Boil the flowers in diſtilled water, then preſs out the decoction, ſtrain it, and ſet it by until the fæces have ſubſided, then re-boil it in a water-bath ſaturated with ſea-ſalt, to a conſiſtence proper for making pills, Lond. Pharm. 1788. This is remarkably antiſeptic, according to the experiments of ſir John Pringle; and in doſes of one or two ſcruples, either given by itſelf, or added to other remedies, proves highly beneficial in flatulency, indigeſtion, and pains of the ſtomach and bowels. In the ſame manner, have the College of Phyſicians of London ordered the extract of broom-tops, gentian, black hellebore, liquorice, rue, and ſaving, to be made. But if the extract of this flower is acquired from ſpirituous tincture, it retains much of their flavour, as well as their bitter taſte. Lewis's and Cullen's Mat. Med.

Chamæmelum vulgare, called alſo leucanthemum Dioſcoridis, *anthemis*, *chamomilla*; common wild, or dog's camomile. It is the anthemis arvensis, Linn. the corn camomile. It is upright, annual, and grows wild in corn-fields. In France, and other countries on the continent, theſe are uſed indiſcriminately with the other ſpecies, but they are weaker and more diſagreeable. The oil obtained from this ſpecies by diſtillation is of a fine blue colour, but the air ſoon changes it to a yellow.

——— Flore pleno, called alſo cham. nobile flore multiplici, cham. Anglicum flore multiplici, cham. repens, cham. Romanum, and double camomile. The *Anthemis nobilis*, Linn. They are produced by culture. They differ in their flowers from the Roman *camomile*, above deſcribed, in being double, or having ſeveral rows of the white petals, and the thick diſk proportionably ſmaller.

The ſingle and the double flowered ſorts are often uſed indiſcriminately: their leaves differ very little; but as the active parts chiefly reſide in the diſk, or tubular part of the florets, which in the ſingle flowers are largeſt, the ſimple flowers are therefore moſt judiciouſly preferred, and generally uſed.

The ſingle ſort affords moſt oil.

Chamæmelum Fœtidum, called alſo *cotula fœtida*, *anthemis cotula*, *cyanthemis*, *cynobotane*, stinking camomile, maiths, and may-weed. It is annual, growing in waſte grounds and amongſt corn. It is

more upright than the other ſpecies; its leaves are finer, and flowers thicker together.

In its qualities it differs greatly from the three preceding. Its ſmell is diſagreeable; its flowers are almoſt inſipid, but the leaves have a ſtrong acrid bitter taſte.

It has been eſteemed ſtrongly ſudorific. Dr. Brown Langriſh gives an account of a decoction of this, recommended by a gypſey, throwing a perſon affected with a rheumatiſm into a profuſe ſweat, and curing him of the diſeaſe.

——— CANARIENSE. The *leucanthemum Canarienſe*.

——— CHRYSANTHEMUM. See BUPHTHALMUM GERMANICUM.

CHAMÆMESPILUS. See ARIA.

CHAMÆMORUS, called alſo *chamæ-rubus foliis ribes Anglica, rubus paluſtris humilis, vaccinia nubis vulgaris Cambro-Britannica, vaccinium Lancaſtrenſe nubis, rubus Alpinus humilis Anglicus, rubus Alpinus foliis ribis, rubo Idæo minori affinis*, CLOUD-BERRY, and KNOT-BERRY.

It is a ſhrub which grows on boggy mountains in England and other northern countries; the leaves reſemble thoſe of the mallow or of the currant-tree; the fruit is like the raſberry, when ripe it is ſweet, tart, and of a yellowiſh red. It ripens in July and Auguſt. This fruit, when ripe, if boiled, without any addition, to the conſiſtence of a pulp, will keep well if cloſely covered in pots; and as an antiſcorbutic, far excels the ſcurvy-graſs and other vegetables of its tribe in common uſe.

The *chamæmorus* Norwegiæ is only another ſpecies of the ſame plant. Raii Hiſt.

CHAMÆPEUCE. See CAMPHORATA.

CHAMÆPITUINUM VINUM. It is wine in which the bruiſed green leaves of the chamæpitys have been infuſed.

CHAMÆPITYS, CHAMÆPITYSMAS; —— *lutea vulgaris ſive folio trifido*; —— *vulgaris*, called alſo *arthritica* vel *arthretica*, ajuga, ibiga; IVA arthritica; —moſchata; *abiga herba*, &c. Dioſcorides ſays, that it was called *halocyron* in Pontus, *Ionia* in Athens, and *ſideritis* in Eubœa. COMMON GROUND-PINE. It is the TEUCRIUM CHAMÆPITYS, or *teucrium foliis trifidis linearibus integerrimis, floribus ſeſſilibus lateralibus ſolitariis luteis, caule diffuſo*. Linn.

It is a low hairy creeping plant with ſquare ſtalks, whitiſh clammy leaves, cut deeply into three narrow ſegments, ſet in pairs at the joints, and yellow labiated flowers without pedicles, and wanting the upper lip. It is annual, grows wild in ſandy and chalky grounds, in ſome parts of England; flowers in July and Auguſt, and has a long ſlender fibrous root.

The leaves are moderately bitter, of a reſinous but not diſagreeable ſmell, approaching in this reſpect, as in their external form, to thoſe of the pine-tree. They are aperient, and corroborate the nervous ſyſtem; are commended in palſies, rheumatiſms, gout, and uterine obſtructions; are very attenuating and diuretic, and in general of ſimilar virtues with the chamædrys.

They give out their virtue to water, but ſomewhat more fully to ſpirit: on diſtillation with water, a very ſmall portion of eſſential oil is obtained, reſembling in ſome degree that from turpentine. But an infuſion of the dried herb in white wine is the beſt preparation. The dried leaves may be taken to a dram for a doſe. They are an ingredient in the Pulvis ad Rheumatiſmum. See CHAMÆDRYS.

——— MAS, cham. odoratior, and ITALIAN GROUND-PINE.

——— MOSCHATA, alſo called *iva moſchata Monſpelienſium*; *chamæp. anthyllis*; FRENCH GROUND-PINE.

Theſe two laſt are weaker, but of virtues ſimilar to the above. See CHAMÆPITYS.

CHAMÆPLION. A name in Oribaſius for the ERYSIMUM, which ſee.

CHAMÆRAPHANUM. So Paulus Ægineta calls the upper part of the root apium.

CHAMÆRIPHES. See PALMA MINOR.

CHAMÆRODODENDRON. See ÆGOLETHRON.

CHAMÆRUBUS. See CHAMEMORUS.

CHAMÆSPARTIUM, GENISTELLA. See GENISTA TINCTORIA.

CHAMÆSYCE. See PEPLION.

CHAMBAR. See MAGNESIA.

CHAMBROCH. See TRIFOLIUM.

CHAMELÆA. See CHAMÆLÆA.

CHAMOIS. See CAPRA ALPINA.

CHAMOMILLA. See CHAMÆMELUM.

CHAMPACAM. A large tall tree in the Eaſt Indies, which bears fragrant flowers twice a year, and not fruit until it is advanced in age. Ray thinks it is the champaca of Bontius. The dried root of its bark is an emenagogue: the flowers are reckoned cordial.

CHANCRE, called alſo *carcli*. The ancients called ſuch like ulcers on theſe parts *cavies pudendorum*.

Theſe do not appear at any certain period, after the application of the virus; ſometimes they form in leſs than twenty-four hours; at others not before ſix weeks. But moſt frequently in three or four days, and are at firſt ſeldom larger than a millet ſeed. They occaſionally make their appearance over all the parts of generation, and in ſome inſtances, even on the contiguous parts, as on the ſcrotum, all over the penis, and on the loweſt region of the abdomen. They may indeed form on all the ſoft parts of the body; but they are moſt frequently ſeated on the glans penis, and on the prepuce, near to its connection with the glans; often about the frænum, and in ſome inſtances on the very point of the glans, and even within the verge of the urethra: here as well as near the frænum, they prove always very troubleſome, and more difficult to cure, than in other parts of the penis. The colour, quantity, and conſiſtence of the matter, is exceedingly variable. It is uſually of a dirty green colour, and often tinged with red. When ſores of this kind, as ſometimes happens, are of a ſimple innocent nature, they uſually heal in the courſe of a ſhort time, merely by being kept clean; whilſt they will gradually become worſe, if they are venereal, ſhould mercury not be employed, or if they are not treated with eſcharotic, or aſtringent applications. A real venereal chancre is ſeldom ſo large at the firſt, as the baſe of a ſplit pea, and the edges of the ſore are elevated, ſomewhat hard and painful: ſtill in ſome few inſtances, we obſerve a ſlight ſuperficial ulceration, not attended with either pain or hardneſs, and which, by the conſequences alone, we find to be venereal. In all ſuch caſes certainty will be acquired from time and obſervation, and in no other manner.

But there are other chancres, which become ſuddenly elevated into extenſive veſications, containing a clear lymph, but more frequently tinged with blood: from this livid appearance, theſe chancres are judged of a more dangerous nature than others; but this has not been found to be the caſe; the colour depends entirely on the blood being mixed with the ſerum; and on their contents being diſcharged, the parts beneath appear clean, the ſurface only excoriated, without being affected in any other manner. In WOMEN, chancres put on preciſely the ſame appearance as in men, and occur chiefly on the internal parts of the labia pudendi, nymphæ, clitoris, and the entrance of the vagina, and urethra; but ſeldom or never altogether within either of theſe paſſages.

If a *chancre* is ſeated in the urethra it may be miſtaken for a gonorrhœa, but may be diſtinguiſhed by the ſmallneſs of the diſcharge, the pain during erection being in the extremity of the penis, or a particular ſpot in the urethra, but principally by examining with the touch of a probe or bougie whether it is callous or not.

IN ORDER TO THE CURE, the venereal infection, if they ariſe from that cauſe, muſt be deſtroyed. They may be dreſſed with the unguentum hydrargyrum ſpread on lint, once in twenty-four hours, and thus they ſometimes are eaſily removed.

If ſoon after expoſure to infection, an ulceration appears, it is moſt probably only a local affection; a cure might be effected by a very ſuperficial dreſſing, yet as we have no means of being certainly ſafe, the cure of even the ſlighteſt *chancre* ſhould never be truſted to any other remedy than the internal as well as external uſe of mercury; at leaſt in moderate doſes. In every caſe of ulcerated *chancre* not attended with much inflammation, after wiping the ſores as clean as poſſible, let them be ſprinkled well with the hydrargyrus nitratus ruber, finely powdered, and pledgits of any common ointment be applied over it; and after two or three dreſſings, the ulcer will be generally clean and nearly healed.

The free uſe of the lunar cauſtic is recommended highly in the cure of this complaint, and particularly in its incipient ſtate; and effectually cures, by deſtroying the diſeaſed parts, which ſoon become clean, and heal as quickly as ſores proceeding from any other cauſe, and of the ſame magnitude, uſually do. In common caſes, the treatment here adviſed, will be in general ſufficient to effect every deſired purpoſe: but for further information on this head, as this complaint ſometimes proves obſtinate, and reſiſts the

modes

modes here recommended, the reader may conſult Aſtruc on the Venereal Diſeaſe, or Chapman's Abridgment of Aſtruc, Heiſter's Surgery, Lond. Med. Tranſ. p. 337; and particularly, Bell on the Venereal diſeaſe; Hunter and Foot on the ſame ſubject.

CHANTERELLA FLAVA GELATINOSA. It is a ſort of fungus, about an inch high, growing in cluſters. Tournefort includes under this name, all thoſe fungi whoſe heads are ſolid, that is, neither lamellated, nor porous, nor latticed, nor prickly, nor turning to duſt when ripe.

CHAOSDA. See Pestis.

CHAOVA. The Egyptian name for COFFEE. See Coffea.

CHAR. PLANT. An abbreviation of character plantarum.

CHARABE. See Succinum.

CHARACIAS, from χαραξ, *a bulwark* or *fence*. An epithet given to ſome plants which require ſupport, as the vine, &c.

CHARACTER, in botany, is that aſſemblage of marks by which each ſpecies of plants is diſtinguiſhed from each other.

Character ſignifies alſo an hereditary diſpoſition to ſome particular diſeaſe.

IN CHEMISTRY it is a mark importing ſome particular thing; or it is a figu invented to repreſent the principal ſubſtances and operations in a conciſe manner, the chief of which will be found on the ſubjoined plates.

CHARANTIA. See Momordica.

CHARDONE See Cinara spinosa.

CHARISTOLOCHIA. See Artemisia.

CHARLET. EXER. An abbreviation of Gualterus Charitonus Exercit. de Differentiis & Nominibus Animalium, 1677.

CHARME, } The name of an antidote mentioned by
CHARMIS. } Galen.

CHARONIUS. CHARONEAN. An epithet for caves, ſome of which are in Italy, where the air is loaded with a poiſonous vapour, that animals ſoon expire if expoſed to it.

CHARTA VIRGINEA. See Amnion.

CHARTREUX, POUDRE DE. See Antimonium, N° 15.

CHASME, χασμη. See Oscitatio.

CHATE. See Cucumis Aegyptius.

CHAULIODONTA. So the Greeks call thoſe animals whoſe teeth grow a great length out of their mouths, as the boar, the elephant, &c.

CHEDROPA. A general term for all ſorts of corn, and pulſe.

CHEILOCACE. See Labrisulcium.

CHEILOCACE, from χειλος, *a lip*, and κακον, *an evil*. The LIP-EVIL. A ſwelling of the lips. See Cancrum oris.

CHEIMETLON, from χειμα, *winter*. See Pernio.

CHEIMIA. COLD, SHIVERING.

CHEIRAPSIA, from χειρ, *the hand*, and απτομαι, *to touch*. SCRATCHING.

CHEIRI, called alſo *keiri*, *leucoium luteum*, *viola lutea*, *cheyri*, COMMON YELLOW WALL-FLOWER. It is the CHEIRANTHUS CHEIRI, Linn.

The ſtalks are woody and brittle; the leaves are oblong, narrow, ſharp-pointed, ſmooth, and of a dark green-colour; the flowers are numerous, yellow, tetrapetalous, open ſucceſſively on the tops, are followed by a long ſlender pod, containing reddiſh flat ſeeds. It grows wild on old walls and among rubbiſh, and flowers in April and May.

The flowers have an agreeable ſmell, but to the taſte are naſeouſly bitter and pungent. Water takes up all their active matter; but no eſſential oil is obtained by diſtillation, though this way a water is obtained that poſſeſſeth much of the flavour of theſe flowers.

The flowers are reckoned among the nervines, deobſtruents, diuretics, and antiparalytics.

CHEIRIATER, from χειρ, *a hand*, and ιατρος, *a phyſician*. A SURGEON, called alſo *cheirurgus*, and *chirurgus*, from χειρ and εργον, *opus*. Hence *cheiriaticus*, a term appropriated to chirurgical remedies and operations.

CHEIRISMA. HANDLING, or a manual operation.

CHEIRIXIS. SURGERY.

CHEIRONOMIA. CHIRONOMIA. An exerciſe mentioned by Hippocrates, which conſiſts of peculiar geſticulations of the hands.

CHEIRURGUS. See Cheiriater.

CHEIROURGICA. See Pharmaceutice.

CHEIZI. See Argentum vivum, and flos.

CHELA. A FORKED PROBE mentioned by Hippocrates for extracting a polypus from the noſe. In Rufus Epheſius it is the extremities of the cilia But moſt commonly it is uſed for claws, particularly of crabs. It alſo ſignifies fiſſures in the heels, feet, or pudenda.

CHEL. CANC. PULV. C. See Cancer fluviatilis.

CHELIDON. The SWALLOW. Alſo the hollow at the bend of the arm,

CHELIDONIA. The GREATER and LESSER CELANDINES. See Chelidonium major.

CHELIDONIUM. See Bryonia Alba.

CHELIDONIUM MAJOR, called alſo *chelidonia*, *papaver corniculatum luteum*, TETTER-WORT, and GREAT CELANDINE. It is the CHELIDONIUM MAJUS, Linn.

Boerhaave takes notice of five ſorts.

This plant hath longiſh leaves, divided to the rib into roundiſh and indented portions, of which thoſe at the extremities are the largeſt, of a bright green colour on the upper ſide, of a bluiſh green underneath, full of a gold-coloured juice, as are likewiſe the ſtalks; from the bottoms of the leaves iſſue long pedicles, bearing cluſters of tetrapetalous yellow flowers, which are followed by browniſh pods, containing flattiſh ſhining black ſeeds; the root is thick at the top, with a number of fibres at the bottom, externally browniſh, internally of a deep yellowiſh red or a ſaffron colour: it is perennial, grows wild in hedges and ſhady places; it flowers in May and June.

The leaves and roots have a faint unpleaſing ſmell, and to the taſte are bitter and acrid: they give out their active matter to ſpirit and to water; the pungency they poſſeſs is not of the volatile kind, for hardly any of it riſes in diſtillation with water: yet it is leſſened with drying the plant, and by inſpiſſating infuſions of it. Drying wholly diſſipates the ſmell of this herb.

It is aperient, attenuant, and uſeful in the jaundice, when not accompanied with inflammatory ſymptoms. The freſh juice is uſed to deſtroy warts; alſo films in the eyes; but for this latter purpoſe it is diluted with milk. Of the dried root from ʒ ſs. to ʒ i. is a doſe; of the freſh root infuſed in wine or in water the doſe may be to ℥ ſs.

——MINUS, called alſo *ſcrophularia minor*, *ficaria minor*, *chelidonia rotundifolia minor*, *curſuma*, *curtuma*, *haemorrhoidale*, vel *haemorrhoidalis herba*, *ranunculus vernus*, PILEWORT, and LESSER CELANDINE. It is the RANUNCULUS SICARIA. Linn.

Boerhaave enumerates four ſpecies. It is a ſmall plant with roundiſh ſmooth ſhining green leaves, ſet on long pedicles; and ſlender procumbent ſtalks, bearing bright gold-coloured ſolitary flowers of eight or nine petals, which ſtand in three-leaved cups, and are followed by cluſters of naked ſeeds; the root conſiſts of ſlender fibres, with a number of tubercles or little knobs. It is perennial, grows wild in hedges and moiſt meadows, and flowers in April.

The leaves are antiſcorbutic, but are without ſmell, and have very little taſte, though on chewing a ſlight pungency is perceived. The roots are reckoned a ſpecific, if beat into cataplaſms and applied to the piles: they yield a large portion of mucilaginous matter to water. Raii Synop. & Hiſt. Some ſay that *othonna* is the juice of *celandine*.

CHELONE. A TORTOISE. It alſo imports a part of a ſurgical machine mentioned by Oribaſius. An inſtrument to make a gradual extenſion in any fractured member, in which motion it reſembles the ſlowneſs of χελωνη, *a tortoiſe*.

CHELONION. A HUMP-BACK, ſo called from its reſemblance to the ſhell of χελωνη, *a tortoiſe*.

CHELTENHAM WATER. This ariſes from a ſpring near *Cheltenham*, in Glouceſterſhire; and is one of the moſt noted purging waters in England. When taken up from the fountain it is clear and colourleſs; has a ſaline, bitteriſh, chalybeate taſte; it ſtrikes a pale but vivid purple colour immediately on being mixed with an infuſion of galls. When expoſed to the air in an open glaſs veſſel, it throws up a quantity of air bubbles, becomes turbid, and loſes its briſk chalybeate taſte, and property of tinging with infuſion of galls. On evaporation it is found to contain a calcareous earth, mixed with ochre, and a purging ſalt. In one gallon were found by Dr. Short, 74 grains of calcareous earth mixed with ochre, and 673 grains of a purging ſalt. Experiment the ſecond

afforded

afforded 42 grains of earth, and 580 purging ſalt. The third 70 calcareous earth, and 622 purging ſalt. Dr. Rutty, 36 grains of earth, 494 of ſalt, which was compoſed of vitriolated magneſia and a ſmall quantity of ſea-ſalt. Dr. Lucas, 4 grains of iron, 181½ grains of calcareous earth, mixed with a ſmall portion of ſelenites, 362½ of ſalt of the nature of Epſom, but drier and finer. Dr. A. Fothergill makes the ſalt to be a native Glauber, mixed with a portion of Epſom ſalt. As a purge, this water is drank from one to three pints; though in general from half a pint to a quart is ſufficient. It operates with great eaſe.

CHELYS. See PECTUS.

CHELYSCION. A SHORT DRY COUGH.

CHEMA. Blancard ſays it is a certain meaſure mentioned by the Greek phyſicians, ſuppoſed to contain two ſmall ſpoonfuls; the Athenians had one of two drams, and another of three.

CHEMIA, vel CHIMIA. CHEMISTRY, or CHYMISTRY. As ſome ſay (though much difficulty attends the diſcovery of its etymology and its orthography) from χυμος, *any ſort of juice*, but particularly from our aliment after digeſtion. Among the Greeks it was called χημια χημεια, and χυμεια; the laſt of which hath been generally followed by the later writers on this ſubject, though the moſt approved editors and other learned men have preferred the former. The modern Greeks write χημεια. As to the word *chemy*, it is a very trifling innovation. It is alſo called ARCHIMAGIA, becauſe by it gold has been attempted to be made: *Pyrotechnia*; from the art being conducted by fire.

Chemiſtry may be called the anatomy of natural bodies, or the reducing them to their component parts by attraction. See AFFINITAS.

Dr. Aiken defines it to be the art of combining or ſeparating the conſtituent parts of bodies by fire.

It is an important branch of natural philoſophy, and hath for its objects the properties of bodies, which it diſcovers by analyſis, and by combinations.

As to its antiquity, TUBAL CAIN is not improperly ſaid to have practiſed it. Thoſe *chemical* arts which are exerciſed without literary ſtudy were introduced by neceſſity, and gradually improved from the earlieſt times; but they were practiſed by thoſe who knew no more than what related to their own buſineſs; one branch occupied each practitioner, as the miner, the aſſayer, the ſmith, the dyer, &c. each confined himſelf to his narrow ſphere; no one deſcribed his art farther than as a mechanic inſtructs his apprentice, ſo they were none of them underſtood ſcientifically.

The firſt grand object which engaged *chemiſts* in this peculiar character was, the tranſmutation of inferior metals into gold: and in the fourth century they diſtinguiſhed themſelves by the name of ALCHEMISTS. This viſionary purſuit ſubſiſted till the ſeventeenth century. In the ſixteenth PARACELSUS was negatively uſeful in reforming *chemiſtry*; for thoſe who deſpiſed his conduct in moſt inſtances of it, and yet were wiſe enough to obſerve that his ſucceſs in the uſe of his *chemical* preparations exceeded theirs with the then uſual ones, they engaged with new views in their purſuit of this art. Theſe were the inventors of modern *chemiſtry*. The inquiſitive and the ingenious now began to obſerve, deſcribe, and unravel the operations of workmen, and they writ clearly on every ſubject. AGRICOLA is one of the firſt of theſe writers, who, though contemporary with Paracelſus, was of a very oppoſite character; mines and metallurgic works are his principal ſubjects. NERI, MERRET, and KUNCLE, beſides their improvements in other reſpects, have very fully deſcribed the arts of making glaſs, enamels, imitations of precious ſtones. KIRCHER and CONRINGIUS ſeem to have quite put an end to the ancient alchemy.

In the beginning of the ſeventeenth century, JAMES BARNER, phyſician to the king of Poland, was one of the firſt who arranged in order the principal *chemical* experiments, to which he added rational explanations; this work is entitled Philoſophical *Chemiſtry*. BOHNIUS, BECKER, STAHL, and BOERHAAVE, all contributed their advancements; MACQUER, NEUMANN, LEWIS, and others of their own nations, poſſeſs diſtinguiſhed honour as improvers of this art. But after all, in the preface to the Dictionary of *Chemiſtry*, it is declared that "*Chemiſtry* remains but little more than a collection of facts, the cauſes of which, and their relations to one another, are ſo little underſtood, that this art is not yet capable either of the ſynthetic or analytic modes of explanation, and is not yet capable of being ranked as a ſcience." However, of late years, it has become a ſubject more univerſally ſtudied, received a variety of conſiderable improvements, and made large ſtrides towards the formation of a regular ſyſtem, as will appear by the peruſal of thoſe modern authors, to whoſe works our readers are referred below, particularly LAVOISIER, CHAPTAL, and BLACK.

Thoſe who would ſee the learned controverſies relating to the antiquity of *chemiſtry* may conſult BORRICHIUS and CONRINGIUS, de Hermetica Medicina, the hiſtory of the Hermetic Philoſophy by the Abbé LANGLET DE FRESNOY; a ſmall ſketch of the ſame may be alſo ſeen in the narrative to the former London College Diſpenſatory, p. 24—27.

Beſides the uſe of *chemiſtry* in various other arts, it hath introduced many improvements into phyſic. It hath furniſhed us with many of the moſt powerful remedies, by putting into our hands ſome of the active principles of bodies diveſted of thoſe other parts which are but clogs while in their natural combined ſtate.

Many authors might here commended for improvement in the preſent ſtate of this art; but, in general, ſatisfaction will be obtained from Lewis's Mat. Med. the Dictionary of *Chemiſtry*, 1771, NEUMANN's Chem. Works. BERGMAN. FOURCROY. CULLENS's Mat. Med. LAVOISIER's and CHAPTAL's Elements of *Chemiſtry*, WEIGLEB's General Syſtem, tranſlated by Dr. HOBSON, and the works of Dr. BLACK.

Indeed, ſo great has been the improvement, that a new Nomenclature has been propoſed by Morveau, Lavoiſier, and others, and inſerted in the Encyclopædia Britannica, vol. 4. p. 598, where a table of the alterations thought neceſſary to be adopted, is publiſhed, to which we refer our readers for information on this head, after preſenting him with a ſpecimen or two of the work itſelf. Here are given us fifty-five ſubſtances, called ſimple or uncompounded; and ſeventeen denominated compound ſubſtances, which combine without decompoſition. This table is divided in the following manner:

SIMPLE

1. SIMPLE AND UNCOMPOUNDED SUBSTANCES.		2. — RENDERED INTO THE STATE OF GAZ, BY MEANS OF CALORIC.		3. COMBINED WITH OXYGEN.		4. OXYGENATED SUBSTANCES IN THE GAZ. STATE.		5. OXYGENATED SUBSTANCES COMBINED WITH BASES.		6. COMBINATIONS OF ACIDIFIABLE BASES, AND OF SUBSTANCES NOT ACIDIFIABLE.	
New or adopted Names.	Former Names.	New or adopted Names.	Former Names.	New or adopted Names.	Former Names.	New or adopted Names.	Former Names.	New or adopted Names.	Former Names.	New or adopted Names.	Former Names.
1. LUX, LIGHT.											
2. CALORICUM, Caloric.	Phlogist. of STAHL, latent heat of BLACK; combined heat of BERGMAN; matter of heat.										
3. OXYGENUM, Oxygen.	Basis of vital, or of fire, air. Acidifying principle.	GAZ OXYGENIUM. Oxygen gaz. N. B. Light contributes to the gaz. state of oxygen.	Nitro atmospherical spirit of MAYOW, 1762. Dephlogisticated air discovered by PRIESTLEY Aug. 1774. Fire, and empyreal air, by SCHEELE, 1774.								
4. HYDROGENIUM; hydrogen.	Basis of inflammable air, or gaz.	GAZ HYDROGENIUM. Hydrogene gaz.	Air fixed of Phlogiston of KIRWAN. Inflammable air of Boyle and Cavendish in 1776; BLACK and PRIESTLEY. Inflammable gaz.	AQUA, ΥΔΩΡ, WATER.	The sole element or principle of every thing, according to THALES. Water, Aqua. Its composition discovered by Synthesis in 1781, published by CAVENDISH, 1784.						
5. AZOTICUM, vel NITROGENIUM. Azote, or radical nitric, or nitrogen.	Basis of phlogisticated air; or of the mephitic air of the atmosphere. Basis of nitrous acid.	GAZ AZOTICUM; GAZ NITROGENIUM. Azotic gaz, or Nitrogene gaz.	Phlogisticated air of PRIESTLEY, and RUTHERFORD. a. factitious, b. native, 1. In the Bath water, PRIESTLY. 2. Buxton water, PEARSON. 3. Atmosphere, SCHEELE, LAVOISIER. Probably the mephitic air of Avernus, caverns, &c. of the antients.	1. OXYDEN NITROGENII, Oxyd. of nitrogen, or azote, its composition by DEIMAN; TROOSTWYK, &c. 1793. 2. NITROUS OXYD. 3. ACIDUM NITROSUM. Its composition discovered by LAVOISIER and CAVENDISH. 4. ACIDUM NITRICUM, Nitric acid.	1. Basis of dephlogisticated nitrous gaz of PRIESTLEY. Azote of nitrogen oxygenated in the first degree. 2. Basis of nitrous air of PRIESTLEY. Azote oxygenated in the second degree. 3. Fuming nitrous acid of GLAUBER. Azote oxygenated in the third degree. Acidum nitrosum Parm Ed. & L. 4. Dephlogisticated nitrous acid of PRIESTLEY. Azote oxygenated in the fourth degree.	1. Gazeous oxyd. of azote of DIEMAN, &c. 2. GAZ. OXYDUM NITROSUM. Nitrous oxyd gaz. 3. GAZ. ACIDUM NITROSUM. Nitrous acid gaz.	1. Dephlogisticated nitrous Gaz of PRIESTLEY. 2. Nitrous air of PRIESTLEY 1773. Nitrous acid air of PRIESTLEY.	NITRATES. Nitrates. Salts formed by the union of nitric acid with metallic oxyds, earthy, and alkaline bases. NITRITES. Nitrites. Salts formed by the union of nitrous acids with different bases.	NITRA, Nitres. No former Nomenclature.	AMMONIACA, Ammoniac. Composed of azote, and hydrogen by BERTHOLET and MILNER.	Volatile alkali. NB. In the original table this substance is in a different compartment: but subsequent experiments have shewn that it consists of azote, and hydrogen.

CHEMICI, called alſo FLATUARII. Men who purſue the art of chemiſtry.

CHEMOSIS, from χαινω, *to gape*, called alſo *chymoſis*. It is when, from inflammation, the white of the eyes ſwells above the black, ſo that there appears a ſort of gap, whence the name. Galen, de Euphorbiſtis calls it a red and carnous inflammation of the cornea tunica: Paulus ſays, it is a *chemoſis*; when through a vehement inflammation, both the eye-lids are turned outwards, ſo as ſcarce to cover the eye, and the white of the eye appears higher than the black, and occupies much of it. Le Dran calls it a tumor on the white of the eye.

This is a ſpecies of ophthalmia, called by SAUVAGES, OPHTHALMIA CHEMOSIS, and alſo by AETIUS, by DE MESEREY, TRAUMATICA. The CHEMOSIC, or CONJUNCTIVA-CORNEA-PALPEBRAIC OPHTHALMY. Sauvages ſays, This ariſes from an external cauſe as a violent contuſion of the eye, whence an hypoſphagma, or from a chirurgical operation performed on the eye, an extraction of a cataract; from the operation for the unguis, or empyeſis, &c. or from an internal cauſe, as metaſtaſis, or ſevere catarrh in cacochymic habits. It is known by the black-red ſwelling of the conjunctiva, with a depreſſion and obſcurity of the cornea, which ſeems to lie, as it were, in a cavity. The inflammation is ſevere with excruciating pains of the eyes and head; a ſenſe of weight alſo above the orbit, pervigilium, fever, pulſation, a ſwelling, occluſion or ſhutting of the eye-lids. It terminates ſometimes in ſuppuration of the eye, whence an irremediable blindneſs; at leaſt leucomata ſucceed it.

In Dr. Cullen's Noſology, it is a variety of that ſpecies of *ophthalmy*, which he names the *ophthalmia membranarum*. It is when the inflammation is very great, cauſing the tunica conjunctiva ſo to thicken or project, that the cornea, or tranſparent part of the ſclerotica, appears depreſſed and ſunk in the globe. When the *ophthalmy* is in this ſtate, it is for the moſt part accompanied with violent pain. As ſome obſerve, in this ſtate of the inflammation, the white part of the eye is become more like raw fleſh; or, as others, that it reſembles the pile of red velvet. All the tranſparent part of the cornea often comes away by ſuppuration, which deſtroys the anterior chamber of the eye. The cicatrix, ſubſequent to the ſuppuration, hinders the cryſtalline and vitreous humours from falling out, and by that means, the entire decay of the globe is prevented: ſometimes both happen." This diſeaſe is often fatal; loſs of ſight always follows; and generally the pain which comes on deſtroys the patient.

In order to relief, the violence of the diſeaſe requires the ſpeedieſt and moſt powerful aids. Bleeding, according to the ſtrength of the patient, after which a purge will be neceſſary; and this repeated as required. A bliſter may be applied on the forehead, or leaches to the temples, and after them a bliſter there, over the part where they were applied. Goulard's ſaturnine poultice may be applied cold over the eye-lids, and renewed as often as it grows warm. Antimonial perſpiratives may be given inwardly, &c. as in general for inflammation of the eyes. Indeed every method ought to be purſued, which can moſt immediately ſubdue the inflammatory ſymptoms. See Noſologia Methodica Oculorum, with notes by Dr. Wallis, and OPHTHALMIA.

CHENALOPEX, from χην, *goose*, and αλωπηξ, *a fox*. See VULPANSER.

CHENOCOPRUS, from χην, *a goose*, and κοπρος, *dung*, GOOSE DUNG. It was formerly uſed as a powerful reſolvent, diuretic, and anti-icteric. The green was thought the beſt; it was collected in ſpring, dried, and given from 3 ſs. to 3 i. for a doſe.

CHENOPODIUM, } from χην, *a goose*, and πους, *a foot*,
CHENOPUS. } GOOSE-FOOT or SOW-BANE; called alſo *atriplex ſylveſtris, pes anſerinus, botrys, botrys Mexicana*, and *atriplex ſilv. latifolia*. It is reckoned among the uterines, but not uſed in the preſent practice. Boerhaave enumerates fourteen ſpecies, beſides two others, with leaves like thoſe of the herb kali: ſee alſo MERCURIALIS.

CHENOPODIUM FOETIDUM. } See ATRIPLEX
——— VULVARIUM. } FOETIDUM.

CHEOPINA. See CHOPINO.

CHERAS. See SCROFULA.

CHEREFOLIUM. See CHAEROPHYLLUM.

CHERIONIUM. It is that in which nature cannot be altered. Thus cryſtal hardened by nature cannot be melted, as that which is made by art.

CHERMES, alſo called *coccum ſcarlatinum, kermes, alkermes, coccibadicum, coccum chermeſinum, coccum tinctorium, coccum baphicum, grana kermes, cocca baptica, grana infectoria, cocum infectorium, coſculia*, SCARLET GRAIN, and KERMES BERRIES; a grain is called *quiſquilium*. They are the produce of the QUERCUS COCCIFERA, Linn.

Kermes, among the Arabians, ſignifies a ſmall worm; and κοκκος among the Greeks; *granum arboris Ilicis, quo punicea inficiuntur*; for theſe grains are full of ſmall worms, the juice of which affords the ſcarlet colour and dye. Hence the worm is taken for the grain itſelf.

An inſect which much reſembles the green houſe bug, lays its eggs on the ſhrub called *ilex aculeata coccigiami-fera*; *ilex coccigera*, the SCARLET OAK. The females of this kind have no wings. The colour of theſe berries or rather inſects, is like that of a blue plum; the brown colour which they have when brought to us, is from their having been waſhed with vinegar. They are about the ſize and ſhape of juniper berries that are cut into two parts; the hole in the flat ſurface leads to the ſkin of the belly. When theſe inſects are freſh, they appear full of minute reddiſh ova, and which, in long keeping, change to a browniſh-red colour. They are cured by ſprinkling with vinegar, which prevents the excluſion of the ova, and kills ſuch of the animacula as are already hatched, and would otherwiſe ſoon fly away. They are brought from France, Spain, Candia, &c. where they are gathered in May, and early in the mornings, while the prickly thorns on which they adhere are ſoft with the dew.

Geoffroy obtained an urinous kind of ſpirit from them by diſtillation. The freſh kermes on expreſſion yield a red juice, of a light agreeable ſmell, and a bitteriſh taſte, that is ſub-aſtringent, and ſomewhat pungent; but before it is brought to us, it is boiled up with ſugar, into the conſiſtence of a ſyrup. The dried grain, if not too long kept, gives out both to water and to ſpirit the ſame deep red colour, the ſame ſmell and taſte, as is in the expreſſed juice. By evaporation the watery tincture loſes nearly all its ſmell and taſte, but the ſpirituous tincture does not: beſides, ſpirit extracts the active parts moſt completely.

They are grateful to the palate, eſteemed cordial and aſtringent, but they are not either one or the other in any conſiderable degree: however, a confection, called CONFECTIO ALKERMES, was made of the juice of chermes berries, and not unfrequently preſcribed; it was invented by MESSUE. It was a favourite medicine of Geoffroy's; but upon it at this time practitioners have no dependence.

CHERMES MINERALIS. See ANTIMONIUM, SULPH. PRÆCIPITAT.

CHERNIBION. In Hippocrates it is an URINAL.

CHERSA. See FÆX.

CHERVA. An Arabian name for CATAPUTIA.

CHES-BOUL. See PAPAVER ALBUM.

CHEVALIER. See CALIDRIS BELIONII.

CHEVASTRE. A double-headed roller, applied by its middle below the chin; then running on each ſide, it is croſſed on the top of the head; then paſſing to the nape of the neck, is there croſſed: then paſſes under the chin, where croſſing, it is carried to the top of the head, &c. until it is all taken up. See FASCIA, N°. 7.

CHEYRI. See CHEIRI.

CHEZANANCE, from χεζω, *to go to ſtool*, and αναγκη *neceſſity*. It ſignifies any thing that creates a neceſſity of going to *ſtool*; but particularly in P. Ægineta, it is the name of an ointment with which the anus is to be rubbed to procure *ſtools*. Aetius gives this name to a plaſter, which was to procure *ſtools* by applying it to the navel.

