as ſpaſmodic, or a convulſion of the clonic kind, from the ſenſe of leaping, which the tendons give to the hand lying upon them. A twitching of the tendons; alſo an involuntary twitching, or ſpaſmodic contraction of the muſcular parts.

SUCCAGO, i. e. the rob of any fruit.

SUCCENTURIATUS MUSCULUS, i. e. Pyramidalis.

SUCCENTURIATI RENES, i. e. Capſulæ atrabilariæ.

SUCCINGENS

SUCCINGENS MEMBRANA. The diaphragm.

SUCCINUM, called alſo carabe, or karabe, and electrum. It is found in ſeveral parts of the world: the moſt conſiderable quantities are taken up from regular mines in ſome of the inland countries belonging to the king of Pruſſia; but the fineſt ſorts are thrown up by the ſea, particularly in ſtormy weather, about Pillau.

There are various conjectures reſpecting the origin of *amber*, but the moſt probable is, that it is inſtantly formed by the concourſe of mineral oil, or petroleum, with vitriolic acid. And thus it is eaſy to conceive how inſects, of the moſt tender kind, are enveloped, without injuring them, or altering their natural appearances. Some aſſert that bitumens are eſſentially mineral; others (and by far the greateſt number) that they proceed originally from vegetable ſubſtances. In favour of this latter opinion, Macquer, in his Dict. of Chem ſays, 1ſt, that no body, the origin of which is certainly mineral, contains the ſmalleſt portion of oil; 2dly, it is probable that the qualities by which bitumens differ from reſins and other oily matters, vegetable and animal, are either the natural effects of time upon theſe oily matters converted into bitumens, or of an alteration produced upon them by mineral acids; or rather they are the effects of both theſe cauſes united; 3dly, by combining mineral acids with vegetable oils, compounds may be formed much reſembling natural bitumens; and to which perhaps nothing but a ſufficiently long digeſtion is wanting to render them true bitumens; 4thly, we cannot doubt that the vegetable and animal matters continually deſtroyed on the ſurface of the earth, the juices of which can penetrate deep therein, muſt introduce into the earth much oily matter, which in time may become bitumens; 5thly, many entire vegetables and animals have been found in large quantities at very conſiderable depths in the earth. Under ground, immenſe beds of turf are daily found, and large branches of half decompoſed bituminous and petrified foſſil wood, which can be nothing elſe but conſiderable portions of the ſurface of the earth, thus buried by accidents now forgot. All theſe matters are ſufficient to furniſh the earth with a large quantity of truly oily ſubſtance, which probably can be formed only in the organized bodies of vegetables and animals. Dr. Saunders, in his Lectures on the Theory and Practice of Chemiſtry, ſays, all foſſil inflammable matter is ſuppoſed to proceed from animal and vegetable matters, altered by time; he further obſerves, that ſulphur is obtained by mixing vitriolic acid and ſpirit of wine rectified, or oil. On the other hand, Dr. Lewis obſerves, that the oil of *amber* differs from all thoſe of the vegetable kingdom; and agrees with the mineral petrolea, in not being ſoluble, either in its rectified or unrectified ſtate, by ſpirit of wine, fixt alkaline lixivia, or volatile alkaline ſpirits; the oil, after long digeſtion or agitation, ſeparating as freely as common oil does from water: he further obſerves, that mineral bitumens are different in their qualities from the vegetable reſins; and in the mineral kingdom we find a fluid oil, very different from vegetable oils. The mineral oil is changed by mineral acids into a ſubſtance greatly reſembling bitumen; and the vegetable oils are changed by the ſame acids into ſubſtances greatly reſembling the natural reſins. From bitumens we gain by diſtillation the mineral oil; and from reſins the vegetable oil, diſtinct in their qualities as at firſt; vegetable oils and reſins have been heated with all known mineral acids, but have never yielded any thing ſimilar to the mineral bitumens. It ſeems, therefore, as if the oily products of the two kingdoms were ſpecifically and eſſentially different. The laws of chemical enquiries at leaſt demand that we do not look upon them any otherwiſe until we are able to produce from one a ſubſtance ſimilar to the other: when this is done, and not before, the preſumption that nature effects the ſame change in the bowels of the earth, will be of ſome weight. See Dr. Lewis's Note in his Tranſlation of Neuman's Chemiſtry, vol. vii. p. 3. Neumann ſays, in ſpeaking of *amber*, it is moſt probable, that *amber* is generated inſtantly from the concourſe of mineral oil, or petroleum with vitriolic acid, in the form of vapours.

The yellow *amber* ſhould be of a citron yellow, or of a golden colour, bright, tranſparent, eaſily taking fire, and exhaling a pleaſant fragrant ſmell.

In Holland, a vegetable reſin, called gummi de loock, is ſold under the name of American *amber*; but it is leſs electric than *amber*, wants the peculiar ſmell thereof when it is burning, diſſolves readily in ſpirit of wine, and when diſtilled it does not afford the ſame principles as the *amber* does.

If *amber* is diſtilled in a retort by a ſtrong heat, it yields a phlegm, or oil, which grows thicker and thicker as the diſtilling continues, and a particular kind of ſalt. The *amber* is powdered and mixed with three times its weight of white ſand before it is committed to diſtillation; a retort is half filled with it, and then the fire is gradually increaſed until a phlegm riſes, but not more than to make water boil; after this the heat ſhould be greater, but gradually increaſed, yet not ſo as to make the *amber* ſmell much; the receiver may be left unluted; thus it can be occaſionally removed, and the ſalt ſwept out, and ſo hindered from melting with the oil that riſes; the diſtillation is continued until no ſalt is ſeen to ariſe. After the diſtillation is ended, gather all the ſalt together, and dry it by preſſing it gently between ſome ſheets of ſpongy paper; then to purify it, boil it in the phlegm that aroſe in the beginning of the diſtillation, (and which is called the ſpirit of *amber*) or it may be boiled in common water, then ſet to cryſtallize; this may be repeated until it is ſufficiently freed from its oil. When this ſalt is pure, it is of a white colour, of a pungent, penetrating, grateful acid taſte; it diſſolves in rectified ſpirit of wine with difficulty, though aſſiſted by heat, but readily in water.

The ſalt of *amber* is mixed with ſal ammoniac; but this is diſcovered by an urinous ſmell ariſing on rubbing it with the ſalt of tartar; it is mixed with nitre, but this is diſcovered by the nitrous taſte. When mixed with cream of tartar, it is diſcovered by diſſolving it in water, for the ſalt of *amber* readily diſſolves and leaves the cream of tartar undiſſolved. When it is mixed with the ſalt of coral, it is diſcovered by laying it on a red hot iron, on which the ſalt of *amber* flies off, but that of the coral remains in the form of a white powder.

This ſalt is given in doſes from gr. iii. to ℈ i. Boerhaave extols it as an antihyſteric, and other phyſicians attribute many other virtues to it. Dr. Alſton of Edinburgh ſays, that when diveſted of the oil, it is no better than common ſalt. At preſent it is rarely uſed, except to render the operation of aloetic and reſinous purges more mild, and alſo more certain.

The oil which riſes in diſtillation may be rectified by diſtilling it from pure water. The rectified oil hath a ſtrong bituminous ſmell, and a pungent acrid taſte; it heats the body, and promotes the fluid ſecretions; it is chiefly uſed as an antihyſteric, and an aſſiſtant to emmenagogues: externally it is applied to weak, rheumatic, and paralytic limbs. This oil agrees with the mineral oils in refuſing to mix with vinous ſpirits.

Several preparations have been made from *amber*, but they are rarely uſed. See Neumann's Chem. Works; Lewis's Mat. Med. Tournefort's Mat. Med. Dict. of Chem.

Succinum Nigrum, alſo called agath, jet, jeat. Black *amber*, and gagates. It is found in many countries, but the fineſt is in England. It is a kind of coal, and is chiefly uſed for making into boxes, cups, &c. It affords by diſtillation an acid liquor, a thick black oil, and a thin black oil. Some ſay it differs from the kennel coal, in that the coal does not flame out except blown upon by the bellows, nor does it contain ſo much bituminous oil.

SUCCISA, alſo called morſus diaboli, ſcabroſo folio integro. Common devil's bit. It is a ſpecies of ſcabious it grows in meadows and paſture grounds, and flowers at the end of ſummer. The roots are ſaid to be alexipharmic; the leaves are often ſold for the leaves of common ſcabious, they are alexipharmic, reſolvent, bitter, and of the ſame qualities as the ſcabious for which they are ſold.

SUCCUBUS. A ſpecies of night-mare.

SUDAMEN. Tranſitory, red, ſtinging ſpots on the ſkin.

SUDAMINA. Heat pimples, or an eruption of puſtules, which ſucceed an inordinate ſweat. That kind of ſymptomatic miliary fever, that is called boa; which ſee.

SUDOR. Sweat. It it that fluid which tranſudes through

through the pores of the ſkin when we uſe much exerciſe, or uſe ſuch means as may increaſe its diſcharge. It conſiſts of a water, a highly exalted oil, a ſalt, and a terreſtrious matter.

SUDOR ANGLICUS. The ſweating ſickneſs. Dr. Cullen thinks it a ſpecies of typhus. See HELODES. This diſorder is thus named from its firſt appearing in this iſland. When Henry the Seventh firſt landed his ſoldiers at Miliford Haven, in the year 1483, it appeared amongſt them. In 1485 it was in London; it ſoon diſappeared, but returned five or ſix times: the laſt return was in 1551. It was remarked that Engliſhmen, whether they reſided at home, or fled into other countries, were attacked, whilſt foreigners in England were unaffected. Different patients were variouſly affected, but ſome on the firſt appearance of the diſorder were ſeized with a pain in the neck, ſcapula, legs, and arms, whilſt others perceived only a kind of warm vapour, or flatulence, running through thoſe parts; and theſe ſymptoms were ſuddenly ſucceeded by a profuſe ſweat, which the patients could not account for. The internal parts became firſt warm, and were ſoon after ſeized with an incredible heat, which thence diffuſed itſelf to the extremities of the body. An intolerable thirſt, reſtleſſneſs, and indiſpoſition of the heart, liver, and ſtomach, were the next ſymptoms, which were ſucceeded by an exceſſive head-ach, a delirium, in which the patient was trifling and talkative, and after theſe a kind of extenuation of the body, and an irreſiſtible neceſſity of ſleeping. In ſome the ſweat ſtopped in the beginning, and their limbs became moderately cool; but this evacuation being afterwards promoted, the matter of it was of a diſagreeable ſmell, of different colours, ſometimes more, and ſometimes leſs in quantity, and of a thickiſh conſiſtence. Some were ſeized with a nauſea, others with a vomiting; all, without exception, were afflicted with a difficulty of reſpiration. The urine had nothing preternatural, except that it was of a thicker conſiſtence, and tinged with a fainter colour than uſual. The pulſe was rather quicker than natural. In thoſe, however, who breathed in the pureſt air, and had the beſt conſtitutions, the diſeaſe was moſt mild.

The means that were found to be the moſt ſalutary, were to keep up the ſweat, after it begun, at leaſt for twenty-four hours, for by that time the diſeaſe terminated. During the ſweat, no more aliment was taken than the ſtrength required; ſleep was forbid; and when the ſweating was over, the patient was to be cautious in going abroad. Caius de Ephe. Britannica.

SUDORIFICA. Sudorifics. Medicines which excite ſweat. When the ſweat is to be excited, it ſhould be conſidered whether the heat of the body is above or below that degree which admits of this evacuation. The uſual natural heat in different perſons may ſomewhat vary, and for this an allowance is to be made; but whatever the degree of heat is in a healthy ſtate, if the perſon is ten degrees hotter by Farenh. therm. he cannot be made to ſweat. It is true, that in ſtriving to raiſe a ſweat by the uſe of diluting liquors he will be increaſed above this, and the ſweat, notwithſtanding, follow; but if the diluting drinks were not uſed, other means would fail. In this caſe cooling methods muſt be uſed, ſuch as cold water for drink, cool air admitted to the body, and cooling medicines given internally. If the heat is below the ſtandard of health, warm water and cordials muſt be uſed, the patient muſt be kept in a warm room or in bed. As ſweating greatly cools the body, it ſhould be cautiouſly uſed in low and putrid fevers. When the patient is very hot, to aſſiſt the effects of cold water, and to haſten it through the ſkin, flannel cloths may be wrung out of hot water, and applied round the legs and thighs, and thus a ſweat will be produced very ſpeedily. When the ſweat is once raiſed, the drink ſhould be warm, and ſupplied more or leſs freely according to the degree and continuance of the ſweating. Sweating is rarely of uſe when bleeding is unſafe; though in ſuch caſes a gentle perſpiration may generally prove ſalutary. See Dr. Home's Medical Tracts and Experiments, p. 220, Exp. v. Mr. Alexander's Experimental Eſſays, Exp. iii.

SUFFIMENTUM. A ſuffumigation. Thoſe made for pleaſure are generally formed of ſuch ſweet ſubſtances as are found to be agreeable, and thoſe which are formed for health are generally calculated to effect the mouth, throat, or other part to which they are to be applied, in ſuch manner as to produce ſome important alteration for the removal of ſome diſeaſe.

SUFFOCATIO STRIDULA, alſo called the croup, the chock, the ſtuffing or riſing of the lights. It is a diſeaſe that hitherto hath only appeared in children, rarely, if ever, appearing in any after twelve years of age. Dr. Cullen places it as a ſpecies of cynanche, and names it cynanche trachealis.

This diſorder appears to be preſent by a peculiar ſharp ſhrill voice, not eaſily deſcribed; a remarkable freedom from all other complaints, though the hour of death be at hand; the breathing is quick, and more or leſs laborious; the pulſe frequent, ſometimes ſtrong at firſt, but always ſoft and weak towards the end; ſometimes there is a dull pain in the trachea, on ſpeaking, or when it is preſſed with a finger; and at others an external ſwelling in the upper part of the ſame tube; the ſenſes are perfect to the laſt: the progreſs of the diſorder is rapid, for generally death ſoon ſteps in to conclude it. The face is generally flushed, though ſometimes it is of a livid colour. Sometimes there is a cough, and when it is attendant, it is ſhort and ſtifled, and not attended with much expectoration. Dr. Cullen deſcribes it as having for its characteriſtic ſymptoms, "a peculiar croaking ſound of the voice, a difficult reſpiration, a ſenſe of ſtraitneſs about the larynx, and a fever: or, a hoarſeneſs with ſome ſhrillneſs and ringing ſound, both in ſpeaking and coughing, as if the noiſe came from a brazen tube." He further remarks, that "the thick mucous that fills up the trachea may be eaſily ſeparated, and ſometimes is found ſo; in thoſe inſtances the inner membrane of the trachea is always free from eroſion or ulceration, but uſually ſhews the veſtiges of inflammation, being covered with a matter reſembling pus, and like to that which is ejected by coughing; and very often a matter of the ſame kind is found in the bronchiæ, in conſiderable quantity.

For the moſt part winter is the ſeaſon in which this diſeaſe occurs; long continued catarrhs from the meaſles, hooping cough, or the ſmall pox, are predisponent cauſes; cold and moiſt weather is ſuppoſed to contribute much as cauſes. It is moſt common about the ſea coaſt, and in low marſhy countries; yet ſometimes is met with in midland countries: and its attacks are frequently repeated in the ſame child.

The ſeat of the diſorder is the cavity of the wind-pipe, from a little below the glottis downwards; and the diſorder itſelf conſiſts of the mucus ſeparated there, and become thick, ſo filling up the paſſage that the air can no longer paſs freely into the lungs; at firſt it forms a thick membranous cruſt, which thickening fills up the cavity of the trachea. The back part of the trachea where there are no cartilages, ſeems from the inſpection of thoſe who die of this diſeaſe, to be its firſt and principal ſeat; as this morbid membrane is often found there, when it is in no other part: and indeed, in this part is lodged the greateſt number of glands deſigned for the ſecretion of mucus. In the mucous glands in general, this diſtemper ſhould be conſidered as originally ſeated; but from particular uſes, more directed to thoſe of the trachea; where, from the nature of the part, it becomes viſible in a different way from what would diſcover it in any other part. It is not evidently contagious.

Some diſtinguiſh the *croup* from the catarrhus ſuffocativus of Etmuller; from a ſevere cold; from peripneumonic complaints; and from ſuch ſymptoms as ariſe from extraneous bodies lodged in the trachea: an inſtance of which Dr. Home mentions in his Enquiry into the Nature, &c. of the *croup*.

There are two different ſituations of this complaint; the firſt is more inflammatory and leſs dangerous; in this caſe the pulſe is generally ſtrong, the face red, the drought great, and evacuations are uſeful: the ſecond is leſs inflammatory and more dangerous; under this the pulſe is quick, ſoft, and weak, the tongue is moiſt, the thirſt inconſiderable, there is great anxiety, and death is haſtened by evacuations. If this diſeaſe comes on with an old habitual cough, or by ſlow degrees, the inflammatory ſtage will hardly be perceived. The urine is thin during the inflammatory ſtage, but in the purulent one it hath a light, ouzy, purulent ſediment.

If on the third or fourth day after the firſt manifeſt at-

tack, the breathing is much affected, the pulſe is quick and weak, the face red, anxiety great, and the patient toſſes himſelf about, the danger is great; but if it is only on the firſt or ſecond day, the breathing not bad, the pulſe though frequent, yet is ſtrong and firm, and the voice not altered, ſome hope may be entertained of a recovery. The cough becoming ſtronger and leſs dry, is uſually the firſt ſign of amendment.

Though this diſeaſe conſiſts in an inflammatory affection, it does not commonly end either in ſuppuration or gangrene. The troubleſome circumſtance of it ſeems to conſiſt in a ſpaſm of the muſcles of the glottis, threatening ſuffocation. When this diſeaſe is fatal, it is ſo from a ſpaſm ſuffocating, or from matter in the bronchiæ, or the mucus in the larynx.

In the inflammatory ſtate bleeding ſhould be uſed as freely as the pulſe will admit; the bowels ſhould be kept lax; a bliſter muſt be applied to the throat or round the neck, as ſoon as bleeding and purging have been uſed; though if the caſe is very inflammatory an emollient cataplaſm is to be preferred; ſteams from hot vinegar and water may be received into the throat with the breath. In the purulent ſtate nothing yet attempted ſeems to have any good effect. Upon the firſt attack of the diſeaſe, vomiting immediately after bleeding, ſeems to be of conſiderable uſe; ſometimes ſuddenly removing the diſeaſe. Antiſpaſmodics do not evidently appear to be uſeful. See Buchan's Domeſtic Medicine, ed. 2. p. 681. the Appendix to Brooks's Practice of Phyſic; the Britiſh Magazine for Feb. 1766; Cullen's Firſt Lines, vol. i. An Enquiry into the Nature, &c. of the *Croup*, by F. Home, M. D.

SUFFUSIO. See CATARACTA. It is alſo ſynonymous with pſeudoblepſis.

SUFFUSIO AURIGINOSA. A jaundice.

SUGILLATIO. It is an inflammation in a part. Thus a blood-ſhot eye is a *ſugillation* in the eye. It is uſed as ſynonymous with ecchymoma or ecchymoſis; but it ſeems not properly ſo, being more like the enchymoma. The words ecchymoſis is derived from *ἐκχέω, to pour out*, and *ſugillatio*, from *ſugo, to ſuck*. However, as theſe words are uſed ſynonymouſly, it may be obſerved that by the word *ſugillatio*, a different cauſe is expreſſed; e. g. an ecchymoſis is cauſed by extravaſation; *ſugillation* is by ſuction; as when cupping glaſſes are applied to a part, which by removing the preſſure of the air there, occaſions the blood to ruſh in and diſtend the veſſels; even into ſuch as do not uſually receive red blood,

Taking the word *ſugillation* as the ſame with ecchymoſis, this diſorder, when ſeated in the eye, takes the name of blood-ſhot; when the ſkin is its ſeat, if the colour is livid, ſome writers term it pelioma; and if black, they call it melaſma. Mr. Bell, in the firſt volume of his Surgery, ſays, that in blood-letting, it often happens that a ſmall tumor is raiſed immediately above the orifice in the vein, by the blood inſinuating itſelf into the cellular membrane of the neighbouring parts. Such a tumor (he adds) when round and ſmall, is termed a thrombus; and when more diffuſed, an ecchymoſis. Linnæus names it *ſugillatio*. Dr. Cullen defines it to be a diffuſed tumor, a little elevated, and growing darker coloured. The cauſes are preſſure; bruiſes; blood-letting, either from the orifice in the ſkin ſliding over that in the vein, or from cutting the vein through. Theſe livid and black ſpots are ſometimes a ſymptom of the ſcurvy.

The ecchymoſis ſhould be diſtinguiſhed in its different cauſes; as when happening from blows, bleeding, or other external injuries, or from the ſcurvy, or other internal cauſe. It ſhould be alſo not miſtaken for the enchymoma, or for the ſpurious aneuriſm.

In ſlight caſes, compreſſes dipped in vinegar, applied frequently, is all that can be neceſſary for the cure. If it tends to ſuppurate, treat it as an abſceſs. If the quantity of coagulated blood is conſiderable, diſcharge it by as many inciſions as are required for that end; then treat it as an approaching mortification.

See Heiſter's Surgery; Van Swieten's Com. on Boerh. Aphor. ſect. 324, and 1151.

SULPHUR. Brimſtone. It is a ſolid brittle concrete, of a yellowiſh colour, inclining a little to greeniſh, and is in ſome degree gloſſy. It conſiſts of the vitriolic acid, and a ſmall portion of phlogiſton. Mr. Edwards, in his Elements of Foſſilogy, deſcribes it as a genus in the claſs of inflammables, which in cloſe veſſels ſublimes in the form of ſtriæ; in the open air is decompounded by heat into penetrating acrid, and ſuffocating fumes; and when deflagrated with nitre, leaves vitriolated tartar. It is ſometimes found native in the earth in pure, bright yellow, ſemitranſparent maſſes; but more commonly in opake ones, of a greeniſh, greyiſh, or other colours, intermixed with various earthy or ſtony matters. The impure ſorts are called *ſulphur* vivum. The native *ſulphurs* are met with chiefly about volcanos in Italy, alſo in ſome of the German, Hungarian, and Swediſh mines. The largeſt quantities that are brought into England are from Saxony, from whence we receive it in irregular maſſes, which are afterwards melted and caſt into rolls, being firſt mixed with coarſe reſin, flour, and ſuch like, whence its pale colour; for before it is thus mixed its colour is deeper. There are *ſulphurs* of a red colour, but they contain a portion of arſenic. *Sulphur* is an ingredient in moſt kinds of ores. The mineral from which the greateſt quantity is extracted is the yellow pyrites, plenty of which is found in Saxony, where the *ſulphur* is ſeparated by means of heat, and is received in veſſels placed for it to run into as it melts.

This *ſulphur* is purified by ſubliming it, and then it is called the flowers of *ſulphur*; this operation is performed by perſons who ſublime large quantities in a way of trade, and the *ſulphur* thus ſublimed becomes an article in medicine.

The flowers of *ſulphur* are uſed againſt cutaneous eruptions, particularly the itch; and for its uſefulneſs in ſome diſorders of the lungs, it hath been called anima pulmonum. Pure *ſulphur* looſens the belly, and is uſeful when the piles are troubleſome; it promotes perſpiration; it paſſes readily through the whole habit, and tranſpires through the ſkin: in coughs, catarrhs, and aſthmas, it is found uſeful, particularly in ſcorbutic habits.

Sulphur is an active medicine, it reſtrains the activity of ſome other very powerful ones; mixed with mercury, the regulus of antimony, or with arſenic, they become inert.

Various are the preparations of *ſulphur*; but, for internal uſe, none excels, nor even equals, the flowers, which may be eaſily contrived for taking without any diſguſt to the palate: amongſt other modes, the troches, as directed in the Diſpenſatory of the London College, is an elegant one.

From *ſulphur* the chemiſts obtain the greateſt part of the vitriolic acid which they uſe. See the Dict. of Chem. Lewis's Mat. Med. Neumann's Chem. Works.

SUMACH, i. e. Rhus folio ulmi. It is the rhus coriaria, Linn.

SUPERBUS MUSCULUS, i. e. Rectus ſuperior oculi.

SUPERCILIARES MUSCULI. They are fleſhy faſciculi. They ariſe from the ſynarthroſis of the oſſa naſi with the os frontis, and thence run along the direction of the eye-brows, and are loſt in the middle of them. They depreſs the eye-brows, and contract the ſkin over the noſe.

SUPERSCAPULARIS INFERIOR, i. e. Infra ſpinatus.

SUPERSCAPULARIS SUPERIOR, i. e. Supra ſpinatus.

SUPINATOR RADII BREVIS, five Minor. Supinator, becauſe it makes the hand ſupine, i. e. when the palm is upwards. It riſes from the outer condyle of the os humeri, goes over the capſular ligament, lies under the longus, and is inſerted into the internal anterior part of the tubercle of the radius.

SUPINATOR RADII LONGUS, five Major. It riſes fleſhy from the outer edge of the os humeri, twiſts round it, goes down the fore-arm all along the radius, covering the artery, and becoming tendinous, where we generally feel the pulſe, it is inſerted into the anterior internal part of the radius.

SUPPLETA ISCHURIA. A ſuppreſſion of urine, from exceſs of other evacuations, which require this defect to ſupply their loſs.

SUPPOSITORIUM, from *ſuppono, to lay under*. A ſuppoſitory. The Greeks call them proſtata. They are convenient for promoting ſtools when clyſters cannot be adminiſtered

adminiſtered. The moſt gentle are made of common ſalt and honey, which may be boiled to the conſiſtence of a ſoft pill, and then rolled to the thickneſs of a gooſe quill, and an inch or little more in length; theſe are introduced into the rectum, where they remain until they are diſcharged by the effect they produce: aloes, colocynth, and other ingredients, may be added, according to the intention of the preſcriber.

SUPPRESSORII. Diſeaſes ariſing from or attended with an oppreſſion of the organs and impeded excretions.

SUPPURANTIA. Suppuratives. There is no univerſal *ſuppurative*. As a proper external application, to promote ſuppuration when there is a conſiderable heat, a poultice of oatmeal, or of bread, with milk, may be applied: when the heat of the part is defective and the temperament habitually cold, add galbanum, onions, and ſuch like materials, to the common bread poultice.

SUPPURATORIA. Suppuratory fever, or fever of ſuppuration.

SUPRA COSTALES, i. e. Levatores coſtarum.

SUPRA SCAPULARIS, i. e. Supra ſpinatus.

SUPRA SEMI ORBICULARES. They are fibres that increaſe the breadth of the muſcles of the upper lip.

SUPRA SPINALIS, i. e. Supra ſpinatus.

SUPRA SPINATUS. This muſcle riſes from each ſide between the upper edge of the ſcapula, and the ſpine thereof runs under the acromion, and extenſors of the ſcapula, goes acroſs the capſular ligament, and is inſerted into the inner tubercle, near the head of the humerus.

SURA. A name for the fibula; for the gaſtrocnemii muſcles; alſo a ſort of wine.

SURALIS ARTERIA, i. e. Tibialis poſterior arteria.

SURALIS VENA. It is a branch from the beginning of the tibialis poſterior.

SURDITAS. Deafneſs. The cauſes are, the loſs of the external ear, wax or other matter lodged in the external ear, a rupture, or a relaxation of the membrane of the drum of the ear, a palſy, or a preſſure on the auditory nerve, violent noiſe, obſtruction of the Euſtachian tube, cold, inflammation, abſceſs, the lues venerea, &c. The moſt frequent of theſe cauſes is hardened wax in the meatus auditorius, which may be ſoftened and removed by frequent injections of warm water. See DYSECOEA.

In caſe of a relaxation of the membrana tympani, a little warm brandy, or ſpirit of roſemary, may be dropped into the ear now and then.

If the Euſtachian tube is obſtructed, relief is ſometimes obtained by chewing a cruſt every morning and evening.

Sometimes ſternutatories have relieved when the cauſe hath not been known.

When a defluxion of humours are the cauſe, an injection may be made as follows and uſed night and morning: ℞ Extract. ſaturni. gut xxv. ſp. vin. C. gut. l. aq. puriſſ. ℥ ſs. m.

SUSPENSOR. A bandage to ſuſpend the ſcrotum. The French call it *la bourſe*. It is a cloth large enough to contain the ſcrotum and the dreſſings, with a fillet on each ſide to ſuſpend it about the waiſt, and one before to faſten it to the other two in the fore part of the belly.

SUSPENSORIUS TESTIS, i. e. Cremaſter.

SUSURRUS, i. e. Paracuſis imaginaria, or hearing ſounds that are not.

SUTURA. A ſuture. In anatomy it is the particular articulation of the bones which is ſeen in the head. Theſe *ſutures* are divided into common and proper. The common are thoſe which join the bones of the cranium with thoſe of the face. The proper are thoſe which connect the bones of the cranium, and are the coronal, the ſagittal, the lambdoidal, and the two ſquamous.

In ſurgery it is the uniting of the lips of a wound by ſewing, and theſe are of five kinds.

1. The dry *ſuture*. It is made by two pieces of ſticking plaſter, each the length of the wound, to which very narrow tapes are fixed at due diſtances. Apply one piece near one edge of the wound, and the other piece near the other edge, then gently draw the two ſides of the wound together, and dreſs over the tapes; the tapes ſhould correſpond exactly; the knots muſt be ſlip knots. Or, take a ſlip of plaſter, the length of the wound, and cut longitudinal holes in it; then apply one ſide near the edge of the wound, bring the lips cloſe, and then apply the other. After this kind of *ſuture* is applied, the uniting bandage is convenient to ſupport it.

2. The twiſted *ſuture*. It is alſo called the circumvoluted *ſuture*. This is uſed for the hare lip, and in a few other inſtances. It is performed by introducing two or more pins through the whole ſubſtance of the lips of the wound, then twiſting a waxed thread about them in the form of the figure 8.

3. The interrupted *ſuture*, alſo called the knotted *ſuture*. It is performed with any needle armed with a waxed thread, by thruſting it through both lips of the wound, then tying the thread in ſlip knots, making a number of ſtitches according to the length of the wound, at an inch from each other. The needle ſhould go to nearly the bottom of the wound. Mr. Juſtamond adviſes a particular regard to the direction of the longitudinal fibres of muſcles in forming this *ſuture*, and not ſo much to regard the direction of the wound; for, if we do not paſs the ligature in the direction of the fibres, it will be a continual ſtimulus, it will excite the muſcle to action, and occaſion a perpetual tugging of the ligature, whence pain, inflammation, &c. will follow. Mr. Bell, in the firſt volume of his Surgery, adviſes, in forming this *ſuture*, to carry the needle and ligature to the bottom of the wound, ſo as to afford but little chance of matter collecting underneath; and, further, he directs both ends of the thread to be paſſed from within outwards; which is readily done by uſing two needles upon each thread inſtead of one. A needle being put upon each end of the ſame thread, and each needle being inſerted at the bottom of the ſore, and puſhed outwardly, ſo as to paſs out at a proper diſtance from the edge of the wound, the needles are then to be taken off, and the threads allowed to remain till all the ligatures are paſſed, which the extent of the ſore ſeems to require. In paſſing the ligatures, pierce the ſkin from near half an inch to near an inch from the lips of the wound; theſe diſtances will include all the varieties in the ſize of wounds. As ſoon as the threads are all paſſed, the lips of the wound ought to be preſſed together and ſupported by an aſſiſtant till all the ligatures are firmly tied.

4. The quilled *ſuture*, ſo called becauſe the knots were tied upon quills, which were laid over the dreſſings that immediately covered the lips of the wound.

5. The glover's, or uninterrupted *ſuture*, called alſo the ſpiral or the continued. It was uſed in wounds of the inteſtines and ſtomach. See Heiſter's Surgery; Le Dran's and Sharp's Operations.

SYCOSIS, from *συκον*, *a fig*. It is a tumor on the anus, which only differs in the ſize from the thymus, The Latins call it mariſca. *Sycoſis* is alſo the name of an ulcer mentioned in Celſus, lib. vi. c. 3. alſo in Vogel's Noſology, which is fungous.

SYMBOLOGICE. That part of pathology which treats of the ſigns and ſymptoms of diſeaſes.

SYMPATHETICI NERVI MAJOR, i. e. Nervi intercoſtales.

SYMPATHETICI MEDII, i. e. Par vagum.

SYMPATHETICI MINORES. So the auditory nerves are called.

SYMPATHIA, from *συν*, *together*, and *παθος*, *ſuffering*. Sympathy. Our bodies are, by means of the brain, not only endowed with feeling and a power of motion, but alſo a remarkable *ſympathy*, which is either general or particular. That every part of the body hath a *ſympathy* with the whole, is evident from cold water being thrown on any part of us that is warm; this produces a ſudden contraction of all the veſſels and pores, and thus ſometimes puts a ſtop to ſmall hæmorrhages. The effluvia of things ſmelled to often communicate new vigour to the whole body. The particular *ſympathy* is manifeſt by various inſtances of diſeaſes complained of in one part when the cauſe is in a very remote one; for inſtance, pain in the head occaſions ſickneſs in the ſtomach, and ſo does pain in the uterus, &c. A ſudden bright light entering the eye occaſions ſneezing. Some particular ſounds affecting the ears ſet the teeth on edge. The ſmell of grateful food makes the ſaliva flow into the mouth, &c. &c. &c.

All *ſympathy* ſuppoſes feeling, and therefore muſt be owing to the brain, which is the only means of ſenſation.

This further appears from that, the changes in the body, occaſioned by the *ſympathy* of the parts, are ſtopped by whatever affects the nervous ſyſtem ſo ſtrongly as to overcome the ſenſations that produced the ſympathetic ſenſations.

Though all *ſympathy* is owing to the brain, it is not eaſy to account ſatisfactorily for all the various inſtances of *ſympathy* in particular caſes; for many of them may depend on ſuch a ſtate of the brain and other parts as do not become the object of our ſenſes.

A diligent attention to this ſubject, whatever difficulties attend it, is followed with conſiderable advantage by enabling us to account for many ſymptoms of diſeaſes, and alſo to proceed ſo certainly to the cure as by any other known method we could not have arrived at. See the authors on irritability and ſenſibility.

SYMPHYSIS, from *συν*, *with* or *together*, and *φύω*, to *grow*. In anatomy it is a kind of articulation, which is divided into four ſpecies. 1. Synchondroſis. 2. Synneuroſis. 3. Syſſarcoſis. And, 4. The *ſymphyſis* of oſſification, to which epiphyſis belong.

In ſurgery it is a coaleſcence of the natural paſſages, as the anus, vagina, noſtrils, &c. It alſo expreſſes the firſt intention of cure when there is a wound, which is to bring together ſeparated parts, and to keep them together.

SYMPHYTUM, from *συμφύω*, to *conglutinate*. It is a name for moſt ſpecies of comfrey, (ſee CONSOLIDA) for ſeveral of the pulmonaria, for the yellow alkanet, a ſpecies of bugle, a ſpecies of ſaxifrage, and of ſome other plants.

SYMPHITUM PETRÆUM. Heath pine. It is a plant which is ranked among the aſtringent and conglutinant medicines, but is not in uſe.

SYMPHITUM PETRÆUM. A name for the prunella, ſanicula, virga aurea, coris monſpeſſulana, hyſſopus vulg. and ſeveral other plants.

SYMPTOMA, from *συμπιπτω*, *to happen together*. A ſymptom. Galen defines it to be a preternatural affection which depends upon a diſeaſe, or follows it. Thus, *ſymptoms* are diſeaſes produced by an original principal diſeaſe: but *ſymptoms* are ſometimes the effect of *ſymptoms* alſo. A *ſymptom* may be a *ſymptom*, and a diſorder at the ſame time; as when a *ſymptomatic* fever is produced by a phlegmon.

A knowledge of the origin and cauſe of *ſymptoms* conduces to confirm the prognoſis, and to the certain removal of the diſeaſe.

SYNANCHE. A quinſey.

SYNARTHROSIS, from *συν*, *with*, and *ἄρθρον*, *a joint*. It is that ſpecies of articulation in which there is no motion, and it is of three kinds; the ſuture, the harmonia, and the gomphoſis.

SYNCHONDROSIS, from *συν*, *with*, and *χονδρος*, *a cartilage*. It is that ſpecies of ſymphyſis in which the bones are connected by a *cartilage*, and is either moveable or immoveable; the firſt is inſtanced in the vertebræ of the neck, back and loins; the ſecond is inſtanced in the os pubis, the two ſides of which are ordinarily immoveable.

SYNCHONDROTOMY. So Dr. Siebold names the ſection of the ſymphyſis of the os pubis.

SYNCHYSIS, from *συγχυω*, *to confound*. A diſeaſe of the eye, conſiſting in a confuſion of the humours, generally proceeding from a violent blow; ſometimes from an inflammation of the uvea, occaſioning a rupture of the veſſels, and an eruption of the humours. Caſtellus.

It is alſo when from the violence of an ophthalmia, the tranſparent cornea is left opaque or corroded, and there is the appearance of confuſion in the humours of the eye. In Cullen's Noſology it is a variety of his ſpecies of caligo pupillæ. Kirkland, in his Inquiry, vol. i. p. 473, defines it as being a confuſion of the humours of the eye from a violent inflammation (the chemoſis) leaving the cornea opaque, or corroded.

SYNCOPE, from *συνκοπτω*, *to cut down*. See LIPOTHYMIA.

SYNDESMOS. A ligament.

SYNDESMOSIS, from *συν*, *with*, and *δεσμος*, *a chain*. i. e. Synneuroſis.

SYNECHES. Various are the uſes of this word as applied to fevers. The Greeks uſe it to ſignify the remitting fevers in general. Some later writers have collected under this word, thoſe inſtances of remittent fevers that are obſcurely deſcribed, of whoſe mode of relief we have no ſatisfactory account. Dr. Cullen places it amongſt the tertian intermittents.

SYNEUROSIS. That ſpecies of ſymphyſis in which the bones are connected by ligaments, as in all the joints that are deſigned for motion.

SYNIZESIS. Blindneſs from an obſtruction of the pupil of the eye, or from a contraction and coalition of it. It is the ſame as the caligo pupillæ of Dr. Cullen. For the cure, ſee IRIS.

SYNOCHA. The ardent or inflamatory fever. See FEVER, and INFLAMATORY FEVER. The *ſynocha*, or *fever* with *inflammatory* irritation, Dr. Cullen places as a genus in the claſs *ſynocha*, and order febris.

SYNOCHUS. A continual fever, whether of the ardent or putrid kind.

SYNOCHUS. Fever compounded of ſynocha, and of typhus, alſo called putrid fever, and malignant fever. Dr. Cullen places this genus of diſeaſe in the claſs pyrexiæ, and order febris. In the beginning it is uſually of the ardent kind, or *ſynocha*, but ſoon degenerates into the *typhus*, and ſo on until it becomes what is called the *putrid fever*, which ſee.

SYNOCHUS. Sometimes it is uſed for ſynocha.

SYNOCHUS PLEURITICA. It is an inſtance of ſynocha.

SYNOCHUS HIEMALIS. An inſtance of ſynocha.

SYNOCHUS RHEUMATISANS. An inſtance of ſynocha.

SYNOSTEOGRAPHIA. Synoſteography. It treats of a bone, its parts, articulations, the nails, and the number and uſes of the bones.

SYNOVIA. It is a gluey tranſparent fluid, which readily mixes with water, and partly jellies when expoſed to cold. It is ſecerned from certain glands in the joints, to preſerve their motions eaſy and free. The *ſynovia* is not found to coagulate in any part of a joint, however long the bone may have been diſplaced. When there is a deficiency of *ſynovia*, there is a crackling of the joint, if the perſon moves much.

SYNOVIÆ GLANDUÆ. Synovial glands. They are ſmall conglomerate *glands*, ſeated in the outer lamellæ of the caſpular ligaments of the joints, and ſo as to be more or leſs preſſed, according to the degree of motion. They are alſo called Haver's *glands*, becauſe firſt diſcovered by him. See GENU.

SYPHILIS. See LUES VENEREA.

SYRIGMUS. It is that ſpecies of depraved hearing called paracuſis imaginaria.

SYRINGMOS. The ſame as ſyrigmus.

SYRUPUS, from the Chaldean word *ſirpi*, or the Arabic word *ſirab*, a *potion*. A ſyrup. The Arabians firſt invented this form of medicines. A *ſyrup* is a watery or other liquor, ſo boiled with ſugar, that if a drop is let fall upon a marble it will not ſpread. If the quantity of ſugar is not ſufficient, the *ſyrup* will ſoon ferment, and if it exceeds what is needful, the overplus will ſeparate and be formed into cryſtals. Acids ſhould have a proper quantity of ſugar added to them, to make a *ſyrup* with a ſimmering heat, for boiling deſtroys the acid in ſome meaſure; this is alſo to be obſerved when the liquor is flavoured, as that of violets, and ſuch as have a fine colour. *Syrups* are now but little uſed, and indeed the *ſyr.* alb. may anſwer every valuable intention of all others, except the *ſyr.* e mecon. Bruno ſays that the Greeks knew not that form of medicine.

SYSSARCOSIS, from *σὺν* and *σὰρξ*, *fleſh*. It is a ſpecies of ſymphyſis of the bones, and is that in which they are connected by *fleſh*, that is, by muſcles, as in the connection of the os humeri with the ſcapula. In ſurgery, it is the method of curing wounds by the growth of new *fleſh*: it alſo expreſſes the intention of cure, which conſiſts in promoting digeſtion and regeneration of the loſt ſubſtance.

SYSTOLE, from *συστέλλω*, *to contract*. A contraction, or conſtriction. It is the motion of the heart and arteries by *contraction*, which is alternate, and contrary to the diaſtole, which ſee.

T.

TAB

TABACUM. Tobacco. See NICOTIANA.

TABANUCCO, or JAVANUCO, which ſee.

TABELLA. A lozenge.

TABES, from *tabeſco*, *to conſume*, or *pine away*. It is often taken for an ulcer in the lungs; is ſometimes uſed as ſynonymous with atrophia.

Dr. Cullen places the *tabes* as a genus of diſeaſe in the claſs cachexiæ, and order marcores. He defines it to be a waſting with extreme debility and hectic fever. He diſtinguiſhes three ſpecies. 1. *Tabes* purulenta; from an ulcer either external or internal. 2. *Tabes* ſcrophuloſa; when it happens in ſcrophulous habits. 3. *Tabes* venenata; when it happens from taking ſome kind of poiſon.

TABES COXARIA. A waſting of the thigh and leg from an abſceſs, or other cauſe in the hip.

TABES DORSALIS. It is only a ſymptom of a gleet, and being a principal ſymptom it gives name to that diſorder. Dr. Cullen ranks it a variety of the atrophia inanitorum. Hippocrates calls it *tabes* oſſis ſacri. What the ancients ſuppoſed to be a waſting of the marrow in the back was nothing more than a gonorrhœa ſimplex, without any virulency in the running; and the pain that this occaſioned moſtly affecting the loins, they therefore judged the marrow to be waſting. At preſent, by the name of *tabes dorſalis* is underſtood a waſting of the body, attended at firſt with pain in the back and loins, and afterwards alſo in the neck and head, cauſed by a too early or a too frequent uſe of venery.

Hippocrates deſcribes the *tabes dorſalis* as follows: "It ariſes from a diſorder in the ſpinal marrow, and it is principally incident to perſons of a ſalacious diſpoſition, or ſuch as are newly married. The patient is free from fever, eats and digeſts well; when he is aſked with reſpect to his ſtate, he ſays he perceives as it were ants falling from the ſuperior parts of his body (his head for inſtance) into the ſpine of his back, and when he diſcharges his urine or excrements, there is at the ſame time a copious evacuation of liquid ſemen, in conſequence of which he is incapable of propagating his ſpecies, or anſwering the purpoſes of marriage. He is generally ſhort-breathed and weak, eſpecially after exerciſe. He perceives a ſenſe of weight in his head, and is affected with a ringing in his ears. The patient is in proceſs of time ſeized with various ſpecies of violent fevers, and at laſt dies of that kind of fever called lipyria." The ſeminal matter which Hippocrates mentions as diſcharged with the urine and ſtools, is mucus, not ſemen. Beſides the ſymptoms already mentioned, the memory fails, and the ſpirits are greatly dejected, the ſight fails, or an incurable gutta ſerena comes on.

In order to a cure, particular care is required with reſpect to the non-naturals. The air ſhould be pure and cool; the diet light, moderately cordial, very nouriſhing, and frequently ſupplied in ſmall quantities; ſleep ſhould be early ſought in the evening, and exerciſe in a carriage or on horſeback may be uſed. And amongſt the different tribes of medicines, cordial, moderately aſtringent, and ſuch as increaſe the heat of the body; the bark, ſteel, elixir of vitriol, &c. according as there is more or leſs of a feveriſh heat; bitters alſo and cold bathing have their uſe toward the end of the cure.

See Hippocrates de Morbis, lib. ii. and vi. Baldwinus Roſſeus in Tract. de Scorbut. epiſt. 4. Sennertus, vol. ii. Lommius's Med. Obſ. Morton's Phthiſiologia.

TABES NUTRICUM, i. e. Atrophia inanitorum.

TABES SUDATORIA, i. e. Atrophia inniatorum.

TABES A SANGUIFLUXU, i. e. Atrophia inanitorum.

TABES SYPHILITICA, i. e. Atrophia cacochymia.

TABES A HYDROPE, i. e. Atrophia cacochymia.

TAM

TABES PULMONALIS, i. e. Phthiſis.

TABES COXARIA, i. e. Phthiſis iſchiadicæ.

TACAMAHACA. It is a reſin obtained from a tree which reſembles a poplar tree. The fagara octandra, Linn. It is a native of the temperate parts of America, and under ſhelter it bears the cold of our climate. The beſt reſin is collected in gourd-ſhells; it is unctuous, ſoftiſh, of a pale yellow or green colour, of a bitteriſh aromatic taſte, and a fragrant ſmell; but this is ſeldom met with. The ſort which is commonly met with is in tranſparent globes, of a white, yellow, brown, or green colour, and leſs grateful than the foregoing. The firſt is ſaid to exude from the fruit of the tree, the latter from inciſions in the trunk. It is chiefly uſed in fumigations and plaſters, to warm, irritate, and gently bliſter. It diſſolves in rectified ſpirit of wine, and gives to water its ſmell and taſte. The Indians uſe it for ripening of tumors. See Lewis's Mat. Med. Neumann's Chem. Works.

TACTUS. The touch. The ſenſe of *touch* is, in the proper acceptation of the word, that change ariſing in the mind from external bodies applied to the ſkin, but more eſpecially at the ends of the fingers; for by the fingers we more accurately diſtinguiſh the tangible qualities of things than by other parts of our body. See Haller's Phyſiology, lect. xiv.

TÆNIÆ. Flat worms. Of all the *worms* that infeſt the human body, this is the moſt troubleſome and dangerous. The roots of the male and female ferns have long been famed for their efficacy in deſtroying and expelling this ſpecies of *worm*. The doſe of theſe roots in powder is to half an ounce, to be taken in honey and water, or mead; and if it is accompanied with ſcammony enough to purge, its efficacy will be greater. The French phyſicians order over-night a glyſter of milk and honey, and a quantity of panada for ſupper; in the morning the powdered fern roots are given to detach the *worm*, of which the patient is ſaid to be ſenſible, by a ceſſation of the pain in the ſtomach, and by a weight that is felt in the lower belly. Two hours after this, the purgative is given to evacuate the looſened *worm*.

TALCUM. Talc, alſo called mica. It is an earthy or a ſtony ſubſtance, conſiſting of thin, flexible, ſhining plates, which, if expoſed to the fire, become brittle, and, by a violent heat, vitreſcible. Some ſpecimens are colourleſs and tranſparent; others are red, brown, green, or black, and generally theſe contain ſome metallic matter. *Talc* is ſoft to the touch, ſomewhat like unctuous ſubſtances. In foſſilogy, it is a genus in the order of ſtones called grittleſs ſtones. Its characters are ſtone, ſoft and unctuous to the touch; cutting and ſcraping eaſily; opake, yet generally very gloſſy, and not of a ſtoney, but of an earthy ſtructure and appearance. As calcareous matter is found in the ſtate both of earth and of ſtone, ſo is this matter, and in the ſtate of earth it often is the ſubſtance of ſteatites. Edwards's Elements of Foſſilogy.

The Venetian *talc* is more or leſs pellucid, and hath been uſed as a coſmetic, but is now neglected, as well as all the other ſpecies. See Dict. of Chem. Neumann's Chem. Works; Lewis's Mat. Med.

TALPA, and Talparia. A tumor on the head, of the atheromatous kind, is thus named. The tumors on the face, &c. called moles, are alſo thus named, and are a ſpecies of wen. See NÆVUS.

TALUS, i. e. Aſtragalus. The ankle bone.

TAMALAPATRA. Indian leaves. See FOLIUM.

TAMARINDUS, alſo called tamaræa zeela, oxyphœnicon. Tamarind. *Tamarindus* Indica, Linn. The *tamarind* tree. *Tamar hendi* are Arabian words for Indian fruit. Some call the *tamarind* tree by the name of Indian dates, and others Indian acacia; but the tree is of

the palm kind, and somewhat resembles an ash tree. It grows in Arabia and both the Indies. The fruit is a pod like that of a bean, including several hard seeds, together with a dark-coloured viscid pulp. The East India *tamarinds* are longer than those of the West, and darker coloured; the former contain six or seven seeds in each, the latter only three or four.

The pulp with the seeds are brought into England, without the shell or pod; the Oriental have most pulp, the Occidental have much sugar mixed with them.

The pulp is an agreeable cooling laxative acid; it was first introduced into practice by the Arabians: it is useful in inflammatory and putrid fevers; it abates thirst and heat, and corrects putrefaction. As a laxative the dose is two or three drams. If the pulp of *tamarinds* is mixed with the laxative sweets, such as cassia and manna, it increases their action, and prevents in a degree the flatulence which they occasion. See Tournefort's Mat. Med. Lewis's Mat. Med.

TAMARISCUS, also called tamarice, myrica, tamarix. Tamarisk. The *tamarix* Gallica, Linn. It is plentiful in France and Germany. The leaves and bark of this tree are astringent, but they are not noticed in the present practice. See Raii Hist.

TANACETUM, also called tenasia, athanasia, Parthenium mas. Common tansy. *Tanacetum* vulgare, or *tanacetum* foliis bipinnatis serratis incisis, floribus luteis. Linn. It is a plant with large leaves, divided to the rib on both sides into deeply indented segments; on the tops of the stalks are many gold-coloured discous flowers, in umbel-like clusters; the seeds are small and blackish. It is perennial, grows wild by road sides, and about the borders of fields; it flowers in June, July, and August. The leaves and flowers have a strong, not disagreeable smell, and a bitter aromatic taste; the flowers are stronger, though rather less unpleasant than the leaves. The curled leaved, and the striped leaved sorts, are but varieties of this species. They give out their virtue both to water and to spirit, most perfectly to the latter. Distilled with water, they yield a greenish, yellow, essential oil, which smells strongly of the herb; the remaining decoction affords a strong, bitter, subsaline extract. The spirituous tincture gives over part of the oil in inspissation, a part remaining with the extract.

This plant is a warm deobstruent bitter, useful in cachectic disorders, and weakness of the stomach; it expels worms from the intestines, for which the seeds are generally used. Many other virtues are attributed to *tansy*, such as its curing some colics and the gout, but it is not much employed in general practice. See Lewis's Mat. Med.

TANACETUM. It is a name for the balsamita, a species of millefolium, a species of leucanthemum, and of some other herbs.

TARANTISMUS. A desire of dancing. The disorder said to be produced by the bite of a tarantula, but this is imposition. Some express by it a kind of St. Vitus's dance.

TARANTULA. It is a species of spider met with in Apulia. It bite is said to produce a species of madness, which is cured by music, but not by any other means; but Dr. Cirillo declares, that he never could make the *tarantula* bite him, nor any other person, though he often had tried to provoke it. So that this affair seems to be only a fraud practised to obtain money.

TARAXACON, or Taraxacum. The dens leonis. Dandelion. Leontodon *taraxacum*. Linn.

TARAXIS, from ταραττω, *to disturb*. A disorder of the eye, such as when it is offended by smoak, or too hard rubbing. It is when the eye is offended by attrition, smoke, dust, or other slight cause. Galen, in 6 epid. com. 5. says, it is a morbid disposition of the eye, preceding an inflammation, and the beginning of an inflamtion. Paulus, lib. iii. cap. 22. defines it to be heat and humidity of the eye, attended with a preternatural redness, proceeding, not from the body, but some external cause, as the sun, smoke, dust, and wind; whence the disorder is very speedily remedied, by removing the cause. Hoffman, in his Practice of Medicine, says, the slighter ophthalmiæ, occasioned by dust, exposure to cold, air, sun, or other slight external causes, are inflammations of the tunica adnata only, and attended with little danger. Perhaps the following, noticed by Mr. Ware, in his Remarks on the Ophthalmy, &c. may be included under this name. He says, it frequently comes on in the most sudden and unexpected manner, without any preceding or concomitant illness. When it happens in this way, the common people call it a blast in the eyes: and it seems to proceed from some peculiar property in the air which surrounds us: like other epidemic diseases, it often affects a whole neighbourhood at the same time; as was the case during the summer 1778, at Newbury, in Berkshire, and in several of the camps, where it was known by the name of the *ocular disease*. In Dr. Cullen's arrangement of the species and varieties of the ophthalmia, he places this as the least violent, and calls it ophthalmia *taraxis*. See OPHTHALMIA. This kind of inflammation gives way to the gentlest remedies used against inflammations of the eyes.

TARCHON. The herb tarragon, also a name of ptarmica.

TARSUS, from ταρσος. The cartilaginous edge of the eye-lids. The edge of each eye-lid is principally formed by a thin cartilage, called *tarsus*, which is adapted to the shape and roundness of the eye. The lower edge of the superior cartilage, and upper edge of the inferior, meet with each other, and are termed the ciliary edges. These cartilages do not terminate in a line like the sharp edge of a knife, but rather flat like the back of it; forming two edges, one external, the other internal. When the eyes are shut, the external edges meet; but the internal are preserved at a small distance from each other, leaving a gutter, or groove, through which the tears are supposed to pass from the lachrymal gland to the puncta lachrymalia, while we are asleep. The cilia, or eye-lashes, arise out of the external edge of the termination of this cartilage; and on the internal, at an evident distance from them, is a line of small orifices, which are the excretory ducts of small glands that lie in the inner surface of the *tarsus*, and are called glandulæ ciliares. Also the space between the bones of the leg and the metatarsus. It consists of seven bones; viz. the astragalus, calcaneum, naviculare, cubiforme, and the three cuneiforme.

TARTARUM, also called argol, tartar, wine-stone. It is an essential acid concrete salt of grapes, thrown off from wines after complete fermentation to the sides and bottoms of the casks; it is of a red or a white colour, and more or less drossy, according to the quality of the wine. The white is usually most pure, but in all other respects they are the same. Chuse such as is clean, solid, somewhat transparent, and hath its outside covered with small shining crystals. The Rhenish white wine *tartar* is the most pure. Its virtues as a medicine are those of a cooling laxative; in doses from ʒ i. to ʒ iii. it is aperient; from ʒ ß. to ʒ i. it moderately purges.

If *tartar* is dissolved in water, it effervesces with fixed alkaline salts, and saturates of the vegetable alkalies near one third of its own weight; the neutral salt formed by this union is more purgative than the *tartar* itself, as is instanced in the soluble *tartar* of the London College. The soluble *tartar* might as well be made with the common white *tartar*, as its impurities are sufficiently removed by the necessary filtration. To secure the neutralization of the salt, the *tartar* may be made to prevail at the first, and the liquor suffered to cool a little before filtration, that the redundant *tartar* may concrete and separate from it. The *tartar* dissolves difficultly in water, and when dissolved therein, it soon concretes again on being removed from the fire, and what the alcali hath not taken up, will remain on the filtre; and, on the other hand, if too much alkali is used, it will remain uncrystallized. The soluble *tartar* is a mild, cooling aperient in doses from ℈ i. to ʒ i. it is laxative in doses of ʒ ii. or iii. and purges if ℥ i. is given; it promotes the operation of resinous purges, and prevents their griping.

Tartar is very difficultly soluble in water: if it is dissolved in twenty times its weight of boiling water, it continues dissolved long enough to be passed through a strainer, but when set in the cool air, it soon begins to run together in the form of crystals on the side of the vessels; these when collected and dried are called crystals of *tartar*. If this solution of *tartar* is strained and boiled until a thick pellicle appears on the surface, and this pellicle being skimmed off, it is again boiled until another pellicle appears, and is skimmed off, &c. until all the *tartar* is obtained, which is when all the water is consumed; then

all theſe pellicles being mixed together, and dried in the ſun, you have the cream of *tartar*. But it is the beſt to have this preparation in the form of cryſtals, as the powder is ſo generally adulterated. See Neumann's Chem. Works, Lewis's Mat. Med.

TARTARUM EMETICUM. Emetic tartar. It is alſo called ſtibiated *tartar*. It is made by boiling the ſaffron, or the glaſs of antimony, in a ſolution of cream of *tartar*, as may be ſeen in the Diſpenſatory of the London college, and that of Edinburgh; but a more certain preparation is obtained as follows:

Take of powdered mercurius vitæ, waſh it with a little fixed alkali to ſeparate the marine acid from it, then gradually throw it into a glaſs veſſel, in which is a boiling ſolution of the cream of *tartar*, continue the boiling and the addition of the mercurius vitæ, until there is no longer any fermentation from the mixture; after this filter the liquor, and ſet it to cool, and cryſtals will ſoon be formed. Theſe cryſtals are an *emetic tartar* that is certain in its operation, and equal in its ſtrength. See Neumann's Chem. Works, Lewis's Mat. Med. Dict. of Chem.

Mr. Beaumé affirms from experiment, that the acid of *tartar* may be eaſily ſaturated with the reguline part of antimony; and the glaſs of antimony is the moſt emetic and moſt ſoluble of all the antimonial preparations by fire, it ſhould be preferred for making a neutral antimonial ſoluble *tartar*; yet reflecting on the nature of the glaſs of antimony, it is not always of the ſame ſtrength. It is made by fuſing the grey calx of antimony calcined to an uncertain degree; and we know that if it be too little calcined, we ſhall obtain an opake matter that reſembles the liver more than the glaſs; if it is too much calcined, it cannot be vitrified, nor even fuſed, by the moſt intenſe heat: between the degree of calcination which is ſufficient to give an opake fuſed matter, and the degree in which it begins to be unfuſible, there are many intermediate ones; all of which are ſufficient to produce glaſſes of antimony; but theſe glaſſes differ in the degree of tranſparency, in tenſity of colour and fuſibility, according as the calcination has been more or leſs complete. We cannot doubt that different glaſſes of antimony muſt be more or leſs emetic, and that perhaps different quantities of theſe glaſſes are required for the perfect ſaturation of the acid of *tartar*; beſides, we are both ignorant of the degree of calcination which renders the glaſs of antimony moſt emetic, and alſo of the method of obtaining it, if we knew it. Hence we are not certain that *emetic tartar* made with glaſs of antimony is equally and conſtantly emetic; therefore inſtead of the glaſs of antimony, we recommend the pulvis algarothi for making the emetic *tartar*. Mr. Beaumé further obſerves, that the pulvis algarothi hath the advantages of the glaſs of antimony, in being convertible into a neutral ſalt, by means of the acid of *tartar*, and is not ſubject, like the glaſs of antimony, to give the *emetic tartar* prepared with it an uncertain degree of ſtrength; tho' of itſelf it is like the other calces, uncertain; but it is the beſt preparation of antimony from which to obtain a certain and uniformly effectual medicine. The pulvis algarothi is not ſaline, and from the quantity of marine acid which it contains, it is ſomewhat cauſtic; but when it is waſhed with a little fixed alkali, all the acid is ſeparated, and then it is totally ſoluble by cream of *tartar*, and is thereby convertible into a ſoluble *emetic tartar*, perfectly neutral; and for which purpoſe prepare to uſe it as follows: mix an equal quantity of cream of *tartar*, and the powder of algaroth, (or as much of the latter as is required to ſaturate the former;) throw this mixture gradually into boiling water, and continue the boiling gently, 'till there is no effervescence, or till the cream of *tartar* is well ſaturated. Filter the liquor, and when this liquor is cool, fine cryſtals will be formed in it, which are ſoluble *tartar* perfectly ſaturated with the algaroth's powder: as ſoon as the cryſtals are formed, carefully dry them, and keep them in a well-cloſed glaſs veſſel.

In preparing the *emetic tartar*, veſſels &c. of glaſs ſhould be uſed, for iron, tin, lead, and copper decompoſe it, by attracting the acid more ſtrongly than the antimony does; whence one cauſe of inequality in different parcels of this preparation, made at different times. The powder of algaroth is a calx of antimony conſtantly of the ſame degree of emetic ſtrength; it is emetic becauſe the regulus of antimony, firſt diſſolved by marine acid, and afterwards ſeparated from that acid, retains the quantity of phlogiſton that is neceſſary to give an emetic quality to the calx of antimony; the quantity of phlogiſton which it retains, and therefore its emetic power, muſt always be the ſame; for the marine acid of the corroſive ſublimate, which afterwards becomes the butter of antimony, is always the ſame in quantity, and in its degrees of concentration, and of activity; conſequently the calx of antimony ſeparated from it muſt always contain an equal quantity of phlogiſton, and is therefore much preferable to the glaſs of antimony, which contains ſometimes more, ſometimes leſs phlogiſton. Thus, by uſing the powder of algaroth inſtead of the glaſs of antimony, we obtain an uniform and certain *emetic tartar*. An uniformly active *emetic tartar* being poſſeſſed, phyſicians will only have to attend to the ſenſibility or irritability of the conſtitutions of their patients.

In the Hiſtory of the Royal Medical Society at Paris, for the year 1776, Mr. de Laſſone prefers the above mode of preparing the *emetic tartar*; but he ſays there is an objection to it, as well as to all other methods of preparing it, which is, that when diſſolved in a very diluted aqueous vehicle, part of the medicine is conſtantly precipitated, and adheres to the ſides of the phial. As this is owing to its not being ſufficiently ſoluble, he recommends the mixing equal quantities of *emetic tartar* and pure ſal ammoniac; and after rubbing them together in a mortar, adding a ſmall quantity, three parts or leſs, of diſtilled water. Thus the two ſalts unite, and are completely diſſolved.

TARTARUM VITRIOLATUM. See NITRUM VITRIOLATUM.

TARTARUS REGENERATUS, i. e. Diureticus ſal.

TAVANUCCO, or rather tabanucco. A kind of reſin brought from the Weſt Indies.

TAXIS. To reduce an hernia merely by the hand is called reducing it by the *taxis*.

TAXUS. The yew tree. There are three different ſpecies, but they are not noted as medicinal. See Raii Hiſt.

TEMPERAMENTUM. Temperament, or conſtitution. Various are the diviſions of *temperaments*, perhaps the following is as proper, and as free from exceptions and difficulties as any other, viz. 1ſt. The ſanguine, or when the habit is full of good blood. 2d. The ſerous or phlegmatic, or when the habit is full of ſerum. 3d. The temperate, or when the red blood and ſerum are in due proportions. 4th. The cacochymic, or when the juices are depraved. Whatever others are named, they are not met with pure and unmixed.

TEMPERANTIA. Temperating medicines. They are thoſe which check the too violent motion of the blood, and moderate bilious acrimony.

TEMPLINUM OL, i. e. ol templinum verum Germanorum. It is a kind of ol. terebinth.

TEMPORALIS ARTERIA. The origin of the *temporal artery* is covered with the parotid gland. It lies behind the meatus auditorius externus, and emerging from the parotid, comes juſt covered by the ſkin to the zygomatic proceſs of the os temporis, it crawls up, and divides into two branches, one of which goes to the frontal, the other to the parietal bone. The frontal part anaſtemoſes with the internal carotid, and the other portion with the occipital *artery*. From the root of the temporal an *artery* paſſes up to the ſcalp behind the ear, and is ſometimes ordered to be opened inſtead of the temporal.

TEMPORALIS MUSCULUS, it is alſo called crotaphites. It riſes broad from the region of the temples, particularly from the oſſa frontis, parietalia, temporalis, and ſphenoides, where it ſpreads like a quarter of a circle, then it forms a tendon, which paſſes under the jugum, and is inſerted into the coronoid proceſs of the under jaw. A ligament from the proceſſus zygomaticus braces this tendon down, and imparts ſome of the internal fibres to it. It is covered with a ſtrong tendinous ſheath, which is loſt in the epicranium. When matter is formed under this tendinous expanſion, it is uſually attended with ſo great a degree of fever, from the pain, as to occaſion delirium. The thickneſs of this tendinous part, prevents the matter from pointing outwardly, where it was firſt formed;

formed; and if left without aid, it runs in the direction of the *temporal muſcle*, and opens into the mouth by the coronoid proceſs of the lower jaw. It is uſual therefore, not to wait for this matter pointing outwardly where it is firſt formed; but, as in other inſtances of matter under faſciæ of tendons, to make an opening directly to it. See ABSCESS *of the temporal muſcle*.

TEMPORUM OSSA. The temple bones are each divided into three parts, viz. the maſtoid, the ſquamous, and the petrous. There are three external proceſſes which ariſe from each of the temporal bones, on the poſterior part is the proceſſus maſtoideus; a little more forward is the zygomatic proceſs, it joins the os malæ, and from the inferior cragey part the ſtyloid proceſs jets out obliquely forward. A little below the maſtoid proceſs there is a cavity, whence the digaſtric muſcle of the lower jaw ariſes. At the inner-ſide of the root of the ſtyloid proceſs there is a cavity where the internal jugular vein is lodged. Between the maſtoid and zygomatic proceſſes the meatus auditorius externus is ſeated, and between the maſtoid and ſtyloid proceſſes is the aqueductus Fallopii, whence the portio dura of the ſeventh pair of nerves makes its exit. Before the ſtyloid proceſs is a glenoid cavity for the reception of the condyle of the lower jaw, near which cavity is an eminence, upon which the condyle ſometimes moves. In the pars petroſa, near the ſtyloid proceſs, is a canal through which the carotid artery enters. Near the laſt foramen, on the anterior edge of the bone, is the tuba Euſtachiana. The internal foramen is the meatus auditorius internus.

TENDINOSA TUNICA, i. e. Tunica albuginea oculi.

TENDO, from τείνω, *to ſtretch*. A tendon. See MUSCULUS.

TENESMUS, from τείνω, *to ſtretch*. A *teneſmus* is a continual painful urging to go to ſtool, when little or nothing can be diſcharged. There is a pain in the anus, and a frequent deſire of going to ſtool, whilſt a mucous ſubſtance, which is ſometimes bloody, is diſcharged. The cauſes are a ſtone in the bladder, an inflammation in the neck of the bladder, acrid humours falling on the rectum, a diarrhœa, a dyſentery, the piles, pregnancy, &c.

This diſorder is very troubleſome, but rarely dangerous.

As the cauſe varies, the cure will alſo differ. If a ſtone in the bladder is the cauſe, its poſition ſhould be altered by means of a catheter, if putting the patient into a proper poſture will not anſwer the end. If an inflammation in the neck of the bladder is the cauſe, ſuch means will be neceſſary as are directed for removing inflammation there. If acrid humours affect the rectum, they ſhould be gently purged off, and then emollient, or balſamic clyſters, ſhould be injected, the ol. ricini is particularly uſeful, both by the mouth and clyſterwiſe. That kind of teneſmus which affects pregnant woman is relieved by clyſters of ſweet oil, and a little of the tinct. Theb. mixed with it; in other inſtances the method of relief will be the ſame as in a dyſentery. See Lommius's Med. Obſ. Lobb on painful Diſtempers.

TENONTAGRA, from τένων, *a tendon*, and ἄγρα, *a ſeizure*. A ſpecies of arthritis, ſeated in the larger tendons. See Cœl. Aurelianus, lib. v. cap. 2.

TENSOR DIGITORUM, i. e. Extenſor digitorum communis.

TENSOR MEMBRANÆ TYMPANI. It lies on the upper-part, above the bony portion of the canal that goes to the noſe, and runs to be inſerted into the inſide of the malleus. It is ſuppoſed to pull the membrana tympani in, and to make it more tenſe.

TENSOR PALATI, i. e. Circumflexus palati.

TEPIDUS. Tepid, i. e. Warm as milk from the cow.

TEREBELLA, i. e. Trepanum.

TEREBINTHINA. Turpentines. The produce of the different ſpecies, &c. of pine trees, and the piſtachiæ chiefly, if not wholly. The Pharmacopœia of the Edinb. Col. ſays it is the produce of the pinus larix, i. e. pinus foliis faſciculatis obtuſis, Linn.

The Chio, or Cyprian *turpentine*. It is generally about the conſiſtence of thick honey, very tenacious, clear, almoſt tranſparent, of a white colour, with a caſt of yellow or blue; it hath a warm pungent, bitteriſh taſte, a fragrant ſmell, more agreeable than that of any of the other *turpentines*. It is the produce of the *terebinthinus* vulgaris, C. B. in the iſland of Cyprus, and the ſouthern parts of Europe. The piſtacia *terebinthus*, Linn. This kind of *turpentine* is ſaid to be the leaſt ſubject to be adulterated.

Venice *turpentine*. It is uſually thinner than the other ſorts, of a pale yellow colour, a hot, pungent, bitteriſh taſte, and a ſtrong ſmell, without any of the fine aromatic flavour of the Chio *turpentine*. It is the produce of the larix, C. B. pinus larix, Linn. and brought from France, Germany, &c.

Straſburgh *turpentine*, or *tereb.* Argentoratenſis. It is of a middle conſiſtence between the two foregoing, more tranſparent, and leſs tenacious than either, of a yellowiſh brown colour, more agreeable to the ſmell than either the common or the Venice, to the taſte it is the bittereſt, but the leaſt acrid. It is extracted in different parts of Germany from the ſilver and the red firs, the pinus picea, Linn. by making inciſions through the bark. In ſome places a reſinous juice is collected from certain knots under the bark. This is called lachryma abiegna, and oleum abietanum.

Common *turpentine*. This is from the wild pine tree; the pinus ſylveſtris, Linn. it is about the conſiſtence of honey, of an opake browniſh white colour; the coarſeſt and heavieſt of all the kinds, and its ſmell and taſte are alſo the moſt diſagreeable.

All theſe *turpentines* diſſolve totally in rectified ſpirit of wine, but give out nothing to watery menſtrua; by the mediation of mucilages, the white of egg, or of gum arabic, they mix with water into a milky liquor. Diſtilled with water they yield a large quantity of a ſubtile, penetrating, eſſential oil, viz. the oil of *turpentine*, which is called alſo the ſpirit of *turpentine*. The oil is difficult of ſolution in ſpirit of wine, though the *turpentine* ſo eaſily diſſolves in it. If this oil is rediſtilled in a retort by itſelf, with a gentle heat, it becomes more ſubtil, and in this ſtate it is called ethereal oil of *turpentine*; the thicker part which remains behind, is called balſam of *turpentine*.

All the *turpentines* are hot, ſtimulating, detergent, and corroborant. When inflammatory ſymptoms do not forbid, they are given from ten grains to half a dram, for cleanſing the urinary paſſages, for healing internal ulcerations in general, and in laxities of the ſeminal and uterine veſſels; they ſeem peculiarly to affect the urinary paſſages, and give a violet ſmell to the urine; they diſſolve and diſcharge mucous matter from the urinary paſſages; but if a ſtone is in any of the parts, they are not ſafely adminiſtered. The Venice is moſt diuretic and detergent; the Chio and Straſburg more corroborant; the common is only uſed externally and for diſtilling. What remains after diſtilling the oil from *turpentine*, is the yellow and the black roſins.

The oils, both the common and the ethereal, are powerfully ſtimulating, detergent, and diuretic; they are given in doſes from a few drops to half an ounce in rheumatiſms. When a large doſe is directed, it is given in the morning, and an opiate at night. Mixt with ſpirit of wine they are uſed as ſtyptics, to check the diſcharge of blood from wounds. They are uſed for rubbing on parts affected with pains. But if too freely uſed inwardly, they diſpoſe to a diabetes, and weaken the urinary paſſages and the ſeminal veſſels. See Neumann's Chem. Works, Lewis's Mat. Med.

TEREBRA, from τερέω, *to bore*. A name of the trepan. See TREPHINE.

TEREBRA. A chirurgical inſtrument for perforating bones, or for extracting hard bodies, as bullets, &c. from wounds.

TEREDO. A kind of worms which eat into wood; a caries in a bone. A name for the ſpina ventoſa.

TEREGAM. A kind of fig tree which grows in Malabar.

TERES LIGAMENTUM. It riſes from the bottom of the cavity of the acetabulum, and runs obliquely backwards, to be inſerted into the head of the os femoris. It ſerves to confine the rotation of the thigh.

TERES MAJOR. This muſcle riſes from the outer part of the lower corner of the ſcapula, paſſes to the os humeri forwards, joined by the latiſſimus dorſi and its tendon,

don, it is inſerted into the poſterior ridge of the biceps groove, to bring the arm downwards, backwards, and inwards to the body. Brown calls this muſcle rotundus major.

TERES MINOR, alſo called octavus humeri Placentini, becauſe Placentinus added it to the number of muſcles belonging to the arm. It riſes from the lower coſta of the ſcapula, and runs with the infra ſpinatus, and is inſerted with it alſo.

TERES. Round worms.

TERMINTHI. Galen deſcribes them as being tumors in the ſkin, nearly reſembling the fruit of τερμινθος, *turpentine trees*, of a blackiſh colour, inclining to green. Wiſeman reckons the epinyctis to be a ſpecies of *terminthus*, and ſays that they are both of them painful tubercles, or angry puſtules, affecting the ſkin of the arms, hands, and thighs. Cullen places them as a variety of phlogoſis phlegmone, and Sauvage ranks them as a ſort of furunculus. Bleeding, purging, and a regular diet, is all that is required for their cure.

TERNA, i. e Impetigo, or mentagra.

TERRA. Earth. In foſſilogy, it is that kind of foſſil body, whoſe component parts imbibe water; and which either fall into a looſe maſs, or when gently rubbed between the fingers, are diviſible, after they have been ſoaked a ſufficient length of time in water. It muſt be obſerved, that in chemiſtry both earths and ſtones are termed earths; but in foſſilogy they are very properly or neceſſarily diſtinguiſhed. See Edwards's Elements of Foſſilogy. In chemiſtry, earth is one of the four ſimple ſubſtances called elements. *Earth* is not found ſo pure as the other elements, fire, air, and water; but it is moſt probable, that as there is only one kind of air, water, and fire, ſo there is but one kind of *earth*, however it may vary, from the different ſubſtances with which it was mixed. The eſſential properties by which earthy ſubſtances differ from the other elements, are their much greater weight, hardneſs, fixity, and infuſibility; and theſe are moſt eminently united in the vitrifiable kinds of *earth*.

Neumann divides the mineral *earths* into five kinds, viz. the cryſtalline, calcareous, argillaceous, talky, and gypſeous.

Animal *earths* Dr. Lewis includes under three kinds, viz. that from ſhells, from calcined bones, and horns, and from the blood, fleſh, and ſkins of animals.

Vegetable *earths* are diſtinguiſhed into three kinds by Wallerius, viz. that obtained by burning ſoft, ſpongy, and farinaceous plants; by burning the harder and leſs ſucculent plants, and by burning wood.

The *earths* that are attended to with a medicinal view are chiefly the inſipid ones, which abſorb acids; whence they are called abſorbent *earths*. Some of the tenacious adheſive *earths* have been uſed, ſuch as the boles, ſealed *earths*, &c. but are now much neglected. See the Dict. of Chem. Lewis's Mat. Med. Neumann's Chem. Works.

TERRA CARIOSA. Rotten ſtone. It is a ſpecies of non-effervеſcent chalk.

TERRA TRIPOLITANA. See ALANA. It is a ſpecies of the non-effervеſcent chalk.

TERRÆ FLOS, i. e. Cœlifolium.

TERRÆ GLANDES. A ſpecies of cataputia minor.

TERRÆ OLEUM, i. e. Petroleum and Naphtha.

TERRA JAPONICA. Japan earth. It is called *Japan earth*, becauſe it was long ſuppoſed to be an earthy ſubſtance from *Japan*; but it is a gummy reſin, obtained by a decoction of ſome vegetable ſubſtance in water. The plant is called coira or caira, by the natives of Bahar Province in the Eaſt Indies. The natives of Pegu name the tree kheir or khadira. It is a ſpecies of the mimoſa of Linnæus. In Dr. Fothergill's Works by Dr. Letſom, vol. ii. it is called mimoſa *Japonica*: in the Pharmacopœia of the Edinburgh college, it is named from Linnæus mimoſa catechu, to which the following deſcription is added from Linnæus, viz. mimoſa ſpinis ſtipularibus, foliis bipinnatis, multijugis; glandulis partialium ſingulis, ſpicis axillaribus geminis. ſ. ternis pedunculatis, Linn. Suppl. 439. In Dr. Fothergill's account of the tree, we are told that the wood is extremely hard and heavy, the interior part varies from a pale brown to a dark red, approaching to black in different plants, but always covered with one or two inches thick of white wood. It is one of the moſt common trees to be met with on the uncultivated mountains of Rotas, and Pallamow, diſtricts of Hindoſtan, in the province of Bahar, weſtward of Bengal, and frequent in many other neighbouring parts. From the interior coloured wood is produced the extract erroneouſly called *terra Japonica*. The extract is thus made: after the tree is cut down, all the exterior or white part is pared off and caſt away; the interior coloured wood is cut into chips, with which a narrow-mouthed unglazed earthen pot is filled, to this as much water is added as will riſe to the upper chips; when this is half evaporated by boiling, the decoction is poured into a flat earthen pot, and boiled to one third part: this is ſet in a cool place for one day, and afterwards evaporated by the heat of the ſun, ſtirring it ſeveral times in the day; when it is reduced to a conſiderable conſiſtence, it is ſpread upon a mat or cloth, which hath previouſly been covered with the aſhes of cow-dung, this maſs is divided into ſquare pieces by a ſtring, and completely dried by turning them frequently in the ſun, until they are fit for ſale. In making the extract, the pale brown wood is preferred, as it produces the fine whitiſh extract: the darker the wood is, the blacker the extract, and of leſs value. The natives call this extract by the name of cutt; the Engliſh who reſide where it is made, call it cutch; authors have named it *terra Japonica*, catechu, cadtchu, caſhow cachou, caitchu, caſljoe, cachore, kaath, cate, &c. The preparers of this extract are very careleſs in keeping it free from foreign matters; in conſequence of which it hath a conſiderable quantity of aſhes, &c. mixed with it. Mr. Kerr, who collected this account, ſays that he never could learn that the *terra Japonica* was produced from the areca, or betel-nut, nor indeed does he think it credible that it ſhould, as its price would be far exceeding that of the *terra Japonica*, if the preparation was from the areca. Where the *terra Japonica* is made, it is uſed in dying; for painting chintz and other cloth joined with vitriolic ſalts, a black colour is produced; mixed with oil, they paint the beams and walls of their houſes, to preſerve them from the deſtructive white ants. The black phyſicians divide diſeaſes into the hot and cold, and thus they divide their medicines; to the hot diſeaſes they oppoſe the cooling medicines, among which the *terra Japonica* is reckoned powerful. For a more particular account of this production, ſee Dr. Lettſom's edition of Dr. Fothergill's Works, vol. ii. p. 191—199. Some ſpecimens of this drug are of a pale reddiſh brown colour, others are of a dark blackiſh brown, or black like bitumen; ſome are ponderous, others light, ſome compact, others porous, ſome more, others leſs aſtringent; and theſe differences happen according to the manner of obtaining them, &c. This drug is brought from Coromandel, Cambaya, and other parts of the Eaſt Indies. The beſt is of a dark reddiſh brown colour, dry, heavy, gloſſy, and compact; if chewed it diſcovers, at firſt, a bitteriſh ſtyptic taſte, which is followed by an agreeable ſweetneſs. When pure it is almoſt totally diſſolved both by water and by ſpirit. An extract made with ſpirit is the moſt agreeable and moſt aſtringent preparation. Where a ſtrong aſtringent is required, whether for external or internal purpoſes, the ſpirituous tincture, or the ſpirituous extract is the beſt; for a milder corroborant, the watery tincture, or extract may be choſen. A little of the watery extract held in the mouth, and gradually ſwallowed, is uſeful in diſorders of the throat; and in diarrhœas and dyſenteries it is a uſeful medicine, whether a fever attends or not. The *Japan earth* (as it is called,) approaches to alum in its aſtringent virtue, as to the quickneſs and the univerſality of its action. See Neumann's Chem. Works, Lewis's Mat. Med.

TERROR. A fright. The general effects of *terror* are a great contraction of all the ſmall veſſels, and a repulſion of the blood in the large and internal ones; hence the ſuppreſſion of perſpiration, the general oppreſſion, trembling, and anguiſh, from the heart and lungs being overcharged with blood, &c. After great *frights*, perſons rarely recover their uſual vivacity; and epilepſies that are cauſed by *frights* are rarely, if ever cured. When a perſon is affected with *terror*, or ſudden, or great *frights*, the principal endeavours ſhould be to reſtore the circulation to its due order, to promote perſpiration, and to allay the agitation, or commotion, in which the patient is obſerved

to be. The cuſtom of giving cold water in theſe caſes is bad. Place the affrighted perſon in a quiet ſituation; a little warm liquor, ſuch as camomile tea, or ſuch like, ſhould be given him to drink; the legs may be put into warm water, and there continue for ſome time; the legs ſhould be rubbed, and the camomile tea repeated every ſix or eight minutes; when the ſkin becomes warm, and there is a tendency to perſpiration, ſleep may be promoted by a gentle opiate.

TERTHRA. The middle and lateral parts of the neck. According to Keil, τερθρον ſignifies the parts about the throat.

TERTIANA FEBRIS. A tertian fever. This *fever* is of the intermittent kind; every firſt and third day it is preſent, and the ſecond is free. Its acceſs is about noon. Hippocrates calls it *ἡμιτριτος*. The management in this cure is the ſame, in general, as under the article INTERMITTENT FEVER. Dr. Cullen places this genus of diſeaſe in the claſs pyrexiæ, and order febres.

Tertian fevers are ſpurious, they are then irregular in their approach, and more mild than the true ſpecies: they are called double, when the fits return at different times every other day. See the authors on intermittent *fevers*.

In intermitting *fevers* Dr. Lind recommends opium as almoſt a ſpecific; he directs it to be given half an hour after the commencement of the hot fit. The draught which he generally preſcribed was as follows: ℞ aq. font. pur. ℥ iſs. aq. alex. ſp. fyr. c mecon. aā ʒ ii l. l gt. xv—xx. m. He obſerves, that the effects of opium given in the hot fit of an intermitting *fever*, are 1ſt, it ſhortens and abates the fit, and this with more certainty than an ounce of the bark is found to remove the diſeaſe. 2dly, It generally gives a ſenſible relief to the head, takes off the burning heat of the *fever*, and occaſions a profuſe ſweat; this ſweat is attended with an agreeable ſoftneſs of the ſkin, inſtead of the diſagreeable burning ſenſation which affects patients ſweating in the hot fit; and is always much more copious than on thoſe who are not under the influence of opium; 3dly, it often produces a ſoft and refreſhing ſleep, to a patient tortured in the agonies of the *fever*, from which he awakes bathed in univerſal ſweat, and in a great meaſure free from all complaints. The Dr. further adds, that the effects of opium are more uniform and conſtant in intermitting *fevers* than in any other diſeaſe, and are then more quick and ſenſible than thoſe of any other medicine. An opiate thus given, ſoon after the commencement of the hot fit, by abating the violence, and leſſening the duration of the *fever*, preſerves the conſtitution ſo entirely uninjured, that where it is given in intermittent *fevers*, a dropſy, or a jaundice rarely follows. In caſes where opium does not immediately abate the ſymptoms of the *fever*, it never augmented their violence: on the contrary, moſt patients reaped ſome benefit from an opiate given in the hot fit; and many of them bore a larger doſe of opium at that time than at any other. A delirium in the hot fit is not increaſed by opium; though opium will not remove it: hence is it not probable, that many of the ſymptoms attending thoſe *fevers* are ſpaſmodic, but more eſpecially the head-ach. If the patient be delirious in the fit, the adminiſtration of the opiate ought to be delayed until he recovers his ſenſes, when an opiate will be found greatly to relieve the weakneſs and faintneſs which commonly ſucceed the delirium. Opium ſeems alſo in this diſeaſe to be the beſt preparative for the bark, as it not only produces a complete intermiſſion, in which caſe alone that remedy can with ſafety be adminiſtered; but occaſions ſo ſalutary and profuſe an evacuation by ſweat, as generally to render a much leſs quantity of the bark requiſite. When the patient is coſtive give the opiate in about two ounces of the tinct. facr. and this particularly if the bark is to be given immediately after the fit: thus at the ſame time, the fit is ſhortened, and the inteſtines cleanſed, previous to the adminiſtration of the bark; the operation of the tinc. facr. not being prevented, though ſomewhat retarded by the opiate. The adminiſtration of an opiate after an emetic given juſt before the fit, ſhould be poſtponed until the hot fit is begun.

TERTIANA DUPLEX. It is when a tertian fever returns every day; but the paroxyſms are unequal, every other being alike.

TERTIANA DUPLICATA. A tertian fever returning every other day; but there are two paroxyſms in one day.

TERTIANA TRIPLEX. A tertian fever returning every day, every other day there are two paroxyſms, and but one in the intermediate one.

TERTIANARIA. Hooded looſe-ſtriſe.

TERTIUM SAL. A neutral ſalt.

TESSERÆ. The os cuboides.

TESTES. The teſticles, from *teſte*, *a witneſs*; they witneſs that we are men. They are originally ſeated in the abdomen, juſt beneath the kidnies; they gradually deſcend near the time of birth through the ſheath of the ſpermatic cord into the ſcrotum, each carrying along with it a peritoneal coat, which makes the tunica vaginalis. This diſcovery was made by Dr. Hunter, in the year 1755, aſſiſted by his brother Mr. John Hunter, and was demonſtrated by the doctor in his lectures that year. Uſually arteries are ſent to glands from ſome adjacent veſſel; however this holds good in the fœtus ſtate, it varies from the general order after the birth of the child, for the ſpermatic veſſels ariſe from the aorta, the vena cava, and the emulgent veins.

Immediately within the tunica albuginea is the body of the *teſtis*, which is of a yellowiſh white colour, compoſed of tubuli, betwixt which the blood-veſſels run. Theſe tubuli are the ſecretory organs of the ſemen: they run in ſhort waves, from the tunica albuginea to the axis of the *teſticles*, and there form larger tubes than are continued through the tunica albuginea, and unite into one canal, which by ſeveral windings, form the epydidymis; and thence continuing, form the vaſa deferentia. The *teſticles* have many lympheducts which diſcharge themſelves into the inguinal glands. The ſpermatic arteries bring blood to the *teſticles*, for the ſeparation of ſpermatic matter, and the ſpermatic veins reconvey the blood to the vena cava. The ſemen ſeparated in the *teſticle*, is further perfected in the epydidymis, and then conveyed by the vaſa deferentia into the urethra.

The *teſticles* are ſometimes detained in the body, or in the groin. See PARORCHIDIUM.

TESTES. The parts of the brain called nates.

TESTICULUS CANINUS, i. e. Orchis.

TESTUDO, i. e. The talpa or mole.

TETANUS, from *τεινω*, *to ſtretch*. There are ſeveral ſpaſmodic or convulſive diſorders, or at leaſt ſeveral modes of a convulſive diſorder, which are called the emproſthotonos, in it the body is rigidly bent forward; pleuroſthotonos, in it the body is bent to one ſide; the opiſthotonos, in it the body is rigidly bent backward; and the *tetanus*, in which the body is rigidly held in an upright poſture. Dr. Cullen places the *tetanus* as a genus of diſeaſe in the claſs neuroſes, and order ſpaſmi. He defines it a ſpaſtic rigidity of almoſt the whole body. Others add, but with ſenſibility remaining, and ſometimes increaſed. This diſorder is moſt frequent in hot climes, but ſometimes happens in the milder. The locked jaw is a kind of *tetanus*. Notwithſtanding Dr. Cullen's arrangement in his Noſology, he, ſince that work, conſiders the *tetanus* emproſthotonos, opiſthotonos, and locked jaw, not as different ſpecies, but variety of *tetani* only. Aretæus, Celſus, and Cœlius Aurelianus ſay, that cold is a principal cauſe, and accordingly direct rubbing the diſordered parts, warm bathing, &c. but there are various other occaſional cauſes, ſuch as when diarrhœas, or dyſenteries are imprudently checked, and when nervous and tendinous parts are wounded, &c. The immediate cauſe is a morbid, or preternatural irritation on the nerves. When it is cauſed by a puncture or other injury of the nerves, it is commonly more violent and more difficult of cure than when proceeding from cold: when it comes on ſuddenly, and advances quickly to a violent degree, it is always more dangerous than that which is ſlower in its proceſs. Accordingly, if the patient paſſes the fourth day, it may be hoped not to be fatal; and every day adds to the favourable proſpect of recovery: not that danger is totally abſent during ſeveral days after the fourth. When its force is conſiderably abated, it is apt to return with its former violence. In order to the cure, opium is principally to be depended on as an internal remedy; a grain of opium, or, if required,

five

five grains, may be given every hour, until the ſymptoms abate, and then the doſe ſhould be gradually leſſened; if it cannot be ſwallowed, let large doſes be diſſolved and injected in glyſters until the patient can ſwallow; warm baths much aſſiſt the efficacy of opium; and if a wound, or other ſuch like external injury is the cauſe, let the part be dreſſed with the Peruvian balſam. It is juſtly obſerved by Dr. Chalmers, that the quantity of opium can only be limited by the violence of the ſpaſms. Muſk and other antiſpaſmodics have their uſefulneſs in this diſorder, but without a free uſe of opium they avail but little. When the cauſe is ſome injury received by a nerve, Dr. Cullen adviſes, if poſſible, to cut off that part from all communication with the ſenſorium, either by cutting through the nerves in their courſe, or by deſtroying, to a certain length, their affected part or extremity.

In the Weſt Indies mercury is uſed with advantage: they preſer it early in the diſeaſe, and apply it by unction; they endeavour to excite a ſpeedy ſalivation, and keep it up until the diſeaſe is overcome in its violence at leaſt.

An internal uſe of the piſſelæum Barbadenſe hath been attended with happy effects. See the Lond. Med. Obſ. and Inq. vol. i. p. 51, &c. 87, &c. vol. ii. p. 130, &c. The Lond. Med. Tranſ. vol. ii. p. 39. Lond. Med. Obſ. and Inq. vol. iii. p. 326, &c. Cullen's Firſt Lines, vol. iii.

TETARTOPHIA. Some reckon this fever among the remittents. It is a continued quartan fever. It is rare and very difficult to diſtinguiſh from the quartan intermittent.

TEUCRIUM. Alſo called chamædrys, ſpeedwell, mountain, or tree germander. It is native in Germany, Italy, and Sicily; but is not in uſe with us.

Pliny attributes the diſcovery of the virtues of *teucrium* againſt obſtructions of the ſpleen to Teucer, who was one of the Greek heroes in the ſiege of Troy.

THALAMI NERVI OPTICORUM. The bed of the optic nerves. They are little eminences in the brain, whence the optic nerves ariſe.

THAPSIA. Deadly carrot. *Thapſia* aſclepias, Linn. The root of this plant operates violently both upward and downward; it is not uſed in the preſent practice; but when imprudently taken, its antidote is vinegar. See Miller's Bot. Off.

THAPSIA. A name for the ſennel giant; for a ſpecies of laſerpitium, and for the French turbith.

THAPSIA ORIENTALIS, alſo called gingidium. Oriental pick-tooth. It is a plant found in the eaſtern countries, but is not in uſe with us.

THAPSUS. See VERBASCUM.

THEA. Tea. It is the leaf of an Oriental ſhrub. It does not appear that there are more than one kind of *tea* plant. The variety of *teas* ſeems to be owing to the different ſeaſons in which the leaves are gathered, and the different modes of curing them. The *tea* ſhrub is cultivated in China and Japan, but principally in the provinces of China, and betwixt the latitudes of 24 and 28. The beſt is from Nankin in China, and Fiſien in Japan. The green *tea* ſhould be choſen freſh, of a fine colour, not inclining to a yelloviſh, or a browniſh colour, which are marks of too great age; it ſhould be well rolled, conſiſt of entire leaves, be thoroughly dry, of a bitteriſh ſubaſtringent taſte, but not ungrateful, and of a pleaſant ſmell; the freſher the *tea*, the greener is the iuſuſion that is made of it with water; its prevailing ſmell is that of violets, or of new hay, but if it is ſtrong of theſe, it is ſo by art. Bohea *tea* is of a blackiſh brown colour; it gives a brown tincture to water, and ſmells of roſes. Of all the ſubſtitutes for *tea*, the male ſpeedwell is the moſt celebrated. The green colour of *tea* reſides wholly in its reſinous part, ſo does its aſtringency.

An infuſion of *tea* in water is a grateful diluent in health, and a ſalutary drink in ſickneſs; it promotes the natural excretions, excites an appetite, checks immoderate ſleepineſs, and relieves the head-ach when cauſed by a debauch. No other plant is known whoſe infuſion more readily paſſes off by the emunctories, or more ſpeedily excites the ſpirits. When the ſtomach is weak, a moderately ſtrong infuſion of *tea* generally provokes a vomiting. Perhaps the principal inconvenience ariſing from the uſe of *tea*, is its preventing the neceſſary nouriſhment being received from more ſubſtantial food; it ſeems better calculated for a ſupper than for a breakfaſt. See Lewis's Mat. Med. Neumann's Chem. Works; Lettſom on *Tea*.

THEMISON. A phyſician of Laodicea, a diſciple of Aſclepiades. He flouriſhed a little before the time of Celſus; he founded the methodic ſect, with a view to the more eaſily teaching and practiſing the art of medicine. He aſſerted it not neceſſary to know the cauſes of diſeaſes, provided we had a due regard to what diſeaſes have in common, and analogous among themſelves; he ranked all diſorders into thoſe from a lax, theſe from a rigid fibre, and thoſe from a mixture of theſe; he obſerved alſo, that all diſeaſes were acute or chronical, and that from theſe principles all practice was to be deduced. *Themiſon* gave the firſt account of diacodium, which was prepared of the juice and decoction of poppy heads and honey. He invented a purging medicine called hiera. The greateſt improver among the methodic ſect was THESSALUS, whom ſee.

THENAR, Θέναρ. The palm of the hand, or the ſole of the foot; alſo a name of the abductor pollicis manus, and the abductor pollicis pedis: theſe are called *thenar* becauſe they make a part of the *thenar*.

THERAPEUTICE, from Θεραπεύω, *to heal* or *cure*. It is that part of medicine which particularly reſpects the *cure* of diſeaſes.

THERIACA, from Θὴρ, *a viper*, or *a wild beaſt*. The medicine called *theriaca*, and all with this name are intended to cure the bites of venomous animals; they differ from alexipharmics, in that theſe latter are uſed as remedies againſt poiſon inwardly taken.

THERIACA GERMANORUM, i. e. Rob. Bac. Juniperi.

THERIACA LONDINENSIS, i. e. Catapl. e Cymino.

THERIACA RUSTICORUM, i. e. Allium.

THERIOMA, from Θὴρ, *tera*, *a wild beaſt*. This term is applied by ſome ancient Greek writers to very malignant or ill-conditioned ulcers. See THERIODES.

THESSALUS. He lived under Nero, about fifty years after Themiſon. He improved Themiſon's plan ſo much as to have obtained the character of the perfecter thereof; but the laſt hand to the methodic ſect was SORANUS, whom ſee.

THLAPSI VERUM. Penny-creſs, or treacle muſtard. The *thlaſpi* arvenſe, Linn. It is a plant with roundiſh pointed leaves, and broad capſules, containing about four ſeeds in each cell. It is annual, grows in fields, and flowers in June.

THLAPSI VULGATIUS. Mithridate muſtard. It hath hoary ſharp-pointed leaves, ſhaped like an arrow's-head, and only one ſeed in each ſhell of the pod. It is biennial, grows in open clayey ground, and flowers in May.

The ſeeds of theſe two plants have been uſed, but the common muſtard ſeed is, in all caſes, preferable.

THORA. A ſpecies of anthora, and of ranunculus.

THORACICÆ ARTERIÆ. The thoracic arteries. The upper one riſes from the axillary artery, and runs down in the ſides of the thorax, giving out many branches in its paſſage. The inferior one ariſes alſo from the axillary artery, and runs along the inferior coſta of the ſcapula, &c. to ſeveral of the neighbouring muſcles.

THORACICUS DUCTUS. See LACTEA VASA.

THORAX, from Θώραξ, *the breaſt*. It is divided into three regions, viz. the anterior, or the *breaſt*; the poſterior, or the back; and the lateral, or the right and left ſides. The *thorax* is lined with the pleura; into the *thorax* deſcends the trachea arteria; behind the ſternum is the thymus gland, the heart is ſeated in the middle of the *thorax*, and on each ſide of it are the lungs. The pericardium immediately covers the heart.

The *thorax* is formed behind of the twelve dorſal vertebræ, on the ſides by the ribs, and before, by the ſternum.

THRACIUS LAPIS. The Thracian ſtone. Wormius ſays it is a kind of lapis ampelites.

THURIS CORTEX, alſo called elutheria, elaterium, caſcarilla, thymiama, ſtorax rubra offic. thus Judæorum. It is ſuppoſed to be the bark of the clathera of Cateſby, which is plentiful in the Bahama iſlands, particularly on one called Elatheria.

Dr. Brown, in his Hiſtory of Jamaica, ſays, that the tree is frequent in the inland woods there; all the parts of the tree, eſpecially the bark, ſmell ſtrong of muſk; and the powder of the bark is uſed there by the negroes as an emetic. He ſays it is called there by the names of Alligator wood and Muſkwood. He gives as its botanic characters the following, viz.

Pericarpium. Capſula craſſa, ſubrotunda, corticoſa, dura, quadrilocularis, quadrifariam ab apice dehiſcens.

Semina. Nuclei ſolitarii oblongo-ovati.

To his definition, he adds one or two more, as follow:

Elutheria. Arborea; foliis majoribus, ovatis, oppoſitis; petiolis brevibus, ſubtumidis, ganglinoſis.

Lauro affinis arbor foliis latioribus, &c. Sloan. Cat. 137. & H. t. 170.

According to the Edinburgh college, it is the croton (caſcarilla) foliis lanceolatis acutis integerrimis petiolatis ſubtus tomentoſis, caule arboreo. Linn.

This bark is brought to us in curled pieces, or rolled up in ſhort quills about an inch in width, covered on the outſide with a rough whitiſh matter, and browniſh on the inner ſide, exhibiting, when broken, a ſmooth, cloſe, blackiſh brown ſurface.

This bark hath a light agreeable ſmell, and a moderately bitter taſte, accompanied with a conſiderable aromatic warmth; it is eaſily inflammable, and yields, while burning, a very fragrant ſmell, ſomewhat like muſk; it is bitter, but leſs rough and leſs diſagreeable than the Peruvian bark.

The virtues of the *thuris cortex* are very ſimilar to thoſe of the cort. Peruv. and where the latter is diſagreeable the former may be ſubſtituted for it. In the gout, and eſpecially in gouty diſorders, it may ſupply the place of the radix ſerpentaria, as a perſpirative. In diſorders of the head the *thuris cortex* is bruiſed and mixed with tobacco for ſmoaking.

Water extracts the virtues of this bark, but ſpirits takes them up more perfectly. Diſtilled with water it yields a greeniſh eſſential oil. See Lewis's Mat. Med. Hiſt. de l'Acad. Roy des Sciences.

THURIS LIGNUM, i. e. Rhodium.

THUS. Frankincenſe. The Greeks call it olibanum, from the mountain Libanus in Syria, whence many ſuppoſe that it grows there; but true *frankincenſe* is not known to grow any where but in Arabia. The common *frankincenſe* of the ſhops is the reſin of the pinus ſylveſtris. Linn.

THUS CORTICOSUM. See OLIBANUM.

THUS JUDÆORUM, i. e. Thuris cortex.

THUYA. A ſpecies of cedar, alſo the arbor vitæ.

THYMALEA MONSPELIACA. Spurge flax. Daphne gnidium, Linn. This ſhrub is clothed with green leaves, which reſemble thoſe of flax; it bears white flowers in cluſters on the tops of the branches; the flowers are followed with red berries, in each of which is one ſeed. This ſeed is ſuppoſed to be the real grana cnidia, though the mezereon is taken for it: coccus is the whole berry with its ſeed, and grana is the ſeed of the berry. Theſe berries are very cauſtic. The ſhrub is a native of the ſouth of Europe.

THYMELÆA LAURI FOLIO, alſo called Laureola, daphnoides. Spurge laurel, ſee LAUREOLA MAS.

Botaniſts enumerate ſix ſpecies of *thymelæa*: their berries are very cauſtic; they ripen in autumn, but are not in much repute.

THYMIAMA, i. e. Thuris cortex.

THYMICÆ ARTERIÆ. The artery of the thymus. The *arteria thymica*, and arteria trachealis on each ſide, are in ſome ſubjects, only branches of one ſmall trunk, which ſprings from the common trunk of the right ſubclavian and carotid; they are generally ſmall, ſometimes running ſeparate, and ſometimes partly ſeparate and partly joined.

THYMICA VENA. The right when it riſes ſeparately goes out from the biſurcation, and when it is wanting the *thymus* gland is furniſhed by the gutturalis, or ſome other neighbouring vein. The left from the ſubclavian.

THYMOXALME. A preparation given by Dioſcorides, of thyme, vinegar, ſalt, and ſome other ingredients.

THYMUS. The name of a ſmall, indolent, carnous tubercle like a wart, ariſing about the anus, or the pudenda; it reſembles the flowers of thyme, whence its name. When this tubercle is large it is called ficus. They are eaſily extirpated. See Wiſeman's and Heiſter's Surgery.

THYMUS. The name of a gland which Haller ſays is a lymphatic one, of the conglobate kind, but divided into lobes. It lies behind the ſternum, partly within, and partly without the cavity of the thorax. It is peculiar to the fœtus, and is ſhriveled in adults. This which is in calves, &c. is called ſweet-bread.

THYMUS. Thyme. It is a low ſhrubby plant, conſiſting of numerous, ſlender, tough ſtalks with little roundiſh leaves in pairs, and looſe ſpikes on the tops with purpliſh or whitiſh flowers.

THYMUS VULGARIS. Common thyme. *Thymus vulgaris*, or *thymus vulgaris* erectus Hiſpanicus, foliis reſolutis ovatis, floribus verticillato-ſpicatis. Linn. *Common* broad leaved *thyme*. It hath upright ſtalks, and dark browniſh green, ſomewhat pointed leaves; it is native in the ſouth of Europe, but common in our gardens; it flowers in June and July. It is moderately warm, pungent, and aromatic; to water it imparts by infuſion its agreeable ſmell, but only a weak taſte; in diſtillation it gives over an eſſential oil, which poſſeſſes the ſmell of the *thyme*, but leſs grateful; to the taſte it is hot and fiery. Spirit of wine takes up the whole of its active matter by infuſion. A conſerve of the leaves, or of the leaves with the flowers, is a good preparation. See Lewis's Mat. Med. Neumann's Chem. Works.

THYMUS. A name of a ſpecies of ſatureia, and of ſerpyllum.

THYODAMAS. He was the ſon of Melampus the Argive. Nothing remarkable is ſaid of his practice. The next eminent phyſician was POLYIDUS, whom ſee.

THYRO-ADENOIDÆUS. See CRICO PHARINGÆI.

THYRO-ARYTÆNOIDÆI. Theſe muſcles ariſe from the inſide of the fore-part of the thyroid cartilage, and are inſerted into the arytænoid, ſerving to compreſs the glottis. Sanctorini calls theſe muſcles thyro-epiglotides, becauſe they are partly inſerted into the membrane of the epiglottis.

THYROIDEÆ GLANDULÆ. The thyroid glands. They ſurround the aſpera arteria laterally and before; its uſe is not known; it is larger in women than in men, whence the fore-part of their neck is not ſo hollow as that of men. It is the ſeat of the bronchocele.

THYROIDES, from θυρεος, *a ſhield*, and ειδος, *likeneſs* or *ſhape*. The name of a cartilage of the larynx, which ſee.

THYRO-CRICO-PHARYNGÆUS, i. e. Cryco pharyngæus.

THYRO-EPIGLOTTICI. They are only ſome muſcles of the thyro-arytænoides.

THYRO-PHARINGÆI. Theſe muſcles are broad, they riſe from along the outſide of the ala of the cartilago thyroides, between the edge of that cartilage and the oblique line in which the thyro-hyoidæi are fixed, and they are a little confounded with the crico-hyoidæi; from thence they run up obliquely backward, and meeting under the linea alba of the pharynx, they ſometimes appear to be but one muſcle, without any middle tendon. See Winſlow's Anatomy; and CRICO-PHARYNGÆI above.

THYRO-PHARINGO-STAPHYLINI, i. e. Thyro-ſtaphylini.

THYRO-STAPHYLINI. Theſe are two ſmall muſcles which accompany the pharyngo-ſtaphylini very cloſely through their whole courſe, except that their poſterior extremities are fixed in the thyroid cartilages, near the other muſcles. They are inſerted into the ſeptum palati. Theſe two pair may be reckoned one pair, and called thyro-pharyngo-ſtaphylini.

THYRSUS. A thyrſe. It differs from a ſpike in having the flowers or fruits ſet more looſely on it, ſo that there are ſpaces viſible between them.

THYRSUS. A ſtalk. See CAUDEX.

THYSSELINUM, i. e. Alſinicium. Alſo a name for the œlinitium.

TIBERIANUM TORMENTUM. The colic.

TIBIA. Tibia, or hautboy, which this bone refembles, and hence is called by this name. The larger bone in the leg; it is alſo called focile majus, arundo major, canna major, canna domeſtica cruris. It is ſituated in the anterior internal part of the leg; its upper extremity is large, and it is divided into two cavities for the reception of the condyles of the os femoris; between theſe cavities is a rough irregular protuberance for the attachment of the ligaments; on the poſterior part is a ſmall cavity for the reception of the fibula, and below the fore part is a large rough tuberoſity, where the ligament of the patella is fixed: the lower extremity is hollow, but ſo as a ſmall tuberoſity riſes in the middle; the internal ſide of this cavity is produced into a proceſs called malleolus internus; the internal ſide of this extremity hath a cavity for the reception of the fibula; the anterior angle of the *tibia* is ſharp, and is called the ſhin or ſpine.

It may be proper here to obſerve a proceſs for relief when bones are carious, which may frequently prevent an amputation. If the *tibia* is carious to a conſiderable depth (ſee CARIES), remove the carious part as follows: firſt cut through the ſkin (the whole length of the part we mean to remove) on each ſide, ſaving as much of it as you can; then cut it acroſs the bone above and below. Having done this, clear off the muſcular fleſh, by diſſecting it as clear as can be admitted from the bone, and preſerving it as much as poſſible: then introduce a thin plate of paſteboard, horn, or tin, over the upper part of the bone to be removed, and ſo as to ſupport the ſkin. After this, clear away the perioſteum from the parts on which you apply the ſaw. The ſaw ſhould be ſtrong, and of a circular form, to prevent wounding the adjacent parts. Having divided the bone above, do the ſame on the lower part, taking care to include all that is diſeaſed. The carious part of the bone being removed, the wound will not appear ſo large as may be imagined. To encou-courage to this operation, it ſhould be remembered, that there have been inſtances of oſſeous matter ſhooting and forming a complete bone, when nine inches or more hath been removed.

TIBIALIS. The nerve thus called is the internal branch of the ſciatic nerve, and is ſent off near the ham; it paſſes behind the popliteus muſcle, and behind the gaſtrocnemii, goes through the upper part of the ſoleus, then runs between it and the flexores of the toes, and to the malleolus internus, behind which it runs, and paſſing betwixt the os calcis and the abductor of the great toe, where it divides into the plantaris internus and externus, the firſt of which furniſhes the toes with filaments, and the latter goes particularly to the little toe, and to that next to it.

TIBIALIS ANTICUS. This muſcle riſes from the head of the tibia, and from the outſide of the ſpine of the tibia; it grows tendinous, and, winding about the inſide of the foot, is inſerted into the os cuneiforme internum, and ſerves likewiſe to turn the ſole inwards.

TIBIALIS ARTERIA. As the poplitea ends it divides into two principal branches, the firſt of which runs between the heads of the tibia and fibula, paſſing from behind forwards on the interoſſeous ligament, where it is called *tibialis* anterior; the ſecond branch divides into two more, the largeſt of which is the innermoſt, and is called *tibialis* poſterior. The anterior lies between the *tibialis* anticus muſcle and the extenſors of the toes; it comes forwards between the head of the tibia and fibula; it paſſes on the foreſide of the interoſſeus ligament, then runs down on the ſide of the tibia for about two-thirds of its length, paſſes down before, under the annular ligament, ſtrait on the inſtep to the ſpace between the firſt and ſecond metacarpal bones, and plunges down into the ſole of the foot, where it anaſtamoſes with the poſterior tibial artery. The poſterior runs between the ſoles, the *tibialis* poſticus, the flexor digitorum communis, and flexor pollicis, and paſſes between the bone and interoſſeous ligament; in its paſſage it gives branches to the tibia, and to its marrow, through a canal in its poſterior and upper part; it runs behind the inner ankle, communicates with the *tibialis* anterior, and, ſurrounded by the neighbouring veins, paſſes to the ſole of the foot, between the os calcis and the thenar muſcle, where it is divided into the plantaris interna and externa, which make a circle like that in the palm of the hand: from this circle branches are ſent to the toes.

Mr. Pott remarks the following important circumſtance. In the upper part of the calf of the leg, under the gaſtrocnemius and ſoleus muſcles, a ſmall hard tumor is at firſt perceived; it is ſometimes painful; at others not much ſo; but always impeding the patient's exerciſes; it does not alter the natural colour of the ſkin until it hath conſiderably increaſed in the bulk; it enlarges very gradually; it does not ſoften as it increaſes, but continues through the greateſt part of it incompreſſibly hard; and when it hath got to a large ſize, it ſeems to contain a fluid which may be felt towards the bottom, or reſting as it were on the back part of the bones. If an opening is made for the diſcharge of the fluid, it muſt be made very deep, and through a very diſtempered maſs; this fluid is generally ſmall in quantity, and conſiſts of a ſanies mixed with grumous blood: the diſcharge of it produces very little diminution of the tumor; and in the few caſes that have occurred to him, he ſays that very high ſymptoms of irritation and inflammation came on, and advanced with great rapidity and exquiſite pain, ſoon deſtroyed the patient, either by the fever which ran high, and was unremitting, or by a mortification of the whole leg. If amputation hath not been performed, and the patient dies after the tumor hath been opened, the mortified ſtate of the parts prevents all ſatisfactory examination; but if the limb was removed without any previous operation, the arteria *tibialis* poſtica will be found to be enlarged, diſtempered, and burſt; the muſcles of the leg to have been converted into a ſtrangely morbid maſs, and the poſterior part of both the tibia and the fibula more or leſs carious. This diſeaſe derives it origin from a burſten artery, or is always accompanied with it, and is remedied by amputation only. See Mr. Pott's Remarks on the Neceſſity, &c. of Amputation in certain Caſes, &c.

TIBIALIS GRACILIS MUSCULUS, i. e. Plantaris.

TIBIALIS POSTICUS. This muſcle riſes from the tibia and fibula cloſe to the ſoleus, and from the interoſſeous ligament, runs through the annular ligament; it plays in a groove of the bone, where it is tied down by the annular ligament, then runs acroſs the foot, and is inſerted into the middle of the os ſcaphoides.

TIBIALIS VENA. There is an interior and poſterior; they are diviſions of the poplitea. They accompany their reſpective arteries in their courſe.

TIGLIA GRANA. Molucca grains.

TIGRIDIS FLOS. This flower is red and ſpotted like the ſkin of a tiger, whence the name. See Raii Hiſt.

TILBURY WATER. It is the ſtrongeſt of the alkaline waters in England; it may be taken to a quart in a day.

TILIA. The lime-tree, alſo called the line or the linden tree. It is the *tilia* Europea, Linn. It is a tall tree, and its branches ſpread far; the leaves are heart-ſhaped, ſerrated, ſoft, and hairy; the flowers are whitiſh, followed by a kind of dry berry about the ſize of filberts. This tree is native in England; it flowers in July.

The flowers have an anodyne and antiſpaſmodic virtue; when freſh they have a moderately ſtrong ſmell, and in this their virtue conſiſts, but it is ſoon loſt in keeping: they have been much eſteemed, but are now neglected in practice. See Raii Hiſt.

TINCAL, and Tincar. Borax. It comes to Europe from the Eaſt Indies in a very impure ſtate, in the form of large, flat, hexangular, or irregular cryſtals, of a dull white or greeniſh colour, greaſy to the touch; or in ſmall cryſtals, as it were cemented together by a rancid, yellowiſh, or oily ſubſtance, intermixed with marl, gravel, and other impurities. In this ſtate it is called brute *borax*, chryſocolla, or *tincal*.

It is purified by ſolution, filtration, and cryſtallization; and the cryſtals thus obtained are calcined to free them ſtill further from greaſineſs, and then diſſolved, filtered, and cryſtallized a ſecond time, ſometimes more mineral alkali is added, as it is ſaid that *tincal* contains an exceſs of ſedative ſalt.

One hundred parts of purified *borax* contain thirty-four of real ſedative acid, ſeventeen of mineral alkali, and

forty-ſeven of water; but of the mineral alkali only about five parts are really ſaturated, the reſt is unſaturated; and hence in many caſes *borax* acts as an alkali.

It hath been long thought that *borax* was a factitious ſubſtance, but it is now beyond all doubt that it is a natural production, ſince Mr. Grill Abrahamſon ſent ſome to Sweden in the year 1772, in a cryſtalline form; as dug out of the earth in the kingdom of Thebet, where it is called *pounxa*, *my poun*, and *houi poun*. As *borax* is purified alſo in the Eaſt Indies, Mr. Engeſtrom ſuſpects that the *tincal* is only the reſiduum of the mother liquor of *borax* evaporated to dryneſs, and that the greaſineſs ariſes from its being mixed with butter-milk to prevent its efflorescence.

It is ſaid that *borax* hath been found in Saxony in ſome coal pits. See BORAX, and SEDATIVE SAL. Kirwan's Elements of Mineralogy.

TINCTORUM GRANA. Kermes berries.

TINCTORIUS FLOS, i. e. Geneſta tinctoria Germanica.