CHIA TERRA. EARTH of CHIOS, now called *Scio*, an iſland in the Archipelago. It is a greyiſh earth, brought from that iſland, formerly uſed as a ſudorific in fevers, but now neglected. Fuller's earth, or pipe-clay coloured, and impreſſed with proper ſignatures, are the general ſubſtitutes.

CHIACUM COLLYRIUM. In P. Ægineta, it is a remedy for diſorders of the eyes, of which the dry ingredients were bruiſed and prepared in Armenian wine.

CHIADUS. See FURUNCULUS.

CHIASMOS. It is the meeting of any two things under the form of a croſs, or of the letter X, *Chi*; whence it is named. The adverbs chiaſti and chiaſticos mean the ſame.

CHIASTOS. The name of a bandage in Oribaſius, ſo

ſo called from its reſembling the letter X, *Chi*. See FASCIA.

CHIASTRE. A bandage for the temporal artery. It is a double-headed roller, about an inch and an half broad, and four ells long. The middle is applied to the ſide of the head, oppoſite to that in which the artery is opened, and when brought round to the part affected, it is croſſed upon the compreſs that is laid on the wound, and then the continuation is over the coronal future, and under the chin; then croſſing on the compreſs, the courſe is, as at firſt, round the head, &c. till the whole roller is taken up. See FASCIA.

CHIBUR. See SULPHUR.

CHICHIAXOCOTL. See MACAXOCOTLIFERA.

CHICOS, or CHICRES. See BOVINA AFFECTIO.

CHIEN-DENT. See GRAMEN CANINUM.

CHIGRES. See HYBOUCOUHU AMERICANUS.

CHILCHOTES. See PIPER INDICUM.

CHILI, BALS. DE, This ſeems to have been an impoſition. Salmon ſpeaks of its being brought from *Chili*, but there is no evidence of any ſuch thing. The Barbadoes tar, in which is mixed a few drops of the oil of aniſeed, is uſually ſold for it.

CHILIOPHYLLON. See MILLEFOLIUM.

CHILLI ARBOR. See CORT. PERUVIANUS.

CHILLI. See PIPER INDICUM.

CHILLI INDIÆ ORIENT. See ZINGIBER.

CHILON. One who hath large prominent lips, applicable to fiſh, as well as the human ſpecies; called alſo *labeo*, or whoſe lip or lips are inflamed and ſwelled.

CHILPELAGUA. } See PIPER INDICUM.
CHILTERPIN. }

CHIMALATH, or CHIMALATL. See CORONA SOLIS.

CHIMETHLON. See PERNIO.

CHIMIA. See CHEMIA.

CHIMOLEA LAXA. Paracelſus means by this word, the powder which is ſeparated from the flowers of ſaline ores.

CHIMUS. A term in Paracelſus of an uncertain meaning; though moſt likely it is the droſs of metals, or of their ores.

CHINA ORIENTALIS. China radix, *ſankira*, *quaquara*, *ſmilax aſpera Chinenſis*, or CHINA ROOT. It is the SMILAX CHINA of LINN.

It is an oblong, thick-jointed root, full of irregular knobs, of a reddiſh-brown colour outwardly, but inwardly of a pale red. There are two ſorts, the Eaſt and the Weſt Indian. The firſt is moſt eſteemed; it is paler and harder than the other, and is the root of a ſpecies of ſmilax, which in CHINA is called *lampatam*.

The plant is a climber, with tendrils, and, like the vine, it bears cluſters of large berries of a red colour. It is a native of *China* and Japan.

The root hath but little ſmell or taſte. An inſpiſſated decoction of it yields an unctuous, farinaceous, almoſt inſipid maſs. It is ſaid to promote perſpiration and urine. Proſper Alpinus ſays, that the Egyptian women uſe this root to fatten themſelves with. It firſt appeared in Europe as an anti-venereal about the year 1535, but now it gives place to ſarſaparilla.

This Eaſt India kind being the beſt, may be diſtinguiſhed from the other by its yellow-brown colour outwardly; its white, or reddiſh-white colour inwardly; by its being in flattiſh long pieces, full of knots, firm, and ſmooth when cut.——OCCIDENTALIS. *China* ſpuria nodoſa, *ſmilax aſpera*, *pſeudo China*, *kaboloſſa*, *kiribunnawel*, *ſmilax Indica ſpinoſa*, *jupicanga*, *olcacatzan*, *pahuatlanica*, China Mexicana. AMERICAN, or WEST INDIAN CHINA.

This plant is a climber, and bears black berries, grows wild in Virginia and Jamaica, and bears the cold of our clime. The root is brought chiefly from Jamaica, in long round pieces, full of knots; whitiſh without, and reddiſh within.

In ſcrophulous diſorders, ſome prefer it to the Oriental kind. In other caſes, it is of like virtue with it, but inferior.—— SUPPOSITA. *Senecio Madraſpatanus*, *parin chakka*, *ſenecio Aſiaticus*, *pſeudo China*, or BASTARD CHINA. It grows in Malabar, the root greatly reſembles the *China* root, both in appearance and qualities. Lewis's Mat. Med. Raii Hiſt.——CHINÆ. See CORT. PER.

CHINENSE. See AURANTIA SINENSIS.

CHINCHINA. See CORT. PERUV.

CHIOLI. See FURUNCULUS.

CHIQUES. A name which the French give to the worms which get under the toes of the negroes, and which are deſtroyed by the oil which flows out of the caſhew-nut ſhell.

CHIRAGRA, from χειρ, *the hand*, and αγρα, *a ſeizure*. See ARTHRITIS.

CHIRONES. See BOVINA AFFECTIO.

CHIRONIA. See BRYONIA NIGRA.

CHIRONIUM. A name of a malignant ulcer, difficult to be cured, with a hard, callous, and tumid margin, ſo called from Chiron the Centaur, who is ſaid to be the firſt who knew how to cure them. It is alſo called *telephium*.

CHIRONOMIA. See CHEIRONOMIA.

CHIROTHECA, and PODOTHECA. In the preparation of anatomical ſubjects, they are a glove and a ſhoe of the ſcarf-ſkin, with the nails adhering to them. They are brought off with very little trouble after the cuticula looſens from the parts below by putrefaction, which comes on by long keeping a ſubject; and this method is better than that of forcing off this ſkin by means of boiling water.

CHIRURGIA, from χειρ, *a hand*, and εργον, *work manual operation*, SURGERY, or that part of medicine which conſiſts of manual operations. In this branch of healing the ancients had great merit in many particulars; but notwithſtanding the ſlight manner in which M. C. Bernard ſpeaks of the moderns, their improvements are an honour to them, and to their profeſſion, both by rendering ancient methods more ſupportable, and introducing new ones entirely unknown to their predeceſſors, and theſe in caſes where with them the patient was left hopeleſs.

Among the ancients, Celſus, Paulus Ægineta, and Albucaſis excel. After them, the principal ſyſtematical writer is Heiſter. Though numerous are the authors among the moderns, whoſe publications on ſubjects in this province deſerve the utmoſt regard, many of which are referred to in this work under their reſpective articles.

CHIRURGORUM SAPIENTIA. See SOPHIA.

CHIRURGUS. See CHEIRIATER.

CHIST. See SEXTARIUS.

CHITON. See MEMBRANA.

CHIUM VINUM. CHIAN WINE. A wine of the iſland now called *Scio*. Dioſcorides ſays, it is leſs diſpoſed to intoxicate than any other ſort.

CHIVES. See STAMENS

CHIVETS. The ſmall parts at the roots of plants by which they are propagated. Miller's Dict.

CHIVIQUILENGA. See CATAPUTIA MINOR.

CHILIASMA. See FOTUS.

CHILMIA. See CADMIA.

CHLORA See CHLOROS.

CHLORASMA, from χλωρος. A paliſh green colour, ſhining with a ſort of ſplendour, and inclining to watery.

CHLOROS, χλωρος or CHLORA. This word is variouſly applied to a green colour, as a pale green, a yellowiſh pale herbaceous green, &c. When *chloros* ſignifies green, it is ſpoken of things recent, and not dry, and it is applied to leguminous plants before they are dry, or come to perfection.

CHLOROSIS, from Chloros, χλωρος, *green*, or χλωροω, *I am green*. The GREEN-SICKNESS, called alſo *Febris alba* the WHITE-FEVER, the VIRGIN'S DISEASE, *amatoria febris*, and *icterus albus* Though Hippocrates does not ſeem to have known theſe names of this diſorder, yet in the 34th and 35th paragraphs of his book De Intern. Affection. he deſcribes it fully; and when it happens to girls, he ſpeaks of it in his book De Virginum Morbis.

Moſt authors treat it as a ſpecies of cachexy, and indeed it is no other, only diſtinguiſhed from other ſpecies by its having retarded or ſuppreſſed menſes for its cauſe. See CACHEXIA. Dr. Cullen ſays, it is only a ſymptom of AMENORRHŒA.—A vitiated appetite, a ſtrong deſire of eating abſorbent ſubſtances, are conſtant attendants on this diſorder; and, if married women become *chlorotic*, they are thereby rendered barren, or elſe the children they bring forth are weakly. THE COMMON SYMPTOMS, *when from difficult menſtruation*, are a paleneſs in the lips, a livid colour about the eye-lids, indolence, coldneſs, particularly in the feet, loſs of appetite, naufea, vomiting, diſturbed ſleep, a languid pulſe, limpid urine, which in time becomes turbid, a tremor, if exerciſe is briſk, or if the patient aſcends up hill; a frequent palpitation of

the

the heart; the feet are puffed up; heart-burn, intermitting head-achs, fainting, &c. See MENSES DEFICIENTES.

CHNUS, χνε, *fine ſoft wool*; but according to ſome, it is chaff, ſound, or wind.

CHOA. See CHU.

CHOACON, } The name of a black plaſter, mention-
CHOACUM. } ed by Celſus, made of a ſpuma argenti boiled in oil, then added to a proper quantity of roſin.

CHOANA, } χοανη, *a funnel*. See INFUNDIBU-
CHOANOS. } LUM. A funnel, or furnace for melting metals.

CHOAVA. See COFFEA.

CHOCOLATA. See CACAO.

CHŒNICIS. The TREPAN, ſo called by Galen and P. Ægineta. From χοινιξ, *the nave of a wheel*. See TREPANUM.

CHŒRADES, from χοιρος, *a ſwine*. See SCROFULA.

CHŒRADOLETHRON, from χοιρος, *a ſwine*, and ολεθρος, *deſtruction*. See BARDANA MINOR.

CHOIRAS, from χοιρος, *a hog*. See SCROFULA.

CHOLADES. See INTESTINA.

CHOLAGO. See ILIUM.

CHOLAGOGA, CHOLAGOGUES, alſo *colegon*, from χολη, *bile*, and αγω, *to drive out*, or *evacuate*. By *cholagogues* the ancients meant only ſuch purging medicines as expelled the internal fæces, which reſembled the cyſtic bile in their yellow colour, and other properties, as brightneſs, tenacity, and bitterneſs. We retain the word for ſuch purgatives as are found moſt uſeful when bile offends, or are of ſervice when the liver is diſeaſed. Of this kind are antimony and calomel, which are ſuppoſed to act more powerfully on bile than any other medicine. Under this deſcription, perhaps, aloes and taraxicum may be conſidered as the firſt, being generally uſeful in occaſioning the bile to paſs freely into the inteſtines.

CHOLAS. See ILIUM.

CHOLE. See BILIS.

CHOLEDOCHUS, from χολη, *bile*, and δεχομαι, *to receive*. It is a common name for the gall-bladder, the biliary ducts, and the common gall-duct, which communicates with the duodenum, called

CHOLEDOCHUS DUCTUS. It ſeems to be a continuation of the ductus cyſticus; for it is often obſerved, that the *ductus* hepaticus runs, for ſome ſpace, within the ſide of the *ductus cyſticus*, before it opens into its cavity: alſo at the opening of the hepatic *duct* into the cyſtic, there is a ſmall looſe membrane to hinder the bile from regurgitating.

CHOLEGON. See CHOLAGOGA.

CHOLERA MORBUS. Cœlius Aurelianus ſays, the name is derived from χολη, *bile*, and ῥεω, *a flux*. It is called alſo *diarrhœa cholerica*, *felliflua paſſio*, and by ſome of the ancients, *holera*.

Hippocrates divides this diſorder into the moiſt and dry; and there is a kind of *cholera morbus* which frequently happens to children from dentition. Dr. Cullen names it *cholera*, and defines it a frequent vomiting and purging of a bilious humor, attended with anxiety, gripings, and ſpaſms of the legs. He ranks it in the claſs neuroſes, and order ſpaſmi. He obſerves two ſpecies: 1. *Cholera ſpontanea*, which happens in hot ſeaſons, and without any manifeſt cauſe; 2. *Cholera accidentalis*, which occurs from too acrid materials taken into the ſtomach.

The *intermittent*, *inflammatory*, *arthritic*, and *verminoſe* cholera, are conſidered truly ſymptomatic.

The true ſpecies is moſt frequent in autumn, and happens chiefly to young perſons.

The ſeat of this diſorder ſeems to be the whole volume of the inteſtines, but more particularly the duodenum and bilious duct, as appears by the vomiting and ſtools, which are bilious.

The *cholera* and bilious diarrhœa are incident to the bilious, dry, and choleric; for thoſe of a ſucculent, phlegmatic, and ſanguine habit, are more frequently ſubject to a pituitous flux. Thoſe who are ſubject to a ſcorbutic acrimony, or who have acid ſordes in the primæ viæ, are ſubject to this diſorder; ſo are thoſe of a paſſionate temper. In ſultry weather it is moſt frequent: hence it is ſaid by Bontius and Thevenot to be endemic in India, Mauritania, Arabia, and America.

The true *cholera* approaches often ſuddenly: ſickneſs, pain, flatulency, and diſtention of the belly, are firſt perceived, and are ſoon followed with frequent vomiting and purging of bilious matter; the vomiting and purging come on both at once, and continue very frequent, and violent pain racks the bowels. The matters voided are at firſt the remains of the food; afterwards bilious humours, more or leſs mixed with frothy mucus, of a yellow, green, and at length often of a black colour; ſometimes bloody, like the waſhings of fleſh, extremely acrid, and almoſt corroſive. The pulſe is frequent, and ſometimes ſmall or unequal; heat, thirſt, and anxiety, now attend; cold ſweats preſently appear, and ſpaſmodic contractions affect the extremities. In greater degrees of this diſorder, the muſcles of the belly, and, indeed, the whole body, are ſeized with ſpaſms, ineffectual ſtrainings to vomit, with an almoſt continual urging to ſtool, uſher in an hiccoughing, lividneſs of the nails, convulſive contractions of the legs and arms, and ſometimes the patient is carried off in twenty-four hours.

In the dry ſpecies, there is a conſiderable diſtenſion of the ſtomach and inteſtines from wind, which is plentifully diſcharged both upward and downward with extreme anxiety, but without either vomiting or purging being attendant.

The remote cauſes are various; as acrid poiſon taken into the ſtomach, rough emetics or purgatives, diet that is acrid, ſuch as ſoon ferments or corrupts, violent paſſions, the gas ſylveſtre from fermenting vegetables, or ſpringy elaſtic liquors, &c.

The immediate cauſe is the vellication of the nervous coat of the ſtomach and inteſtines, which induces a convulſive conſtriction of the viſcera, and which conſtitutes the diſeaſe, alſo produces the painful ſymptoms that attend, and are various, according as different parts are moſt affected.

Hoffman ſays, that the dangerous vomiting and purging which infants are thrown into from the vehement anger of the nurſe, and thoſe which follow the exhibition of arſenic, and ſome other poiſons, and the virulent cathartics and emetics, ſeem to be no other than the true *cholera*.

The dry *cholera* proceeds from a collection of acrid and flatulent humours in the ſtomach, by which the adjacent nervous parts are vellicated and diſtended, in which reſpect it reſembles the humid *cholera*.

The *cholera morbus* muſt be diſtinguiſhed from a bilious looſeneſs, a dyſentery, and the dry *cholera*.

It is often fatal; no diſtemper is more ſpeedily ſo, except the plague. The more corroſive the matter is that is diſcharged, the more intenſe the heat and thirſt, the greater is the danger. Hippocrates ſays, that if black blood and black bile are voided together, death is certainly at hand. An exorbitant diſcharge of green humour, both upward and downward, fainting, hiccough, convulſions, coldneſs of the extremities, cold ſweats, a ſmall intermitting pulſe, and the continuance of the other ſymptoms after the looſeneſs and vomiting ceaſe, are mortal ſigns. Danger is extreme, if what is vomited ſmells like the internal excrements. If the vomiting ceaſes, ſleep ſucceeds, and the patient ſeems relieved, there is good hope; alſo if the diſeaſe continues more than ſeven days. But the beſt ſign is a free diſcharge of flatus downwards.

The general indications of cure are:

1ſt, To correct and ſoften the acrid peccant matter, and fit it for expulſion, and, if neceſſary, to expel it by art.

2d, To check the violent commotions.

3d, To ſtrengthen the weakened nervous parts.

When this diſorder is cauſed by corroſive poiſon, treat it as directed in the articles ARSENIC and MERC. COR. ALB.

If rugged emetics or purgatives gave riſe to it, foment the region of the ſtomach and belly with ſpirituous fomentations, and afterwards with a liniment of ol. nerv. ol. n. m. &c. and give internally warm opiates, ſuch as the conf. opiat.

Fermenting and corruptible diet ſometimes gives riſe to this diſorder; in which caſe, give draughts of warm water, to excite two or three evacuations by vomiting; after which the bowels may be gently moved downwards, and the patient well ſupplied with thin gruel, which may be drank plentifully.

If violent anger brought on the diſorder, carefully avoid emetics and purgatives, and any kind of cold drink, for ſome time after its approach, leſt an inflammation of the ſtomach ſhould be produced. In this caſe, abſorb-

ents

ents mixed with nitre, water-gruel, barley-water, decoction of hart's-horn ſhavings, &c. after which, a few grains of ipecac. may be admitted of, and a gentle doſe of manna with rhubarb.

In the true *cholera*, Aretæus long ſince commended frequent ſmall draughts of tepid water, to evacuate the preſent contents of the ſtomach; after which, when bilious diſcharges appear, loathing, reſtleſſneſs, &c. come on, give the patient a quarter of a pint of cold water, to check the purging, to cool the ardent heat of the ſtomach, and to abate the thirſt: this he adviſes to be repeated, as often as the patient throws up what he drinks: and if fainting, with other ſymptoms of weakneſs, come on, he ſays, a little wine may be added to each draught of water.

Many ſince Aretæus have extolled cold water, and the more ſo, as the climate, ſeaſon, and conſtitution of the patient, are warm: for it cools, blunts acrimony, and reſtores the tone of the parts.

Sydenham commends a ſimilar practice for the moſt part. He orders, if called in at an early period of the diſeaſe, a chicken to be boiled in three gallons of water, but ſo as that the water hardly taſtes of the fleſh: of this the patient is to drink freely, and, at the ſame time, receive it glyſterwiſe, until the whole is conſumed: thus the offending matter will be evacuated both by vomit and ſtool, and alſo obtunded. The glyſters may be repeated as often as they return, at leaſt until the pain abates.

In want of chicken-water, as adviſed by Sydenham, barley-water may be uſed; water in which a little gum arabic is diſſolved, or any other inſipid mucilage; butter-milk, which ſome prefer above every liquid; gentle acid drinks; or, as Dr. Douglas hath adviſed in the Edinb. Med. Eſſ. a decoction of oat (or other) bread, that is firſt toaſted, until it is brown as coffee, but not burnt: as much of this toaſted bread ſhould be boiled in the water, as will render the decoction of the colour of weak coffee.

Theſe liquors ſhould be plentifully drank, until the patient is ſufficiently reduced to render the exhibition of opium ſafe.

If the ſymptoms are not exceedingly violent, from a quarter to half a grain of tart. emet. may be given in part of the drink, every three or four hours; or, if the vomiting is not very troubleſome, from twenty to thirty grains of rhubarb may be taken in a draught of any of the above liquors.

When the ſtrength is reduced by the evacuations, and the primæ viæ cleared, the vomiting and purging may be checked with opiates. Sydenham directs the tinct. opii, from twelve to twenty drops, or more, in a little mint-water, to be repeated two or three times a-day, or oftener, as the urgency of the pain, or frequency of the evacuations require, and to continue it, at leaſt night and morning, until the patient recovers ſome degree of ſtrength.

If the diſorder hath continued ſome hours, and the patient is already weakened, begin immediately with the tinct. opii, and proceed with it as already directed. If the ſymptoms of weakneſs are extreme, the pulſe weak and intermitting, and convulſions are approaching, give the tinct. opii to twenty-five or thirty drops, in a large ſpoonful or two of ſtrong cinnamon water, and after it a draught of whatever liquor the patient hath to drink, mixed with an equal quantity of wine.

Nitre is uſeful when great anxiety attends.

The ſaline draughts given in the act of fermentation often allay the vomiting very ſoon: they may be repeated after each evacuation upwards.

But, perhaps, it will be found, that a free uſe of the columbo-root will be alone an adequate remedy againſt this dangerous diſeaſe. It rarely requires any means to be employed for promoting the diſcharge of bile, or to cleanſe the primæ viæ, previous to its adminiſtration. As ſoon as aſſiſtance is demanded, begin with this medicine, and give from ʒ ſs. to ʒ ii. of it finely powdered, in a glaſs of peppermint-water, and repeat it every three or four hours, more or leſs, according to the urgency of the ſymptoms. In hot climes, this remedy is almoſt ſpecific: it ſoon abates the violent evacuations; and by continuing it a few days, every other ſymptom vaniſhes.

Hoffman obſerves, that in *choleras* and bilious diarrhœas, eſpecially ſuch as are excited by paſſion, it is neceſſary to abſtain from ſudorifics and a ſudorific regimen, particularly at the beginning; theſe being apt to bring on violent rheumatic or arthritic affection.

The *cholera morbus* ſometimes deſtroys the patient in twenty-four hours. If it is cured, the patient is much relieved in three or four days: it rarely continues a week, beyond which it never laſts, except it turns into ſome other diſeaſe. See Aretæus, Cœl. Aurelianus, Hoffman, Fothergill's Eſſ. p. 2. Edinb. Med. Eſſ. vol. v. Wallis's Sydenham. Cullen's Firſt Lines, vol. iv. 39.

CHOLERA SICCA. See Colica Accidentalis, under COLICA.

CHOLERICA. See DIARRHŒA HEPATARRHŒA.

CHOLOBAPHINON. See Æs.

CHOLOMA, from κωλος, *lame, maimed.* Galen ſays, that in Hippocrates it ſignifies any diſtortion of a limb. In a particular ſenſe, it is taken for a halting, or lameneſs in the leg.

CHOLOSIS. In Vogel's Noſology, this is a genus of diſeaſe, which he defines to be lameneſs, from one leg being ſhorter than the other. It is ſometimes the caſe with children, that one leg ſeems to be longer than the other, and the patient walks rotatorily in conſequence of it. Mr. Pott thinks, that this is owing to a kind of paralyſis of the part. In theſe inſtances, the glutæi muſcles are in a very relaxed ſtate, and the diſeaſe moſt probably in a very great meaſure originates from a weakneſs of the ſciatic nerve. Amongſt the moſt uſeful means of relief, are the cold bath, the bark, iron, ſetons, the vitriolic acid, &c.

CHONDRILLA vel CONDRILLA. It is a ſpecies of SUCCORY, the root of which is perennial, and the leaves finely jagged.

Boerhaave enumerates the following ſpecies:

1. *Chondrilla* cœrulea, *lactuca ſylveſtris peren. lactuca humilior flore cœruleo.* GUM SUCCORY.

It grows wild in Germany and Italy. A gum-like maſtich is found about its branches, which is uſed with myrrh as an emenagogue.

2. *Chondrilla* vel *lactuca ſylv. flore albo.*

3. *Chondrilla* vel *lactuca ſylveſtris majore flore incarnato.*

4. —— vel *lactuca perennis humilior dentata.* BLUE FLOWERED GUM SUCCORY, with broad cut leaves.

There is another kind of *chondrilla*, with different characters from the juſt named. The ſeeds of this kind are oblong and narrow, and the calyx, in a manner, fiſtular and cylindrical. Of this there are five ſpecies, as follow:

5. *Chondrilla* vel *ſonchus lævis parvis floribus*; *lactuca ſylveſtris murorum flore luteo.*

6. *Chondrilla* vel *lactuca ſylveſtris purpurea*; *ſonchus montanus purpureus.*

7. *Chondrilla* hieracii folio annua. The ANNUAL GUM SUCCORY, with hawkweed leaves. *Hieracium pulchrum, hieracium montanum.*

8. *Chondrilla* viminea, chondrilla cichoroides; chond. junica; chond. viminalibus virgis; *lactuca ſylveſtris perennis lutea*, &c. GUM SUCCORY, with yellow flowers.

9. *Chondrilla* viminea viſcoſa Monſpeliaca.

CHONDROGLOSSUS. See HYOGLOSSUS.

CHONDROS. See ALICA, CARTILAGO, and XIPHOIDES CARTILAGO. It alſo ſignifies any grumous concretion, as of maſtic, &c.

CHONDROSYNDESMUS. A cartilaginous ligament. From χονδρος, *cartilago*, and συνδεσμος, *colligo.*

CHONDROPHARYNGÆUS. See PHARYNX. It riſes from the cartilaginous appendage of the os hyoides, and is inſerted in the membrane of the fauces. Douglas.

CHONE. See INFUNDIBULUM.

CHOPIN. An Engliſh WINE QUART.

CHOPINO. A CHOPINE; alſo *chopina.* A pint meaſure at Paris. Some ſay it contains fifteen ounces and a half, others ſay ſixteen ounces.

CHORA. A REGION. Galen in his work De Uſu Part. expreſſes by it particularly the cavities of the eyes; but in other of his writings, he intimates by it any void ſpace.

CHORDA, χορδη. Properly a muſical *chord.* Metaphorically it is uſed to ſignify a *tendon.* Poets often expreſs by it the *inteſtines.* Paracelſus, in his work De Orig. & Cur. Morb. Gal. calls the pudenda by the name of *chordæ.* A painful tenſion of the penis in the lues venerea is called *chordé.*

—— MAGNA. See TENDO ACHILLIS.

—— TYMPANI. The fifth pair of nerves from the brain divides into three capital branches, one of which

it called the inferior maxillary. See TRIGEMINI NERVI. A branch of the inferior maxillary nerve forms the lingual, which, ſoon after it leaves its origin, is accompanied by a ſmall diſtinct nerve, which runs upward and backward towards the articulation of the lower jaw, in company with the lateral muſcle of the malleus, and paſſes through the tympanum, between the handle of the malleus and the long neck of the incus, by the name of the *chorda tympani*. It afterwards perforates the back ſide of the *tympanum*, and unites with the portio dura of the auditory nerve.

CHORDÆ TENDINEÆ. See COR.——WILLISII. See DURA MATER.

CHORDAPSUS. See COLICA, and ILIACA PASSIO.

CHORDATA GONORRHŒA. See GONORRHŒA.

CHORDEE, ſo the French call what others name *cordæ*, *chordæ*, *cordé*, and *chordé*, from χορδὴ, the *chord* of a muſical inſtrument.

It is a painful, involuntary erection of the penis, happening at all times of the day, but more commonly when the patient is warm in bed: under which circumſtance, the penis becomes hard, and painful to the touch; and is moſt frequently curved downwards in a conſiderable degree. It ſometimes remains, after the heat of urine, and other ſymptoms of gonorrhœa, are gone off; but is uſually more ſevere during the continuance of the inflammation, and becomes more or leſs violent, according to the greater or leſſer degree of that ſymptom.

Aſtruc diſtinguiſhes it, when the whole body of the penis is regularly drawn downwards in the form of a ſemicircle, from inflammation, or an ulcer in the membrane that lines the urethra, or in the corpus cavernoſum urethræ, and when the glans only is drawn down by inflammation, or ſpaſmodic ſtricture in the frænum. He alſo obſerves, that, beſides the *chordee*, there are other diſtortions of the penis; e. g. if the ſuſpenſory ligament that connects the penis to the os pubis is inflamed, or if only one of its cavernous bodies is injured, the penis will either be bent upwards, or to one ſide; and theſe are relieved in the ſame manner as the *chordee*.

Dr. Rutherford of Edinburgh, in his Clinical Lectures, ſays, that inflammation and ſwelling in the corp. cavern. ureth. is the cauſe of the *chordee*.

BELL concludes, that *chordee* is the effect of inflammation, which proceeds from irritation, communicated from the nerves of the urethra to thoſe of the contiguous muſcles, by which thoſe unequal degrees of contraction are produced over the whole ſubſtance of the penis, which univerſally takes place in this diſeaſe.

In order to the cure, if the patient is coſtive, gentle laxatives ſhould be adminiſtered; and in full habits, bleeding is eſſentially neceſſary. Cold ſolution of acetated litharge, or the camphorated oil, applied to the part, and ſleeping in tight drawers, have been recommended; or rubbing the parts with tincture of opium, or a ſtrong ſolution of it in water, or pledgits immerſed in either, kept upon the parts. Emollient injections, impregnated with opium, are extremely efficacious in leſſening the violence of this complaint: but taking thirty or forty drops of tincture of opium at bed-time, is the remedy moſtly to be depended upon, as it ſeldom fails to prevent or remove the affection: and this is conſidered as one of the moſt effectual remedies *in every ſtage of this ſymptom*, particularly where it has been of long continuance. If opium fails, the hyoſcyamus niger may be tried, beginning with one grain of the extract, and gradually increaſing the doſe, according to its effects. Though, in ſlight degrees of chordee, blood-letting is never neceſſary; ſtill, whenever it is ſevere, particularly if the habit is plethoric, and the pulſe ſtrong and full, it ſhould never be omitted: and, perhaps, the beſt mode is by the application of leeches to the part affected; particularly as it prevents the chordee remaining after every other ſymptom of gonorrhœa diſappeared, which is ſometimes the caſe, and then is very diſtreſſing. Frictions with mercurial ointment have been ſtrongly recommended; but as inconveniences ſometimes occur from their uſe, they are better avoided.

See Aſtruc, or Chamberlyn's Account; FOOT, HUNTER, and BELL, on the Lues Venerea. SWEDIAUR, alſo, may be conſulted.

CHOREA, } SANCTI VITI, a χορὸς Cœtus
CHORION, } Saltantium. St. VITUS'S DANCE.
Alſo called *vitiſaltus*; by Paracelſus, *laſcivus*. HORSTIUS ſays, that there were ſome women who once every year paid a viſit to the chapel of St. Vitus, near Ulm, and there exerciſed themſelves day and night in *dancing*, being diſordered in mind, till they fell down like thoſe in an extaſy. Thus they were reſtored till the return of the following May, when they were again ſeized with a reſtleſſneſs and diſorderly motion of their limbs, in ſo great a degree, as to be obliged, at the anniverſary feaſt of St. Vitus, to repair again to the ſame chapel, for the ſake of *dancing*. From this tradition, a ſort of convulſion, to which girls are principally ſubject before the eruption of the menſes, took its name. But yet the diſorder above deſcribed by HORATIUS, is different from what we call *St. Vitus's dance*.

MEAD and PITCAIRN ſay, that this diſorder is of the paralytic kind; SYDENHAM ſays, it is convulſive; BISS and CHEYNE ſay, that it partakes both of the convulſive and paralytic kinds. Dr. CULLEN calls it *chorea*. He uſed to rank it as a ſpecies of convulſion: but on account of the age at which it attacks, as well as the motions which it exhibits, it greatly differs from every other ſpecies of convulſion, he marks it down as a genus, under the CLASS NEUROSES, and ORDER SPASMI; and ſays it affects thoſe of either ſex before the time of puberty, for the moſt part between the tenth and fourteenth year. It manifeſts itſelf by ſpontaneous convulſive motions of ſome parts, commonly of one ſide, reſembling the geſtures of buffoons, in the movement of the arms and hands; the patients, in walking, often rather dragging one foot than raiſing it up.

SYDENHAM thus deſcribes it: "A kind of convulſion, which principally attacks children of both ſexes from ten to fourteen years of age. It firſt ſhews itſelf by a lameneſs, or rather unſteadineſs of one of the legs, which the patient draws after him like an ideot, and afterwards affects the hand on the ſame ſide, which being brought to the breaſt, or any other part, can by no means be held in the ſame poſture for a moment, but is diſtorted or ſnatched by a kind of convulſion into a different poſture or place, notwithſtanding all poſſible efforts to the contrary. If a glaſs of liquor be put into the hand to drink, before the patient can get it to his mouth, he uſes a thouſand odd geſtures; for, not being able to carry it in a ſtraight line thereto, becauſe his hand is drawn different ways by the convulſion, as ſoon as it hath reached his lips, he throws it ſuddenly into his mouth, and drinks it very haſtily, as if he only meant to divert the ſpectators."

Its cauſe is from an acrid humour falling on the nerves; ſometimes from worms: Cheyne ſays, it ſometimes riſes from an epilepſy, which is leaving the patient as his ſtrength increaſes; and Pitcairn intimates, that its cauſe is from a paralytic affection of the muſcles. From the variety of ſymptoms obſerved in different patients, whatever can be a cauſe of convulſions, and paralytic relaxation, may alike conduce to the forming this diſorder.

Thoſe who have once ſuffered under this diſeaſe, are very ſubject to a relapſe. However violent the ſymptoms are, they never are ſuddenly deſtructive. When recent in a young perſon, of an otherwiſe good conſtitution, there is hope of a ſpeedy cure. If the menſes or hæmorrhoids are obſtructed, their return will mitigate, if not cure the diſeaſe. If the temperament is very ſenſible, the diſeaſe hereditary, or become habitual, the cure is very difficult. Through ill management, it may degenerate into an epilepſy or hypochondriac melancholy.

Dr. Cheyne, in his Treatiſe on the Gout and Bath Waters, intimates, that the indications of cure are, 1. To *evacuate*. 2. To *attenuate*. 3. To *corroborate*. And he informs us, that he effects *the firſt* by a vomit once a week, until the diſeaſe abates; and then he lengthens the intervals. *The ſecond* he effects, by giving for a month or ſix weeks, on the days in which the emetic is not adminiſtered, a large doſe of Æthiops mineral, with Bath water. *The third*, by an anticachectic regimen and nervous corroborant; ſuch as the bark, orange-peel, iron, cold bathing, &c.

Valerian in large doſes, e. g. three drams in a day, hath been followed with ſucceſs. The *cardamines*, which SEE, has, by ſome, been conſidered almoſt a ſpecific. Of purges, the vinum aloes, or pil. ex aloe cum myrrha, are the moſt proper. Dr. Mead particularly cautions us to adminiſter medicines at and about the changes of the moon.

See Wallis's Sydenham, vol. ii. p. 327; Mead's Influence

fluence of the Sun and Moon upon Human Bodies; Cheyne's Engliſh Malady, and his Eſſay on the Gout, &c. Biſs's Medical Eſſays; Cullen's Firſt Lines, vol. iii. edit. 4.

CHORION. Membrana externa, quâ fœtus involvitur, a χωρα receptaculum. Vide H. Steph. Theſ. Sometimes called *camiſia fœtus*, SHIRT OF THE FŒTUS. A name of the external membrane of the fœtus. In women, as in ſome animals, the *chorion* at the firſt is without any ſenſible placenta. It is alſo ſaid to have its name from the chorus or crowd of blood-veſſels which are ſpread upon it. It adheres to the amnios by a gelatinous ſubſtance, and is diviſible into two lamellæ: the *internal*, or true *chorion*, is even more thin and pellucid than the amnios; whilſt the *external*, or falſe *chorion*, is thick and ſpongy. This ſpongy *chorion* adheres to the uterus at every part, and grows thicker as it approaches the placenta; whilſt the internal lamina adheres inſeparably to the inner ſurface of the placenta: hence it is plain, that the ſubſtance of the placenta is betwixt theſe two lamellæ of the *chorion*. This membrane hath abundance of lymphatic veſſels: but in the human placenta, the veſſels cannot be traced by injection on the amnios and *chorion*; yet the uterus ſends veins to the outer *chorion*: perhaps the arteries do the ſame. See DECIDUA.

The uſe of the *chorion* is to ſuſtain the umbilical veſſels.

CHOROIDES, from χοριον, the *chorion*, and ειδος, *likeneſs*. It is an epithet of ſeveral membranes, which, on account of the multitude of their blood-veſſels, reſemble the *chorion*. It is the *tunica retiformis oculi*, a name of one of the coats of the eye. See RETIFORMIS. It lines the ſclerotis, is a thin vaſcular coat of a browniſh colour, generally ſaid to derive its origin from the pia mater's covering of the optic nerve. From the colour of part of this membrane, it hath been called *uvea*; the external ſurface of which is called the *iris*; but at preſent the whole fore-part of this coat is called iris; and the reſt is called *choroides*. It conſiſts of two laminæ: the exterior is ſlightly connected with the ſclerotica, and is alſo covered with a black matter, called *nigrum pigmentum*. Both laminæ are extremely vaſcular: the extremities of the veſſels of the inner ſurface project therefrom, and are termed villi and papillæ. As this internal lamina was firſt noted by Ruyſch, it is called *Ruyſchiana tunica*. The black ſubſtance which lies between the ſclerotica and choroides, is alſo found betwixt it and the retina. Near where the ſclerotica becomes tranſparent, the *choroides* is firmly united to it; and at this circle of adheſion, the *choroides* ſeems to change its colour and texture, appearing as a whitiſh kind of ring, of a compact ſubſtance, and is termed *ciliare ligamentum*. Here the internal lamina of the *choroides* dips inwards, to make what are termed the proceſſes. The ciliary proceſſes are on the inſide, between the iris and *choroides*, as the ligamentum ciliare is on the outſide. The *choroides* is continued on the inſide of the tranſparent part of the ſclerotis, and there forms the iris: the perforation, in the middle, is called pupilla. The artery is a branch of the carotid. The veins empty themſelves into the optic ſinuſes, which are again diſcharged into the internal jugulars, but ſome of theſe veins communicate with the external veins of the eye, ſo part of the blood is emptied into the external jugulars. The nerves are from the ophthalmic branch of the fifth pair, and a branch of the third pair.

Oppoſite to the inſertion of the optic nerve, the *choroides* is wanting; and thus is formed that white ſpeck, on which if the picture of an object falls, we are incapable of ſeeing it.

CHOU DE PALMISTE. The cabbage of the *palm-tree*. See PALMA NOBILIS.

CHOVANA MANDARU. See MANDARU.

CHRISTI MANUS. See SACCHARUM.

CHRISTOS, from χριω, *to anoint*. It is whatever is applied by way of unction.

CHRONICUS, or CHRONIUS, from χρονος, *time*. CHRONICAL.

Diſeaſes which continue long, and are without any fever, or at leaſt a conſiderable degree of it, are thus called, to diſtinguiſh them from thoſe which proceed rapidly, and terminate ſoon, and are called acute.

In the cure of *chronical* diſorders, Dr. Fothergill intimates, that thoſe means or medicines which enable the ſtomach duly to perform its office, are the moſt effectual, if not the only remedies. See what he hath inſerted on this ſubject in the firſt vol. of the Lond. Med. Obſ. p. 314. Dr. Cadogan ſeems to corroborate this by his obſervations on the cauſes of *chronical* diſorders; which he ſays are indolence, intemperance, or vexation: though now and then he allows, that an ill-cured acute diſorder may be the cauſe of *chronical* ones. See his Eſſay on the Gout and *Chronical* Diſeaſes. Wallis's Sydenham, vol. i. p. 4.

CHROS. Galen ſays, that the Ionians mean by this word, the fleſh in our bodies, i. e. all except bones and cartilages.

CHRYPSORCHES. See PARORCHIDIUM.

CHRYSANTHEMUM, called alſo *bellis lutea foliis profunde inciſis major*; chryſ. ſegetum; CORN MARIGOLD.

Botaniſts enumerate fourteen ſpecies. It is an annual plant, frequently met with amongſt corn. The Germans commend it in the jaundice; but it does not obtain in practice with us.

It is likewiſe a name for the GARDEN MARIGOLD. See CALENDULA.

CHRYSANTHEMUM BIDENS. See ACMELLA.

—— COTULÆ FOLIO. See BUPHTHALMUM VERUM.

—— INDICUM. See BATTATAS CANADENSIS.

—— LEUCANTHEMUM. See BELLIS MAJOR.

It is alſo the name for ſeveral ſpecies of *ſun flower*, *cotula*, and the *common ox-eye*.

CHRYSATTICUM. An epithet of a ſort of *paſſum*, recommended by P. Ægineta to be drank with the ſeed of atriplex, for the jaundice.

CHRYSE. The name of a plaſter in P. Ægineta for freſh wounds.

CHRYSISCEPTUM. See CARLINA.

CHRYSITIS, or CHRYSITIS SPODOS. See LITHARGYRUM.

CHRYSOBALANUS GALENI. See NUX MOSCHATA.

CHRYSOCALLIA. See CHAMÆMELUM.

CHRYSO CERAUNIUS. See AURUM FULMINANS.

CHRYSOCHALCUM. See ÆSECAVUM.

CHRYSOCOLLA, from χρυσος, *gold*, and κολλα, *glue*, or *ſolder*. See TINCAL and BORAX.

CHRYSOCOME, from χρυσος, *gold*, and κομη, *hair*. See ELICHRYSUM.

CHRYSOGONIA, from χρυσος, *gold*, and γινομαι, *to be made* or *generated of*. It is the AURIFIC TINCTURE. Pharm. Schroderi Medico Chemica, 1669.

CHRYSOGONUM. RED TURNEP.

CHRYSOLACHANON. See ATRIPLEX.

CHRYSOMELIA. See AURANT. HYSPAN.

CHRYSOPŒIA, from χρυσος, *gold*, and ποιεω, *to make*. The art of changing inferior metals into *gold* by the help of mercurius philoſophorum.

CHRYSOPUS. See GAMBOGIA.

CHRYSULCA. See NITRUM, N°. II.

CHRYSUN, from χρυσος, *gold*. An epithet of two collyria for the eyes, and alſo of two peſſaries for the uterus, in Actius.

CHU, or CHUS. The name of a meaſure. The ſame as CHOA, *congius*—this was a liquid meaſure among the Athenians, containing ſix *ſextarii*, twelve Attic *cotylæ*, or nine pints or pounds of oil, ten of wine, thirteen and an half of honey, according to GALEN. LINDEN ſays, at leaſt eight of wine and four ounces. RHODIUS aſſerts, that the *Chus*, or *congius*, weighs ten pounds. CASTELLI.

CHUNDRILLA VERCURIA. See ZACINTHA.

CHUNNO. See BATTATAS.

CHYBUR. See SULPHUR.

CHYLARIA. See DYSURIA, the ſpecies MUCOSA.

CHYLIFERA VASA. See LACTEA VASA.

CHYLIFICATIO. CHYLOSIS. CHYLIFICATION. The firſt digeſtion or the changing of the aliment into chyle by the power of the ſtomach.

CHYLISMA, from χυλος, *juice*. In Dioſcorides it ſignifies expreſſed juice.

CHYLISTA. Hartman's *chyliſta* is glaſs of antimony obtunded by levigating it with maſtich diſſolved in rectified ſpirit of wine; the oleoſe part of this ſpirit blunts the ſpicula of the vitr. ant.

CHYLOPOIETIC, χυλος, *chylus*, ποιεω, *facio*, applied to the organs which form chyle.

CHYLOSIS. See CHYLIFICATIO.

CHYLOSTAGMA DIAPHORETICUM MINDERERI.

DERERI, called alſo *theriacalis bezoardica aqua*. It is a liquor diſtilled from the ther. Andromachi, or from Mithridate, or ſuch like matters.

CHYLUS. χυλος. The CHYLE, called in Paracelſus, *chymoſum*. In general it is a juice inſpiſſated to a middle conſiſtence between humid and dry.

In HIPPOCRATES the word χυλος is uſed to expreſs the juice and ſorbile liquor of barley, which liquor they call ſtrained ptiſan, being the expreſſed ſubſtance of the barley; not what the Latins call *cremor*, which is only the expreſſed water of the barley. To χυλος is oppoſed ptiſan unſtrained.

The aliment received into our ſtomachs is converted into a fluid ſtate, the oily part of it mixed with the ſaliva and other juices ſecerned into the ſtomach and duodenum, becomes like milk, and is called *chyle*. The bile mixing with the digeſted aliment when it is conveyed into the duodenum, aſſiſts the ſeparation of the nutritious *chyle* from the excrementitious part. The nutritious *chyle* is conveyed by the lacteals into the circulation, to be converted into blood. The *chyle* ſeems to conſiſt of oil, mucilage, water, a coagulable part, and fixed air.

From the *chyle* proceeds the milk which flows into the breaſts of nurſes, as well as all that is required to recruit the waſte made by the actions of living bodies. See LAC.

The *chyle* when it enters the blood does not immediately mix with it, but in many inſtances is proved to paſs in a ſeparate ſtate through the whole circulation; for the *chyle* hath been ſeen to float on the ſurface of blood which was taken from the arm: in the laſt ſtage of a diabetes the urine manifeſtly points out the preſence of *chyle* in it. See Haller's Phyſiology on the Chyliferous Veſſels; Percival's Med. Eſſays, edit 2. p. 251, &c.

CHYMATION. The name of a penetrating medicine in Marcellus Empiricus.

CHYMIA. See CHEMIA.

CHYMIATER. A chemical phyſician, or one who cures by chemical medicines. Called alſo *iatrochimicus*.

CHYMIATRIA, from χυμεια, *chemiſtry*, and ιατρευω, *healing*. The art of curing diſeaſes by chemical medicines.

CHYMOSIS. See CHEMOSIS.

CHYMOSUM. See CHYLUS.

CHYMUS, χυμος, *humour* or *juice*. In the common ſignification of the word it is *every kind of humour which is inraſſated by concoction*. Sometimes it means *the fineſt part of the chyle when ſeparated from the fæces*. In GALEN it is the *guſtatory faculty or quality in plants and animals*.

CHYTLON. In HIPPOCRATES it means a plentiful inunction with oil and water.

CIBARIUS, SAL. See MARINUM SAL.

CIBATIO. By this is meant the aſſumption of meals and aliments. In CHEMISTRY it means corporatic, incorporating. It is alſo conſidered as nutrition of the dry parts of our machine; or is an accumulation of what is ſubtile or fine, or a ſubtilization of thick, or groſſer parts. Caſtelli.

CIBORIUM, } See FABA ÆGYPTIA.
CIBOTIUM. }

CIBOUL. A ſort of ONION nearly allied to the ſcallion. They have no bulb at the root, and are cultivated in the kitchen garden.

CIBUR. See SULPHUR.

CIBUS ALBUS. WHITE FOOD. It is a ſpecies of jelly, whiich in Fuller's Pharmacopœia is thus made: take four pints of milk, the breaſt of a boiled capon, and two ounces of blanched ſweet almonds; let them be beat and ſtrong impreſſion made; then boil them over a gentle fire, adding three ounces of rice meal; and when they begin to coagulate, add eight ounces of white ſugar, and ten ſpoonfuls of roſe-water; mix all well together.

The Spaniards give the name of *cibus albus* to a certain American plant. But by WHITE MEATS, we now mean milk, butter, cheeſe, cuſtards, and other foods conſiſting of milk or eggs; as, WHITE POT made of milk, or cream, baked with the yolks of eggs, fine bread, ſugar, and ſpice in an earthen veſſel. There are a variety of diſhes under this form, and denomination; ſuch as *rice white-pot*, Weſtminſter and Norfolk *white pot*, &c. Some alſo add to the catalogue of white meats, *fiſh*, *veal*, and *chicken*.

CICADA. The BAUM CRICKET. An inſect common in Italy, ſomewhat reſembling a cricket. It hath wings, is very noiſy, and is ſaid to live on dew, which it ſucks from the dwarf aſh-manna-tree. Theſe inſects, when dried and burnt, are uſed in the colic, and ſtone, as a ſolvent.

CICATRISANTIA. See EPULOTICA.

CICATRIX. A ſeam or elevation of callous fleſh, riſing on the ſkin, and remaining there after the healing of a wound or ulcer, and is commonly called a SCAR.

It is the deſtruction of the cellular membrane by inflammation that cauſes *cicatrices* to tuck inwards, as they are always obſerved to do. Some commend the ſteams of hot water to be often applied to the growing ſkin, to prevent a *cicatrix*, and to dreſs with a cerate of wax and the oil of eggs.

CICER, album, nigrum, vel rubrum; *cicer* ſativum, *cicer* Arietinum, *erebinthus* CHICHES, CICHES, CICERS, and CICH PEASE. The ſort uſed in medicine is the *cicer* Arietinum. Linn.

Chiches, a ſort of pulſe, cultivated in warmer climates, where our finer peas do not thrive ſo well. They are a ſtrong flatulent food, hard of digeſtion. They are ſown in France, Italy, &c. flower in June, and the peas are ripe in July.

CICERA. See POMACEA.

—— TARTARI. Small pills compoſed of turpentine and cream of tartar.

CICHOREUM, } SYLVESTRE, and SATIVUM.
CICHORIUM. } WILD and GARDEN SUCCORY. The wild is the CICHORIUM INTYBUS. Linn.

It is a plant with oblong, dark green, hairy leaves, deeply jagged like thoſe of dandelion, but larger; in the boſom's of which, towards the tops of the branches, the flowers come forth in ſpikes, conſiſting each of a number of blue flat floſculi, ſet in a ſcaly cup, which afterwards become a covering to ſeveral ſhort angular ſeeds: the root is long and ſlender, of a brown colour on the outſide, and white within. It is biennial, grows in hedges, and by roadſides, and flowers in June and July.

It abounds with a milky juice, of a penetrating bitteriſh taſte, and of no remarkable ſmell: the roots are bitterer than the leaves or ſtalks, and theſe much more ſo than the flowers. But by culture in gardens it loſes its green colour, and in a great meaſure its bitterneſs, and in this ſtate is a common ſallad herb: the deeper coloured and the deeper jagged the leaves are, the bitterer is the taſte of the whole plant.

The whole plant is mildly aperient, and if freely uſed it looſens the belly. The virtue reſides in the milky juice, which may be extracted by coction in water, or by preſſure. The wild and the garden ſorts may be uſed indifferently, but ſhould be uſed as food rather than phyſic. If the root is cut into ſmall pieces, dried and roaſted, it reſembles coffee, and is a good ſubſtitute for it.

CICHOREUM LATIFOLIUM. See ENDIVIA.

CICHOREUM VERRUCARIUM. } See ZACINTHA.
—— VERRUCARUM. }

CICILIANA. See ANDROSÆMUM.

CICINDELA. The GLOW-WORM, alſo called λαμπυρις, *noctiluca terreſtris*, *ſcarabæus*, cicindela mas & fœmina.

The flying *glow-worms* are males, and the reptile ones are the females. Some reckon them anodyne, others that they are uſeful againſt the ſtone in the bladder.

CICINUM OL. See RICINI ol. under CATAPUTIA.

CICIS, κικις. In ſome places of Hippocrates and Theophraſtus it is put for κηκις. A GALL. See GALLÆ.

CICLA. See BETA ALBA.

CICONGIUS. Blancard ſays, it is a meaſure containing twelve ſextaries or pints.

CICONIA. The STORK.

CICUTA. HEMLOCK, called by ſome *camarum*, and according to EROTIAN, *Cambeion* is an old Sicilian word for *cicuta*.

CICUTA MAJOR FOETIDA. The CONIUM MACULATUM, vel CONIUM MAJUS SEMINIBUS STRIATIS. CLASS, PENTANDRIA; ORD. DIGYNIA; LINN. Gen. Plant. 336. SPOTTED HEMLOCK. It grows wild almoſt all over the world, and with us is found about the ſides of the fields, under hedges and in moiſt ſhady places. It is a tall umbelliferous plant, with large leaves, of a blackiſh green colour on the upper ſide, and a whitiſh green underneath, divided into a number of ſmall oblong ſomewhat oval ſegments, which ſtand in pairs on middle ribs; theſe ſegments are again deeply cut, but not quite divided on both ſides; and many of theſe ultimate ſections have one or two ſlighter indentations. They much reſemble

ſemble parſley or chervil, eſpecially the leaves of the ſmalleſt ſorts, whoſe poiſonous quality is the moſt violent. The ſtalk is round, ſmooth, hollow, irregularly variegated with ſpots and ſtreaks of a red or blackiſh purple colour: the flowers are white, and blow in June or July; the ſeeds greeniſh, flat on one ſide, very convex, and marked with five furrows on the other. The root is oblong, about the ſize of a middling parſnep, yellowiſh without, white and fungous within, and part of it hollow; it changes its form according to the ſeaſon. The leaves have a rank ſmell, but do not much affect the taſte.

It agrees with all ages, and every circumſtance of patients. Joined with pectorals it promotes perſpiration. It hath been of great efficacy in epilepſies and convulſions. *Internally* and *externally* it abates inflammations of the eyes; it is narcotic and anodyne, it promotes reſt and eaſes pain. It ſeldom creates thirſt or head-ach, which ſucceed opiates next morning, and as rarely creates coſtiveneſs, but commonly produces a lax ſtool the day following. It poſſeſſes a property of altering thin, corroſive, cancerous ichor, and renders it mild. It hath been uſed with conſiderable advantage in ſanious ulcers, gleets, painful diſcharges from the vagina, fixed pains from acrid ſerum, fluor albus, and ſcirrhous tubercles. It powerfully promotes the menſes, particularly when ſuddenly reſtrained by colds, &c. Inveterate itches have been cured by an internal uſe of the extract. Cancers have had their virulence much abated by it. It neither heats, nor cools, nor diſturbs the animal functions. It promotes perſpiration in ſome, and a copious diſcharge of urine in others. Though it is not a cure in cancers, yet it is a ſpecific anodyne; when the uterus is affected therewith, relieving more effectually than opium,

It is uſeful in ſyphilis according to Mr. John Hunter. Dr. Cullen obſerves, *that when hemlock, either in form of powder or extract, has no ſenſible effect, when taken to twenty grains for a doſe, the medicine may be ſuppoſed to be imperfect, and that, if it is to be continued, another parcel of it ſhould be employed.* He ſays alſo, that he has known it uſeful in reſolving and diſcuſſing ſcirrhoſities of different kinds, and particularly thoſe of a ſcrophulous nature: alſo in healing ulcers which had come upon ſcirrhous tumors, and which continued to be ſurrounded with ſuch ſcirrhoſity; and in ſome ulcers, certainly that approached to the nature of cancer; nay, in thoſe that might be conſidered truly cancerous, he has known it relieve the pains, mend the quality of the matter proceeding from the ſore, and even to make a conſiderable approach towards the healing of it, but never completed it. Mat. Med. It has been conſidered by ſome as very uſeful in the chincough, and rheumatic complaints.

When *hemlock* is imprudently eaten, it cauſes a vertigo, a dimneſs of ſight, hiccough, a ſort of madneſs, and coldneſs of the extremities, convulſions, and death, by an utter interception of reſpiration: ſometimes by the ſpaſms, which it produces in the ſtomach and other nervous parts, hæmorrhages are the conſequence; or if this happens not, an epilepſy comes on, which, without very ſpeedy relief, is fatal. The proper method of relief is to diſcharge the ſtomach of its contents by means of the moſt active emetics, and then to adminiſter frequent doſes of ſharp vinegar, &c. as in the articles AMANITA and VENENUM.

The proper method of adminiſtering *hemlock* inwardly is, to begin with a grain or two of the powder, or inſpiſſated juice, and gradually to increaſe the doſe until the full one is arrived at, which is thus known: for the moſt part a giddineſs affects the head; there is a motion in the eyes as if ſomething puſhed them outwards; a ſlight ſickneſs and trembling agitation of the body; a laxative ſtool or two the morning after the doſe. One or more of the ſymptoms are the evidences of a full doſe: and here continue until none of theſe effects are obſerved; and then, after a few days, increaſe the doſe; for little advantage can be expected but by a continuance of full doſes. In ſome conſtitutions even ſmall doſes greatly offend, occaſioning ſpaſmodic twitchings, heat and thirſt; in ſuch inſtances its uſe muſt be diſcontinued.

The College of Phyſicians of London order, inſtead of the former extract, the inſpiſſated juice of *hemlock*, SUCCUS CICUTÆ SPISSATUS, made in the following manner: let the expreſſed juice of *hemlock*, cleared from its fæces, be evaporated in a water bath, faturated with muriatic ſalt to a proper conſiſtence. Ph. Lond. 1788.

As the powder of the dried leaves has been thought to act, and may be depended upon with more certainty than the extract; the following direction ſhould be obſerved in the preparation: gather the leaves about the end of June, when the plant is in flower; pick off the little leaves, and throw away the leaf-ſtalks; dry the ſmall ſelected leaves in a hot ſun, or in a tin or pewter diſh, before the fire. Preſerve them in bags made of ſtrong brown paper, or powder them, and keep the powder in glaſs phials, in a drawer or ſome place from whence the light may be excluded: for light diſſipates the beautiful green colour very ſoon, and thus the medicine loſes its efficacy: this mode is recommended by Dr. WITHERING. The extract ſhould alſo be made of the plant gathered at this period. And we muſt obſerve, that which grows in expoſed places, is generally ſtronger, than what grows in the ſhade, and that in dry places is alſo to be preferred.

After all, this plant is not found to be ſo injurious as has been related, for it has been taken a long time without any bad effect. The *cicuta aquatica* is probably the ſort which is ſo poiſonous, and is miſtaken for it. Externally it is applied with advantage, and particularly in the form of fomentation and poultice.

FOTUS CICUTÆ.

℞ Fol. cicutæ recent. ℥ 6. vel. ſiccæ ℥ iij. coq. in aquæ fontanæ ℔ iij. & ℔ ij. & fiat fotus. This is commonly made uſe of to foment cancerous or ſcrophulous ulcers, previous to the application of the ſucceeding cataplaſm.

CATAPLASMA CICUTÆ, *hemlock cataplaſm.*

℞ Fotus cicutæ. q. v. inſpiſſetur avenæ farinâ ad craſſitudinem propriam pro cataplaſmate. This is not only applied in cancerous and ſcrophulous caſes, but to moſt inveterate ulcers, and very often both meliorates their diſcharge, and leſſens their ſenſibility, though Mr. JUSSIEU preferred the application of the freſh herb bruiſed. An ointment is alſo made of hemlock, by bruiſing the plant very well in a marble mortar, then mixing with it an equal quantity of hog's lard, and gently melting them over the fire; afterwards the compoſition is to be ſtrained and ſtirred till cold. This has been recommended to be applied to cancerous or ſcrophulous ſores.

In this mode, it has been uſeful in reſolving ſome indurations, eſpecially thoſe of the ſcrophulous kind, but in the indolent ſcirrhoſities in the breaſts of women, it is ſeldom of any ſervice; and the frequent applications of *hemlock* poultices have been known to do much harm by bringing theſe tumors ſooner to an open cancer. See Wilmer's Obſervations on Poiſonous Vegetables. Withering's Bot. Arrangement, vol. i. p. 161. Cullen's Mat. Med.

—— AQUATICA vel VIROSA. WATER HEMLOCK, alſo called *ſium alterum oluſatri facie*, *ſium majus alterum auguſtifolium*, *ſium erucæ folio*. LONG LEAVED WATER HEMLOCK and COW-BANE. It is the CICUTA VIROSA of Linn. Dr. WITHERING gives the following deſcription of it; rundle roundiſh, with many equal ſpokes. Rundlets roundiſh, with many briſtle-ſhaped ſpokes. Empalement; general fence none. Partial fence of many leaves; little leaves, briſtly, ſhort. Cup ſcarcely evident. Bloſſom, general, uniform. Florets all fertile. Individuals: petals five, egg-ſhaped, nearly equal, bent inwards. Chives; threads five, hair-like, longer than the petals. Tips ſimple. Pointal; ſeed-bud beneath. Shafts two, thread-ſhaped, longer than the petals permanent. Summits roundiſh. Seed-veſſels none. Fruit nearly egg-ſhaped; ſlightly furrowed; diviſible into two. Seeds two, ſomewhat egg-ſhaped; convex, and ſcored on one ſide; flat on the other. To this he adds, with rundlets oppoſite the leaves. Leaf-ſtalks with blunt borders; leaves with about ſeven pair of little leaves, which are variouſly divided and indented. Petals yellowiſh pale green. It is met with in ſhallow waters, and flowers in July.

It is one of the moſt active of the vegetable poiſons. Early in the ſpring, when it grows in the water, cows often eat it, and are killed by it; but as the ſummer advances, and its ſmell becomes ſtronger, they carefully avoid it.

Mr. WILMER obſerves, that the poiſon is of that claſs which produces epileptic ſymptoms. WEPFER notices ſome children, who, on taking ſome of the roots of this plant, were ſeized with pains of the præcordia, loſs of ſpeech, abolition of the ſenſes, and terrible convulſions; the jaws were locked, blood ſtarted from the ears, the eyes were diſtorted, and ſome of theſe children died in

half

half an hour. Others have obſerved that the old roots are a more active and ſudden poiſon than arſenic, or than corroſive ſublimate.

If any of this plant is taken, a quick vomit ſhould be inſtantly given, after which give vinegar in water, to be drank now and then. See VENENUM.

See Lewis's Mat. Med. Lond. Med. Obſ. and Inq. vol. iii. p. 229, &c. 400, &c. vol. iv p. 104, &c. Neumann's Chemical Works. Medical Muſæum, vol. iii. p. 566. Withering's Botanic Arrangement, vol. i. p. 177.

CICUTARIA AQUATICA; —— PALUSTRIS. See PHELLANDRIUM AQUATICUM.

—— VIROSA. See CICUTA AQUATICA.

CICUTARIA. See CHÆROPHYLLUM SYLVESTRE, &c. and MYRRHIS.

CIDRA. See POMACEA.

CIGNUS. A meaſure ſo called, containing about two drams.

CILIA. The extreme parts, or edges of the eye-lids; they are ſemi-circular, and cartilaginous, with hairs fixed in them, which by ſome are called *cilia*. See TARSUS.

CILIARES vel MEIBOMII GLANDULÆ. On the inner edge of each eyelid, in the tarſus, is a row of ſmall holes, which are the excretory ducts of what are called the *ciliary*, or *Meimbomia's glands*; theſe *glands* appear of a whitiſh colour, and are ſituated on the internal ſurface of the tarſus; their ducts are ſhort, reſembling white lines running down towards the edge of the eye-lids. Theſe *glands*, like the miliary ones, ſecern an unctuous matter, which prevents the attrition of the eye-lids from their frequent motion, to keep the edges ſoft and free from excoriation, and to prevent the tears from falling down the cheeks. See TARSUS.

CILIARE LIGAMENTUM, alſo called *proceſſus ciliaris*. It is a range of black fibres, circularly diſpoſed, having their riſe in the inner part of the choroides, and terminating in the prominent part of the cryſtalline, where the ſclerotis, choroides, retina, cornea, proceſſus ciliaris, and iris end; they ſurround the cryſtalline humour, or rather the ſclerotica joins the choroides, and round the edge of the cornea, they adhere firmly; at this circle, the *choroides* (which ſee) ſeems to change its colour and texture, appearing as a whitiſh kind of ring; this ring is termed *ligam. ciliare:* here the internal lamina of the choroides dips inwards, to make what are termed the proceſſes, which are little folds of the inner lamella of the choroides. Theſe folds become broader until they terminate in a broad point in the cryſtalline humour; the whole radiated ring, made by the *ciliary* proceſſes, is ſometimes called *corona ciliaris*. See CHOROIDES.

CILIARIS MUSCULUS. That part of the muſc. orbicularis palpebrarum which lies neareſt the cilia, miſtaken by Riolanus, who gave it this name for a diſtinct muſcle.

CILLO. One who is affected with a perpetual trembling of the upper eye-lid, from *cillendo*, being in continual motion.

CILLOSIS. A trembling of the upper eye-lid.

CILO. One whoſe forehead is prominent, and temples compreſſed, called BEETLE-BROWED.

CIMEX. *Cimex* domeſticus, *cimex* lectularius. The WALL-LOUSE, or BUG, called alſo *cotula*. It is of a rhomboidal figure, a dark brown colour, and hath ſix legs. The ſkin is extremely tender, ſo that it burſts with the leaſt compreſſion, and emits an offenſive ſmell. Six or ſeven are given inwardly to cure the ague, juſt before the fit comes on.

CIMOLIA ALBA, TERRA: called alſo *Creta fullonica, terra candida, terra fullonica, argilla candida, argilla alba, Creta cimolia*. TOBACCO-PIPE-CLAY.

It obtained the name Cimolia from the iſland *Cimolus*, now called Argentiere. It hath nearly the ſame quality with the boles, and is often ſubſtituted for them. Its ſoft viſcous quality is its only medicinal one, and in this particular it excels moſt of the earths of its kind.

The *Cimolia alba* of the ancients ſeems to have been a ſort of looſe marle; probably it was our fuller's earth. In Cornwal there is a ſort of clay called *ſteatites*, which is uſed as ſoap, as well as the *Cimolia alba* of the ancients. This ſort, which is called ſteatites, is marked with a ſeal, and called *terra ſigillata alba*, and ſome call it *terra Samia:* but it is only a fatter pipe-clay.

—— PURPURESCENS TERRA; called alſo *ſmectis, terra ſaponaria Anglica, terra fullonica*, and FULLER'S EARTH. It has its name ſmectis, from σμηχω, *to abſterge*.

It is a kind of marle rather than a compact earth, and of the ſame qualities as bole. Edwards, in his Foſſilogy, ranks it as a ſpecies of bole.

CINA CINÆ. See CORT. PERUV.

CINARA. The ARTICHOKE. Alſo called *ſcolymus, alcocalum, articoca, articocalus, artiſchocus lævis, coſtus nigra, carduus ſativus non ſpinoſus*, cinara hortenſis, *carduus ſativus, ſcolymus ſativus*, cuſara maxima alba, *carduus domeſticus capite majore, carduus altilis*. The ſpecies uſed in medicine is the CYNARA SCOLYMUS *foliis ſubſpinoſis pinnatis indiviſiſque, calycinis ſquamis ovatis*. Var. γ. CLASS, SYNGENESIA; ORD. POLYGAMIA ÆQUALIS. LINN. Gen. Plant. 928.

Boerhaave mentions ſix ſpecies.

Artichokes are ſufficiently known not to require a deſcription; they are natives of the ſouthern parts of Europe, perennial, and cultivated in our kitchen gardens.

The bottoms of the heads, and the fleſhy parts of the ſcales, are eaſily digeſted, though flatulent, and afford but little nouriſhment. The leaves are bitter, and give out their bitterneſs along with the juice, on being bruiſed and preſſed. This juice is powerfully diuretic and uſeful in dropſies; it ſhould be mixed with an equal quantity of white wine, and three or four table-ſpoonfuls taken every night and morning. An infuſion of the leaves is likewiſe diuretic, and may be employed with the ſame intention.

In England we only eat the heads, but the Germans and French eat the young ſtalks after boiling them.

CINARA SPINOSA, called alſo CARDUUS ESCULENTUS VEL SPINOSISSIMUS ELATIOR, *chardone, cactos*. The CHARDON.

As a medicine it is ſimilar to the *artichoke*. It is a culinary plant, which is blanched like celery, and, like that, eaten raw with pepper and ſalt in Italy.

CINARA SYLVESTRIS, alſo called SCOLYMUS SYLVESTRIS, *agriocinara*, wild ARTICHOKE, or CARDONET. They grow in Italy and France, but the flowers are only uſed. See Dale, Ray.

CINARA ACAULIS GUMMIFERA. See CARDUUS PINEA.

CINCHONA. See CORT. PERUVIAN.

CINCLESIS, in Vogel's Noſology, ſignifies a morbid nictitation, or an involuntary winking.

CINCLISIS, or CINCLISMOS, from κινκλιζω, *to ſhake*. Hippocrates means by it a ſmall and repeated motion.

CINERARIUM. The aſh-hole of a furnace.

CINERES RUSSICI. See CLAVELLATI CINERES.

CINERITIUM. See CUPELLA.

CINERULAM. See SPODIUM.

CINETUS. See DIAPHRAGMA.

CINGULARIA CLUBMOS. See LYCOPODIUM.

CINGULUM. A GIRDLE or BELT. Dr. Cheyne, in his Eſſay on Regimen of Diet, &c. ſays, "*Cincture*, with a broad quilted belt about the loins, to keep the bowels in their natural ſituations, and the chylous veſſels in their beſt locality, and in flabby conſtitutions, weak bowels, and atrophies, is of great benefit."

—— MERCURIALE. A MERCURIAL GIRDLE, called alſo *cingulum ſapientiæ & cingulum ſtultitiæ*. It was an invention of Rulandus's; different directions are given for making it, but the following is one of the neateſt.

Take three drams of quickſilver; ſhake it with two ounces of lemon juice until the globules diſappear; then ſeparate the juice, and mix with the extinguiſhed quickſilver, half the white of an egg; gum-dragon finely powdered, a ſcruple; and ſpread the whole on a belt of flannel.

CINGULUM SANCTI JOHANNIS. See ARTEMISIA.

—— SAPIENTIÆ, —— STULTITIÆ, } See CINGULUM MERCURIALE.

CINNABARINUM BALSAMUM. The ſimple balſam of ſulphur is a proper ſubſtitute, and a better medicine, as a pectoral particularly.

CINNABARIS, CINNABAR. Alſo called *cinnab. nativ. minium purum, minium Græcorum, (magnes epilepſiæ*, ſo called, becauſe of its ſuppoſed uſefulneſs in epilepſies), alſo ALZEMAFOR, *ammion, amogabriel, amongabriel, aremaros, azamar, azemaſor, azymar*. VITRUVIUS calls it *anthrax*.

Native *cinnabar*, a ponderous, red, ſulphureous ore of quickſilver. It is found in Spain, Hungary, Eaſt Indies, &c. The fineſt is brought from the Eaſt Indies.

Sometimes it is brought to us in large irregular maſſes, at others it is in ſmaller roundiſh ones, ſmooth without, and ſtriated within; and of a deep red colour throughout.

This ore conſiſts of ſulphur and quickſilver, in the proportion of from four to ſeven parts quickſilver to one of ſulphur;

ſulphur; the finer the colour, the more quickſilver it contains: with theſe conſtituents there is generally much earthy matter, from which it is eaſily ſublimed. If this earth be of the calcareous kind, iron-filings, or ſuch ſubſtances as abſorb quickſilver more than ſulphur does, may be added; ſome of the ſulphur will be detained by them. One part lime, &c. one part iron-filings, is uſually ſufficient for extricating all the quickſilver from four parts of *cinnabar*; or the ſulphur is eaſily ſeparated by boiling the *cinnabar* in a lixivium of wood-aſhes, or rather of decrepitated nitre, and then precipitating it with vinegar. See ARGENTUM VIVUM.

The hete ogeneouſneſs of the native *cinnabar* renders it leſs fit for uſe than the artificial. See Dict. of Chemiſtry, Lewis's Mat. Med. Neumann's Chem. Works.

Cinnabar is a name now confined to the native and factitious ſorts; but formerly it was applied to *dragon's blood*, *madder-root*, *ceruſs calcined to redneſs*, and to ſome other articles.

CINNABARIS ANTIMONII. See ANTIMONIUM.

CINNABARIS FACTITIA. *Artificial* CINNABAR, now called *hydrargyrus ſulphuratus ruber*, RED SULPHURATED QUICKSILVER. It has alſo had the name of *Mercurius cinnabarinus*.

Take of purified quickſilver, forty ounces; of pure ſulphur, eight ounces. Stir the quickſilver into the ſulphur melted; and if the mixture takes fire, it is to be extinguiſhed by covering the veſſel. Then let the matter be reduced to powder and ſublimed. Ph. Lond. 1788.

The quickſilver in the *cinnabaris* is too much reſtrained by the ſulphur to be efficacious as an internal medicine. The factitious or native cinnabar is ſuppoſed never to be active, without having loſt a portion of its ſulphur, though it has been eſteemed an uſeful medicine in diſeaſes of the ſkin; arthritic, rheumatic, and epileptic caſes. Their chief uſe is for fumigating venereal ulcers; in which caſe the quickſilver is reſolved into fume, and blends in part with a volatile vitriolic acid, derived from the ſulphur, forming a mercurial ſalt, from whence its efficacy.

If it is adulterated with red lead, it may be diſcovered by putting a little on a hot iron; for thus the *cinnabar* is all evaporated, and the lead remains behind.

This preparation is uſed by painters under the name of VERMILION; and to improve the colour, the leſs ſulphur uſed, the better; and if a little arſenic be added in the ſublimation, though the preparation is thereby ſpoiled as a medicine, it is more perfect as a pigment.

An oval earthen jar is the beſt ſubliming veſſel. The great art of making this *cinnabar* is firſt to manage the fire ſo as continually to keep the matter ſubliming, yet not ſo as to force its way through the mouth of the veſſel, which is covered with an iron plate. Secondly, to put in but little at a time.

—— GRÆCORUM. See SANGUIS DRACONIS.

CINÆ, SEM. See SANTONICUM.

CINNAMOMUM, alſo called cinnamum, *canella*, *canella Zeylanica*, *laurus Zeylanica*, *caſſia cinnamomea*, *caſſia fiſtula*, *canella cuurdo*, *kurudu*; CINNAMON. The beſt ſort of which the Arabians diſtinguiſh by the term *karfe*, and the ordinary, by *darſini*; the choiceſt ſort by many is called *moſyllon*; the wood of the tree *xylocinnamomum*; and it is alſo called *darchem*.

It is the bark of a tree of the bay kind, growing in the iſland of Ceylon, freed from the outer green or greyiſh part, and cut into long ſlices, which curl up in drying into quills or canes, the form in which it is brought to us; very thin, light, of a reddiſh yellow, or pale ruſty iron colour, ſomewhat tough in breaking, and of a fibrous texture. The tree is the LAURUS CINNAMOMUM, or LAURUS *fol. trinerviis ovato-oblongis, nervis verſus apicem evaneſcentibus, floribus parvis albis.* CLASS, ENNEANDRIA; ORD. MONOGYNIA, LINN. Gen. Plant. 509. The CINNAMON-TREE.

It is often mixed with the caſſia bark, which is thus diſtinguiſhed; the caſſia hath a cloſe ſmooth ſurface, which it ſhews on being broken, and when chewed, it is ſlimy; it is alſo of a dark brown colour, whereas the *cinnamon* is rougher to the ſight and taſte, having an aſtringency and brittleneſs in chewing, and is of a paler brown colour.

It is one of the moſt grateful aromatics, both to the palate and ſtomach, of a fragrant ſmell, moderately pungent, but not fiery, ſweetiſh to the taſte, and ſomewhat aſtringent, but not ſo conſiderable as to be truſted to by itſelf. It likewiſe corroborates the viſcera, and proves of great ſervice in ſeveral kinds of alvine fluxes, and immoderate uterine diſcharges. The fine flavour is ſaid to reſide in the thin pellicle which lines the interior ſurface of the bark, and which abounds with veſicles of eſſential oil; the reſt of the bark, while freſh, being merely aſtringent, receiving its flavour from the inner pellicle; accordingly the thinneſt pieces are the moſt cordial, and the thicker moſt aſtringent. In uſing it we ſhould never loſe ſight of its being ſtimulant and aſtringent, for even the ſimple diſtilled water, when frequently employed, has proved hurtfully irritating to the fauces.