TINCTURA. A tincture. *Tinctures* differ from diſtilled waters, in that waters take out only the lighter parts that will aſcend in vapour; but *tinctures* take up all ſuch parts as are capable of being ſuſpended in a menſtruum. *Tinctures* differ from elixirs in that *tinctures* are watery, ſpirituous, or other liquors impregnated with the active parts of ſome one ſimple; elixirs contain the active parts of more than one ingredient, ſo are compound *tinctures*. Watery extracts from vegetables are indeed called infuſions or decoctions, according as they are prepared by macerating, or by boiling the plant in water; the ſpirituous are named *tinctures*, eſſences, and elixirs, according as the ingredients are numerous, or the menſtruum ſaturated with the virtues thereof; when the *tincture* is of a thickiſh conſiſtence it is called a balſam.

TINEA. See ACHOR. This ulcer eats like the *tinea* or moth. Dr. Cullen places the *tinea* as a genus in his claſs of locales, and order dialyſes. Bell, in his Treatiſe on Ulcers, ranks it as a variety amongſt cutaneous ulcers.

TINNITUS AURIUM, from *tinnio*, *to ring*. A noiſe in the ear like that of a bell; all other kinds of noiſes are alſo *tinnituſſes*. Hoffman attributes this diſorder to ſpaſmodic affections in the inner membranes of the ears. It is the ſpecies of depraved hearing which Dr. Cullen calls paracuſis imaginaria. And Heiſter propoſes for the cure to give diaphoretics inwardly, and outwardly to fumigate the meatus auditorius externus with the vapours of hot wine, in which is roſemary leaves and thoſe of lavender, and to put the feet into warm water. Etmuller obſerves, that when this diſorder is the effect of chronical diſorders it is difficult to cure. See Du Verney on the Ear, and its Diſorders.

TITHYMALUS. Spurge. Euphorbia paluſtris, Linn. A plant with ſmall ſmooth leaves, round ſtalks that are full of a milky juice; the flowers are in umbel-like cluſters; each flower is followed by a capſula, in which are three ſeeds. Botaniſts enumerate fifty ſpecies.

TITHYMALUS HELIOSCOPIUS, alſo called ſolſequium, eſſula ſoliſequa, ſun ſpurge, wart-wort, and common water-ſpurge.

TITHYMALUS MARITIMUS, alſo called eſſula marina. Sea ſpurge.

The juice of theſe, and of moſt of the other ſpecies, are very acrid, and therefore not uſed, except externally, for deſtroying warts, &c. See Raii Hiſt. Lewis's Mat. Med.

TITILLARES VENÆ. The iliac veins.

TITILLICUM. The arm-pit.

TOLÆ, Toles, and Tolles. The tonſils. M. A. Severinus applies this word to glandular abſceſſes in the limbs.

TOLUTANUM BALSAMUM. The balſam Tolu. It is a reſinous juice, flowing from inciſions made in the bark of a tree, of which we have various accounts. Neumann ſays it is a kind of fir-tree, which is called tolu, and that grows in the province of Tolu. It is the Toluifera balſamum, or the Toluifera Carthaginenſis, foliis ceratiæ ſimilibus, flore luteo, Linn. The balſam is brought to us in gourd-ſhells, or ſmall callibaſhes; it is of a yellowiſh brown colour, inclining to red; its conſiſtence is uſually thick and tenacious; by age it grows hard and brittle, without loſing any of its odoriferous parts. Its ſmell ſomewhat reſembles that of lemons, particularly if rubbed on the hand; it hath an agreeable warm, ſweetiſh, glutinous taſte; it is ſlightly pungent, and without any mixture of a nauſeous reliſh. Its virtues are in general the ſame with thoſe of the balſ. Copaiba, and balſam Peru, differing only in being milder, and more grateful to the palate and in the ſtomach.

This balſam totally diſſolves in rectified ſpirit of wine. Forty grains of this balſam diſſolved in an ounce of rectified ſpirit, gives a ſtrong flavour to a quart of the white ſyrup, if mixed gradually with it, and then placed in a water-bath until the ſpirit is exhaled. In diſtillation with water it impregnates the liquor with its fragrance, and if the quantity committed to diſtillation be large, a ſmall proportion of very fragrant eſſential oil is obtained. If diſtilled in a retort without addition, it ſometimes yields a ſaline concrete like the flowers of Benjamin.

TOMENTUM. Flocks. It is when the leaves or the ſtalks of plants are covered with a thick down.

TONICUS. Tonic. Every veſſel, membrane, and muſcle, with every fibre in ſenſible parts, have a natural tendency to ſhorten themſelves, and this is their tonic power. See SPASMUS TONICUS.

TONICI. Diſeaſes from tonic ſpaſm. See SPASMUS TONICUS.

TONSILLÆ. The tonſils, called alſo amygdalæ, or almonds. Theſe glands are ſeated on each ſide, at the lower part of the ſpace which is left between the lateral half arches of the palatum molle; they are of a reddiſh colour, and externally they have many holes, which communicate with an irregular cavity in their inſide, and which contains a viſcid fluid, which is gradually diſcharged from the holes into the throat.

TOPAZIUS. A topaz. It is a precious ſtone of a gold colour; the fourth in hardneſs from a diamond.

TOPHUS. A toph. See GUMMA. Alſo the concretions in the joints of gouty people.

TOPICA, from τόπος, *a place*. Topics, or local applications.

TOPINARIA. A ſpecies of tumor in the ſkin of the head. It is the ſame as talpa.

TORCULAR. The tourniquet. It is a kind of bandage uſed to check hæmorrhages after wounds or amputations. The moſt ſimple of theſe is a fillet, long enough to encircle the wounded limb, with a ſmall ſtick to twiſt it round with, and a ſmall bolſter to preſs upon the principal veſſel. The fillet muſt be tied looſely above the orifice of the veſſel; under this fillet, and over the artery, the bolſter muſt be placed, and then the fillet muſt be twiſted by means of the ſtick, until it is ſufficiently tight. If a *tourniquet* is applied on the arm, place it near the armpit, for there the artery is moſt ſuperficial. The firſt account of this inſtrument is in a treatiſe writ by Mr. Lowdham, an Engliſh ſurgeon, and publiſhed in 1679: that improved by Mr. Crane, of Bartholomew's-hoſpital, is the moſt complete

TORCULAR HEROPHILI. It is a ſinus of the dura mater; it is ſo called from Herophilus, who firſt diſcovered it. It is the place where the ſinuſes of the dura mater meet.

TORDILIUM. It is a plant, of which Boerhaave mentions ſeven ſorts; the roots of ſome of them poſſeſs the ſame qualities as thoſe of ſkirret, but they are not much noted in medicine.

TORMENTILLA, alſo called heptaphyllum, conſolida rubra, ſeptfoil, tormentil. Tormentilla erecta, or tormentilla ſylveſtris, caule erectiuſculo, foliis ſeſſilibus, Linn. Upright ſeptfoil, or *tormentil*. It is a plant with ſlender upright ſtalks, oblong indented leaves, which uſually ſtand ſeven at a joint. The flowers are ſmall, and of a yellow colour; the root is crooked and knotty, of a dark brown and blackiſh colour on the outſide, and reddiſh within. It is perennial, grows wild in woods and on commons, and flowers in June.

The roots are a ſtrong and almoſt flavourleſs aſtringent; what flavour it hath is ſlightly aromatic. It gives out its aſtringency both to water and to ſpirit, but moſt perfectly to rectified ſpirit of wine. It is uſually given in a decoction, an ounce and a half of the root being boiled in three pints of water to a quart; at the end of the boiling about a dram of cinnamon is added. Three or four table ſpoonfuls of this decoction is a doſe. This root and that of biſtort are ſo ſimilar, that they are uſed for one another. See Lewis's Mat. Med.

TORMINA. Gripes. A dyſentery.

TORNADO. From the Spaniſh, a hurricane, a whirlwind. Dr. Schotte gives the following account of the *tornados*, which happen at Senegal. The rainy ſeaſon there begins about the middle of July, and ends about the middle of October, during this time, the wind is generally between the points of eaſt and ſouth, the quarter from which the *tornados* come. A *tornado* is preceded by a diſagreeable cloſeneſs and weight in the air (which ſeems to be much hotter than the thermometer ſhews it to be); and it is known to come on by the riſing of the clouds to the ſouth-eaſt, which by joining grow darker, ſo as to make the horizon look quite black, accompanied with lightning and thunder, at a diſtance. The breeze dies away by degrees, as the *tornado* advances, and an entire calm ſucceeds; the air grows yet darker; animals and birds retire and ſhelter themſelves; every thing is ſilent, and the aſpect of the ſky, from whence the *tornado* approaches, is moſt dreadful. A violent ſtorm comes on all at once, which is ſo cold as to occaſion the thermometer to fall ſeven or eight degrees in a few minutes, and ſtrong enough to overſet negro huts, and veſſels, or drive the latter from their anchors, and throw them on ſhore. The ſtorm abates, and heavy rain follows, accompanied with much lightning and ſtrong claps of thunder. Sometimes *tornados* happen without rain, or at leaſt a very little, but then the ſtorm is more violent, and laſts longer. It hath been imagined by ſome, that this kind of ſtorm brings ſome peſtiferous quality with it, becauſe they had obſerved, that out of a number of people, ſeveral fell ſick in one night after a *tornado*. Dr. Schotte thinks, that no ſuch ill quality is thus produced by it; and that the juſt named phenomenon may be attributed to the change it produces on the air, and of conſequence on the body; it may therefore be conſidered, as the occaſional cauſe of a diſorder, to which the body was prediſpoſed long before. Schotte's Treatiſe on the Synochus atrabilioſa.

TORPOR. Galen ſays it is a ſort of intermediate diſorder between a palſy and health. It is a numbneſs, or deficient feeling and motion.

TORTIO. A ſtrain in a joint.

TORTURA. A wry mouth.

TORTURA ORIS. The locked jaw.

TORTICOLLIS. The wry neck. An inſtance of contractura.

TOURMALIN. It is a compound earth, conſiſting of the argillaceous, ſilicous, and calcareous, and iron, in proportions determined within certain limits, and forms ſimple ſpecies. It is moſtly cryſtallized, in polygon priſms but ſometimes amorphous. The thickeſt parts are opake: the thin are more or leſs tranſparent.

It hath hitherto been found only in Ceylon, Brazil, and the Tyrol.

That of ceylon is of a dark brown colour, or yellowiſh. It melts per ſe, into a black frothy ſlag. Borax is its beſt flux. Its proportions are as follow: argill 39, ſilex 37, calcareous earth 15, iron 9.

That of Brazil, is green, blue, red, or yellow. It does not melt by itſelf in the fire; it burns only into a brittle ſcoria. Borax is its beſt flux. Its proportions are as follow; argill 50, ſilex 34, calcareous earth 11, iron 5.

That of the Tyrol, by reflected light, is of a blackiſh brown, but by refracted light, yellowiſh, or in thin pieces green. It melts per ſe into a black frothy ſlag. Borax is its beſt flux. Its proportions are as follow; argill 42, ſilex 40, calcareous earth 12, iron 6.

They are all electric when heated to about 200 of Farenheit. Their texture is lamellar, and their ſurface hath a glaſſy appearance. Kirwan's Elem. of Mineralogy.

TOUT SAIN, i. e. Androſæmum.

TOXICODENDRON, from τοξικον, *a fox*, and δενδρον, *a tree*. The poiſon tree. This tree is ſo noxious that no inſects ever come near it. See Raii Hiſt.

TOXITESIA. Mugwort.

TRACHEA ARTERIA, from τραχὺς, *rough*. The wind-pipe.

TRACHEALIS ARTERIA. It runs up from the ſubclavia in a winding courſe, along the aſpera arteria to the glandulæ thyroideæ and larynx, detaching ſmall arteries to both ſides, one of which runs to the upper-part of the ſcapula.

TRACHEALIS VENA, i. e. Gutturalis vena.

TRACHELO MASTOIDEUS, i. e. Complexus minor.

TRACHELOPHYMA. The bronchocele.

TRACHEOTOMIA. Tracheotomy. It is the making of an opening into the trachea. This operation is alſo called bronchotomy, and laryngotomy. This operation is made by inciſion, or by puncture, betwixt the third and fourth ring of the trachea; or if this place cannot be choſen, the opening may be made a little lower. When the ſkin is cut through, a ſmall inciſion may be made into the wind-pipe, and then a ſhort but crooked canula may be fixed there for the air to paſs through. See Sharpe's Operation.

Mr. Sheldon obſerves, that it is very happy both for the ſurgeon and the patient, that this operation is very rarely required. When it is attempted, he adviſes to perforate below the thyroid gland; to cut cautiouſly between the two ſterno-maſtoid muſcles longitudinally, carefully avoiding to wound the vein of the thyroid gland, as it will bleed plentifully. Care muſt alſo be taken that no blood is permitted to fall into the larynx, as it will undoubtedly ſuffocate the patient. Laſtly, when the trochar is introduced, let it not touch the back part of the larynx, becauſe of the irritability of its membrane. It is a difficult operation, but it is beſt performed on thoſe who have thin long necks.

TRACHOMA, from τραχὺς, *rough*. In Cullen's Noſology it is a variety of the ophthalmia tarſi. A roughneſs of the eye-lids, particularly their internal parts. This roughneſs is from a ſort of ſcabs, which differ much in their appearances in different inſtances. Theſe complaints are attended with a weight and heavineſs in the eye, a ſwelling in the eye-lids, a pain and itching, a heat and redneſs in the corners and in the conjunctiva, a viſcid humour mixed with pungent tears flowing from the ulcers, which when very glewy, cloſes the eye-lids together. If this complaint continues long in old people, the lower eye-lid grows thick, and turns downwards, ſo that the cartilage reſembles raw fleſh. The original cauſe is a ſaline humour, which is thrown on the eye-lids; the immediate cauſe is little ulcers there. A cure is ſometimes performed by touching the part with a cauſtic; but the cauſtic is no ſooner applied, than the pain which it occaſions muſt be allayed by waſhing with warm water; apply the cauſtic twice a week. St. Yves on the Diſorders of the Eyes.

Mr. Ware calls this diſorder the pſorophthalmia, and deſcribes it as follows. The ducts of the ciliary glands are ulcerated; when it happens that the oily ſoft fluid, ſecreted by theſe glands, being mixed with the diſcharge from the ulcers, is changed into an acrid humour, which quickly inſpiſſates into an hard adheſive ſcab. This ſcab lodging on the orifices of the ducts, ſpreads the complaints, by the irritation which it occaſions, over the whole internal edge of the eye-lid, and prevents the poſſibility of its being relieved, until the local remedies are applied, to prevent the formation of the ſcab, by curing thoſe ulcers which ſerved to produce it. This inflammation of the eye-lids being attended with an ulceration of their edges, a glutinous matter iſſues out, and when they have been ſome time in contact, as during ſleep, they become ſo cloſely connected, as to require painful efforts for their ſeparation. Uſually, the ulcers are confined to the edges of the eye-lids, but ſometimes they ſpread over the whole external ſurface, and even excoriate the greater part of the cheek: in caſes of the latter kind, the inflamation which accompanies, has often much the appearance of an eryſipelas. This diſorder is ſometimes attended with a contraction of the ſkin of the lower eye-lid; in conſequence of which, it is drawn down, and the inner part turned outward, ſo as to form a red, fleſhy, and very diſagreeable appearance.

To form a clear idea of this diſeaſe, it ſhould be remembered, that, on the inſide, and near to the edges of the eye-lids, is ſituated a number of ſmall glands, ſecreting a ſebaceous fluid, which is excreted by a row of ducts opening immediately on the inner edges of their border. Theſe ducts, and ſometimes the glands themſelves, appear to be the parts principally affected; and the fluid which is ſecreted by them, inſtead of being moiſt and mild, ſerving as a defence againſt the acrimony of the tears, is changed into a ſharp, acrid, and adheſive humour; which cauſes a conſtant irritation of the eye and eye-lids, ulcerates the inner edges

edges of the latter, and, for want of proper attention, has often perpetuated the diſorder for a great number of years. Monſ. St. Yves obſerves, in his chapter on the ophthalmy, ſubſequent to the ſmall-pox, that "the puſtules on the edge of the cartilage of the eye-lids, which penetrate between the cilia, and their inner ſurface, do not cicatrize, by reaſon of the acrimonious ſerofity, which inceſſantly humects the eye; hence follow ulcers, which laſt ſometimes ſeveral years, and even during life, if they be not remedied." But though the ſmall-pox and meaſles, are frequent cauſes of this complaint, they are not the only ones; an inflammation of the globe of the eye, in itſelf but ſmall, will ſometimes affect the lids, ſo as to cauſe them to ſwell, and become red; in conſequence of which, there will be an adheſion of one to the other, and often an univerſal ulceration of their edges. The ſmall puſtules, alſo, which form on the outer margin of the ciliary edge, where the laſhes grow, and are known by the name of ſtyes, have, in ſome inſtances, brought on an inflammation, which has been continued to the ſebaceous glands, and produced all the conſequences above deſcribed. This diſorder is often ſpoken of as ſymptomatic, and the effect of ſcrophula, ſcurvy, or lues venerea; but it is very often, if not moſt frequently, a local complaint; it cannot be known to be any other, except by ſuch ſymptoms as evidence the preſence of theſe diſorders. Yet, though this diſeaſe moſt commonly takes place without any other complaint, at leaſt, as far can be diſcovered, it is yet neceſſary to be obſerved, that it is ſometimes accompanied with the plaineſt marks of a ſcrophulous conſtitution, and ſeems evidently to ariſe from it.

Monſ. St. Yves obſerves, that we ſhould diſtinguiſh this kind of complaint from the tetters on the eye-lids; the two differing only in the tetters never being accompanied with the ectropium, or turning out of the eye-lid, which frequently happens in the pſorophthalmia.

Thoſe ulcerations that appear to be ſuperficial, are not generally tedious to remove; but if they are deep, they are much more difficult to cure than thoſe attended with fungous fleſh.

In order to the cure, it hath been the general cuſtom to touch the edges of the eye-lids, where the ulcers were ſpread, with the lapis infernalis, perhaps two or three times a week; but to moderate the ſeverity of this method, the part was preſently waſhed with pure water. However, the pain excited by this application ſeems much to have deterred from its uſe; and Mr. Ware hath propoſed a method of relief, equally effectual, but by far leſs exceptionable. He directs, when this kind of inflammation extends over the whole ſurface of the eye-lid, and on the cheek, taking on the appearance of an eryſipelas, that it be treated with antiphlogiſtics and ſedatives; and when the extreme irritability is removed by proper applications, to finiſh the cure by means of the ungt. citrinum Ph. Ed. uſed, as hereafter directed.

Sometimes the lower eye-lid turns outward in this diſeaſe, which then proves obſtinate to cure, but with due perſeverance it is overcome by the general method only propoſed for the pſorophthalmy.

If in any inſtance, other ſymptoms evidence the preſence of a ſcurvy, ſcrophula, or venereal taint, thoſe diſeaſes muſt be relieved, before any benefit can be procured for that of the eye-lid. When a ſcrophula is the ſource of this diſeaſe, though the patient is perfectly cured, as far as reſpects the external ſymptoms, there is ſtill a danger of its returning; to prevent which, ſuch means as are uſed in ſcrophulous caſes ſhould be continued for a conſiderable time after.

With reſpect to the pſorophthalmia, the firſt endeavour ſhould be to ſoften the ſcabs, and remove them, and to uſe ſuch applications to the ulcers, as may correct the acrimony of the diſcharge, promote digeſtion, and bring them into a ſtate of healing. The intention of Monſ. St. Yves, in his direction for the cure of the ulcers, on the edges of the eye-lids, ſubſequent to the ſmall-pox, does not appear to be much unlike that which I have here mentioned, as appears from the following quotation. "Ophthalmic waters, in general, are of very little ſervice; but I have found, from my own experience, that, by touching them with the lapis infernalis, they cicatrize eaſily. The violent heat of the cauſtic muſt be abated as ſoon as they have been touched, by waſhing the eye in a ſmall glaſs full of warm water; you muſt, above all, take care that the part of the eye-lid, which was cauterized, may not bear againſt the globe of the eye, till the pain is entirely gone off. They may be touched in this manner, once or twice a week, until they ſeem to require no more uſe of the cauſtic: then lay on theſe places tutty, finely powdered, to cicatrize them." Monſ. St. Yves here recommends a very ſtrong cauſtic; but on a part ſo tender, a milder application will ſucceed, as is evident from the advantages attending that which I have preferred, viz. the ungt. citrin. which may be uſed as follows. Hold the ointment before a lighted candle, ſo that its ſurface may be melted into an oily conſiſtence; take this oil on the end of the finger, and carefully rub it on the edges of the affected eye-lids. The uſe of it, once in twenty-four hours, will be ſufficient; and that ſhould be when the patient goes to bed: immediately after the application, a ſoft plaſter, ſpread with the cerat. alb. Ph. Lond. is to be bound looſely over the eye-lids, which will preſerve them moiſt and ſupple in the night, and contribute to prevent their adheſions to each other. If notwithſtanding this cerate being applied, it ſhould be difficult to open the eye-lids in the morning, they may be waſhed with milk and freſh butter, well mixed together, and warmed, by which the patient will be able to open them without pain. If the eye-lid is very irritable, the melted ointment may be applied with a camel-hair pencil: indeed, ſometimes the irritability is ſo great, that before the ointment can be applied, other means muſt be uſed to remove that ſymptom, as is already noticed.

If in conſequence of this diſeaſe of the eye-lid, the eye itſelf ſhould be inflamed, the uſual methods of relieving an inflamed eye, may be uſed.

See St. Yves on the Diſeaſes of the Eye. Ware's Remarks on the Ophthalmia.

TRAGACANTHA. Goat's thorn, from τράγος, *a goat*, and ἄκανθα, *a thorn*, becauſe its pods reſemble a goat's-beard. It is alſo called ſpina hirci, and aſtragalus. Aſtragalus-tragacantha Linn. It grows in the ſouth of France, Italy, &c. but it is only thoſe which grow in the eaſtern countries that yield the gum.

TRAGOPOGON. Goat's-beard. This plant is thus named, becauſe its downy ſeed, while incloſed in the calyx, reſembles the beard of a goat.

There are ſeveral ſpecies; their roots are ſoft, ſweet, nutritive, and laxative, ſomewhat diuretic and expectorant, but in too ſmall a degree to have gained a place in practice. See Raii Hiſt.

TRAGOPYRUM. Fagopyrum.

TRAGORCHIS. A ſpecies of orchis.

TRANSVERSALES MAJORES COLLI. Theſe muſcles are long and thin; they are placed along the tranſverſe apophyſes of the neck, and the four, five, or ſix upper bones of the back, between the complexus major and minor. They riſe from the tranſverſe apophyſis, and are inſerted into the next neareſt apophyſes, and ſometimes to other more remote ones.

TRANSVERSALES COLLI MINORES. i. e. Inter-tranſverſales.

TRANSVERSALES NASI. Theſe muſcles riſe from the upper-part of the upper-lip, and run to the ridge of the noſe.

TRANSVERSALIS. A name for the teres minor.

TRANSVERSALIS ABDOMINIS. The tranſverſe muſcle of the belly. Theſe muſcles (one on each ſide) take their name from the direction of their fibres. They riſe from the tranſverſe proceſſes of the lumbal vertebræ, the ſpine of the os ilium, the ligamentum pubis, and the cartilaginous endings of the ribs below the ſternum, from whence their fleſhy parts run over the peritoneum, and become a broad, expanded tendon, before they run under the rectus, to their inſertion into the whole length of the linea alba. When they act, they preſs the belly inwards, depreſs the ribs, &c.

TRANSVERSALIS ANTICUS PRIMUS. It is ſituated between the baſis of the occipitis, and the tranſverſe apophyſis of the firſt vertebra of the neck.

TRANSVERSALIS ANTICUS SECUNDUS. It is fixed by one extremity very near the middle of the tranſverſe apophyſis of the ſecond vertebra of the neck, and by the other, near the baſis of the firſt.

TRANSVERSALIS DIGITORUM. This muſcle lies tranſverſely under the firſt phalanges of the toes: it is fixed to the firſt phalanx of the great toe, and its other end is inſerted into the firſt phalanx of the little toe.

TRANSVERSALES DORSI MINORES. Winſlow ſpeaks of theſe as being fixed to the extremities of the lowermoſt tranſverſe apophyſes of the back.

TRANSVERSALIS PEDIS PLACENTINI, i. e. Adductor minimi digiti.

TRANSVERSALIS URETHRÆ. It is a digaſtric muſcle: it lies along the lower part, or the looſe edge of the ligamentum pubis interoſſeum; its two extremities are fixed in the branches of the oſſa pubis, its middle tendon lying on the middle of the edge of the ligament juſt named.

TRANSVERSO SPINALIS COLLI, DORSI, & LUMBARES, i. e. Multifidus Spinæ.

TRANSVERSUS, i. e. Pronator.

TRANSVERSUS EXTERNUS CARPI LIGAMENTUM. It begins by a broad inſertion, fixed in the large extremity of the radius, about two fingers breadth above the ſtyloid apex, it afterwards croſſes obliquely, partly over the convex ſide of the baſis radii, and partly over that of the carpus, and then turning towards the os orbiculare is inſerted therein.

TRANSVERSUS INTERNUS CARPI. It is an annular ligament.

TRAPEZIUM, [Os]. The firſt bone of the ſecond row in the wriſt. So called from its ſhape, which is that of a trapezium.

TRAPEZIUS MUSCULUS. See CUCULLARIS.

TRAPEZOIDES, [Os]. The ſecond bone of the ſecond row in the wriſt. It is ſhaped more like a pyramid with its point broken off, than like a trapezium.

TRAULOTIS. The Pſelliſmus Ringens.

TRAUMATICA, from τραυμα *a wound*. Vulnerary medicines. Thus the Greeks called corroborants that were aſtringent agglutinants.

TREMOR. See HORROR. *Tremors* happening from too free a uſe of ſpirituous liquors, and other exceſſes, uſually require the ſame treatment as palſies.

Dr. Cullen, conſiders it as always ſymptomatic, and conſequent on extreme debility, palſy, or convulſion. It is a trembling, without a ſenſation of cold.

TREPANATIO. The operation of trepaning. As much as this operation is commended by ſome, there are others among the moſt eminent modern practitioners, who forbid it in all caſes of injury done to the head, except when the ſkull is depreſſed.

This operation is propoſed to relieve the brain from depreſſed parts of the ſkull, fragments of the broken bones of the ſkull, extravaſations of matter upon or under the membranes of the brain, and other cauſes of preſſure, of irritation, and of inflammation, &c. Many parts about the ſkull are objected to, but the operation hath been performed on moſt of them with the happieſt ſucceſs; and as to the reſt, ſimilar objections lay againſt ſome parts on which cuſtom allows the *trepan* to be uſed. The operation reſolved on, the inſtruments, dreſſings, &c. muſt be in readineſs; then the head being ſhaved, muſt be held ſteady upon a perſon's knee, with a proper knife and the ſcalprum, a piece of the ſcalp, muſt be removed: enough ſhould be ſeparated at the firſt to give room for a ſufficient number of perforations. In cutting be careful to cut through to the bone at the firſt eſſay, and the edge of the knife ſhould be ſo inclined as to cut more of the pericranium than of the ſkin, then raiſing the pericranium a little with the point of the knife, quite round the inciſion, and then with the ſcalprum clear the ſkull of its membranes. The trephine is the moſt commodious inſtrument, for it works both backward and forward. When the ſaw hath entered well into the bone, take out the central pin of the trephine, and ſometimes take out the ſaw to examine the depth to which it hath paſſed, and to bruſh out the ſmall portions of bone that might impede the operation; the diploe is ſometimes wanting, ſo ſhould be attended to; as ſoon as the piece is looſe, take it out with the forceps, and if the lower edge of the perforation is rough, ſmooth it with the lenticular; this done, raiſe the depreſſed piece of ſkull with an elevator, which now is made with fulcra to reſt on the ſound bone; after this, if extravaſated matter ſeems lodged under the dura mater, open it with a lancet for its diſcharge. When the trephine is uſed on account of a fiſſure, it muſt be applied ſo as to include part of it, if not directly over it, as is moſt likely that the extravaſated blood or lymph will be found directly under it; and when the fiſſure is of a conſiderable extent, a perforation muſt be made at each end, if not more. When ſeveral perforations are to be removed, in order to the removal of ſeveral depreſſed fragments of bone that have their internal ſurface larger than their external, it is neceſſary to apply the trepan as near the fractured parts as they will admit of, making the perforations adjoining to ſave the trouble of cutting the intermediate ſpaces with the head-ſaw. In places where the unequal thickneſs of the ſkull is obſerved, it is beſt to elevate the piece that is ſawed before it is cut quite through, thus the membrane will be unhurt. When an injury happens on a ſuture, and it is not thought adviſable to uſe the trepan there, make a perforation on each ſide of it. By the trephine having removed the pieces of bone, and thereby prevented all the preſent and future ills dependent on their remaining; after this, the dreſſing ſhould accord with the general intention of not irritating, and ſhould be as innocent in quality, and ſmall in quantity as poſſible; clean dry lint to abſorb the matter, is all that can be wanted, this may be kept on by a common woollen cap, which is preferable to all bandages whatever. After dreſſing, lay the patient in as eaſy a poſture in bed as poſſible, and with his ſhoulders raiſed high. Perfect quietude, open bowels, and the veſſels emptied by veneſection, and a low diet, are to the full as neceſſary before as after removing the pieces of the ſkull. The air of the patient's room ſhould be temperate. In young people the perforations are in time filled up with a ſubſtance that is of a bony hardneſs; but in adults this does not happen ſo perfectly. Sometimes a fungus proves troubleſome, but it is beſt prevented by applying a plate of lead, as invented and deſcribed by Belloſte See his Hoſpital Surgeon, Heiſter's Surgery, Sharpe's Operations, Gooch's Caſes and Remarks.

TREPANUM. A trepan. An inſtrument to bore the ſkull with.

TREPHINE. An inſtrument with which we perforate a bone; chiefly uſed in the operation, called trepanning. It hath been variouſly formed, and thence received different names: e. g. Abaptiſta, abaptiſton, anabaptiſton, modiolus, terebra, terebellum, and trepan. Until lately, the trepan was, and ſtill is very generally uſed on the continent; however, the *trephine* is more commodious, and acts as quickly as the trepan. See TREPANATIO.

TRIANDRIA DIGYNIA. So Linnæus terms the ſecond order of the third claſs of vegetables.

TRIANGULARES STERNI. Theſe muſcles riſe from the ſide and edge of the ſternum and xiphoid cartilage internally, and are inſerted into the cartilages of the ſixth, fifth, fourth, third, and ſecond ribs, to depreſs them.

TRIANGULARIS. A name of the following muſcles, viz. the depreſſores labii ſuperiores, ſcaleni, deltoides, tranſverſales urethræ, &c.

TRIANGULARIS VENA. A name for the external jugular vein, where it paſſes through the muſculus triangularis.

TRIBULUS AQUATICUS. Water caltrops. It is a plant which grows in watery places in ſome parts of Germany and in Italy; but it is not noticed in practice.

TRICA LUMBORUM. A ſpecies of plica Polonica.

TRICAUDALIS, i. e. Abductor auris.

TRICEPS AURIS, i. e Abductor auris.

TRICEPS. Thus it is named in Galen's works. It riſes by its firſt head from the fore part of the os pubis and its tendon is inſerted into the linea femoris aſpera, and is then blended with another head which runs down to the knee. The ſecond head riſes from the forepart of the os pubis, and is inſerted higher in the linea aſpera. The third head takes its origin from the ſmall proceſs of the iſchium, cloſe to the obturator externus, and is inſerted in the linea aſpera behind the little trochanter. The fourth riſes from the iſchium and its tuberoſity, and it is inſerted in the linea aſpera, and, joining with the firſt, forms a tendon which goes to the knee, blended with that of the vaſtus externus.

They move the thigh bones inward, according to their

different directions, and bring them to each other. Douglas makes this into four muſcles, and calls the firſt, adductor femoris primus; the ſecond, adductor femoris ſecundus; the third adductor femoris tertius; the fourth, adductor femoris quartus. The fourth head he makes by dividing the upper part of the third head into two. The third and fourth are deſcribed by Albinus and Winſlow, as one muſcle, under the adductor magnus femoris, & le troiſieme muſcle du *triceps*.

TRICHIA, or Trichiaſis, from θρὶξ, *a hair*. It is alſo called entropium, diſtichiaſis, diſtrichiaſis. It is, when the cartilage on the edge of the eye-lid is ſo inverted as to bear upon the conjunctiva, and the cornea tranſparens; then the friction of the eye-laſhes excites an inflammation in the eye. According to the author of the Definit. Medicæ, it is, "A falling of the eye-lids and a preternatural generation of hairs on them." He makes three ſorts, to which he gives the names of phalangoſis, ptoſis, and hypophyſis, and as ſome ſay, a fourth, viz. diſtichia. Actuarius calls the *trichiaſis* by the name of trichoſis.

The friction of the eye-laſhes in this caſe, brings on defluxions and inflammations, if not prevented by pulling out the hairs, one by one, at ſuch diſtances of time, as may be neceſſary for preventing inflammation thereby.

In Dr. Cullen's Noſology this diſeaſe is an inſtance of ſymptomatic ophthalmy, called ophthalmia *trichiaſis*.

The word entropium, i. e. the turning inward of the eye-lid, is referred to this article, as being occaſionally a cauſe of inflammation in the eye, by directing the eye-laſhes againſt the conjunctiva. Indeed Heiſter calls the inverſion of the eye lids the trichiaſis. Mr. Ware, in his remarks on the ophthalmy, &c. diſtinguiſhes as follows, betwixt the inverſion of the upper and under eye-lids, both as to the cauſe and cure. And ſpeaks,

Firſt, of the inverſion of the upper lid.

The upper lid and its ciliary edge (he obſerves) are preſerved, both in motion and reſt, in their natural ſituation, by the equal, though contrary, actions of the muſculus orbicularis, and levator palpebræ ſuperioris. The ſkin of the upper lid is always very thin, flaccid and folded. When therefore the *trichiaſis* affects the upper lid, it appears to be produced by a relaxation of the levator palpebræ ſuperioris, and a contraction of the ſuperior part of the orbicularis. The cure, either in the upper or lower lid, is palliative, or radical. It is only palliative, when in order to relief the eye-laſhes are extracted by their roots. The radical cure is affected by detracting the ciliary edges, and preſerving them in their natural ſituation. The cauſe being a relaxation of the levator palpabræ ſuperioris muſcle, an inciſion muſt be made through the integuments of the upper eye-lid, from the inner angle of the eye to the outer; then the fibres of the orbicularis muſcle muſt be ſo ſeparated, as to denudate the expanded fibres of the levator muſcle, as near to their termination in the edge of the lid as poſſible; which being done, apply a ſmall cauteriſing iron, adapted to the convexity of the globe of the eye, and made pretty warm, by paſſing it two or three times over the tendino-carneous fibres. Thus, by producing a ſlight irritation, (which produces the ſame effect, as is often obſerved to happen after burns, particularly in the hands, after which the fingers often contract, and in many inſtances have remained contracted ever after) a cure may be expected.

Secondly, of the inverſion of the lower lid.

The lower lid, whoſe motion is very ſmall, in compariſon with that of the upper, is preſerved in its natural ſtate, by the equal action of the orbicular fibres ſpread over it, and the thickneſs and renitency of the ſkin which covers it. When therefore a *trichiaſis* is produced in the lower lid, it can only ariſe from a relaxation of the ſkin, and a contraction of the inferior part of the orbicularis. The cure will neceſſarily be effected by increaſing the renitency of the ſkin to ſuch a degree, as to prevent the contraction of the muſculus orbicularis. When the caſe is recent, a cure hath ſometimes been effected, by forming a fold in the ſkin before the inverted lid, to draw its edge from the eye, and preſerving the ſkin in that ſtate by the application of ſticking plaſter: or, by means of an inſtrument ſimilar to that contrived by Bartiſchius, (and repreſented by Heiſter, plate 15, fig. 20.) to pinch up a ſmall portion of the ſkin, and hang thereby on the cheek; which by its weight, anſwers the ſame purpoſe as the plaſter, and is leſs liable to loſe its hold. In ſlight caſes, the ſkin may recover its tone by theſe means; but in others, it will be neceſſary to cut off a ſmall tranſverſe portion of the looſe ſkin below the edge of the lid, and afterwards confine the ſides of the wound together by means of a future.

Sometimes there are inſtances in which none of the above methods will ſuffice; as, where the ciliary edges are not only inverted but likewiſe contracted or ſhortened in their length. In this caſe, the circumference of the ciliary edges muſt be enlarged either by an inciſion at the outer angle, or by a complete diviſion of the cartilage, called tarſus, in the middle. The firſt of theſe operations is no more than a ſimple ſtraight inciſion, which may be made with a ſharp-pointed curved biſtoury. The laſt, which is ſeldom neceſſary, will be beſt performed by the ſame inſtrument; only obſerving, that the point be carefully introduced between the globe and eye-lid, and carried below the cartilage, (that is about $\frac{1}{4}$ of an inch;) whence it is to be puſhed outward in a horizontal direction, till it hath cut its way through the lid. The cartilage being thus entirely divided, each portion will recede towards the angles, and a ſeparation be left between them, which will not only take off the complaint at preſent, but prevent its return for the future.

TRICHIASIS. It is an affection of the urine, in which ſomething like hairs is ſeen floating. In Erotian, it ſignifies fiſſures, or a roughneſs in the ſkin of the breaſt, though he calls an abſceſs in a woman's breaſt thus.

TRICHOMA. See PLICA POLONICA.

TRICHOMANES. See ADIANTHUM.

TRICORNES. So muſcles are called which have three terminations.

TRICUSPIDES VALVULÆ. The name of the three valves which are placed at the mouth of the right ventricle of the heart, juſt at its juncture with the auricle.

TRIFOLIUM. Trefoil. Boerhaave takes notice of thirty-ſix ſpecies, ſeveral of which are called clover, and are uſed for feeding of cattle only. See Raii Hiſt.

TRIFOLIUM ACIDUM. Wood-ſorrel.

TRIFOLIUM PALUDOSUM. Marſh trefoil, or buck-bean. Menyanthes Trifoliata, or Menyanthes paluſtris latifolia foliis ternatis, Linn. It is a plant with large oval leaves, pointed at each end like thoſe of the garden-bean; ſet three together on long pedicles, which embrace the ſtalk to ſome height, and there parting, leave it naked to near the top, where iſſues forth a ſhort ſpike of pretty large reddiſh white monopetalous flowers, each of which is cut into five ſegments, hairy on the inſide, and followed by an oval ſeed veſſel. It is perennial, grows wild in marſhy places, and flowers in May. The leaves are of a penetrating bitter taſte, which they impart both to watery and to ſpirituous menſtrua, without any remarkable flavour; they are uſed as alternative and aperient, in hydropic and rheumatic caſes. They are uſually infuſed in water, with the addition of ſome grateful aromatic, ſuch as orange peel, or the canella alba. ℔ i. of this infuſion ſhould be drank in a day; it paſſes off by urine, and renders the belly lax. See Lewis's Mat. Med.

TRIFOLIUM. It is a name for many plants which are not included in the kind which bear this name.

TRIGEMINUS MUSCULUS, i. e. Complexus.

TRIGLOCHINUS, i. e. Tricuſpides.

TRIGONELLA. Fenugreek. The ſpecies in uſe, is the trigonella fœnum-græcum, or trigonella Monſpelienſis, foliolis obovatis, leguminibus ſeſſilibus ſtrictis erectiuſculis ſubfalcatis acuminatis, caule erecto. Linn. Fenugreek. The ſeeds only are uſed. See FOENUM GRÆCUM.

TRINITAS. A name of the trifolium, and for the viola tricolor.

TRIORCHIS. A perſon with three teſticles, alſo a name for a ſpecies of orchis.

TRIPLEX MUSCULUS, i. e. Triceps.

TRIQUETRA OSSA. They are alſo called Wormiana, from Wormius, who firſt obſerved them. They are ſmall irregularly ſhaped pieces, principally betwixt the parietal and occipital bones, and are joined by true ſutures to their adjacent bones.

TRIPASTRUM APPELLIDES. A machine for reſtoring fractures and luxations, thus named, becauſe it reſembled a machine invented by Apellides and Archimedes, and becauſe it was worked with three cords.

TRIPASTRUM ARCHIMEDES, i. e. Tripaſtrum Apellides.

TRISMUS. The locked jaw. Dr. Cullen places this genus of diſeaſe in the claſs neuroſes and the order ſpaſmi: he defines it to be a ſpaſtic rigidity of the lower jaw. He obſerves two ſpecies. 1. *Triſmus* Naſcentium. To this, infants are ſubject during the firſt two weeks after their birth. 2. *Triſmus* Traumaticus. To this perſons of any age are ſubject, either from a wound, or from cold. See *Tetanus*.

TRISSAGO, i. e. Chamædrys, alſo Scordium.

TRISTITIA. Grief, or ſorrow. *Grief* relaxes the ſolids, ſlackens the motion of the fluids, and deſtroys the health; it particularly weakens the ſtomach and inteſtines, occaſions flatulence and every ſymptom of weakneſs. Opiates, if not given in large doſes, are good cordials in this caſe.

TRITÆOPHYA, from τριταῖος, a tertian, and φύω importing ſimilitude of nature, or original; it is an epithet of a fever, much of a nature with a tertian, and taking its riſe from it. This ſort of fever is almoſt continual, its intermiſſions are obſcure or ſhort. Linnæus calls it a continued tertian. Erotian and ſome others ſay, it is a fever which gives ſigns of its approaching paroxyſms, but whoſe intervals are regular, as it never arrives at perfection; and that it takes its name from its great reſemblance of a tertian; and that it is called a ſmall ſemitertian. See James's Med. Dict. art. TRITÆOPHYES.

TRITÆOS, τριταῖος. A tertian.

TRITÆUS. The ſame as Tritæophya.

TRITICUM. Wheat. Triticum Hybernum. Linn. Whether in the form of flour, or of ſtarch, it is the moſt glutinous of the farinacea. In Italy they make vermicelli of the fineſt flour of wheat.

TRITORIUM. A glaſs for ſeparating the oil from the water, which is obtained by diſtilling. It is alſo called a ſeparatory glaſs.

TROCAR. The name of an inſtrument uſed to diſcharge the water with, in an aſcites. The word *trocar* is a corruption of the French words *un trois quart*, *a three quarters*, from the three ſides with which the point is made.

TROCHANTERES. Two proceſſes of the thigh-bone, one of which is larger than the other. See FEMORIS, OS. From τρέχω, *to run*, becauſe ſeveral muſcles that move the thigh are inſerted into them.

TROCHISCI. Troches. It is a form agreeable enough for children, and thoſe who object to every thing that is not a ſweet-meat, and a preparation from the confectioner. *Troches* are alſo called tablets and cakes. They are made by mixing the medicine with a proper quantity of ſugar, and the mucilage of gum tragacanth; and when formed into a ſtiff paſte, it is cut into proper portions, and dried.

TROCHLEA. Τροχλία, *a pulley*. A kind of cartilaginous *pulley*, through which the tendon of one of the muſcles of the eye paſſes.

TROCHLEARIS MUSCULUS, i. e. Obliquus major oculi, or Obliquus Superior.

TUBA ARISTOTELICA, i. e. Tuba Euſtachiana.

TUBA EUSTACHIANA. It was firſt diſcovered by Alcmæon, a diſciple of Pythagoras; he called it the auditory paſſage. Euſtachius claims the firſt diſcovery, and from him it hath its preſent name. Fallopius calls it the aquæduct; ſome call it ductus auris palatinus. This tube paſſes from the fore-part of the drum of the ear, to the back part of the noſe, above the root of the velum pendulum palati, and allows the air to paſs inwards.

TUBÆ FALLOPIANÆ. Theſe tubes will receive a hog's briſtle from out of the uterus, where they begin; they then proceed in a tortuous manner, and terminate at the ovaria, in an irregular round jagged extremity, where their diameter is about a third of an inch; this fringe is called morſus diaboli, and is hung upon a membrane like the meſentery, between the doublings of which the veſſels run to the tubes. Fallopius diſcovered them.

TUBÆ NOVUS VALSALVÆ MUSC. i. e. Palato-ſalpingæus.

TUBERA. Tumors of the ſolid parts, not dropſical; as hardened glands, &c.

TUBERCULUM. A tubercle, or little tumor, the ſame as Phyma. See VOMICA.

TUBERCULUM LOWERI. See COR.

TULIPA. The tulip, or the Dalmatian cap. *Tulipa* is a Turkiſh word, ſignifying a turbant. The *tulip*, firſt deſcribed by Geſner, was brought from Conſtantinople, A. D 1590. No flowers are ſo variable in their colours as the *tulip* and poppy; their colours change by tranſplanting the roots. The ſeeds of one *tulip* produces flowers of all colours. The roots have the ſame virtues as the common parſnep; but it is only the flower that is regarded, and that as an ornament in gardens.

TUMIDOSI. The ſame as Intumeſcentiæ.

TUMIDUM, i. e. Bronchocele.

TUMOR. A tumor. It is a diſeaſe in which the parts of the body recede from their natural ſtate by an undue increaſe of their bigneſs. In Dr. Cullen's Noſology, *tumores* is an order in his claſs, locales, &c. ſignifies a morbid enlargement of a part, without being cauſed by inflammation. *Tumors* receive different names, according to their ſituation, figure, contents, &c. and there are but few general names but what are again divided into different ſpecies, e. g. when pus is the contents of a *tumor*, it is called an abſceſs; if an abſceſs is in the lungs, it is called a vomica; if in the finger-end, it is called whitlow, &c. all theſe ſee in the article ABSCESSUS. When the matter is contained in a bag, the *tumor* is called an encyſted *tumor*; and theſe take different names according to their contents, as atheroma, meliceris, ſteatoma, &c. and theſe are to be extirpated whilſt ſmall, if ſituated where the knife can be ſafely uſed; though when their contents are ſoft, they may be ſuppurated and diſcharged by an opening, then the cyſt is to be deſtroyed by eſcharotics. Œdomatous *tumors* generally depend on ſome other diſeaſes, and on the removal thereof theſe kind of *tumors* uſually diſappear. Scrofulous *tumors* are only relieved by removing the habit on which they depend, ſee SCROFULA; and for other *tumors*, ſee the reſpective articles under which each of them is treated in, as the ANEURISM, the VARIX, the different kinds of HERNIAS, &c.

TURBINATA OSSA. See ETHMOIDES Os, and SPONGIOSA OSSA.

TURBINATUM. The pineal gland.

TURBITH, alſo called turpethum, and turpetum. It is the cortical part of the root of a ſpecies of convolvulus which is met with in the Eaſt Indies; the convolvulus turpethum, Linn. It is in oblong pieces, of a brown, or an aſh colour on the outſide, and whitiſh within. The beſt is ponderous, not wrinkled, eaſy to break, and diſcovers to the eye a large quantity of reſinous matter. This bark is cathartic, but ſo unequal in its ſtrength, that it is now neglected in practice. See Neumann's Chem. Works, Lewis's Mat. Med.

TURBITH. A name of ſome kinds of ſeſeli.

TURCICA SELLA, i. e. Sphenoidalis Sella.

TURPETHUM, i. e. Turbith.

TURPETHUM MINERALE, i. e. Merc. emet flav.

TURRITIS. Tower muſtard. There are ſeveral ſpecies of this plant, but they are not noticed in the preſent practice.

TURUNDÆ. Tents. They are uſually made of lint, and introduced into deep wounds. They are uſed, 1. To convey medicines to the bottom of a wound. 2. To hinder the external part of a wound from healing before the bottom. 3. The better to clean wounds from what ſhould not be retained in them; but they ſhould be very ſoft, that they may neither obſtruct the diſcharge of matter, nor hinder the healing of the wound in general. *Tents* are made of ſponge, for dilating the orifices of wounds; they are alſo made of the dried roots of gentian, turneps, comfrey, calamus aromaticus, &c.

TUSSILAGO, alſo called bechium, farfara, farfarella. Colt's-foot. *Tuſſilago* Farfara; or, *Tuſſilago* foliis ſubcordatis angulatis denticulatis, ſcapo imbricato unifloro, floribus radiatis. Linn. It is a low plant, producing early in the ſpring ſingle ſtalks, each of which bears a yellow floſculous flower, followed by ſeveral ſeeds winged with down; the leaves, which ſucceed the flowers, are ſhort, broad, angular, ſlightly indented, green above, and hoary underneath. It is perennial, and grows wild in moiſt grounds.

grounds. The leaves and flowers are mucilaginous, bitterish, and roughish; they have little or no smell; infusions of the leaves are sweetened with liquorice for a common drink, when a troublesome cough attends: but if any considerable advantage is expected, a strong decoction should be made, and used freely. See Lewis's Mat. Med.

TUSSIS. A cough. It is a violent expulsion of some sort of matter from the bronchia of the lungs, by means of a convulsive force in them, and it is accompanied with a violent expiration. Dr. Cullen observes that it is generally a symptomatic catarrh.

The seat of every *cough* is in the breast, but the remote cause is variously situated. The diversity of this cause produces a variety in the species of this disorder. The principal seat is the aspera arteria, and the bronchia; these are irritated, or the morbid irritation may be in some part adjacent, as the diaphram, the stomach, the œsophagus, the pleura, the external surface of the lungs, &c. What in the stomach causes a vomiting, in the bronchia will cause a coughing. Vellications may be produced in the bronchia by consent of parts, as happens when *coughs* attend in pleurisies, wounds about the neck, inflammation of the liver, &c. Exhalations which float in the air, &c. are sometimes a cause; defluxions of rheum, or an acrid mucus falling from about the head, may irritate the aspera arteria, and excite a *cough*. Acrid matter in the stomach, or in the duodenum, is a frequent cause of this complaint. Spasmodic disorders are often attended with a *cough*, the lungs suffering either by consent from the seat of the spasm, or becoming in their turn the seat of that which produced the spasm in some distant part; but, perhaps, of all the causes, there are not any so frequent as that of defective perspiration.

A dry *cough* generally becomes a moist one; which, if of long continuance, destroys the appetite, weakens digestion, induces a cachectic habit, and a hectic fever. Lommius observes, that a *cough* passing into one of a dry kind, and leaving a sense of weight in the breast, subjects the patient to a putrid, or to a hectic fever. *Coughs* which succeed a scirrhus in any of the viscera, are generally incurable. It often happens that when a *cough* ushers in a disease, that it ceases as the approaching disorder is more manifest. A moderate heat in the night, an equable moisture all over the body, a copious discharge of urine, a due solubility of body, tranquil sleep, and an easy expectoration, are sure signs that the *cough* is in a fair way to be removed.

Coughs are generally dry ones at the first, and, whilst in this state, they may usually be cured by chewing, immediately after every fit of coughing, about a scruple of the bark; the belly must be kept lax, and the feet warm, and perspiration must be promoted. Dry *coughs* generally become moist by spoiling the digestion; though it is proper to observe, that in hypochondriac, and some other habits, the *cough* is usually dry, and in phlegmatic relaxed habits it is moist.

If the bronchia are obstructed with viscid phlegm, the best resolvents are the rad. irid. flor. rad. scllar. gum ammon. or rad. allii.

Thin acrid humours are best carried off by incrassating medicines, such as the rad glychiz. gum. trag. spermacæti, &c.

When catarrhous *coughs* are habitual, and accompanied with a loss of appetite, there is danger of a consumption; and the cure must be attempted by asses milk, whey, Seltzer water, &c.

When there is a defluxion and congestion of serum about the lungs, it is necessary to derive the serum from thence, partly by the anus, and partly by the skin. In all *coughs* perspiration must be promoted, and the belly kept soluble. As a purge, manna, or the ol. ricini, should be preferred; and to allay the cough in the night, let the following pill be given a little before bed-time. ℞ Pil. styrac. gr. vi. pil. Rusi gr. x. m. As a perspirative, many of the antimonial preparations are peculiarly useful.

When the *cough* abates, stomachic bitters, with saffron, should not be neglected.

These general methods, with a due attention to the non-naturals, will, with such peculiarities as circumstances suggest to the practitioner, prove generally efficacious to relieve, and always prove palliative in this violent disorder.

Sweet and oily medicines should rarely be admitted of, though so frequently recommended. The elix paragoric. is an excellent anodyne, and assists perspiration if taken at bed-time. When a blister cannot easily be complied with, a plaster of Burgundy pitch may be substituted for it, a fresh one being used as soon as the old one begins to separate from the skin.

When a bad digestion is the cause, or acrid matter in the stomach, a vomit may be directed, and after it a mixture of tinct. rhab. sacra, of each equal parts, may be taken so as to keep the bowels lax, until the disorder is removed.

Spasmodic *coughs* are removed by opiates, and nervous medicines, with the bark. See Celsus, Hoffman, Sydenham, Buchan's Domestic Medicine, Brooks's and the London Practice of Physic.

TUSSIS CATARRHALIS, i. e. A Catarrh from cold.

TUSSIS FERINA, i. e. Pertussis.

TUSSIS CONVULSIVA, i. e Pertussis.

TUSSIS FERINA. The hooping-cough.

TUTENAG. A name for zinc, also for a white metal which is compounded in China, and is called also Chinese copper. See Zinc.

TUTIA. Tutty. It is an argillaceous ore of zinc, found in Persia, formed in cylindrical moulds into tubulous pieces, like the bark of a tree, and baked to a moderate hardness. It is generally of a brownish colour, full of small protuberances on the outside, smooth and yellowish within, but sometime whitish, and at others of a bluish cast.

When *tutty* is finely levigated, it is drying and cicatrising; it is used in collyriums to repel slight inflammations in the eyes. See Lewis's Mat. Med.

TYLLOMA. A corn.

TYMPANI MEMBRANA. The membrane of the drum of the ear, is a thin, transparent, flattish pellicle, the edge of which is round, and strongly fixed in the circular groove, which divides the bony meatus of the external ear from the tympanum, or barrel. This membrane is very tense. The modulations of external air, by impressing the membrane, moves the mallees which is fixed to it, and so it proves a means of sounds being readily conveyed to the common sensory.

TYMPANITES. A tympany. It is also called a flatulent dropsy. Notwithstanding what is asserted by many eminent authors and practitioners, there are others who dispute the existence of the disorder described under this name. Dr. Cullen places this genus of disease in the class cachexiæ and order intumescentiæ. He distinguishes two species. 1. *Tympanites* intestinalis. 2. *Tympanites* abdominalis. Its immediate cause is said to be flatulencies, which are pent up in the colon, or in the rectum, according to some, and in the smaller intestines according to the description of others. Some say that the matter is partly water and partly wind.

However opinions may vary in other respects, it is generally agreed that the belly is distended principally with flatus; and as in such circumstances the chief intention is to discharge the flatulencies by the anus, antispasmodics, anodynes, and laxatives, will be indicated to relieve, and aromatic corroborants to prevent a relapse. The first intention will be probably answered by means of the sp. nitri dulc. cum tinct. Theb. and such doses of the pil. Rusi as may be required without purging too freely; the second intention will be effected by a proper use of the rad. zedoar. cort. aurant. summit. centaur. minor, &c. See Celsus, Juncker. Hoffmann, Heister, Mead, &c.

TYMPANUM. The drum, or the barrel of the ear. It is the hollow part in the bone, in which the bones of hearing are lodged, and is betwixt the pars petrosa, and the pars squamosa of the temple bones; it is of an irregular oblong figure. The cavities in the *tympanum* are, the opening of the mastoid cells, the opening of the Eustachian tube, the bony half canal, the fenestra ovalis, and the fenestra rotunda.

TYPHA AROMATICA, i. e. Acorus Verus.

TYPHA PALUSTRIS MAJOR. Typhus. See Nervous Fever. Great cat's-tail, or reed mace. It grows in marshy grounds, and the brinks of rivulets. Boerhaave takes notice of three species, but they are not used in medicine.

TYPHODES, τυφώδης. A particular kind of fever attended with colliquative sweats, and hath at the same the tongue dry and hard.

TYPHOMANIA,

TYPHOMANIA, from τύφος and μανία. In Galen's Exegeſis, it is ſaid to be "A diſorder complicated of a phrenſy and a lethargy," in which the patient is delirious, and labours under a ſleepy coma. This affection thus complicated of a phrenſy and lethargy, may be called a lethargic madneſs or delirium, or a mad and delirious lethargy, according to the author of the Definitiones Medicæ.

TYPHONIA. The ſame as Typhomania.

TYPHOS, τύφος. Hippocrates ſays there are five ſpecies of this diſorder.

Firſt. A legitimate continual fever, which reduces the ſtrength; is attended with pains in the belly; heat in the eyes, which hinders the patient from looking ſteadily on any object; the pain prevents him from anſwering any queſtions, though he begins to ſpeak and fix his eyes on any object when he is at the point of death.

Second. A tertian or a quartan fever, ſucceeded with pain in the head; ſaliva and worms are copiouſly diſcharged by the mouth; the eyes ſuffer great pain; the countenance is pale, ſo are the feet, and the whole body is ſometimes ſeized with ſoft ſwellings; the breaſt and back are now and then painful, the belly rumbles, the eyes are fierce, the ſaliva adheres to the throat and renders the voice hoarſe.

Third. There are intenſe pains in the joints, and ſometimes all over the body: the blood is hot and ſtagnates in the limbs; ſome bile retained in the joints, becomes endurated there, and produces lameneſs.

Fourth. There is violent tenſion, elevation, and heat of the belly, ſucceeded by a diarrhoea, which ſometimes terminates in a dropſy, and is ſometimes attended with fever.

Fifth. There is paleneſs and a ſort of tranſparency of the whole body, as if it was a bladder full of water, though without any inflation; on the contrary, the body is weak and extenuated. The patient winks his eyes, and feels the bed cloaths as if he wanted to catch ſomething on them, &c.