Infuſed in boiling water in a cloſed veſſel it gives out the greateſt part of its virtue. The watery decoction, after diſtillation, yields, on being inſpiſſated, a mild aſtringent maſs, but without the flavour of the *cinnamon*.

Rectified and proof ſpirits extract its virtues better than water, and that without heat; but in diſtillation they carry over very little of the flavour.

An extract made with rectified ſpirit of wine has all the virtue of the ſpice: *cinnamon* affords about 1-16th of its weight of extract.

The London College directs the following waters, viz.

AQUA CINNAMOMI. CINNAMON WATER.

Take of *cinnamon*, one pound; of water, as much as is ſufficient to prevent burning; macerate for twenty-four hours, and diſtil off a gallon. As the oil of *cinnamon* is very heavy, in time it falls to the bottom; and as this water loſes its milky appearance, it loſes alſo its aromatic and cordial quality; to prevent which, ſome let it run upon ſugar, which keeps the oil divided and ſuſpended

AQUA CINNAMOMI SPIRITUOSA. *Spirituous* CINNAMON WATER. *Now called* Spiritus Cinnamomi. SPIRIT *of* CINNAMON.

Take of *cinnamon*, a pound; of proof ſpirit, a gallon; of water as much as is ſufficient to prevent burning. Diſtil a gallon. In diſtilling with proof ſpirit, the ſpirit which ariſes firſt is almoſt flavourleſs; the water which ariſes after, bringing the oil with it, and this oil being diſſolved by the ſpirit, is the reaſon why it is ſo limpid. As the oil of *cinnamon* is the heavieſt of almoſt any vegetable oil, therefore, when *cinnamon* water is diſtilled, uſe a low flattiſh ſtill, and a quick equal fire. As very little of the oil riſes with the ſpirit, the beſt method is firſt to diſtil the *cinnamon* with water only, and then to add a proper quantity of rectified ſpirit of wine.

The aromatic principle in *cinnamon* reſides in the eſſential oil, which ariſes when diſtilled with water, ſlow and difficultly, rendering the liquor rather milky. When a large quantity is diſtilled at once, a ſmall portion of the oil is found ſunk to the bottom of the receiver. To obtain this oil more eaſily and plentifully, let the water, after it is diſtilled, ſtand in a cold place. A pound of good *cinnamon* affords a dram or a dram and a half of this oil, which, if expoſed to the air, loſes its virtue without any ſenſible loſs of its weight; ſo that it is not the oil that is efficacious, but the ſpirit in the oil. The oil of caſſia bark is ſubſtituted for the oil of *cinnamon*; however, as they are the ſame in their medicinal virtues, no objections can be reaſonably made. The ol. canel. alb. is alſo mixed with the ol. *cinnam.* ſo is the ol. caryoph.

Oil of *cinnamon* is one of the moſt immediate and moſt powerful cordials in languors, hiccoughs, and all debilities; it is ſo extremely pungent, that on being applied to the ſkin, it produces an eſchar, though a drop or two may be given in a draught mixed up with a little ſugar or mucilage of gum arabic.

Cinnamon, when freſh, affords much more oil than what is above mentioned; but the Dutch extract great part of it before they ſell it, ſo that the beſt method is to buy it of them. In proportion as the oil is ſeparated, the *cinnamon* loſes its pungency. It is ſaid that the Dutch obtain above an ounce of eſſential oil from every pound If this oil is genuine, and you dip a pen-knife point into it, it will not flame at a candle, but ſmoak; if it ſoon flames, it contains rectified ſpirit of wine. The uſe of the cinnamon tree is not confined to the bark; for the leaves, root, and fruit, all yield oils of different qualities, and of conſiderable value. That produced from the leaves is called oil of cloves, and *oleum malabathri*; from the bark of the root, an aromatic eſſential oil, or what has been called oil of camphor, and of great eſtimation as a medicine, and alſo a ſpecies of camphor, which is much

much purer and whiter than that kept in the ſhops; and that obtained from the fruit, a white ſebaceous matter, extremely fragrant, reſembling the ol. n. m. per expreſſ. of a thick conſiſtence, and at Ceylon is made into candles for the ſole uſe of the king. It is white, and is called *cera cinnamomi*.

The London college directs the following tinctures:

TINCTURE OF CINNAMON.

Take of *cinnamon*, an ounce and a half; of proof ſpirit, a pint. Digeſt without heat, for ten days, and ſtrain. It contains all the cordial and reſtringent qualities of the *cinnamon* itſelf: if it is continued for ſome time daily, it warms and ſtrengthens the ſtomach.

Caſp. Neumann, in his Prælect. Chem. ſays, that a pound of *cinnamon* contains near three-fourths of its quantity of an indiſſoluble earth, two ounces of a reſinous ſubſtance, an ounce and a half of gummy ſubſtance, and about two ſcruples and a half of eſſential oil. See Neumann's Chem. Works, Lewis's Mat. Med. and Cullen's Mat. Med.

TINCTURA CINNAMOMI COMPOSITA. COMPOUND TINCTURE OF CINNAMON. *Formerly the Tinctura Aromatica.* AROMATIC TINCTURE.

Take of *cinnamon* bruiſed, ſix drams; leſſer cardamom ſeeds freed from their huſks, three drams; long pepper and ginger, reduced to powder, of each two drams; proof ſpirit, two pints: digeſt for eight days, and ſtrain. Ph. Lond. 1788.

CINNAM. ALBUM.—*Malabaricum.* See CANELLA ALBA.

—— CRASSIORE CORT. VULG. i. e. MALABATHRUM. See FOLIUM.

—— MAGELLANICUM, vel CORTEX MAGELLANICUS. See CORT. WINTERANUS.

—— MALAB. See CASSIA LIGNEA.

—— SPURIUM, i. e. CORT. CARYOPHYLLOIDES.

CINNIOGLOTTUS CINNATUS. Paracelſus coined theſe words to expreſs the total deſtruction and corruption of mineral bodies.

CINNUM, or CINNUS. See CYCEON.

CINZILLA. See ZONA.

CION, κιων. See UVULA, HIMAS. Hippocrates gives this name to a carunculous excreſcence in the pudendum muliebre.

CIONIA. In Dioſcorides it is the middle part of a whelk or purple fiſh, near the centre of the ſtriæ, which being calcined, is more cauſtic than the other parts.

CIONIS. A painful thickneſs of the uvula.

CIRCÆA, from Circe, the famous inchantreſs. ENCHANTER'S NIGHTSHADE. Called alſo *Dipcæa*. Its leaves reſemble thoſe of the garden nightſhade: the flowers are ſmall and black; the ſeeds are like thoſe of the millet; they are incloſed in a ſort of corniculated capſule; the roots are three or four ſpans long, white, ſcented and heating. It grows on rocky ground, where it is expoſed to the ſun.

Boerhaave ſays, that there are two ſpecies, viz.

Circæa Lutetiana, *ocymaſtrum verrucarium*, or ENCHANTER'S NIGHTSHADE.

Circæa minima, the ſmalleſt enchanter's nightſhade.

The virtues of the firſt ſpecies reſemble the garden nightſhade.

CIRCOCELE, from κιρσος, *varix*, and κηλη, *a tumour*. See CIRSOCELE.

CIRCULATIO, CIRCULATION. For what is underſtood by it in chemiſtry, ſee CIRCULATORIUM and DIGESTIO.

IN ANATOMY it is the *circulation* of any fluid through the veſſels deſtined for its conveyance. But properly *circulation* is only applied to the blood, becauſe it moves from the heart to return to it again; but the other fluids do not return to where they firſt were ſeparated.

Dr. HUNTER ſays, there are only three men who have any claim to the diſcovery of the *circulation*, viz. SERVETUS, SESALPINUS, and HARVEY.

SERVETUS diſcovered the blood going from the right ventricle, by the pulmonary artery, to the lungs, where it was mixt with the inſpiratory air, and returned by the veins to the left auricle, and ſo into the aorta. He traced the *circulation* through the lungs; but, like the old anatomiſts, he attributed the functions of the arteries to the veins.

SESALPINUS ſays, that the blood cannot be returned to the heart by the arteries of the valves, but by the veins, where the paſſage is open; but his ideas were confuſed and neglected. He obſerves, that the arteries and veins come from the heart. He improves greatly upon Columbus, who, in 1559, deſcribed the *circulation* through the heart and lungs. Thus improving on Servetus, he ſhews the uſe of the valves; but ſtill abides in the track of the old anatomiſts. He does not carry the *circulation* from the aorta to the vena cava; but he ſays, the blood cannot return by the arteries, and that it paſſes through the veins. He imagines that the blood is in the arteries whilſt we are awake, and being received into the veins by their anaſtomoſing with the arteries, is returned to the heart whilſt we are aſleep. Here is the *circulation* completed ſo far as that one could not well read it without being ſtruck with the notion, and almoſt convinced of the truth of it. But his account is ſo jumbled with the notions of the ancients, and in other parts of his works he ſpeaks ſo contrary to this, that one would really imagine he did not thoroughly underſtand what he there advanced.

HARVEY led to the diſcovery in full, by a Treatiſe on the Valves of the Veins, in the beginning of the ſeventeenth century. When he firſt publiſhed his Hiſtory of the *Circulation*, its novelty and merit drew upon him the envy of the moſt learned men in Europe, who accordingly oppoſed him; but afterwards, incapable of arguing againſt truth, they ſtrove to rob him of the diſcovery, alleging that it was known to Hippocrates; but this will not bear a controverſy.

However, with regard to the *circulation*, it is thus clearly deſcribed. The blood is conveyed from the left ventricle of the heart by the aorta and its branches to the minuteſt and moſt remote parts of the body, and then paſſing from the extremities of the ſmalleſt arteries into the incipient veins, circulates through them into their larger branches, and ſo on into the right auricle of the heart, thence into the right ventricle, from whence it is forced (with the freſh ſupplies that it receives from the chyle in paſſing through the ſubclavian vein) into the pulmonary artery, and after *circulating* through, and being acted upon by the lungs in its paſſage through them, is returned by the pulmonary vein into the left auricle, and thence into the left ventricle, and ſo on the ſame round, until death concludes the progreſs.

Dr. Shebbeare obſerves, in his Theory and Practice of Phyſic, that during the dilatation of the heart, when the blood enters the ventricles, the coronary arteries receive that fluid, contrary to all the other arteries of the body, and thus ſupply the body of the heart with the blood; and perhaps this blood is partly the cauſe of the vital heat being attracted ſtronger into the heart by the nerves at that time than at any other; though there is another reaſon for its paſſing at this time rather than at any other, viz. the paſſage of the blood is freer through the arteries during the heart's inflation than at the contraction, becauſe thoſe veſſels then approach nearer the direction of a ſtraight line. That the heart is not the one and ſole cauſe of *circulation*, appears, becauſe the arteries all perform their diaſtole at the ſame inſtant, in healthy people. If the heart's propelling the blood was the ſole cauſe of the *circulation*, the pulſation of the artery would be an undulation, and in different parts it would be perceived at different times, as the impreſs at different diſtances of the artery from the heart would be in ſucceſſion.

That ſome other power than the velocity of the blood dilates the capillary arteries to give paſſage to the globules, ſeems evident alſo from the experiments of Dr. Hales. He poured water into the aorta and other arteries of dogs; and though water is ſo much a more limpid fluid than blood, and its force and velocity equal to that given to the blood by the heart, yet it never paſſed by the anaſtomoſes of the arteries and veins, but through the ſides of the arteries; and this ſeems to prove that the arteries are totally ſtopped by the contraction of their fibres, after the vital fire no longer continues to act, and that the force of the heart hath not a power equal to what is required to dilate them. Beſides, it ſhould be remembered, that fire acts momentaneouſly in all the diſtances in which it hitherto hath been tried.

The cauſe of the great velocity of the blood's motion is diſtributed to the whole arterial tube; and the heart, inſtead of moving a weight equal to more than that of the blood, in this way, impels no more than about two ounces, the quantity ſuppoſed to be contained by the ventricle in each diaſtole. See ANIMALIS MOTUS, alſo Haller's Phyſiology, lect. iv. Berdoe on the nature and *Circulation* of the Blood may be conſulted.

The

The *circulation* of the blood in a fœtus hath ſome peculiarities different from what is obſerved in adults. 1ſt, The blood does not all paſs through the lungs; a very ſmall part only each time that it returns to the heart. 2dly, The blood brought by the two venæ cavæ into the right auricle of the heart, paſſes chiefly into the right ventricle, but not entirely, for ſome portion goes immediately through the foramen ovale into the left auricle, and eſpecially that brought up by the cava inferior. Suppoſe then two thirds of the blood got into the right ventricle, in order to paſs along the pulmonary artery; yet all the blood that flows into it in the fœtus will not *circulate* through the lungs, for a conſiderable part muſt neceſſarily paſs by the ductus arterioſus, directly to the aorta, before it hath arrived at the lungs; ſo that probably not above one third of the blood *circulates* through the lungs every time it is brought back to the heart. That blood which was thrown out directly from the right to the left auricle, goes thence to the left ventricle, and ſo on to the aorta, without touching at either the right ventricle or pulmonary artery, and conſequently not coming to the lungs. After the child is born, and a little grown up, the foramen ovale becomes cloſed up in moſt ſubjects, though in ſome inſtances it is found to continue more or leſs open during the whole life of the perſon.

CIRCULATORES. See AGYRTÆ.

CIRCULATORIUM. A CIRCULATORY GLASS. It is a veſſel in which the contained liquor, when put over the fire, performs certain gyrations, and circulates by aſcending and deſcending in ſuch a manner, that the more volatile parts of the liquor, raiſed by the fire, not finding a paſſage, may always fall back again. Thus chemical *circulation* is only a ſpecies of digeſtion. Repeated diſtillation anſwers the end of *circulation*. See DIGESTIO.

CIRCULATUM. According to Boerhaave, the *circulatum* of Paracelſus was a liquor prepared from ſea-ſalt. Paracelſus obtained from this ſalt a perpetual oil, which he called *circulatum* minus, *circulatus ſal minor*, *ens primum ſalium*, *oleum ſalis*, *liquor ſalis*, *aqua ſalis*. He had alſo a *circulatum majus*, which he called alſo *materia mercurii ſalis*, and *ignis vivens*. Different writers aſſert variouſly concerning theſe *circulatums*; and thoſe whoſe curioſity leads to an enquiry into the proceſs for obtaining them, may ſee Barchuſen in his Pyroſophia-Maets, and the Collectanea Chim. Leydenſ. and Blancard's Lexicon Renovatum.

CIRCULATUS SAL MINOR. See CIRCULATUM.

CIRCULI IGNEI. See ECLAMPSIS.

CIRCULUM LACTEUM. See GALAXA.

CIRCULUS. A CIRCLE. Beſides its proper ſignification, it is applied to parts of the body; as by Hippocrates to the balls of the cheeks, the orbs of the eyes, or the cavities which ſurround the eyes, &c. *Circulus* is alſo the name of an iron inſtrument uſed by the chemiſts for cutting off a neck of glaſs veſſels, as retorts, &c. the *circulus* is heated, then preſſed cloſe to the glaſs where it is to be divided; and when the glaſs is hot, a blaſt of cold air, or a few drops of water, divides it, if applied thereto: it is alſo called *abbreviatorium*.

The *circulus* is reckoned among ſurgical inſtruments, figures of which may be ſeen in Scultetus's Armamentarium Chirurgicum, tab. xxii. fig. 6, 7, tab. xliii. fig. 5.

CIRCULUS QUADRUPLEX. See CIRCUS QUADRUPLEX.

——— ARTERIOSUS IRIDIS. It is compoſed of two arteries going round the baſis of the iris. From the arteries of the external lamina are ſent ſeveral ramifications to the circumference of the iris, where they produce a vaſcular circle, called *circulus* arterioſus. From this vaſcular circle, paſs off many ſmaller veſſels, which form themſelves into arches; and from theſe arches ſtill finer veſſels are ſent, which probably ſecrete the aqueous humour.

CIRCUMCALUALIS. See ADNATA.

CIRCUMCISIO. CIRCUMCISION. Albucaſis deſcribes ſeveral methods of performing this operation; but the beſt is to ſtretch the prepuce over the glans, and make a ligature about it, then with a razor cut off all that extends farther. In warm countries, this operation ſeems to be convenient, in point of cleanlineſs; for the glandulæ odoriferæ lying under the prepuce, corrupt, and become acrid, corrode the glans, inflame both it and the prepuce; and thus ſometimes health, as well as neatneſs, may require it.

CIRCUMFLEXUS PALATI, called alſo *muſculus tubæ novus Valſalvæ*, *palato-pharyngæus*, *ſpheno-ſalpingo-ſtaphylinus*, *peri-ſtaphylinus externus*, *tenſor palati*. Of this muſcle VALSALVA was the diſcoverer. It riſes from the ſpinous proceſs of the ſphenoid bone, behind the foramen ovale, which tranſmits the third branch of the fifth pair of nerves, from the Euſtachian tube, not far from its oſſeous part; it then runs down along the pterygoides internus, paſſes over the hook of the internal plate of the pterygoid proceſs by a round tendon, which ſoon ſpreads into a broad membrane. It is inſerted into the velum pendulum palati, and the ſemilunar edge of the os palati, and extends as far as the future which joins the two bones. Its uſe is to ſtretch the velum, to draw it downwards, and to a ſide towards the hook. It has little effect upon the tube, being chiefly connected to its oſſeous part. Innes.

CIRCUMFORANEI. See AGYRTÆ.

CIRCUMGYRATIO. CIRCUMGYRATION. A turning of the limb round about in its ſocket.

CIRCUMLITIO, in general, is any medicine applied by way of unction, or as a litus; but in a particular manner, it is appropriated to ophthalmic medicines, with which the eye-lids are anointed.

CIRCUMOSSALIS. See ADNATA and PERIOSTEUM.

CIRCUMSTANTIÆ. CIRCUMSTANCES. In medicine, they are whatever are not eſſentially neceſſary connected with the principal indicant. Of this kind, in what are commonly called *res naturales*, are the condition of the patient and the part affected; the ſtrength, age, ſex, cuſtom, and way of life. In the *præternaturales*, are the times of diſeaſes, paroxyſm, number, and ſymptoms. In the *non-naturales*, are the air and ſoil. Theſe regulate the conduct of a phyſician.

CIRCUS, QUADRUPLEX; alſo *circulus*. The fourfold circle. It is a kind of bandage; called alſo *plinthius laqueus*. See Galen de Faſciis.

CIRRHUS, rather CIRRUS, from κιρρος, cornu, a horn, becauſe cirri reſemble the figure of horns; one of the fulcres of plants, called alſo *clavicula*, *claviculus*, *tendril*, *claſper*, *capreolus*. That ſpiral ſtring by which ſome plants fix themſelves to other bodies, and has different terms, according to the part from whence it proceeds, or the number of chords of which it conſiſts; as *cirrus axillaris ſimplex*, &c. They are of various textures: ſome of them emit a glue at their termination, by which they ſtick, as well as cling; others have points, by which they ſtick into trees, walls, &c. which points ſerve alſo for roots.

CIRRI. In Pliny, they ſignify the four leſſer claws of the polypus fiſh. See alſo CERÆÆ.

CIRSIUM ARVENSE. See CARDUUS HÆMORRHOIDALIS.

CIRSOCELE, from κιρσος, a *varix*, and κηλη, a *tumor*. It is alſo called *varicocele*, *circocele*, *ramex varicoſus*, and *hernia varicoſa*.

This is an irregular, claſtic tumor of the ſpermatic arteries and veins. Any large tumor in the abdomen, or external force preſſing the veins, or a large tumor of the ſcrotum ſtretching the veſſels, or impeding the return of the blood, may occaſion the veins of the ſcrotum, or the ſpermatic veins, to be dilated with blood; in which caſe, they are alſo here and there diverſified with large and unequal knots, and the teſticles hang lower than in their natural ſtate. But moſtly this diſorder depends on a relaxed ſtate of the veins themſelves.

Sometimes young men of a ſalacious turn, abounding with ſeminal matter, are ſubject to this diſorder, moſtly in the ſcrotum. However, when neither pain nor other troubleſome ſymptoms attend, no regard need to be paid to the caſe, except it be to apply to matrimony for the cure. As this diſorder is ſymptomatical, to remove the circumſtances on which it depends, will be its cure. It ſometimes depends on the preſſure of an hernial truſs upon the ſpermatic proceſs; and then an alteration in the bandage will probably anſwer the purpoſe. If tumors of a ſcirrhous kind are the cauſe, and they are ſo ſituated as to admit of extirpation, let them be removed. However, when the veins have been long diſtended, ſo that their coats are become very weak, inciſions may be made lengthways into them, after which, dreſſing as in a common wound, a cicatrix will be formed, and the return of the complaint prevented. Before inciſions are

made in the veins, it will be proper to try a ſuſpenſory bandage, the cold bath, the application of a ſolution of alum, or other aſtringents. Before opening the knot in theſe veins, it will be proper to try evacuants, lying in an horizontal poſture, by which the courſe of the returning blood is facilitated; the ſcrotum and its contents ſhould be ſupported by a proper bandage, and ſtrengthening embrocations may be applied to the part affected. See Heiſter's Surgery, Bell's Syſtem of Surgery, vol. i. p. 493. Pott's Works, 4to. White's Surgery, 334.

CIRSOIDES. It is an epithet in Ruſus Epheſius for the upper part of the brain. He alſo applies this name to two of the four ſeminal veſſels.

CIRSOS. κιρσὸς. See VARIX.

CISSA. See PICA.

CISSAMPELOS PAREIRA. See PAREIRA BRAVA.

CISSARUS. See CISTUS.

CISSINUM. The name of a plaſter mentioned by P. Ægineta.

CIST, or RIST. A meaſure of wine containing about four pints.

CISTERNA. A CISTERN. A name of the FOURTH VENTRICLE OF THE BRAIN, and of the concourſe of the lacteal veſſels in the breaſts of women who give ſuck.

CISTHORUS, } The *ciſtus*, or ROCK-ROSE; alſo
CISTUS, κίστος, } *ciſſarus*, *ciſtus Creticus*, *Doryenium*. It is a ſhrub which grows in ſtony places: it is full of branches and leaves, but not tall: the leaves are round, black, and hairy. The leaves of the male *ciſtus* reſemble thoſe of the pomegranate tree, but thoſe of the female are white. See LADANUM. Boerhaave mentions ſeventeen ſpecies.

—— HUMILIS. See PARNASSIA.

—— LADANIFERA. See LADANUM.

CISTUS LEDON. See LEDUM PALUSTRE.

CITHARUS. According to Heſychius, it ſignifies the breaſt, the ſide, and a ſpecies of fiſh.

CITRAGO. } See MELISSA.
CITRARIA. }

CITREUM, called alſo *cedro*, *citron*, *malum citreum*, *malus medica*, *malus citria*, citreum vulgare, *mala Aſſyria*. The CITRON-TREE.

It was firſt brought from Aſſyria and Media into Greece, and thence into the ſouthern parts of Europe, where it thrives and produces perfect fruit, called *cedromela*, which is larger and leſs ſucculent than the lemon; but in all other reſpects the *citron* and lemon trees agree.

As to its medicinal qualities, the chief difference from thoſe of the lemon are, that the *citron* juice is leſs acid, the yellow rind is hotter, bitteriſh, and its flavour more volatile, even ſo that it riſes with rectified ſpirit of wine. The citron juice, when ſweetened with ſugar, is called by the Indians *aigre di cedre*.

Oils obtained from the freſh peels of the more odoriferous kinds, by rolling the fruit on a plane ſtuck full of points, are brought from Italy, and uſed as perfumes; theſe are more grateful, and leſs pungent, than ſuch as are drawn by diſtillation with water. The oil prepared either of theſe ways is ſubject to loſe its flavour, and become thick and reſinous in keeping; when diſtilled with rectified ſpirit of wine, and afterwards ſeparated from the ſpirit by dilution with water, it retains much longer its odour, fluidity, and limpidneſs. See Lewis's Mat. Med.

CITRONELLE. So the French name the liquor which we call BARBADOES WATER. Take the dry yellow rind of *citrons* ℔ iii. of French brandy ℔ vi. infuſe cold for a month, then diſtil in B. M. in a retort, with a receiver luted to it. When the ſtrongeſt part of the ſpirit is drawn off, add to the remainder the pulps of the *citrons*; let them macerate five or ſix days; then diſtil, and add what comes over to the former ſtrong ſpirit; add to this mixture as much ſugar and orange-flower water as is needful to render it agreeable.

CITRINATIO. COMPLETE DIGESTION.

CITRINULA. SPEAR-WORT. See RANUNCULUS LONGIFOLIUS, &c.

CITRON. See CITREUM.

CITRULLUS, called alſo *anguria*, *Jace Braſilienſibus*, *tetranguria*; the WATER MELON, or CITRUL. It is the CUCURBITA CITRULLUS, Linn. It is a kind of gourd. The Greeks call it αγγουριον, from αγγος, which ſignifies any veſſel, or receptacle. This name was probably given, becauſe when the pulp was taken out, a veſſel may be made of the ſhell for holding any liquor. The branches run along the ground; the fruit is large, ſometimes as big as a man's two fiſts, and at others as a man's head; the rind is ſmooth, of a green colour, variegated with ſpecks of a paler green, though in this it is not always the ſame. The pulp is grateful to the taſte; the ſeeds are oblong, broad, rhomboidal, and blackiſh. The ſeeds only are uſed in medicine; they are one of the four greater cold ſeeds.

CITRUM. See LIMONUM.

CITRUS AURANTIUM, vel PETIOLIS ALATIS. See AURANTIA HISPALENSIS.

—— LIMONUM. } See LIMONUM.
—— MEDICA. }

CITTA. See PICA.

CIVETA, or CIVETTA. See ZIBETHUM.

CLÆR. A chemical term for the BONE-FLOUR, which is prepared from the bones of the forepart of the cranium of a calf, depurated from the fat by boiling, then calcined to whiteneſs, and levigated finely, afterwards moiſtened with water, and calcined again in an earthen pot cloſed, and after cooling, reduced again to a ſubtil powder, which is ſprinkled through a ſieve upon earthen veſſels, to prevent their contracting chinks.

CLAMOR. A ſolicitous exaltation of the voice.

CLANGOR, or as the Greeks write, Clange, κλαγγη. It is properly the cry of cranes, geeſe, &c. A SHRILL NOISE. Clangoſum de voce dicitur, quæ a gravi tono inchoata in acutum definit. See Ainſworth's Lat. Dict.

CLARETA. See ALBUMEN OVI.

CLARETUM. CLARET, or CLAIRET, a diminutive of *clair*, bright, tranſparent. By this name is generally underſtood an infuſion of aromatic powders in wine, which is afterwards edulcorated with ſugar and honey. This ſort of liquor is alſo called *vinum Hippocraticum*, and by the Germans *Hippocras*; becauſe when the infuſion is finiſhed, it is ſtrained through Hippocrates's ſleeve. It is prepared of various ingredients, according to the intentions to be anſwered.

Extemporaneous *clarets* are made by pouring into thoſe wines a ſmall quantity of tincture, according to the intention, made with ſpirit of wine, which ſome keep under the name of tincture of *claret*. It is alſo a name given by the French to ſuch of their red wines as are not of a deep, or high colour. See VINUM.

CLARIFICATIO. See DEPURATIO.

CLARUM. Any thing made of cryſtal.

CLASIS, } See FRACTURA, from κλαω, *to break*.
CLASMA. }

CLASPER. See CIRRHUS.

CLASSIS. CLASS. An appellation given to the moſt general ſubdiviſions of any thing; thus, ANIMAL is ſubdivided into the CLASSES, *quadrupeds*, *birds*, *fiſhes*, &c. which are again ſubdivided into *orders*, and theſe into *genera*. LINNÆUS, in his botanical arrangement, defines it to be an agreement of ſeveral genera in the parts of fructification, according to the principles of nature diſtinguiſhed by art. He divides the vegetable kingdom into twenty-four claſſes. Noſological writers preſerve ſimilar diſtinctions, dividing diſeaſes into CLASSES, theſe into *orders*, ORDERS into *genera*, and GENERA into *ſpecies* and *varieties*; ſo that we are ſupplied with a concatenation of dependencies: the ORDER upon the CLASS, the GENERA upon the ORDER, the SPECIES and VARIETIES upon the GENERA. See Cullen, Sauvages, Linnæus, &c. Botanical and Noſological Arrangements.

CLAUDIACON. The name of a collyrium in P. Ægineta.

CLAUDICATIO. STAGGERING, HALTING, or LIMPING, as when one leg is ſhorter than the other.

CLAUSTRUM vel CLEITHRON GUTTURIS. The paſſage to the throat, which lies immediately under the root of the tongue and tonſils.

—— VIRGINITATIS. See HYMEN.

CLAUSURA. An imperforation of any canal or cavity in the body. Thus,

—— UTERI, is a preternatural imperforation of the uterus.

—— TUBARUM FALLOPIANARUM. A morbid imperforation of the *Fallopian tubes*, mentioned by Ruyſch as one cauſe of infecundity.

CLAVA RUGOSA. See CALAMUS AROMATICUS.

CLAVATA. The name of a future. See SUTURA.

CLAVATIO. See GOMPHOMA.

CLAVELLATI CINERES, alſo called *alumen catinum*, *ſoda*, *ſal alkali fixum*, *cineres Ruſſici*, *cali*, *kali*, *poteſſa*,

potaſſa, gaſtrinum, gatrinum, alkin, lix. POT-ASH, and PEARL-ASH.

The ancients called the aſhes of burnt wood, LIX; the moderns call them *cineres clavellati*, from clavæ, or clavi, billets, into which the woods were cleft. The Engliſh name *pot-aſh* is from the pots in which the lixivium was boiled.

Pot-aſhes are made in moſt countries that abound with the hard kind of wood; as Scotland, Ireland, Sweden, Pruſſia, Poland, Hungary, Ruſſia, and many parts of North America, from which laſt the beſt is brought to us.

It is produced from the aſhes of vegetable ſubſtances, by diſſolving their ſalt in water, decanting the clear ſolution from the aſhes which ſubſide, and then evaporating the clear liquor to dryneſs.

Oak, aſh, and other trees that ſhed their leaves in autumn, are proper, and the ſmaller ſhrubs, &c. commonly called underwood; but evergreens, as the pine, cypreſs, &c. yield very little ſalt. Fern, bean-ſtraw, and moſt annual plants, afford a large quantity of ſalt; dead trees are ſeldom good, but old hollow trees are the beſt.

The timber may be cut down at any ſeaſon of the year, but ſhould be burnt as ſoon as poſſible. Pieces of eight or ten feet long may be laid in piles, filling the interſtices with the chips and ſmaller wood; then the fire ſhould be kindled at both ends of the pile As ſoon as the pile is burnt down, rake ſuch aſhes as lie thin on the outſide, a little in towards the middle; add no freſh fuel, nor throw on any of the brands. The aſhes muſt lay without being ſtirred, till you can bear your hand in them, and no longer; then place them in a ſhade on a plank floor; there wet them, until they are brought near to the conſiſtence of mortar in the firſt mixture of lime and ſand, or ſo as to ſtick together, and ram them in a heap, in which they muſt continue not leſs than twenty days, but may continue many months. This is called WOOD-ASH.

Kilns are alſo made for the more advantageous burning of wood into aſhes.

Wood-aſhes, put into veſſels with falſe latticed bottoms, covered with clean ſtraw, are to be firmly preſſed together; then cover their ſurface four or five inches deep with ſoft water, and as it ſubſides, add more; place a receiver underneath to receive the ſolution, and continue adding water until the ley is very weak; paſs this ley through a freſh parcel of aſhes, until it is ſtrong enough, which is when it weighs eighteen carats, or more. This ley muſt be conveyed, as it is wanted, into a pan to be evaporated to dryneſs, and the produce is called *pot-aſh*.

If the ley of *wood aſhes*, made ſtrong enough to bear an egg, is boiled briſkly, until a pellicle appears on the ſurface, then gently boiled until it thickens, then continued juſt bubbling until it is very hard, after which taken out in pieces, which muſt be cut out with a cold chiſſel, and ſpread on the floor of a furnace, the middle door of which is to be kept open, and the flues ſtopped up ſo as to make a gentle fire at firſt, and to keep the ſalt juſt covered with the flame: if it is thus continued until it begins to look fair, and incline to look red, then kept red-hot, and turned now and then, until it is of a pearl colour, it is called PEARL-ASH. When this *pearl-aſh* is cold enough to handle, put that which is imperfectly calcined, with ſuch as falls into powder, back into a caldron, with freſh ley. From contact with ſome inflammable matter it hath ſometimes a blue colour, but it ſhould be of a pearl colour.

POT-ASH is ſaid to be a creature of the fire. In ſome parts of Germany it is prepared from the ſame wood of which charcoal is made. A number of tubes made of copper, or of iron, are ſo diſpoſed in the pile of wood intended to be burnt into charcoal, that the water, acid, and oil, which are obtained in ordinary diſtillations, ſhall, when ſeparated from the wood by fire, paſs through theſe tubes into buckets placed to receive them. The oil is then to be ſeparated from the acid liquor, which is then to be boiled in copper or iron veſſels, and the reſiduum dried and calcined. By this calcination, the acid ſalt is alkalized. This method, and the preparation of ſalt of tartar, by calcining tartar, ſhews that vegetable alkali is produced by converſion of an acid to an alkali; but the general practice, wherever *pot-aſh* is made, is to burn wood, lixiviate the aſhes, evaporate the ley, and calcine the produce. Sometimes in calcining, too much heat being admitted, ſome part of the *pot-aſh* will be fuſed, and then it appears of a blue colour, but this circumſtance ſhould be guarded againſt.

PEARL-ASH is entirely ſoluble in water, and is, in all reſpects, the ſame as the fixed ALKALINE SALT. See ALCALI.

POT-ASH, if good, is equal to *pearl-aſh* in every conſideration, particularly if prepared according to Mr. Stevens's method.

The Ruſſian *pot-aſh* contains a large portion of quick-lime.

Pot-aſh often, though carefully prepared, contains ſome portion of neutral ſalt, which is either a vitriolated tartar, or ſea-ſalt. It alſo contains ſome earth. The earth is ſeparable by diſſolving the ſalt in water. The neutral ſalt diſſolves with difficulty. and ſo may eaſily be ſeparated by ſolution in cold water, which readily diſſolves the alkaline ſalt, but leaves the neutral unaffected; or the *pot-aſh* may be left to deliquiate in the air, and thus its ſeparation will be perfect, for no part of the neutral ſalt will be thus diſſolved. The ſea-ſalt diſcovers itſelf by decrepitating, if laid on red-hot iron; and is ſeparated by diſſolving one part of *pot-aſh* in two parts of water, for in this the ſea-ſalt will not diſſolve.

Pot aſh is met with of various colours; but when good, if it is expoſed to the air, it firſt grows clammy, then runs to an oily liquid, which, when dried, leaves an impalpable powder of a whitiſh colour. It hath but little ſmell, and is of a quick, pungent, urinous taſte; does not crumble in ſolution, but diſſolves gradually; it ferments, but does not foam, with acid; and it unites with oil.

As a medicine, the virtues of the alkaline ſalt of *pot-aſh* are the ſame as thoſe of any other vegetable fixed alkaline ſalt.

See ALCALI. Neuman's Chem. Works; Dict. of Chemiſtry, 4to. and Mr. Stevens's Plan for making *Pot-aſh*.

CLAVI SILIGINIS. See Secale.

CLAVICULA. In botany. See CLAVICULUS.

CLAVICULÆ. In ANATOMY, the CLAVICLES. From *clavis, a little key*, So the COLLARBONE is called from its likeneſs to an ancient key, called alſo FURCULÆ, ſometimes *cleidion*, or *elidion*; *claves*.

Each *clavicle* reſembles the Italian letter *ſ*: they bend forwards near the ſternum, and backwards near the ſcapula. They are more ſtrait in women than in men. They are placed almoſt horizontally, between the ſternum and acromion, and are connected to the ſternum by a ſort of arthrodia. At their extremities, next the ſternum, is a ligament, which runs acroſs to the other *clavicle*, and it is connected to the firſt rib likewiſe by a ligament. Theſe bones, by keeping the ſcapulæ in their proper ſituation, ſerve for the more free and eaſy motion of the arms.

CLAVICULUS, vel CLAVICULA. See CIRRHUS.

CLAVIS. IN ANATOMY, the ſame as *clavicula*. IN CHEMISTRY, it is any menſtruum, particularly of minerals, which unlocks them, as it were, and penetrates to their inner ſubſtance.

CLAVUS. An inſtrument in ſurgery mentioned by Amatus Luſitanus, which was deſigned to be introduced into the ulcerated palate, for the better articulation of the voice. Sometimes this word ſignifies indurated tubercles of the womb. Alſo

——— A CORN. Called likewiſe *callus*, *condyloma* and *tylloma*. Dr. Cullen defines it a lamellated hard thickening of the cuticle. He ranks it as a genus of diſeaſe in the CLASS, LOCALES, and ORD. TUMORES.

Corns are a ſort of horny excreſcence growing on the feet and toes, and on the hands of labouring people. Theſe calloſities reſemble an inverted wart, and are ſeated in the cutis and cuticle, ariſing chiefly from preſſure and attrition, and are exceſſively painful when rooted near a tendon. The eaſieſt and beſt way to get rid of them, is to take off all uneaſy preſſure, and apply a piece of plaſter, ſpread with ſoap, or plaſter of litharge, little more than the ſize of the corn, which may be cloſe on the part for four or five days together, to render its ſurface ſoft, and that part which appears ſodden pared away, but by no means ſo low as to touch the quick, after which the plaſter is to be renewed, and the whole proceſs may be repeated in five or ſix days, till the *corn* appears likely to turn out at the root, or waſte away. Soaking the part in bran and warm water, is very uſeful previous to each cutting. Hog's gall dried in the bladder, ſpread thin upon rag and applied to the *corn* only has often proved efficacious; it is apt to inflame the part a little, but the *corn*

generally

generally withers after a few applications of this kind, and turns out at the root. See White's Surgery, alſo Bell's Surgery, vol. v. p. 539.

CLAVUS HYSTERICUS. A ſymptom attending ſome hyſteric patients, which is thus deſcribed by Sydenham: "Hyſterics ſometimes attack the external part of the head, between the cranium and the pericranium, occaſioning violent pain, which continues fixed in one place, not exceeding the breadth of one's thumb; and it is alſo accompanied with enormous vomiting." See CEPHALALGIA. Such again attends a venereal caries, or an exoſtoſis of ſome bone of the cranium.

——— OCULORUM. See STAPHYLOMA.

CLEIDION, vel CLIDION. An epithet of a paſtil deſcribed by Galen and P. Ægineta. It is the name of an epithem, deſcribed by Actius. Sometimes it ſignifies the ſame as *clavículæ*.

CLEIDOMASTOIDEUS. See CLINOMASTOIDEUS.

CLEISAGRA, from κλεὶς, the *clavicle*, and ἄγρα, a *pain*. See ARTHRITIS.

CLEITHRON. See CLAUSTRUM.

CLEMA. A twig or tendril of a plant.

CLEMATIS. See ATRAGENE and VINCA PERVINCA.

CLEMATIS RECTA. See FLAMMULA JOVIS.

CLEMATITIS PERUVIANA. See BEXUGO.

CLEONIS COLLYRIUM. The name of a collyrium deſcribed by Celſus.

CLEONIS GLUTEN. Is mentioned by Oribaſius, lib. iv. and recommended for reſtraining fluxes; it conſiſts of terra Samia, myrrh, grains of frankincenſe, of each equal parts; the white of egg, a ſufficient quantity; ſpread on linen cloth, to be applied to the temples, and forehead.

CLEPSYDRA, from κλέπτω, *to conceal*, and ὕδωρ, *water*. Properly an inſtrument to meaſure time by the dropping of water through a hole from one veſſel to another; but it is uſed to expreſs a chemical veſſel perforated in the ſame manner. It is alſo an inſtrument mentioned by Paracelſus, contrived to convey ſuffumigations to the uterus.

CLIBANUS. A little portable oven.

CLIDION. See CLEIDION.

CLIFTON-WATER This well lies a mile from Deddington in Oxfordſhire. It is a weaker water of the ſame ſort with TILBURY, which ſee.

CLIMACTERICUS ANNUS. From *climacter*, *a round of a ladder*. The CLIMACTERIC YEAR. According to ſome, this is every ſeventh year; but others reckon only thoſe years that are produced by multiplying ſeven by odd numbers, viz. 3, 5, 7, 9, to be *climacterical*. Theſe years they ſay bring with them ſome remarkable changes with reſpect to health, life, or fortune. The grand *climacteric* is the ſixty third year; ſome making two, add to this the eighty-firſt year. The other remarkable ones are the ſeventh, twenty-firſt, forty-ninth, and fifty-ſixth. The credit of *climacteric* years depends on Pythagoras's introduction of the doctrine of numbers.

CLIMAX, alſo called *ſcala ſacra*. A name given by the ancients to ſome antidotes, the ingredients in which gradually diminiſhed in quantity, e. g. Chamædryo ℥iij. centaurii ℥ij. hyperici ℥j. See PULVIS AD RHEUMATISMUM, under CHAMÆDRYS.

CLIMIA. See CADMIA.

CLIMIA EREPS. Rulandus explains it by cadmia auripigmenti.

CLINICUS, from κλίνη, *a bed*, alſo *cataclines*. CLINICAL. It is applied to patients who keep their beds. Hence a *clinical* phyſician is one who attends the ſick.

CLINOIDES. The four ſmall proceſſes of the os ſphenoides, which form the *ſella turcica*, from εἶδος, *reſemblance*, and κλίνη, *a bed*.

CLINO-MASTOIDEUS vel CLEIDOMASTOIDEUS. See MASTOIDEUS MUSCUL.

CLINOPETES. A perſon who, on account of great weakneſs, or any diſorder, is obliged to lie in bed, or on a bed.

CLINOPODIUM. See MARUM.—*Majus acinos*. See BASILICUM.

CLISSUS. In Paracelſus, it is a certain virtue, or occult viciſſitude of things, which go and return; thus the flowers of all vegetables grow flaccid in the evening, but revive, and are expanded in the morning. It is alſo a chemical technical term, and denotes mineral compounded ſpirits. But particularly antimony is conſidered. Baſis clyſſi. Hence ſpiritus antimonii, is called CLYSSUS.

CLITORIDIS FLOS TERNATENSIBUS. A beautiful flower growing in the iſland of Ternate. The inhabitants boil and eat it; but it hath no medical virtues attributed to it.

CLITORIDIS MUSCULUS. Innes calls it *erector clitoridis*, and deſcribes it as ariſing from the crus of the os iſchium internally, and in its aſcent covers the crus of the clitoris, as far up as the os pubis It is inſerted into the upper part of the crus and body of the clitoris. Its uſe is to draw the clitoris downwards and backwards, and may ſerve to make the body of the clitoris more tenſe, by ſqueezing the blood into it from its crus.

CLITORIS, called alſo *æſtrum Veneris*, *columella*, *dulcedo Veneris*, *epideris*, *hypodermis*, *myrtus*. It is a part of the external pudenda, ſituated at the angle which the nymphæ form with each other. In the angle between the labia externa, and the upper angle, we obſerve the prominent extremity of the *clitoris*, which is covered with a preputium ſimilar to that of the penis. It is very vaſcular and villous; the villi are very nervous, and full of veſſels, to occaſion a greater irritation in coitu. The *clitoris* is in many reſpects analogous to the penis; the two *crura clitoridis*, which are two ſpongious bodies, and form the clitoris by their union, ariſe from the iſchium, and running along the lower edge of the os pubis and the os iſchium, unite, to form the corpora cavernoſa of the *clitoris*. It is furniſhed with two erector muſcles, whoſe origin and inſertion are the ſame as in the penis; but though the *clitoris* has a glans, there is no corpus ſpongioſum urethræ; its trunk is ſuſtained by a ſuſpenſory ligament, fixed in the ſymphyſis of the oſſa pubis. Like the penis it has an erection, and it is thought to be the principal ſeat of venereal pleaſure.

The *clitoris* is of different ſizes in different women; but in general, it is ſmall and covered with the labia.

The preternaturally enlarged *clitoris* is what conſtitutes an hermaphrodite.

When the *clitoris* is too large, it is ſtyled *cercoſis*, and may be ſo extirpated as to remove the unneceſſary part; but this requires much care, for a farther extirpation ſubjects the patient to an involuntary diſcharge of urine.

CLITORISMUS. A morbid enlargement, or ſwelling of the clitoris,

CLOACA. A JAKES. In comparative anatomy, it imports the canal in birds, through which the egg deſcends from the ovary in its exit. In this it is remarkable, that the part which is next the ovary is jagged like the morſus diaboli, and fluctuates in the abdomen without any attachment to the ovary; hence anatomiſts have been puzzled to comprehend by what means the egg falls into it.

CLONICUS. See CLONOS,

CLONICI. Diſeaſes from clonic ſpaſm. See SPASMUS CLONICUS.

CLONODES. An epithet for a ſort of pulſe which is vehement and large, at the ſame time unequal in one and the ſame ſtroke.

CLONOS. Κλόνος, alſo *clonicus*. Any tumultuary, interrupted, or inordinate motion. It is applied to the epileptic and convulſive motions. See SPASMUS CLONICUS.

CLOUS. See CARYOPH. AROMAT.

CLUNES. The BUTTOCKS, called alſo *ephidſama pygæ*. Theſe are the two poſterior and lower parts of the abdominal cavity; and are ſeparated by a foſſa, which leads to the anus, and each buttock is terminated downwards by a large fold, which diſtinguiſhes it from the reſt of the thigh. They conſiſt of ſkin, fat, and muſcles, principally thoſe of the glutæi.

CLUNESIA. See PROCTALGIA.

CLUPEA. See ALOSA.

CLUS. & CLUS. HIST. An abbreviation of Caroli Cluſii rariorum Plantarum Hiſtoria.

CLUS. HISP. An abbreviation of Caroli Cluſii rariorum aliquot ſtirpium per Hiſpanias obſervatorum Hiſtoria.

CLUS. CUR. POST. An abbreviation of Caroli Cluſii Curæ Poſteriores.

CLUTTONI DOM. SPIRITUS FEBRIFUGUS. See FEBRIFUGUS SPIRITUS, &c.

CLYDON. A fluctuation and flatulency in the ſtomach and inteſtines.

CLYMA. The fæces of ſilver and gold.

CLYMENUM ITALORUM. See ANDROSÆMUM.

CLYPE-

CLYPEALIS CARTILAGO. See ASPERA ARTERIA.

CLYPEUS. It is ſuppoſed to be an inſtrument uſed in the ancient baths, to increaſe or diminiſh their heat, by admitting or excluding air.

CLYSMA. See CLYSTER.

CLYSSIFORMIS DISTILLATIO. A diſtillation of ſuch ſubſtances as are ſubject to take fire, and fulminate, by a tubulated retort.

CLYSSUS. *Cliſſus* vel *Cliſtus*. Among the ANCIENT CHEMISTS, this word imported an extract prepared of various ſubſtances mixed together. Among the MODERNS, it ſignifies a mixture, containing the various productions of one ſubſtance united with each other: e. g. when the diſtilled water, the ſpirit, the oil, the tincture, and the ſalt of wormwood are ſo blended, that the mixture is poſſeſſed of all the united virtues of the ſimple, from which theſe preparations are obtained. *Cliſſuſes* were formerly prepared from the vapours of different matters joined with nitre; ſeveral inſtances of which may be ſeen in the Dictionary of Chemiſtry; and as their virtues merit not the trouble of preparing them, the curious are referred thereto.

CLYSSUS ANTIMONII, } It is obtained by deflagrating
——— MINERALIS, } a mixture of antimony, nitre, and ſulphur, in a red-hot retort, fixed to a receiver, in which is ſome water. But as it is no other than a weak ſpirit of ſulphur, it is not worth the labour of preparing. See Dict. of Chemiſtry, and Neumann's Chemical Works.

CLYSTER. A CLYSTER, alſo CLYSMA. From Κλυζω, *to waſh* or *cleanſe out*. See ENEMA.

CNAPHOS. See HIPPOPHÆS.

CNECUS. See CARTHAMUS; alſo the ſeeds of the carthamus.

CNEMIU. Galen expounds it, ſomething belonging to the tibia.

CNEMODACTYLÆUS. See EXTENSOR DIGITORUM LONGUS.

CNEORON. See THYMALÆA.

CNESIS, } Κνησις, the ſame as *cniſmos*, and *cnyma*,
CNESMOS, } from κναω, *to ſcratch*. That eager, hurrying ſcratching obſerved in brutes; but is more generally meant of the itching itſelf.

CNESTON. It is a ſpecies of thymalæa; a RASP, which is alſo called cneſter, and particularly a raſp for ſcraping cheeſe.

CNESTRUM. See THYMALÆA.

CNICELÆON, from κνικος, *cnicus*, and ελαιον, *oil*. Oil made of the ſeeds of *cnicus*. The virtues are the ſame as of the ol. ricin. only weaker.

CNICION. A name of the trifolium.

CNICUS. The heads are ſurrounded with a crown, formed of a complication of a multitude of leaves. Boerhaave ſpeaks of nine ſpecies, among which are the *carduus benedictus*, the TANGIER PERENNIAL BLUE DISTAFF THISTLE, the *cnicus* Hiſpanicus arboreſcens fœtidiſſimus, STINKING SPANISH TREE-DISTAFF THISTLE, *carduus pinea*, which ſee.

CNICUS, ſee alſo ATRACTYLIS. That uſed as a purge by Hippocrates, is ſuppoſed to be the *carthamus*, which ſee: but modern botaniſts exclude it from the ſpecies of this plant.

——— ALBIS MACULIS NOTATUS. See CARDUUS LACTEUS SYRIACUS.

——— SYLVESTRIS. See CARDUUS BENEDICTUS.

CNIDE. See URTICA.

CNIDELÆON. Oil made of the cnidia grana.

CNIDIA COCCUS. See THYMALÆA.

——— GRANA. CNIDIAN BERRIES; called *Ætolion*. *Cocca cnidia*. *Coccalos*. *Coccum*. *Gnidia grana*. Some ſay theſe are the fruit of the thymalæa, which ſee; others of the mezereon. Ray ſays, the berries of the thymalæa are not the grana *cnidia*, but the ſeeds contained in the berry.

CNIDOSIS. An itching and ſtimulating ſenſation, ſuch as is excited by the cnide, or nettle. Celſus renders it prurigo.

CNIPOTES. ITCHING. Some take it to ſignify a dry ophthalmy.

CNISMOS. See CNESIS.

CNISSOREGMIA, from κνισσα, *a nidorous ſmell*, and ρηγνυμι, *an eructation*. A nidorous eructation.

CNYMA, from κνυω, *to ſcrape*, or *grate*. In Hippocrates it ſignifies a raſure, punction or vellication; and alſo the ſame as *cneſmos*. See CNESIS.

COAACHIRA INDORUM. See INDICUM.

COACUS. An epithet of a treatiſe of Hippocrates, called Coacæ Prænotiones, from Cos, his birth-place.

COAGULANTIA. In general ſuch things as coagulate fluids; but in medicine it ſignifies more particularly ſuch remedies or poiſons as coagulate the blood and juices flowing from it.

COAGULATIO. COAGULATION, is when a fluid, or ſome part of it, is rendered more or leſs ſolid. This is variouſly effected, and from the different methods, as well as means, the appellations vary.

Heat and cold are the two principal natural agents for *coagulating* fluids. When heat is uſed by art, its effect is called *coagulatio* per ſegregationem, vel ſeparationem. When cold is thus made uſe of, its effect is called *coagulatio* per comprehenſionem, which is when no part of the fluid is loſt, and all its parts are brought into a ſolid ſtate.

Different means *coagulate* different matters; thus heat *coagulates* ſalts by diſſipating their moiſture; cold *coagulates* water by freezing it; water *coagulates* camphor, if it is diſſolved in ſpirit of wine; ſpirit of wine, if pure, *coagulates* the white of egg and other matters; and motion *coagulates* milk into butter.

The *coagulatio*-continua is produced either by impaſtation, that is, when powders, &c. are mixed with the fluid; or by condenſation, that is, when coldneſs is applied to water ſo as to congeal it.

The *coagulatio*-partis is when one ſubſtance ſo adheres to another, as to form a more ſolid body; for example, dry things with moiſt, oil with water, &c.

The *coagulatio*-totius is preternatural, when heterogeneous matter is united; and natural, when homogeneous fluids are coagulated by way of generation.

COAGULUM. Curdled concretions, formed by the mixture of two liquors, are thus called; ſuch as the curd for cheeſe, ſeparated from the ſerous part of milk, by means of rennet infuſed in warm water, &c. It means alſo RENNET, or RUNNET; and is the concreted milk found in the ſtomachs of ſucking quadrupeds, which as yet have received no other nourithment than their mother's milk. In ruminating animals, which have ſeveral ſtomachs, it is generally found in the laſt, though ſometimes in that which is contiguous.

If *rennet* is dried in the ſun, and then cloſe kept, it may be preſerved in perfection for years.

Not only the *rennet* itſelf, but alſo the ſtomach in which it is found, curdles milk, without any previous preparation. But the common method is, to take the inner membrane of a calf's ſtomach, clean it well, ſalt and hang it up in brown paper: when this is uſed, the ſalt is waſhed off, then it is macerated in a little water during the night, and in the morning the infuſion is poured into the milk to curdle it.

The medicinal qualities of *rennet* are its acrimony, reſolvent power, and uſefulneſs in ſurfeits from food of difficult digeſtion.

COAGULUM ALUMINIS, called alſo *cataplaſma aluminis*. In ophthalmia it is found very ſerviceable, particularly in that ſpecies called purulent, applied between two pieces of fine ſoft linen rag. It is alſo very effectual as a remedy for chilblains. See alſo ALUMEN.

COALESCENTIA. COALESCENCE. The union, or growing together of two bodies, which before were ſeparate.

COALTERNÆ FEBRES. Fevers mentioned by Bellini, which are moſt probably imaginary. He deſcribes them as two fevers affecting the ſame patient, and the paroxyſm of one approaching as that of the other ſubſides.

COARCTATIO. COARCTATION. A rendering the canals more narrow, or contraction of the diameters of the veſſels. A *coarctation* of the pulſe is its diminution of the capacity of the arteries.

COARTICULATIO. See ARTICULATIO.

COATLIS. See BEN.

COAVA. The infuſion of coffee, as it is uſually drank. See COFFEA.

COBALTUM, called alſo *cadmia metallica*. COBALT. It is a ponderous hard foſſil, or metallic and earthy mineral, or a kind of marcaſite. It hath been found in ſome parts of Aſia, is now chiefly dug up in Saxony, and alſo met with in ſome parts of England. The beſt way of diſtinguiſhing it from other mineral matters, is to turn it into glaſs, or to melt it therewith, for it gives thereto a ſapphire blue colour.

Cobalt is the foundation of *ſaphera*, *zaffer*, or *ſmaltum*; and from it the greateſt quantity of arſenic is obtained, that is uſed all over Europe.

The *cobalt*, when dug up, is mixed with various other

ſubſtances; it is then broken into ſmall pieces, and calcined in a reverberating furnace, ſo formed as that the flame of the fire may paſs over the calcining matter, and keep it ignited: the flame, in paſſing over the *cobalt*, carries off a copious fume, which is conveyed from the top of the furnace into a large winding wooden chimney, which is ſome ſcores of yards long, to the inſide of which the fumes adhering in the form of a white ſoot, are at proper intervals ſwept down, and when melted form the white arſenic.

After the arſenic is thus ſeparated, the *cobalt* is calcined two or three times; and then being finely ground with two or three times its weight of powdered flint, with which being melted, ZAFFER is produced. The zaffer being powdered and waſhed, the whitiſh part that ſeparates from it thereby, is called *eſchel*, and the blue powder is named *blanc turbe*.

If two parts of calcined *cobalt*, one part of pot-aſh, and three parts of common ſand, are melted together, a vitreous, opake, bluiſh maſs is formed, which when ground to powder is called *ſmaltum*, SMALT, or *encauſtum cæruleum*, POWDER-BLUE.

Biſmuth, ſmall portions of ſilver, and other matters, are found in different parcels of *cobalt*.

On the outſide of the mines where *cobalt* is found, there is a mineral of the colour of ſtreaked roſes, called the FLOWER OF COBALT.

The chief uſe of this mineral is for obtaining arſenic, and the reguline part, which is the blue made uſe of for colouring glaſs, china, and other ſuch like manufactures. See Lewis's Mat. Med. Dict. of Chem. 4to. and Neumann's Chem. Works.

COBASTOLI. ASHES.

COBBAN. A ſmall tree much like the peach-tree. It grows in Sumatra: the fruit quenches thirſt, and the kernel affords an oil by expreſſion, which is externally uſed againſt pains. Raii Hiſt.

COBHAM-WATERS. Theſe ariſe from a ſpring which lies a mile ſouth from Church Cobham, about twenty-four miles from London. It is conſidered as one of the weaker ſaline purging waters. See AQUÆ CATHARTICÆ AMARÆ.

COBRA DE CAPELLO. A venomous ſerpent, which is alſo called *ſerpens Indicus coronatus*, *vipera Indica vittata geſticulatio*, *vipera pileata*. The INDIAN SERPENT. The part in uſe is a ſtone taken out of its head, called *pedra del cobra*, and by miſtake *piedra di cobra*: it is of an oval figure, plain on the outſide, and gibbous on the other, of a brown colour, ſhining, with pores interſperſed. It is ſaid to be an antidote to the poiſon of venomous animals; but neither this quality, nor the truth of its being a natural production are aſcertained. For the Pierres de Cobras are diſcovered by FELIX FONTANA to be artificial productions, and to conſiſt only of calcined hartſhorn.

COBRE VERD. See BOJOBI.

COBRELLO. See EPILEPSIA.

COBUS DE CIPO. See BOITIAPO.

COCAO AMERICÆ. See CACAO.

COCCA BAPTICA. See CHERMES.

——— CNIDIA, or GNIDIA, } See CNIDIA GRANA.
COCCALOS. }

COCCARIUM. The name of a very ſmall pill mentioned by Oribaſius in his Synop. lib. iii.

COCCEIRA INDICA. See PALMA COCCIFERA.

COCCI CNIDII. See LAUREOLA FŒMINA.

——— ORIENTALES. See COCCULUS INDUS.

——— RADICUM. See CHERMES.

COCCIÆ MINORES PIL. *colocynth.* pil. cum aloe. See CATHARTICUM EXTRACTUM.

COCCINILLA, alſo called COCCINELLA, *ficus Indiæ grana*, *ſcarabæolus hæmiſphericus*, *cochinelifera cochenilla*, *coccus Americanus*, *cochinelle*, *cochinille*, *cochinilla*, *cochinille*, *coccus Indicus tinctorius*, COCHINEAL.

It is an inſect, but, as brought to us, appears in little grains, that are wrinkled, of an irregular figure, convex on one ſide, and flat or hollow on the other; externally they are of a dark red colour, generally ſprinkled with a whitiſh clammy powder; internally of a deep bright red. It is brought from Mexico and New Spain; and found adhering to the leaves and branches of the OPUNTIA, called *nochetzli*, *nopalli*; or *nochezuapatli* in New-Spain, or the AMERICAN PRICKLY PEAR-TREE, or INDIAN FIG. COCCUS CACTI, CACTI COCCINELLIFERI, Linn. The natives carefully collect, preſerve, and cure them. The male inſects have wings, and are about the ſize of a flea; the females have no wings, and are larger: when full of young they ſwell ſo as to reſemble berries, in which ſtate they are ſwept off from the leaves and branches of the *opuntia* with a pencil: if left until the young ones creep out, the parent dies, and its body becomes an empty huſk. It is the female ſort that we uſe.

The greateſt conſumption of this article is amongſt the ſcarlet dyers, and for making carmine. By different management it affords all the ſhades of red, from the loweſt to the higheſt.

Carmine is a fecula or powder that ſettles at the bottom of the water wherein *cochineal* hath been mixed; with this the drapers rub ſcarlet cloth where it miſſes to take the dye.

Aq. regia, impregnated with pewter, improves the Bow ſcarlet into a flame colour.

Aq. fortis, impregnated with pewter, produces from *cochineal* a ſcarlet dye.

Cochineal affords alſo the fineſt lake.

Rags dyed in the dregs of the ſcarlet dye made from *cochineal*, take the name of TURNSOLE, which is uſed to colour wines, &c.

Cochineal gives a fine durable red to proof and rectified ſpirit, and a deep durable crimſon to water, and none of them loſe any of their colour by inſpiſſating them to an extract.

This inſect hath been commended as diuretic, diaphoretic, and corroborant. See Neumann's Chem. Works; Dict. of Chem. Lewis's Mat. Med. But in the preſent practice, they are very properly conſidered of no uſe, except as a colouring ingredient.

COCCOBALSAMON. The fruit of the true balſam.

COCCONES. The grains or acini of the pomegranate. See GRANATA MALA.

COCCOS. See PALMA COCCIFERA.

——— or COCCUM. In Hippocrates, when without any addition, it ſignifies the *cnidia grana*: but *coccus* implies any berry or grain.

COCCULI INDI AROMATICI. See PIPER JAMAICENSE.

COCCULUS INDUS, called alſo cocculæ officinarum, *cocci orientales*. INDIAN BERRY. It is a brown fruit, of the ſize of a very large pea; it is rough, brittle, and when perfect hath a white kernel. It is brought from Malabar and the Eaſt Indies, where it grows in cluſters on a large tree called *natſiatam*. It is poiſonous; it brings on a nauſea, fainting, and convulſion, if ſwallowed. The noxious quality reſides in the kernel, and it operates both as an emetic and purgative. It is only uſed externally, and that very rarely: made into ointment, or infuſed in water, it deſtroys lice more effectually than the ſtaves-acre. Mixt with paſte it ſtupifies fiſhes ſo that they will lie on the water and not attempt to eſcape from the hand that takes them. Condronchius wrote a treatiſe on theſe berries. Wepfer takes notice of ſeveral experiments made with them in his work De Cicuta Aquatica. See alſo Raii Hiſt. and Neumann's Chem. Works.

COCCUM. See CNIDIA GRANA.

COCCUM BAPHICUM, *infectorium*, *tinctorium*, *chermeſinum* vel *ſcarlatinum*. See CHERMES.

COCCUS AMERICANUS, } See Cocc-
——— INDICUS TINCTORIUS. } NILLA.
——— DE MALDIVIA. See PALMA COCCIFERA.
——— POLONICUS. } It is ſaid to be
——— RADICUS TINCTORIUS. } found of different

ſizes, from a poppy-ſeed to a pepper-corn, and in greater or leſſer numbers adhering to one plant. Breynius deſcribes it as being round, ſmooth, and of a purple violet colour; it has a thin ſkin, incloſing a blood-red juice; one half or more of it is covered with a rough dark-brown cruſt, by which it adheres to the roots. It is gathered in ſummer and dried in earthen platters. One of theſe expoſed to the ſun, by the latter end of July produces a ſmall worm, which worm, after a few days, produces from 50 to 100 or more eggs; theſe in a month after are hatched, and the young ones fixing to the roots of the plant, and its loweſt branches, live by ſucking its juice. Theſe berries are uſed as a colour in dying, for they abound with a purple juice. As a medicine, their virtues are the ſame with the chermes, and for theſe they are a good ſuccedaneum. See Neumann's Chem. Works, and Raii Hiſt. Plant.

COCCYGÆUS Muſc. It riſes from the ſpine of the iſchium, and is inſerted into the ſide of the os coccygis: this muſcle and its fellow form a ſling to bring that bone upwards

upwards and inwards. It is nothing elſe but a continuation of the poſterior part of the levator ani. It is Winſlow's *coccygæus poſterior*.

COCCYGÆUS ANTERIOR, called alſo *Iſchio-coccygæus*. This muſcle is fixed in the anterior portion of the ſmall tranſverſe ligament, at the upper part of the foramen ovale of the os innominatum; from thence it runs between the great tranſverſe ligament of the pelvis and the muſculus obturator internus, and is inſerted in the lower part of the os *coccygis*.

——— POSTERIOR. This muſcle is fixed to the inner concave edge of the two firſt vertebræ of the os ſacrum, to the inner and lower edge of the ligamentum ſacro-ſciaticum, and to the ſpine of the os iſchium, and is inſerted in the inſide of the os coccygis, above the *coccygæus* anterior, it is called alſo *ſacro coccygæus*.

COCCYGIS OS. Alſo called *cauda*; *coccyx*; *oſſis ſacri acumen*. It is ſituated at the extremity of the os ſacrum, and is in ſome meaſure an appendix thereof; it is bent forward towards the pelvis; the fore ſide is flat, the back part rather convex; it is made up of four or five pieces, like falſe vertebræ, joined together by cartilages, more or leſs pliable; ſometimes all the pieces are cemented together. The firſt piece is the largeſt; it hath two ſhoulders, betwixt which and the os ſacrum is a notch, through which a pair of nerves paſs. The other pieces are irregular ſquares, diminiſhing in ſquares as they deſcend.

Daventer and ſome other writers ſay, that difficult labours are often cauſed by theſe bones being anchyloſed; but experience manifeſts that theſe gentlemen were ſometimes impatient, and waited not always long enough for nature to do her own buſineſs: for it is generally found that when the head is confined in the pelvis, and advances but ſlowly, or not at all, by waiting and leaving the work to nature, the head is moulded into the ſhape of the pelvis, and comes along very well.

COCCYS. See PALMA COCCIFERA.

COCCYX. See COCCYGIS OS, κόκκυξ.

COCCHENILLA. } See COCCINILLA.
COCHENILLE. }

COCHIA. A name formerly of ſome officinal pills: the etymology of this word is obſcure. There were two compoſitions bearing this name; the pil. *coch.* majores, which were taken from Rhaſes, and the pil. *coch.* minores, which were taken from Galen: the firſt is totally excluded from practice; the ſecond is called *pil. colocynth. cum aloe*, or *extractum colocynthidis compoſitum*. See COLOCYNTHIS.

COCHINILLA. } See COCCINILLA.
COCHINILLIFERA. }

COCHLEA, } Called alſo *antrum buccinoſum*. The
COCHLIA, } firſt mention made of this part of the
COCHLIAS. } ear is by Plutarch, who ſays that Empedocles, a ſcholar of Pythagoras, was acquainted with it and its uſe, for he ſaid that ſounds were formed there. It is a winding cavity, which turns round a nucleus in a ſpiral manner. It is larger where it begins, and becomes ſmaller like a horn, the ſecond turn almoſt within the firſt, and the third within the ſecond, making about two turns and a half. It is divided into a ſuperior and inferior cavity, by a partition in the middle, perpendicular to the axis of the ſpindle of the *cochlea*: that part of the partition next the axis is bony, which terminates in an edge, where it is membranous; it grows narrower towards the apex. The ſcala, which is next the baſis, opens into the tympanum by the feneſtra rotunda; that towards the apex into the veſtibulum by the feneſtra ovalis.

That the *cochlea* is a part of the organ of hearing, may be concluded from its ſpiral lamina, which is hard, dry, ſlender and eaſily broken; all which conditions are required in bodies ſuſceptible of tremulous motions. Again, when the large branch of the portio mollis of the ſeventh pair of nerves ariſes at the baſis of the *cochlea*, it is divided into a great number of ſmaller branches, which paſſing through all the ſmall meatuſes with which the ſpindle is perforated, are diſtributed to the various windings and meanders of this ſpiral lamina, where they loſe themſelves. This lamina is not only calculated for receiving the vibratory motion of the air, but its ſtructure ought alſo to be looked upon as a convincing proof that it is qualified and diſpoſed for accommodating itſelf to the different characters and degrees of theſe motions; for ſince it is broader at the beginning of its firſt circumvolution than at the extremity of its laſt, and ſince the breadth of its other parts are in like manner proportionably diminiſhed, we may venture to affirm that its broadeſt parts are only fit for the reception of ſlow and languid vibrations, which are productive of grave tones, ſince they may be put into a commotion without the other parts undergoing any change; and vice verſa, that when its narrower parts are ſtruck, their vibrations are briſk and lively, and conſequently produce acute tones. Therefore, according to the various commotions of the ſpiral lamina, the nerves diſtributed through its ſubſtance receive the various impreſſions of the air, which exhibit and repreſent various tones or modulations of ſound. See SONUS.

COCHLEA CELATA. See ARDROSACE.

——— FOSSILIS and LAPIDEA. See COCHLITA.

COCHLEÆ, κοχλιαι, *to wind*, or *wreathe*. SNAILS.

The *ſnail* is an animal lodged in a ſhort thick turbinated ſhell, whoſe aperture is cloſed in the winter with a kind of cement. The land *ſnails* are called *operculares*: that ſort which adheres to briars and tendrils of vines, &c. are ſometimes called *ſeſelon* and *pomaticæ*.

Before the time of Serenus Samonicus, who flouriſhed in the third century after Chriſt, ſhell-*ſnails* were not recommended in phthiſical caſes. But indeed, abſtracted from the ſhell, *ſnails* without ſhells do not differ from thoſe that have them; it is the different ſhells that form the different ſpecies.

Snails abound with a viſcid ſlimy juice, which they readily give out, by boiling, to milk or water, ſo as to render them thick and glutinous. They are a tender ſubſtance, therefore eaſily digeſtible; very nutritious and demulcent. Employed in caſes of emaciation and hectic fever, though as animal food, they cannot be refrigerant according to the opinion of many, ſtill perhaps they are only ſlightly ſtimulant.

In Holland the ſea-*ſnail*, called the PERIWINKLE, is eaten; in France the land-*ſnail*, called the vine ſhell-*ſnail*, is eaten; but the ſmall white ſhell-*ſnail* is the moſt valued.

Naturaliſts deſcribe a great variety; the following only have medical virtues attributed to them, though the large aſh-coloured *ſnail* is ſaid to be that which is intended for medicinal uſe; but the ſmaller, dark-coloured, ſpotted, or ſtriped ſort, more common in gardens, is taken indiſcriminately, and their qualities do not appear to differ.

Earth-worms, or any other jelly, are as good as *ſnails*, if not better.

If ſalt is put upon the *ſnail* it ſoon dies, but it firſt contracts itſelf ſo as to force out all its mucus.

Cochlea aquatica. The WATER-SNAIL or PERIWINKLE.

—— *cælata*, *antinomaſtica*. This is a good ſhell-*ſnail*, found in the Mediterranean. Its operculum or cover is, according to ſome, the *umbilicus marinus* of the ſhops.

—— *margaritifera*. See CONCHA MARGARITIFERA.

COCHLEARE, cochlear, *doedyx*, and cochlearium. A SPOON. Perhaps ſo called from reſembling a ſhell. The ancients had two kinds of *cochlearia*; the greater, which contained a dram, and the leſſer, which contained a ſcruple. Various indeed are the accounts of the ancient *cochlearia*; but in the preſent London and Edinburgh Diſpenſatories, a *cochleare* is, of ſyrup half an ounce in weight, and of diſtilled waters three drams in weight, by meaſure half an ounce.

COCHLEARIA. SCURVY-GRASS, a low plant, with thick juicy leaves, ſomewhat hollowed, ſo as to reſemble a ſpoon, whence its name; thoſe from the root ſtanding on long pedicles; thoſe on the ſtalk joined cloſe to it without pedicles; producing toward the upper parts of the ſtalks ſmall white tetrapetalous flowers, followed by roundiſh ſeed veſſels. It is annual, grows wild in ſeveral parts of England, particularly about the ſea-coaſts and ſalt-marſhes, and flowers in May or ſooner. In Greenland and ſome other northern parts it is mild and totally deſtitute of pungency, and yet as effectual as that which grows with us, when eaten for the ſame purpoſes. The COCHLEARIA OFFICINALIS is the COCHLEARIA *foliis radicalibus ſubrotundis, caulinis oblongis ſubſinuatis*, caulis ramoſus. CLASS, TETRADYNAMIA; ORD. SILICULOSA; LINN. Genera Plant. 803. The COMMON or GARDEN SCURVY-GRASS. And a variety of this, viz. COCHLEARIA OFFICINALIS MINOR, i. e. COCHLEARIA MINOR *rotundo folio noſtras*, Linn. SMALL-LEAVED SCURVY-GRASS.

—— BATAVA, called alſo cochl. hortenſis, vel rotundifolia; ROUND-LEAVED, DUTCH, or GARDEN SCURVY-GRASS. The radical leaves are unevenly roundiſh, and thoſe

thoſe on the ſtalks are oblong. It is cultivated in gardens. It does not change its qualities with the ſoil.

—— Britannica, called alſo cochl. marina, cochl. folio ſinuato. English scurvy-grass or sea scurvy-grass. It is the cochlearia Anglica, Linn. All its leaves are alike, oblong, pointed, deeply and irregularly indented and ſinuated.

The freſh leaves of both ſorts have a diſagreeable ſmell, and a penetrating acrid taſte: the firſt ſort is by much the ſtrongeſt. The leaves are the ſtrongeſt part of the plant: they are antiſeptic, attenuant, aperient, and diuretic, and are ſaid to open obſtructions of the viſcera, and remoter glands, but neither heat nor irritate ſo much as their pungency would cauſe one to ſuſpect. It has long been conſidered as one of the moſt effectual antiſcorbutic plants. Sydenham and Lewis recommend this plant highly, combined with arum, and wood-ſorrel, in rheumatic and wandering pains, accompanied with fever. It is of ſervice alſo in paralytic and cachectic indiſpoſitions.

A ſmall quantity of nutmeg covers their diſagreeable flavour.

Their active parts are wholly in the expreſſed juice. Water or ſpirit alike extracts their whole virtue. The pungent part exhales in drying, and in evaporating the liquors which poſſeſs it.

The method of preſerving the herb with all its virtues, is by beating it up with ſugar into a conſerve, and keeping it in a cloſe veſſel. But as an antiſcorbutic, this does not promiſe ſo much benefit as the freſh plant, eaten as a ſallad, or the expreſſed juice as directed in the Pharmacopœias.

The principal virtue reſides in an eſſential oil, ſeparable in ſmall quantities by diſtillation in water; this oil ſinks in water, yet it is very volatile, ſubtil, and penetrating. Rectified ſpirit of wine carries the oil with it in diſtillation as eaſily as water does. A pint of ſpirit will take with it all the oil from two pounds weight of the leaves. See Lewis's Mat. Med.

Spiritus Cochleariæ. *Spirit of* Scurvy-grass.

Take ten pounds of the leaves of freſh *ſcurvy-graſs*; of rectified ſpirit of wine, five pints: macerate the herb twelve hours, and with a water-bath draw off five pints. This is called ſimple ſpirit, in contradiſtinction to what is called golden. The doſe is from twenty to an hundred drops. Horſe-radiſh may be mixed, or wholly ſubſtituted, without any ſenſible difference in any point of view.

Succus Cochleariæ compositus Compound juice of scurvy-grass; formerly succi scorbutici; scorbutic juices.