TYPHUS CARCERUM. Jail-fever. It is one of ſeverer kinds of *typhus*.

TYPHUS CASTRENSIS. The camp-fever. It is one of the ſeverer kinds of *typhus*.

TYPHUS ICTERODES. See BILIOSUS ARDENS FEBRIS.

TYPHUS. The nervous fever.

TYROSIS. A diſorder of the ſtomach proceeding from milk coagulated therein.

U.

ULCEROSA, e. i. Gutta Roſacea.

ULCUS. An ulcer. It is a ſolution of continuity in a ſoft part made by eroſion. Wounds degenerate into ulcers, when by a fault in the humours there is a further loſs of ſubſtance. A loſs of ſubſtance in the bones from eroſion, is called a caries. Though when an abſceſs is opened for the diſcharge of its contents, it is uſually ſpoken of as an ulcer Dr. Cullen places this genus of diſeaſe in the claſs locales and order dialyſes. He defines it to be a purulent or ichorus ſolution of a ſoft part.

Ulcers receive different names from their cauſes, figure, the parts they affect, &c.

External *ulcers* are diſcerned by the eye, but when they are internal they are diſcovered by what is diſcharged in one or other of the excretions.

Their danger will be judged of by the quality of the *ulcer*, the part affected, and the ſtrength of the patient.

The ſymptoms which attend and retard the healing of *ulcers* are inflammation, pain, a fluxion of morbid humours, ſpungy fleſh, &c.

Mr. Sharpe obſerves, that except the callous and the ſinuous *ulcer*, and the *ulcer* with a caries in the bone, the cure of all the other kinds depend chiefly on that of the morbid habit of the body in general. If the body is free from every degree of cacochymy, the healing of an *ulcer* is the work of nature, and all that topical applications have to effect, is the maintenance of the fibres in ſuch a moderate ſtate betwixt laxity and rigidity, as will render them moſt able to carry on this natural operation. While an inflammatory hardneſs exiſts, an emollient poultice laid over the dreſſings will relieve, after which dry lint generally ſuffices, or at the moſt it may be moiſtened in ſome mild aſtringent, to give a tone to the new fleſh. When a too great laxity, or a ſpongineſs is obſerved in *ulcers*, gently ſtimulating and bracing applications take place.

The three kinds of *ulcers* which Mr. Sharpe mentions as more particularly depending on external management, are ſo frequently joined with, or ariſe from a morbid habit of body, that regard is firſt to be had thereto, and when this kind of obſtacle to healing is removed, apply emollients to the callus on the edge of the *ulcer*; or in many inſtances ſucceſs will follow the uſe of a mixture of baſilicon, with a little finely powdered precipitate. As to the ſinuous *ulcer*, ſee FISTULA; and for the carious, ſee CARIES. See Heiſter's Surgery, Sharpe's Operations, in the Introduction.

Mr. Bell, in his Treatiſe on *Ulcers*, divides them into two claſſes, viz. 1. Such as are merely local, and that do not depend upon any diſorder of the ſyſtem. 2. Such as are the conſequence of, or that are connected with any diſorder of the conſtitution.

The ſpecies belonging to the firſt claſs, are, 1. The ſimple purulent *ulcer*. 2. The ſimple vitiated *ulcer*. 3. The fungous *ulcer*. 4. The ſinuous *ulcer*. 5. The callous *ulcer*. 6. The carious *ulcer*. 7. The cancerous *ulcer*. 8. The cutaneous *ulcer*.

The ſpecies belonging to the ſecond claſs are, 1. The venereal *ulcer*. 2. The ſcorbutic *ulcer*. 3. The ſcrophulous *ulcer*.

The ſimple purulent *ulcer*, is a local affection; it hath the ſymptoms common to all ſuch diſorders, as pain and inflammation, in a very inconſiderable degree, whilſt the diſcharge afforded, is always of a mild purulent nature, and of a proper conſiſtence; the granulations which ariſe in it are of a firm, freſh red, healthy appearance. This *ulcer* is the moſt ſimple that can occur, both in its ſymptoms and method of cure; and it is to its ſtate, that all others muſt be reduced before a permanent cure can be expected. In the cure of this ſpecies of *ulcer*, as there is very little inflammation, and no preternatural ſwelling ſuppoſed to take place, but merely a vacuity, either from a real loſs of ſubſtance, or from a retraction of parts ſimply divided, the diſcharge at the ſame time being of a mild purulent nature, the only indications that appear neceſſary are, 1ſt. To diminiſh, as much as poſſible, any vacancy the *ulcer* may have occaſioned; to accompliſh which, the formation

of new granulations, and the decay of ſuch parts as be immediately contiguous to the *ulcer* are requiſite. To effect the formation of new granules, inflammation and acrimony muſt be removed, and pledgets of lint ſpread thinly with the ungt. cereum Ph. Edinb. may be applied every twelve or twenty-four hours, to the ſurface of the ſore. If inflammation attends the *ulcer*, moderate it by the application of warm emollient cataplaſms; but as ſoon as this inflammation ſubſides, omit the cataplaſms, leſt an exceſs of laxity be produced. Thus, by mild dreſſings irritation is prevented, and by preſerving a proper degree of heat in the part, a good matter will be produced and firm granulations. To diminiſh or deſtroy the parts about the *ulcer*, ſuch as fungous fleſh; as ſoon as the inflammatory ſtate is over, and good matter is induced, ſlight compreſſion, by means of a roller, may be immediately applied, and ſhould be continued during all the remainder of the cure. The roller ſhould be applied ſo, as not only to act as a gentle preſſure upon the parts immediately ſurrounding the *ulcer*, but likewiſe to ſerve as a ſupport to the ſkin, and other teguments, ſo as to prevent their retraction, which otherwiſe in large *ulcers* eſpecially is very ready to happen. 2dly: To induce the formation of a cicatrix. This is frequently effected by nature alone; but, in many caſes, when every deficiency appears to be even thoroughly ſupplied, yet ſtill a cure is tedious in accompliſhing; the ſurface of the ſores remaining raw, and, at the ſame time, diſcharging conſiderable quantities of matter. In ſuch caſes, the ointment uſed for the preceding part of the cure muſt be laid aſide, and dreſſings of a more drying nature ſubſtituted in its ſtead. In this view the ungt. alb. ex ceruſſ. a. &c. is preferable to the cerot. epulot. Sometimes the cicatrization will be ſoon perfected, by dabbing the part or parts, twice a day, with aq. calc. ſi. and ſtill dreſſing with the ungt. e ceruſſ. If the cicatrization is prevented by ſpongy granulations or even firm ones ariſing above the ſkin, they may be checked by dry lint applied to them, or perhaps a gentle compreſs may alſo be required; ſometimes a ſlight application of the vitriol. r. may be neceſſary to check the luxuriancy. It is very rare that a cauſtic is required.

The ſimple vitiated *ulcer* differs from the ſimple purulent *ulcer*, chiefly, in the appearance and nature of the diſcharge afforded. The moſt common appearances of ſuch deviations in the matter afforded by *ulcers*, from the more natural ſtate of purulent matter are ſanies, ichor, or ſordes. In every *ulcer* diſcharging any of theſe matters, in conſequence of the acrimony that ſubſiſts in them, the parts, inſtead of filling up with firm granulations, waſte away, more and more, and inſtead of a reddiſh complexion, have either a dark brown, or a blackiſh, rough ſloughy appearance. The pain in all of them is more or leſs conſiderable, according as the matter is more or leſs corroſive. As the ſimple purulent *ulcer*, happens moſt frequently in the fleſhy parts, where the cellular membrane affords a fluid moſt plentifully that is proper for the formation of pus; ſo the ſimple vitiated *ulcer* is moſt frequently ſeated near the tendons or aponeurotic expanſions of the muſcles, from theſe parts not naturally affording that ſpecies of ſerum neceſſary for the formation of ſalutary pus. Accidental inflammation about the *ulcer*, or a general ill habit of body, may alſo be occaſional cauſes of this ſpecies of *ulcer*, even in parts beſt diſpoſed to produce the matter formed in the mildeſt kind of ſores. In order to moderate the ſymptoms peculiar to this kind of *ulcer*, and reduce it to the ſtate of the ſimple purulent one, the principal endeavours will be, to eaſe pain and to abate irritation; to which end, warm emollient fomentations and cataplaſms are effectual; they ſhould be continued until all appearances of inflammatory tendency is removed. The part may be fomented three or four times a day, for half an hour each time, with an emollient decoction, and then a pledgit ſpread with the ungt. cerum Ph. Ed. may be applied, as the pain is more or leſs: ſo a more or leſs free uſe of opiates inwardly, will be neceſſary to remove irritation. The habit of body demands attention alſo; if too much exalted it muſt be lowered, if too low it muſt be ſupported and raiſed; and generally it is in this latter inſtance that theſe *ulcers* are met with. Here a free but prudent uſe of the cort. Peruv. is ſingularly beneficial; ſometimes ʒj. is required ſix or eight times a day: in plethoric habits and in inflammatory conſtitutions, great caution is required in the uſe of this medicine. If any general diſeaſe attends, its removal muſt be duly attended to, in order to the cure of this as well as every other *ulcer*. This *ulcer* now reduced to the ſtate of a ſimple purulent *ulcer*, proceed as in that caſe directed. Sometimes more difficulty attends the cicatrization of theſe *ulcers*, when they have been of long ſtanding; but, beſides the method propoſed for cicatrizing the ſimple purulent *ulcer*, an iſſue inſerted in a proper ſituation, will generally finiſh the cure. Some have extolled the efficacy of nitre, in this ſpecies of *ulcer*.

The fungous *ulcer*, by ſome called the ſpongy *ulcer*. Fungous excreſcences frequently occur in different ſpecies of *ulcers*. By the term fungous, is underſtood ſuch preternatural riſings of the parts in ſores, as are more ſoft and ſpongy than ſound healthy granulations are; and though ſoft at firſt, by continuance they acquire an extraordinary hardneſs. Theſe excreſcences are ſometimes very painful alſo. In young and healthy habits the new granulations which ariſe in *ulcers*, often advance too quick, and preſently are above the ſurface of the neighbouring parts; and in other inſtances, for want of care, wounds and *ulcers* are permitted to fill up without being ſound at their bottoms; whence, as cauſes, this ſort of *ulcer* generally occurs. In order to a cure, the two juſt named cauſes are to be regarded. If the fungous aroſe from luxuriance of health merely, its ſurface may be ſlightly touched with the cauſt. lunar. once in two or three days, and immediately after, a pledgit of dry lint may be applied. If the baſis of the fungous is narrow, it may be beſt removed by a ligature. The fungus removed, proceed as in caſes of the ſimple purulent *ulcer*. When the fungus is of that kind which happens when the bottom of the *ulcer* is not ſound, it riſes quickly, and is not ſo firm as the firſt mentioned ſort; in this caſe, firſt give a free vent to any impacted matter, and then attend to the progreſs of healing from the bottom. This fungous is ſoft, and waſtes away in the progreſs of the cure, without requiring eſcharotics.

The Sinuous *Ulcer*. See FISTULA.

The Callous *Ulcer*; called alſo the varicous *ulcer*, from a miſtaken opinion that they proceeded from and were nouriſhed by matter from the ſwelled veins, which ſeem to open into them. An *ulcer* is ſaid to be callous, when its edges inſtead of contracting, and ſo diminiſhing the ſize of the ſore, keep at a ſtand, turn ragged, and at laſt, by acquiring a preternatural thickneſs, often riſe conſiderably above the level of the neighbouring parts: and as it is generally from neglect or improper treatment that *ulcers* do turn callous, the diſcharge afforded by them is commonly a thin vitiated matter. It is in this ſpecies of *ulcer* chiefly that varicoſe veins occur as a ſymptom, eſpecially when the complaint is ſettled in the lower extremities. This ſeems to be owing chiefly to the ſtricture occaſioned by the calloſities on the courſe of the different veins, a circumſtance, which in extenſive ſores of this kind, muſt, no doubt, have a conſiderable influence. Eſcharotics have generally been uſed to deſtroy callofity on the edges of *ulcers*, but as they tend to increaſe the diſeaſe by the continual inflammation they excite, they are now much laid aſide, and in their ſtead, emolliens with the aſſiſtance of warmth are ſubſtituted. By the uſe of a warm emollient poultice, and a reclined poſture, *ulcers* have been healed; though on adopting this method, their ſtate was very unpromiſing. Yet ſometimes the calloſities are ſo hard, as to require their deſtruction either by the knife, or the cauſtic; and if the laſt is preferred, the lunar is the beſt; with this the hardened parts may be touched, every two or three days, and when they are duly waſted, the *ulcer* will probably be reduced to the ſtate of the ſimple purulent one, and like that may then be treated. To ſtrengthen and reſtore the veins, that were rendered varicous about the calloſities, a tight ſtocking, or a ſpiral bandage will be uſeful, but not before their having been continued for a long time. Callofity frequently attends venereal and cancerous *ulcers*: in theſe caſes the ſtate of the conſtitution in general muſt be adverted to.

The Cancerous *Ulcer*. See CANCER.

The Carious *Ulcer*. By this term is intended that ſpecies of the diſorder, which is connected with a local affection of a bone. If ſuch an accident happens, as bruiſes,

bruiſes, tears, and injuries of the perioſteum, it ſometimes terminates in a caries; in ſuch a caſe, by the end of three, four, or five days, the bone begins to loſe the natural healthy appearance, turns firſt of a pale white, then gets a ſlight tinge of a yellow complexion; and whenever this begins to appear, there cannot be a doubt of what will be the conſequence. Sometimes it will continue in this ſtate for many days, and by degrees acquires a more deep tallow-like appearance, in which way it commonly remains for a longer or a ſhorter time, according to the violence of the inflicting cauſe, and afterwards goes through the ſtages of brown, light, dark, &c. until it hath acquired a darkneſs of the deepeſt dye. The diſcharge from ſuch *ulcers*, is never of the conſiſtence of good pus; it is generally thinner, and from the firſt appearance of caries, acquires a moſt diſagreeable fœtor, which always increaſes, as the different ſtages of the diſorder advances, at laſt it appears blackiſh, as well as the bone underneath, and the diſcharge at this time is exceedingly acrid. As the ſeveral degrees of blackneſs go on, ſmall holes are formed in the diſeaſed parts, and by degrees increaſe conſiderably, until even the moſt ſolid bones acquire a kind of ſpongy appearance. In this ſituation, the mortified portion of the bone generally becomes looſe, and when preſſed upon, a quantity of greaſy like matter, with a moſt diſagreeable fœtor, is generally forced out; this matter ſo taints the whole diſcharge from the *ulcer*, and gives it ſuch a peculiar ſmell as to render it ſcarce poſſible, after once ſeeing an inſtance, ever to miſtake it again. This laſt circumſtance alone, is a certain characteriſtic of a carious *ulcer*. Further, in *ulcers* attended with a carious bone, the fleſhy parts never have a healthy appearance, are ſoft and more flabby than in their natural ſtate, and inſtead of a florid red, have rather a dark brown, together with ſomewhat of a glazed complexion. The granulations puſh forward too quickly and too far, if they are not prevented by art, which is always neceſſary to be done, until the diſeaſed part of the bone is either caſt off by nature's proceſs, or cut out by the ſurgeon, ſo as that the cure may take place with certainty, from the bottom of the ſore. And when neglected for any conſiderable time, theſe ſoft productions in carious *ulcers* frequently increaſe ſo remarkably as to form very large and troubleſome exſcrecencies. Theſe appearances happen whether a portion of the bone, or its whole ſubſtance is carious. When the whole bone is affected, the progreſs and its various ſymptoms are more rapid, and the whole bone muſt be removed; whereas, when a part of the bone only is affected, perhaps a ſingle lamina to the extent of the diſeaſed part, is all that will be ſeparated and removed. So long as the caries remains, it effectually prevents the *ulcer* about it from healing; if by chance it appears to be healed, it ſoon breaks out again. When a probe can be introduced at any opening, and admiſſion can be got thereby to the bone, if a roughneſs of its ſurface is diſcovered, the caſe becomes then altogether evident. Though the bone cannot be reached by the probe, for want of an opening, the appearances of the *ulcer*, and the kind of diſcharge will rarely fail to determine what kind the *ulcer* is of; for, if the bone is carious, the *ulcer* is flabby, and inſtead of a regular ſurface, the new granulations, ſprout up in different cluſters of the ſize of ſmall nuts, and inſtead of a healthy ſtrong appearance, have uſually a dark-brown complexion; the diſcharge is thin, dark-coloured, and greaſy, there is alſo more or leſs of the peculiar fœtor above named. Before this *ulcer* can be cured, the carious part of the bone muſt be ſeparated from the ſound and taken out; in order to which, ſee CARIES. After the removal of the carious bone, the remaining ſore muſt be treated in the ſame manner as directed for that ſpecies of *ulcer*, to which, at the time, it appears to belong.

The Cutaneous *Ulcer*. See HERPES and TINEA.

The Venereal *Ulcer*. See LUES VENEREA.

The Scorbutic *Ulcer*. See SCORBUTUS.

The Scrophulous *Ulcer*. See SCROFULA.

However ſimilar the general practice may be, there are ſome peculiarities proper to *ulcers* on particular parts, ſome inſtances of which are as follow.

An *Ulcer* in the Bladder. It ſhould be diſtinguiſhed from an *ulcer* in the kidnies, which ſee. *Ulcers* are not ſo frequent in any of the urinary paſſages as they ſeem to be thought; they are often ſuſpected from a ſlimy diſcharge, which is of a yellowiſh colour, and proceeds from weakneſs. When an *ulcer* is formed in the bladder, there is a diſcharge of fetid matter, or blood, and ſometimes a ſort of ſcales, or a membranous pellicle, are ſeen in the urine. There is alſo a continual dyſuria, and a pain in the urinary paſſages. The means of relief are ſimilar to thoſe for an *ulcer* in the kidnies.

An *Ulcer* with a Caries. When a caries in the bone attends an *ulcer*, the fleſh over the caries is ſoft, flaccid, fungous, inflated, and tumid; the lips of the *ulcer* are inverted, the ſanies clear, ſubtile, hardly at all glutinous, fetid, and full of ſmall black ſcales; and if the *ulcer* heals, it is only ſuperficially, and it ſoon breaks out again, never healing firmly before the cure of the faulty bone, and that accompliſhed, the *ulcer* becomes a ſimple one, and ſoon filling up with common fleſh, is healed. See CARIES.

An *Ulcer* in the Kidnies. Dr. Hunter obſerves, that though the kidnies are often found waſted, they are hardly ever ſeen ulcerated. Cheſelden obſerves, that it is very rarely that an ulcerated bladder is met with in the bodies that are obtained for diſſection. Oribaſius obſerves, that an *ulcer* in the kidnies may be diſtinguiſhed by the following circumſtances, from the ſame diſorder in the bladder: 1ſt, When the bladder is affected, the pain is felt in the pubes, and the bottom of the belly; but when the kidnies ſuffer, the pain is in the back-part of the loins. 2dly, When the bladder is the ſeat of the diſeaſe, there is a diſficulty, if not a ſuppreſſion of urine; but when the kidnies are in fault, the urine paſſes freely. 3dly, From the bladder there is voided membraneous ſcales, but from the kidnies fibrous pieces of fleſh are voided. 4thly, A violent pain is felt in the bladder when it is ulcerated; but when the *ulcer* is in the kidnies, the pain is of a dull kind.

The urine looks like milk when it is firſt made from an ulcerated kidney, but is not fetid; but on ſtanding a while the white matter falls: when the pain is conſiderable in the kidnies, it occaſions a nauſea, and ſometimes a vomiting. When an *ulcer* is ſuſpected in the kidnies, the patient ſhould abſtain from acrid, ſour, and ſalt diet; he ſhould live on mild mucilaginous aliments; ſuch as the broths of young animals, whey, milk, ſweet butter-milk, &c. Violent exerciſe muſt be avoided, chalybeate waters ſhould be drank a long time, and ſolutions of the mildeſt balſams may be taken now and then.

Ulcers in the Legs. In theſe caſes a confinement in bed is uſually demanded as neceſſary in order to the cure. In ſome inſtances amongſt labouring people ſome advantage is obtained from reſt: but, in general, theſe *ulcers* are moſt firmly healed when moderate exerciſe is continued during the cure. Some are afraid of healing *ulcers* in this part, leſt an aſthma, or other complaint, ſhould follow; but if the general health is not defective, or if it can be reſtored, there will rarely, if ever, any ill conſequences follow from the healing of them. On this ſubject, Mr. Bell obſerves, in his Treatiſe on *Ulcers*, that it has been almoſt univerſally recommended never to attempt the cure of ſuch as have been of long ſtanding, as, from the very acrid matters which they are frequently known to diſcharge, it has been commonly imagined that drying up ſuch ſores might prove dangerous to the conſtitution. But he is of opinion, that no ſuch acrid matters, as are frequently obſerved to be diſcharged from *ulcers*, ever ſubſiſted in the blood. The acrimony which, in ſuch caſes, occurs, is produced, he thinks, in a great meaſure, by ſome particular affection of the organs, which ſeparate thoſe fluids from the blood, from which the matter, by its remora in the cavities of *ulcers*, is afterwards formed. He further obſerves that, *ulcers* are hurtful or beneficial to the conſtitution, not by the quality of matter diſcharged, but by the quantity; hence he ſays, the cure of every ſore, of what ever continuance, may be rendered perfectly ſafe by the previous introduction of an iſſue, which diſcharges a quantity of fluids, equal to the diſcharge occaſioned by the ſore to be healed up. He aſſerts from extenſive experience, that no inconveniencies ever reſult from the practice; and hence concludes that the cure of every *ulcer* may be attempted. The general intentions in the cure of *ulcers* being attended to, and a tight ſtocking worn over the dreſſings, ſuch other means may be directed as the experience of the practitioner, and the circumſtances of the caſe may ſuggeſt. Mr. Underwood obſerves that, in the cure of an

ulcer

ulcer, the firſt object is, to bring it to diſcharge a laudable pus, and this, he aſſerts the moſt inveterate *ulcers* on the legs may be brought to afford, as freely as ſores ſeated any where elſe. He recommends the mere. cor. R. finely levigated, as one of the beſt applications for this purpoſe. He adds that, this powder muſt not be lightly ſprinkled on the ſore, when its ſurface is ill conditioned, but the *ulcer* muſt be filled with it. This writer ſpeaks of a ſpecies of *ulcer* which is uſually ſmall, and particularly affects the parts about, and ſometimes below the ancle; it is exquiſitely painful. In this caſe, as in others, he aſſerts that reſt is not neceſſary to the cure; but inſtead of confinement, he carries the roller ſeveral times over the ancle and foot, ſo as to leave no part but the point of the heel uncovered, and thus a tolerable compreſſion is made below the *ulcer*. He further adds, that caſes of this ſort, are often attended with conſiderable puffings, and a tetterous appearance of the ſurrounding ſkin, accompanied with a thin acrid diſcharge, which renders the parts additionally tender; whilſt the little ulcer is almoſt perfectly dry, and cannot eaſily be brought to ſuppuration, until the complaint of the ſkin is removed; which is moſt ſpeedily effected by drying applications ſuch as bol. armen. alumen pulv. ungt. rub. defic. and in more obſtinate caſes, a ſolution of the ſac. ſaturn. and vitriol. alb. with one or two ounces of the ſp. vini. c. in a pint of water. If the ſore does not ſoon change its complexion, on the diſappearance of the affection of the ſkin, he adviſeth to fill the *ulcer* with precipitate, diſſolved lunar cauſtic, or any ſimilar eſcharotic, and when the ſlough is come out, to repeat it. Here he ſays that theſe cauſtics are only to be uſed after active degeſtives aided by proper bandages and exerciſe, prove ineffectual. Laſtly, he recommends in the healing of *ulcers* in the legs, particularly thoſe of long ſtanding, that the ſurgeon proceeds ſlowly and cautiouſly, avoiding the too early uſe of drying applications, and gradually weakening the digeſtive. It may be laid down as a general maxim, that the ſore ſhould rather be ſuffered, than invited to ſkin over. When the ulcer is healed, temperance, a continuance of the bandage for ſome time, and occaſional purgatives will be neceſſary. On this particular ſpecies of ulcer, ſee the Lond. Med. Obſ. and Inq. vol. iv. p. 347, &c. and Rowley's Eſſay on the Cure of ulcerated Legs. Underwood's Treatiſe upon Ulcers of the Legs.

Ulcers in the Tonſils. This diſorder is far leſs frequent than is ſuppoſed. Dr. Hunter obſerves, that the tonſils open over all their ſurface, by ſmall orifices which emit a ſlimy mucus; and that when they are inflamed, the mucus being purulent and white, and the ſurface irregular, there is the appearance of ulceration, when in reality there is none. Not to be deceived in this caſe, deſire the patient to waſh his mouth and throat well with ſome proper fluid, before you determine whether or no ulcers are here. When ulcers are formed, they may be touched with mixtures of honey, alum, borax, ſpirit of ſalt, &c. according as their cauſe, or attending circumſtances may require.

Ulcers in the Womb. Whilſt a viſcid, yellow, or bloody humour is evacuated, the ulcer is in a mild ſtate; but when it becomes ſanious, fetid, and is attended with pain, a cancer is for the moſt part attendant, and then palliatives only can be propoſed. In the milder kind keep the belly lax, with manna, tamarinds, and ſuch like cooling purgatives, and inject an infuſion of elder flowers in milk and water. When the caſe is cancerous, demulcent and lenitive medicines, with anodynes to moderate the pain, are all that can be propoſed. See CANCER *in the Womb*.

ON *Ulcers*, beſides the different ſyſtems of ſurgery, as Heiſter's, Turner's, Wiſeman's, Bell's, Kirkland's, Pott's, &c. ſee Bell's Treatiſe on *Ulcers*.

ULMARIA, alſo called regina prati. Queen of the meadow, and meadow ſweet. Spiræa *ulmaria*, Linn. It is a plant with tall, ſmooth, reddiſh, brittle ſtalks; on the tops are cluſters of white flowers, which are followed by crooked ſeeds ſet in a roundiſh head. It is perennial, common in moiſt meadows, and flowers in June. The leaves have an agreeable ſmell, the whole plant is alexipharmic, but not uſed in the preſent practice. See Lewis's Mat. Med.

ULMUS. The elm-tree. The *ulmus* campeſtris, i. e. *ulmus* foliis duplicato ſerratis: baſi inæqualibus. Linn. It is a tall tree covered with a rough, chapt, browniſh, brittle bark, under which lies a white, ſmooth, tough, coriaceous one. In the ſpring, before the leaves appear, it produces imperfect flowers, which are followed by flat roundiſh capſules, containing each a ſingle ſeed. The inner tough bark hath no ſmell, but on being chewed, it diſcovers a copious ſlimy mucilage; the outer brittle bark is leſs ſlimy.

Dr. Lyſſons of Bath relates his ſucceſs, by the uſe of a decoction of the inner bark of elm, in ſeveral caſes, in which obſtinate eruptions appeared on the ſkin, ſome of which approached very near to, if they were not of a leprous kind. He made the decoction as follow: ℞ Cort. interioris *ulmi* recent. ʒ iv. coq. in aq. font. ℔ iv. ad ℔ ii. He obſerves that if this bark is rich of the juice, and is boiled too long, the decoction will be mucilaginous and not quite agreeable, but that otherwiſe it hath an agreeable, mild, aſtringent taſte. As the decoction was uſed during the ſpring and autumn ſeaſons only, the bark was taken from the trees as it was required; in the ſpring it was ſtripped from the ſmall, but not the ſmalleſt branches; and in autumn from the branching roots, as being at thoſe ſeaſons the fulleſt of ſap. Half a pint of this decoction is to be taken every evening and morning, and continued as long as the continuance of the eruptions may require it. On the firſt uſe of this medicine this diſorder ſeems to be ſomewhat aggravated. See the Lond. Med. Tranſ. vol. ii. p. 203.

ULNA. Ulna, the great bones of the arm contracted; from ὠλένη, *the cubit*. It is one of the bones of the fore-arm, it is alſo called cubitus. At its upper extremity it hath two proceſſes, the poſterior called olecranium is the larger. Its concave ſurface moves upon the trochlea of the os humeri, into its upper-part, all the extenſors of the cubit are inſerted. The anterior proceſs is not ſo large, nor does it reach ſo high, but is ſharper at its extremity, and therefore named coronoid. Between theſe two proceſſes, a large ſigmoid cavity is left, adapted to the trochlea of the os humeri; on the other part is a cavity, where the extremity of the radius moves. The lower extremity of the ulna terminates in a very ſmall head, which internally is received into the ſemilunar cavity of the radius, whilſt from its external ſide a proceſs jets out called the ſtyliform, from which a ſtrong ligament is extended to the os piſiforme and unciforme of the carpus.

ULNARIS ARTERIA, i. e. Cubitalis Arteria.

ULNARIS EXTERNUS, i. e. Externus Carpi Radialis.

ULNARIS GRACILIS, i. e. Palmaris Longus.

ULNARIS INTERNUS. It is a long muſcle, ſituated on the outer part of the ulna; it is fixed by its upper part in the back ſide of the long or internal condyle of the os humeri, in that part of the olecranum which is next the condyle, along the upper half of the ulna very nearly, and to the middle common tendon of the profundus; it ends by a long tendon on the os piſiforme of the carpus, reaching alſo to the os unciforme.

ULNARIS. The nerve ſo called. See CERVICALES.

ULON. Plur. Ula. The gums. Pollux ſays, the fleſh on the outſide of the teeth is called ula, and on the inſide enula. Ula ſometimes ſignifies a tumour on the gums.

ULTRAMARINUM. Ultramarine. See LAZULI LAPIS.

ULVA. A barren kind of moſs is thus named.

UMBILICALES VASÆ. Umbilical veſſels. There are four ligamentary ropes called by this name; the uppermoſt runs from the navel to the fiſſure, between the two lobes of the liver, and is the remains of a vein, which, in the fœtus ſtate, anaſtomoſed with the vena cava hepatica, covered with the falciform proceſs. The urachus is another of the ligamentary ropes. The other two ligamentary ropes are the extremities of the umbilical arteries, which at the top of the bladder approach each other, and join the urachus.

UMBILICALIS, as comprehending the navel. It is the middle external region of the belly in its fore part; it reaches from an imaginary line drawn betwixt the loweſt falſe ribs, to another imaginary line drawn betwixt the two criſtæ of the os ilium. This region is divided into three parts, viz. the middle, which is properly the umbilicalis, and the two lateral, called flanks.

UMBILICALIS ARTERIA. It is a continuation of the

the HYPOGASTRIC ARTERY, which ſee. It aſcends on the ſide of the bladder, and from thence it aſcends to the navel. It is ſhriveled in the adult ſtate, being only of uſe to the fœtus.

UMBILICUS. The navel, quaſi umbo ilium. The middle of the loins.

UMBILICUS VENERIS. i. e. Cotyledon Major. It is alſo the name of a ſpecies of ſaxifrage.

UNCIFORME OS. The fourth bone of the ſecond row in the wriſt. It hath an apophyſis ſhaped like a claw, whence its name.

UNGUENTARIA. The nut-meg.

UNGUENTUM. An ointment. It differs from a plaſter only in its conſiſtence; if as much oil is added to a plaſter as reduces it to the conſiſtence of ſtiff honey, it forms an ointment. It is uſual to boil the freſh leaves of plants in lard, and other greaſy and unctuous matters, but they retain very little of the virtue of the plants, nor indeed do freſh herbs give out much of their virtue to greaſy and unctuous ſubſtances.

UNGUES. The nails. They are continuations of the epidermis. Their ſubſtance is like that of horn; they are compoſed of ſeveral planes of longitudinal fibres ſoldered together; theſe ſtrata end at the extremity of each finger, and are all nearly of an equal thickneſs, but of different lengths. The principal uſe of the nails is to ſtrengthen the fingers and toes.

UNGUIS. Alſo called pterygion. It is a collection of matter in the pupil of the eye, in the ſhape of a man's nail, (whence the name.) It is a kind of PHLYCTÆNÆ, which ſee. Some deſcribe this diſorder as a film formed on the external part of the eye, extending over the pupil, and when it hath a red appearance, they call it Pannus; and in order to its removal, the veſſels which run into it being divided near the great angle of the eye, it ſhrivels and may then be ſeparated.

UNGUIS. So the ancients called that ſort of articulation which we call ſuture.

UNGUIS OSSA. Theſe are two thin bones, very brittle, placed at the inner canthi of the eyes, covering ſome of the ſinus ethmoidalis, and are really part of the os ethmoides; their ſurface is ſmooth and hollow, and is divided by a ridge; the hind cavity forms a portion of the orbit, the fore-part is a perpendicular canal which contains the lachrymal ſac and duct.

UNGUIS ODORATUS. Sweet hoof. See BLATTA BYZANTIA.

UNGUIS. In botany; it is the white and inferior part of the leaves of roſes, and of ſome other flowers.

UNGULA. The diſorder in the eye called unguis.

UNGULA CABALLINA. The herb coltsfoot.

UNIO. A pearl. See MARGARITA.

UPSILOIDES, i. e. Os hyoides.

URACHUS, from οὖρον, *urine*, and ἴχω, *to have* or *contain*. In the fœtus ſtate the urine paſſes from the bladder into the allantois, through the *urachus*; but after the birth it is ſhrivelled and becomes a ligament.

URCEOLA, Urceolaris, Urceoli vitrei. A name for the parietaria, from its uſe in ſcouring glaſſes.

UREDO. A blaſt. Alſo the name of a particular head-ach, an inſtance of which is related in the Philoſ. Tranſ. June 1668. It is the URTICARIA, which ſee.

URETERES. Ureters. From οὖρον urine. See RENES.

URETERITICA. (Iſchuria.) A ſuppreſſion of urine from inflammation in the urethra.

URETEROLITHICA. (Iſchuria.) A ſuppreſſion of urine from a ſtone in the urethra.

URETEROMBOIDES. (Iſchuria.) A ſuppreſſion of urine from grumous blood in the ureter.

URETEROPHLEGMATICA. (Iſchuria.) A ſuppreſſion of urine from pituitous matter in the ureter.

URETEROPYICA. (Iſchuria.) A ſuppreſſion of urine from purulent matter in the ureters.

URETEROSTOMATICA. (Iſchuria.) A ſuppreſſion of urine from obſtruction in the lower orifice of the ureter.

URETHRA. From οὖρον urine. The inner membrane of the *urethra* or paſſage for the urine from the bladder is a continuation of that which lines the bladder; it is very ſmooth and ſenſible; in it are ſeveral lacunæ, which are the ſeat of the clap. In women the *urethra* is wider than in men, and its length is only from an inch to an inch and a half. Sometimes a ſtone is fixed in ſome part of the *urethra*. This produces pain, then inflammation, tumefaction of the parts, and always a partial and frequently a total ſuppreſſion of urine. In ſome inſtances, when the diſorder is long neglected, this ſuppreſſion and conſequent tumefaction, terminate in a rupture of the *urethra*; in conſequence of which the urine eſcapes into the contiguous cellular ſubſtance, and very troubleſome ſwellings are produced, not only in the body of the penis, but frequently in the ſcrotum, and through the whole courſe of the perinæum, when a ſtone has been long fixed at one particular part without yielding in any degree, and when the pain and inflammation produced by it are conſiderable, a chirurgical operation ought to be immediatly employed for removing it; but, in the incipient ſtages of this diſorder, other means of a more gentle nature ſhould be firſt put in practice. In order to ſolicit the paſſage of the ſtone one important endeavour is, to remove ſpaſm; with this view, if the patient is plethoric, bleed; if he is thin and emaciated a proportionable quantity of blood ſhould be taken by means of leeches, directly from the part affected. A quantity of warm oil ſhould be repeatedly injected into the *urethra*, to lubricate the paſſage; the patient ſhould alſo be immerſed into a warm bath; and a full doſe of the tinc. Theb. ſhould be at the ſame time given. A proper quantity of blood having been diſcharged; the patient having remained for a ſufficient length of time in the warm bath; and the opiate having begun to operate, the parts will thus be as completely relaxed as poſſible: and this is the period when ſome attempt ſhould be made for extracting the ſtone. To this end, inſtead of any of the inſtruments recommended for this purpoſe, which often do harm by increaſing irritation, the ſurgeon ſhould at firſt endeavour by very gentle preſſure to puſh the ſtone forward along the courſe of the *urethra*: In this manner large ſtones may be brought off, for the removal of which a very painful operation might otherwiſe be neceſſary. When the ſtone, fills up the *urethra*, or notwithſtanding the uſe of means as above, it will not paſs, it will be neceſſary to proceed to the operation, which is performed by cutting upon the ſtone, and extracting it either with a ſcoop or with a pair of ſmall forceps. When the ſtone is fixed in the *urethra* near the neck of the bladder, lay the patient on a table, ſecure him as for the operation of lithotomy: an aſſiſtant ſuſpending the ſcrotum and penis, the ſurgeon, after oiling the firſt and ſecond fingers of his left hand, ſhould introduce them into the anus, and by means of them ought to preſs firmly upon the parts immediately behind the ſtone; which will not only enable him to lay it bare with more eaſe, but will be the ſureſt method of preventing it from being puſhed into the bladder by the neceſſary preſſure of the knife, this being done, an inciſion ought to be made through the common integuments and *urethra*, ſo as to lay the ſtone completely bare; which may now be either turned out by a due degree of preſſure applied with the fingers in the rectum; or, if this is not found to be ſufficient, it may be taken out either with a ſcoop or with a pair of forceps. The after-treatment is the ſame as after the operation of lithotomy. When the ſtone hath paſſed further into the *urethra*, in order to extract it, the ſkin ſhould be drawn as much as poſſible paſt it, either in a backward or a foreward direction; and the ſtone being now ſecured in its ſituation by preſſure, a longitudinal cut ought to be made directly upon it through the *urethra*, of a ſufficient ſize to allow of its eaſy extraction either with the ſcoop or the forceps. The edges of the wound are now to be completely cleared of fabulous particles and the ſkin allowed to regain its natural ſituation; by which means, if the operation has been properly done, the wound in the *urethra* will be entirely covered by ſkin that has not been injured; a circumſtance which tends to render this operation by far leſs exceptionable than otherwiſe it would be, for thus the wound uſually heals by the firſt intention. If the ſtone fixes near the point of the yard, as it ſometimes does, if it is ſo near as to be obſerved by the eye, it may frequently be taken out with a pair of ſmall diſſecting forceps: and in order to facilitate the extraction, when it cannot be otherwiſe effected, the *urethra* may be ſomewhat dilated from its extremity with the point of a ſcalpel. But if ſucceſs

ſtill fails us, an inciſion muſt be made upon the ſtone as where the *urethra* is covered with ſkin. Soft dreſſings ſhould be applied to the wound; and when the cure is nearly completed, a hollow bougie, a ſhort ſilver tube, or a ſmall catheter of the elaſtic gum, ſhould be introduced into the *urethra*, in order to preſerve it of a proper ſize. The worſt ſituation in which a ſtone can be fixed in the *urethra*, is juſt below the ſcrotum; for if the ſtone either makes its way into the ſcrotum, or if it is neceſſary to make an opening into it with a ſcalpel, ſuch large collections of urine are apt to occur, as commonly occaſion much diſtreſs. To obviate this, ſo ſoon as a ſtone is diſcovered in this ſituation the greateſt attention ought to be given, either to get it carried farther into the *urethra*, or, if this cannot be effected, to puſh it back into the perinæum by means of a ſtaff. If either of theſe are impracticable, and it is neceſſary to extract the ſtone, an inciſion muſt be made into the *urethra*, by beginning the cut at the under part of the ſcrotum immediately to one ſide of the ſeptum, and continuing it upwards till the ſtone is diſtinctly felt, when it is to be laid bare and extracted as above directed. In applying the dreſſings after the operation, conduct them ſo as that the ſore may heal firſt at the bottom; if this is not duly attended to, the parts below will be filled with matter, or perhaps with urine, and thus very troubleſome ſinuſes may be formed. In females the *urethra* is ſhort, and dilates readily, ſo that ſtones rarely are detained in it: but when they do, they generally may be turned out by paſſing the end of a blunt probe behind them, and then pulling forward: or if this does not ſucceed, the end of the *urethra* may be ſlit a little way ſo as to admit the introduction of a pair of forceps by which the ſtone may be extracted. See Bell's Surgery, vol. ii.

URETHRELMINTHICA. (Iſchuria.) A ſuppreſſion of urine from worms in the urethra.

URETHRITICA. (Iſchuria.) A ſuppreſſion of urine from inflammation in the urethra.

URETHROHYMENODES. (Iſchuria.) A ſuppreſſion of urine from a membrane obſtructing the urethra.

URETHROLITHICA. (Iſchuria.) A ſuppreſſion of urine from a ſtone in the urethra.

URETHROPHLEGMATICA. (Iſchuria.) A ſuppreſſion of urine from mucus obſtructing the urethra.

URETHROPYICA. (Iſchuria.) A ſuppreſſion of urine from pus obſtructing the urine.

URETHROMBOIDES. (Iſchuria.) A ſuppreſſion of urine from grumous blood obſtructing the urine.

URINA. The urine. It is a fluid which is ſecreted from the blood by the kidneys, conveyed by the ureters to the bladder, and from thence it is diſcharged from the body through the urethra. It is ſo acrid and diſpoſed to putrify, that if retained long in the bladder it endangers the patient's life. When ſuppreſſed, it has been known to paſs through the pores of the ſkin. The ſudden diſcharge of ſome fluids after ſwallowing them hath cauſed ſome to imagine that there is ſome ſhorter paſſage to the bladder than through the kidneys; but though difficulties attend this circumſtance, ſome of the moſt eminent in their profeſſion are of opinion that all the *urine* is ſecreted by the ſame veſſels.

Many are the ſigns which different authors have pointed out in the *urine*, by which to judge of the different ſtates of the body; but Dr. William Hebberden well obſerves that this excretion affords the practitioner but little uſeful information. As to the pretenſions of ſome who require only the ſight of a patient's *urine* by which to diſcover the nature of the diſeaſe, its ſtate as to ſafety and danger, and alſo the method of cure; it need only to be obſerved that the ſame kind of *urine* is not always diſcharged in the ſame diſorders, and ſuch as is voided in one is alſo voided in ſeveral other very different complaints.

The appearances obſerved in the *urine* at the criſis of acute diſeaſes are generally included in the three following, viz. the nubes or nubecula: it is when a cloud, as it were, is diffuſed through the *urine* after it hath ſtood a while in a glaſs; the enæoremata, or, as the Latins call it, the ſublimationes, ſuſpenſa, or ſublimia, which is, when the cloud ſinks a little, leaving the *urine* above, ſomewhat tranſparent; and laſtly the hypoſtaſis, or as the Latins name it, the ſubſidentia ſubjecta, or ſedimenta, which is when the whole cloud falls and makes a thick ſediment at the bottom.

Urine contains a peculiar ſalt, called microcoſmic ſalt, and which is found no where but in *urines*; marine ſalt; and if diſtilled in a retort, it yields not only the volatile ſalt, and empyreumatic oil, common to animal matters, but alſo a peculiar kind of phoſphorus. *Urine* is uſed in ſundry arts.

See Haller's Phyſiology, lect. 37. Fordyce's Elements, part 1ſt. p. 16—18. Prolper Alpinus's Præfages, Neumann's Chem. Works, Lewis's Mat. Med.

The *urine* is ſometimes too copiouſly diſcharged, ſee DIABETES; it is alſo ſometimes difficultly paſſed or totally ſuppreſſed, ſee ISCHURIA; it is ſometimes mixed with blood, and in ſome inſtances it is involuntarily diſcharged.

Bloody *urine*. Hæmaturia. Hippocrates obſerves that if pure blood is copiouſly and ſuddenly diſcharged without pain, it flows from the vaſcular ſubſtance of the kidneys; but when the quantity of blood is ſmall, of a blackiſh colour, and eſpecially if there is pain, or heat, or both, during or after the diſcharge, it proceeds from the bladder. When ruptures of the veſſels in the bladder happen, the ſymptoms are ſevere, ſuch as intenſe pains, fainting, difficulty of breathing, a low, ſmall, frequent pulſe, naufea, anxieties of mind, and cold ſweats. If a rough ſtone wounds the ureters, the pain is felt in the back, and there is a difficulty in making water. A ſtone in the bladder ſometimes cauſes this diſorder, and in the Edinb. Med. Eſſays, vol. vi. is an inſtance of a worm in the bladder ſometimes producing this diſeaſe. Cœlius Aurelianus ſpeaks of a ſpecies of hæmorrhoids diſcharging blood with the *urine*: and it is ſometimes obſerved both in young and aged men that, on a ceſſation of the hæmorrhoids, blood paſſes with the *urine*. Hoffman obſerves that ſometimes an hæmorrhage happens from the veſſels of the bladder, or rather of its ſphincter, diſtended and opened in the ſame manner as from the hæmorrhoidal veſſels: in this caſe, the flux is periodical, a retention of the blood occaſions a pain about the pubes, the blood drops away ſometimes without urine and is never equally mixed with the *urine*, as that always is which comes from a higher ſource. Some aged women who live luxurioufly after the ceſſation of their menſes, have their *urine* often mixed with blood. In putrid fevers this is a frequent ſymptom, from the diſſolution of the blood. Strong purges, too forcing diuretics, or other cauſes of ſpaſms in the belly, are alſo cauſes of bloody *urine*. Bloody *urine* is always ſymptomatic.

The *urine* ſometimes appears to be bloody when there is no blood diſcharged with it; this is known by ſtraining it through a linen cloth, for if it is bloody, the cloth will be tinged, but otherwiſe not.

Bloody *urine* ſhould be diſtinguiſhed from bloody diſcharges in a gonorrhœa, from that ſpecies of piles which diſcharge themſelves into the urinary paſſages; and critical diſcharges of the blood in the urinary paſſages ſhould be diſtinguiſhed from thoſe that are not ſuch.

When bloody *urine* is mixed with pus, there is an ulcer ſomewhere in the urinary paſſages. All diſcharges of bloody *urine* are to be feared, though thoſe from hæmorrhoids the leaſt ſo; but the moſt dangerous are thoſe from ulcers and from wounds of the kidneys or bladder. Hæmorrhages from the kidneys, and from the ſphincter of the bladder, are often critical and ſalutary, and return at certain intervals. In plethoric men, both young and old, from the omiſſion of cuſtomary veneſection or from hæmorrhoidal obſtructions in women of eighty, who were hale and of high life, who had neglected to ſupply by bleeding, the evacuations which nature had made formerly from the uterus, theſe diſcharges continue for a conſiderable time, in no ſmall quantity, without any ill conſequence: yet, though at firſt they may appear ſalutary, from their ſupplying other evacuations, they are far from being without danger, from gradually waſting the ſtrength, &c.

When the patient is plethoric, or when a ſuppreſſed ſanguine excretion is the cauſe, bleed, and keep the bowels lax. If there is any tendency to, or actual inflammation, frequent draughts of an infuſion of linſeed may be taken, and ſmall portions of nitre may be diſſolved in each draught juſt before it is drank. The uva urſi is eſteemed a ſpecific, but other medicines of the aſtringent kind ſhould not be ventured on. The ſal Glaub. may be repeated in doſes, to procure gentle evacuations, every or

every other day. When a ſtone in the bladder is the cauſe, reſt ſhould be indulged; as much manna may be taken twice a week in a pint of whey as will paſs off readily by ſtool, and, if need be, an anodyne may be taken after the operation. When the diſcharge is from the kidneys or the ureters, an infuſion of the ſeeds of wild carrot is of ſingular benefit. See DAUCUS CRETICUS. If ſuppreſſed hæmorrhages produce this diſorder, bleed and give aloetics. When a putreſcence in the blood and juices are attendant, the bark with the vitriolic elixir will be the neceſſary means of relief. When ulcers are ſuſpected in any of the urinary paſſages, give ſuch medicines and direct ſuch liquors for the common drink as ſheathe acrimony. See Hoffman's Rat. Med. Syſt.

Incontinence of *urine*. This diſorder may be occaſioned by pregnancy, a palſy in the ſphincter of the bladder, a weakneſs in the ſphincter of the bladder from hard labour, or from a violent extraction of a ſtone through the urethra, perforation in the bladder, a ſtone in the bladder, wounds on the head, a laceration, or a relaxation of the ſuſpenſory ligament of the bladder, &c.

The moſt frequent cauſes are, a weakneſs or palſy in the ſphincter of the bladder, in which caſes a bliſter is generally a ſucceſsful remedy; it ſhould be placed on the lumbar vertebræ and the os ſacrum, and may be kept open ſome days by means of the ungt. veſicat. If the ſphincter of the bladder is relaxed from the extraction of a ſtone, it uſually recovers ſpontaneouſly; however, ſome mildly aſtringent medicine may be applied. When this diſorder is obſerved in children, it is ſometimes relieved by drinking an infuſion of ſtrawberry leaves, and rubbing the pubes with rectified ſpirit of wine. When pregnancy is the cauſe, the patient muſt wait until after delivery. When a ſtone of the bladder produces this diſorder, lithotomy ſometimes relieves, but cannot be truſted to, for ſometimes it proves a cauſe of this diſorder when before it had no exiſtence. See Hoffman's Rat. Med. Syſt. Lond. Med. Obſ. and Inq. vol. ii. and iii. Bell's Surgery vol. ii. See ENURESIS.

URORRHŒAS. The urine paſſing from the urethra through ſome eroſion of the perinæum.

URTICA. The nettle. Bœrhaave mentions eight ſpecies, but none of them obtain in the preſent practice, though the common ſtinging and the ſpecies called white Archangel are ſtrongly recommended; the firſt for checking internal hæmorrhages, and the ſecond for moderating the fluor albus. The college of Edinburgh orders the *urtica* dioica or *urtica* foliis oppoſitis oblongo cordatis, racemis geminis, amentis cylindricis. Linn. The common nettle.

URTICA MARINA. Sea blubber. It ſwims on the water, being a round compreſſed pellucid ſubſtance, reſembling jelly, with red veins interſperſed. Its virtues are the ſame with thoſe of the lepus marinus.

URTICARIA. The acute nettle raſh. Dr. Cullen places this genus of diſeaſe, in the claſs locales, and order exanthemata. He obſerves that all agree that it is a mild diſeaſe, ſeldom requiring the uſe of remedies. It is generally ſufficient to obſerve an antiphlogiſtic regimen, and to keep the patient in a temperature that is neither hot nor cold.

URTICATA. i. e. urticaria.

USNEA CRANII HUMANI. Moſs of a dead man's ſkull. It is different from the moſs on ſtones and trees, but is often found on the bones of horſes, &c. It is now neglected as a medicine.

UTERARIA. Uterine or hyſteric medicines. Theſe are of three ſorts, viz. the emmenagoga, ariſtolochia, and ecbolica.

UTERI HÆMORRHAGIA. Exceſſive menſes.

UTERUS. The womb. The *uterus* is ſituated between the bladder and the rectum; it is covered with the peritoneum, which comes from the back part of the bladder, aſcends up the fore part of the *uterus*, from thence over the fundus, down the poſterior ſide, and ſo to the rectum. On each edge of the *uterus* this poſition of the peritoneum forms a broad duplicature, which is extended on each ſide, more or leſs, directly to the adjoining lateral parts of the pelvis, forming a ſort of membranous partition between the anterior and poſterior halves of the cavity of the pelvis; and then is continued looſely with the peritoneum on the ſide of the pelvis; theſe two duplicatures are called the ligamenta lata: the laminæ of which are connected by a cellular membrane, and contain the tubæ Fallopianæ, the ovariæ, and part of the ſpermatic veſſels, and thoſe which go to the *uterus*, alſo the ligamenta rotunda, and the nerves. The *uterus* is rather triangular in its ſhape, the fundus is almoſt a ſtrait line, the two ſides approaching each other, makes it narrow where the cervix begins, then it grows larger, then narrow again at the os tincæ, which is received into the vagina. The inſide of the *uterus* is ſmooth; at the upper part the *uterus* is very vaſcular, at the ſides and below it is white. The cervix uteri, on each ſide, is divided into two lateral parts by a ridge, whence the fibres go off in the manner of a feather. At each angle of the fundus we may introduce a briſtle into the beginning of the Fallopian tubes, which go in a tortuous manner, and terminate at the ovaria in an irregular round jagged extremity, where their diameter is about one third of an inch; this fringe is called morſus diaboli, and is hung upon a membrane like the meſentery, between the doublings of which the veſſels run to the tubes. The tubes are not ſmooth internally, but there are innumerable longitudinal rugæ placed cloſe upon one another. See OVARIÆ and TUBÆ FALLOPIANÆ. The *uterus* is furniſhed with blood-veſſels from the hypogaſtrics and the ſpermatics. The ſpermatics riſe as in the male, and when they get to the pſoas muſcle, they paſs upon the ligamenta lata, and go to the tubæ Fallopianæ, the ovaria, and the *uterus*. On the ſides of the *uterus* the hypogaſtrics paſs to the vagina, &c. and theſe anaſtomoſe with the ſpermatics; they run in a ſerpentine manner. The ſpermatics are moſtly above, and the hypogaſtrics below.

See De Graaf de Mulierum Organis Generationi Inſervientibus, Winſlow's Anatomy, Haller's Phyſiology, lect. 34 and 35.

UTRICULUS. The uterus.

UTRIFORMIS ABSCESSUS, i. e. Œdemoſarcoma.

UVA GRUINA. Crane berries. They are brought from New-England, and are reckoned antiſcorbutic.

UVA URSI. Bear's whortle berry, bear's whorts, or bear's bilberries. It is the arbutus *uva urſi*, i. e. arbutus caulibus procumbentibus, fol. integerrimis. Linn. The bear-berry ſtrawberry-tree. The plant is an evergreen trailing ſhrubby one; it hath many ſmall, oblong, oval leaves; monopetalous white flowers, with a fleſh-coloured edge, cut into five ſections; the berries are red. It greatly reſembles the common red wort buſh, from which it may be diſtinguiſhed by the leaves being more oblong, and by the flower having ten ſtamina, and the berry five ſeeds; whereas the flower of the common whortle hath only eight ſtamina, and the berry often twenty ſeeds. It is found on the ſnowy hills in Auſtria and Styria, but more plentifully in Sweden, and it is cultivated in gardens in England; it is alſo found in Scotland.

The leaves have a bitteriſh aſtringent taſte, without any remarkable ſmell, at leaſt when dry; they are celebrated by De Haen, in nephritic and calculous complaints; and ulcers in the urinary paſſages, in which caſes ʒ ſs. of the powder were taken faſting, or two or three times in a day. It is very uſeful to many in moderating the pain which often attends calculous complaints; but in other reſpects hath not yet been attended with thoſe advantages in England, for which it is ſo ſtrongly recommended by the juſt named profeſſor. See Med. Muſ. vol. i. n. 13.

UVA PASSA. A grape dried in the ſun, the fruit of the vitis vinifera, Linn.

UVATIO, i. e. Staphyloma.

UVEA. So the poſterior lamina of the iris hath been called; ſome called the choroides by the name of *uvea*, and the coloured part they called iris. The ancients called it *uvea*, becauſe they obſerved it to be of the colour of an unripe grape in grazing animals, for they chiefly diſſected brutes. Mr. Pott calls the iris a circular muſcle. See ACINIFORMIS.

UVULA. It is alſo called cion and gargareon. From the middle part of the palatum molle, the *uvula* hangs down into the throat, acting as a valve, by means of whoſe different actions we can breathe either through the mouth or the noſe. It is of an irregularly conical ſhape, and is glandulous.

VACCARIA,

V.

VACCARIA, i. e. Uva urſi.

VACCINI. A name for ſeveral ſorts of the vitis idæa, alſo of the uva urſi.

VAGA. An errattic kind of intermitting fever, returning at more than ten days from each fit.

VAGINA. In botany it is the ſheath or covering of a bud.

VAGINA. It is the paſſage from the external pudenda to the mouth of the uterus. Its courſe is upward and backward; its inſide is very vaſcular and villous, and the villi are very full of veſſels and nerves. The *vagina* is contracted at its orifice by the ſphincter *vaginæ*, and in its whole length by the levator ani. Each ſide of the anterior portion of the *vagina* is covered externally by a thin broad expanſion of veſſels called the plexus retiformis; theſe two planes run down each ſide of the clitoris behind the nymphæ, and likewiſe cover the urethra like a collar before they are ſpread on the *vagina*; this plexus is capable of being erected, and in coitu it is compreſſed by the ſphincter vaginæ, which is contrived for the greater pleaſure. The *vagina* is a fleſhy membranous tube, which lies immediately before the rectum, is incurvated, hath the turn of the bones as the uterus hath, is collapſed and compreſſed between the bladder and the rectum. The ſtructure of the *vagina* is very vaſcular; on its inſide it is very rugous. It is commonly reckoned muſcular. The *vagina* is ſometimes too narrow; this may be either natural from original conformation; or accidental, in conſequence of diſeaſe. Cicatrices may be formed from a laceration after ſevere labour; in conſequence of ulceration, eroſion, &c. Preternatural conſtrictions may be induced from the uſe of ſtyptic applications, or fumigations. The cure may be attempted by emollient fomentations, as by the ſteams of warm water directed to the parts; and by introducing a ſmall tent of compreſſed ſponge. If theſe fail, recourſe muſt be had to the knife: though, in the ſimple contraction of the cavity of the *vagina*, this expedient is ſeldom neceſſary, and the attempt is often attended with the utmoſt danger; therefore ſhould never be determined on until every other method hath failed. The dilatation, which was previous to impregnation, has very often been accompliſhed by labour pains. Sometimes there is a natural defect, ſo that the *vagina* is either imperforated altogether, or a foramen only remains ſufficient to tranſmit the menſtrual blood. If, from a coalition of the parieties of the *vagina*, the paſſage be entirely ſhut up, an attempt to force it would be vain. The orifice in the latter caſe will afford a proper direction for the knife; but the operator muſt be cautious not to miſtake the urethra for the paſſage into the *vagina*. When the *vagina* is impervious altogether, the uterus has been ſometimes found wanting.

Fleſhy, fungous, or polypous tumors ariſe from all parts of the *vagina*. They happen to women at every period of life, but moſt frequently towards the decline. They generally proceed from an obſtruction of the ſmall glands of the parts, and are leſs or more difficult to diſcover or remove, as their origin is low or high in the *vagina*. Their texture is various; ſometimes they are tender and mucilaginous, like thoſe in the noſe; at other times firm and ſolid, like a wen; ſometimes their baſes is very conſiderable; though they generally adhere by a ſmall neck. They ſometimes, like ſcirrhi, continue indolent for many years; and are alſo liable to degenerate into ſcirrhus and cancer. In their mildeſt ſtate, they are attended with perpetual ſtillicidium from the *vagina*, and ſometimes with profuſe and dangerous floodings. Carefully diſtinguiſh betwixt theſe tumors and herniæ, or prolapſus uteri, &c. Polypi, when curable by an operation, may generally be removed by ligature; a ſafer method than cutting, as they are often ſupplied with large blood-veſſels. For fixing the ligature, the fingers of the operator will be ſometimes ſufficient. When this method fails, Dr. Hunter's needle, or M. Levret's double canula, for applying and fixing the ligature over the tumor, are the moſt ſimple and ſucceſsful expedients. M. Levret's inſtrument is a piece of flexible gold or ſilver wire, paſſed through a double hollow probe in the form of a nooſe: this is to be conveyed into the *vagina*, and carried over the tumor, till it reach the baſe. The ends of the wire muſt be gently drawn, or it muſt be twiſted round as tight as the patient can eaſily bear; the canula muſt afterwards be fixed to the thigh, and the wire tightened every day as it ſlackens. Thus the circulation in the tumor is ſtopped, and in two or three days the polypus will drop of. In fixing the ligature, the operator muſt be cautious not to miſtake the tubercle of the os tincæ for the polypous tumor. See Hamilton's Outlines.

VAGINA. It is a name which is given to other parts of the body, as to the capſula Gliſſonis, which is called *vagina* portæ. A coat of the teſtes is called vaginalis tunica (ſee TESTES); and this name is given alſo to a coat of the œſophagus and of the ſpinal marrow.

VALERIANA. Valerian. Boerhaave enumerates thirteen ſpecies. In warmer countries the ſort diſtinguiſhed by the name of ſetwall, or of great-garden-*valerian*, is preferred; but in colder climates the beſt is the *valeriana* ſylveſtris major of Caſp. Bauhine; it is alſo called phu Dioſcoridis, and great wild *valerian*. *Valeriana* officinalis, vel *valeriana* phu, vel *valeriana* major, foliis omnibus pinnatis, floribus triandris, Linn. Great wild *valerian*. It is a plant with channelled ſtalks, the leaves in pairs, each leaf is compoſed of a number of long, narrow, ſharp-pointed ſegments, indented about the edges, of a dull green colour, ſet along a middle rib, which is terminated by an odd one; producing on the tops of the ſtalks umbel-like cluſters of ſmall monopetalous flowers, which appear in May, June, and July, each of which is followed by a ſingle naked ſeed, winged with down; the root conſiſts of tough ſtrings, with numerous ſmall threads matted together, iſſuing from one head, of a duſky browniſh colour approaching to olive. It is perennial, and grows wild in dry mountainous places.

Valerian roots when dry have a ſtrong and grateful ordour rather a diſagreeable, warm, bitteriſh, ſubacrid taſte; the ſtrength of their ſmell and taſte are the only marks of their genuineneſs and goodneſs. Theſe roots have often a diſagreeable ſmell from the urine of cats; and ſometimes there are a mixture of the roots of a ſpecies of crowfoot amongſt them, but on chewing them they are ſomewhat cauſtic, and thus they are diſcovered.

As a medicine theſe roots are an excellent antiſpaſmodic in nervous diſeaſes, and take a place amongſt themildeſt of the fetids. The powder hath been extolled in epilepſies for which end ℈ ii. of it are given three times a day.

The powdered root, digeſted in water, or in ſpirit of wine, impregnates both menſtrua ſtrongly with the ſmell and taſte; water diſtilled from it ſmells ſtrong of the root, but no eſſential oil ſeparates, though ſeveral pounds are committed at once to the ſtill. The watery extract is ſtrong, diſagreebly ſweetiſh, and a little bitter; the ſpirituous extract is agreeable, and much reſembles the root.

The root is the beſt preparation, and when its flavour diſguſts, the mixture of a little mace renders it more agreeable. Next to the powder, a ſtrong tincture made with a proof ſpirit is to be choſen. If to ℔ i. of this tincture, ℥ ii. of the ſpt. vitr. fort. is added, it proves an uſeful remedy in thoſe head-achs which affect the ſtudious, it ſtrengthens the ſtomach, and relieves many flatulent and ſpaſmodic ſymptoms. See Neumann's Chem. Works. Lewis's Mat. Med. Med. Muſ. vol i. no. vii.

VAL-

VALERIANA. A name for the lactuca agnina; a ſpecies of polemonium, of the celtic-nard, and ſpecies of eruca, and a ſpecies of eupatorium.

VALERIANELLA. Small valerian. It is a plant which reſembles the valerian, and grows in warm places. Boerhaave enumerates ſix ſpecies, but they are not noticed in the preſent practice.

VALERIANELLOIDES. An American plant deſcribed by Boerhaave, but no medicinal properties are attributed to it.

VALERIANTHEMUM, i. e. Rapunculus valerianoides cæruleus umbellatus.

VALGI. Children with diſtorted ancles and feet.

VALGUS. Bow or bandy legged. The legs bending outward. Some children are bow-legged from their birth; others become ſo from ſetting them on their feet too early. The tibia of ſome is crooked, the knees of others are diſtorted, from a fault in the ancle; the feet of ſomeare turned inwards, theſe are called vari; and in others they turn outwards, they are called valgi. The beſt method of preventing theſe diſorders in weakly children, is to exerciſe them duly, but not violently, by dancing or toſſing them about in one's arms, and not ſetting them much on their feet, at leaſt not without properly ſupporting them: if the diſorder attends at the birth, or increaſes after it is begun, apply emollients, then apply boots of ſtrong leather, wood, &c. as required to diſpoſe the crooked legs gradually to a proper form; or other inſtruments may be uſed inſtead of boots, which, when not too coſtly, are uſually to be preferred. Slighter inſtances of theſe diſorders yield to careful nurſing without inſtruments. See Hildanus, Le Clerc, Solingen, and Heiſter's Surgery.

VALLUM. The eye-brow. Alſo a ſpecies of bandage.

VALVA, from *valvæ folding doors*. A valve. It is any thing that opens and ſhuts over the mouth of a veſſel. In anatomy it is a membrane which opens certain veſſels to admit the blood or other fluid, and which ſhuts again to prevent is returning.

VALVULÆ CONNIVENTES. They are looſe circular folds, chiefly in the ſmall inteſtines towards the ſtomach, and are productions inwards of the villous coat; their uſe is to mix the chyle with the bile and pancreatic juice, and to retain the chyle that it may not eſcape the lacteals.

VALVULA PALATI, i. e. Palatum Molle.

VALVULUS. See Iliaca Passio.

VANILLA, alſo called banilia, banilas, and vanelloes. They are the fruit of a climbing plant in the Spaniſh Weſt Indies. They are only uſed to give an agreeable flavour to chocolate: but they are greatly extolled for their efficacy in cheering the ſpirits of melancholy perſons. See Med. Muſ. vol. iii. p. 342, &c.

VARICELLA. The chicken-pox. Dr. Cullen places this genus of diſeaſe, in the claſs pyrexiæ and order exanthematæ. He defines it to be, a ſynocha. After a moderate fever ſpots break out, which ſomewhat reſemble the puſtules of the ſmall-pox, but hardly advance to ſuppuration; theſe eruptions, after a few days, dry away in ſcales, without leaving any mark behind them.

VARICIFORMES PARASTATÆ. They are continuous to the epididymides, and are veſſels ſo called becauſe they appear full of flexures and contortions, like the varices, for the better elaboration of the ſemen.

VARICOSA CORPARA, i. e. Spermatica Vaſa.

VARICOCELE, It is a varicoſe diſtenſion of the veins of the ſcrotum; which in this ſtate form a tumor of hard knotty inequalities, ſeldom attended with pain, and in general productive of no inconvenience except what ariſes from its bulk. In order to the relief of this diſorder, it may be treated as the cerſocele, which ſee.

VARICULA. A diminutive of varix. Thus M. A. Severinus calls an intumeſcence of the veins in the tunica adnata of the eye, when it is cauſed by black blood.

VARIOLA. The ſmall pox. Dr. Cullen places this genus of diſeaſe in the claſs pyrexiæ and order exanthematæ. It is an acute, eruptive, infectious diſeaſe, of its own kind; it is accompanied with inflammation, which terminates by ſuppuration, in cuticular puſtules; it is, in a natural way, uſually completed by three diſtinct continual, ſymptomatic fevers, viz. the fever of depuration, which is nervous; of ſuppuration, which is ardent; and of retroceſſion, which is putrid. The firſt account we have of this diſorder was writ by Rhazes, about the end of the ninth, or the beginning of the tenth century, and his deſcription of it was ſo complete, that little or nothing was added to it for five hundred years after: he alſo uſed the cool method in the management of it. Rhazes ſays that Aaron, an Alexandrian phyſician, was the firſt who deſcribed it, and that he writ A. D. 622. The next to Rhazes was Sydenham; he obſerved that the flower the eruption the more favourable the diſeaſe was; he admirably deſcribes it, and improved the management of it in the firſt period, that is, to the ſixth or ſeventh day, when the ſecondary fever came on; at this period he obſerved that on a ſudden the pulſe became regular, and all the puſtules were out all over the body, the urine was well coloured, or thick, the eyes cool and free from the fiery luſtre which was obſervable before; that the ſecondary fever came on by degrees at the firſt, but ſoon the eyes are inflamed and watery, a delirium comes on, the urine is pale, the pulſe quick and hard, throat is ſore, &c. and here he takes the patient out of bed, and orders cool air; the patient's feet to be put into warm water, and an opiate to be given and repeated as required until the rage is abated. The next was Helvetius, who obſerved the uſefulneſs of purging when the fatal ſymptoms came on, which Sydenham had remarked in the laſt ſtage; and Dr. Freind introduced the practice in England. Boerhaave ſtill advances, with reſpect to the nature and management of the *ſmall-pox*; he ventured to reſtrain the too ſudden eruption of the puſtules, and commends the attempt to cure the *ſmall-pox* without permitting the ſuppuration to come on. The next to Boerhaave was Dr. Thompſon; he obſerves the propereſt method of reckoning the time of the eruptions continuance, their ſuppuration, and that as circumſtances attend, theſe vary; alſo that the ſwelling of the face, and the ſpitting at the turn, are beſt kept up by moderating the fever. Many other judicious and uſeful obſervations have alſo appeared, but they are almoſt ſuperſeded by the practice of inoculation.

When the *ſmall pox* is epidemical, it uſually begins about the vernal equinox. Sydenham obſerves that when it is irregular and dangerous it begins ſooner, as in January or February. Boerhaave ſays that if it ariſes in a place where it hath been ſix years abſent, and makes its appearance in January or February, the following ſummer will be attended with a fatal kind; but if it firſt appears in May, it will be of a gentle kind.

Sydenham divides the *ſmall pox* into the diſtinct and the confluent kinds; the diſtinct is when the puſtules do not touch each other; the confluent are when the puſtules more or leſs run into one another. Dr. Mead divides them into the ſimple and malignant; the ſimple is when the ſymptoms are mild, the ſuppuration kindly, and at laſt the puſtules fall off in dry ſcabs; the malignant is when the fever is great, the puſtules advance but ſlowly, and do not ſuppurate well, and the other ſymptoms are violent.

As Sydenham excels in his deſcription of this diſeaſe, ſo as that Boerhaave ſays, "Sydenham's book is the only one worth reading on the *ſmall pox*;" his account of it in its riſe, progreſs, ſpecies, and termination, here follows. The diſtinct *ſmall pox* begins with a chillineſs and ſhivering, which is immediately followed by extreme heat, violent pain in the head and back, vomiting, and in adults a tendency to ſweat; this laſt is not obſerved in children; pain juſt under the *ſcrobiculum cordis*, if it is but gently preſſed with the hand, ſleepineſs and ſtupor particularly in children, and ſometimes convulſions, which laſt, if they happen after dentition is completed, you may always ſuſpect the *ſmall pox* to be juſt approaching, and the eruptions appearing in a few hours afterwards generally verify the prognoſtic; ſo that, for inſtance, if a convulſion fit attacks a child over night, as it uſually happens, the *ſmall pox* appear in the morning following; and it frequently happens that the *ſmall-pox* immediately ſucceeding ſuch fits, throws out large eruptions, but they are of a mild kind, and rarely confluent. Theſe are almoſt all the ſymptoms that accompany this diſeaſe in the beginning, and they generally precede the eruption of the

puſtules: but where the blood is of a looſer texture, and ſo eaſily admits of a change, it ſometimes happens that the ſeparation is performed by degrees, without any conſiderable ſickneſs before the expulſion of the matter ſhews itſelf by the eruption of the puſtules.

The diſtinct *ſmall pox* comes out moſtly on the fourth day, incluſive from the beginning of the illneſs, and ſometimes a little later, but ſeldom ſooner, at which time the ſymptoms are uſually much abated, or even go quite off, ſo that the patient thinks himſelf pretty well; but grown perſons are ſo inclined to ſweat, that it can hardly be prevented, however lightly they are covered, and this diſpoſition continues until the puſtules begin to ripen, and then vaniſhes ſpontaneouſly; this ſweating foreſhews a diſtinct ſort. The eruptions proceed nearly as follows: pale red puſtules, as large as the head of a ſmall pin, ſhew themſelves here and there on the face firſt, or on the neck and breaſt, afterwards on the body, and during this ſtage of the diſeaſe the throat is affected with a ſoreneſs, that increaſes as the puſtules ariſe, which growing every day fuller, inflame the ſkin and fleſh of the neighbouring parts; for about the eighth day from about the beginning of the diſeaſe, the ſpaces between the puſtules that appeared before of a pale white begin to grow red, and ſwell in proportion to the number of the puſtules, with a throbbing pain of thoſe parts, which continually increaſing occaſions the inflammation and ſwelling above mentioned, ſo that in the progreſs of the diſeaſe the eye-lids are ſo filled and diſtended, as ſometimes to make the patient blind; and this tumor looks like a ſhining inflated bladder drawn over them. The blindneſs comes on ſooner if a great number of puſtules fix on the eyes at the beginning of the eruption; immediately after the face, the hands, and fingers ſwell, in proportion to the number of the eruptions. The puſtules on the face, that until this day were ſmooth and red, now grow rough and whitiſh, which indeed is the firſt ſign of a beginning ſuppuration, and they likewiſe gradually diſcharge a yellow matter, in colour reſembling a honey-comb. The inflammation of the hands and face, in the mean time, come to its height, cauſes the ſpaces between the eruptions to look of a pretty florid colour, like a damaſk roſe; and the more mild and genuine the *ſmall pox* is, ſo much more the eruptions, and their intermediate ſpaces approach this colour. As the puſtules in the face appear rougher and yellower every day as they ripen; ſo, on the contrary, thoſe of the hands, and other parts, appear ſmoother, and not ſo white. On the eleventh day, the inflammation and ſwelling manifeſtly abate, and the eruptions, both of the face and the reſt of the body, being come to their maturity and juſt bigneſs (which is nearly the ſize of a pea), they dry and ſcale off, and in this kind of *ſmall pox*, uſually quite diſappear on the fourteenth or fifteenth day; but the eruptions on the hands being generally more obſtinate than thoſe of the other parts, and yet freſh and white, remain a day or two longer. Thoſe on the face and body dry and ſcale off, but thoſe on the hands burſt, and ſo vaniſh. The puſtules on the face are ſucceeded by a ſcurf, or branny ſcales, and thoſe ſometimes by pits, or marks; for when the puſtules firſt fall off, the ſkin is ſmooth, but thoſe ſcales coming on and falling off alternately, do at length make thoſe pits: yet it often happens that this diſtinct ſort leaves no marks behind.

The confluent *ſmall pox* is attended with the ſame ſymptoms in common with the diſtinct ſort; but they are all more violent, particularly the fever, anxiety, ſickneſs, vomiting, and the pain in the back, by which you may foretel that the confluent ſort are approaching. The patient is not ſo ready to ſweat in this ſort, but a looſeneſs ſometimes precedes, and continues a day or two after the eruption, which is not ever obſerved in the diſtinct kind. The confluent ſort generally comes out on the third day, ſometimes earlier, but rarely later; and the ſooner the puſtules come out before the fourth day, the more they run together: however, though to ſpeak in general, the confluent kind ſcarce ever appear ſo late as the fourth day, yet ſometimes the eruption may be deferred by ſome violent ſymptoms to the fourth or fifth day: e. g. 1ſt, Sometimes a ſharp pain in the loins reſembling a fit of the ſtone. 2d, A pain in the ſide like that in a pleuriſy. 3d, A pain in the limbs like that in a rheumatiſm. 4th, A pain in the ſtomach, attended with ſickneſs and vomiting. In theſe caſes, which indeed rarely happen, the ſpots are retarded, and they alſo foretel great danger. Though the ſymptoms accompanying this diſeaſe in the beginning of the diſtinct kind, go off immediately after eruption, it nevertheleſs happens much otherwiſe in the confluent kind, in which the fever, and other ſymptoms, afflict the patient for ſeveral days after the puſtules appear. Sometimes this ſort comes out like the eryſipelas, and ſometimes like the meaſles, from which it is next to impoſſible directly to diſtinguiſh them by external appearances; but by attending to the different time of the eruption in theſe diſeaſes, and other circumſtances, which from their reſpective hiſtories will be found to differ greatly, you will be able to diſtinguiſh them. As the diſtemper increaſes, the puſtules, eſpecially thoſe of the face, do not riſe ſo high as thoſe of the diſtinct kind, but, running together, appear at firſt like a red bladder, covering the whole face, and making it ſwell ſooner than in the diſtinct ſort, and at laſt they appear like a thin white pellicle cloſely adhering to the face, and riſing a little higher than the ſurface of the ſkin. After the eighth day, this pellicle grows gradually rougher, as appears by the touch, and inclines to a brown, and not to a yellow colour, as in the diſtinct kind. The roughneſs and colour of the ſkin daily increaſes, until at length the pellicle falls off in large ſcales; but when the diſeaſe hath been ſevere, it uſually ſticks to ſome parts of the face till after the twentieth day. The more violent the *ſmall pox* proves, the nearer the eruptions, as they ripen, incline to a dark brown colour, and the longer they are in falling off, if left to themſelves; whereas, on the contrary, the leſs they run together, the yellower they grow, and the ſooner they ſcale off. When the pellicle, which covers the face, firſt falls off, it leaves no roughneſs behind, but it is immediately ſucceeded by branny ſcales of a very corroſive nature, which not only make larger pits than the diſtinct kind generally do, but alſo much diſfigure the face with unſeemly ſcars; and in the confluent kind, if the diſeaſe hath been very violent, the ſkin of the ſhoulders and back ſometimes ſcale off, leaving theſe parts bare. In the confluent *ſmall pox*, the eruptions on the hands and feet are larger than thoſe of the other parts, and are gradually leſs, as they approach the body. Peculiar to the confluent *ſmall pox* is a ſalivation in adults, and a looſeneſs in children; the former never fails to attend, the latter rarely. The ſpitting begins as ſoon as the eruption appears, and ſometimes a day or two after; the matter is at firſt thin, and eaſily and plentifully expectorated; but towards the eleventh day the ſaliva becomes viſcous, and is raiſed with difficulty; the patient is thirſty, coughs often while he drinks, and the liquor flies out of his noſtrils, and from this day the ſalivation generally ſtops, though ſometimes but very rarely: after it hath ceaſed entirely for a day or two, it returns again. On the ſame (i. e. the eleventh) day, the ſwelling of the face, and the ſpitting begin to abate, but then the hands commonly ſwell, or at leaſt ought ſo to do. A looſeneſs does not ſeize children ſo ſoon as a ſalivation does; but whenever it begins, if it is not ſtopped by art, it attends throughout the diſeaſe. In both the diſtinct and the confluent ſort, the fever rages moſt from the beginning to the time of the eruption, after which it abates, and continues much more moderate, until the ſuppuration begins, which being finiſhed, it goes off entirely. Again, when the diſeaſe proves violent, the patient hath a kind of fit towards the evening; at which time, eſpecially, the moſt dangerous ſymptoms ariſe, and rage moſt ſeverely.

As to the prognoſtics of this diſorder, it is uſually obſerved, that the danger is proportioned to the number of the puſtules on the head, and particularly on the face. If many puſtules are on the body, and but few on the face, the danger is ſmall; but though few are on the body, if there are many on the face, the danger is great. If the pain in the head and eyes, which attends in the beginning, (but uſually goes off at the appearance of the eruption) continues through the ſeveral ſtages of the diſtemper, it leaves a diſorder in the head after the *ſmall pox* diſappears, and ſometimes a gutta ſerena is the effect. Bloody urine, and a diſcharge of blood from the lungs, are uſually fatal ſymptoms; but a convulſion fit preceding the eruption in children, and a ſweating coming on in adults, are tokens of the diſtinct and mild ſort.

The principal indication in the management of the *ſmall pox* is, to prevent the too haſty aſſimilation of the *variolous* matter in the beginning of the diſeaſe; but as the greateſt advantages attend the treating of patients who labour under this diſorder from natural infection, as thoſe are treated in whom it is artificially introduced, the reader is referred for direction therein to the management of the inoculated *ſmall pox*, and to the authors referred to in the concluſion of this article.

Of the SMALL POX by inoculation. Sydenham practiſed in the preſent cool method of treating the *ſmall pox*, and writ in defence of the ſame. Boerhaave propoſed, as already obſerved, to cure the *ſmall pox* without permitting a ſuppuration. In 1713, Dr. Woodward received a letter which gave an account of the ſucceſs of inoculating the *ſmall pox* in Conſtantinople. In 1721, George I. king of Great Britain, conſented that a trial ſhould be made on ſeven condemned criminals, and ſucceſs attending the experiment, ſome of our nobility were inoculated, and, in 1722, ſome of the royal family followed their example. In three years after, 447 people were inoculated in England, of whom only nine died. In 1727, Neumann writ in the German language on the *ſmall pox* by inoculation; but ſome favoured and others oppoſed its progreſs; and the practice was but little encouraged, until the courage of Mr. Sutton led him into the preſent improved method of communicating the *ſmall pox*, and of treating thoſe who are the ſubjects of it; for which he hath reaped the deſerved emolument, viz. an affluent fortune, and a place in the liſt of fame. But the benevolence which accompanied the ſame ſagacity in doctor (now baron) Dimſdale, led him to teach the world the art of relieving themſelves from the terrors of that diſeaſe which Sydenham deſcribes as above; thus he is fixed on the ſcale of merit, and imperial favour hath crowned him with glory. His preſent method of inoculating for the *ſmall pox* is the ſtandard of practice, and his plan is here purſued as the moſt complete on the ſubject.

It hath been queſtioned by ſome, whether or no the genuine *ſmall pox* was conveyed by inoculation? But there is in reality much more difficulty in conceiving, that a contagious ſubſtance ſhould propagate, inſtead of its own, another diſeaſe. Dr. De Haen, amidſt all his oppoſitions to inoculation, never ſuppoſed that the matter of the *ſmall pox* produced any diſeaſe but the *ſmall-pox* itſelf.

As to whether the matter for inoculation be from patients labouring under this diſorder received in the artificial or in the natural way, experience does not manifeſt any difference; nor does it ſignify whether the matter is taken from a mild kind, or from the more virulent ſort. The crude matter received from the place of inoculation before the patient ſickens, ſuffices for this operation. The advantage of inoculation depends more on the diſpoſition of the conſtitution than on the kind of matter which may be conveyed by it; and the next advantages to a proper habit are, the mode of the diſorder's being communicated, and the manner of treating the patient whilſt it is preſent.

The principal advantages of inoculating the *ſmall pox* are, that the puſtules can be made to be fewer in the face; the marks on the face are not ſo deep from the inoculated as from the natural *ſmall pox*; the ſecondary fever rarely follows inoculation; meaſures can be taken to provide againſt the violence of the future fever, and other ſymptoms; the loathſomeneſs and the difficulty of managing this diſeaſe is greatly leſſened, from thoſe which attend in the natural *ſmall pox*. It is probable that the infection being received in a vital part in the natural way may have more violent effects than when communicated by the extremities.

The ſubjects of inoculation are thoſe of every age. If an exception is admitted of againſt any, it is during the firſt two years after the birth of infants, or until they have cut their teeth; for until then their irritable frames render them ſuſceptible of violent effects from ſlight cauſes. Old age is no objection, the aged are uſually moſt ſecure from danger. Infants are proper ſubjects, from their birth to the time that their teeth begin to trouble them; and when detention is over, the vigour of the child's health will always determine for or againſt the operation.

Conſtitutions of moſt kinds admit of inoculation with ſafety. The ſcrophulous, ſcorbutic, arthritic, the corpulent, and even the intemperate, all do well. Thoſe who labour under acute or critical diſeaſes, or in whom are ſymptoms of great debility, ſhould be treated with proper means for the recovery of health previous to their being inoculated.

In general, the temperate ſeaſons are preferred; but the only exceptionable one is, the hot months in ſummer, though cold conſtitutions are ſafely inoculated in the warmeſt weather. When inflammatory or putrid diſeaſes prevail, they are unfriendly, and during their continuance, inoculation ſhould be omitted.

The beſt preparation is, to produce a healthy ſtate of the body. If the health is perfect, preparation is uſeleſs; if defective, it muſt be reſtored. That peculiar diſpoſition on which a mild *ſmall pox* depends is yet unknown; an healthy one comes the neareſt to it, and could that be aſcertained, perhaps, it is it.

In the *ſmall pox* the inflammatory ſymptoms are uſually the principal ſource of our care, and that method which reduces and maintains the vis vitæ near, or rather below the medium of perfect health, whilſt it guards againſt danger, ſupports the patient's vigour, and enables him to ſurmount the morbid attack.

Before the patient is inoculated, a due regard muſt be had to the ſtate of his body, and to the removal of ſuch ſymptoms, &c. as may embarraſs or endanger. The diet ſhould be of the cooling vegetable kind, and ſuch as tends to keep the bowels lax and promotes the urinary diſcharge. Whatever is the particular diet, full meals are not to be allowed until ſuppuration begins, and then, as well as after the eruptions are fallen off, a gradual return to the uſual diet is moſt proper. Animal food and cordial liquors are only to be uſed if needful for ſupporting the ſtrength and ſpirits of the patient, and, when admitted, great care is required not to exceed theſe intentions in their uſe.

The patient conſidered as a proper ſubject, inoculate him, and in the evening give as much calomel mixed with 1-16th part of the emetic tartar, as will gently move the belly, and in the morning aſſiſt its operations with as much Glauber ſalts, or other ſuitable purging medicine, as will procure three or four evacuations; repeat theſe every ſecond night and morning, until the ſymptoms of eruption appear. Mercury ſeems to be ſpecific in the *ſmall pox*, and may be given ſo freely as to affect the gums and excite a gentle ptyaliſm. When infants at the breaſt are inoculated, the nurſe may take the medicines above preſcribed. When the inflammation at the puncture is too little, increaſe the doſe of the calomel, for then it both promotes the inflammation there and accelerates the general eruption.

To communicate the infection, the *variolous* matter muſt be introduced into a ſenſible part; and, as the ſmalleſt ſenſible quantity of *variolous* matter ſuffices to produce the *ſmall pox*, the point of a needle, or of a lancet, may be dipped in the ſerum that ouzes from a puncture made in any patient for producing the *ſmall pox*, or in a *variolous* puſtule, and then introduced into the ſkin, juſt deep enough to wound it; but it is not neceſſary that blood ſhould be diſcharged. The needle, or lancet, dipped in the *variolous* matter, will ſuffice ſeveral days after for communicating the infection. One puncture may ſuffice, but generally one is made in each arm, any where above the elbow.

Inflammation about the puncture is a ſure ſign of infection having taken place; but this cannot be diſcerned if either an inciſion is made, or any dreſſings are applied where the infection was communicated; therefore, the puncture being made, leave it to heal, or to whatever may occur in conſequence of the infectious puncture. By making a puncture only we may obſerve the progreſs of the infection and ſubſequent diſeaſe; but theſe cannot be obſerved if an inciſion is made, or if plaiſters, &c. are applied to the punctured part. Beſides, no ſore, abſceſs, nor mortification, follows the puncture, as is obſerved when inciſions are made.

If a perſon happens to receive the infection by inoculation and in the natural way at the ſame time; that which

was

was received by a wound, operating ſooneſt, deſtroys the diſpoſition in the body to be affected by the natural infection. The progreſs of the infection is obſerved as follows: about the punctured part, and from thence, a juſt prognoſtic is uſually formed of the future ſtate of the diſtemper, and thus future inconveniences may be guarded againſt. Sometimes the effect of the infection is obſerved in a few hours after the patient is inoculated, by ſharp pains darting up the ſhoulder (when the puncture is made in the arm), a ſhivering through the body, a red tumor on the arm, or a ſmall riſing where the matter was applied; but moſt frequently its progreſs is as follows. Suppoſe the infection to have been communicated in the morning, though it takes effect, nothing is obſerved on that day. On the ſecond day, if the puncture is viewed with a lens, an orange coloured ſtain is obſerved about its edges, and they ſeem to contract; ſometimes the puncture inflames on the firſt or ſecond day, and then vaniſhes without any further effect; in this caſe, if the patient had not the *ſmall pox* before, except the punctured part becomes tumid as well as inflamed, and alſo ſuppurates, or is attended with uneaſineſs in the axillary glands, the efficacy of the infection remains doubtful, and after a few days the operation may be repeated. On the fourth or fifth day, an hardneſs may be perceived where the puncture was made, an itching is felt there, and generally a ſlight inflammation is alſo obſerved. On the ſixth day, there is generally a pain and ſtiffneſs felt in the axilla, which continues until the tenth or eleventh day. This is a favourable ſymptom; it foretels the near approach of the eruption, and denotes a favourable progreſs through the whole of the diſeaſe. Pain in the head and limbs, with ſtiffneſs under the arms, are among the certain proofs that the infection hath taken place. On the ſeventh or eighth day, the eruptive ſymptoms appear, ſuch as ſlight remitting pains in the head and back, ſtiffneſs in the arm-pits, tranſient ſhiverings, alternate heats, &c. which continue more or leſs until eruption is completed: the inflammation in the arm ſpreads, and little puſtules are begun there, which increaſe in ſize as the diſeaſe advances. On the tenth or eleventh day an efflorescence ſurrounds the puncture, and ſometimes extends half way round the arm; the larger this efflorescence is, the fewer are the puſtules uſually; when it accompanies the eruption, the fever and other uneaſy ſymptoms ſubſide, and all difficulty and danger is at an end. As ſoon as the eruptive ſymptoms are perceptible, give a doſe of calomel with the emetic tartar as above, and a few hours after give a doſe of the ſal. Glaub. and thus for the moſt part all is done that is required from medicine.

It ſometimes happens that none of the ſymptoms on the arm appear before the eighth day, and then the inflammation, &c. about the puncture riſes ſuddenly: this late appearance of ſymptoms is generally regarded as foretelling an untoward diſeaſe, but this is not always the caſe. Mr. Sutton repeats the evacuations from the time of infection to this time, ſo as that no longer appearances of the rigid fibre remains; and obſerves that when the ſkin is hot and dry, repeated doſes of ſalts do much better than the mercurial medicine.

Among the favourable ſymptoms are, an orange coloured ſtain about the edges of the puncture on the ſecond day, an itching there in two or three days, a kind of veſication, without much inflammation on the third or fourth days, a pain and ſtiffneſs in the axilla, the ſooner the better; but if on the ſixth day it is well; the large efflorescence about the puncture on the tenth or eleventh day or ſooner; an hardneſs which ſpreads from the puncture as from a centre, and to the touch forms ſtar-like points, and when the part inflamed on the arm, riſes as it were to an apex with a little dry ſcab on it.

The leſs favourable ſymptoms are, a purpliſh inſtead of a red coloured inflammation about the puncture, a narrow deep red circle ſurrounding the puncture, and when the incruſtation about the puncture becomes depreſſed and concave in the middle.

The firſt ſymptoms of a fever being manifeſt, a doſe of calomel and the purging ſalts muſt be given. The higher the fever, the more numerous are the eruptions; at this time, if the fever runs high, give the febrifuge ſpirit in cold water, as directed in the article FEBRIS, or give the ſlibiated nitre in water, for common drink, and let the patient's thirſt determine the quantity; expoſe the patient to the cold air. As ſoon as by the above means, or by the uſe of other acidulated, or cooling liquors, a perſpiration appears on the ſkin, let the drink be tepid baum tea, or other agreeable ſmall liquor. This cooling method muſt be urged more or leſs according to the conſtitution of the particular patient. In this ſituation, though the patient is not able to walk, he may be carried out into the air, whatever be the weather, and this though he be ſhivering in a rigor, cold water muſt be given for drink if the patient requires it; the aged and feeble may be allowed white wine whey. Thus either alarming ſymptoms or a large crop of puſtules are prevented. As to the heat or cold to which the patient is ſubjected, that degree which is moſt agreeable to his ſenſation is the proper one. In caſe of great ſickneſs, languor, delirium, eſpecially if attended with a weak pulſe, cordials may be allowed, repeat them as the pulſe and other circumſtances require.

When the eruption is completed, and the ſtate of maturation is begun, allow the patient a little broth, veal, mutton, or jelly, and now and then a glaſs of ſome ſmall vinous, or malt liquor. Some tender conſtitutions indeed require at this time to be kept in bed, and to be ſupplied with a cordial and nouriſhing diet.

Whether the cooling or the cordial method is purſued, the heat of the body ſhould be kept, as nearly as may be, to that of health; the languid may require to have more heat preſerved than is neceſſary in the robuſt, and it may be obſerved that, as the cool method is to prevent the too great abundance of eruptions being formed on the ſkin, ſo when they are determined there and fixed, a moderate heat is required to perfect them; ſo a regard to heat, according to the ends expected from it, is to be the rule of management.

During the ſtate of maturation opiates are not neceſſary, except there is great pain and reſtleſſneſs; and if an opiate is adminiſtered, a clyſter ſhould accompany it; for during the whole courſe of the *ſmall pox*, a lax belly, and a free diſcharge by urine, are eſſentially neceſſary.

Whether the *ſmall pox* are produced in the natural or the artificial way, the violent and dangerous ſymptoms are from either an ardent or a putrid fever attending; and an attention to the methods propoſed in thoſe diſorders, as they are applicable here, will enable the practitioner to proceed properly when they attend this complaint.

On the *ſmall pox*, ſee Swan's Tranſlat. of Sydenham's Works; Stack's Tranſlat. of Mead's Diſc. on the *Small-Pox*; Huxham on the *Small Pox*; Thompſon's Enquiry into the Origin, &c. of the *Small Pox*; Tiſſot's Practical Obſervations on the *Small Pox*; Brooks's Practice of Phyſic; and on the inoculated *ſmall pox*, ſee Kirkpatrick and Dimſdale. For particular obſervations, ſee Percival on the Advantages and Diſadvantages of Inoculating Children; Blake's Letter to a Surgeon on Inoculation; alſo Baker, Burges, Matty, Watſon, Glaſs, Bromfield, Gatty, Chandler, &c.

VARIOLA DISCRETA. The diſtinct ſmall-pox.

VARIOLA JAPONICA. The confluent ſmall-pox.

VARIOLA LYMPHATICA, i. e. Varicella.

VARIOLÆ. So Boerhaave calls the ſmall-pox.

VARIUM [os], i. e. Os cuboides.

VARIX. A preternatural diſtenſion of parts of the veins are called varices. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order tumores. Sometimes *varices* are formed in the legs, and are ſo large and troubleſome as to require being cut away. See Gooch's Treat. on Wounds, page 188. Pregnant women frequently have them in their legs, and ſo have thoſe in whom the liver is ſcirrhous. Generally a tight ſtocking is all that is needful for relieving the inconveniences occaſioned by this complaint. See Heiſter's Surgery.

VARUS. A pimple on the face.

VARUS. A pimple. Dr. Cullen places theſe as a variety of phlogoſis phlegmone. The bacchia or gutta roſacea, he conſiders as ſynonymous with *varus*. See GUTTA ROSACEA. It alſo ſignifies the bending inward of the legs. See VALGUS.

VASA PRÆPARANTIA. The ſpermatic cord.

VASA BREVIA. See SPLENICA ARTERIA.

VASTUS EXTERNUS. See VASTUS INTERNUS.

VASTUS INTERNUS. The crureus, the vaſtus externus, and the *vaſtus internus*, may be conſidered as one muſcle, whoſe outer part riſes from the external part of the femur, the inner part from the internal part, and the middle from the anterior part, in ſuch a manner as to ſurround the whole thigh, except the linea aſpera, taking its origin likewiſe from the ſurface of the bone: theſe muſcles join the tendons with their rectus.

VEGETABILIS. Vegetable. *Vegetables* are thoſe natural productions in the terraqueous globe which have life and growth, but not ſenſe, as trees, herbs, &c. The bodies of *vegetables* are of a regular organic ſtructure, analogous in ſome degree to that of animals: they are furniſhed with a variety of veſſels, for receiving, tranſmitting, and perſpiring different fluids; with organs too, by which the aliment they imbibe from the earth, water, or air, is changed into new forms, into juices peculiar to particular plants. The ſubſtances naturally contained in *vegetables*, and ſeparable from them by art, are gum, reſin, a ſubtil oil, camphor, a groſs oil, a ſaline matter, phlegm, and an earth: theſe are called the native principles of *vegetables*; native, becauſe they naturally exiſt in plants; and principles, not as being ſimple, but as it is by theſe that one plant differs from another, and that each exerts its ſpecific power; and as they cannot be further reſolved without totally deſtroying their peculiar qualities. Various are the diviſions into which *vegetables* are diſtinguiſhed, whether conſidered as the ſubjects of botany, or of medicine, &c. and numerous alſo are the preparations they afford to pharmacy and other branches of art, as may have been already obſerved from what is delivered in the preceding ſheets. Amongſt a variety of other preparations of the *vegetable* kind, by fermentation we obtain inflammable or vinous ſpirit, ether, malt liquors, wines, vinegars, tartar, &c. by fire, or burning, are procured empyreumatic oils, fixed *vegetable* alkaline ſalts, &c.

On the culture, nutrition, &c. &c. &c. of *vegetables*, See Linnæus, Malpighi, Grew, Hill, &c.

VELAMENTUM BOMBYCINUM. The interior ſoft membrane of the inteſtines, from *bombyx, a silk-worm.*

VENÆ. Veins. A *vein* is a thin ramifying elaſtic tube, which ariſes in the extremities of the body, and terminates in the heart or in the liver. The blood is diſtributed all over the body by two arteries, the aorta, and the pulmonary artery; and it is returned by three kinds of *veins*, viz. the *vena* cava, the pulmonary *veins*, and the *vena* portæ.

In general the arteries have their correſpondent *veins*, ſo the courſe of the one is known by that of the other.

Veins begin where the arteries end, and proceed from the branches to the trunk, making a conoid figure, in the ſame ſenſe that the arteries have been ſaid to do.

The extremities of the arteries in the brain are continued into their *veins*, whoſe trunks vary much in their continued poſition from the arteries, theſe entering the brain at its baſis, and diſtributing themſelves as noted in ſpeaking of them; whereas the trunks of the *veins* are extended on the ſurface of the brain, and diſcharge their blood into the longitudinal ſinus; nor do the *veins* of the brain accompany their arteries at their ingreſs as in other parts, and as the arteries and *veins* of the dura mater do.

The *veins* which are ſubject to frequent compreſſion from the action of the muſcles, have valves which open towards the heart; in all the *veins* alſo which are perpendicular to the horizon, excepting thoſe of the uterus and portæ, there are valves with their mouths towards the heart; theſe valves prevent the return of the blood in the *veins*.

Beſides the deep ſeated *veins* which accompany the arteries in the extremities, there are other *veins* more ſuperficially ſeated, the reaſon of which is to prevent the circulation being interrupted by the action of the muſcles compreſſing the internal *veins*.

The coats of the *veins* are the ſame as thoſe of the arteries, but they are thinner, being compoſed of fibres in all directions, they bear ſtretching better than the artery, whoſe chief ſtrength is in the circular fibres; the coats of the *veins* are thicker in the extremities than among the viſcera, particularly the ſaphæna is of a remarkable thickneſs.

The capacity of the *veins* is much larger than the arteries, except in the pulmonary veſſels, where the four *veins* taken together are not equal to the artery. See Winſlow's Anatomy; Haller's Phyſiology of the *Veins*.

VENENUM. Poiſon. This word ſeems to be a relative term only; what are called *poiſons*, have, in their reſpective inſtances, ſalutary effects; they injure by miſapplication. The ancients made no diſtinctions between *poiſons* and medicines, they went both by the ſame name. In our day we are uſed to conſider thoſe articles which have not been employed with any ſalutary effect, as abſolute *poiſon*; but in this we do not think duly. Again, we annex the idea of *poiſon* to thoſe things which produce their ill effects in very ſmall quantities, and of whoſe form and action we are little or not at all acquainted. When any thing acts mechanically, though it deſtroy, we never rank it with *poiſons*. Things that kill unavoidably, though not mechanically; things that are of a ſpecific nature, and produce ill effects; thoſe injurious things whoſe effects are relieved by ſpecifics; and thoſe for which we have no cure, are all called *poiſons*. In ſhort, it is difficult to give a definition of the word *poiſon*, perhaps impoſſible. Surely that alone could be properly called a *poiſon*, or be conſidered as abſolutely a *poiſonous* ſubſtance, which at all times, in any quantity, and on all occaſions of applying it, would without exception be deſtructive. Such a ſubſtance is unknown.

To ſpeak in uſual phraſe, *poiſons* are the produce of the animal, vegetable, and mineral kingdom. Their action is either mechanical (when they are not ſo properly ranked) chemical, or on the principle of life.

The animal *poiſons* act chiefly on the living principle; they are natural or morbid. The natural are found in particular animals for ſome uſe or benefit to the individual in which it is found: the natural *poiſons* do not, like the morbid ones, produce more of their own kind. The natural *poiſons* firſt affect the part to which they are applied; then, either by abſorption, or by ſympathy, the whole habit ſuffers. The morbid animal *poiſons* are various, and many of them appear without our being able to diſcern the cauſe of their production. The ſmall pox, meaſles, &c. are of this claſs; the cancer alſo, and the hydrophobia too; both which ariſe ſpontaneouſly. Morbid *poiſons* are produced from a ſimilar diſeaſe before affecting, as the ſmall-pox, &c. or they ariſe ſpontaneouſly, from ſome morbid actions of the parts endowed with life, as the cancer, &c. And theſe, when produced, have the power of increaſing and forming freſh matter of the ſame kind, and propagating their own ſpecies. The morbid animal *poiſons* are leſs active than the natural ones; they do not produce their effects ſo rapidly.

Mr. Wilmer, in his Obſervions on the *Poiſonous* Vegetables found in Great Britain, ſeems to claſs them into, 1ſt, Thoſe from which the maniacal ſymptoms are to be expected, or the various nervous affections, from a vertigo to a fatal apoplexy. In this claſs he includes the ſoporiferous plants. Of theſe there are the following, very generally met with in our iſle, viz. HYOSCIAMUS NIGER, SOLANUM LETHALE, ACONITUM, MERCURIALIS SYLVESTRIS, STRAMONIUM, CICUTA MAJOR FOETIDA, AGARICUS MUSCARIUS, AGARICUS PIPERATUS, which ſee.

And, 2dly, Thoſe which produce epileptic ſymptoms: a loſs of underſtanding, ſpeech, and all the ſenſes will take place in a few minutes after theſe *poiſons* are in the ſtomach: the muſcles will be convulſed, and death will cloſe the ſcene in a few hours. Of theſe there are found in moſt parts of Great Britain, the following, viz. ŒNANTHE CHÆROPHYLLI FOLIIS, CICUTA AQUATICA, LAURO CERASUS, which ſee.

The danger of theſe laſt is very great; they do not offend the palate, ſo may paſs unſuſpected into the ſtomach; when there, they do not produce any ſickneſs, ſo are not likely to be diſcharged without the aſſiſtance of art; and they are ſo quickly active that they ſcarcely admit of any opportunity for that aſſiſtance to be given.

Mr. Wilmer further obſerves, that, *poiſonous* vegetables appear to act by an oppreſſion upon the nervous ſyſtem, rather than by an inflammation of the ſtomach and duo-

denum, which from the beginning produce thoſe other intervening ſymptoms that uſually end in death. He very judiciouſly obſerves, that theſe vegetable *poiſons*, in different conſtitution will have various and ſometimes oppoſite effects. The moſt contrary ſymptoms are produced in different perſons who have taken the ſame *poiſon*. They gave proofs that both the utmoſt irritation and appearances which indicated that the office of the nerves was deſtroyed, might ariſe from the ſame cauſe, working its effects in different conſtitutions.

Mineral *poiſons* are acrid or corroſive, as arſenic, cobalt, and mercury ſublimate; or they are ſedative, as the preparations of lead, &c. Mineral *poiſons* act mechanically, chemically, and on the principle of life.

As to the prognoſtics when *poiſonous* ſubſtances are taken, in general it may be obſerved, that, as to thoſe of the animal kind, little more can be ſaid than to refer to the particular inſtances thereof. Thoſe of the vegetable world have uſually but little effect after being ſpeedily evacuated. The mineral *poiſons* are ſometimes carried off by vomiting, but uſually ill effects follow notwithſtanding that diſcharge.

In order to relief, when mineral *poiſons* are taken, if a vomiting does not follow, attempt the expulſion by any quick emetic; e. g. vitriolum album gr. x. vel vitriolum coeruleum gr. i. iii. aſſiſted by copious draughts of warm water, and milk, or oil; then endeavour to decompoſe the *poiſonous* article by means of the fixt alkaline ſalts, diluted in large quantities of water. Thus whether the merc. cor. a. areſenicum, fac. ſaturni, tart. emet. or any metallic ſalt be taken, the ſame method may be purſued. If the emetic is worked off with a ſolution of the fixt alk. ſalt, the effects may be expected as more agreeable to our diſtreſs. In ſhort, what ſteps appear to be the moſt eligible in caſe of arſenic being ſwallowed are the ſame in caſe of any other *poiſon* of the mineral kind. Theſe kind of *poiſons* act mechanically and chemically.

In moſt inſtances of the vegetable *poiſons*, their firſt powerful action when ſwallowed is on the ſtomach; an emetic therefore begins the cure. When theſe *poiſons* are evacuated, the danger is over, (which is not the caſe with the minerals); diſcharge them then with the utmoſt ſpeed. After due evacuation upwards, vinegar ſeems to be the beſt known antidote; in want of it, give the crude juice of acid fruits; but as vinegar is leſs ſharp and contracting, it can be uſed in larger quantities, and is therefore preferable. Vegetable *poiſons* act on the nervous ſyſtem, and attack the principle of life. If opportunity hath not favoured a diſcharge by vomiting very ſoon after this kind of *poiſon* has been ſwallowed, beſides an emetic let a laxative by the mouth or glyſterwiſe be adminiſtered; then give frequent draughts of cyder, perry, ſouriſh ſmall beer, or vinegar and water: ſome practitioners of the firſt rank extol the efficacy of the ſaline draughts, if given in the act of fermentation. If paralytic ſymptoms remain, apply ſinapiſms, bliſters, &c. Unhappily, thoſe vegetable *poiſons* which produce epileptic ſymptoms, ſo affect the ſtomach as generally to prevent evacuation either upward or downward; on this account there is leſs hope from the above means; however, they are the only known reſources, and, if any diſcharge is procured, a favourable hope may be indulged.

Animal *poiſons* act very variouſly, and in order to a proper management in any inſtance of the kind, ſee HYDROPHOBIA, VARIOLA, &c. all which are inſtances of this kind.

After all, this ſubject of *poiſons* is very difficult to inveſtigate; it is abſtruſe in its nature, and important in its conſequences. Many have writ on this ſubject, but very little hath been ſaid from which any thing ſatisfactory can be derived. See Mead on *Poiſons*; Grevinus de *Venenis*.

VENTER, *κοιλία, the belly.* In the moſt extenſive ſenſe it is taken for a remarkable cavity, in which any one of the principal viſcera is contained; in this reſpect the whole body is divided into three venters, viz. the head, the breaſt, and belly. Hippocrates uſes the word κοιλίη ſometimes to expreſs only the cavity of the breaſt and lower *belly*, and ſometimes he calls the thorax the upper and the abdomen the lower *belly*. But the term *venter*, or κοιλίη is moſt generally underſtood for the lower *belly* only. But various are the ſignifications of this word, as the ſtomach, the colon, the excrements of the *belly*; and amongſt the chemiſts *venter* is the ſame as terra, and *venter* equi is horſe-dung.

VENTRICULUS. The ſtomach. Diminutive of venter.

VENUS. This name of the goddeſs of beauty and love alſo ſignifies venery. On a due regulation of this appetite much of the vigour of conſtitutions depends; and a too great continency is often productive of diſorders ſimilar to thoſe that ariſe from an exceſs of indulgence in this inſtance; though, in ſome conſtitutions, plethoric and inflammatory ſymptoms are the reſult. The delicate and tender ſhould be very cautious in their venereal engagements, as ſmall degrees of exceſs very ſenſibly injure them.

VERATRUM. See HELLEBORUS ALBUS.

VERBASCUM. Mullein. It is a large white woolly plant. Boerhaave mentions eleven ſpecies. The Edinburgh college orders the *verbaſcum* thapſus, or *verbaſcum* foliis decurrentibus utrinque tomentoſis, caule ſimplici, flo. Linn. The great white *mullein*, high taper, or cows lung-wort.

VERBENA, called alſo verbenaca, verbena mas & cœrulo, herba ſacra, hierobotane. Common vervain. In Wales it is called cas gangythrel. It is the verbena officinalis, Linn.

The roots are fibrous, of a light brown colour, hard, bitteriſh, and irregular; they ſend up many ſtalks, half a yard high, ſquariſh, ſolid, roughiſh, of a purpliſh green colour, and branched; the leaves ſtand on the ſtalks in capſules oppoſite to each other, they are hairy on both ſides, wrinkled, and jagged with deep cuts, and wide at the ſtalk end, ſomething like oak leaves when half grown, of a deeper green above than below; the flowers are ranged in long ſpikes, of a pale purple colour, divided into five parts at the top, ſucceeded by four ſmall longiſh ſeeds joined together; they blow in July, &c. to October.

This herb is found in highways, in chalky, gravelly, and uncultivated grounds. The root is hung at the pit of the ſtomach, and a freſh piece is placed there twice in a year, as a cure for the ſcrofula. An ointment made by boiling the whole plant in lard, as is directed for the green ointment of elder, is recommended as uſeful in ſcrofulous ulcers. See Raii Hiſt.

VERDITER, from the French *verd de terre, earth green*, or *green earth*. It is an individual in the green ſpecies of clay. See Edwards's Foſſilogy. It is chiefly uſed by painters.

VERMES. Worms. The moſt frequent ſeat of *worms* in the human ſpecies is the inteſtinal tube; but occaſionally they have been found in almoſt every other part of the body.

In the ſtomach and inteſtines are the following ſpecies of *worms*: 1. The round *worms*, called alſo teres or teretes, and by Hippocrates ſtrongylus. 2. The tape-*worm*, called alſo the gourd-*worm*, tænia, ſolium, and inteſtinorum lumbrici lati. See TÆNIÆ. 3. Aſcarides.

The round *worms* are about a ſpan long, round and ſmooth: they are ſeated for the moſt part in the upper ſmall inteſtines, but ſometimes they are lodged alſo in the ſtomach, and in any part of the inteſtines, even to the rectum. The tape-*worms* are from two to forty feet long, according to the teſtimony of Platerus; they generally poſſeſs the whole tract of the inteſtines, but eſpecially the ileum: they very much reſemble a tape in their appearance, whence their name of tape-*worm*. The aſcarides have uſually their ſeat in the rectum. See ASCARIDES.

Worms are rarely found but in perſons with weak ſtomachs, or where digeſtion is ill performed. As to certain aliments producing *worms*, it is objected that all we eat may be expected to generate them, as well as thoſe articles uſually ſpecified. It is ſaid that they cannot be hatched in a healthy inſide, for the gall, in particular, would deſtroy them; in children the gall is generally as inert as it is redundant, and in caſes of indigeſtion, when adults are the ſubjects of theſe vermin, the gall is alſo defective in its quality, and probably hence is the mediate cauſe of *worms* in the human inteſtines.

Numerous are the ſigns of *worms*, ſuch as colicky pains, a copious diſcharge of ſaliva when faſting, a diſ-

agreeable

agreeable breath in the morning, itching in the noſe, an irregular appetite, a ſwelled and hard belly, troubleſome ſleep, grinding the teeth during ſleep, palſies in the limbs, thirſt and feverithneſs; but as theſe, and all other ſigns, are common to this, and to other diſorders, the only one to be depended on is their being diſcharged; and this may be obſerved with reſpect to the round, the tape *worm*, and thoſe called aſcarides.

Amongſt the variety of remedies propoſed for the deſtruction of *worms*, none ſeem more to be depended on than thoſe which purge briſkly, in conjunction with thoſe that ſtrengthen the chylopoetic organs. Various are the ſpecifics for deſtroying them, but their efficacy may be attributed to their purging or corroborating quality, or to both. Mercury, rhubarb, aloes, Indian pink, ſea ſalt, ox gall, are thus efficacious; water, in which a portion of quickſilver is boiled, is ſuppoſed to receive its efficacy from a portion of arſenic which it takes up from this mineral; tin, as recommended in the Edinburgh medical Eſſays, is ſuppoſed to deſtroy the *worms* by its mechanical action on them, though, more probably, the arſenic in the tin is that to which the benefit is to be attributed. Dr. Biſs extols the baſtard black hellebore as a moſt certain deſtroyer of the round *worm*; but purging, by leſſening the ſlime, always relieves, and probably the *worms*, that are not forced away by this quickened motion of the inteſtines, may, for want of ſlime, languiſh and die. It does not appear that one kind of purge is preferable to another, let the kind of *worms* be what they will; the *worms* being always defended from the immediate action of the medicine by the ſlime, and therefore purges which act briſkly, and of which a frequent repetition can be born, are the beſt. Of this ſort are purging waters, particularly the ſulphureous, jalap, &c. Dr. Storck ſays that he hath deſtroyed all ſorts of *worms*, viz. the round, the aſcarides, and the tape-*worm*, by the following mixture repeated, as here directed. ℞ Sal polychreſt. pulv. rad. jalap & rad. valer. ſilv. pulv. āā ʒ i. ox. ſcillit. ʒ iv. m. exhibeatur adultis quater per diem ʒ ſs. junioribus vero ʒ i. aut ʒ ii.

See Andry, Linnæus, Doeveren, Coulet, on *Worms* in general; and ſee Van Phelſum on the Aſcarides, and Beddoe on the Tape-*worm*. See Edinb. Med Comment. vol. iv. p. 283, &c. Dr. Lewis's Tranſlation of Hoffman's Practice of Medicine, vol. i. p. 353. 483. vol. ii. p. 156.

The diſorder called the *worm*-fever, Dr. Muſgrave obſerves, is generally confined to children, and as it too frequently baffles the beſt endeavours, he gives the following account of the diſorder, with the method of treating it, which in his practice hath been moſt ſucceſsful. The difficulty of curing what is called a *worm*-fever, ariſes, according to this author, from its being frequently attributed to *worms*, when the cauſe of the diſorder is of a quite different nature. He does not deny that the irritation cauſed by them doth ſometimes produce a fever; but he apprehends theſe caſes to be much more uncommon than is generally imagined, and that great miſchief is done by treating ſome of the diſorders of children as *worm* caſes, which really are not ſo. Dr. Hunter, it is obſerved, was of the ſame opinion on this point; and he has diſſected great numbers of children who have been ſuppoſed to die of *worm*-fevers, and whoſe complaints were of courſe treated as proceeding from *worms*, in whom however, there appeared, upon diſſection, to be not only no *worms*, but evident proofs of the diſorder having been of a very different nature. The ſpurious *worm*-fever, as Dr. Muſgrave calls it, has, in all the inſtances he has ſeen of it, ariſen evidently from the children having been indulged with too great quantities of fruit; though a poor cold diet may, he thinks, occaſionally give birth to it. Every ſort of fruit eaten to exceſs will probably produce it; but an immoderate uſe of cherries ſeems to be the moſt common cauſe of it. The approach of this diſorder has a different appearance, according as it ariſes from a habit of eating fruit in rather too large quantities, or from an exceſſive quantity taken at one time. In the former caſe, the patient gradually grows weak and languid; his colour becomes pale and livid; his belly ſwells and grows hard; his appetite and digeſtion are deſtroyed; his nights grow reſtleſs, or at leaſt, his ſleep is much diſturbed with ſtartings, and then the fever ſoon follows; in the progreſs of which, the patient grows comatoſe, and at times convulſed; in which ſtate, when the event is not favourable, he dies. The pulſe at the wriſt, though quick, is never ſtrong or hard; the carotids, however, beat with great violence, and elevate the ſkin ſo as to be diſtinctly ſeen at a diſtance. The heat is at times conſiderable, eſpecially in the trunk; though, at other times, when the brain is much oppreſſed, it is little more than natural. It is ſometimes accompanied by a violent pain in the epigaſtric region, though more commonly the pain is ſlight, and terminates in a coma; ſome degree of pain, however, ſeems to be inſeparable from it, ſo as clearly to diſtinguiſh this diſorder from other comatoſe affections. Where a large quantity of fruit has been eaten at once, the attack of the diſorder is inſtantaneous, and its progreſs rapid; the patient often paſſing, in the ſpace of a few hours, from apparently perfect health, to a ſtupid, comatoſe, and almoſt dying ſtate. The ſymptoms of the fever, when formed, are in both caſes nearly the ſame, except that, in this latter ſort, a little purulent matter is ſometimes diſcharged, both by vomit and ſtool, from the very firſt day. The ſtools, in both caſes, exhibit ſometimes a kind of curd, reſembling curdled milk, at other times a floating ſubſtance is obſerved in them, and ſometimes a number of little threads and pellicles, and now and then a ſingle *worm*.