Take of the juice of garden *ſcurvy-graſs*, two pints; of brooklime, and water-creſſes, each a pint; of Seville oranges, twenty ounces; mix them, and after the fæces have ſubſided, decant off the liquor, and ſtrain. Doſe from two ounces to four, twice a day. This is antiſcorbutic, gently diuretic, and maintains a laxative habit

Succus cochleariæ aureus, golden spirit of scurvy-grass.

To a pint of the ſimple ſpirit of *ſcurvy-graſs* add an ounce of gamboge. The doſe is from twenty to ſixty drops. This operates as an aperient and diuretic ſtimulant, and participates much of the virtues of the gamboge, which is thus made to act in a mild manner. See Gambogia.

—— Armoracia. See Raphanus rusticanus.

COCHLIA, Cochlias. See Cochlea.

COCHLIAXON. A name for a part in a machine deſcribed by Oribaſius.

COCHLITA. It is alſo called *cochlea foſſilis* or *lapidea*. It is a ſtone of the ſhape and figure of a certain ſhell-ſnail. It is ſaid to be lithontriptic.

COCHONE. Galen explains this to be the juncture of the iſchium, near the ſeat or breech; whence, ſays he, all the adjacent parts about the ſeat are called by the ſame name. Hippocrates often mentions theſe parts. Heſychius ſays, that *cochone* is the part of the ſpine which s adjacent to the os ſacrum and breech, and tells us that ſome call the parts on both ſides the os ſacrum by this name, and adds, that the iſchia are thus called.

COCILIO. A weight of eleven ounces.

COCKENILLE. See Coccinilla.

COCO. See Palma Coccifera.

COCOLATA. See Cacao.

COCOMICA Signa. A term uſed by Paracelſus, but his meaning is unknown.

COCOS. See Palma Coccifera.

COCTIO. Boiling. Alſo *decoctio*, *aphepſema*, *apozema*. The effect of *boiling* differs from that of infuſion in ſome material particulars. In the heat of *boiling* water the eſſential oils of vegetables, in which their virtue generally reſides, are diſſipated; and when the medicine to be obtained is to conſiſt of the more volatile parts of the ingredients, infuſion is obviouſly preferable to decoction.

In decoctions, thoſe ingredients ſhould be boiled firſt from which their virtues are moſt difficultly extracted; and thoſe which more readily give them out may be reſerved until the latter end of the *boiling*; ſuch volatile ones as hardly bear the heat of *boiling* water may be added when the decoction is removed from the fire; they may ſtand cloſely covered until the liquor is cool enough to be ſtrained off.

Agglutinants, aſtringents, and emollients, are the chief ſubjects of this operation, and ſuch other materials as require ſome force to ſeparate their parts. See Decocta.

By decoction the fermentation of fermentable liquors is deſtroyed. See Dict. Chem. &c.

By the *coction* of humours is meant the digeſtion of the aliment into chyle with the *firſt coction*; the reduction of the chyle into blood, which is the *ſecond*; and the ſeparation of the juices from the blood by means of the glands, is the third and laſt.

COCUSTA. See Courbaril.

COCYTA. See Malis.

CODAGA Pala. See Conessi.

CODDAM-PULLI. See Carcapuli and Cambogia.

CODESELLA. See Carbunculus.

CODIA, in Hippocrates, ſignifies a poppy-head. See Papaver album. The heads of other plants are alſo thus named.

CODIAMINUM. } See Narcissus lutæus syl-
CODIANUM. } vestris.

CODI-AVANACU. An under-ſhrub growing in ſandy ſoils in the Eaſt Indies. The juice of the whole plant taken in wine is a good remedy for fluxes. Some other preparations are made from it.

CODOSCELLA. See Bubo.

CŒCALIS VENA. A branch from the concave ſide of the vena meſaraica major; it runs to the beginning of the colon; it divides by two arteries, one of which communicates with the gaſtro-colica; the other, after ſending branches to the inteſtinum cœcum and appendicula vermiformis, communicates below with the extremity of the great meſaraic vein.

CŒLA. The hollow of the eyes, or rather above and below the eye-lids They are puffed up in a cachexia. The *cœla* of the feet are the hollow parts at the bottom of the foot, adjacent to the heels.

CŒLESTINUS COLOR. In Paracelſus it ſignifies a ſky colour.

CŒLIA. It ſignifies a cavity in any part of the body, or in any of the viſcera; it is alſo the ſame with alvus: if *ανω* is joined with it, it ſignifies *ſtomachus*, and ſometimes the *thorax*; and κατω joined with it, is the *abdomen*, or lower-belly, or inteſtinal tube, from the cardia to the anus.

CŒLIACA ARTERIA, κοιλια, *venter*. The *cœliac artery* ariſes anteriorly from the *aorta deſcendens*, as ſoon as it has paſſed through the diaphragm; its trunk is ſhort, but it ſends off from the right ſide two ſmall *diaphragmaticæ*, though ſometimes there is but one. The left branch, which riſes from the *intercoſtales* and *mammariæ*, ſends ramifications to the ſuperior orifice of the ſtomach, and to the glandulæ renales of the ſame ſide, as the right furniſhes the renal gland on the right ſide, and the pylorus. After theſe the *cœliac artery* ſends off the *arteria ventriculi coronaria*, and the *gaſtrica ſuperior*; then divides into the *arteria hepatica* on the right hand, and the *arteria ſplenica* on the left. Sometimes this *artery* is divided into the *coronaria*, *hepatica*, and *ſplenica*; in the ſame place, very near its origin, the trunk going out from the aorta in a ſtraight line, and the branches from the trunk almoſt at right angles, like radii from an axis, whence this trunk hath been called *axis arteriæ cœliacæ*.

CŒLI-

—— Mucosa, } See Diarrhoea.
—— Chylos, }
—— Lactea. }

—— Passio. The coeliac passion is a species of diarrhœa, in which the aliment is carried off in a liquid state, but not well digested; the discharges resemble chyle. Aretæus calls those afflicted with this disorder κοιλιακοι; Cœlius Aurelianus calls them *ventriculosi*; Hippocrates does not name the disease. Sauvages enumerates four species, the chylosa, purulenta, mucosa, and lactea; but the first is generally understood by the *cœliac passion*, which is a chronic discharge of liquid indigested aliment; in this disease, on account of the debility of the digestive power, the aliment is left half digested, and becomes depraved both in colour, smell, and consistence, for the colour is white; the excrementitious matter filthy, and offensive; there is a rumbling in the intestines, and flatus break forth with some violence, the pain of the stomach is severe, resembling pricking; the patient becomes weak, and emaciated. The disease continues long, is periodic, and difficult to cure. Dr. Cullen considers it as synonymous with diarrhœa, and mentions it, in his third and fourth species, under the terms mucosa, chylosa, lactea, making the purulenta only symptomatic

It is caused by a disorder in the first passages, which admits of the aliment being dissolved, but not properly digested. Dr. Freind says, that it originates from an obstruction of the intestinal glands, on which account a sufficient quantity of lymph cannot, by these, be supplied for diluting the chyle, and rendering it fit to pass into the lacteals; hence it passes off with the excrements. He distinguishes it from the chylous flux, by observing that in this the cause is an obstruction of the lacteal vessels.

The symptoms attending this disorder are in general such as are met with in different patients labouring under a diarrhœa, which are as the constitution and various other circumstances differ.

It must be distinguished from other intestinal discharges, and from what Celsus calls *cœliacus* ventriculi morbus.

The cure is tedious at best, but often uncertain. It sometimes abates, but is apt, upon the least irregularity, to return.

As the cause is in part an interception of the humours which used to be discharged from the glands in the first passages, astringents are obviously prejudicial; and those remedies which gently irritate the bowels, and deterge the mouths of their glands, are manifestly the means of relief; to this end vomits of ipecacuanha may now and then be given, and gentle purges frequently repeated in small doses. As indigestion or weakness of the stomach in part contributes to the production of this disorder, warm strengthening stomachics will be useful; the diet and other non-naturals also must be properly regulated. See Diarrhoea.

See Aretæus, lib. ii. cap. 7. Cœlius Aurelianus Morb. Chron. lib. iv. cap. 3.

Cœlie. See Venter.

Cœli-flos. } Paracelsus called this *nostoch*
Cœlifolium. } and *cerefolium*; others call it *flos terræ*. In some places it is known by the name of star-fall. *Purgamentum stellarum.*

It is a species of jelly, sometimes clear, at others greenish, and agitated with a kind of tremulous motion so long as it is fresh.

It is found after rain in meadows, and in dry parched grounds, generally betwixt the spring and summer seasons. If it is not gathered before the rising of the sun, it will be shrivelled up to a thin membrane of a browniſh colour. Magnol, in his Botanicum Monspelienſe, calls it *muscus fugax*; *membranaceus pinguis*. And Tournefort calls it nostoch ciniflonum.

It is a production of the earth, to which it adheres by one or more slender roots. The embryo at first appears like a small tubercle, which is fleshy, soft, and diversified with inconsiderable inequalities, like those on strawberries, at first of a greenish blue colour, but afterwards clear. Afterwards this membrane is unfolded on the earth, and thus it remains while the weather is moist, not fading till the wind and sun dries the earth. It affords a clear insipid liquor, that turns hydrargyrus muriatus white, and syr. violar. green. It affords a volatile salt well crystallized, a volatile urinous spirit, and a fetid oil.

The Germans use it to make the hair grow.

Coeli Spectator. See Uranoscopus.

Cœloma. κοιλωμα, *hollow*. See Bothrion.

Cœlostomia, from κοιλος, *hollow*, and στομα, *the mouth*. A defect in speaking, when a person's speech is obscured by sounding as if his voice proceeded from a cavern.

Cœmentatio. } Cement, also Cæmentum,
Cœmentum. } *cementum, cementatio.* It is a tenacious matter by which two bodies are made to adhere. What is used by the chemists is commonly called lute. See Lutum.

Besides, *cements* are those powders and pastes with which any body is surrounded in pots or crucibles, and which, by the help of fire, produce changes in the bodies about which they are spread. The common cement which Schroder directs, is the following: Take half a pound of finely powdered brick-dust, four ounces of common salt prepared, and of nitre and verdigrise, each an ounce; mix.

There are many compositions for *cementing*, which may be seen in chemical writings; one of the chief of them is what is called the royal cement, because used in purifying gold from silver. It is thus made: Take four parts of fine brick-dust, one part of green vitriol, calcined to redness, and one part of common salt; mix them well, and then work them into a firm paste with water See Dict. of Chem. 4to. Newmann's Works.

Cœna. Supper. *Suppers* that are heavy should be avoided, because the stomach is more oppressed with the same quantity of food in an horizontal posture than in an erect one, and because digestion goes on more slowly when we sleep than when we are awake. They should also be eaten long enough before bed-time, that they may be nearly digested before going to sleep, and then a draught of pure water will usefully dilute that which remains in the stomach. Indeed suppers, in many cases, are very pernicious, inducing disagreeable dreams, disturbed rest, the incubus or night mare, and laying the foundation for visceral obstructions, particularly in those who have weak digestions, bringing on a variety of unpleasant complaints.

Cœnotes, from κοινος, *common*. The physicians of the Methodic sect asserted that all diseases arose from relaxation, stricture, or a mixture of both. These were called *cœnotes*, because diseases have these in common.

Cœruleum montanum. Mountain blue. It is a blue ore of copper.

—— Fossile. See Armenus lapis.

Cœruleus lapis. See Vitriolum coeruleum.

Coffea, called also *jasminum Arabicum, castanea folio flore albo odoratissimo*, coffe, *chaava, jasminoides*, coffee tree or bush. It is the coffea Arabica, Linn. called also ban, bon, and buna arbor. When made fit to drink, it is then named *cauva, chaava, csava.*

The fruit of the *coffee*-tree, called its berries, is of a pale colour and oval shape, rather less than a common bean, convex on one side, and flat on the other, with a remarkable furrow.

The tree is of the jessamine kind, with leaves like those of the bay-tree: it grows in Arabia Felix; from thence it was introduced into the West Indies. The fruit is a juicy berry, including two of the seeds, joined by the flat sides, and covered each with a thin shell.

Coffee was but little known in Europe before the seventeenth century. The first *coffee*-house in London was erected in the Tilt-Yard, in the year 1652. In Paris it was scarcely known until 1669; though at Marseilles it was used in 1644. Rauwolfius, a German, and Prosper Alpinus, an Italian, were the first Europeans who writ on the use of it.

The Arabian *coffee* is called the Levant *coffee*, and is the smallest; the Java *coffee* is called the East India *coffee*; it is larger, and of a whitish livid colour: the American *coffee* is called English or Surinam *coffee*; the berries are large and of a greenish colour; but the best are small, close, and somewhat transparent.

The Arabic word *cahoua*, signifies any kind of liquor, consequently the liquor made with *coffee*. Hence the Turks derive their *cahveh*; whence again the European word *café*.

In Arabia, persons of rank only use the seminal capsules, and the pellicles immediately covering the berries; these produce a grateful liquor, but for this purpose the

capſules, &c. muſt be freſh. The French call this *caſé à la ſultane*.

The *coffee*-berries have a farinaceous, ſomewhat unctuous bitteriſh taſte; and little or no ſmell. They are roaſted to deſtroy that flatulence that they have in common with all farinaceous ſubſtances. Many ſeeds, &c. by roaſting, acquire the flavour for which *coffee* is admired. Dillenius hath given a diſſertation in the Ephem. Nat. Curioſ. on the ſubſtances which in ſmell and taſte reſemble *coffee*; and finds that roaſted rye, with a few roaſted almonds, to furniſh the neceſſary proportion of oil, comes the neareſt to it.

From ſixteen ounces of roaſted *coffee*, Neumann obtained ſeven ounces, two drams, and two ſcruples of watery extract; and afterwards five drams and one ſcruple of ſpirituous extract. On reverſing the operation, he obtained four ounces and four ſcruples of ſpirituous extract, and four ounces of watery; the reſiduum, in both caſes, was nearly the ſame, viz. about one half of the whole.

The roaſted ſeeds ground into powder ſoon loſe their flavour in the air, impart it to water and to ſpirit by light coction, or digeſtion, and give over a great part of it with water in diſtillation. The roaſted berries keep very well; to recover their briſk flavour, lay them before the fire a few minutes, and, when they are warm, they may be ground for uſe, and are then as agreeable as when firſt roaſted.

Coffee ſhould be boiled eight or twelve hours before it is drank, and if the liquor is mixed with an equal quantity of milk, it is excellent.

If *coffee* is drank warm within an hour after dinner, it is of ſingular uſe to thoſe who have head-achs from a weakneſs in the ſtomach, contracted by attention, or from drunkenneſs. It is uſeful when digeſtion is weak. The phlegmatic and corpulent are much benefited by its uſe. In ſome delicate habits it produces nervous ſymptoms. It is ſlightly aſtringent and antiſeptic, moderates alimentary fermentation, and is powerfully ſedative. See Lewis's Mat. Med. Newmann's Chem. Works; Percival's Eſſ. Med. and Exp. vol. ii. Letſom's edit. of Fothergill's Works, vol. ii.

COHOB. *Cohobatio, cohobium, cohoph.* COHOBATION. It is the returning of a liquor, diſtilled from any ſubſtance, back again upon the ſame ſubſtance, and diſtilling it again, either with or without an addition of freſh ingredients. The alembic, called a pelican, was invented for the more eaſily effecting this operation. Modern chemiſts neglect it.

COHOL. See ALCOHOL. Caſtellus ſays, it is uſed in Avicenna, to expreſs dry collyria for the eyes, in fine powder.

COHOPH. See COHOB.

COILIACOI. See CŒLIACA PASSIO.

COILIMA. A ſudden ſwelling of the belly from wind.

COIRA. See TERRA JAPONICA.

COITIO. The act of venery. See VENUS.

COLATORIA LACTEA. See FLUOR ALBUS.

COLATORIUM. A ſtrainer of any kind.

COLATURA. So any ſtrained or filtered liquor is called. See DEPURATIO.

COLCAQUAHUITL. An American plant commended in palſies and uterine diſorders. Raii Hiſt.

COLCESTRENSIS AQUA. COLCHESTER WATER. This mineral water is of the bitter purging kind, ſimilar to that at Epſom, but not ſo ſtrong. See AQUÆ CATHARTICÆ AMARÆ.

COLCHICUM, called alſo COUM, *colchicum autumnale*;—*commune*;—*Anglicum, purpureum*, & *album*.

Boerhaave mentions eight ſpecies. It is the *colchicum foliis planis lanceolatis erectis*. CLASS, HEXANDRIA; ORD. TRIGYNIA; LINN. Gen. Plant. 457. MEADOW SAFFRON.

It grows in meadows that are moiſt and rich; and ſometimes it is found in marſhy grounds. It hath two fleſhy bulbous roots, the one producing from its lower part a ſmaller bulb. From the laſt ariſes in autumn, along a furrow, in the ſide of the old root, a ſlender, hollow, tranſparent pedicle, widening at the top into a flower like thoſe of the crocuſes, divided into ſix ſegments, of a purpliſh or whitiſh colour, withering in two or three days. From the ſame root there come forth in the next ſpring three or four upright leaves, like thoſe of the lily, in the middle of which appear, on ſhort pedicles, commonly three triangular pods, about the ſize of ſmall walnuts, divided into three cells, full of roundiſh dark-coloured ſeeds. The outer root is barren and ſhrivelled, the inner one produces the plant.

When the root is young and freſh, its taſte is very acrid; but when old, it is mealy and faint. For medical purpoſes it is beſt when full of ſap. Two drams of this root killed a large dog; after putting him to great torment for about thirteen hours, it operated violently by vomit, ſtool, and urine. One grain of it being ſwallowed by a healthy man, produced heat in the ſtomach, and ſoon after flaſhing heats in different parts of the body, with frequent ſhiverings, followed by colicy pains; after which an itching in the loins and urinary paſſages was perceived, and then came on a continual inclination to make water, a teneſmus, pain in the head, a hurrying pulſe, thirſt, and other diſagreeable ſymptoms.

Notwithſtanding theſe effects, when made into an oxymel, it becomes a ſafe, but powerful medicine. The roots ſhould be freſh, and full of ſap, when they are uſed. In ſlicing them, they emit acrid particles, which affect the head, irritating the noſtrils, throat, and breaſt; the fingers that hold them when cutting, become numb for a time, and loſe their ſenſation; though, after being ſteeped in vinegar, they are almoſt inſipid, their acrimony being taken up by it.

When this root is imprudently ſwallowed, the following method gives the ſpeedieſt relief. To a pint of water add an ounce of vinegar, or lemon-juice, and half an ounce of the ſyrup of poppy heads. Of this take three ounces every quarter of an hour. After the uſe of this hath removed the immediate effects of the *colchicum*, finiſh the cure with demulcents.

Acetum Colchici. VINEGAR OF MEADOW SAFFRON.

Take of the freſh roots of *meadow ſaffron*, ſliced, an ounce; white wine vinegar, a pint. Mix and digeſt in a glaſs veſſel, over a gentle fire, during forty-eight hours, then ſtrain off the liquor.

To render this vinegar more mild, and leſs diſagreeable, it is made into an oxymel, as follows:

Oxymel Colchici. OXYMEL OF MEADOW SAFFRON.

With a pint of the vinegar of the *meadow ſaffron*, mix two pounds of clariſied honey; gently boil the mixture, frequently ſtirring it with a wooden ſpoon, to the thickneſs of a ſyrup. Pharm. Lond. 1788. It is of conſequence that the bulbs be in perfection, they ſhould therefore be taken up in autumn.

This oxymel is agreeably acid, gently vellicates the tongue, is moderately aſtringent, excellent for cleanſing the tongue from mucus; in an increaſed doſe it is an emetic, and ſometimes a purge; but its moſt general effect is as a diuretic, and as ſuch it is very conſtant, and remarkably powerful.

The doſe ſhould be ſmall at the firſt; half a tea-ſpoonful may be given two or three times a-day, increaſing the doſe as the ſtomach will admit. In dropſies, and tertian agues, its ſucceſs has been great; as an expectorant it ſucceeds when ſquills fail; and, when opiates are joined with expectorants, this oxymel ſhould be preferred, for no medicines in conjunction interfere with its operation. See Dr. Storck's Eſſay on the Uſe and Effects of the Root of the *Colchicum Autumnale*. Its uſe in dropſies, ſee London Med. Journal, vol. i. p. 395. In *Germany* and *France*, it continues ſtill to be a favourite medicine. In *England*, from its want of ſucceſs, it is generally thought a leſs efficacious diuretic than the ſquill, which yet excels it more as an expectorant.

—— ILLYRICUM. See HERMODACTYLUS.

—— ZEYLANICUM. See ZEDOARIA.

COLCOTAR. See VITRIOLUM.

COLCOTHAR, SAL. When the *colcothar* of vitriol is waſhed in water, a ſalt is obtained from it which is thus called; it is alſo named fixed ſalt of vitriol. If borax is added to this ſalt, and the mixture expoſed to the fire, it eaſily ſublimes in the form of ſilver-coloured ſaline flowers, thus forming the *ſal ſedativus Hombergii*. Two ounces of this fixed ſalt of vitriol, well calcined, muſt be diſſolved in a quart of warm water; the ſame quantity of borax muſt be diſſolved alſo in a quart of warm water: theſe ſolutions being mixed and filtered, the clear liquor muſt be evaporated in a glaſs alembic to dryneſs, then the dry maſs muſt be ſublimed. By mixing oil of vitriol with twice its weight of borax, the ſame ſedative ſalt may be obtained.

COLES, or COLIS. See PENIS.

COLI DEXTRUM, LIGAMENTUM. Where the meſentery changes its name for that of meſocolon (which is about the extremity of the ileum) the particular lamina, which

which is turned to the right ſide, forms a ſmall tranſverſe fold, which is thus named.

COLI SINISTRUM, LIGAMENTUM. It is a contraction of the meiocolon, a little below the left kidney.

COLICA. The COLIC; *tiberianum tormentum*, alſo termed *rachialgia*; but this term is more particularly confined to the *colica pictonum*, ſpecies 2, below.

The appellation of *colic* is commonly given to all pains of the belly, almoſt indiſcriminately, but properly it is confined to pains ſeated in the colon; however it is not neceſſarily ſo limited. From the different cauſes and circumſtances of this diſorder it is differently denominated, and ſome difference in the mode of cure is alſo to be obſerved in different caſes.

When the pain is accompanied with a vomiting of bile, or with obſtinate coſtiveneſs, it is called a BILIOUS COLIC; if flatus cauſes the pain, it takes the name of flatulent or WINDY COLIC; theſe two laſt named are varieties only of the ſpaſmodic *colic*: when accompanied with ſymptoms of heat and inflammation, it takes the name of INFLAMMATORY COLIC, &c. The different kinds ſeem to be properly included under the diſtinctions of inflammatory, ſpaſmodic, or from irritation, and flatulent, or from wind.

The INFLAMMATORY is when actual inflammation ſeizes ſome part of the inteſtinal canal, the diſorder will then be conſidered and treated as an inflammation of the reſpective part. See INFLAMMATIO VENTRICULI, & INTESTINORUM.

The SPASMODIC is when pain affects the belly principally about the navel, attended with an obſtinate coſtiveneſs, and either a naufea, or actual vomiting. In the beginning it is abſolutely void of inflammation, though, as a conſequence, this ſymptom ſometimes appears.

The FLATULENT is when, from a ſudden rarefaction of vapours in the inteſtinal canal, there is pain; and as an effect of the diſtenſion, or of the pain, a conſtipation of the belly.

Dr. Cullen places this genus of diſeaſe in the CLASS NEUROSES, and ORD. SPASMI; and defines it, pain of the abdomen, particularly running round the umbilicus, attended with vomiting and coſtiveneſs. He enumerates ſeven ſpecies. 1. *Colica ſpaſmodica*, with retraction of the navel, and ſpaſm of the muſcles of the belly. 2. *Colica Pictonum*, called alſo *rachialgia pictonum*; *metallica*; *abdiapneuſtia*; *traumatica*; *ſpaſmodica*. It is alſo called *bellon*, when produced by lead. Beaſts and poultry, as well as men, are ſubject to it, if they remain much about ſmelting houſes. The ſymptoms of this ſpecies are a ſenſe of weight or uneaſineſs, firſt affecting the abdomen, particularly round the navel; ſucceeded by a colicy pain in the beginning, ſlight, not continued, and encreaſed eſpecially after eating: at length its violence increaſes, and remains almoſt conſtant, with pains of the arms and back, terminating in paralyſis. 3. *Colica ſtercorea*, which happens from obſtinate, and long continued coſtiveneſs. 4. *Colica accidentalis*, called alſo *cholera ſicca*, from ſharp undigeſted matters. 5. *Colica meconialis*, in infants, from a retention of meconium. 6. *Colica calloſa*, from a ſenſation of a ſtricture in ſome part of the colon, and frequently before this, of flatulence, collected with ſome pain; which flatulence, gradually paſſing off, vaniſhes; the habit being coſtive, and parting at length with liquid fæces, but in ſmall quantity. 7. *Colica calculoſa*, from calculi formed in the inteſtines, attended with a fixed hardneſs in ſome part of the abdomen, having before parted with calculi downwards.

THE SPASMODIC COLIC is treated of under a variety of names: Hippocrates ſeems to include it under pains of the belly, where he calls all pains of the inteſtines, iliac; others, ſince him, have named it CHORDAPSUS, ILEUS, VOLVULUS, &c. Writers of a more modern date have named it differently, according as it appeared epidemically in a particular country, or was apprehended to proceed from a particular cauſe, or had certain ſymptoms attending it: hence the names *colica Pictonum*, *colica* ſaturnina, *colica* plumbariorum, *colica* Damnoniorum or of Devonſhire, bilious *colic*, dry belly-ach, the painter's *colic*, ſpaſmodic *colic*, nervous *colic*, *colic* of Surinam, &c. &c.

Pains of the bowels are common to all ages, but the tender, and eaſily irritable are moſt frequently ſubject to them.

As to the ſeat, the whole region of the inteſtines is the ſubject of this diſorder; in any part of them it may manifeſt its preſence.

Whatever be the preceding, *the immediate cauſe is always a ſpaſm*: and with reſpect to the theory of pains in the inteſtines, it may be obſerved, that the cauſe from whence they ariſe, hath its ſeat in a part diſtant from where the uneaſineſs is felt. Whenever an inflation happens in an inteſtine, there is either an obſtruction from excrements, or a ſpaſm in another part. When either obſtruction or conſtriction happens in ſome part of the ſmall inteſtines, or a compreſſion on them; or when a load of excrement is lodged in the beginning of the colon on the right ſide, there ariſes a great and painful inflation of the belly above and below the navel, and alſo in the middle of the ſame. If the lower part of the colon, or the inteſtinum rectum, is thus affected, the colon in the left hypochondrium, towards the ſpleen, together with that part of it which is ſeated beneath the ſtomach, and near the liver, becomes greatly inflated. When, as it often happens in hypochondriac and hyſteric diſorders, the beginning of the jejunum, or end of the duodenum, is ſpaſmodically affected, there preſently ariſes a ſevere pain in the loins, on account of the ſuperior meſenteric, and intercoſtal branch of the nerves, which ſpread themſelves on the jejunum. In this caſe the duodenum and ſtomach are inflated, the breathing is thereby affected, and great anxiety comes on.

Spaſms may be excited by extraordinary agitations of mind, or uneaſy affections thereof; alſo by acrid and ſtimulating matter thrown upon the bowels. Bile, and other excrementitious ſordes, may be too long retained, or otherwiſe have changed their healthy qualities; acrid ſubſtances may be ſwallowed, or conveyed to the inteſtines by other means; vapours from lead, in the various employs where its uſe is frequent, as well as ſolutions of it from the tinning, by which kettles, &c. are lined, and various other methods by which this pernicious metal is conveyed into our bodies; the matter of the gout, &c. diverted from their original ſeat to the inteſtines; worms; obſtructed periodical evacuations, &c.

Whatever be the cauſe, the approach and progreſs of this diſorder is nearly the ſame. It begins with a ſenſe of weight, or pain, at the pit of the ſtomach, attended with loſs of appetite, yellowneſs in the countenance, a ſlight ſickneſs and coſtiveneſs; the pain gradually increaſes, and from wandering about becomes fixed ſomewhere about the navel, from whence painful dartings proceed, at times, in various directions; wherever pain is felt, a forenefs and tenderneſs remain ſome time afterwards; the ſickneſs keeps pace with the pain, and, at length, a vomiting of bilious matter comes on; the urine is diminiſhed in its uſual quantity, and a teneſmus ſometimes adds to all the other grievances. While the pain is ſpaſmodic, the pulſe remains unaffected, except concurring circumſtances produce a change in it; the urine is various; if the ſmaller inteſtines are the ſeat of the pain, it is felt more acutely; if the larger inteſtines are the parts aggrieved, the ſenſe of the pain is more dull and heavy; ſometimes there is a bitter taſte in the mouth, and a yellowneſs in the countenance: if the ſymptoms are not relieved, an inflammation or a gangrene may enſue; or the excrements returning, are ejected by vomit, and the iliac paſſion puts an end to the whole, by opening the way for death.

The *colic* ſhould be diſtinguiſhed from a fit of the gravel; ſtones paſſing through the ureters; rheumatic pains in the muſcles of the belly; a beginning dyſentery; the blind piles; from a ſtone paſſing through the gall-duct; and from the flatulent pains which receive the denomination of flatulent *colic*.

Of the remarkable ſymptoms that ſometimes come on in conſequence of this diſorder, a palſy is the chief. Dr. Thierry ſays, that it is the natural criſis of a *colic*: however, it may be obſerved, that though it ſometimes comes on during the fit, it generally follows; and, ſecondly, it ſeldom appears after the firſt fit, if the *colic* was not ill-treated.

When the *colic* attacks with a ſhivering, and the pain is very violent, great danger attends it, for an inflammation is denoted thereby. When lead is the cauſe, the *colic* is apt to terminate in a ſpaſmodic aſthma, or a palſy. A ſweat, a ſalivation, an hæmorrhage at the noſe, or from the hæmorrhoidal veins, ſpontaneouſly occurring, ſometimes terminates the *colic*: though, if after the ſtrength is exhauſted, a colliquative ſweat comes on, a ſtupor of the hands or feet is to be feared, if not a true palſy. If the violence of the pain continues to increaſe, fatal effects are to be expected.

As

As preventives of this complaint, thoſe who are at times afflicted with pains in the belly, ſhould be careful to keep from all violent agitations of the mind, ſhun expoſures to the northern winds, keep the feet dry and warm, abſtain from flatulent food, and ſpirituous liquors. Thoſe whoſe occupation ſubjects them to the fumes of lead, or to the influence of any of its preparations, ſhould breakfaſt on fat broth, or eat bread that is ſpread with ſweet lard, before they begin their work.

IN ORDER TO THE CURE, as a ſpaſm is declared to be the immediate cauſe, its reſolution is the chief indication; to which end relaxing and antiſpaſmodic medicines, with purges, which, while they ſolicit the internal diſcharge, will not increaſe the morbid irritation, are the proper means.

If the pains are violent, and the pulſe full, take away blood in proportion to the ſtrength of the patient; after which the ſtomach may be cleanſed with as much warm camomile tea as will excite two or three diſcharges by vomiting, or, if need be, a few grains of ipecacuanha may be given.

After the ſtomach is cleanſed, opium ſhould be given, and the doſe, which may be more or leſs, according to the violence of the pain, muſt be repeated every two or three hours, until ſleep is procured, and eaſe obtained. The notion that a free uſe of opium may cauſe the palſy, is erroneous.

As ſoon as by a due uſe of opium the ſickneſs and pain abate, let gentle purges, that is, ſuch as operate with the leaſt irritation, be given: when the pain is firſt moderated by the uſe of opium, take ʒ ii. of the ſal amar. in warm water; if repeated every two hours it will operate with ſufficient efficacy; though the ol. ricini ſhould be preferred, becauſe its repetition need not be ſo frequent as the other purgatives; however, in want of it, ʒ i. of cryſtal. tart. or ʒ ſs. of ſulph. præcip. may be repeated every hour or two. The ol. ricini may be given to ℥ i. with an equal quantity of the tinct. card. comp. Ph. Lond. or any other agreeable mixture. If the ol. ricini is not to be had, any other purgative, that is not painful in its operation, may be uſed. When a free paſſage is obtained downwards, laxatives muſt ſtill be continued, until all danger of a relapſe ſeems to be removed.

If doſes of a grain or two of opium, repeated every ſix hours, fail to relieve, forty drops of the tinct. opii may be mixed with four ounces of warm olive oil, and injected clyſterwiſe. This may be repeated as often as the pain returns.

In caſe of a relapſe, after the good effect of purges, the propereſt method is to begin as at the firſt, and moderate the pain by means of opium, before the uſe of purging medicines.

Fomentations, and warm baths, may prove auxiliaries, but no great dependence is to be had on them. It is true, that while the patient is ſet in the warm bath, the pain abates, but when he is taken out, it returns. In this diſorder, the pain muſt be allayed during ſome hours before the inteſtines will be diſpoſed to perform their office of excretion; and few, if any patients, can continue in the bath ſo long as eaſe is required. Some aſſert, that the warm bath being uſed before the belly is evacuated, is hurtful, by conveying the offending humours into the blood, inſtead of determining them to the ſkin, and thus may be cauſe of convulſions.

Drs. Warren and Biſs relate their ſucceſs in attempting the cure of the *colica Pictonum*, as it is denominated by one, and the dry belly-ach by the other, by means of a ſalivation with mercury; and obſerve, that as ſoon as the ptyaliſm was perceived, the pain abated, and returned no more. One of theſe gentlemen obſerves, that in mild caſes, where a ſalivation ſeemed not neceſſary, bliſters applied to the upper and fore-part of the thighs, near the groin, were ſometimes effectual. Dr. Hugh Smith adviſes to apply the bliſters on the belly.

Dr. Graſhuis commends alum as a ſpecific in this diſorder: and Dr. Percival, in his Eſſ. Med. and Exp. relates the ſucceſs which hath attended his uſe of this medicine in various painful diſorders of the bowels. He gives it from gr. x. ad xx. every four or ſix hours; and a few doſes, thus adminiſtered, never failed to procure relief, and, duly repeated, to effect a cure.

Dr. Percival alſo propoſes as follows, in a letter to Dr. Duncan, which is inſerted in the 5th vol. of Edinb. Med. Comment. p. 172, &c. In violent *colics*, attended with vomiting and an obſtinate conſtipation of the bowels, it has been the common practice amongſt phyſicians to give opiates, in conjunction with purgatives. This method of treatment has been lately improved by adminiſtering the opiate firſt, and the purgative an hour or two afterwards. But I take the liberty of ſuggeſting to you another mode, which, as far as my own experience extends, has proved the moſt ſucceſsful. I direct three or four ounces of a ſtrong decoction of poppy heads, with twenty, thirty, or forty drops of tinctura opii, to be injected into the inteſtines, and retained as long as poſſible. If it be ſpeedily diſcharged, the glyſter is repeated till the pain is relieved, and the vomiting ceaſes. A doſe of calomel and jalap, or of any other briſk cathartic, is then adminiſtered, and its operation quickened by the uſe of ſena tea, of a ſolution of the neutral ſalts, or of caſtor oil. By this proceſs, evacuations are procured with more eaſe, certainty, and expedition, than by any other which I have tried. For opium, when given in a clyſter, does not check the periſtaltic motion of the inteſtines, nor counteract the operation of any purgative, ſo powerfully as when received into the ſtomach. And, in this way, it is moſt efficacious in alleviating the ſickneſs, and in putting a ſtop to the violent retchings with which *colics* are often attended. The taſte of laudanum is often ſo nauſeous, that it is frequently rejected as ſoon as ſwallowed. And, if the extractum opii be given in a ſolid form, time muſt be allowed for its ſolution, before any effect can be expected from it.

The *columbo-root* infuſed in boiling water, and given to the patient in the beginning of this diſorder, may be uſeful to abate the ſickneſs and vomiting.

The palſy which remains after the removal of the *colic*, is beſt relieved by the uſe of Bath-water; but as the circumſtances of many do not admit of this method, the whole length of the ſpine may be rubbed with Barbadoes tar, diſſolved in rum; and ſuch other antiparalytics may be uſed, as the conſtitution of the patient, and other circumſtances, may admit.

See Dr. Tronchin on the *Colica Pictonum*, with Dr. Schomberg's Notes. Dr. Thierry on the *Colica Pictonum*. Dr. De Haen on the *Colica Pictonum*. Dr. Huxham on the *Colic* of Devonſhire. Dr. Warren's account of the *Colica Pictonum*, in the Lond. Med. Tranſ. vol. i. ii. Dr. Sydenham's Works, with Notes, by Dr. Wallis. Dr. Percival's Eſſays, Med. and Exp. vol. ii. p. 194, &c. Med. Muſ. vol. iii. p. 579, &c. Cullen's Firſt Lines, vol. iv.

COLICA FLATULENTA. The FLATULENT COLIC is uſually a ſymptom or conſequence of ſome other diſorder, and is neither accompanied with fever nor thirſt; however, the pain is acute, as the ſeat of the complaint is in the ſmall inteſtines; cardialgic ſymptoms, with efforts to vomit, ſometimes attend, and a coſtiveneſs is the conſequence of the great diſtenſion.

Sometimes it is cauſed by wetting the feet, or otherways checking the perſpiration; in which caſe, inſtead of taking heating medicines, rubbing the legs with warm cloths, and afterwards keeping the feet for ſome time in warm water, will be the moſt effectual remedy.

When a perſon is ſubject to frequent returns of this diſorder, it proves that the digeſtive powers are weak; and in order to the cure, this circumſtance is to be attended to.

To promote the diſcharge of wind, clyſters of warm water, with a little common ſalt, may be frequently repeated. Warm camomile tea may be now and then drank, and tinct. of rhubarb, with a few drops of the oil of mint.

Cryſtals of tartar, diſſolved in water, form a uſeful drink.

Sometimes the conf. opiata, joined with rhubarb, gives ſpeedy relief.

COLICA COLCOTOR. See VITRIOLUM.

—— SINISTRA, ARTERIA. } See MESENTERICÆ.
—— SUPERIOR, ARTERIA. } ARTERIÆ.

—— VENA. It is a branch from the *meſeraica vena major*. It runs from the anterior part of the trunk before it joins the artery, to the middle of the colon, where it divides to the right and left, and forms arches. On the left it communicates with the upper branch of the hæmorrhoidalis, and on the right with the ſecond branch of the meſeraica.

—— RECTA, VENA. It is a branch of the *gaſtro-colica vena*; it goes to the right portion of the colon, from thence to the upper part thereof, where it divides, and anaſtomoſes with the *colica*, and the cœcalis.

COLIFORME OS. See ETHMOIDES OS.

COLINIL. Called alſo *Nil*; *Indigo ſpuria*; *Polygala Indica*

Indica minor. The name of an American plant, the juice of which, with a little honey, cures puſtules in the mouth. Raii Hiſt.

COLIPHIUM. Bompournickel. A ſort of bread made of the flour and bran, as it comes from the mill. It was made for wreſtlers, and uſed by the Greeks. Bread made of fine flour neither nouriſhes nor ſtrengthens ſo much as the coarſer made with the addition of the bran. Indeed bread made of bran alone is more ſtrengthening, than that of fine flour, when made for labouring men. The Romans, for three hundred years, only made bread of bran. In *Norfolk*, that ſort of bread is now in uſe, and alſo in *Weſtphalia*. The name *Coliphium* is derived from the Greek words, which imply ſtrength of limbs, κωλον, *a member*, and ιφι, *ſtrength*. Some of the moſt ancient nations called the bread thus made *panis furfuraceus*. See Aulius Gellius, lib. ii. cap. 9. *Panis impurus*. See Hippocrates. Athenæus, lib. iii. calls it *ſyncomiſton*, *bread* prepared of unſifted meal. Cœlius Rhodiginus, lib. ix. c. 16. calls it *panis cibarius*, and *panis gregarius*. Terence calls it *panis ater*.

COLIS. See Penis.

COLLATENNA. A certain ſpecific for the cure of wounds. It is mentioned by Paracelſus in his work De Vita Longa.

COLLATERALES. See Erectores penis.

COLLATITIUM. A ſort of food prepared, according to Blancard, of the fleſh of a capon, or a pullet bruiſed, and then mixed with mutton broth, and given with verjuice, or lemon-juice.

COLLETICA, from κολλα, *glue*. Conglutinating medicines.

COLLICLÆ. The union of the ducts which convey the humours of the eyes from the puncta lachrymalia to the cavity of the noſe.

COLLICULA } A diminutive of *collis*, *a hill*. See
Colliculum. } Nymphæ.

COLLIGAMEN. See Ligamentum.

COLLIQUAMENTUM. An extremely tranſparent fluid in an egg, obſervable after two or three days incubation, containing the firſt rudiments of the chick. It is included in its own proper membranes, diſtinct from the albumen. Harvey calls it *oculus*.

COLLIQUATIO. Colliquation, from *colliquo*, *to melt away*. A diſſolving, or waſting.

COLLISIO. See Contusa.

COLLIX. A ſort of round loaf or cake; but in Hippocrates, and other Greek medicinal writers, κολλυξ imports a ſort of paſtil, or troche, of the form above mentioned. See Trochisci.

COLLOBOMA. The growing together of the eyelids.

COLLODES, from κολλα, *glue*. Glutinous.

COLLUM. See Cervix.

COLLUTORIUM ORIS. See Gargarisma.

COLLUVIES, from *colluo*, *to waſh*, *or rinſe*, in its primitive ſenſe means *filth*, *ſink*, *hogwaſh*: hence the term applied to people, means the *rabble*. In a medical ſenſe, it is expreſſive of any corrupted or contaminated fluid.

COLLYRIUM, from κολλα, *glue*, and ουρα, *a tail*, becauſe the ancient collyria were in the form of a rat's tail, and prepared of powders made up of ſomething glutinous; according to ſome, from κελυω, *to ſtop*, and ρυσις, *a running*. Suppoſitories, tents, and other things, have been called *collyria* from their form; but as they were uſed whole, or in their proper form, they were called *entire*; but what were called *collyria*, without the epithet *entire*, were powdered fine and applied to the eyes.

At preſent a *collyrium* only means a topical medicine for the eyes, called eye-water. It differs not from a lotion; but as applied to the eyes, it is now called a *collyrium*.

Collyriums made with vegetables and ſalts that entirely diſſolve, are more elegant, and agree better with the eyes, than when they are made with powders.

Hoffman condemns all acrid, aſtringent, cooling, drying, and mucilaginous applications to the eyes. Wedelius ſays, that opium does not eaſe pain in the eyes when externally applied, but rather excites greater heat. He ſays, that aloes relieve the eyes more than opium. Experience however proves this erroneous, particularly in ophthalmia; after proper evacuations have preceded, two drams of tincture of opium, mixed with two ounces of roſe water, will very often produce every deſired effect; or in ſome obſtinate caſe, the tincture of opium may be uſed alone with ſucceſs. See Ophthalmia. Beſides there are a variety of other collyria againſt inflammations and other complaints of the eyes, of which the principal ones in uſe may be found in the Pharm. Chirurg. p. 25, to p. 29.

Collyr cœruleum. See Cupri ammoniati aqua.

—— Siccum. See Plumbum. No. 1.

COLOBOMA, from κολοδω, *to maim*, the growing together of the eye-lids. Alſo the want of a particular member or part of the body.

COLOBOMATA. In Celſus, this word is expreſſed by *curta*. Both the words ſignify a deficiency in ſome part of the body, particularly the ears, lips, or alæ of the noſtrils.

COLOCASIA. See Faba Ægyptia.

COLOCHIERNI CARDUUS CRETENSIUS. A plant which differs very little from the atractylis.

COLOCYNTHIS. Bitter-apple. Alſo called *handala*, *alhandala*, *colocynthidis medulla*, *coloquintida*, *alandahal*. *Bitter* or wild-gourd. It is the dried pulpy part of a ſpecies of *gourd*. The cucumis colocynthis, or cucumis *foliis multifidis*, *pomoſis*, *globoſis*, *glabris*. Class, Monœcia; Ord. Syngenesia. Linn. Gen. Plant. 1092: differing from the common ſort only in the leaves being deeper jagged, and the fruit not eatable. It is brought from Aleppo, and grows in many parts of Turkey. It is very light, white, and of a fungous texture, compoſed as it were of membranaceous leaves, with a number of roundiſh ſeeds lodged in the cavities.

The ſeeds are unctuous and ſweetiſh like thoſe of cucumbers, but not purging: the fungous medulla, freed from the ſeeds, is acrid, nauſeous, and bitter to the taſte, and is a ſtrong, irritating cathartic; ſome commend it alſo in leſſer doſes, as an alterative in chronical diſorders. It is rarely uſed alone, though ten or twelve grains will purge violently, frequently producing violent gripes, bloody diſcharges, and even diſordering the whole ſyſtem; but is mixed with other purgatives, to quicken their operation.

When boiled in water, it gives out a large quantity of ſlime; to proof ſpirit it does the ſame; the watery decoction, inſpiſſated to an extract, purges briſkly, but with leſs irritation than the *colocynth* itſelf, and half its weight. Mr. Balduc ſays, that the active matter reſides in its ſalts, which far exceed the reſin and the oil in quantity, and that hence water is its beſt menſtruum. But the beſt method of abating its virulence, without diminiſhing its purgative qualities, ſeems to be by triturating it with gummy farinaceous ſubſtances, or the oily ſeeds, by which means its reſinous particles are prevented from adhering, and ſticking upon the membranes of the inteſtines, ſo as to irritate, inflame, or corrode them.

COLOCYNTHIDIS compositum extractum. See Catharticum extractum.

Colocynthis fructu rotundo major. The greater *coloquintida*. It grows where the above ſpecies is met with, and poſſeſſes ſimilar virtues.

COLON, from κολον, *hollow*. It is the firſt of the large inteſtines, and the moſt conſiderable of them all, called alſo *enteron*. From the cœcum it reaches in the form of an arch above the umbilical region, and extends to the lower part of the left hypochondrium, then runs down before the left kidney, to which it is connected, and below which it turns toward the ſpine, and forming two oppoſite convolutions, terminates in the rectum, which having paſſed below the laſt vertebra of the loins to the inſide of the os ſacrum, is bent backwards on the concave ſide, to which it is joined, and running in the direction of the os coccygis, bends a little forwards, and terminates in the extremity of that bone.

The continuity of the *colon* is a little interrupted by the inteſtinum ileum, which advances into the cavity of the *colon*, and, together with a certain fold of that inteſtine, forms what is called *valvula coli*.

The whole convex ſide of the *colon* is divided longitudinally into three parts by three ligamentary bands, continued from thoſe of the cœcum, and of the ſame ſtructure with them. Two of theſe bands run on each ſide along the great curvature of the colon, and the third along the ſmall curvature. This laſt was firſt noticed by M. Morgagni. Between theſe ligaments the inteſtine is formed into cells, called the cells of the *colon*, which are proceſſes of all the coats. The cellular coat does not differ from that of the ſmall inteſtines; the internal coat is not villous, but papillous; the rugæ are waved and irregular.

Where the ileum terminates, there is a valve called *valvula cæci*, *coli*, *or ilei*. Its figure is oval, it keeps

ſoft and looſe, and upon the very edge there is a diſtant ſphincter, which acts ſo as to hinderthe fæces from returning into the ileum.

The whole courſe of this inteſtine is ſuch, that when warm clyſters are plenteouſly injected, their efficacy is by it applied to almoſt all the abdominal viſcera, for it begins under the right kidney, and runs up on its fore-part, paſſes under the gall-bladder, then runs upon the firſt curvature of the duodenum, to all which it adheres; from thence it runs before the great convexity of the ſtomach, then touches the ſpleen, and goes on to the left kidney, &c. as above mentioned.

The *colon* on its upper part receives arteries from the meſenterica ſuperior and inferior: the lower portion is ſupplied from the meſenterica inferior, one of which forms the internal hæmorrhoidal artery. The veins are from the vena portæ ventralis, the meſeraica major and minor, or hæmorrhoidalis interna. The nerves of the arch of the *colon* are the two meſenteric plexuſes.

When pain is in the *colon*, it is *leſs acute*, and with *a ſenſe of weight*; when in the ſmall guts, there is *not any ſenſe of weight*, but *an acute pain*. If fever attends pain in the *colon*, the pain extending to the ribs gives a ſuſpicion of pleuriſy, though the *colon* in reality is only affected. The *colon* is narrower in the right ſide than elſewhere, whence colic pains riſe more frequently, and rack more violently in this part. The excrements are long retained here, and often are much indurated before they paſs further on.

COLOPHONIA. COLOPHONY, or BLACK ROSIN, called alſo *berrionis*;—*fricta*;—*rezina torta, vel nigra*; DRIED or BLACK ROZIN. PHRYCTE is uſed alone in this ſenſe, as a diſtinction from the liquid ſort called HYGRA. It is only *roſin* whoſe humid and volatile parts are moſt diſſipated. It receives its name of *colophonia* from Colophon, a city of Ionia, becauſe the beſt was formerly brought from thence

Two ſorts are mentioned in ancient writings, the one dry, the other in a liquid form. The latter ſeems to have been liquid pitch, which is the crude *reſin* of the pine brought from Colophon, the former was the reſina fricta. The latter Greeks called every kind of *reſin*, *colophony*.

The beſt *colophony* is the *reſin* of turpentine, which, after the ethereal oil is diſtilled, is again urged by a ſtrong continued fire.

COLOQUINTIDA. See COLOCYNTHIS.

COLOR INDUS. It is a mixture of blue and purple.

COLOSTRUM. The firſt milk of any animal after bringing forth its young, is thus called; that from cows is alſo called BEESTINGS. It is gently cathartic, and purges off the meconium: thus it ſerves both as aliment and medicine.

An emulſion prepared with turpentine, diſſolved with the yolk of egg, is ſometimes called *coloſtrum*.

COLOTOIDES. Variegated like the ſkin of a lizard. Hippocrates applies it to the excrements.

COLPOCELE, from κολπος, *ſinus*, and κηλη, *hernia*. A hernia of the urinary bladder protruding into the vagina. Hence called *cyſtocele vaginalis*, ſeu——*in vagina, elytrocele*. A patient had been for many years liable to violent hyſteric affections, which at laſt were ſucceeded by a dry, convulſive kind of cough. When in courſe of time, this cough diſappeared, ſhe was ſeized with a ſuppreſſion of urine, together with great pain and tenſeneſs in the abdomen. Other remedies failing, the catheter was had recourſe to, for evacuating the urine, but it was with difficulty introduced. This ſuppreſſion returned very frequently; was always preceded by the convulſive cough, and ſometimes even with convulſions, which commonly ended in faintings. The obſtruction which occurred to the introduction of the catheter, ſeemed to proceed from a conſiderable weight and pain which the patient complained of in the forepart of the genitals, and which was always moſt ſevere when the ſuppreſſion of urine was not conſiderable. On examining the parts, the hypogaſtric region was tenſe and painful, but there was no conſiderable tumor perceivable, as there uſually is, in the under part of the belly, when the urine has been long ſuppreſſed; but, upon introducing the finger into the vagina, while the ſuppreſſion continued, a large tumor was diſcovered, which occupied the whole cavity of the vagina. In this ſwelling, a fluctuation was perceived, but no urine could be evacuated by compreſſing it, unleſs the catheter was at the ſame time introduced, and then a plentiful evacuation enſued; though, even in this manner, the contents of the ſwelling could not be entirely diſcharged, unleſs the compreſſion was continued. When the urine was entirely evacuated, the catheter could be eaſily introduced; the tumor diſappeared; the ſuperior part of the vagina felt lax and flaccid; and the finger could be eaſily puſhed up to the mouth of the uterus, till the tumor began again to increaſe, by the urine collecting in the bladder. Then the ſuppreſſion returned, attended with tenſion and pain as before, which commonly ended in convulſions, unleſs the urine was in due time evacuated by the introduction of the catheter. The urine, which at firſt was of a natural appearance, after the diſorder had ſubſiſted for ſome time, became leſs pure, and ſeemed to contain a number of ſmall membranous filaments, as if the internal coat of the bladder had been eroded by it. From this time, the ſenſibility of the bladder became ſo much increaſed, that it was found neceſſary to introduce the catheter much more frequently than before. On conſidering the caſe, it appeared, that a peſſary, properly adapted for the ſupport of the relaxed parts, would, in this caſe, probably be the moſt effectual remedy; and an inſtrument of that kind being procured, and ſo conſtructed as not to prevent the diſcharge of the menſtrual flux, it was introduced; and being continued for ſeveral years, till the parts had again recovered their tone, a complete cure was at length obtained. The peſſary was then no longer neceſſary, and the patient diſcharged her urine with perfect eaſe. See Edin. Med. Comment. Vol. V. p. 257. Sauvages, Noſol. Meth. Vol. I. p. 216.

COLPOS. See SINUS.

COLPOPTOSIS. See PROCIDENTIA VAGINÆ.

COLUBER BERUS. See VIPERA.

COLUBRINA. See SERPENTARIA, DRACONTIUM, and BISTORTA.

COLUBRINA LUSITANICA, HERBA. See CAACICA.

COLUBRINUM, called *colubrinum lignum, radix colubrina, nux vomica* minor Molicana, *modira, canirum, nux vomica* altera, *ſolanum arboreſcens Indicum*, SNAKE-WEED TREE.

It is the wood of the trees on which the nux vomica grows, and of other trees of a ſimilar kind. Linnæus mentions two ſpecies of ſtrychnos, viz. *ſtrychnos nux vomica*, and *ſtrychnos colubrina*. See STRYCHNOS. They are brought from the Eaſt Indies in pieces about the ſize of a man's arm, covered with a brownith or ruſty-coloured bark, internally of a yellow colour, with whitiſh ſtreaks.

It hath a faint ſmell, but not a diſagreeable one; on chewing it ſome time, it is bitteriſh: it gives a gold colour to water and to ſpirit. It affords a fourth of its weight of extract by means of ſpirit, but not ſo much by water.

It hath been given in doſes to half a dram, as an anthelmintic; in quartan agues and ſome other diſorders. It operates differently, ſometimes paſſing off by urine, at others by ſweat, and alſo by ſtool. In a leſſer degree it poſſeſſes the ill qualities of the nuces vomicæ.

COLUBRINUS LAPIS, alſo called *ſerpentis lapis*. It hath its name from the *coluber* ſnake, from which it was thought to be taken; but it is now known to be an artificial compoſition. It is made of hartſhorn, luted up in an earthen pot, where it burns to a blackneſs, and is afterwards poliſhed. The Moors ſay it is made of a kind of clay. It is fabled to be a cure for the bites of ſerpents, by applying it to the wound.

COLUMBA. See COLUMBO.

COLUMBAC. See AGALLOCHUM.

COLUMBO, COLUMBA, COLUMBE, or in the Portugueſe language, *raijs de Moſambique*.

It is produced in Aſia, from whence it was tranſplanted to *Columbo*, a town in the iſland of Ceylon, whence its name, and from whence all the Eaſt Indies are ſupplied with it.

It is brought into Europe in circular pieces of different ſizes, up to three inches diameter; its ſides are covered with a thick wrinkled bark, of a dark brown hue externally; when cut tranſverſely they exhibit a large central diſk with brown ſtreaks, and yellow points. The root conſiſts of three laminæ, viz. the cortical, which in the larger pieces is a quarter of an inch thick; the ligneous, which is about half an inch; and the medullary, which forms the middle, and is near an inch in diameter. This laſt is ſofter than the other parts, and when chewed, ſeems to be very mucilaginous. Many ſmall fibres run longitudinally through it. The cortical and ligneous parts are divided by a circular black line.

It hath an aromatic ſmell, but is diſagreeably bitter, and ſlightly pungent to the taſte.

It is almoſt a ſpecific in the cholera morbus, naufea, vomiting,

vomiting, purging, diarrhœa, dyſentery, bilious fever, indigeſtion, want of appetite, acidity in the primæ viæ, and moſt diſorders of the ſtomach and bowels. It is powerfully ſedative, corroborant, and antiſeptic. The bark more powerfully reſiſts the putrefaction of animal fleſh, but this root exceeds it in preſerving the bile from putridity, and alſo in correcting its begun putreſcency. It is a good ſubſtitute for the bark where an averſion thereto renders the taking of it difficult. As it does not belong to the claſs of heating bitters, it may be uſed in hectic fevers. A tincture of this root in brandy is the moſt uſeful remedy known for moderating the retchings ſo commonly attendant on pregnant women during the firſt months of pregnancy. Dr. Cullen ſays it is a ſtrong and agreeable bitter, and has employed it in many inſtances of dyſpepſia with great advantage. In ſtopping vomiting, it has frequently anſwered, but not always, even where there ſeemed to be a redundancy of bile; but in changing the acrimony, and correcting the putreſcency of the bile, he has not found it more powerful than other bitters.

It may be given in powder from three grains to two drams, but the common doſe is from ten to thirty grains, every three or four hours; and in bilious caſes, it ſhould be joined with equal part of vitriolated kali. The powder has been applied to ulcers which by common remedies cannot be brought into a healing ſtate; and Mr. Home thinks it next to rhubarb; nay even when rhubarb begins to loſe its effect, columbo will frequently renew the healing proceſs, and ultimately be ſucceſsful.

Diſtilled with ſpirit, it ſends over little or nothing of its taſte or ſmell; but the extract, made by evaporating a decoction of it in rectified ſpirit of wine, is better than the root itſelf in powder: about two-thirds of this root is obtained in the ſpirituous extract.

The College of Phyſicians, London, order the following tincture:

TINCTURA COLUMBÆ, *Tincture of* COLUMBO.

Take of *columbo-root*, powdered, two ounces and an half; proof-ſpirits of wine, two pints; digeſt for eight days, and ſtrain: one or two drams, or more of which may be taken repeatedly in mint-water, or an infuſion of orange-peel, which laſt renders it the moſt grateful. It powerfully and ſpeedily relieves colicky pains from flatulence or from indigeſtion.

EXTRACTUM COLUMBÆ. *Extract of* COLUMBO-ROOT.

Take twelve ounces of *columbo-root* in powder, digeſt it four days in rectified ſpirit of wine, three pints; filter this tincture; boil the reſiduum repeatedly in different waters, until it yields little or no taſte to the liquor; ſtrain the decoction, and evaporate until ſix pints only remain; then evaporate in a vapour-bath, and, when nearly finiſhed, add to it the tincture, and reduce the whole to the conſiſtence of a pill.

In diſorders of the ſtomach, attended with a violent fermentation of the food, with flatulence and great acidity, no other known medicine equals this extract. See APEPSIA.

See Dr. Cullen's Mat. Med. Dr. Percival's Eſſays, Med. and Exp. vol. i. ed. 2. Notes to Sydenham by Dr. Wallis, vol. iv. p. 221.

COLUMELLA. The *clitoris*, alſo the *uvula*, and *hypoſtaphile*, or falling down of the uvula. See alſo CAPSULA.

COLUMELLARES DENTES. See CANINI DENTES.

COL. ET COLUM. ECPH. An abbreviation of Fabii Columnæ minus cognitarum rariumque ſtirpium Ecphraſis, 1, 2. Romæ, 1616. 4to.

COL. ET COLUM. PHYT. An abbreviation of Fabii Columnæ Phytobaſanos ſive Plantarum aliquot Hiſtoria. Neap. 1592.

COL. ET COLUM. IN RECH. An abbreviation of Fabius Columna in Rechum in Hernandez. Romæ, 1649.

COLUMNÆ. See CARDUUS PINEA.

—— ORIS. See UVULA.

COLUMNÆ CORDIS, vel *Carneæ*. Theſe are ſmall, long, and round fleſhy productions in the ventricles of the heart. According to Le Dran, the baſis of the heart is alſo thus named. See COR.

COLUMNA NASI. The loweſt and fleſhy part of the noſe, which forms a part of the ſeptum.

—— SEPTIPALATI. See PALATUM MOLLE.

COLUMOBE. See COLUMBO.

COLUTEA, called alſo *ſenna pauperum*, *colutea veſicaria*, *ſenna Mauritanorum*, *pſeudo-ſenna*, *ſenna Europea*, *ſenna ſpuria*, BASTARD SENNA. Botaniſts enumerate ſix ſpecies.

It is a buſh whoſe flowers are ſucceeded by large, ſwelled, thin bladders, flattiſh on the upper part, ſharper and boat-faſhioned underneath, with a crooked appendix at the end, full of black kidney-like ſeeds. It grows wild in Italy, and flowers in July. The leaves and ſeed purge violently both upward and downward. Miller's Bot. Offi.

COLUTEA, caule geniſtæ fungoſo. See POLYGALA VERA.

COLUTEA INDICA HERBACEA. See INDICUM.

—— SCORPIOIDES, MAJOR & HUMILIS. } See E-
—— SILIQUOSA. } MERUS.

COLYMBADES. Olives pickled in ſalt. Some ſay, olives pickled, and ſwimming in their own oil.

COLYMBETHRA. See DEXAMENE.

COLYTEA. See SILIQUASTRUM.

COMA. (κωμα, a head of hair.) The hair of the head. In BOTANY, a ſpecies of Bracte, terminating the ſtem in a tuft, or buſh. A ſpike of flowers terminated by a coma is called *comoſe*. And plants with ſuch flowers are ranged in the thirty-ſixth of the natural orders of LINNÆUS's *Philoſophia Botanica*.

In Galen's Exegeſis it is expounded by *cataphora*, and in his treatiſe of a *coma*, he ſays, that *coma* includes every cataphora, both the ſleepy and wakeful. By the word *coma* the author of Prorrheticon often expreſſes a lethargy. Some call the *coma* by the name typhomania, being ſuppoſed to conſiſt of a mixture of phrenzy and the lethargy. It is the *coma* ſomnolentum of authors. In reality, it is a leſs violent degree of apoplexy, in which the loſs of ſenſation is not ſo conſiderable. See CAROS.

COMA AUREA. GOLDEN LOCKS, alſo GOLDEN CUDWEED. See ELICHRYSUM.

—— VIGIL; called alſo *agrypnocoma*. A diſeaſe, wherein the patients are continually inclined to ſleep, but ſcarce can. Blancard. See CAROS.

COMAROIDES. } See ARBUTUS.
COMARUS. }

COMATA. The ſecond claſs, NEUROSES, *nervous diſeaſes*, and FIRST ORDER, COMATA of Dr. Cullen's Noſologia, defined, a diminution of voluntary motion, attended with ſleep, or a deprivation of the ſenſes. Under which he ranks APOPLEXIES, PALSIES, and mentions TREMORS. We therefore find, in this order, he comprehends thoſe affections which have generally been called ſoporoſe diſeaſes; but ſays they are moſt properly diſtinguiſhed by their conſiſting in ſome interruption or ſuppreſſion of the powers of ſenſe and voluntary motion, or of what are called the animal functions. Theſe (he adds) are uſually ſuſpended in the time of natural ſleep; but in all theſe diſeaſes, ſleep, or even the appearance of it, is not conſtantly a ſymptom. Theſe are alſo termed *nervorum reſolutiones*.

COMBUSTIO and COMBUSTURA, from *cōn* and *uro*. See CALCINATIO.

COMEDONES. A ſort of worms. See BOVINA AFFECTIO, and CRINONES.

COMETES. See AMYGDALOIDES.

COMETZ. HALF A DROP.

COMISDI. See GUMMI ARABIC.

COMISTE, } See EPILEPSIA.
COMITIALIS MORBUS. }

COMITISSÆ PULVIS. See CORT. PERUV.

—— PALMÆ, or PALMERI PULV. See MAGNESIA ALBA.

COMMAGENUM. The name of an ointment mentioned by Galen. It is alſo called *Syriacum unguentum*.

COMMANDUCATIO. See MASTICATIO.

COMMANSUM. See APOPHLEGMATICA.

COMMEL. PLANT. USU. An abbreviation of Caſpari Commelinis Horti Medici Amſtælodamenſi Plantarum Uſualium Catalogus. Amſtel. 1724.

—— PRÆLUD. An abbreviation of Caſpari Commelini Præludia Botanicæ, Ludg. Batav. 1715.

—— FLOR. MAL. An abbreviation of C. Commelini Flora Malabarica, ſive Horti Malabarici Catalogus.

—— INDIG. An abbreviation of Caſp. Commelini Catalogus Plantarum Indigenarum Hollandiæ.

COMMENDATORIUM (BALS.) The balſam of the commander of Berne, Balſ. Traumaticum. Now *Tinctura benzoes comp.* See BENZOINUM.

COMMI. See GUMMI ARABICUM.

COM-

COMMINUTIO. COMMINUTION. From *comminuo, to break to pieces*, alſo *contritio*. It is the reduction of any ſolid body into finer particles by any means whatever, and is of two kinds, viz. CONTUSION or PULVERIZATION, and LEVIGATION or TRITURATION.

Subſervient to pulverization, where extremely fine powders are required, two ſecondary motions are neceſſary, viz. SEARCING and ELUTRIATION: the *firſt* is the paſſing of any pounded matter through a ſearce of a proper degree of fineneſs; the latter is by diffuſing the powdered ſubſtance in a proper quantity of water; then decanting the liquor with the lighteſt part of the powder, &c. as directed in the preparation of crude antimony. See ANTIMONIUM.

In powdering any ſubſtance, care ſhould be taken to accommodate the ſubſtance to the inſtruments: ſuch things as will diſſolve metals ſhould be prepared in ſtone or glaſs mortars; very hard bodies will abrade ſoft marbles: to prevent then the mixture of the inſtruments made uſe of, with the medicine that is prepared by them, ſuch mortars, ſtones for levigating on, &c. muſt be choſen, as cannot be affected by the uſes they are employed in.

Light dry ſubſtances, reſins, roots of a tenacious texture, are more eaſily pulverized if the mortar is previouſly rubbed with oil; camphor and cortex require a little water; tough ſubſtances may be grated or raſped; hard minerals, as flint, calamine ſtone, &c. ſhould previouſly undergo an *extinction*, that is, ſhould be made red-hot and then quenched in water; the alkaline and calcareous ſtones need not this proceſs, for they would thereby be converted into lime.

Some metals, if heated to a proper degree, are rendered brittle, and then by agitation are eaſily powdered: of this kind is tin. This *comminution* of metals is called GRANULATION.

Simple as this pharmaceutic operation is, its importance is conſiderable in medicine: reſinous purgatives, when well triturated, are more eaſily ſoluble in the animal fluids, and operate more briſkly with leſs irritation: antimony, finely powdered, diſcovers but little efficacy; but exquiſitely levigated, is a powerful alterative. Mercury, and many other medicines, owe their virtue to *comminution*.

Roots, and ſuch other articles as conſiſt of different parts, viz. a reſinous, ligneous, &c. ſhould be wholly powdered, and then the whole powdered ſubſtance ſhould be well mixed together, for without this precaution one part will be too active, and another too inert.

In levigating, ſome fluid muſt be added to the levigated matter. Earthy and other hard bodies that are not ſoluble in water, muſt firſt be finely powdered in a mortar, then levigated with water on a hard marble ſtone, and afterwards dried on a chalk ſtone.

Bezoar, on account of its colour, ſhould be levigated with ſpirit of wine.

COMMISSURA. See SUTURA, & ARTICULATIO.

COMMISSURES. See LABIÆ PUDENDÆ.

COMMOSIS, κομόω, *ornatum accuratum & ſupervacuum adhibeo*. The firſt ſtratum of gummy matter with which bees line their hives. It alſo ſignifies that art which is employed in concealing natural imperfections with reſpect to beauty: this is diſtinguiſhed from the coſmetic art, which conſiſts in preſerving the beauty which is natural.

COMMUNICANTES FEBRES. According to Bellini, they are two fevers which infeſt a perſon at one and the ſame time, the paroxyſm of one beginning as ſoon as the other ceaſes.

COMMUNIS SAL. See MARINUM SAL.

COMOSE. See COMA.

COMPASSIO. COMPASSION. In Noſology it is the ſuffering of one part on account of an affection of ſome other part: this is called ſuffering by conſent, or *ſympathy*. See SYMPATHIA.

COMPEBA, } See CUBEBÆ.
COMPIPER. }

COMPRESSOR NARIS. See NASALIS.

COMPLEXUS, called alſo *Trigeminus*. This muſcle runs obliquely, riſing from the tranſverſe proceſſes of the ſix inferior cervical vertebræ, and ſixth, ſeventh, or eighth ſuperior dorſal vertebræ: it then directs its courſe upwards, and is inſerted into the concavity, below the tranſverſe line of the occiput, and bends the head back. It ſometimes receives a few ſlips from the ſpinal proceſſes of ſome of the vertebræ of the dorſum. The complexus being removed, we ſee the two recti and the two obliqui.

COMPLEXUS MINOR, called alſo *maſtoideus lateralis, trachelo-maſtoideus, & capitis, par tertium Falloppii*. When the ſplenius muſcle is removed, we ſee the *complexus* and the *complexus minor*; the *complexus* is neare the ſpine, and the *complexus minor* is under the upper edge of the ſplenius; it is various in different bodies. Albinus deſcribes its originations twelve different ways: it riſes from the tranſverſe proceſſes of the three uppermoſt vertebræ of the back, and from the five lowermoſt of the neck, where it is connected to the tranſverſalis cervicis, by as many thin tendons, which unite into a belly, and run up under the ſplenius. It is inſerted into the middle of the poſterior ſide of the maſtoid proceſs, by a thin tendon. Its uſe is to aſſiſt the *complexus*, but it pulls the head more to a ſide. Innes.

COMPREHENSIO. See CATALEPSIS.

COMPRESSUS. See CEREBRI COMPRESSIO.

COMPUNCTIO. See PARACENTESIS.

CONARIUM, See CEREBRUM.

CONCAUSA. A cauſe which co-operates with another in the production of a diſeaſe.

CONCENTRANTIA. Abſorbents of acids are ſometimes thus named.

CONCENTRATIO. CONCENTRATION. To *concentrate* a body is to approximate its principal parts by removing thoſe which keep them aſunder, and which are not proper to the body *concentrated*. This word is generally applied to the dephlegmation of acids, and particularly of the vitriolic by diſtillation, and of vinegar by congelation.

CONCEPTIO. CONCEPTION. After all the conjectures, inquiries, obſervations, &c. to diſcover this proceſs in nature, with many others, it is ſtill only to be reſolved into the divine contrivance. Dr. Berdoe, in his Enquiry into the Influence of the electric Fluid, defines conception to be, "The firſt occult ſenſation by which the unformed being unites itſelf to its parent." He farther obſerves, that the fœtus is not perfected at once, but paſſes through different gradations of its exiſtence as follow:

"1ſt. The fecundating powers of the uterus are employed to collect the colliquamentum, in which the gonè of Hippocrates is to eſtabliſh the rudiments of the future embryo. This firſt diviſion in the formation of the fœtus, is perhaps the primitive attractive power of the animated mucus, collecting together the firſt particles of the nervous ſyſtem to form the cicatricula, medulla oblongata, &c.

"This 2d diviſion is what Hippocrates calls *cuèma*, or the *conception*, and is what *conception* is above defined to be.

"The 3d diviſion in the formation of man was called *embryon, cuema, cyema*, by Hippocrates; in this ſtate it conſiſts of a trunk without limbs, the expanding of which completes the embryo ſtate.

"The laſt diviſion is called *courot, paidion, fœtus*, or CHILD."

However ſecretly conception is effected, its effect on thoſe who are its ſubjects is very manifeſt by ſymptoms that immediately appear, particularly in the human ſpecies; all which are produced by a preternatural irritability being induced into the uterus, and indeed into the general habit. If we conſider that the fœtus is ſometimes extra-uterine, we are certain that impregnation has taken place in the Fallopian tubes, ovaria, or even within the graſp of the fimbria called morſus diaboli. Hence the appellation of tubal, ovarial, or abdominal fœtus, for the placenta has been found adhering within the two former, and inſtances have occurred, where the membranes of the abdomen have been the ſeat, without any appearance of the leaſt alteration occurring in either the tubes, or ovaria. Might it not therefore be concluded, that impregnation is the effect of the vital principle, or aura vivificans a ſemine maſculino influencing the ova?

See Malpighius, De Graaf, and Harvey; alſo Berdoe's Enquiry, Kirkland's Treatiſe on the Child-bed Fever, Hamilton's Outlines.

CONCEPTUS. The very firſt rudiments of the fœtus in the uterus after conception.

CONCHA. A SHELL ANIMAL. Some confine this word to the ſhell, whilſt others intend by it the animal with its ſhell. Some uſe it only to ſignify fiſhes with two ſhells, the hiſtory of which ſort ſee in the Spectacle de la Nature, tom. i.

Sea *ſhell-fiſh*, when boiled, are eaten as wholeſome food,

food, and are alcalescent: their shells are absorbent; if calcined, become a quick-lime, possessing a lithontriptic virtue.

CONCHA ANATIFERA. These shell-fishes are thus called, because it was fabulously said that a species of duck was formed in them.

—— AURICULÆ. See AURICULA.

—— CYTHERIACA. } See CONCHA VENEREA.
—— ERYTHRÆA. }

—— MARGARITIFERA. This word belongs to every shell-fish in which pearls are found; but because the best pearls are found in the East Indies, it is confined for the most part to the CONCHA INDICA MAGNA, whose shells are moderately hollow, thick, and externally of a yellowish colour, rough, uneven, and not striated; internally they are smooth, and shine like pearls. It is a species of oyster, and is eaten raw or roasted. It is principally found in the Persian sea. The shell of this fish is the *mater perlarum*. It is also called *cochlea margaritifera*.

—— MATER UNIONUM, } See MATER PERLA-
—— VALVIS ÆQUALIBUS. } RUM.

—— STRIATA. The COCKLE. This is a shell-fish employed as a nutrient, but being of a firmer substance than the oyster, is not so easily digested: in other respects it seemingly possesses the same properties. See OSTREA.

—— VENEREA, VENERIS, or ERYTHRÆA. VENUS'S SHELL.

It is an univalve wreathed shell having a small longitudinal and denticulated chink or aperture in it. It is also called *concha porcellana*, from its aperture resembling the mouth of an hog, and *concha cytheriaca*, from Venus, who received the epithet Cytherea from Cythera, a Grecian island.

As a medicine, for these shells the cockle shell may be substituted.

CONCHA. A liquid measure among the Athenians, which contained half an ounce, or, according to some, three spoonfuls, and others again say five spoonfuls, or six drams. Galen says that the *concha magna* was the same as the *acetabulum*, which of liquid contained an ounce and a half, and in weight fifteen drams; and that the *concha minor* was half an ounce of liquid, and five drams of weight.

CONCHÆ NARIUM INFERIORES, the inferior spongy laminæ of the nose. Also called CONVOLUTA INFERIORA, *laminæ spongiosæ inferiores*. They are situated in the nasal fossæ, one in each side; they are suspended like the ethmoidal *concha*, without resting on any thing. The inferior edges are the most considerable of their three edges; they are rough, thick, a little rounded, and turned outwards, that is, toward the os maxillare. By their anterior superior edge, they are joined to the anterior transverse eminences of the os maxillare; their posterior superior edge is the longest, and is joined backwards to the small transverse eminence of the middle portion of the os palati. See Winslow's Anatomy.

—— NARIUM SUPERIORES. So Winslow calls the inferior part of each lateral portion of the os ethmoides. Also named *convoluta superiora ossa*, and *laminæ spongiosæ interiores*.