Strong purgatives, or purges frequently repeated in this diſorder, are greatly condemned by Dr Muſgrave, as they in general not only aggravate the ſymptoms already preſent, but are ſometimes the origin of convulſions. Blood-letting is not to be thought of in any ſtage of the diſorder. But, although frequent purging is not recommended, yet a ſingle vomit and purge are adviſed in the beginning of the diſorder, with a view to evacuate ſuch indigeſted matter and mucus as happens to remain in the ſtomach and bowels. Theſe having operated properly, there is ſeldom occaſion for repeating them; and it is ſufficient if the body be coſtive, to adminiſter every ſecond or third day, a clyſter, compoſed of aloe. opt. ʒſs. and infuſ. flor. chamæm ℥v. The principal part of the cure, however, depends upon external applications to the bowels and ſtomach; and as the cauſe of the diſorder is of a cold nature, the applications muſt be warm, cordial, and invigorating; and their action muſt be promoted by conſtant actual heat. In this caſe, ℞ Fol. abſ. & rutæ, āā p. æq. aq. pur. q. ſ. f. decoct. ſaturatiſſimum, quo calide foveatur regio ventriculi et abdomen, 4ta vel 5ta quaque horæ, per horæ quadrantem. Magma ex herbis coctis poſt fotus uſum iiſdem partibus perpetuo appoſitum teneatur, et quoties refrixerit, aliud calidum opponatur. For internal uſe, ℞ Aq. cinnam. ſp. & cinnam. ſi. āā ℥ſs Ol. amygd. D. ℥ſs. Syr. balſ. ʒiij. m. et tempore uſus fortiter concutiantur in phiala capiat pro ratione ætatis, ʒij ad ʒvj. tertia quaque hora. When any nervous ſymptoms come on, or remain after the diſorder is abated, they are eaſily removed, by giving a pill of four grains of aſſafœtida, once or twice a day.

When *worms* really infeſt the bowels, Dr. Muſgrave obſerves, that their diagnoſtics are very uncertain; but that in real *worm* caſes, the treatment above recommended would, he imagines, be much more efficacious than the practice commonly had recourſe to. As *worms* either find the conſtitution weakly, or ſoon make it ſo, the frequent repetition of purges, particularly mercurials, he aſſerts, are injurious. Fomenting the belly, night and morning, with a ſtrong decoction of rue and wormwood, is much recommended; for, by invigorating the bowels, it has thereby a conſiderable influence in rendering them capable of expelling ſuch *worms* as they happen to contain. After the fomentation, he adviſes to anoint the belly with a liniment, compoſed of one part of eſſential oil of rue, and two parts of a decoction of rue in ſweet oil. Of internal medicines, the beſt is aſſafœtida, with an aloetic pill or two at proper intervals. The diet of children diſpoſed to *worms*, he adds, ſhould be warm and nouriſhing, conſiſting, in part at leaſt, of animal food, which is not the worſe for being a little ſeaſoned. Their drink may be any kind of beer that is well hopped, with now and then a ſmall draught of porter or negus. A total abſtinence from butter is not ſo neceſſary as is generally thought. Poor cheeſe muſt be wholly avoided, but ſuch as is rich and pungent, may be moderately allowed,

for

for it is peculiarly uſeful. It is equally an error to feed children too well with rich food, rich ſauces, and a very free uſe of wine; and to confine them to too ſtrict or too poor a diet, which weakens their digeſtion, and renders them liable to diſorders in their bowels.

Dr. Butter, in his Treatiſe on the Infantile remittent Fever, which he ſays is the *worm*-fever of authors, aſſerts, that there is not the ſmalleſt rational ground for regarding *worms* in the cure of this fever. That, though the exiſtence of *worms* be a ſign of diſeaſe in children, yet, in his judgment, they are properly neither cauſe nor ſymptom of ſuch diſeaſe; and therefore ought not to influence, in any reſpect, medical practice. It hath long been known that fevers deſtroy *worms*. As a definition, he ſays, that the infantile remittent fever is diſtinguiſhed by drowſy exacerbations, wakeful remiſſions, pain of the head and belly, total loſs of appetite, little thirſt, and ſlimy ſtools. In his deſcription he obſerves, that this fever is accompanied with a great many ſymptoms, but they ſeldom all occur in the ſame caſe. Theſe ſymptoms he arranges under three different heads, conſtituting ſo many varieties of the diſeaſe. Theſe varieties he names the acute, the ſlow, and the low infantile remittent fevers; as cauſes, the doctor points out irritability and indigeſtion; this fever may be accelerated by cold, fatigue, &c. but the principal cauſes are crude accumulations in the firſt paſſages, which, with a very irritable prediſpoſition, draw the inteſtinal canal into ſpaſm, which is ſoon communicated to the reſt of the body, conſtituting the fever. The two ſymptoms commonly attributed to *worms*, he refers to debility as their cauſe; theſe ſymptoms are the loſs of voice, and of ſpeech. In order to the cure, Dr. Butter propoſes but one indication to be regarded, viz. the removal of the febrile irritation. This irritation is owing to a ſpaſmodic affection of the inteſtinal and other membranes of the body, ſupported by morbid accumulations in the firſt paſſages. The means preferred are, reſt, quietneſs, and ſtillneſs. The bedroom ſhould have but little light admitted into it. Diluting and nouriſhing drinks ſhould be frequently given, ſuch as ſmall broth, gruel, and barley-water. Solid food ſhould not be allowed. The neutral ſalts, particularly the ſal polychreſt. is uſeful by its abating the inteſtinal ſtricture, and rendering the bowels rather lax. For a child of five years old, a dram of the ſalt may be diſſolved in four ounces of water, ſweetened with any convenient ſyrup, or with ſugar, and two table ſpoonfulls may be given every four hours. This mixture ſhould be given ſo as to keep the bowels open; in general when the fever is low, one ſtool ſhould be produced every day, two in the ſlow, and three or four in the acute kind. When the bowels are rendered ſoluble, nitre may be uſed inſtead of the ſal. polychreſt. If a looſeneſs attends, the neutral ſalts muſt not be given, but in their ſtead, give the following mixture in the ſame manner as the above with ſal. polychreſt. In four ounces of water diſſolve five grains of the extr. cicutæ, and add to it a dram of ſugar. In the ſlow kind of this fever, the mixture with the extr. cicutæ is to be preferred to that with the ſalt. A grain for every year of the patient's age may be given, diſſolved in water as already directed. If required to keep the belly lax, when the extract is uſed, the ſal. polychreſt. may be given twice a day, or as much rhubarb may be given every night as may be required. The general treatment takes place in the beginning of the low fever; but after the ſymptoms of lowneſs abate, the treatment varies a little. In caſe of coſtiveneſs, half a dram of the ſal. polychreſt. may be given, diſſolved in two ounces of water ſweetened, the one half at night the other in the morning. If the child hath a ſtool daily, the nitre may be uſed inſtead of the ſal. polychreſt. Four drops of the elix. vitr. a. may be given every four hours in the patient's drink. Small wine-whey ſhould be uſed inſtead of barley-water, by turns with the gruel and broth; ſometimes a little wine may be added to the gruel. If this low fever is complicated with looſeneſs, the extr. cicutæ given as above, ſhould be the only medicine employed, except a drop or two of the tinct. theb. after each ſtool. To relieve the vociferation and reſtleſſneſs, foment the belly with flannel cloths wrung out of a decoction of camomile, agreeably warm, and repeated as required.

VERMIFORMIS. A prominence of the cerebellum, ſo called from *vermis*, *a worm*, and *forma*, *ſhape*.

VERONICA, called alſo betonica Pauli, thea Germanica, fluellin, and male-ſpeedwell. Veronica officinalis, Linn. It is a low, hairy, trailing plant, with firm leaves ſet in pairs. From the joints ariſe ſlender pedicles, bearing ſpikes of blue monopetalous flowers, each of which is divided, as is the cup, into four ſegments, and followed by a flat bicellular capſule, which opens at the upper broad part, and ſheds ſmall brown ſeeds. It is perennial, grows wild on ſandy grounds and dry commons. It flowers in June.

The leaves have a weak, but not diſagreeable ſmell, which in drying is diſſipated, and which they give over in diſtillation with water, but without yielding any ſeparable oil; to the taſte they are bitter and rough. They give out their virtue to water and to ſpirit, but moſt perfectly to the latter.

An infuſion of the leaves drank as tea is diuretic; the water diſtilled from them is called European tea, and by ſome is preferred to the Aſiatic. Both the infuſion in water, and the diſtilled water, poſſeſs all the virtues of the Aſiatic tea, and have the ſame good effects. See Francus on the Virtues of *Veronica*.

VERRICULARIS TUNICA, from *verriculum*, i. e. Amphibliſtroides.

VERRUCA. Warts. A *wart* begins in the cutis, and ſeems to be either an efflorescence of the ſerum hardening on the ſkin, or making a dry tumor, or a ſmall luxuriancy of the little arteries of the cutis, making a little ſarcoma, or ſoft *wart*. When it ariſes with a broad baſis, it is called *verruca* ſeſſilis. Sometimes a few capillaries putting out together, after they are grown to a ſmall length, enlarge themſelves into a greater compaſs, and make the penſile tumor called acrochordon.

Dr. Cullen places this genus of diſeaſe in the claſs locales and order tumores.

Warts are generally removed by inciſion, or by the uſe of cauſtics. The juice of celandine, of euphorbium, the gall of the pike, or of the eel, the mineral acids, the lunar cauſtic, or an actual cautery, after which laſt they are ſaid never to return.

When *warts* are on the knuckles they are difficult to be ſeparated, without hurting the tendons, and are generally to be left to themſelves. Heiſter obſerves, that on the face, lips, or eye-lids, there are ſometimes a ſort of livid and bluiſh *warts*, which in their tendency are next to a cancer. Theſe are beſt let alone, for if they are diſturbed they degenerate into a cancer. See Heiſter's Surgery, Tiſſot's Advice to the People.

VERTEBRÆ, from *verto*, *to turn*. See SPINA.

VERTEX, from *verto*, *to turn*. The crown of the head, ſo called becauſe the hairs turn there.

VERTIGO, from *vertendo*, in which the head ſeems to turn, or at leaſt all things about the patient ſeem to do ſo. It is always ſymptomatic. When a miſt is alſo before the eyes, it is called ſcotidinos, or ſcotedinos. When a giddineſs, with only a dimneſs of the ſight, or a ſparkling before the eyes attend, it is called ſcotomia. Etmuller divides it into three kinds: 1. A ſimple *vertigo*, in which there is only a tranſient and ſhort continued gyration of objects. 2. A dark *vertigo*, or ſcotomia, when the eyes are darkened, or ſo affected, as if ſeveral colours were before them. 3. The *vertigo* called caduca, in which the patient preſently falls down.

The cauſes are a compreſſion on the brain from a depreſſion of the ſkull; an extravaſation of matter on the membranes of the brain, &c. In acute diſeaſes, the larger veſſels being diſtended with blood, either from its unuſual quantity, or its rarefaction preſſing the brain. Any cauſe that can preſs, diſtend, or contract the arteries, ſuch as ſudden ſurprize, ebriety, voracity, &c. by which the regular influx of the ſpirits, and their reflux into the optic nerves are prevented. An acid, or other acrimony in the ſtomach, may affect the nerves, and, by conſent of parts, produce this diſorder of the head. Dr. de Meza obſerves that *vertigo* may proceed from ſix different cauſes, viz. 1. From a ſanguineous plethora. 2. From a foulneſs in the primæ viæ. 3. From debility in conſequence of exceſſive evacuations. 4. From compreſſion. 5. From poiſons of different kinds; as opium, mercury, fumes of charcoal, &c.

&c. And 6. From a ſerofa colluvies, in conſequence of a ſtoppage of iſſues, ulcers, or any other habitual drains.

In a *vertigo*, there is generally an apparent rotation of external objects, though ſometimes all things ſeem to aſcend, and ſometimes they ſeem to have a contrary tendency. As the diſorder increaſes, the objects appear of various colours, and ſoon after follows a tottering of the whole muſcular frame; the patient begins to be afraid of falling, and catches hold of every thing near him, to ſuſtain himſelf; the diſorder increaſing, there comes on a dimneſs, then a loſs of ſight, then the nerves fail all at once, and the patient falls to the ground. If the diſorder proceeds further than this, it terminates in a lipothomy, epilepſy, or apoplexy. When a loſs of ſight attends a *vertigo*, there is alſo a ringing of the ears.

If the diſorder is recent, happens ſeldom, the patient young, the cure is eaſy; if it is original and confirmed, happens frequently, or if it ſeizes old perſons, and is accompanied with great dimneſs of ſight, and inability to ſtand, the cure is difficult; if the ringing of the ears proceeds from a diſorder of the brain, it is often troubleſome for many years, and forebodes an epilepſy, or an apoplexy.

If there is a ſanguine plethora, bleeding will be neceſſary, and the taking of blood from the temporal artery hath ſucceeded, when for a long time all other methods have failed. If there is a nauſea, or other diſorder of the ſtomach, an emetic is generally to be preſcribed. This diſorder is moſt frequently ſymptomatic, and then purging with the tinct. ſacra, or the pil. Rufi is amongſt the moſt effectual remedies. To theſe may be added mild chalybeates, and ſuch nervous medicines as the peculiarity of the conſtitution in general, or ſymptoms in particular may require. When a ſymptom of the gout, &c. the original diſorder being removed, the ſymptomatic will of courſe follow. See Swan's Tranſlation of Sydenham's Works, Etmuller, Mead, Hoffman, Heiſter, &c.

VESANIA. Melancholy. Defect of judgment, as in delirium, madneſs, idiotiſm, &c. Alienation of the mind. In particular a tranquil partial *melancholy*.

VESICA URINARIA. The urinary bladder. It is of an oblong form, its fundus lies againſt the os pubis, and its neck upon the os ſacrum, and coccygis. The neck does not come out at the end of the *bladder*, but at the flat and moſt depending ſide, through the proſtate gland, which lies flat upon it, ſo that there is properly no neck, being nothing of that ſhape. The fundus is the ſmalleſt end; the erect attitude ſeems to be the principal reaſon of this difference between this ſhape and that of quadrupeds. The *bladder* of a fœtus is very ſimilar to that of a quadruped. The ureters enter into the *bladder* near the veſiculæ ſeminales. The coats of the *bladder* are, 1ſt, a partial one from the peritoneum. 2d, A muſcular coat, the greateſt part of the external fibres of which are longitudinal, ariſing from the proſtate gland. Under theſe is a ſtratum principally circular, under which, on the inſide, is a very complex net-work of fibres, running in all directions, by which diverſity, and being fixed to the proſtrate gland, they, in motion, bring all parts towards the gland, for the expulſion of the urine, and to contract the *bladder*, lying looſe when empty. The inner coat is a very thin tranſparent membrane, of a very denſe texture, which prevents the tranſudations of urine. Many deſcribe another coat, but it is nothing more than the cellular membrane. The ligamentous remains of the urachus upon the fundus of the *bladder* is never pervious. The ureters have ſmall oblique orifices, and paſs obliquely through the coats, which hath the effect of valves. The urethra ariſes from the flat ſurface of the *bladder*. The arteries are from the hypogaſtric, or internal iliac, being branches of the arteria ſciatica, epigaſtrica, and umbilicalis, on each ſide. The nerves are from the crurales, and the ſympathetici maximi, by means of their communication with the crurales; ſome branches are from the plexus meſentericus inferior. See Haller's Phyſiology in the articles Renes, Winſlow's Anatomy.

VESICÆ (RARUS) MORBUS, Hoffm. It is a copious diſcharge of mucus with the urine. It is an inſtance of the dyſuria mucoſa of Cullen.

VESICULA FELLIS. The gall-bladder. Under the great lobe of the liver, a little to the right, we ſee the *gall bladder*. It is ſituated in a ſulcus on the under ſide of the great lobe, in the fiſſure between the two lobes, and being attached to the liver, hath a coat from the peritoneum. In a ſtanding poſture it lies forwards and downwards. Its fundus is raiſed by a fulneſs, and depreſſed by the emptying of the ſtomach; whence that uneaſy ſenſation which attends hunger. Its coats are like thoſe of the inteſtines, the inner is not villous, nor papillous, but a net-work of plicæ in all directions. The hepatic and cyſtic ducts run almoſt parallel, and quite contiguous (not as repreſented in figures), and uniting, form the ductus communis cholidochus, which, going on, joins the ductus pancreaticus, and opens into the duodenum, in the moſt depending concave part of the inteſtine. See Winſlow's Anatomy, Haller's Phyſiology in the article Jecur.

VESICULÆ DIVÆ BARBARÆ. The confluent ſmall-pox.

VESICULÆ GINGIVARUM. The Thruſh. See Aphthæ.

VESICULÆ SEMINALES. They are two membranaceous cellular tubes, lying on each ſide between the bladder and the rectum, on the outſide of the vaſa deferentia; they are about three fingers breadth long, and one broad; they are convoluted like the inteſtines, and kept in their ſituation by a ligamentous membrane, the internal fibres of which are muſcular. The inſide of the veſiculæ ſeminales is cavernous, and of a villous appearance.

VESTIBULUM. It is an irregular round cavity, not quite ſo large as the tympanum, and ſituated rather more inward and forward. The veſtibulum and tympanum are, as it were, ſet back to back, with a partition between them, and communicating near the middle by the feneſtra ovalis.

VETERNUM. The anaſarca.

VETERNUS. A lethargy.

VIBEX. *Purple* ſpots, and wheals under the ſkin, of a *ſcarlet* colour.

VIBURNUM, called alſo lantana. Pliant mealy tree, wayfaring tree. Boerhaave mentions nine ſorts. It is an arboreſcent ſhrub; its wood is fungous; the leaves reſemble thoſe of alder; the flowers grow in umbellas, ſmall like elder flowers, are white, and conſiſt of five petals; the flowers are ſucceeded by berries which are green, then red, and at laſt black; they are ſweet and viſcous. This ſhrub is found in hedges, and clayey uncultivated grounds. The leaves and berries are aſtringent. See Raii Hiſt.

VICIA. The tare or vetch. The pod is full of roundiſh or angulated ſeeds; the leaves are numerous, pinnated, and generally conjugated by pairs to a rib which ends in a tendril. Boerhaave enumerates twenty-two ſpecies. The tares, or vetches, are heating and aſtringent.

VINCA PERVINCA, called alſo clematis daphnoides major, pervinca major. The greater periwinkle, or pervinkle. From a ſtringy, creeping, fibrous root, ſprings ſmooth ſlender ſtalks that are long and creeping. The flower is monopetalous, and is followed by two pods, in which are oblong, ſulcated, and almoſt cylindrical ſeeds. This plant grows on banks at the ſides of ditches. An infuſion of the leaves is commended againſt the fluor albus, hæmoptoe, hæmorrhoids, and exceſſive menſes. See Raii Hiſt.

VINCETOXICUM. Swallow-wort, i. e. Aſclepius vincetoxicum, Linn.

VINUM. Wine. The juices of ſweet fruits, ſuch as grapes, currants, apples, &c. are called wines when they are fermented; but the name is more particularly applied to the fermented juice of the grape. One and the ſame kind of grape proves greatly different in taſte and flavour, according to the climate and expoſure to the ſun. Thoſe wines which have ſcarcely been at all fermented, and are boiled, are called muſt, and boiled wines. It is the thin watery juices that are extremely prone to ferment, and in which fermentation, when once begun, can ſcarcely be ſuppreſſed, until it hath run beyond the vinous ſtate, that is thus treated. By boiling, the fermentative quality is reſtrained, the liquor becomes richer, and continues fit for drinking at leaſt a year or two; but it is not ſo wholeſome as the fermented wine. Muſt relaxes the conſtitution, and if drank immoderately, it is apt to produce dangerous fluxes; on the contrary, perfect *wine* conſtringes and corroborates. Another claſs of *wines* is thoſe which have undergone fermentation, but not a complete one; of theſe there are two kinds, 1ſt, The thin

ſweet *wines*, which are only muſt, partially fermented, or whoſe fermentation is checked before the ſweetneſs is gone off; theſe *wines* can ſcarcely be kept a year. 2d, The ſtrong full bodied *wines* that are rich and ſweet; theſe are generally a mixture of fermented and inſpiſſated muſt, the latter being added to increaſe the richneſs of the liquor, and prevent the fermentation from running beyond its due limits. Theſe *wines* heat the conſtitution, and ſhould be ſparingly drank; of this kind are the Malmſey, Canary, &c. 3d, Thoſe which have been completely fermented, and have thrown off their groſs matter. Theſe are the the moſt perfect, and the moſt ſalutary.

The goodneſs of *wines* is judged of by their being bright, clear, and ſparkling in the glaſs, of an agreeable reviving ſmell and taſte, leaving, when in the mouth ſome time, a ſlight ſenſe of aſtringency, being moderately ſtrong and ſpirituous, paſſing freely by urine, exciting appetite, producing a gentle ſweat in the night, and keeping the body open next day, without being followed by any head-ach, heavineſs of the limbs, or other uneaſineſs.

The principles of which *wine* conſiſts are water, inflammable ſpirit, a fine ſaline matter which ariſes in diſtillation immediately after the ſpirit, called by Becher media ſubſtantia vini; a groſſer ſalt called tartar, which ſeparates on ſtanding, and adheres to the ſides of the caſks; a gummy or mucilaginous ſubſtance; and a groſs unctuous or reſinous kind of matter.

With us the five following kinds of *wine* only are ordered for pharmaceutic and medicinal uſes, viz. 1ſt, The *vin.* alb. Hiſpanicum, or mountain *wine*. 2d, *Vin.* alb. Gallicum, or French white *wine*. 3d, *Vin.* Canarinum, Canary or ſack. 4th, *Vin.* Rhenanum, or Rheniſh *wine*. 5th, *Vin.* rubrum, or red Port. The firſt are generally ſtrong and ſweet, conſiſting of half fermented *wine* and muſt. The ſecond are moderately ſpirituous, grateful to the ſtomach, and paſs freely by urine, but ſome of them affect the head. The third are very rich and ſtrong, their effects are more durable than the thinner, and they are nutritious. The fourth are the moſt acid, and are alſo the moſt diuretic; they alſo render the bowels lax. The fifth are the moſt aſtringent and ſtrengthening.

Conſidered as a medicine, *wine* is a valuable cordial in languors and debilities, more grateful and reviving than the common aromatic infuſions and diſtilled waters; it is particularly uſeful in the low ſtage of malignant and other fevers; it raiſes the pulſe, ſupports the ſtrength, promotes a diaphoreſis, and reſiſts putrefaction. Uſed dietetically, it is uſeful to the weak and aged, and to thoſe who are expoſed to a warm and moiſt air, or to a corrupted one. Uſed externally, it cools, ſtrengthens, and reſiſts putrefaction. Dr. Harris, in his Diſſert. Chirurg. ſays, that ulcers ſhould be waſhed with warm *wine*; external inflammations are removed by it. In an eryſipelas, and eryſipelatous pains in wounds, warm *wine*, and fomentations with the the ſpirit of *wine*, are the moſt uſeful. See Neumann's Chem. Works, Dict. of Chem. Lewis's Mat. Med.

VINUM ADUSTUM, called alſo vinum ardens, ſpiritus vini. Vinous, inflammable, and vegetable fermented ſpirit, ſpirit of wine, which laſt is the general name when it is rectified. It is never applied to that which is of the ſtrength of brandy, and which is called proof *ſpirit*. When this *ſpirit* is brought to the higheſt degree of purity from phlegm and oil, it is called alcohol.

This *ſpirit* is obtained by diſtillation of fermented liquors. In France it is all drawn from wines; in England and Germany it is drawn from malt liquors. Some is drawn from molaſſes; and in America it is diſtilled from ſugar after fermenting it, and is there called rum. This *ſpirit*, whatever be the ſubject from which it is obtained, if freed from its phlegm and groſs oil, is found in every trial to be the ſame.

When this *ſpirit* is firſt drawn faom any fermented vegetable liquor, it contains much of the phlegm thereof, and of the eſſential oil of the reſpective vegetable which afforded it; it is therefore rectified, or purified, by redиſtilling it with a very gentle heat; and when on adding a ſmall quantity of this *ſpirit* to a little cotton, and ſetting it on fire, it burns away ſo perfectly, as that at laſt the cotton alſo takes fire, and flames alſo, it is called rectified *ſpirit of wine*. If an equal meaſure of this rectified *ſpirit*, and of pure water are mixed, it will be of the ſtrength of what is called a brandy, or proof *ſpirit*. If to the rectified *ſpirit* as much well dried, and yet warm alkaline ſalt be added, as that a part of it remains undiſſolved at the bottom, it will abſorb the remaining aqueous humidity, and the *ſpirit* may be poured from its ſurface. After which, if a little calcined vitriol, or burnt alum be added to this dephlegmated *ſpirit*, and it be again diſtilled, it will ariſe pure and free from either ſuperfluous phlegm, or any of the alcaline ſalt that may be detained therein. The *ſpirit* after this treatment is called alcohol.

Pure *ſpirit*, even after brought to the ſtate of alcohol, is no other than an intimate combination of water with an oil which hath been highly ſubtilized by the proceſs of fermentation, and a ſmall portion of acid. From the beſt rectified *ſpirit* ſomewhat more than one half of its quantity of water may yet be extracted from it.

This *ſpirit* is of extenſive uſe in chemiſtry; it ſeparates the medicinal parts of vegetable and animal ſubſtances from the inactive matter; it extracts their flavour and colour; it diſſolves reſins and oils for varniſhes, &c. and extracts them from woods which contain them; it preſerves animal and vegetable bodies from corruption; it diſſolves all vegetable reſins and diſtilled oils, the ſubtil oils of aromatic herbs, flowers, ſeeds, fruit, woods, and roots; it diſſolves empyreumatic oils; it mingles with water, and produces much heat by being mixed therewith; it coagulates milk, blood, and the white of egg, and moſt animal juices, except the urine and bile; it mingles with all acids concentrated or diluted, whether of the mineral or vegetable kingdom; on mixing it with the concentrated mineral acids, a ſtrong ebullition and heat enſues, the acidity is obtunded or deſtroyed, and the compound proves a ſubtil, volatile, fragrant fluid, and thus produces the dulcified acid *ſpirits*.

As a medicine, *ſpirit of wine*, when externally applied, ſtrengthens the veſſels, and thickens the juices in them, and thus reſtrains hæmorrhages; it inſtantly contracts the extremities of the nerves, and deprives them of ſenſe and motion, thus it eaſes their pain, but deſtroys their uſe; if received into the ſtomach in an undiluted ſtate, it produces the ſame effects as when externally applied; and if the quantity taken is conſiderable, a palſy or apoplexy follows, and ſoon proves mortal. Proof *ſpirit*, and ſuch as is diluted below the ſtrength of proof, when externally applied in conjunction with corroborant, anodyne, and antiſeptic fomentations, is of conſiderable efficacy; if it is inwardly taken in ſmall quantities, it ſtrengthens lax fibres, incraſſates thin fluids, and warms the habit. A moderate internal uſe of this *ſpirit* is the moſt ſerviceable to thoſe who are expoſed to heat and moiſture, to corrupted air, or other cauſes of colliquative and putrid diſeaſes. See Neuman's Chem. Works; Dict. of Chem. Lewis's Mat. Med.

VIOLA. The violet. Boerhaave takes notice of eighteen ſorts, but it is only the ſweet-ſcented purple kind that is in uſe with us. *Viola* odorata, or *viola* acaulis, foliis cordatis, ſtolonibus reptantibus teretibus, pedunculis, radicalibus, flora ſimplici purpureo odorato, Linn. The ſingle purple ſweet *violet*. The flowers have a very agreeable ſmell, and a weak mucilaginous bitteriſh taſte. If taken to the quantity of two drams they are gently laxative; the ſeeds are ſomewhat more laxative, and alſo gently emetic. The flowers give out to water both their virtues and fine colour, but ſcarcely impart any tincture to rectified ſpirit of wine, though they impregnate the ſpirit with their fine flavour.

A ſyrup is made with the blue flowers, and is uſed as a laxative for infants; but both the flowers and the ſyrup loſe their fine colour by long keeping. See Lewis's Mat. Med.

VIPERA. The viper. The coluber berus, i. e. coluber ſcutis abdominalibus, 146. ſquamis caudæ, 39. Linn. It is a viviparous reptile, about an inch or leſs in thickneſs, and from twenty to thirty inches in length. It is diſtinguiſhed from the ſnake by an undulated black line on its back, and the ſmallneſs of its tail. It is found in the heat of ſummer under hedges, and in winter it retires into holes in the earth. Its poiſon is at the baſis of its fangs, or long teeth, through which it is emitted by a ſlit when the animal bites. A ſmall portion of this poiſon when

when communicated to the blood by a wound produces dreadful effects, though when taken into the ſtomach it is inoffenſive. If a *viper* bites itſelf or another *viper*, they die as ſpeedily as any other animal which hath ſuffered the ſame accident. The famed cure, when the *viper*'s poiſon is received by a wound, is immediately to rub the fat of *vipers* into the wounded part, and the patient muſt take as much vinegar in all he drinks for ſome time after the accident, as is at leaſt agreeable to the palate. See alſo the famed cure for the bite of a rattle-ſnake in the article BOICININGO.

As a medicine, the fleſh of *vipers* does not appear to excel that of eels; and the jus *viperinum* of the London college ſeems to be the beſt preparation of it. A wine is made by adding two ounces of the dried fleſh, coarſely powdered, to three pints of good white wine, and digeſting them for a week. See Mead on Poiſons; Lewis's Mat. Med.

VIRGA AUREA, alſo called herba doria, conſolida Saracenica. Common golden-rod. It is the ſolidago virga aurea, Linn. It is a plant with long, and ſomewhat oval leaves, pointed at both ends, ſlightly, or not at all indented, with upright ſpikes of ſmall yellow flowers, which are followed by ſmall ſeeds, winged with down. It is perennial, grows wild in woods and on heaths, and flowers in Auguſt. The leaves and flowers are corroborant, aperient, and diuretic; they communicate all their virtues to water and to ſpirit. The extracts are the beſt preparations. See Lewis's Mat. Med.

VIRGATA SUTURA, i. e. Sutura Sagittalis.

VIRGINALE CLAUSTRUM. The hymen.

VIRIUM LAPSUS, i. e. Lipothymia.

VIS CONSERVATRIX. The preſerving power, or the exertion of the plaſtic power, as far as it maintains organization.

VIS GENERATRIX. The generative power, or the generative exertion of the plaſtic power.

VIS MEDIATRIX. The healing power or the plaſtic power employed in extinguiſhing diſeaſe and reſtoring health; this is often expreſſed by the words Nature, and Natural Cure.

VIS PLASTICA. The plaſtic power.

VISCERA. The bowels. The *viſcera* in the head are the brain, eyes, ears, noſe, mouth, tongue, &c. In the breaſt, they are the heart, lungs, larynx, trachea, pleura, mediaſtinum, pericardium, thymus gland, diaphragm, &c. In the belly, they are the peritoneum, omentum, œſophagus, ſtomach, inteſtines, meſentery, liver, ſpleen, pancreas, kidnies, ureters, bladder, and parts of generation.

A knowledge of the ſituation of the abdominal viſcera, is of great advantage to the medical practitioner. The abdomen may be conſidered as divided into three regions, the ſuperior, the middle, and inferior. In the firſt are comprehended thoſe parts that are bounded by the diaphragm and ribs; the ſecond extends from the ribs to the pelvis; and the pelvis itſelf conſtitutes the laſt. Theſe three regions form one large cavity, in which are contained all the viſcera of the lower belly; the extent, however, of theſe different diviſions varies in different ages, in different ſubjects, and is altered likewiſe by diſeaſe. In new born infants, the diſtance between the ſternum and the pelvis is near to a third of their whole length; in adults, the length of the abdomen does not extend to a fifth of the whole. In children of three feet in height, the abdomen meaſures nearly one foot, and it is not found to exceed that, in adults five feet high. This difference with reſpect to the abdomen in infants and in adults is confined entirely to the middle region, which, in children, is not only much longer, but, in proportion, much more extenſive in every reſpect, than in people come to their full ſize. In the former, it is wider from before backwards, in children the ſpine being almoſt entirely ſtraight, whereas, in adults, it becomes conſiderably crooked. In children too, it is much wider from one ſide to the other than in adults, as in them the ribs bend more outwards than they do in the latter. Although this middle abdominal region, however, is in children ſo extenſive, yet both the ſuperior and inferior diviſions are not proportionally ſo; nay, they are even ſmall, in compariſon to thoſe of adults. The pelvis is incomparably ſmaller in the fœtus than in adults; in the former, the under extremity of the os ſacrum bends conſiderably over towards the pubis. The horizontal branch of the pubis is both ſhort and flat, and the tuberoſities of the iſchia are turned backwards. Every circumſtance, therefore, concurs to ſhorten the cavities of both the inferior and ſuperior abdominal regions; inſomuch that, in young children, all the *viſcera* of the lower belly are contained in what we have termed the middle diviſion, and remain there, until, by degrees, they inſinuate themſelves into the other two regions, as theſe, in courſe of time, come to be enlarged. Before treating, however, of the changes the *viſcera* undergo in point of ſituation from the infantine ſtate to that of adults, it will not be improper firſt to give a more particular deſcription of their ſeveral ſituations in the former. The ſtomach in infants, in place of being ſituated tranſverſely, as is the caſe in adults, hangs almoſt perpendicularly. It extends from what is commonly called the epigaſtric region, to the umbilical, inclining a very little to the left above, and to the right ſide below; having its convex ſide or great curve turned to the left, and the ſmall curvature towards the right. In conſequence of this ſituation of the ſtomach, the omentum, which is always attached to its great curvature, lies more towards the left than the right ſide; and, from want of knowledge of this circumſtance, practitioners have often treated, as diſeaſes of the colon, ſuch complaints in children, as, on opening the bodies after death have been found ſeated in the omentum only. The liver is very large in the fœtus, in proportion to its ſize in adults, and is ſituated almoſt entirely in the middle region of the abdomen; it appears to the touch externally, indeed, much nearer the linea alba than it is ever found to be in a more advanced age. At this period the duodenum is placed almoſt entirely behind the ſtomach. The ſpleen in infants is always eaſily diſcovered by the touch, immediately below the falſe ribs; this, in adults, never can be done, but in a diſeaſed ſtate of that viſcus. In the former, a conſiderable part of it is ſituated in the middle region of the abdomen; whereas, in the latter, its ſeat is always in the left hypochondrium. In very young ſubjects, the urinary bladder is ſituated entirely without the pelvis, is remarkably large in proportion to the other parts, and extends to within a very ſmall diſtance of the navel; when full of urine, it makes a very evident prominence near about the middle and inferior part of the abdomen. This poſition of the bladder, above the os pubis, ought to be particularly attended to; for when, in infancy, it is neceſſary, to have recourſe to lithotomy, the high operation ſhould always be preferred to thoſe where the opening is made in the perinæum. This operation, however, has never been favourably looked upon. But, as the ſhorteſt and eaſieſt paſſage to the bladder is, in lithotomy, a principal object, it ought certainly, in children, to be preferred to every other, the bladder in them lying ſo near to the external teguments above the pubes. In young girls, the womb, with its two ovaria, are conſiderably raiſed above the os pubis, and when ſwelled, a circumſtance, which, at this age, ſeldom occurs, it can eaſily be diſtinguiſhed by the touch externally.

Such are the ſituations of the *viſcera* in childhood. In a more advanced age, they are entirely changed; the ribs become leſs crooked, the diaphragm more vaulted, and the liver gets a higher ſituation, inſomuch that, about the fifteenth year, it is almoſt entirely covered under the ribs, when the perſon is in an horizontal poſture. This change of ſituation in the liver occaſions a manifeſt alteration likewiſe in the poſition of the ſtomach. By degrees it deviates from the perpendicular horizontal line; and according as it changes its ſituation, the omentum recedes entirely from the left ſide, and proceeds to occupy the middle part of the lower belly. Although the horizontal lobe of the liver can be diſtinguiſhed by the touch in adults, yet never by any means ſo evidently as in children; it is ſituated almoſt upon the under extremity of the œſophagus, ſo that, when it becomes preternaturally enlarged, it compreſſes that canal ſo entirely as to prevent the entrance of the aliments into the ſtomach: in which caſe, the perſon ſuffers greatly from very violent vomitings with which he is attacked ſome time before death. In the mean time, the pelvis becomes every way larger; the pubis turns conſiderably longer, and acquires a greater height; the os ſacrum ſtretches farther back, and the tuberoſities of the iſchium

puſh

puſh outwards, and to a greater diſtance from the os coccigis. Such a conſiderable augmentation in the cavity of the lower part of the abdomen, gives riſe to ſuch changes in the poſition of the different *viſcera*, as deſerves, from practitioners, very particular attention. Thoſe which, from their make and nature, have been accuſtomed to float in the middle region of the abdomen, now fall down into the pelvis; this is particularly the caſe with the bladder, which, in falling down, has its ſuperior part carried forward, and the urachus, which had been attached to the fundus, is torn away, and never again connected with it. This fact was firſt taken notice of by Mr. Lieutaud, and is not as yet believed by many anatomiſts. The ſame cauſe which produces the change of poſition in the bladder, occaſions alſo that of the uterus. The womb, which, in childhood, had been placed above the pubis, by degrees falls into the pelvis, inſomuch that in adult women, who are not pregnant, it is always, in a ſound ſtate at leaſt, entirely ſunk into it. Both the bladder and the uterus acquire an oblique ſituation in the pelvis, owing to the deſcent of the inteſtines; this obliquity, that becomes in a manner natural to both theſe *viſcera*, was obſerved by Gunzius, and Camper.

See Edinb. Med. Com. vol. ii. p. 152, &c. from M. Portal's paper in l'Hiſtoire de l'Academie Royale des Sciences de Paris, année 1771, 4to. Paris.

VISCUM. Bird-lime.

VISCUS. Miſſeltoe. Viſcum Album, Linn. It is a buſhy evergreen plant, which bears imperfect white flowers, that are followed by tranſparent whitiſh berries. It grows only on the trunks and branches of trees. Formerly bird-lime was made of the berries, by boiling them in water until they burſt; then they were well beat in a mortar, and after that waſhed in water, until all the branny huſk was waſhed away; but now bird-lime is made from the holly-buſh. The miſſeltoe hath been famed for its medicinal virtues, but it is not much noticed in the preſent practice. See Raii Hiſt. Plant. Sir John Colbatch's Treatiſe on the Miſſeltoe.

VISIO. The ſight. The light we have in our atmoſphere proceeds either from that of the ſun, or from ſome other lucid body; from whence the rays ſpread every way, as from a center to all points of a large ſphere, ſo as to fall upon the ſurfaces of bodies, from whence again they are reflected into the eye from the enlightened ſurfaces in angles, equal to that of their incidence, ſo as to render the bodies from whence they thus flow to the eye, both viſible, and of ſome colour. The rays of light fall upon the cornea of the eye, where they are refracted, and paſs on to the cryſtalline humour, where they are ſtill more *refracted*; then proceeding through the vitreous humour, by which they are directed to the retina, where they form the image of the object ſeen. It is called the focal point, where the images of objects are formed by the cryſtalline humour on the retina, and there the image of the object ſeen is painted in an inverted poſition, or, as it were, upſide down, though perceived by the mind according to the ſituation of the object of *ſight*. See Boerhaave's Med. Inſtit. Haller's Phyſiology, lect. xviii. Prieſtley on Viſion, &c.

VIS MEDIATRIX NATURÆ, i. e. Vis Vitæ.

VISNAGA, alſo called gingidium Hiſpanicum. Spaniſh Picktooth. It is an annual plant growing in Italy, remarkable for the agreeable ſcent and ſtiffneſs of the pedicles of the flowers, which are made uſe of for picking the teeth only. In other reſpects the virtues of the plant are ſimilar to thoſe of fennel. See Raii Hiſt.

VIS VITÆ. Boerhaave uſes this term to ſignify the joint action of all the parts of a human body, whereby the machine is contiuually recruited and put in order. But when any thing proves too hard to be conquered by this *vis*, a diſeaſe enſues. Dr. Aitken, in his Elements of Phyſic, alſo defines it to be, the ſtate, or condition of animal or vegetable organization indiſpenſably requiſite to the capability of function. Different writers variouſly conſider this ſubject. Hippocrates and many others conſidered it as heat or fire. See CALIDUM INNATUM.

VITELLUS. The yolk of egg. It contributes to nouriſh the chick, only in preparing the white for the purpoſe, or almoſt becoming like the white. In pharmacy it is uſed as a medium for uniting balſams, &c. with water. As a medicine it is anodyne, maturating, digeſtive, and relaxing, and hence it is often uſed in glyſters.

VITEX. It is a kind of buſh which is common in Malabar, &c. Boerhaave takes notice of ſix ſpecies, but though applied to ſome uſes in its native country, it is unknown in our medical practice. See Raii Hiſt.

VITIA. Linnæus expreſſes by this word, his claſs of cutaneous, external, or palpable diſeaſes. *Vitia* is a ſynonym with Cullen's locales in his Noſology.

VITILIGO. A ſpecies of white leproſy. See ALPHUS.

VITIS. The vine tree. The Vitis Vinifera Linn. Of the *vine tree* botaniſts have enumerated above twenty ſpecies, and there are almoſt twenty of its productions in uſe. Its leaves are aſtringent. If the trunk is wounded in ſpring, it affords a watery juice, which hath been uſed as a diuretic refrigerant. The flowers have a grateful ſmell, which is elevated with water in diſtillation. Along with the water a ſmall portion of eſſential oil ariſes, which poſſeſſes the flavour of the flowers in great perfection. The unripe fruit is called agreſtæ, they are ſour and harſh, and from them is expreſſed the omphacinum, which is cooling and aſtringent. The ripe fruit are called uvæ, they afford wine, whence we have inflammable ſpirit, vinegar, and tartar. When the uvæ, or grapes, are dried in the ſun, they are called uvæ paſſæ, or paſſulæ. See Lewis's Mat. Med.

VITIS ALTUS, i. e. Chorea ſancti Viti.

VITRIOLUM. Vitriol. Combinations of metals with the vitriolic acid, are called *vitriols* of thoſe metals. It ſeems as if the metallic part of all *vitriols* had been formerly ſuppoſed to be copper only; for even the ferruginous *vitriols* have the name of copperas, which is expreſſive of copper: the *vitriol* of zinc is alſo called white copperas.

There are three neutral *vitriolic* ſalts, with metallic baſes; or three *vitriols* of three metallic bodies, produced ſpontaneouſly, or with very little aſſiſtance from art, viz. thoſe of iron, called green *vitriol*; of copper, called blue *vitriol*; and zinc, called white *vitriol*. The factitious *vitriols* are eſſentially the ſame as the native.

Vitriols are prepared in Sweden, Germany, England, and in many other countries, where there are plenty of pyrite ſtones.

VITRIOLUM VIRIDE. Green vitriol. The Latins call it atramentum ſutorium, becauſe it is uſed for blacking leather.

The method of preparing it is as follows: the pyrite ſtones are ſpread about in a large area, the height about three feet, and there they lie expoſed to the air, but are now and then turned, that they may all be alike expoſed thereto; thus they are reduced to a *vitriolic* earth, which being well waſhed with rain water, the liquor is conveyed by pipes into ciſterns; then it is boiled to a due conſiſtence in large leaden veſſels, throwing in a quantity of old iron, which is ſoon conſumed by the lixivium; at laſt the liquor is ſet to cool in other veſſels, in which are placed ſticks for the *vitriol* to cryſtallize upon.

On analyzing the beſt *green vitriol*, it appeared that ℥ xvi. contained ſomewhat more than eight of water, ſix of iron, and one and a half of pure acid. The Engliſh *vitriol* is purely ferrugineous, but there is ſcarcely any other without ſome admixture of copper. Sixteen ounces of Goſlarien *vitriol*, were found to contain ℥ vii. of water, ʒ iii. of acid, ℥ v. ʒ vii. and ℈ i. of iron, and nearly ʒ ii. of copper; but it often contains much leſs of the acid.

The *vitriol* of iron diſſolves in about twice its weight of water, and on evaporating the ſolution, and ſetting it to ſhoot, concretes again into thick rhomboidal cryſtals. A ſolution of *vitriol* in water depoſits upon ſtanding a part of its metallic baſis; the precipitation is greatly expedited by boiling heat, by which more of the metal ſeparates in a few minutes, than by ſtanding without heat for a year. The further the cryſtals of *vitriol* are freed from their metal, the more eaſily do they part both with their water and with their acid.

It is from this kind of *vitriol*, as being the cheapeſt, that the vitriolic acid, called oil of *vitriol*, hath been uſually extracted; but at preſent this acid is extracted from ſulphur.

The medicinal uſes of *green vitriol* are the ſame as thoſe of the other preparations of iron, but the pure ſort only muſt be uſed. The acid of *vitriol* retards fermentation and putrefaction, but in a leſs degree than the nitrous and marine acids do; when it is largely diluted with water, it is employed for preventing a putrefactive diſpoſition, correcting bilious acrimony, abating heat, quenching thirſt, ſtrengthening the ſtomach, &c.

VITRIOLUM CŒRULEUM. Blue vitriol, alſo called Roman vitriol, vitriol of copper, and Cyprian vitriol.

It is prepared in Sweden, Germany, &c. from the pyrite ſtones and copper. It contains much leſs water than is in the *vitriol* of iron, and requires about four times the weight thereof for its ſolution. It hath been, and ſtill is recommended, as a powerful medicine in ſeveral diſorders, as in intermittent fevers, epilepſies, &c. but when internally uſed, its effects are ſo violent, that very few have ventured to admit it into their practice. Externally it is uſed as a mild eſcharotic, and for reſtraining hæmorrhages; alſo for removing films from the eyes.

VITRIOLUM ALBUM. White vitriol, or vitriol of zinc. The metallic part of this kind of *vitriol* is zinc; its other conſtituents are, the vitriolic acid and water. Sometimes it contains iron, and then it hath an ochry appearance on its ſurface. It diſſolves in twice its weight of water. It is ſometimes given as an emetic, and, as ſuch, it is ſpeedy in its effect, and, in debilities of the ſtomach, is preferred to other emetics; it is principally uſed externally in collyria againſt heat, defluxion, and inflammation in the eyes; it is a powerful and ſafe errhine, uſeful in obſtructions of the noſtrils from indurated mucus. See Neumann's Chem. Works, Dict. of Chem. Lewis's Mat. Med.

VOLSALLA. Little Forceps, from *vello*.

VOLVULUS. See ILIACA PASSIO.

VOMER. The plough-ſhare. It forms the poſterior and inferior part of the ſeptum naſi, and is placed between the oſſa ſphenoides and palati. It receives at its ſuperior part the ſpine of the body of the os ſphenoides, and the perpendicular plate, or naſal lamella of the ethmoid, and below it receives the cartilaginous part of the ſeptum.

VOMICA. See ABSCESS of the LUNGS. Dr. Reid obſerves in his Eſſay on the Phthiſis Pulmonalis, that tubercles are found, on diſſection of thoſe who have died of this diſeaſe, of all ſizes; from the ſmalleſt granules, to the bigneſs of a horſe bean, and commonly in cluſters. On cutting into them, he ſays, they appear of a white ſmooth cartilaginous ſubſtance. In the ſmalleſt, no cavity or opening appears; in thoſe farther advanced, on the cut ſurface we diſcover ſmall pin-holes; in thoſe ſtill larger, are one or more cavities containing a fluid like pus; which being cleared off, in the bottom is perceived ſeveral ſmall openings or holes; through which, on preſſing the tubercle, matter iſſued, ſimilar to that contained in its cavity. The larger tubercles, when emptied of their contents, appear like a ſmall capſula, into which entered a branch of the aſpera arteria. When the tubercles increaſe, they are termed *vomicæ*. Theſe are alſo of various ſizes, from half an inch to two or three inches diameter; and are uſually oviform. When found entire, their contents are whitiſh, yellow, aſh-coloured, greeniſh, and ſometimes fetid matter; and when ruptured, more or leſs reddiſh. Several branches of the aſpera arteria are found opening into theſe *vomicæ*; and they alſo communicate with others that lie contiguous; the apertures of the latter, are ragged and irregular; of the former, round and ſmooth. The larger *vomicæ* are uſually found empty, but on preſſing the lungs, matter iſſues into the bronchia. The branches of the pulmonary artery and vein running upon the *vomicæ*, are found much contracted; and ſometimes filled up with a fibrous ſubſtance; their pendulous ends, hanging looſe in the cavities of the *vomicæ*, completely ſhut up and covered with a thick ſlough. By this we ſee the reaſon, why hæmoptoe does not more frequently happen, when ſo great a part of the ſubſtance of the lungs is deſtroyed. And alſo, when it does take place, in what manner the mouths of the bleeding veſſels are ſhut up again. The parts of the lungs contiguous to the *vomicæ* are found inflamed, more or leſs ſolid, and impervious to air blown into the trachea; for when the other parts are thus diſtended, they remain depreſſed; nor is air admitted into the *vomicæ*, or at leaſt in very ſmall quantities. Wherever tubercles or *vomicæ* are found, they firmly adhere to the patricles of the lungs near them; by which means a communication between their cavities and that of the thorax, is entirely prevented. It is farther obſerved that, it ſeems probable that the ſmall pin-holes perceived in the ſubſtance of the tubercles, are the apertures of the exhalent veſſels; and that the pus found in them, and iſſuing out upon preſſure, is the lymph changed into that fluid. There is no abſolute criterion by which we can determine, when tubercles are firſt formed in the lungs. They are to be ſuſpected, when the cough is violent; continued with ſhort intermiſſions, particularly at night; and viſcid phlegm is expectorated with difficulties. But when the cough is accompanied with coldneſs, ſucceeded by fever, and matter ſpit up, which precipitates in water, there is every reaſon to believe that *vomicæ* are completely formed.

VOMITUS. Vomiting. It is a diſorder of the ſtomach. A *vomiting* and naufea ſeem to be ſpaſmodic retrograde motions of the muſcular fibres of the œſophagus and ſtomach, attended with convulſions of the muſcles of the belly and the diaphragm, which, when gentle, creates a naufea; when violent, a *vomiting*. *Vomiting* is moſtly an inſtance of dyſpepſia.

The matter diſcharged gives different denominations to this diſorder; a mucous chylous diſcharge of the reliques of undigeſted foods is called a pituitous *vomiting*; a congeſtion of bilious matter evacuated this way, conſtitutes what is called a bilious *vomiting*; blackiſh, corrupt, green, æruginous, porraceous, &c. are accidents of colour, &c. in the contents of the ſtomach that are diſcharged; when black blood is thrown up, it is called the black diſeaſe; and when the cauſe is in a part diſtant from the ſtomach, as when a ſtone paſſes the ureter, &c. it is called a ſymptomatic *vomiting*.

The cauſes are various, viz. pregnancy, poiſons, hurts on the brain, inflammation of the diaphragm, or other abdominal viſcera, the motion of a ſhip, or coach, &c. the quantity or the quality of the food, irritation of the gula, the tranſlation of the morbific matter of ſeveral diſorders to the ſtomach, worms, a ſtone in the ureters, a congeſtion of blood about the ſtomach, &c. The proximate cauſe is a ſtimulus of the nervous fibres of the ſtomach, gullet, or the duodenum.

Crudities in the primæ viæ are known by pituitous *vomiting*, and a preſſive pain about the region of the ſtomach. A laxity of the biliferous ducts are known by bilious, chronical, and periodical *vomiting*. An injury, or a ſcirrhus in one of the viſcera, is indicated by chronical *vomitings* of long ſtanding, and in which the food is thrown up before it is digeſted. A ſtone in the kidney, or the ureter, may be ſuſpected, if there is a pain in the loins, and a diminution of urine. Worms are probably attendant if the countenance becomes pale, and if there are pains and a gnawing ſenſation in the inteſtines, with an unuſual ſpitting and itching in the noſtrils.

All critical *vomitings* are ſalutary. Symptomatic *vomitings* are bad when excited by a ſubtil cauſtic acrimony; violent bilious *vomitings* threaten an inflammation; *vomiting* from worms is often a dangerous ſymptom; fetid *vomitings* are often fatal; a conſtant, or very frequent *vomiting* for ſeveral months, gives a ſuſpicion of an ulcer in the ſtomach; when a pain attends in the ſoles of the feet, hard drinking is generally the cauſe.

The different cauſes indicate as different methods of relief. When pregnancy produces this diſorder, bleeding at proper intervals, and gentle laxatives to keep the bowels eaſy, are the propereſt means of relief; though, in thoſe inſtances where bleeding endangers a miſcarriage, the plethora ſhould be removed by frequent gentle purges: when theſe methods fail, and the patient is greatly fatigued, ſhe may take the pulv. ipecac. gr. ii. vel iii. an hour before the *vomiting* comes on, and repeat it as it is required. A light breakfaſt, before the ſickneſs comes on, relieves in ſome inſtances; and in others, the columbo root, in mint or pepper-mint water, is moſt uſeful.

When the *vomiting* proceeds from a weakneſs, or irritability of the ſtomach, or acrid matter lodged there, in conſequence of the gout, &c. affecting this viſcus, the

columbo root, in conjunction with aromatics, the bark, chalybeates, and magnesia or rhubarb, will give the most effectual relief.

When the disorder is symptomatic, the original disorder being relieved, this of course subsides.

When bilious *vomitings* produce spasms in the stomach and biliary ducts, the acrimony of the bile must be corrected by diluents and dulcified mineral acids, with brandy and water, or negus, for the common drink, and if required, give a little laudanum.

When a copious and pungent acid prevails in the stomach, let the patient drink plentifully of weak mutton broth, to excite the discharges, until what is thrown up is without any change in its taste; after which give magnesia alba in doses, from ʒ ss. to ʒ i. and repeat it as often as any uneasy symptoms may require it. When the stomach is appeased, the bark, bitters, and chalybeates may be used.

When hard drinking produces frequent *vomiting*, after a gentle emetic, give the bark, with bitters, and the elixir of vitriol. Light chalybeates, particularly the Bath-water, may be used as a finish to the cure.

In any of the above cases, to palliate the *vomiting*, the saline draughts given in the act of fermentation, the balsam. traum. with the elix. vitr. or a few drops of the tinct. theb. may be now and then repeated. The sp. nitri dulc. relieves when these fail.

Sometimes when wounds inflame, the stomach, though distant from the injured part, will be rendered so irritable as to eject its contents; in this case warm oil being poured on the inflamed wound, by removing irritability there, relieves the stomach also.

Bilious *vomitings* are powerfully relieved by gentle antimonial emetics, or with small doses of the tart. emet. with rhub. after which bitters, particularly the columbo root, and cordials, &c.

Vomiting of blood or hæmatemesis, is when dark coloured clotted blood is thrown up from the stomach: it is usually mixed with much phlegm. This discharge is always symptomatic. A *vomiting* of blood is usually preceded by a tensive pricking pain in the stomach, or the left hypochondrium, and the eruption itself is almost always attended with a nausea, anxiety of the præcordia, and a compressing pain, as also a kind of girding on the same side; a fainting too often attends. In this case there is no cough, as happens when the lungs are the seat of the disorder.

Bloody *vomiting* is the effect of an indurated spleen, a varicous state of the *vasa brevia* in the upper left portion of the stomach, or of other vessels thereabout; women are particularly subject to this symptom about the time of the eruption, or on a suppression of the menses, from passion, frights, grief, pregnancy, &c. It happens in men from suppressed hæmorrhoids.

There is danger from the extravasated blood lodging in the bowels, and becoming putrid; by which means a dysentery, or a putrid fever, may be produced. The bloody *vomitings* which happen about the middle of pregnancy, in some plethoric habits, are rarely injurious. The same happening during labour, or even in child-bed, if the quantity be small, is not often hurtful. Too generally this is a fatal discharge; if there is no fever, if the habit is plethoric, if any usual vacuation is obstructed, hope may be indulged; but if a fever attends, if the blood discharged be very black and fetid, or if the cause is an enlargement of the spleen, an induration of the liver, or if faintings are considerable, there is but little hope.

Distinguish the pain and heat in the stomach, from an inflammation there; also from blackish hæmorrhoidal excretions.

Until the discharge by the mouth is stopped, abstain from purging medicines; let the diet be cooling, and in small quantities; except there is a manifest inflammation, or plethora, omit bleeding; astringents must not be administered, for they stimulate the stomach, but opiates, such as the tinct. theb. may be given to four or five drops two or three times a day, or give the following draught as the symptoms, viz. pains and spasms, may require it.

℞ Nitri purif. ʒ i. aq. fort. ʒ ii. syr. e mecon. ʒ ii. m.

If the patient is hot, and the circulation hurried, give sal nitri ʒ i. m. in every pint of water that is drank. Emollient glysters with nitre relieve the spasmodic affections in the stomach. If suppressed menses are the cause, give mild emenagogues by the mouth, bleed according to the strength, &c. of the patient, and give frequent emenagogue glysters. If the cause is erosion, from acrid substances in the stomach, absorbents and demulcents will be proper.

When the *vomiting* ceases, and the patient seems griped from the stagnant blood, give him a gentle purge or two. See Meibomius Dissert. de Vomitu. Hoffman's Pract. of Med.

VULNUS. A wound. Boerhaave gives the following description of a *wound*. "A *wound* is a recent, bloody solution of continuity in the soft parts, made by a hard, sharp instrument." But it may be observed, that obtuse instruments *wound*, and sharp ones cut into the bones. Dr Cullen places this genus of disease in the class locales and order dialyses.

Wounds that are superficial, when cleaned from the blood, &c. are perceptible to the sight; but when they are too deep to be seen into, it is better to examine them with the finger than with a probe, and, where the *wound* is too small for the finger, a bougie is better than a probe, on account of its flexibility, especially where it is winding. In examining a *wound*, we should know the attitude of the patient when he received it, the kind of weapon, how far it penetrated, how it was directed, with what force the blow was given; it should also be observed, what kind of fluid discharges, or did discharge itself from the *wound*. The knowledge of these with the knowledge of our frame, the use, &c. of each part, enable us to judge rightly on the nature of the *wound*, its cure, and consequences.

The danger of the *wound* is, as the size of the vessels that are divided, and the importance of the injured part with respect to life. The nearer a *wound* is to a vital part, the more dangerous it is. *Wounds* in the joints are healed with difficulty; so are those that are situated in any part subject to constant motion, as in the lungs or belly. The attending symptoms render a *wound* more or less dangerous. The age, constitution, customs, habits, and the inconveniencies that may be expected, though the patient does not die, should be pointed out, or hinted at least. Dividing a principal artery in a limb, endangers mortification; a principal nerve, insensibility, and an atrophy thereof. Separation of a tendon destroys as much motion as depends on that muscle. A *wound* in the medulla spinalis causes a palsy, or a mortification in the lower parts. An immoderate suppuration in a deep *wound*, by absorption may cause a hectic fever, and consume the patient in a marasmus. Great loss of blood endangers a dropsy. A *wound* in the breast and lungs, when healed, may be the occasion of a phthisis pulmonalis; and in any other considerable organ, an ulcer may remain, and prove the source of a hectic fever, or of a consumption; but great caution is necessary in determining the prognostics of *wounds*, particularly those which penetrate into the breast, or belly, on account of the different situation of the viscera, of which we have no sign during life. Van Swieten says, that he hath met with many such cases. See instances of this kind in the Lon. Med. Obs. and Inq. vol. i. p. 26—35.

The different states of a *wound* are included under those of digestion, or the discharge of matter; incarnation, or filling up with flesh; a cicatrization, or skinning over.

In order to the cure of *wounds*, especially when they are considerable, the non-naturals demand our particular attention. The air should be dry, and moderately warm, but not hot; the diet should be moderate, though it may be necessary to allow for customs, and regard should be had to the present habit of body; rest is generally necessary, but motion hurts the superior parts less than it does the inferior; as to the excretions, strong purges, &c. are injurious, but costiveness must be carefully guarded against; the affections are to be well regulated, if they are excessive in their degree, or if long continued, though but moderately excited, they will be injurious.

When extraneous bodies are extracted, if it can be done prudently, the hæmorrhages suppressed, all morbid tension in the wounded part removed, and the lips of the *wound* (where this is required) brought properly together, the dressings may be pledgits of soft lint, covered with one of tow, spread with some digestive ointment, and large enough to cover the whole; these may be secured by means of such bandages as the situation of the *wound* best admits of; the first dressings usually remain two or three days, or until the discharge of matter renders the separation of them easy. After the first dressings are removed,

moved, the dreſſing may be repeated every twelve or twenty-four hours, according as the diſcharge is more or leſs abundant or acrid. If after the firſt dreſſing a warm digeſtive is required, add to the ung. baſilicon. flav. a little of the ol. tereb. vel balſ. capiv. Theſe applications need not be warmed, except when very cold, after ſpreading the pledgit its ſurface may be juſt warmed by holding before the fire; each time that the ſurface of the *wound* is cleanſed, it ſhould be performed by dabbing it gently with ſoft lint, and not wiping it, leſt the tender granulations ſhould be deſtroyed; the ſurface of the *wound* ſhould not be made quite dry, but is better for being left ſomewhat moiſt, for thus the digreſſion is leſs interrupted.

Mr. Sharpe obſerves, that the principal interruption to the healing of a *wound* made with a ſharp inſtrument is the fungus, and this he would have ſuppreſſed by dry lint and a proper compreſs upon it; or if it advances above the ſurface of the ſkin, to touch its edges only with ſome gentle eſcharotic; but it ſometimes happens that an obſtruction to healing is the flabbineſs of a *wound*, and which is generally removed by dabbing it at each dreſſing with the following or ſome ſuch application ℞ Aq. calcis ſim. ℔ſs. tinct. cor. Peruv. ſim. ℥ ii. tinct. myrrh. ℥i. m. Thus, if an ill conſtitution or bad habit of the body is no impediment, *wounds* on the exterior parts are generally ſoon healed.

When the *wound* is filled up with fleſh, pledgits of the epulotic cerate uſually effect the laſt intention of cure, or the cicatrizing of the *wound*.

There are many accidents which occaſionally are attendants on *wounds* in one ſtage or another, ſuch as fever, inflammation, a callus, &c. the management of which will be learnt from what is already ſaid under the different articles in which they are noticed.

When a ſmall artery is wounded, if it is divided, it retracts, and the hæmorrhage is ſoon ſpontaneouſly reſtrained; if it is punctured, or partially divided, if it can conveniently be come at, it may be wholly divided, or the wound enlarged, and then the artery may be tied, if proper preſſure proves ineffectual. When a large artery is punctured or divided, it muſt be taken up and ſecured with the needle and ligature. *Wounds* in the axillary artery and alſo of the femoral, if near the body, generally demand an amputation of the limb.

Wounds ſometimes penetrate the cavity of the breaſt and belly, and ſometimes injure one or more of the viſcera; the firſt are known by the probe, the latter by the diſcharge that iſſues from them; if the ſymptoms attending a *wound* that penetrates into the cavity of the breaſt or belly are favourable, and there is no diſcharge from any of the viſcera, we may conclude that they are ſafe when the viſcera are unhurt; in which caſe, after excluding the air that may have ruſhed into theſe cavities, treat them as ſimple *wounds*. The air may be excluded as follows: make the patient inſpire ſtrongly, keeping the *wound* cloſely covered, then uncover it after this full inſpiration, and let the patient at the ſame time make a full and powerful effort as in expulſion of the fæces; thus the included air will be driven out at the orifice: repeat this proceſs as often as it may ſeem neceſſary. If any of the viſcera have protruded and are unhurt, return them with all ſpeed; but, if wounded, uſe the glover's ſuture, leaving three or four inches of the ligature out of the wound. If the protruded viſcera have been expoſed to the air, it may be neceſſary, before the return of them, to uſe a fomentation of warm milk and water, with a little ſweet oil. In all theſe caſes flannel is the beſt bandage, becauſe it gives way and retreats as the breath doth require.

Wounds in the principal internal blood-veſſels are all deemed mortal; but blood is ſometimes diſcharged from ſmaller veſſels into the cavity of the breaſt or of the belly; if this happens in the breaſt it occaſions a difficulty of breathing, which difficulty is worſt when the patient is in an erect poſture; though, if blood is diſcharged into both the cavities of the breaſt, the patient can only lie on his back, and ſtand in an erect poſture. To diſcharge this blood, if the *wound* is in the lower part of the breaſt, lay the patient on the wounded ſide, and with a probe puſh back the lungs, that the blood may paſs out; if the *wound* is in the upper part of the breaſt, an opening muſt be made at the back part thereof, allowing the other to cloſe; the proper place for this aperture is between the third and fourth of the falſe ribs, counting from below upwards, and about five inches from the ſpine. But, until the hæmorrhage appears to have ceaſed, which may be judged of by the ſtrength and equality of the pulſe, and the warmth of the patient's extremities, the operation will be uſeleſs. When the opening is made, the expulſion of the matter is aſſiſted by the efforts of reſpiration, as already hinted at, for the diſcharge of air. In theſe caſes the patient muſt be kept ſtill, mild aſtringent balſamic injections may be uſed, and gentle opiates may be given if a cough attends. If blood is poured into the belly, here will ſoon be laborious breathing, anxiety, and intermitting pulſe, &c. if the diſcharge of blood is ſmall, the patient ſometimes recovers, but, if conſiderable, it generally proves fatal.

When a nerve is wounded, a variety of alarming ſymptoms comes on in proportion to the fineneſs and tenſeneſs of the part it is attached to, and the peculiar irritability of the conſtitution; when the pain occaſioned thereby is extreme, it ſometimes is relieved only by dividing the nerve: this accident is ſoon diſcovered by the ſharp ichor which diſtils from the part, and its excoriating the circumjacent parts. When a tendon is wounded, the ſame ſymptoms follow as when a nerve is injured, but only they do not ſo ſuddenly appear. The moſt common applications to wounded nerves and tendons have been the ſubtil ſpirituous ſorts, ſuch as the ol. tereb. &c. but they are productive of the worſt ſymptoms; inſtead of theſe, put the limb into the eaſieſt poſition, keep the wounded part free from cold air, avoid ſpirituous and hot applications, and in their ſtead, apply a warm bread poultice, having firſt covered the *wound* with lint; or inſtead of the poultice, cloths may be applied after dipping them in warm oil, or warm oil and vinegar mixed in equal parts, warm fomentations may be uſed before the application of the poultice, if inflammation attends, or ſeems to be approaching.

Wounds in the joints, when they are inflicted with cutting inſtruments, or with heavy weapons falling on them, are attended with danger. Though the *wound* is ſmall, its conſequences are often grievous, from irritation, from deſtruction of the ligament, from the loſs of ſynovia, &c. Much depends on the habit; from a large *wound* in the ancle, cauſed by a fracture, nothing remarkable hath followed; and fatal conſequences have been the reſult of a ſmall one. However favourable appearances may be, a guarded prognoſtic ſhould always be given. Large *wounds* of the joints almoſt always require amputation. The ligament of the patella being divided by a ſharp-edged inſtrument hath frequently been followed by a loſs of the leg. The tibia being broke from the aſtragalus, and attended with laceration, makes an amputation adviſeable. A mere inciſed *wound* into a joint, from letting in air and injuring the ligamentous parts, have often proved fatal, when a timely amputation would have ſaved the patient. In contuſions of the joints from heavy bodies cruſhing them, if a gangrene is waited for before amputation is performed, it will be left until it is too late: the patient ſeldom lives until the mortification begins to ſeparate; but is taken off by the fever and local malady. The two great conſequences to be avoided in *wounds* of the joints are inflammation and pain; the firſt is to be attempted by bleeding and purſuing the antiphlogiſtic plan; the latter, by the poſition of the limb and by opiates. The moſt relaxed poſition of the limb is the beſt. If no tumefaction comes on, emollient applications are not wanted, but repellents and preventatives; if tumefaction, tenſion, &c. appear, immediately apply emollients. There is a ſymptomatic fever generally attendant, excluſive of any other circumſtances, and this is ſometimes attended with ſuch a diſcharge as to reduce the patient greatly, and on this account amputation becomes neceſſary. Where the joint is ſpoiled by preſſure, or by gun-ſhot, the injuries of the bone require attention as well as that of other parts, and the diſcharge of the ſynovia: theſe ſeldom do well under the greateſt care.

Gun-ſhot *wounds*. See SCLOPETOPLAGA.

See Celſus, Boerhaave's Aphoriſms, the Engliſh Tranſlation, p. 40, &c. or the ſame Aphoriſms with Van Swieten's Commentaries, Heiſter's Surgery, Gooch's Practical Treatiſe of *Wounds*.

WARNAS.

W.

WAR

WARNAS. Vinegar of philoſophers.

WINTERANUS CORTEX. Winter's bark, called alſo cort. Magellanicus. The tree is called Magellanica aromatica arbor, and Winter's cinnamon tree. In Dr. Lettſom's edition of Dr. Fothergill's works, is given a drawing of a branch from the tree with the flowers, and there the tree is named Winterana aromatica.

Captain Winter was the firſt who made the bark of this tree known in Europe: he brought it from the Streights of Magellan in the year 1579. Cluſius deſcribes this bark in his Exot. p. 75, and calls it by the name of its firſt importer; hence the name of *cortex Winteranus* or *Winter's bark*. It has rarely been brought amongſt us, and hath been ſo little known, that Pomet, in his Materia Medica, deſcribes the canella alba for it; others have copied him, and cuſtom hath eſtabliſhed the uſe of the canella inſtead of the *cort. Winteran.* the canella is alſo generally called *cort. Winteranus*. In 1691, Mr. George Handaſyd brought ſome ſpecimens of branches, &c. from this tree, and gave them to Sir Hans Sloane, who drew up an account of the tree, and it was inſerted, with a figure, in the Philoſ. Tranſact. for 1693. But a more perfect deſcription hath been obtained by the joint aid of Captain Wallis, Joſeph Banks, eſq. and Dr. Solander, who, in the year 1766, were in thoſe parts where it is indigenous. It is only the bark of this tree that is of any value, and that is deſcribed as being of different degrees of thickneſs, from a quarter to three quarters of an inch, a dark cinnamon-colour; if it is rubbed it hath an aromatic odour, and to the taſte is pungent, hot, and ſpicy, its effect on the palate is ſlowly imparted, but durable when given out.

Dr. Morris inſerted in the fifth vol. of the Lon. Med. Obſ. and Inq. ſome experiments on the *Winter's bark*, by which it appears to be a peculiar kind of aſtringent; alſo, that though it gives its virtues very freely to rectified and to proof ſpirit, yet water diſſolves its ſoluble parts moſt freely. The Doctor recommends this *bark* as excellent for covering the diſagreeable taſte of ſena and ſome other drugs, not more agreeable to the taſte.

When Captain Winter firſt brought this *bark* from the Streights of Magellan, the ſailors uſed it as a ſpice, and afterwards found it uſeful in the ſcurvy; for which laſt it hath been extolled; but unhappily as its ſubſtitute the canella alba hath been almoſt always uſed. The *Winter's bark* is much more powerful as a ſtimulant than the canella alba; it is uſeful to promote digeſtion, alſo as a ſtimulant in paralytic and dropſical diſorders; in which laſt, when the ſecretions may probably be promoted by a ſtimulus, the *Winter's bark* deſerves to be preferred. In ſome inſtances of remitting and intermitting fevers, it hath been given with advantage, as a ſubſtitute for the Peruvian bark: whence the canella alba muſt evidently be a very improper ſubſtitute for it.

The *Winter's bark* is in larger pieces than the canella alba, of a more rugged ſurface, a deeper colour, more agreeable ſmell, a warmer taſte, is more pungent, and leſs bitter. The canella alba is in rolls, ſomewhat thicker than cinnamon, and is the double bark of the tree from whence it is taken.

WORMIANA os, i. e. Triquetra os.

X.

XAN

XANTHIUM, i. e. Bardana major.

XERANTHEMUM, ξηρός, from *dry*, and ἄνθος, *a flower*. The dry flower. Cluſius calls it ptarmica. It is commonly called the immortal herb, becauſe its flowers may be preſerved many years. It has no known medical virtues.

XERASIA, from ξηρός, *ary*. A ſpecies of alopecia, conſiſting in a dryneſs of the hairs, for want of due nouriſhment. They look woolly like powder.

XEROPHTHALMIA, from ξηρός, *dry*, and ὀφθαλμία, a pain in the eyes. A *dry* lipitude, i. e. when the eye is itchy, *dry*, hot, rough, the eye-lids covered with *dry* ſcales, and it is painful to behold the light. It is alſo called ſclerophthalmia, from ξηρός, *hard*, and ὀφθαλμός, an *eye*. A ſclerophthalmia, or *hard* lippitude, is an inflammation of the *eye*, attended not only with a hardneſs and ſlowneſs of motion, but with a pain and redneſs. The eyelids, in this affection, are *hard* and *dry*, never effuſing any moiſture, with ſmall, writhed, dryiſh, mucous concretions, in their corners, and a difficulty of opening them after ſleep, on account of their dryneſs. The xerophthalmia is ſaid to be a leſſer degree of the ſclerophthalmia. James's Med. Dict.

In Dr. Cullen's Syſtem of Noſology, this is a variety of the ſpecies called ophthalmia tragi, and is ſynonymous with Sauvage's ophthalmia ſicca. Dr. James obſerves that it

is

is a kind of inflammation, whoſe general characters are pain and redneſs, but it differs from an inflammation in a property peculiar to itſelf, which is dryneſs.

XIPHIUM. It hath the fruit and flower like the iris, with a bulbous root. Boerhaave takes notice of eleven ſpecies. Their virtues are like thoſe of the gladiolus.

XIPHŒIDES. The enſiform cartilage of the ſternum, from ξιφος *a ſword*, and ειδος *a ſhape*.

XIRASIA, i. e. Xeraſia.

XYLOCASIA, i. e. Caſia lignea.

XYLOCINNAMOMUM. The wood of the cinnamon tree.

XYDOCOCCA. The internal grains of the fruit of the carob tree.

XYLON. It is a ſhrubby plant in Egypt, which bears a kind of cotton; the leaves have the ſame qualities with the althæa.

XYRIS. Stinking gladdon.

Y.

YA

YAWS. See FRAMBOESIA. It is a diſtemper endemial to Guinea and the hot climates in Africa. The people there have it only once in their lives.

At firſt it is unattended with pain or ſickneſs; it makes its firſt appearance in little ſpots on the cuticle, not bigger than a pin's point, which increaſe daily, and become protuberant like pimples; ſoon after the cuticle frets off, becomes white, and then, inſtead of pus or ichor, there appears a clear lymph which dries into white ſloughs or ſordes, under which is a red fungus; theſe increaſe gradually; ſome to the ſize of a ſmall wood-ſtrawberry; others to that of a raſberry; others again exceed the largeſt mulberry, which in ſhape it much reſembles; they are on all parts, but moſt in the genitals, anus, arms, and face; when they are large there are few, when ſmall there are many. The black hair in the *yaws* turns white and tranſparent.

This diſorder is not dangerous if ſkilfully managed. It is infectious.

As ſoon as the patient is obſerved to be infected with this diſeaſe, he muſt be confined to a place where he may remain alone; then give the quantity of a nutmeg morning and evening with forty or fifty drops of the antimonial wine in a draught of a decoction of ſarſaparilla.

℞ Æth. mineral. ʒ i. ſs. antim. crud. ppt. & theriac. androm. ā ā ʒ i. ſyr. alb. q. ſ. f. electar.

When the diſeaſe ſeems to be at a ſtand, give calomel ſo as to excite a ſalivation, to the quantity of a pound and a half in twenty-four hours; let the diſcharge then decline gradually, purge gently, and give the decoct. ſarparil. The ulcers may be touched with the following ſolution:

℞ Merc. ſublim. corroſiv. ʒ i. ſp. vin. R. ʒ. ii. m. f. ſolutio.

If the ſalivation in its progreſs ſeems ineffectual to ſtop the ſpreading of the diſeaſe, deſiſt, and give alteratives, ſuch as recommended in the lepra, and dreſs the parts with the following.

℞ Ungt. baſil. flav. ʒ. i. merc. cor. rub. lævigat. ʒ i. alum. uſt. ʒ ſs. m.

Then cicratize with the epulotic cerate mixed with a little burnt alum.

The ſolution of the merc. coroſ. alb. in ſp. vin. is ſometimes given as an internal. When nodes attend, the diſeaſe is incurable. If after the cure of this diſeaſe a pain is fixed in the feet, in this caſe warm bathing, paring the callous ſkin, and the uſe of an eſcharotic ointment, will be found very effectual.

See Edinb. Med. Eſſays; James's Med. Dict. Brooks's and the London Practice of Phyſic.

YPSILOGLOSSI. The muſcles called baſiogloſſi.

YPSILOIDES OS, i. e. Hyoides os.

YUCCA. Indian bread. It is a plant with a thick tuberous root, and leaves reſembling thoſe of the aloe. It grows in America. It is not the caſſavi, but a thick fleſhy root, affording a ſoft pulp. See Raii Hiſt.

Z.

ZAR

Z. An ancient character for myrrh, but at preſent it ſignifies ginger.

ZAARA. A name for the morbous watching.

ZACINTHA, alſo called cichoreum verrucarium. Wart ſuccory. It grows in Italy, and is noted for its power of deſtroying warts.

ZAC

ZARNICH, i. e. Arſenicum.

ZARUTHAN, A hard and unequal tumor of the breaſt,

breaſt, attended with pain, which is not quite continual; and a burning heat, much like what happens in a cancer, whence it is called a ſpurious cancer.

ZEDOARIA, called alſo gedwar, colchicum Zeylanicum, haronkaha, zedoary. It is the root of an Eaſt Indian plant. According to Weſton, in his Univ. Botaniſt, &c. It is coſtus Arabicus, or coſtus Arabicus ſcapo veſtito, floribus ſpicatis albis, bracteis ovalibus, fructu in pedicula ſingulari. Linn. Arabian *zedoary*. But according to the Pharmacopœia of the Edinb. college, it is the ammomum ſcapo nudo, ſpica laxa truncata. Berg. Mat. Med. p. 4. Mr. Curtis, in his Catalogue of Medicinal, &c. Plants in the London Botanic Garden, ſays, it is the Kæmpferia rotunda, Linn. It is brought chiefly from Bengal, in oblong pieces, about the thickneſs of a little finger, and two or three inches long; or in roundiſh ones, called zerumbeth, about an inch in diameter, of an aſh colour on the outſide, and white within. The long and the round are the roots of the ſame plant, the body of which is round, and theprot uberances long.

Chuſe ſuch as is denſe, ſolid, of a fine taſte and ſmell, bitteriſh, moderately acrid, and that emits an aromatic flavour in powdering or chewing, and ſuch as is large, and not wrinkled, nor perforated. It ſhould be kept dry.

It impregnates water with its ſmell and a light bitteriſh taſte. The ſpirituous tincture ſmells weaker than the watery, but it taſtes ſtronger; diſtilled with water it yields a ponderous eſſential oil, which is hot and pungent.

This root is a warm ſtomachic; its ſpirituous extract is the beſt preparation. In colics, attended with a diarrhœa and pain in the inteſtines, ℈ i. of the powder, taken three times a day, gives great relief. In flatulencies it is very uſeful, eſpecially if joined with opium. Simon Pauli ſays that it excels in diſpelling wind. In general, the doſe is from gr. v. to ʒ ſs. See Lewis's Mat. Med.

ZERNA. An ulcerated impetigo. Some expreſs by it lepra.

ZERUMBET. See ZEDOARIA. It is alſo a ſpecies of ginger, viz. amonium *zerumbet*, or amomum ſcapo nudo, ſpica oblonga obtuſa. Linn. Broad-leaved wild ginger.

ZIBACH. Quickſilver.

ZIBETHUM. Civet. It is an unctuous odoriferous ſubſtance, about the conſiſtence of honey or butter, of a whitiſh, yellowiſh, or browniſh colour, ſometimes blackiſh. It is brought from Brazil, the coaſt of Guinea, and the Eaſt Indies. It is found in bags, ſituated in the lower part of the belly of an animal of the cat kind. The bag hath an aperture externally, by which the *civet* is extracted. Its ſmell is fragrant, and too ſtrong to be agreeable, except it be diluted. It hath an unctuous and ſubacrid taſte, and is uſed in perfumes. It does not diſſolve in ſpirit nor in water, but unites with oils both expreſſed and diſtilled, and with animal fats. Water by diſtillation is impregnated with its odour, and ſpirit by digeſtion. Rubbed with mulcilage it mixes with water.

The black ſort from the Eaſt Indies is not ſo good as the American, but this latter is often adulterated. See Neumann's Chem. Works; Lewis's Mat. Med.

ZINCUM, alſo called zinchum, zincthum, tutenague, or tutenag, ſpelter, blende, blackjack, and zinc. It is a metalline marcaſite, or a bluiſh white metal, ſomewhat reſembling lead. Stahl firſt explained what it was, ſee his Metallurgia.

Zinc crackles during the bending of it, and quickly breaks, though it is ſomewhat ductile. It is about ſeven times ſpecifically heavier than water; it begins to melt in a moderate red heat, and very ſlowly calcines on a continuance of the fire. In a moderate white heat it flows thin, burning, fulminating, with a bright deep green or bluiſh green flame, and ſubliming into white light flowers, which concrete about the upper part of the veſſel into thin cruſts, or ſoft looſe filaments, like down or cobwebs, called philoſopher's wool.

It is extracted from a ſort of lapis calaminaris, which is its ore. In its metallic form, and in that of a calx, it diſſolves readily in all acids, and precipitates from them almoſt all the other metallic bodies.

The white vitriol is made from pure *zinc*, by diſſolution in the diluted vitriolic acid, and cryſtallization. The calx (commonly called flowers of *zinc*) were formerly kept under the names of pompholix, and of nihil album.

The preparations of *zinc* are employed in external applications, as ophthalmias, particularly againſt thin defluxions of rheum, and as aſtringents, which effect they have if the *zinc* is finely levigated, without acrimony or irritation. Taken internally they prove emetic.

The flowers of *zinc* were firſt uſed as an internal medicine by the celebrated chemiſt Glauber, but were little known in practice till Dr. Gaubius, of Leyden, gave an account of their virtues in his Adverſaria. They have ſince been much employed in convulſive and ſpaſmodic diſeaſes, and ſometimes with good effects. Even obſtinate epilepſies have been rendered much leſs violent by their uſe. Like all other medicines, however, in diſeaſes of this claſs, their good effects are often only temporary, and they often fail altogether. When the flowers are genuine, a grain or two generally at firſt excites a nauſea or ſickneſs; but by degrees a conſiderable doſe may be taken with little or no ſenſible effect. As they are liable to be adulterated, it may be proper to mention, as teſts of their purity, that they make no effervescence with acids; and that, when expoſed to a ſtrong heat, they become yellow; but, on cooling, turn white again.

By a mixture of *zinc* with copper, in different proportions, are made the compound or artificial metals, called braſs and prince's metal. See Neumann's Chem. Works; Dict. of Chemiſtry; Lewis's Mat. Med. edit. 3.

ZINGIBER. Ginger. Alſo called zinziber, gingihil fœminia, and iris latifolia tuberoſa. It is the root of a reed-like plant, growing ſpontaneouſly in both the Indies, in China, &c. It is brought to us in knotty, branched, flattiſh pieces, freed from the outer bark, of a pale colour, and fibrous texture. It is diſtinguiſhed into white and brown, but they are both the ſame root; the former is cleaned and dried, the latter is ſcalded, more ſhrivelled, and rendered leſs aromatic. That which is the leaſt fibrous is reckoned the beſt. It is the amonium *zingiber*, or amonium ſcapo nudo, ſpica ovata. Linn. Common *ginger*.

This root is warm and aromatic, but not ſo heating as one would expect from its penetrating heat, and the pungency of its taſte, as well as from the fixedneſs of its principles. It gives out all its virtues to rectified ſpirit of wine, and the greater part of them to water. In diſtillation water raiſes its whole flavour, but ſpirit leaves it nearly all behind.

Ginger is uſed in cold and flatulent diſorders with ſome advantage; alſo when there is a laxity, or debility of the inteſtines. Its effects are more durable than thoſe of the peppers, but it is not ſo heating. See Lewis's Mat. Med.

ZONA. A kind herpes, and runs round the body. The eryſipelas phlyctænodes.

ZOÓTOMIA, from ζωον, *an animal*, and τεμνω, *to cut*. The diſſection of *animals*.

ZOSTER ERYSIPELAS, i. e. Eryſipelas Phlyctænodes.

ZOSTER. The phlogoſis erythema of Cullen.

ZOSTER (Herpes) i. e. Eryſipelas phlyctænodes.

ZYGOMA, i. e. Os Mala. See MALARUM OSSA.

ZYGOMATICUS MUSCULUS. It is called *zygomaticus* major, by Albinus and Winſlow. It ariſes fleſhy from the zygomatic proceſs of the cheek bone; and is inſerted into the cornea of the mouth, which this muſcle with its partner draws outwards and upwards.

ZYGOMATICUS PROCESSUS. From the anterior middle part of the temporal bone goes a proceſs, which joining another from the cheek-bone, they together form an arch called by this name.

Siculus Albus — Bezoar Foſſile
Siderites — Chamæpitys
Siderites — Magnes
Angelica — Panax Coloni
Sideratio Oſſis — Spina Ventoſa
Sight — Viſio
divided into two — Hemalopia
by Day only — Hemeralops
loſt at Night — Hemeralopia
(Long) — Preſbytæ
(Falſe) — Pſeudoblepſis
(Difficult) — Dyſopia
(Dim) — Achlys
Sigillum beatæ Mariæ. — Bryonia Nigra
Solomonis — Polygonatum
Sign — Signum
Commemorative, Demonſtrative, Prognoſtic — Anamneſtica
Siler Montanum — Seſeli Vulg.
Silicula — Adianthum
Siligo — Secale
Siliqua Edulis — Siliqua Dulcis
Siliquaſtrum Pliinii — Piper Indicum
Silk — Sericum
Silphium — Aſafetida
Silver — Argentum
Silver Buſh — Barba Jovis
Silver Tree — Conocarpodendron
Silver Weed — Argentina
Simplex — Fol. Simplex
Simſon — Erigeron
Sinapi Arvenſe — Rapiſtrum
Echinatum — Erucago
Sylveſtre — Eryſimum Latifol.
Sinapiſm — Cataplaſma & Epithema Sinapi & Epitpaſtica
Sinon — Amomum
Sinuatum — Fol. Sinuatum
Sinus — Fiſtula
Siomanna — Ameſpodi
Siphunculus Maris — Entalium
Sirenca — Bovina Affectio
Siriaſis — Adуſtion
Sirii Bos — Betle
Sirones — Bovina Affectio
Siſarum Mont. — Genſing
Peruv. — Battatas Hiſp.
Siſon — Amomum
Siſymbrium — Barbarea, Sophia, & Naſturtium Aq.
Naſturtium — ib.
Siſymbrium, Menthaſtrum — Mentha Aquatica
Sium, &c. — Cicuta Aquatica
Aromaticum — Amomum
Skeleton — Scelcton
Skin — Cutis
Skin (Scarf) — Cuticula
Skink — Scincus
Skirrets — Siſarum
Skirrhus — Scirrhus
Skull — Cranium
Depreſſed — Depreſſio
Slaters — Aſeli
Sleep — Somnus
(Diſturbed) — Oneirodynia
Sling — Faſcia
Sling Bone — Aſtragalus
Sloe Buſh — Prunus Sylveſtris
Tree — Acacia
Slow Worm — Cæcilia
Smallage — Apium
Small Pox — Variola
Smalt — Cobaltum
Smeeltis — Cimolia Purpuraſcens
Smell
loſt or difficult — Anoſmia
Smelling — Olfactus
Smelt — Eperlanus
Smilax Aſpera — China Orientalis, China Occidentalis
Aſpera Peruv. — Sarſaparilla
China — China Orientalis
Hortenſis — Phaſeolus
Indica — China Occidentalis
Lævis Off. — Convolvulus Maj.
Lævis Min. — Convolvulus Min.
Sarſaparilla — Sarſaparilla
Virginiana — ib.
Umbilla humil. — Monophyllon
Smyrnion — Imperatoria
Smyrnium. — Apium & Hippoſelinum
Snake-root
(Virginian) — Serpentaria Virginiana
(Black) — Anapodophyllon
Snakeweed — Biſtorta
(Black) — Aſarum Virginianum
(Tree) — Colubrinum
(Virginian) — Serpentaria Virg.
Snails — Cochlæa
Snap Dragon — Antirrhinum & Barleria
Snap Tree — Adhatoda
Snatcher — Ambra
Sneeze-wort — Ptarmica
Snoring — Rhenchos & Rhochmos
Snorting — Rhochmos
Snow Flower — Carchichoe
Soap — Sapo
of Glaſs — Manganeſe
Berries — Saponaria Nuculæ
Rock — Steatites
Wort — Saponaria
Soda — Anatron. Cardialgia, & Clavellati Cineres
Sol — Aurum
Solamen Inteſtinorum — Aniſum
Solanum Arborеſcens — Colubrinum
Indicum — Colubrinum
Dulcamara — Solanum Lign.
Furioſum — Solanum Lethale, & Stramonium
Lycopерſicum — Amoris Poma
Maniacum — Solanum Lethale, & Stramonium
Magnum — Phytolacca Americana
Nigrum — Solanum Hortenſe
Offic. — ib.
Pomifera — Amoris Poma
Pomiferum — Melongena
Quadrifolium — Alkekengi
Racemoſum — Phytolacca Americ.
Somniferum — Solanum Lethale, & Stramonium
Scandens — Solanum Lign.
Tuberoſum, &c. — Pattatas
Urens — Piper Indicum
Veſicarium — Alkekengi
Vulg. — Solanum Hortenſe
Solatrum — ib.
Soldier (Freſh Water) — Aloides
Solidagini — Doria
Soldanella — Braſſica Maritima
Solidago Virga Aurea — Virga Aurea
Solen — Onyx
Solitary Worm — Dracunculi
Solum — Metatarſus, Vermes
Solomon's Seal — Polygonatum
Solſequia — Calendula
Solſequium — Tithymalus Heliоſc.
Solvent — Solutio
Somnambulo — Noctambulatio
Sonchus lævis — Chondrilla
Sonchus repens — Hieracium Majus
Soot — Fuligo
Soporoſe Diſeaſes — Coma
Sora — Eſſera
Sorgo — Milium Indicum
Sorghum — Milium Indicum
Sortel — Acetoſa
Sorrow — Triſtitia
Soudic Blanche — Anatron
Sound — Sonus
Southernwood — Abrotanum
Sow Bane — Chenopodium
Sow Bread — Arthanita
Spaniſh White — Album Hiſpanicum, & Biſmuthum
Sparagus — Aſparagus
Sparrow-graſs — Aſparagus
Sparta polia — Amianthos
Spartium Scoparium — Genиſta
Arborеſcens — Geniſta juncea
Majus — Geniſta Spinoſa Maj.
Spaſm — Spaſmus
Clonic — Spaſmus Clonicus
Tonic — Spaſmus Tonicus
Spaſmodic Diſeaſe — Spaſmi
Spatula Fœtida — Iris Fœtida
Spearwort — Ranunculus Longifolius
Species Fracaſtoria — Bolus
Spectacles — Coeſpicillum
Speedwell — Teucrium
(Female) — Elatine
(Male) — Veronica
Spelter — Zincum
Sperage — Aſparagus
Sphacelus Oſſes — Spina Ventoſa
Sphærocephala Elatior — Echinopus
Sphena Spinalis — Duræ Matris, Arteriæ
Spica Mas — Lavandula Latifol.
Vulgaris — Lavandula Anguſtifol.
Fœmina — ib.
Spica
Spica Indica — Nardus Indica
Spica Nardi — Nardus Indica
Spica Celtica — Nardus Celtica
Hortulana — Stœchas
Spicatus — Flos Spicatus
Spice — Piper Nigrum
Spiderwort — Hieraſtrum
Spiderwort — Ephemerum
Spigelia — Anthelmia
Spignel — Meum
German or Mountain — Meum Alp. Germ.
Baſtard — Meum Latif. Adult.
Spikenard (Celtic) — Nardus Celtica
Ploughmans — Baccharis
Spina Acida — Berberis
Cervina, Solutiva, Infectoria — Rhamnus
Spina
Egyptiaca — Acacia
Burgi Monſpel. — Alaternus
Alba — Meſpilus Apii folio
Hirci — Tragacantha
Solſtitialis — Calcitrapa Offic.
Ventoſa — Pædarthrocace
Spinachia fragifera — Chenopodio
Spinacia — Spinachia
Spinæ Ventoſitas — Spina Ventoſa
Spinage (Common) — Spinachia
Spinalis Colli Minores — Interſpinales Muſculi
Colli — Spinalis Muſculus
Dorſi — ib.
Spindle Tree — Euonymus
Spine — Spina
Curved — Spina Ventoſa
Spinoſa — Hydrorachitis
Spinoſum
Syriacum — Alhagi
Spiræa Ulmaria — Ulmaria
Spt. Camphor. Tartar. — Camphora
Proof — Vinum Adуſtum
Sal. Marin. Coag. — Marinum
Glaub. — ib.
Vini — Vinum Adуſtum
Vini C. — Camphora
Rect. — Vinum Adуſtum
Vol. fœtid. — Aſafœtida
Mineral — Aer
Æthereus — Æther
Vini Æthereus — ib.
Cornu Cervi — Alcali
Sal Ammon. — ib.
Sal Ammon. Dulc. — ib.
Sal Ammon. Cauſtic — ib.
Sal Ammon. cum Cala Viv. — ib.
Vol. Arom. — ib.
Cochlariæ — Cochlearia
Nitri — Nitrum
Nitri Glaub. — ib.
Nitri Dulc. — Nitrum
Spit — Sputum
Spitting Blood — Hæmoptyſis
Splay-footed — Leiopodes
Spleen — Splen
Abſceſs in the — Abſceſſus
Inflamed. — Splenitis & Inflammatio
Spleen — Hypochondriacus Morbus
Spleen-ſtone — Opites
Spleenwort — Aſplenium
(Rough) — Polypodium Anguſt.
Splenium — Aſplenium
Spodium — Succharum
Spodium
Græcorum — Album Græcum
Spondylium — Paſtinaca
Sponge — Spongia
Spongia Solis — Bononienſis Lapis
Spoufa Salis — Ros Solis & Cacondula
Spoon — Cochlearia
Spot — Macula
Spunge (Baſtard) — Alcyonium
Spunk — Boletus
Spurge — Eſſula, Catapuſia, & Tithymalus
(Garden) — Eſſula Major
(German) — ib.
(Great Marſh) — ib.
(Pine) — Eſſula Minor
Spurgeflax — Thymalea Monſp.
Spurgewort — Iris Fœtida
Squash — Melopepo
Squill — Scilla
Spuilla Crangon — Crangon
Squinancy wort — Rubia Synanchica
Squinanthum — Juncus Odoratus
Squinting — Strabiliſmus
Stachys — Marrub Verticill.
Fœtida — Galeopſis
Paluſtris — Panax Coloni
Staffe — Myrrha
Stag — Corvus
Staggering — Claudicatio
Stalk — Caulis
Stalk — Culmus
Stalk (Without a) — Acaulis
Stamineus — Flos Stamineus
Stammering — Pfelliſmus
Stapes — Malleus
Star — Aſtrum
Star of Bethlehem — Ornithogalum
Starch — Amylum
Starfall — Cœlioſum
Star-gem — Aſteria
Star-ſtone — Aſtrochites
Star-wort — Inguinalis
Staves Acre — Staphis Agria
Steatites — Cimolia Alba
Steel — Chalybs
(Candied) — Ferrum
Stellæ Lapis — Aſtrochites
Stellaris — Aſperula
Stellata — ib.
Stella Terræ — Coronopus
Stelochites — Oſteocolla
Sterilis — Flos Sterilis
Sterno Maſtoides — Maſtoideus
Sterno Maſtoideus — Muſculus
Sternomaſtoideus — Sterno Hyoides
Sternutamentoria — Ptarmica
Sternutatories — Errhina
Stertor — Ronchos
Stibium — Antimonium
Stickadore — Stœchas
Stillicidium Urin. — Dyſuria
Stimmi — Antimonium
Stinking Exhalations — Dyſodia
Breath — ib.
Exhalations from the Bladder — Ecphyſe
Exhalations from the Womb — ib.
Stirrup — Stapes
Stœchas Citrina — Elichryſum
Golden — ib.
Stomach — Stomachus
Rupture of the — Abdomen
Inflamed — Inflammatio
Stomacace — Scorbutus
Stone — Lapis
Stone — Calculus
(Cutting for the) — Lithotomia
(Extracting) — ib.
(Nephritic) — Staticka
(Serpentine) — ib.
Stones (Precious) — Quæcu
Storax — Styrax
Rubra — Thuris Cortex
Strabiſmus — Strabiliſmus
Strabolitas — ib.
Strain — Stremma
Strannen Camelorum. — Juncus Odoratus
Strangury — Dyſuria
Stratiotes — Microleuco-zymphæa, Millefolium, & Aloides
Strawberry — Arbutus & Fraga
Eaſtern — Arbutus Andrachne
Strawberry Bay — Andrachne
Spinage — Chenopodio Morus Maj.
Strengtheners — Corroborantia
Stretching — Pandiculatio
Strongylus — Vermes
Struma — Scrofula
Struthium — Saponaria Lutea & Imperatoria
Strychnos — Colubrinum Stuffing

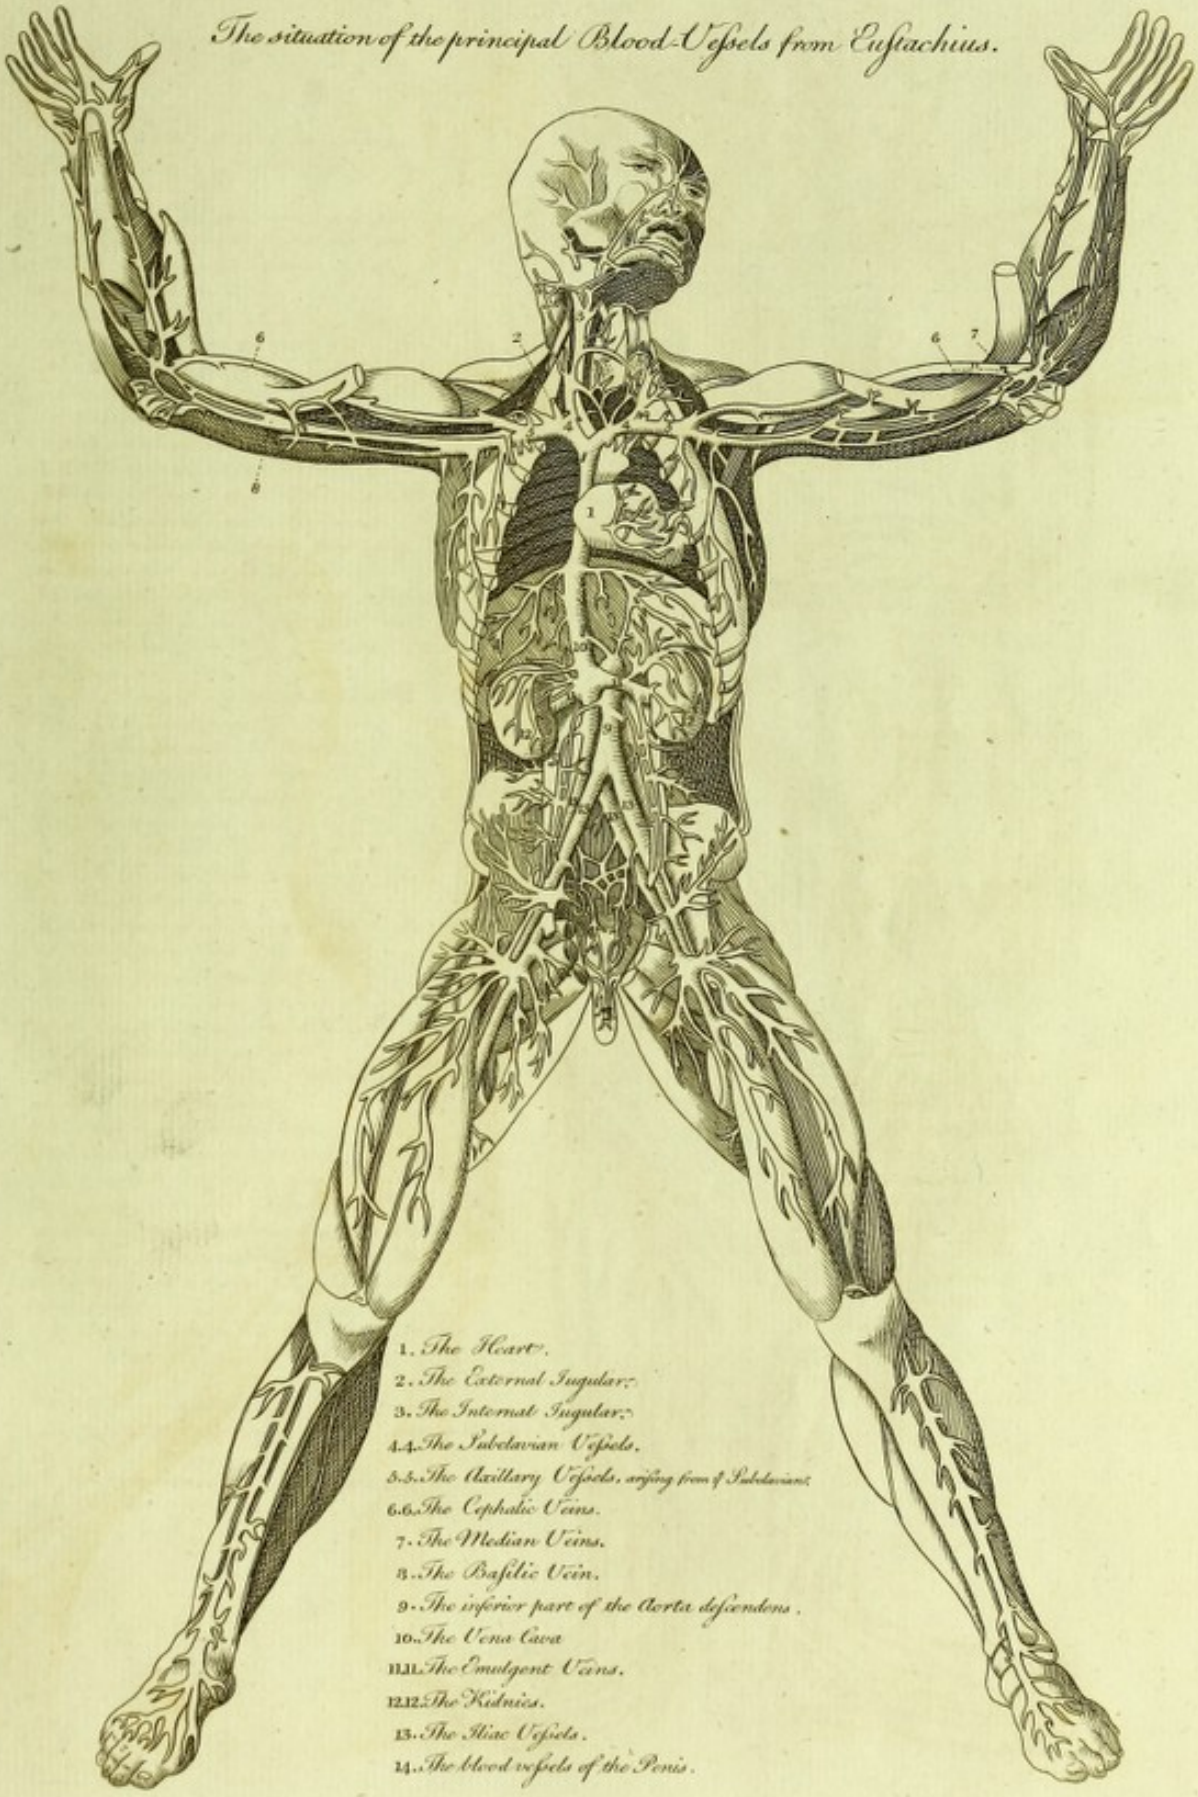
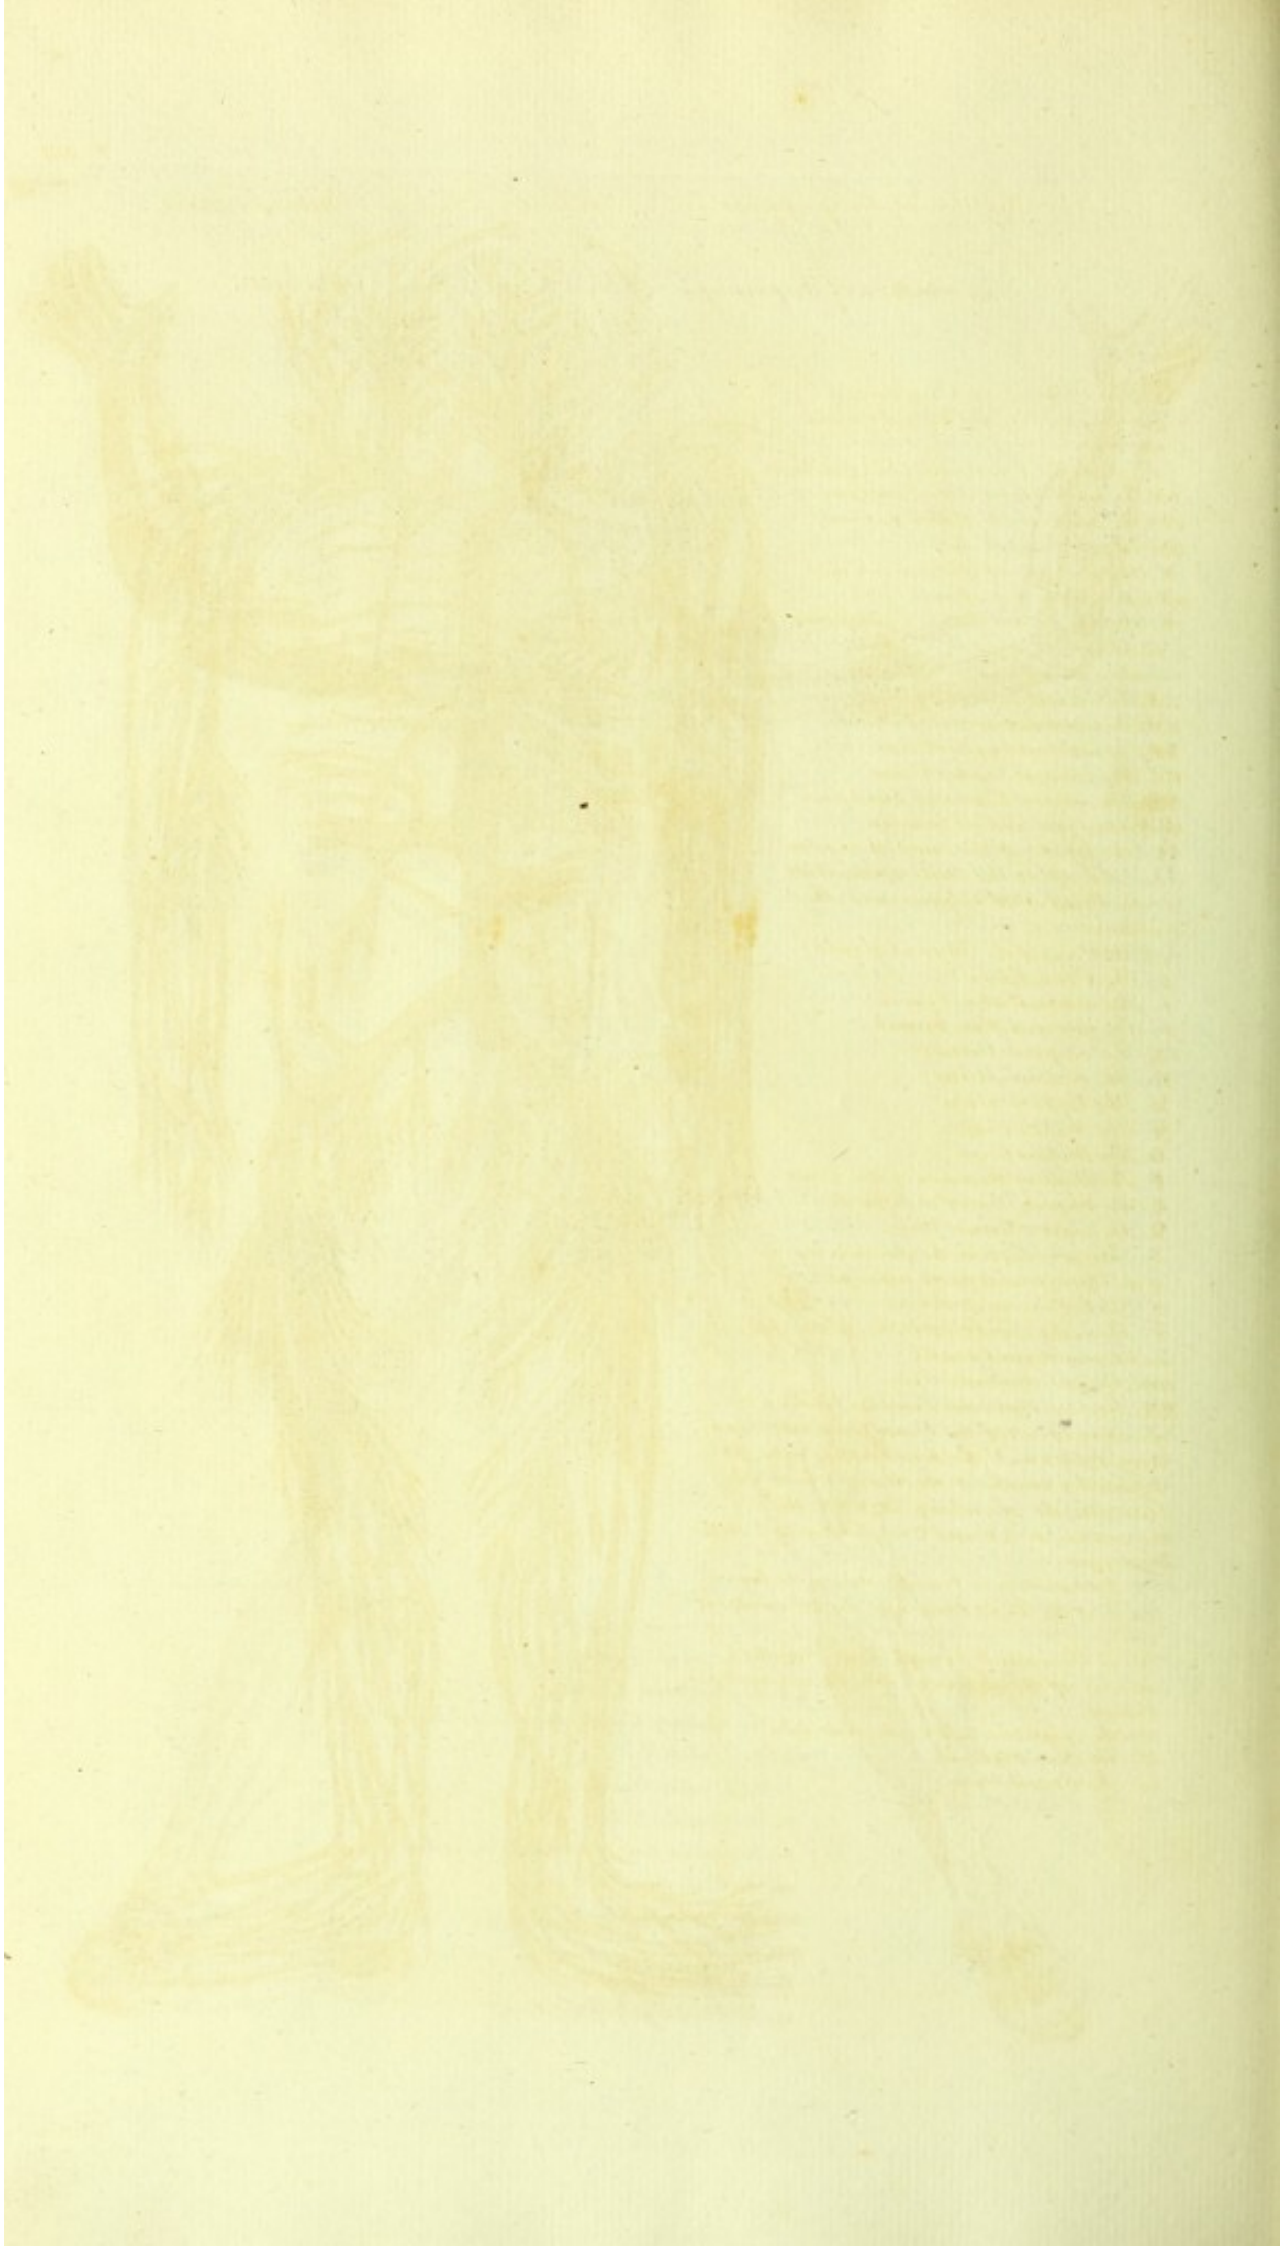
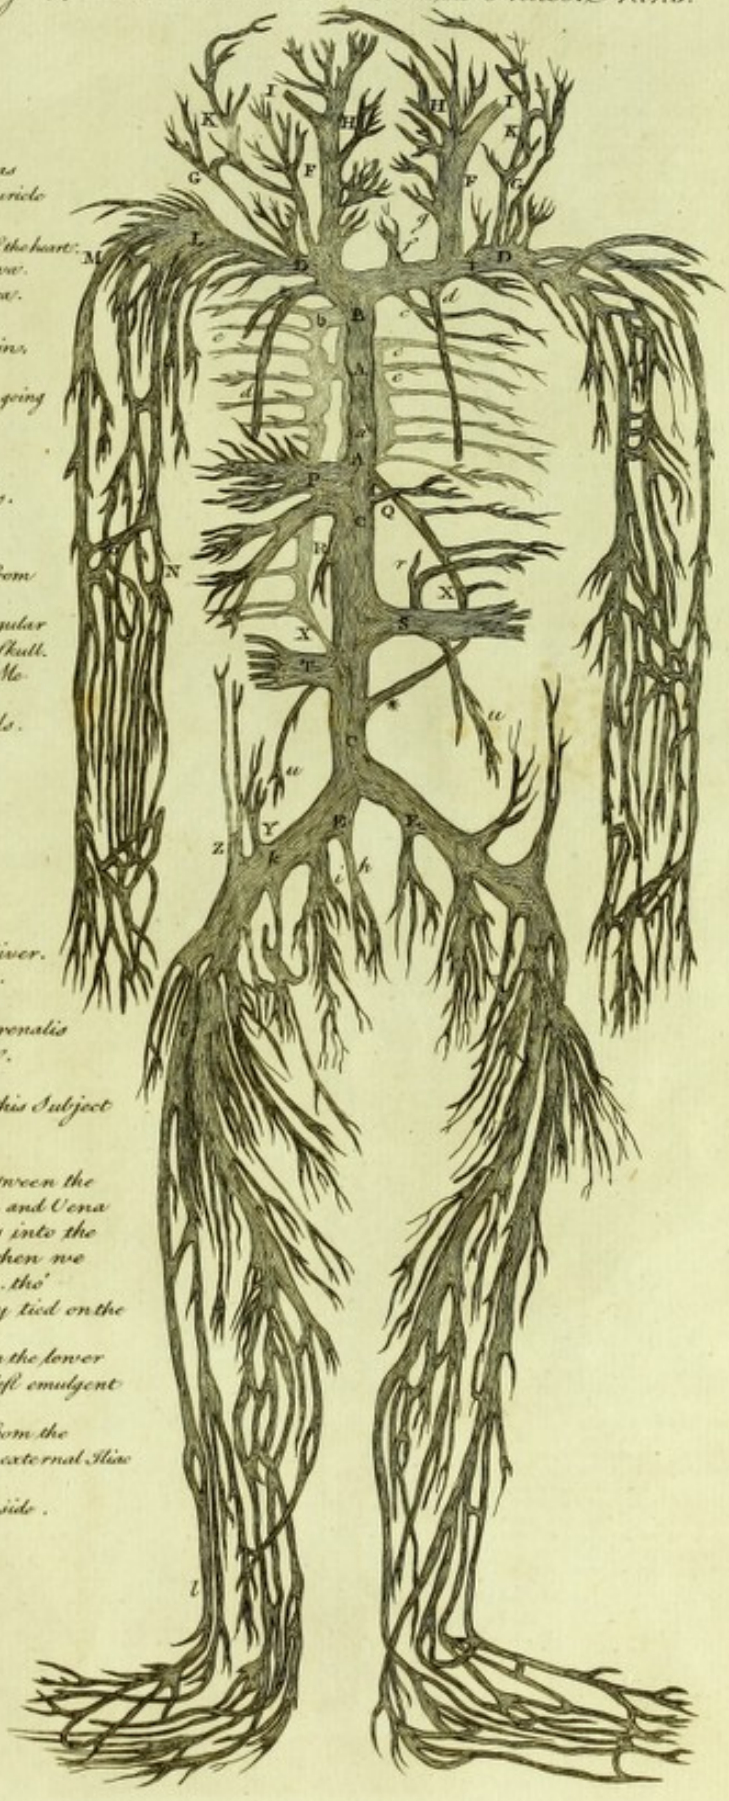
The situation of the principal Blood-Vessels from Eustachius.



1. The Heart.
2. The External Jugular.
3. The Internal Jugular.
4.4. The Subclavian Vessels.
5.5. The Axillary Vessels, arising from the Subclavians.
6.6. The Cephalic Veins.
7. The Median Veins.
8. The Basilic Vein.
9. The inferior part of the Aorta descendens.
10. The Vena Cava
11.11. The Emulgent Veins.
12.12. The Kidnies.
13. The Iliac Vessels.
14. The blood vessels of the Penis.



The Veins, as they appear in an Adult. From the Philos. Trans.



AA. The Orifice of the Vena Cava, as it appears when cut from the right auricle of the Heart.

a. The Orifice of the Coronary vein of the heart.

BA. The superior trunk of the Vena Cava.

CCA. The inferior trunk of the Vena Cava.

DD. The Subclavian Veins.

†. That part of the left Subclavian Vein, where the thoracic duct enters.

b. The Vena Azygos, with its branches going to the ribs c.c.

c. The Superior intercostal Veins.

d.d. The internal mammary Veins.

E.E. The right and left Iliac branches.

F.F. The internal Jugular Veins.

G.G. The external Jugular Veins

HH. The veins which bring blood from the lower jaw and its muscles.

I.I. The trunks of the internal Jugular veins, cut off at the basis of the Skull.

f. The Veins of the Thymus and Mediastinum.

g.g. The Veins of the Thyroid glands.

h. The Vena Sacra.

i. The internal Iliac branch.

k. The external Iliac branch.

KK. The occipital Veins.

L. The Axillary Vein.

M. The Cephalic Vein.

N. The Basilic Vein.

O. The Median Vein.

P. The trunk of the veins of the Liver.

Q. The Phrenic Vein of the left side.

R. The right Phrenic Vein.

r. A large vein from the glandula renalis of the left side and parts adjacent.

S. The left emulgent Vein.

T. The right emulgent Vein (in this Subject much lower than is usual)

uu. The two spermatic Veins.

XX. Two communicant branches between the ascending trunk of the Vena Cava, and Vena Azygos, by which the wind passes into the descending trunk of the Cava, when we blow into the ascending at A.P.C. tho' the trunk at A.P. and C. is firmly tied on the blow pipe.

*. An uncommon branch between the lower trunk of the Vena Cava and the left emulgent Vein.

Y. A Vein which brings blood from the muscles of the abdomen, into the external Iliac branch.

Z. The epigastric Vein on the right side.

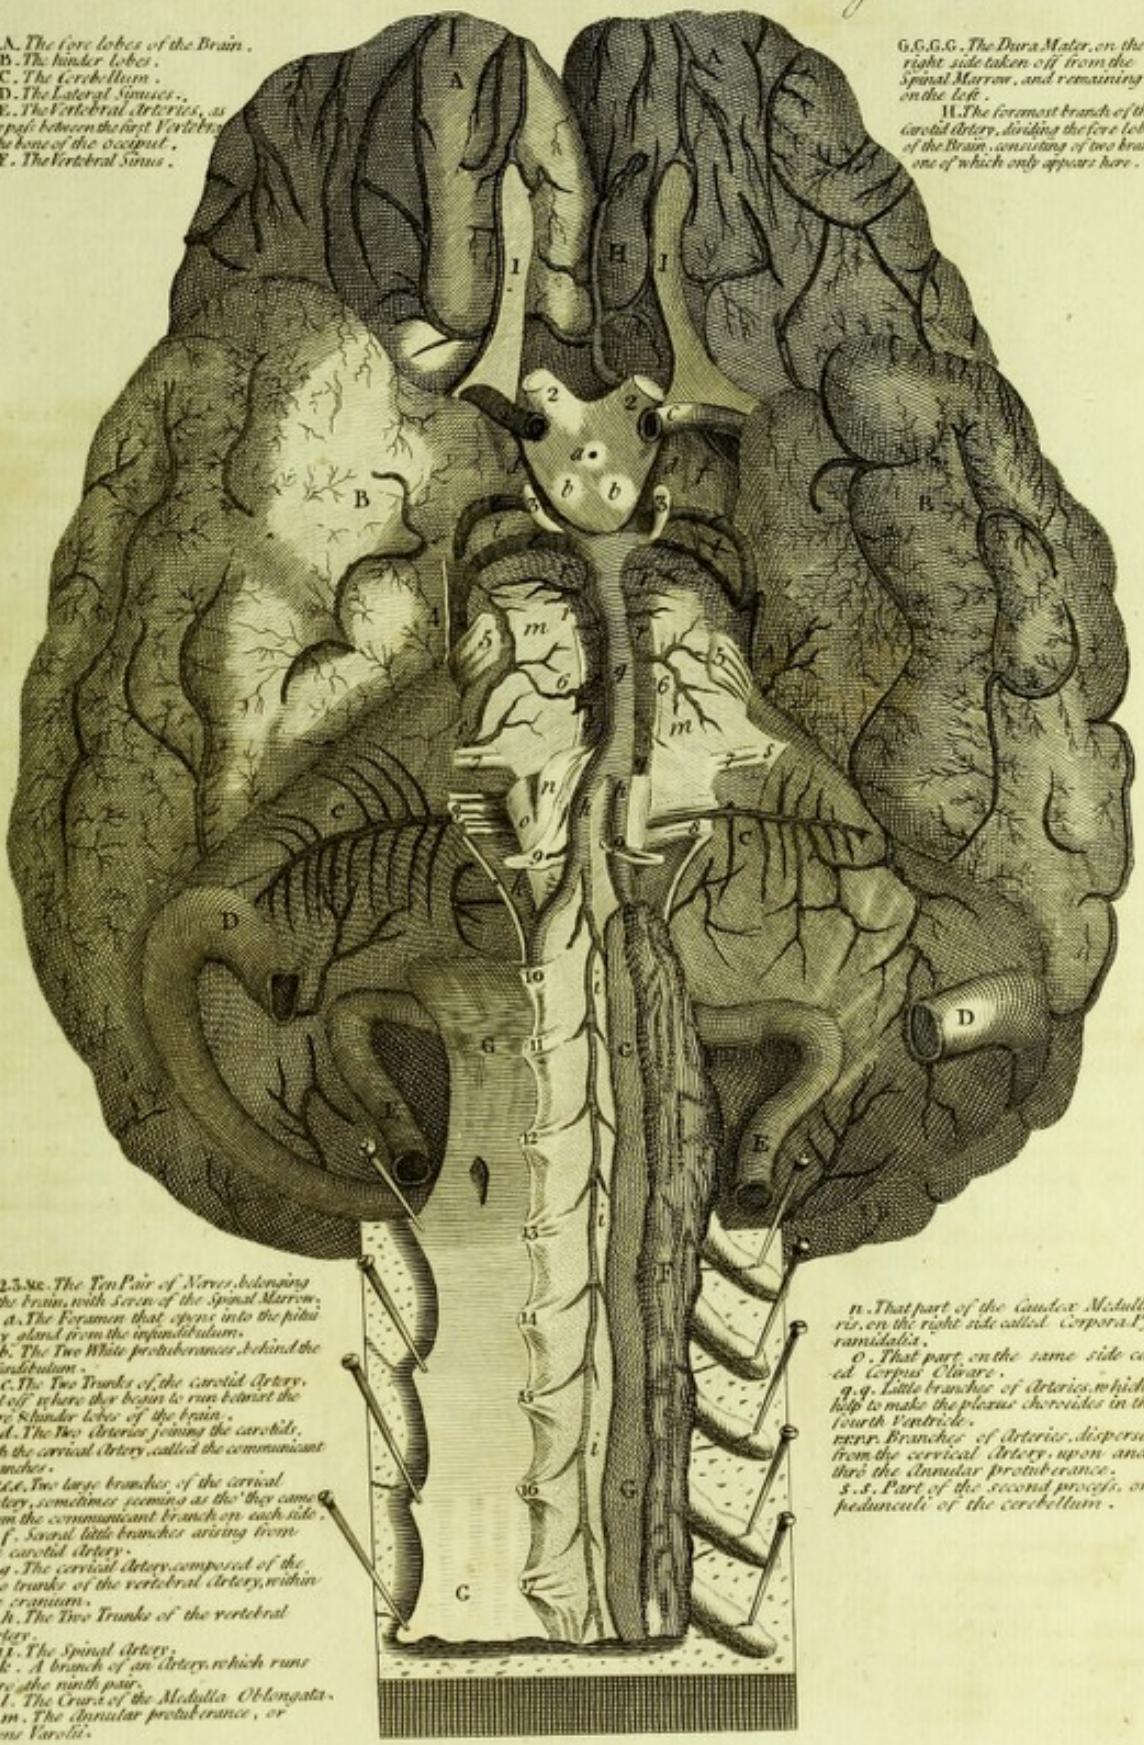
l.l. The Vena Saphena.

m. The Crural Vein.

The Basis of the Brain. From Ridley.

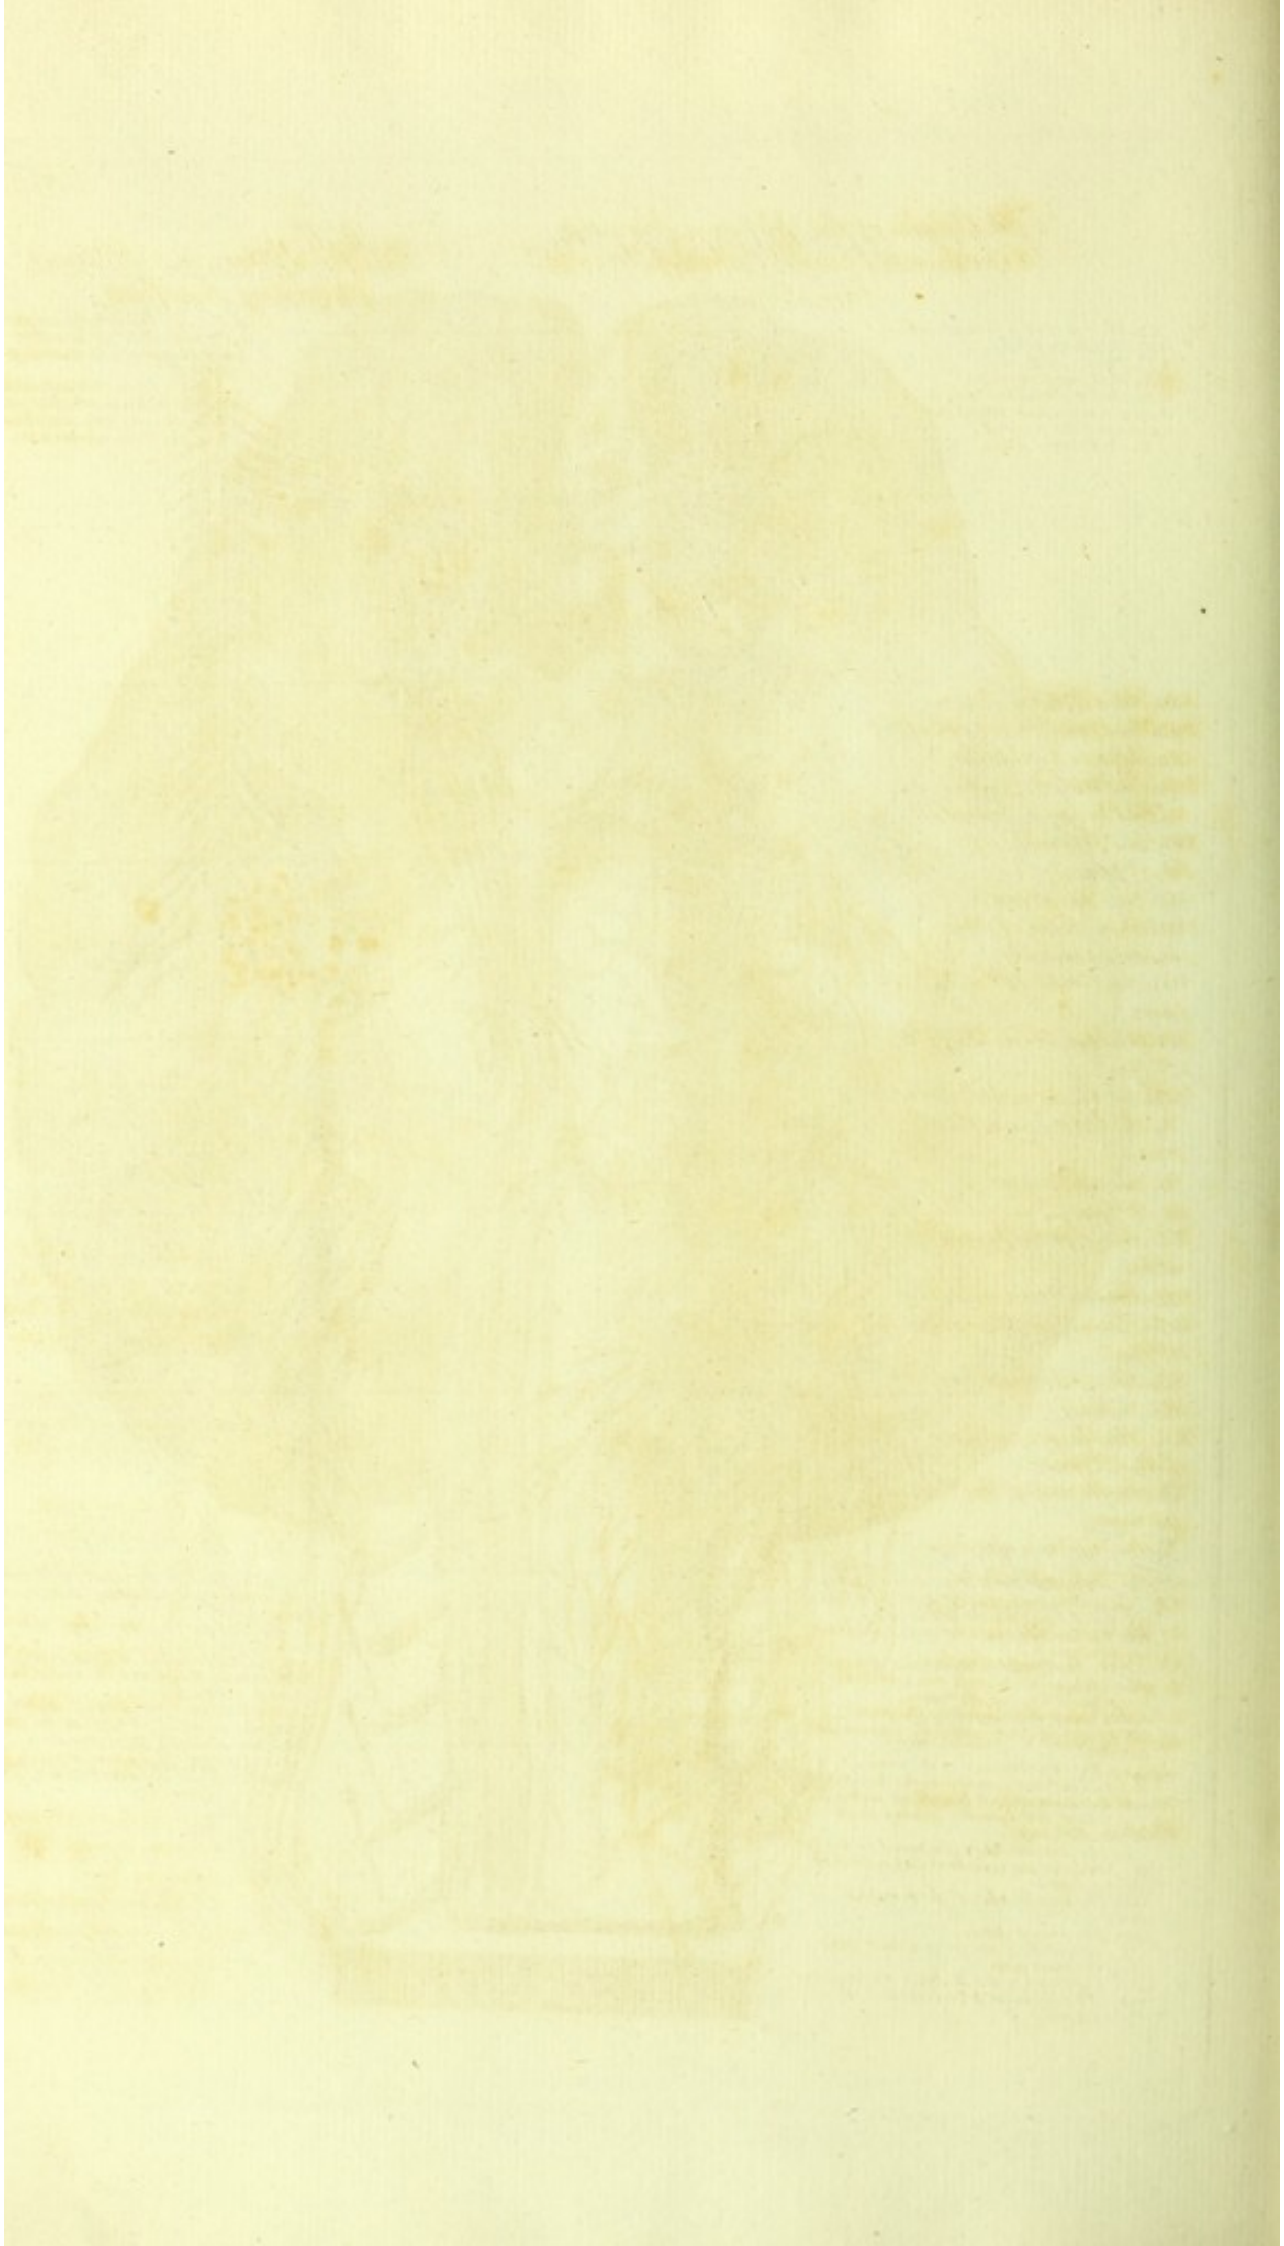
A.A. The fore lobes of the Brain.
B.B. The hinder lobes.
C.C. The Cerebellum.
D.D. The Lateral Sinuses.
E.E. The Vertebral Arteries, as they pass between the first Vertebra & the bone of the occiput.
F. The Vertebral Sinus.

G.G.G.G. The Dura Mater, on the right side taken off from the Spinal Marrow, and remaining on the left.
H.H. The foremost branch of the Carotid Artery, dividing the fore lobes of the Brain, consisting of two branches one of which only appears here.

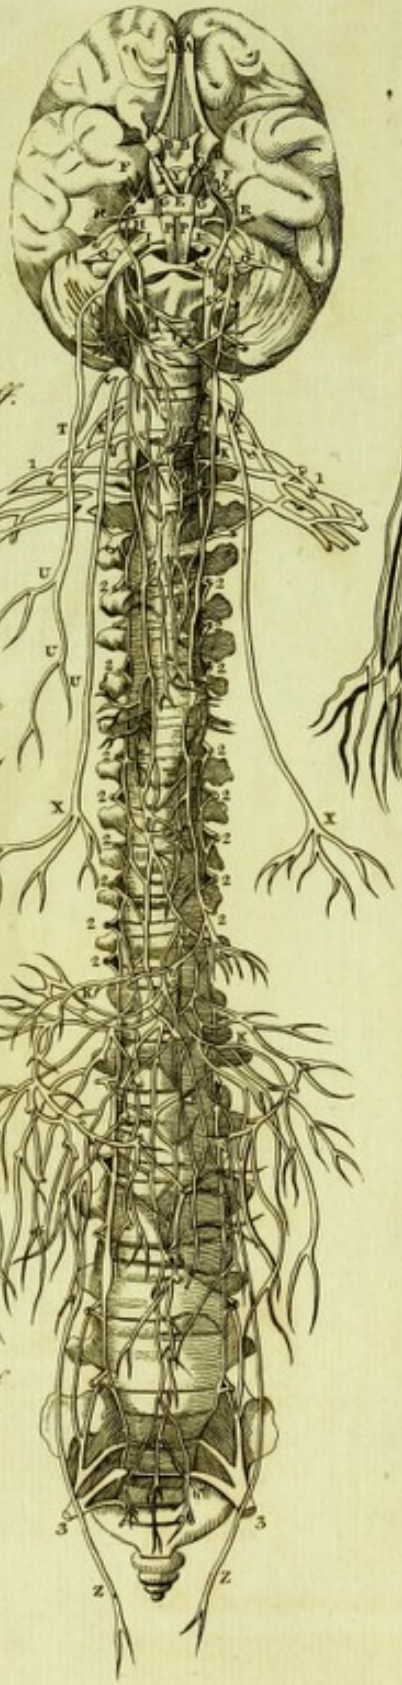


1.2.3.&c. The Ten Pair of Nerves, belonging to the brain, with Seven of the Spinal Marrow.
a. The Foramen that opens into the pituitary gland from the infundibulum.
b.b. The Two White protuberances behind the infundibulum.
c.c. The Two Trunks of the carotid Artery, cut off where they began to run betwixt the fore & hinder lobes of the brain.
d.d. The Two Arteries joining the carotids, with the cervical Artery, called the communicant branches.
e.e.e.e. Two large branches of the cervical Artery, sometimes seeming as tho' they came from the communicant branch on each side.
f. Several little branches arising from the carotid Artery.
g. The cervical Artery composed of the two trunks of the vertebral Artery, within the cranium.
h.h. The Two Trunks of the vertebral Artery.
i.i.i. The Spinal Artery.
k. A branch of an Artery, which runs thro' the ninth pair.
l.l. The Crura of the Medulla Oblongata.
m.m. The Annular protuberance, or Pons Varolii.

n. That part of the Caudex Medullaris, on the right side called Corpora Pyramidalia.
o. That part on the same side called Corpus Olivare.
q.q. Little branches of Arteries, which help to make the plexus choroides in the fourth Ventricle.
r.r.r.r. Branches of Arteries dispersed from the cervical Artery, upon and thro' the Annular protuberance.
s.s. Part of the second process, or peduncule of the cerebellum.



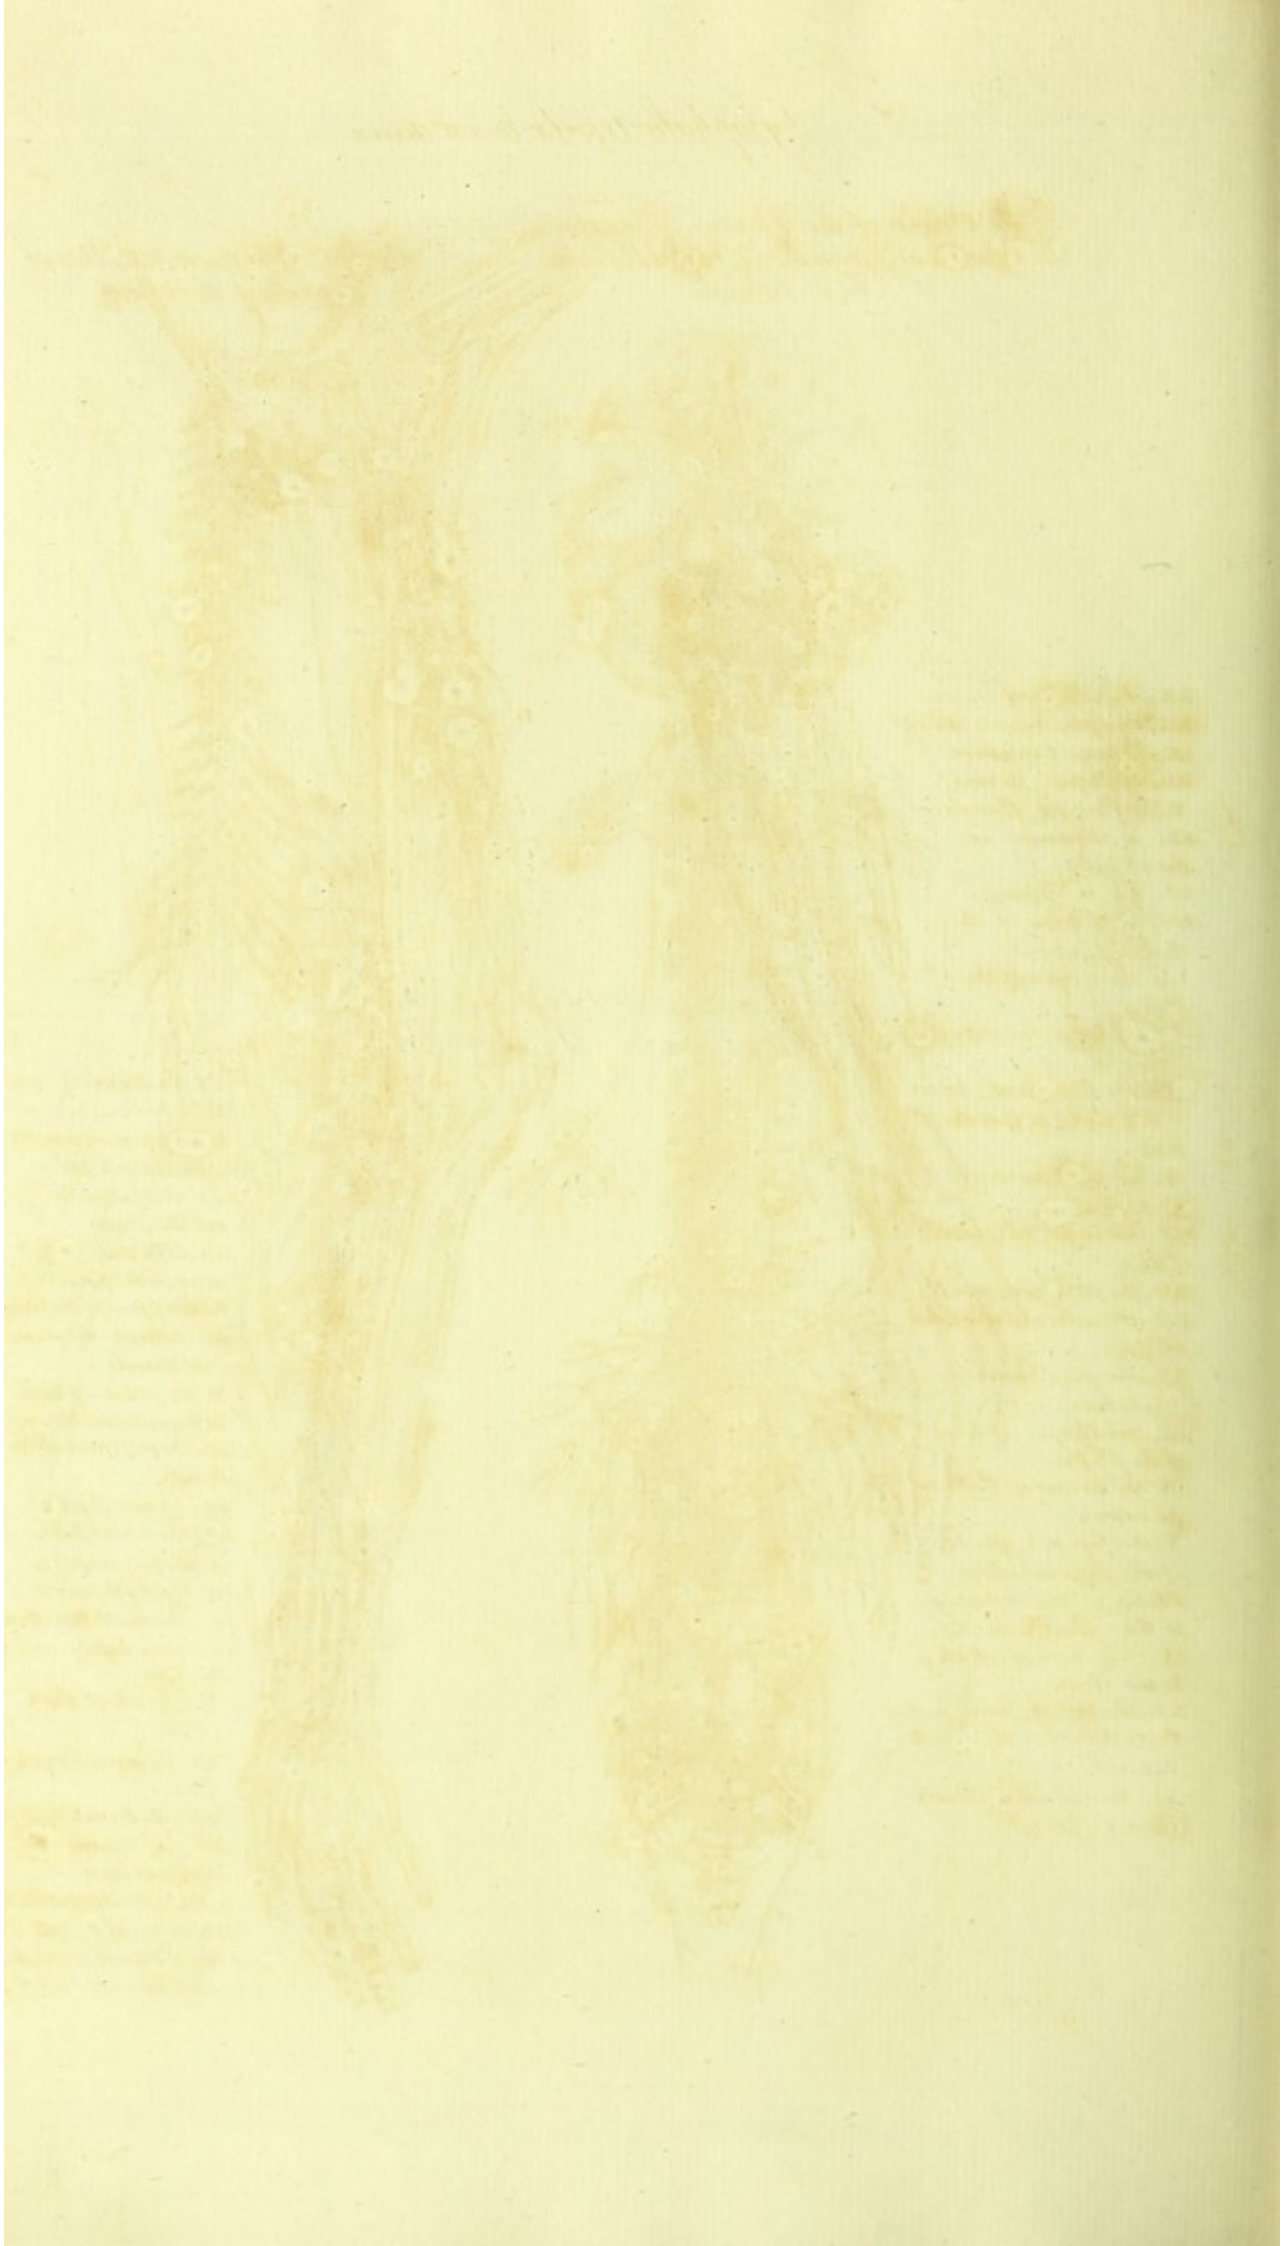
The Origin of the Nerves, from the Brain, and from the Spinal Marrow. From Lancisi.



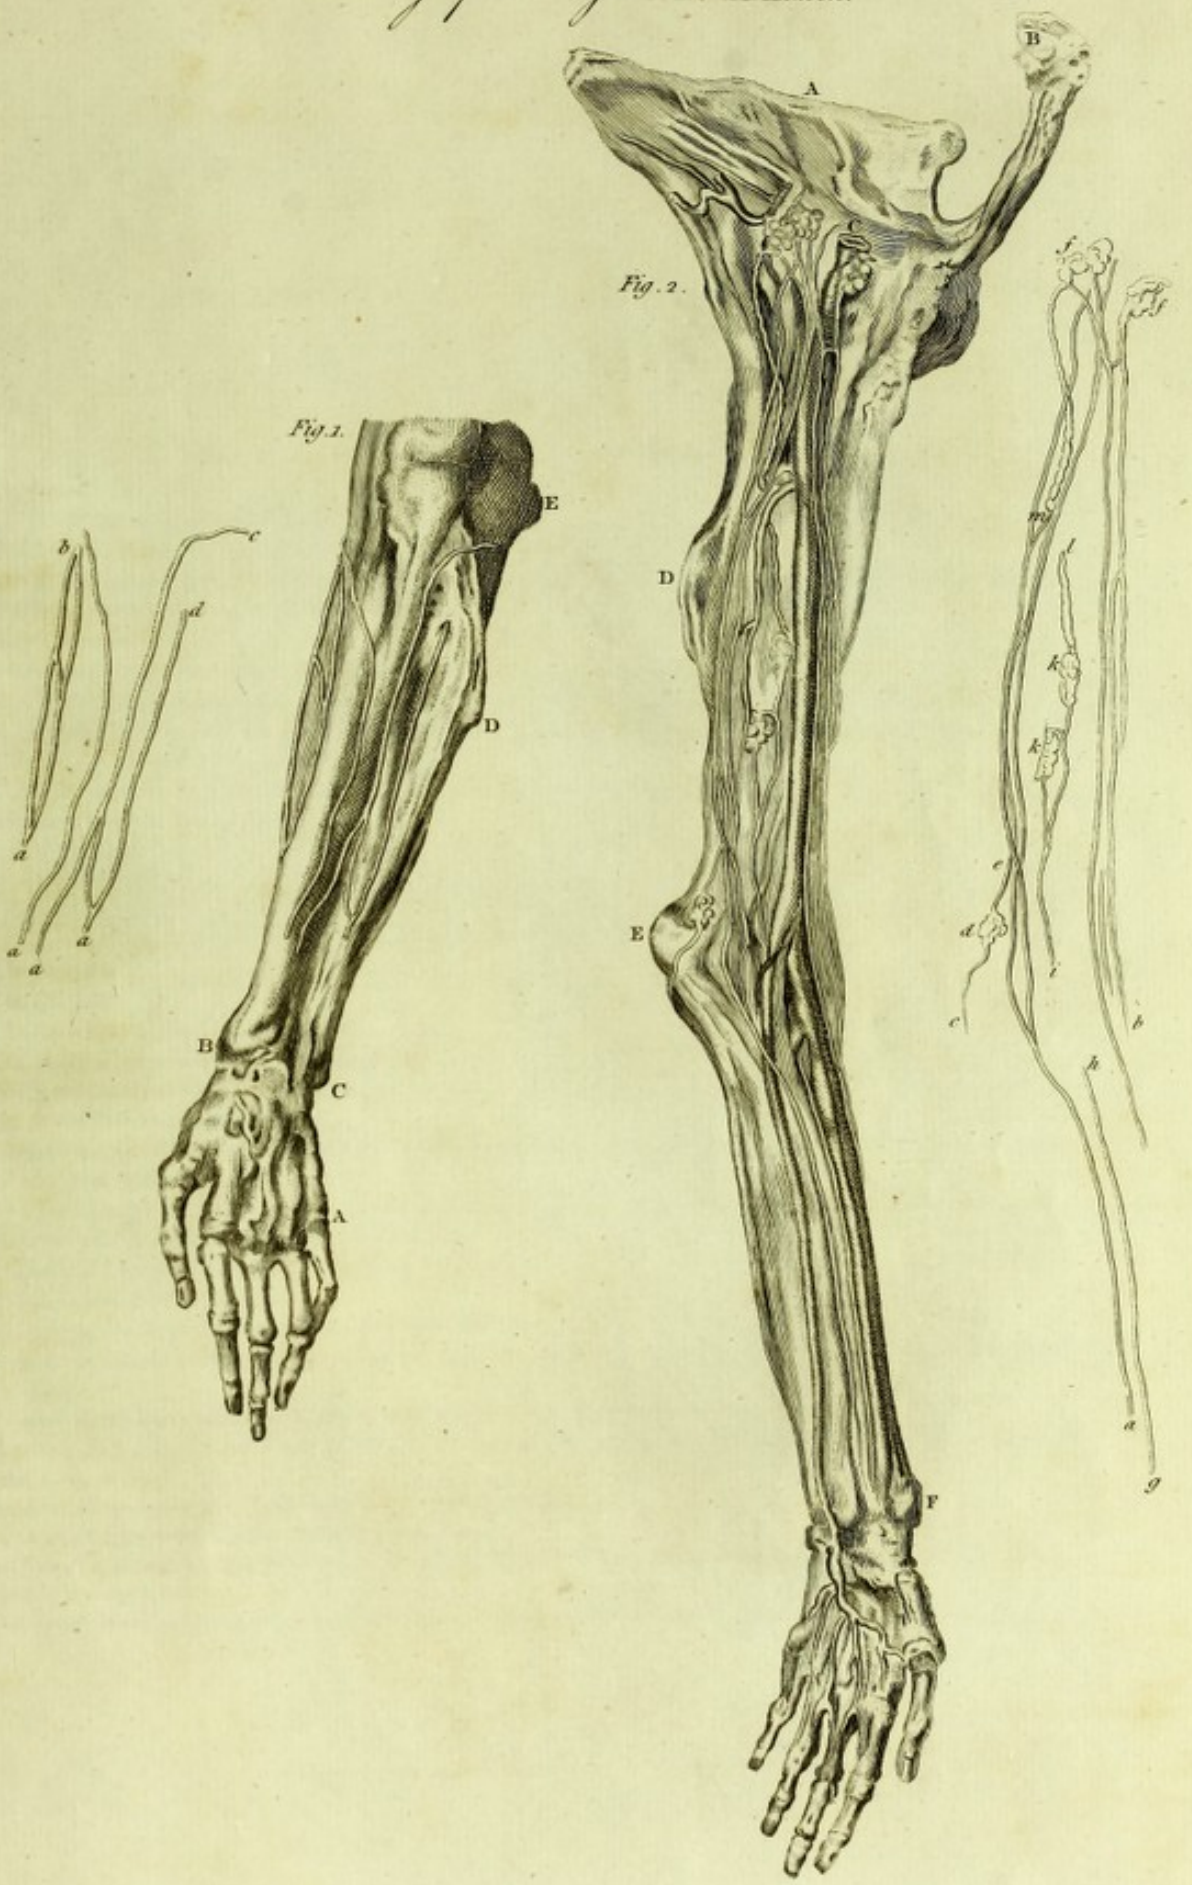
A.A. The Olfactory Nerves.
B.B. The Optic Nerves cut off.
C.C. Motores Oculorum.
D.D. The Pathetic Nerves.
E. The Processus Annulares.
F.F. The 3 Branches of the 5th pair.
G.G. The Sixth pair.
H.H. The portions of the Auditory Nerves.
I.I. The Origin of the 8th pair.
K.K. The large Trunks of the 5th pair.
M.M. The Recurrent Nerves
N. The left nerve of the 9th pair.
O. The right nerve of the 9th pair.
P.P. The Corpora Pyramidalia.
Q.Q. The 10th pair cut off.
R.R. The extremities of the 11th pair.
S.S. The great Trunks of the Nerves.
T.U. The Accessory nerve of the 8th pair.
X.X. The Nerves of the Diaphragm.
Y. The Inferior aperture of the Infundibulum.
Z.Z. The Nerves which go to the testes Uterus, &c.
1.1. The Nerves which go to the Arms.
2.2. The communications of the vertebral & intercostal Nerves.
3.3. The Crural & Sciatic Nerves cut off.

The Spinal Marrow, & the Nerves, proceeding therefrom.

A.A. The Spinal Marrow.
b.b.b.b. A series of nervous branches passing from the P. Spinal Marrow.
C.C.C. The Body of the Spinal Marrow.
D.D. d.d. Branches which arise from 3 pair of the Neck & 2 pair of the Breast proceeding to the Arms and Hands.
E. The plexus of these last mentioned Nerves
f.f. The first pair of the Hands.
g.g. The Second pair.
h.h. The Third pair.
i.i. The Fourth pair.
k.k. The Fifth pair.
l.l. The Sixth pair, these lye immediately under the Skin.
M. The First Crural Nerve.
N.N. The second Crural Nerve.
o.o.o. The Branch thereof which accompanies the Saphena vein.
P.P. The third crural Nerve
Q.Q.Q. The Fourth Crural Nerve
r.r. The external branch.
s.s. The internal branch.



Lymphatic Vessels. From Mr. Hewson.



LYMPHATIC VESSELS. From Mr. HEWSON.

TO FACE PLATE XVI.

FIG. I.

A Back View of the Fore Arm and Hand.

A. The Hand.
B. The lower Extremity of the Radius.
C. The lower Extremity of the Ulna.
D. The Muſcles on the Back of the Fore Arm turned aſide to exhibit a deep ſeated Lymphatic Veſſel, which perforates the Interoſſeous Ligament to get to the Forepart.
E. The Olecranon.
a a a. Lymphatics appearing on the Back of the Fore Arm, immediately under the Skin.
b. Some of the Lymphatics bending over the upper Extremity of the Radius to get to the Forepart of the Arm.
c. A Lymphatic paſſing over the Ulna, immediately under the Olecranon, and under the inner Condyle of the Os Humeri, to get to the Forepart of the Arm.
d. A Lymphatic which has penetrated the Muſcles, perforates the Interoſſeous Ligament, and gets to the Forepart of the Arm near the Radial Artery.

FIG. II.

A Fore View of the Upper Extremity.

A. The Scapula.
B. The Clavicle.
C. The Extremity of the Brachial Artery.
D. The Muſcles lying on the inſide of the Arm.
E. The inner Condyle of the Os Humeri.
F. The lower Extremity of the Radius.
a. A Lymphatic Veſſel which lies in the Cellular Membrane immediately under the Skin, and paſſes up on the inſide of the Arm to the Axillary Glands.
b. Superficial Lymphatic Veſſels paſſing over the Muſcles from the Back of the Fore Arm, and likewiſe over the Biceps to the Glands in the Axilla.
c. A ſuperficial Lymphatic from the Back of the Fore Arm.
d. A Gland through which it paſſes.
e. The Lymphatics from the Anterior and the Poſterior Part of the Fore Arm uniting.
ff. Lymphatic Glands in the Axilla. They are common both to the ſuperficial and the deep ſeated Lymphatic Veſſels.
g. A deeper ſeated Lymphatic Veſſel lying cloſe to the Radial Artery which it accompanies all the Way to (*b*).
h. The deep ſeated Lymphatic Veſſel paſſing under the Interoſſeous and Ulnar Arteries, and appearing again on the Arm, at (*i*).
i. The deep ſeated Lymphatic Veſſel lying cloſe to the Brachial Artery.
k k. Two ſmall Lymphatic Glands through which it paſſes.
l. The ſame Veſſel now become much larger and paſſing under a Branch of the Artery and ſome Cellular Membrane, and appearing at (*m*).
m. The Trunk of the deep ſeated Lymphatic Veſſels paſſing upwards to the Axilla, where it enters the Glands (*ff*).

LYMPHATIC VESSELS.

TO FACE PLATE XVII.

FIG. III.

A Back View of the lower Extremity, diſſected ſo as to ſhew the deeper ſeated Lymphatic Veſſels, which accompany the Arteries.

A. The Os Pubis.
B. The Tuberoſity of the Iſchium.
C. That Part of the Os Ilium which was articulated with the Os Sacrum.
D. The Extremity of the Iliac Artery appearing above the Groin.
E. The Knee.
FF. The two cut Surfaces of the Triceps Muſcle, divided to ſhew the Lymphatic Veſſels that paſs through its Perforation along with the Crural Artery.
G. The Edge of the Muſculus Gracilis.
H. The Gaſtrocnemius and Soleus, much ſhrunk by being dried, and by the Soleus being ſeparated from the Tibia to expoſe the Veſſels.
I. The Heel.
K. The Sole of the Foot.
L. The ſuperficial Lymphatic Veſſels paſſing over the Knee, to get to the Thigh.
M. The Poſterior Tibial Artery.
a. A Lymphatic Veſſel accompanying the Poſterior Tibial Artery.
b. The ſame Veſſel croſſing the Artery.
c. A ſmall Lymphatic Gland through which this deep ſeated Lymphatic Veſſel paſſes.
d. The Lymphatic Veſſel paſſing under a ſmall Part of the Soleus which is left attached to the Bone, the Reſt being removed.
e. The Lymphatic Veſſel croſſing the Popliteal Artery.
f g h. Lymyhatic Glands in the Ham, through which the Lymphatic Veſſel paſſes.
i. The Lymphatic Veſſel paſſing with the Crural Artery through the Perforation of the Triceps Muſcle.
k. The Lymphatic Veſſel, after it has paſſed the Perforation of the Triceps, dividing into Branches which embrace the Artery (*l*).
m. A Lymphatic Gland belonging to the deep ſeated Lymphatic Veſſel. At this place thoſe Veſſels paſs to the Fore-part of the Groin, where they communicate with the ſuperficial Lymphatic Veſſels.
n. A part of the ſuperficial Lymphatic Veſſels appearing on the Brim of the Pelvis.

FIG. IV.

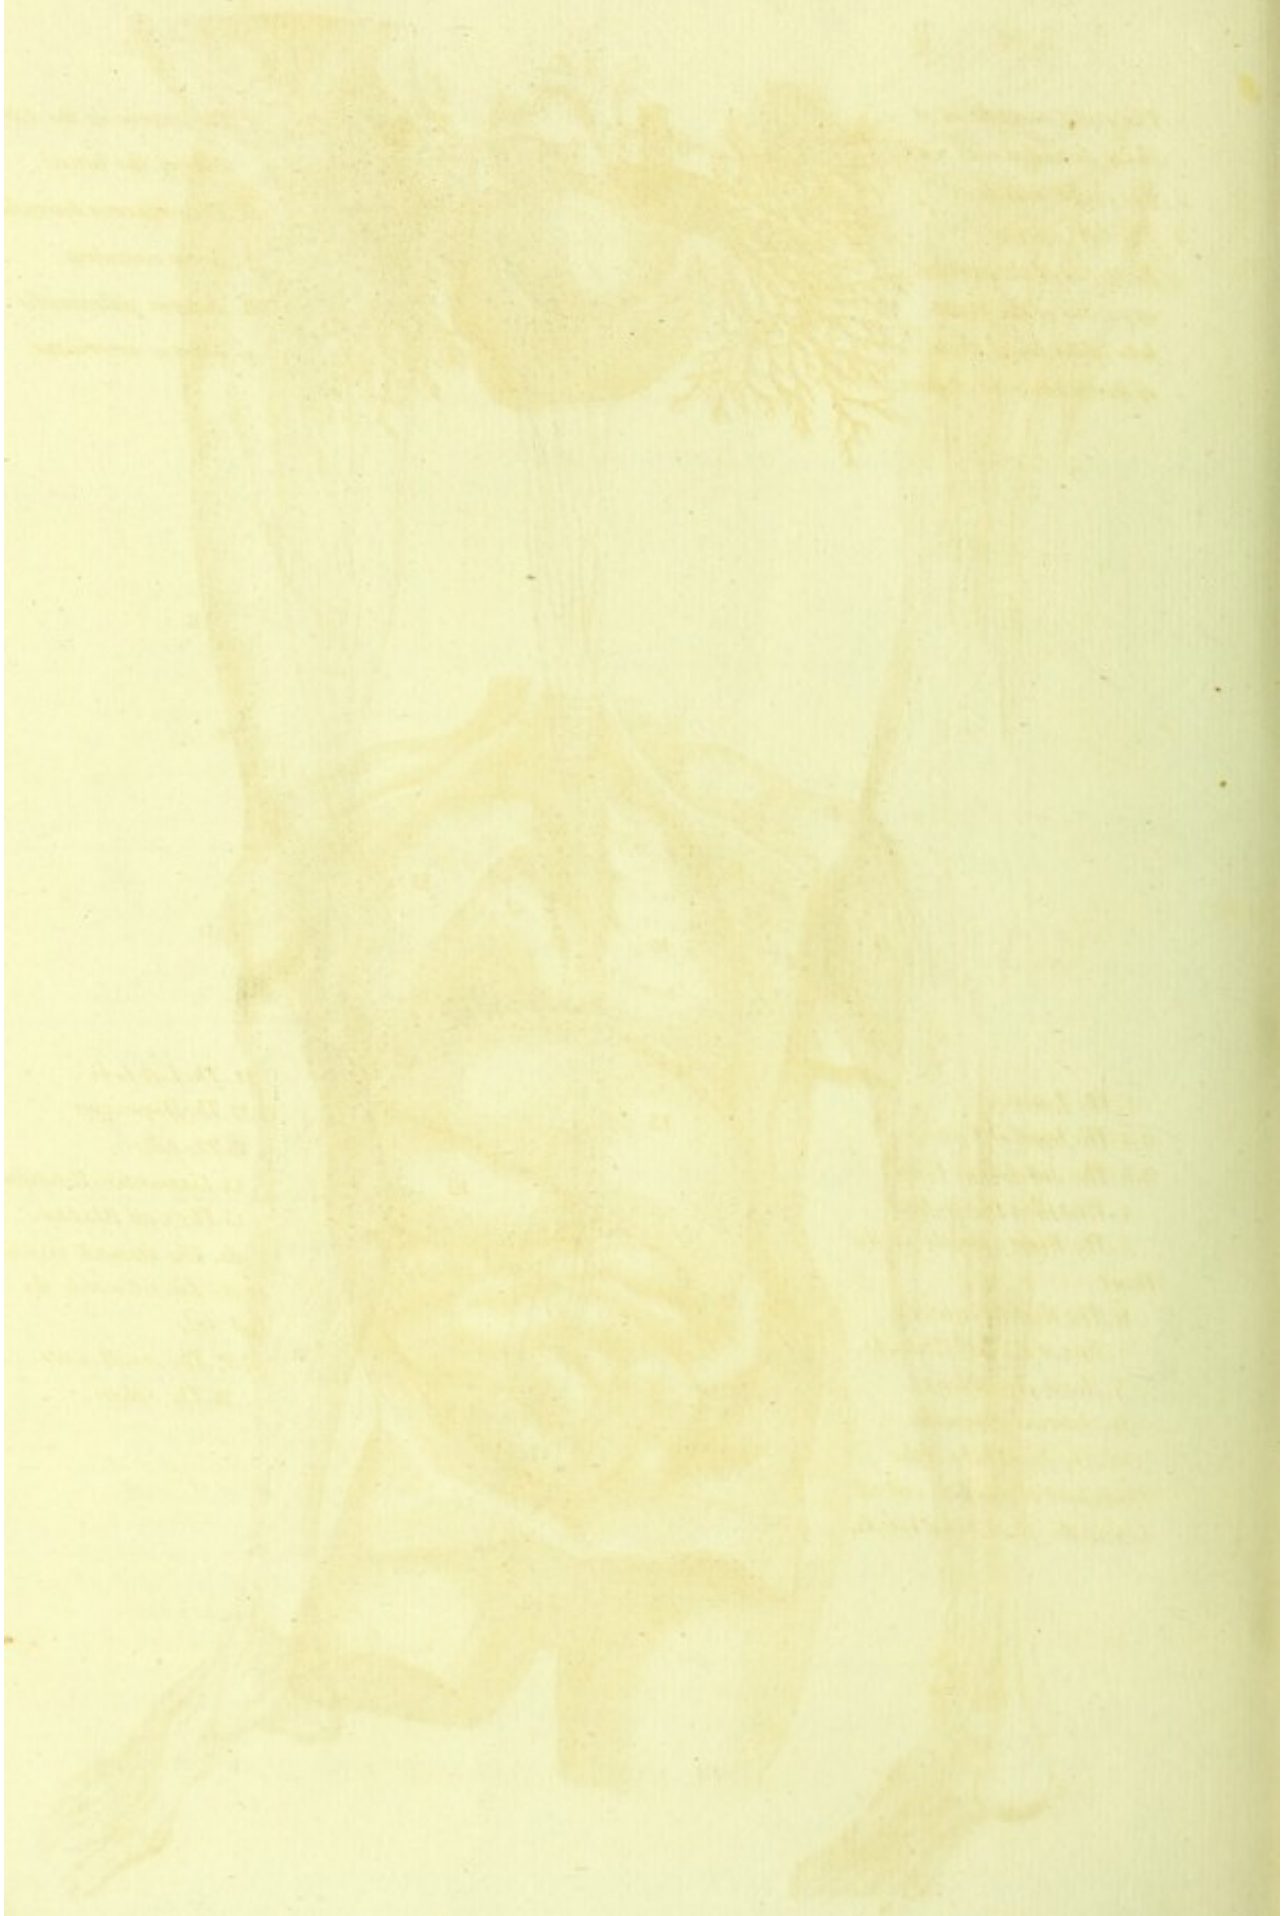
The more ſuperficial Lymphatic Veſſels of the lower Extremity.

A. The Spine of the Os Ilium.
B. The Os Pubis.
C. The Iliac Artery.
D. The Knee.
EEF. Branches of the Crural Artery.
G. The Muſculus Gaſtrocnemius.
H. The Tibia.
I. The Tendon of the Muſculus Tibialis Anticus.
a. A Lymphatic Veſſel belonging to the Top of the Foot.
b. Its firſt Diviſion into Branches.
c c c. Other Diviſions of the ſame Lymphatic Veſſel.
d. A ſmall Lymphatic Gland.
e. The Lymphatic Veſſels which lie between the Skin and the Muſcles of the Thigh.
f f. Two Lymphatic Glands at the upper Part of the Thigh below the Groin.
g g. Other Glands.
h. A Lymphatic Veſſel which paſſes by the Side of thoſe Glands without communicating with them; and, bending towards the inſide of the Groin at (*i*), opens into the Lymphatic Gland (*k*.)
l l. Lymphatic Glands in the Groin, which are common to the Lymphatic Veſſels of the Genitals and thoſe of the lower Extremity.
m. n. A Plexus of Lymphatic Veſſels paſſing on the inſide of the Iliac Artery.

Lymphatic Vessels. From M.r Hewson.

Fig. 3.

Fig. 4.



1 *The right ventricle of a fœtus distended with wax.*
2 *The right auricle.*
3 *The left auricle.*
4 *Branches of the pulmonary veins of the right lobe of the lungs, those of the left being cut off short.*