CONCHARUM ANTIFEBRILE. In Bate's Pharmacopœia it is thus directed: pour vinegar upon the muscle shells, and macerate them for twenty-four hours, wipe off the external mucus, dry and reduce them to a powder, during which operation add a spoonful of carduus water, to prevent the light parts from flying off. A dram is a dose as a febrifuge and diaphoretic.

CONCHIFOLIA. See MANGA.

CONCHIS. Among the Romans it is an entire bean wrapped up in its entire capsule.

CONCHYLIA FOSSILIA. FOSSILE SHELLS. They are lithontriptic.

CONCHYROIDES. See CORACOIDES PROCESSUS.

CONCIDENTIA. A decrease of bulk in the whole or any part of the body, or the subsiding of a humour.

CONCOAGULATIO. The *coagulation*, concretion, or crystallization of different salts, first dissolved together in the same fluid.

CONCOCTIO. CONCOCTION. It is generally understood to be such a work upon the morbid matter, by the power of nature or assistance of art, as renders it fit for separation from the healthy parts of our fluids, and to be thrown out of our bodies. But this doctrine, at least in fevers, is doubtful, if not false. That morbid matter passes off from the blood in a crude state, or in the state it was first formed in, appears from the matter of the small pox and measles, both which are effectual in inoculating, in whatever state of the disease it is taken. And it is most probable that, in every infectious fever, the morbid matter, after assimilating some of the humours into its own nature, passes off in the same state that it was in when the body was first disordered by it. Farther, acrimony in the blood is not rendered mild by any process in our frame; on the contrary, it is always expelled by some of the emunctories. And as to what is observed in pus, none of a kindly nature is formed whilst the heat of the body much exceeds the degree that is proper to health; but in its stead there is an ichor.

Sydenham's notion of *concoction* was, that "the *concoction* of the febrile matter means no more than a preparation and separation of the morbific from the sound particles."

See Kirkland on Fevers, p. 14, 27.

CONCREMATIO. See CALCINATIO.

CONCRETIO. In CHEMISTRY it is the condensation of any fluid substance into a more solid mass, importing the same as coagulation. In SURGERY it is the growing together of any parts which are separate in a natural state.

CONCURSUS. See SYNDROME.

CONCUSSIO. A CONCUSSION, from *concutio, to shake*. A JOLT or SHOCK OF THE BRAIN by blows or falls.

Extravasation and commotion is what old writers, when they found no fracture or depression of the scull, and yet the patient died in consequence of the injury received, called a *concussion*. A *concussion* of the brain is a sudden and a violent motion thereof, and of the pia mater, with such a sudden distension of their blood-vessels (occasioned by a determination of their contained blood, both arterial and venal, into one direction by the force of the accident) as occasions them to lose their power of propelling their contents as formerly, or of continuing the circulation of the blood as before. Mr. Deafe, in his Observations on Wounds of the Head, remarks, that the two carotid, and the two vertebral arteries, supply the brain with blood; that these arteries lose their strong elastic coats on entering the cavity of the cranium; that their capacities are enlarged, and their tunics become similar to those of veins. That elevation and descension we see on exposing the dura mater, and which corresponding with expiration and inspiration, gives us room to imagine the brain is not always in so close a contact with this membrane, as is generally supposed. From this disposition, he adds, we can readily conceive, how easily the *concussion*, in consequence of fractures or smart strokes on the head, will be transmitted, so as to affect the vessels of the pia mater and brain. And the degree may appear from a temporary suspension of the faculties of the brain, to a total abolition of them, as happens when death ensues. Many of these cases are not attended with any immediate alarming symptoms, and yet those vessels will suffer so much by the shock, as to be rendered incapable, by their oscillating powers being weakened, to continue the circulation; and which, after some time, if not restored, will infallibly lay the foundation of their future inflammation. When we consider the infinite number of vessels that run through this viscus, and the general communication that exists between them; we shall not be surprised that a great number may be obstructed, or rather rendered incapable of the office of circulation, and the fluids be suspended in them, and no immediate injury arise that will impede the functions of the brain, and, of course, the patient feel no present complaint. However, we know that our fluids cannot long exist in this situation, without being liable to degenerate from their original mild nature, and become a principle of irritation, which will excite the surrounding vessels to quicker oscillations, so as to determine their fluids with redoubled velocity towards the point irritated; and of course an inflammation will succeed. Dr. Whytt, on the Motion of the Fluids in the small Vessels, p. 240, says, an inflammation is not owing to an increased force of the heart and large arteries, consequent upon an obstruction, as some say; but to an increased alternate contraction of the small vessels, whether this arises from some obstructing matter overstretching their fibres, or acrid matter irritating them. Mr. Schmucker, in his Chirurgical Observations, published at Berlin, deserves to be consulted on this subject. He observes, that in many cases of wounds of the head, especially in those from gun-shots,

which at firſt, and for many days after being inflicted, appear to be attended with no kind of danger, at laſt turn worſe, and frequently carry off the patients. He adds, that on the opening the heads of ſuch patients after death, either pus was found diffuſed upon the pia mater, or a gelatinous ſemi-purulent kind of matter was obſerved. Moſt frequently the brain itſelf appeared perfectly ſound. Mr. Schmucker attributes the loſs of life in theſe caſes, chiefly to an affection of the tunica arachnoidea, (i. e. upper lamina of the pia mater) and of different lymphatics. The contuſion occaſioned by gun-ſhot wounds, and ſimilar accidents, produces always, he ſays, an effuſion and ſtagnation of lymph, which, in cachectic and debilitated ſubjects, is with difficulty abſorbed, and is commonly therefore either converted into pus or ichor.

It is often very difficult, when an accident from external violence happens to the inſide of the head, to know of what kind it is, and where is its ſeat: in ſuch circumſtances, conſider the ſymptoms; how the misfortune happened, with any other circumſtance that may throw light on the caſe; ſometimes the misfortune proves fatal, only for want of knowing what part is injured.

The ſigns of a concuſſion do not always appear immediately after the injury is received Mr. Pott remarks, that the ſymptoms attending a *concuſſion* are generally in proportion to the degree of violence, which the brain itſelf has ſuſtained; and which, indeed, is diſcoverable only by the ſymptoms. *If the concuſſion be very great*, all ſenſe and power of motion are immediately aboliſhed, and death follows ſoon: but, between this degree, and that ſlight confuſion, (or ſtunning as it is called) which attends moſt violences done to the head, there are many ſtages. SOMETIMES *a concuſſion produces the ſame kind of oppreſſive ſymptoms as an extravaſation*, and the patient is either almoſt or totally bereft of ſenſe; AT OTHER TIMES, no ſuch ſymptoms attend, but *the patient gets no ſleep at all, hath a wild look, an eye much like that of a perſon who hath long watched through apprehenſion and anxiety; talks much, and very inconſiſtently; hath a hard labouring pulſe, ſome ſmall degree of fever*, and *ſometimes an inclination to vomit; if not retained, the patient will get out of bed, and act with a kind of frantic abſurdity, and appears in general much hurt by a ſtrong light.* Stunning is a ſlight degree of commotion, which ſoon goes off. Mr. Deaſe, in his Obſervations on Wounds of the Head, ſays, that if the inſtrument with which the blow was given, was not heavy, nor the force very great, the patient, after a few minutes, perceives no complaint more than might be expected from a ſimple wound. If the patient be attended, it is very ſeldom that the ſurgeon will be able to determine, the firſt days, whether any farther injury has actually taken place or not. The wound digeſts as kindly, and the patient performs all the functions neceſſary to health, as well as before he received it. In ſuch as became afterwards affected, whether they underwent profuſe evacuations, or were entirely left to nature, it made ſo very little difference as to the time or manner in which they were firſt invaded by the ſymptoms that uſually attend an inflamed or ſuppurated ſtate of the parts underneath the cranium, that the variation could never be attributed to the treatment. The firſt ſymptoms, that generally alarmed thoſe patients who were brought to the hoſpital, were ſlight ſhiverings, attended with an inclination to puke. In ſome, this was preceded by a languor, accompanied with more or leſs fever, and often with a dull pain in the head, and melancholy look. The wound, in ſome, put on the appearance which Mr. Pott deſcribes in his book on Wounds of the Head, p. 63. But this was not always that infallible ſign of the inflammation and putrefaction of the dura mater he makes it; nor did this appearance often take place, until the fever and other ſymptoms were far advanced. In ſome, theſe ſymptoms made a rapid progreſs, ſo as to carry off the patient in a few days. In others, they ſeemed to advance more ſlowly, and were leſs ſevere, although not leſs fatal. Mr. Deaſe goes on to obſerve, that he hath ſeldom ſeen *theſe ſymptoms appear earlier than the eighth, or later than the ſixteenth or ſeventeenth day*, between the eighth and the ſixteenth being in general the period moſt to be dreaded. If the trepan was applied at any time after thoſe ſymptoms took place, the appearance of the dura mater was invariably this; either it was detached and in a ſtate of ſuppuration and ſloughy, or found in every reſpect. If the injury was confined to it, the operation was uſually ſucceſsful. If the patient died, he ever found the cauſe of his death in the ſuppuration of the pia mater, or brain, but more generally both.

A violent blow on the head, not beating the head to the ground, nor againſt any hard body, moſt frequently cauſes a fracture or fiſſure, with but ſmall *concuſſion*; when a blow is given with ſuch violence as to knock the perſon down, and his head hits the ground, if the ſkull is not thereby broken, a *concuſſion* will be the conſequence. If the head ſtrikes againſt a hard immoveable body, in conſequence of a fall from a conſiderable height, a *concuſſion* with an extravaſation uſually follows, and generally death is the conſequence. A *concuſſion* of the brain ſeldom is attended, if ever, with extravaſation, unleſs when re-action follows the blow. A *concuſſion* with a fracture is leſs dangerous than one with a fiſſure, becauſe in the firſt caſe the extravaſation is leſs.

To diſtinguiſh betwixt a *concuſſion* and an extravaſation of and in the brain, is ſometimes extremely difficult, though, in many inſtances, very eaſy. The firſt ſtunning or deprivation of ſenſe, whether total or partial, may be from either, and no man can tell from which; but when theſe firſt ſymptoms have been removed, or have ſpontaneouſly diſappeared; if ſuch patient is again oppreſſed with drowſineſs, or ſtupidity, or total or partial loſs of ſenſe, it then becomes moſt probable that the firſt complaints were from commotion, and that the latter are from extravaſation. But when, after ſeveral days from the accident, at which time the ſymptoms were inconſiderable, or ſoon paſſed off, the watchfulneſs above noticed, &c. attends, the caſe is clearly a *concuſſion*. See COMPRESSIO CEREBRI.

In thoſe who recover from a commotion of the brain, the office of ſome particular nerve or nerves is often deranged or deſtroyed; as a ſquint of one eye produced, which laſts for life; a diſtortion of the corner of the mouth; an incapacity of retaining the urine for a great length of time; and often a total incapacity through life of diſtinguiſhing by the ſmell the rankeſt leek from the ſweeteſt roſe.

The caſe diſcovered, bleeding and antiphlogiſtics ſhould be uſed, to prevent if not remove the inflammation; and if the injured part of the inſide of the head cannot be diſcovered, the chief dependence is on bleeding, purging, and ſweating.

Bleeding may be performed in the temporal artery, or in the jugular vein, though generally from the arm ſuffices.

Except there is a depreſſion of the ſkull, the trepan does not ſeem neceſſary. On this ſubject authors vary much.

Lenient purges, which operate with the leaſt irritation, are of ſingular efficacy: according to Joba Meekren and ſome others, they prevent an abſceſs forming itſelf in the liver, which ſometimes, when they are omitted, follows in conſequence of a *concuſſion* of the brain.

The diet ſhould be cooling and ſlender.

If great heat is perceived in the head, apply thereto an embrocation of oil, vinegar, and ſal ammoniac.

From Mr. Schmucker's view of the cauſe of the diſorder, is ſuggeſted the idea of aſtringent applications as proper; and he informs us, that he employed them with the greateſt advantage. The following he ſeems to prefer. ℞ Aq. pur. ℔ x. acet. acerrim. ℔i. ſal. nitri ℥ iv. ſal. ammon. crud. ℥ ij. m. With this embrocation he orders the part affected to be frequently well bathed; at the ſame time that blood-letting is preſcribed, together with the internal uſe of nitre, ſtimulating injections and laxatives. In all the ſlighter affections of the head, the greateſt ſucceſs, he ſays, has been obſerved from ſuch a courſe; and, even in ſuch as have required the trepan, Mr. Schmucker thinks he has often ſeen it put in practice with advantage. In *concuſſions* of the brain, even without any external wound, cold epithems and fomentations, he ſays, are very ſerviceable, eſpecially if conjoined with ſtimulating clyſters, and the application of leeches to the temples. Mr. Schmucker farther obſerves in the ſame work, that violent *concuſſions* of the brain are often produced merely from the paſſage of cannon-balls near to the head, without any external affection being obſervable. In ſuch caſes, and in all ſimilar *concuſſions*, emetics, he ſays, are commonly attended with the beſt effects; venæſection, however, muſt always be premiſed to the uſe of theſe remedies.

Mr. Bromfield aſſerts the happieſt ſucceſs in theſe caſes from the uſe of Dover's ſweating powder; after bleeding, if required, he orders the bowels to be evacuated by

by means of a clyſter, and then a ſcruple of Dover's powder, the operation of which muſt be encouraged by putting the patient between blankets, and repeating it every twelve or twenty-four hours, according as the violence of the ſymptoms requires. As it is chiefly from the attenuating property of the opium that relief is expected, he uſes ſuch a proportion of the vin. antim. mixed with tinct. opii, as will be needful to keep up a diaphoreſis when the violent ſymptoms are allayed, and until ſuch a freedom from complaint, as needs no farther ſimilar aid, is brought about: of this he gives ten or fifteen drops every four or ſix hours. As oft as the violent ſymptoms return, he hath recourſe to the powder: and ſuch was his ſucceſs, that in more than a hundred caſes he ſucceeded, and in two which were attended with fractures of the ſkull, cures were thus effected without the uſe of the trepan. Mr. Juſtamond ſays, that the trepan is never required, and that the beſt we can do, is to leave the patient entirely at reſt.

From all which, we may collect, that gentle evacuations, ſufficiently continued, are chiefly to be depended upon, to which, from Mr. Bromfield's account, we may add, that they are not a little aſſiſted by the ſedative power of opium, more than from any attenuating property it poſſeſſes.

See Bohnius, in Renunciatione Vulnerum de Vibratione Cerebri; Berengarius de Commotione Cerebri; Monſ. Bertrandi's Diſ. on the *Concuſſion* of the Brain, in the 3d vol. of the Mem. of the Royal Acad. of Surgery; Wiſeman's Surgery, book v. ch. ix. obſ. x. Gooch's Caſes and Remarks, ed. 2. and Bromfield's Chirurgical Obſ. and Caſes, vol. i. ch. i. Deaſe's Obſ. on Wounds of the Head; Pott's Works; Bell's Surgery, vol. iii. p. 132.

CONDENSATIO. CONDENSATION. It implies a contraction of the cutaneous pores by means of cooling, drying, or aſtringent medicines. It is alſo an inſpiſſation of any ſort of fluid, whether in or out of the body: hence *condenſantia medicamenta* are medicines that condenſe or inſpiſſate the juices.

CONDER. See OLIBANUM.

CONDIMENTUM. *Artyma, conditura.* A CONDIMENT or PRESERVE. From *condio, to ſeaſon, pickle,* or *powder.* It ſignifies whatever procures ſweetneſs and a grateful taſte to any ſubſtance. But, in a more reſtrained ſenſe, that is called *condimentum* which is uſed in preparing aliments, whether with an intention of rendering them palatable or aſſiſting their digeſtion. See CONDITUM.

CONDIO. *To embalm*; alſo *conditura.* The Latins call it *pollincio.* The practice of embalming is as ancient as the firſt record of the character of phyſician. See Geneſis, ch. l. v. 2. In the Eaſt it is ſtill practiſed, but ſeems not ſo general as formerly. On this ſubject ſee Paré Dionis's Surgical Operations, Gooch's Treatiſe on Wounds, p 456; Greenhill's Art of Embalming; Bell's Surgery, p. 465.

CONDITUM. PRESERVES. They are made by ſteeping or by boiling recent ſimples (of the vegetable kind) firſt in water, then in ſyrup or a ſolution of ſugar. The ſubject is afterwards either kept moiſt in the ſyrup, or taken out and dried, that the ſugar may candy upon it: this laſt is the moſt uſual method. This art was formerly a branch of the apothecary's buſineſs, but now is wholly in the hands of confectioners.

The Latins and the latter Greeks meant by *conditum* a ſort of *acratomeli*, that is, a wine impregnated with honey and aromatics. See MULSUM.

CONDITURA. See CONDIMENTUM; alſo CONDIO.

CONDRILLA. See CHONDRILLA.

CONDUCTIO, in Cælius Aurelianus, is a ſpaſm or a convulſion.

CONDUCTOR, from *conduco, to guide.* A CONDUCTOR. It is an inſtrument uſed in ſurgery for the direction of a knife when a ſinus is laid open. It is alſo a name of the inſtrument called a GORGET, which is uſed in the operation of lithotomy.

CONDUPLICATUM FOLIUM, *con* and *duplicor, to be doubled,* a term in foliation, ſignifying, that the ſides of the leaf within the gemma are parallel, and approach each other, or are doubled over each other at the midrib. It is uſed alſo in the ſleep of plants in the ſame ſenſe, when the leaves during the night fold together, like the leaves of a book.

CONDYLI. Knots in the bones about the joints of the fingers, which make them thicker.

CONDYLOIDÆ. APOPHYSES. See MAXILLA INFERIOR.

CONDYLOMA, κονδυλος, *a joint,* or *tubercle.* A tumor ſo called from its reſemblance to a *condyle,* a joint bent, or a tubercle. It is a hard eminence, which ariſes in the folds of the anus, or a hardening or a ſwelling of the wrinkles there. Theſe tumors often happen in the orifice of the uterus, and other parts. It is variouſly deſcribed in authors; one ſays it is a tumor of the cuticle; another ranks it as an inſtance of ſarcoma. An anonymous French writer ſays, it is in general a fleſhy excreſcence which appears on the fingers, hands, feet, and principally about the anus, the perinæum, and the private parts of both ſexes. He adds, that warts, the tumors called *ficus, mariſca, ſycoſis, thymus,* &c. are all but different inſtances of *condylomas.* See ATRICES.

It generally proceeds partly from a fault in the quality and partly from a fault in the quantity of the fluids flowing there. At firſt it is named a tubercle, but when hardened, a *condyloma.*

Authors abound with unneceſſary diſtinctions reſpecting tumors, &c. but all tubercles and fungi, whether within the verge of the anus or more outward, are of the ſame nature, and are cured by the ſame method, whether called *condyloma, ficus, fungus, criſta,* or whatever elſe, and are tumors of the glandules of the part, which increaſing, like a polypus of the noſe, prove troubleſome, being often painful. Thoſe who are troubled with the piles have them very much. They often appear in the pudenda from the lues venerea.

If the roots are ſmall, a ligature may extirpate them; if broad, they are beſt removed by a cauſtic, if care is taken that it doth not injure any other part.

See P. Ægineta, Celſus, Heiſter, Turner, Wiſeman; Bell's Surgery, vol. ii. p. 264.

CONDYLOMA. A CORN. See CLAVUS.

CONDYLUS. A CONDYLE. It is a knot in any of the joints, formed by the epiphyſis of a bone. In the fingers it is called the knuckle. See PROCESSUS. IN BOTANY it ſignifies the joints of plants.

CONEION. In Hippocrates it imports the *cicuta.* It is ſaid to be thus named from κωνειν, *to turn round*; becauſe it produces a vertigo in thoſe who take it internally.

CONESSI, called alſo *codaga pala,* coneſſi ſeca, *cadaguſpali.* It is the bark of a ſmall tree, called *arbor Malabarica lacteſcens;—jaſmini flore odoro, ſiliquis oblongis,* growing in Ceylon and Malabar, and on the Coromandel coaſt, where it is called *coneſſi.* It is blackiſh outwardly, and covered more or leſs with a whitiſh moſs or ſcurf, which ſhould be ſcraped off. To the taſte it is gratefully auſtere and bitter. When powdered and made into an electary, it is commended in diarrhœas; half a dram may be taken three times a day; or taken in four milk, it alſo reſtrains, not only alvine fluxes, but hæmorrhages. The root, boiled in water, makes good fomentations againſt inflammatory tumors; and taken inwardly, deſtroys worms. When uſed it ſhould be freſh powdered, for it ſoon loſes its medical qualities under any form or preparation. When taken to reſtrain an alvine flux, an emetic of ipec. ſhould precede its uſe. Thoſe with whom a diarrhœa is frequent in moiſt weather, are much benefited by its uſe, if a dote is taken morning and evening. Raii Hiſt.

CONFECTA COMFITS or SUGAR-PLUMS. Seeds or other ſubſtances incruſted with ſugar. Theſe, when impregnated with purging ingredients, are given to children when they will not take the uſual forms of medicines.

CONFECTIO. A CONFECTION, called alſo *aliguius.* In general it is any thing prepared with ſugar In particular it is the ſame as *conditum.* Theſe articles are alſo called dry confects. The word *confectio,* when alone, ſignifies a ſoft electary. The dry confects are now a branch of the confectioner's buſineſs, though formerly a part in the apothecary's: they are dry ſubſtances, ſuch as the roots of eringo, the peels of oranges, &c. which are incruſted with ſugar, and are called CANDIED ROOT, OR PEEL. As to the ſoft electaries, the London College preſcribes the following:

Confectio Cardiaca. The CORDIAL CONFECTION, now called *Aromatica. The* AROMATIC CONFECTION.

Take of zedoary in coarſe powder, ſaffron, of each half a pound; diſtilled water, three pints; let them macerate for twenty-four hours, then preſs and ſtrain them. Evaporate the ſtrained liquor to a pint and an half, to which

add

add the ſubſequent ingredients reduced to very fine powder; compound powder of crabs' claws, ſixteen ounces; cinnamon, nutmegs, of each two ounces; cloves, one ounce; leſſer cardamom ſeeds huſked, half an ounce; double-refined ſugar two pounds: and thus form the *confection*. Pharm. Lond. 1788. This is altered from the laſt Diſpenſatory, and may be conſidered as an improvement. It is certainly an agreeable cordial, and carminative, but ſhould not be long kept, as by that means it loſes its efficacy. This is ſubſtituted for the confect or cordial of ſir Walter Raleigh.

CONFECTIO ALKERMES. See CHERMES.

—— ANACARDII. See ANACARDIUM.

—— AROMATICA. See CONFECTIO CARDIACA.

Confectio *Damocratis*. DAMOCRATES'S CONFECTION, called alſo *Diaſcinci*.

This was formerly called *Mithridatium*, from Mithridates king of Pontus and Bithynia, who, after the example of Attalus of Pergamus, is ſaid firſt to have experienced the virtues of ſimples ſeparately, and then combined them. But it ſhould be noted that the original compound, as prepared by this king, conſiſted of but a few ingredients. Serenus Sammonicus ſays, that when Pompey took the baggage of this prince, he was ſurpriſed to find that this antidote conſiſted of only twenty leaves of rue, two walnuts, two figs, and a little ſalt. Of this he took a doſe every morning, to guard himſelf from the effects of poiſons. It is now, however, very judiciouſly thrown out of the London Diſpenſatory of 1788.

—— OPIATA. See PHILONIUM.

—— SAPIENTUM. See ANACARDIUM.

CONFERTUS. See ATHROOS.

CONFIRMANTIA MEDICAMENTA. Medicines which reſtore or confirm the ſtrength of the body, or any part of it: or medicines which faſten the teeth in their ſockets.

CONFLUENTIA. A term uſed by Paracelſus to expreſs the agreement, conjunction, or confederation of the microcoſm with the ſtars, or of a diſeaſe with remedies: hence,

CONFŒDERATIO, is of the ſame import.

CONFORMATIO. CONFORMATION. Some diſeaſes are called *morbi malæ conformationis*, or organical diſeaſes; that is, which depend upon the ill *conformation* of the parts. Theſe, if external, may admit of a chirurgical cure; and proper exerciſe, regimen, and medicines may ſometimes contribute much to the relief, even of thoſe which are internal, or at leaſt may render them ſupportable. See alſo DIAPLASIS.

CONFORTANTIA. } See CARDIACA.
CONFORTATIVA. }

CONFRICATIO. In pharmacy, is the reducing of any eaſily friable ſubſtance to powder by rubbing it with the hands, as ſtarch, for inſtance: or it ſignifies the rubbing any ſoft and ſucculent vegetable with the hands, to expreſs the juice.

CONFRICATRICES. Laſcivious women, who gratify their luſtful deſires with what the Greeks call ὀλισβος, *penis coriaceus*, and hence plunge themſelves into a variety of chronic diſeaſes.

CONFUSÆ FEBRES. Bellini ſays he met with ſuch, and that they were two fevers attending at the ſame time, beginning and ending together, but ſo confuſedly as not to be diſtinguiſhed.

CONFUSANEUS PANIS. Bread made of meal, from which the bran has not been ſeparated.

CONFUSIO. A diſorder of the eyes, which happens when, upon a rupture of the internal membranes which include the humours, they are all confounded together.

CONGELATI, or CONGELATICI. Perſons afflicted with a catalepſis are ſo called. See CATLEPSIS.

CONGELATIO. CONGELATION; alſo CONGLACIATIO; COAGULATIO. It is ſuch a change produced by cold in a fluid body, that it becomes condenſed; thus *conglaciation* is when a liquid is converted into ice.

Water is rarefied or expanded by *congelation*; but pinguious bodies and fixed metals are rendered more compact by it.

The condenſation of any liquor, by ſetting it in a cold place, is called *congelation*.

The ſtones produced in ſome caverns from the drops of petrifying waters are called *congelations*.

CONGELATIVA MEDICAMENTA. Medicines which ſtop fluxions, inſpiſſate and dry.

CONGELATUS. *Frozen*, or *froſt-bitten*. Perſons thus affected by the cold are compared to cataleptic patients, but ſtill there is much difference between a catalepſy and a *froſt-bitten* caſe.

Cold draweth up the body when applied to it in a certain degree; upon this conſtriction being increaſed, the humours are carried in a larger quantity to the internal parts, and are principally accumulated in the head; they ſtagnate in the veſſels of the brain, and diſtend them; hence they produce a ſtricture in, or a compreſſion on the nerves that ariſe from the brain, which is the origin of a catalepſis, attended with an abolition of the ſenſes. The cold continuing, with its effects juſt mentioned, at length there is an extravaſation of the blood or ſerum in the head, by which the cerebellum is compreſſed, whence death enſues, which is aſhered in by a lethargy, ending in an apoplexy.

When a man is pierced with cold, ſo as to be benumbed, if he attempts to warm himſelf by the fire, pains are preſently produced in the part expoſed to the heat, and a mortification is too often the conſequence; juſt as is ſeen in frozen fruit, which if put into cold water that is near freezing, it recovers, but if put into warm water, or in a warm place, it ſoon rots; and if men, when too ſeverely affected with cold, would firſt put the frozen part into cold water, or cover it with ſnow, until a ſenſe of warmth is perceived, or ſome degree of motion returns, at which time a little warm wine, mixed with camomile tea, might be drank, or either of theſe alone, and then proceed gradually to allow of warmth, a mortification would be avoided.

When travellers begin to be drowſy, in the cold they ſhould redouble their ſpeed to extricate themſelves from danger: for though their ſleepineſs is eaſy, it is often fatal.

The heat of our bodies, when in health, exceeds that of the ambient air, even in the hotteſt weather; whence a conſiderable degree of cold is required to freeze the ſoft parts of our bodies: it is becauſe our extremities are the coldeſt parts, that froſt always affects them ſooneſt. And when a mortification from cold approaches, Van Swieten obſerves, that the part affected by it is firſt pale, then red; this redneſs is attended with a troubleſome pain, and a violent itching; after this the colour becomes almoſt purple, and at laſt black.

That ſudden heat, applied after extreme cold, ſhould produce the ſame ſymptoms and conſequences, will be readily underſtood by what follows. As water cools, it condenſes, until it comes to the freezing point; but in the act of *congelation* it expands with a violence that nothing can reſiſt. When a perſon goes into the cold air, his fluids are gradually condenſed, the veſſels collapſe, and the ſkin is pale, the circulation again puſhes the blood into the arteries, whoſe contracted extremities allow it only to paſs ſlowly, and make the ſkin look red; alſo produces an itching, becauſe of the obſtruction that it meets with; the blood being puſhed from behind, whilſt the obſtruction is increaſed before, a livid colour is produced, and a tingling pain; at laſt the circulation being ſtopped, a gangrenous black finiſhes the ſcene, with a loſs of all ſenſation, the veſſels being ſtretched far beyond their natural dimenſions by the frozen juices. In this caſe, applying of cold water diſſolves the frozen juices, and condenſes them; thus the veſſels have room to contract, and are aſſiſted in ſo doing by the coldneſs of the water: after this, if warm diluting liquor is drank, a diaphoreſis is produced, and all danger is overcome; if warmth is applied at the firſt, the outer parts are quickly thawed, but the inner veſſels, ſtill obſtructed, ſoon burſt by the rarefaction of their contents, and deſtruction to the part is inſtantly produced.

See Tiſſot's Advice to the People; Van Swieten's Com. on Boerh. Aph. 422, 427, 454. Med. Muſ. vol. i. p. 71.

CONGENERES. When ſpoken of muſcles, it imports thoſe which concur in the ſame action.

CONGER, or CONGRUS. The CONGER-EEL. It is a large ſea-eel. It is often called the ſea-ſerpent.

CONGESTIO. CONGESTION, or COLLECTION. From *congero, to gather into a heap*. A ſwelling which gradually ariſes, and takes time to ripen; in oppoſition to that defluxion, which ſoon is formed, and ſoon terminated.

CONGIUS. A GALLON. This is a very ancient meaſure, and is generally ſaid to have been equal to ten pints of wine, and nine of oil. The Athenian congius, or conchus, weighed nine pounds, and the Roman weighed

weighed ten, or contained ten Roman pints of wine. In the London and Edinburgh Diſpenſatories the gallon is only eight pints. See CHU.

CONGLACIATIO. See CONGELATIO.

CONGLOBATA GLANDULA. A CONGLOBATE GLAND, from *conglobo, to gather ſingly into a ball.* All the glands are either *conglobate*, or conglomerate. A *conglobate gland* is a little ſmooth body, wrapped up in a fine ſkin, by which it is ſeparated from all other parts, only admitting an artery, and a nerve to paſs in, and giving way to a vein and excretory canal to paſs out. Of this ſort are the glands of the brain and the teſtes.

Under the title of *conglobate glands* Winſlow includes the lymphatic glands alone; and he calls all the other conglomerate. See Winſlow's and Keil's Anatomy.

CONGLOMERATA GLANDULA, from *conglomero, to heap up together.* A *conglomerate gland* is compoſed of many little *conglobate glands* all tied together, and wrapped up in one common membrane. Sometimes all their excretory ducts unite, and make one common pipe, through which the liquor of all of them runs, as the pancreas and parotids do. Sometimes the ducts uniting form ſeveral pipes, which only communicate with one another by croſs canals, and ſuch are the mammæ. Others again have ſeveral pipes, without any communication with one another; of which ſort are the glandulæ lacrymales & proſtatæ; and there is another ſort when each *gland* hath its own excretory duct, through which it tranſmits its liquor to a common baſin, as the kidneys. See Winſlow's and Keil's Anatomy.

CONGLUTINANTIA. Healing medicines; from *conglutino, to glew together.*

CONGRUS. See CONGER.

CONIA. LIME, κονια. When joined with ΠΙΤΥΟΣ, it imports lixivium, or ley of vegetable aſhes; alſo wine impregnated with fir. Dioſcorid. lib. v. c. xlviii.

CONIFERÆ ARBORES. *Coniferous trees.* They are ſuch which bear cones, as the cedar, fir, pine, &c.

CONILE. See MYRRHIS.

CONIS, κονις, *duſt*; fine powder; aſhes; a nit in the hair; ſcurf from the head; and ſometimes it ſignifies lime.

CONISTERIUM. See APODYTERIUM.

CONIUM MACULATUM. } See CICUTA MAJOR FOETIDA.
—— MAJUS. }

CONJUNCTA CAUSA. The *conjunct cauſe*, or the immediate cauſe. See CAUSA.

—— SIGNA. The pathognomonic ſigns of a diſeaſe are ſo called.

CONJUNCTIVA TUNICA. The *conjunctiva* is erroneouſly confounded with the adnata; they are two diſtinct coats, and both but partial coverings of the forepart of the eye, though the *conjunctiva* is alſo ſpread over the inſide of the eye-lids. This is a thin tranſparent membrane, which lines the inner ſurface of the eye-lids, and, at the edge of the orbit, has a fold, and is continued forward, over the anterior half of the globe of the eye. It is exterior to all the other coats of the eye, and connected with the albuginea, by means of a cellular ſubſtance; from which it may eaſily be ſeparated in the dead ſubject by diſſection. See Ware's Remarks on the Ophthalmy, &c. p. 5. Some call it the *mucous coat.*

CONNA. See CASSIA FISTULARIS.

CONNECTIO. See SYMPHYSIS.

CONOIDES. } See PINEALIS GLANDULA.
CONOIDES CORPUS. }

CONQUASSATIO. CONQUASSATION. In pharmacy it is a ſpecies of comminution, or an operation by which moiſt concreted ſubſtances, as recent vegetables, fruits, the ſofter parts of animals, &c. are agitated and bruiſed, till partly by their proper ſucculence, or by an affuſion of ſome liquor, they are reduced to a ſoft pulp.

CONSERVA. A CONSERVE. *Conſerves* are compoſitions of recent vegetable matters, and ſugar, beat together into one uniform maſs.

On account of the large quantity of ſugar contained in *conſerves*, it is obvious that their uſe in medicine is as an auxiliary to other more efficacious drugs. Though of the *conſerves* of lavender, roſemary, orange and lemon peels, arum, wormwood, an uſeful doſe may be taken.

Mucilaginous ſubſtances, if mixed with ſugar, become glutinous; aſtringents become ſoft; bitters are every way improper for this form; and lightly flavoured vegetables ſoon ſpoil: ſo none of theſe are proper to make *conſerves.*

The general obſervations for properly making *conſerves* are but few: 1. Leaves are to be picked from their ſtalks. 2. Flowers are to be ſeparated from their cups. 3. When the flowers or leaves are properly prepared, they muſt be beat into an uniform maſs, in a marble mortar, with three times their weight of powdered lump ſugar.

Orange peel may be raſped, or ground in a mill, and then beat up with the ſugar.

Roſes are to be ground before being beat up into a *conſerve.*

CONSERVATIO. In pharmacy, the ſame as *aſſervatio*: it is preſerving, pickling, or keeping from putrefaction, and evaporation, by the addition of ſome other ſubſtance, or the repoſiting things ready for uſe.

CONSERVATIVA MEDICINA. That part of medicine which relates to the preſervation of health.

CONSILIGO. See HELLEBORUS NIGER HORTENSIS FLORE VIRIDI.

CONSISTENTIA. When uſed *with reſpect to diſeaſe*, it imports the ſtate or acme thereof. When applied *to the humours, excrements, or excretions*, it imports their conſiſtence.

CONSOIDES. See AMIANTHUS.

CONSOLIDA, COMFREY, called alſo *alum*, *alus*, *alus Gallica.* Of this there are many ſpecies.

CONSOLIDA MAJOR, called alſo *ſymphytum majus*, GREATER COMFREY.

It is the SYMPHYTUM OFFICINALE, or, SYMPHYTUM *foliis ovato-lanceolatis decurrentibus, flore purpureo.* Linn.

A rough hairy plant, with large, ſomewhat oval, pointed leaves, producing on the tops of the branches ſpikes of white or purpliſh pendulous, nearly cylindrical flowers, followed each by four ſhining black ſeeds. The root is thick and fleſhy, black on the outſide, and white within. It is perennial, grows wild in moiſt grounds, and flowers in May or June. There is a ſort with purple flowers, but it is rarely met with. The purple and the white flowers are but varieties of the ſame ſpecies.

The whole plant is uſed, but the root is the only part that deſerves much notice; it gives out to water by decoction about two thirds of its weight of mucilage, that is almoſt void of ſmell and taſte, and ſimilar to that from the althæa, but more tenacious; whence in all the purpoſes for which the althæa root is uſed, the *comfrey* is to be preferred. This mucilage is its only medicinal principle. See Lewis's Mat. Med. Neumann's Chem. Works. Raii Hiſt.

—— AUREA. } See CHAMÆCISTUS.
—— AUREA CORDI. }

—— MEDIA. DAISY. See BUGULA, and BELLIS MAJOR.

—— MINIMA. See BELLIS MINOR.

—— MINOR. See BRUNELLA.

—— RUBRA. See TORMENTILLA.

CONSOLIDA SARACENICA. See VIRGA AUREA.

CONSOLIDANS. CONSOLIDATING, from *conſolido, to make firm.* This is applied to medicines that produce new fleſh.

CONSOMMÉ. See CONSUMMATUM.

CONSPERSIO. See CATAPASMA.

CONSPICILIUM, or CONSPICILLUM. A PAIR of SPECTACLES.

Theſe helps to the ſight are with convex, concave, or plain glaſſes. The *firſt* magnifies the objects looked at, the *ſecond* diminiſhes them, and the *third* are called conſerves, being made of white or green glaſs, for preſerving the ſight.

It is a caution of importance not to uſe *ſpectacles* too ſoon; and, when they are begun with, not to change them too often, for it may happen that in time none can be obtained that will ſuit.

Sometimes, after the uſe of *ſpectacles* during ſome years, it has been known that the cryſtalline reaſſumes its proper form, ſo that they are no more required. See Martin's Eſſay on Viſual Glaſſes.

CONSTANS. When applied to the ſtrength, or vital powers, it imports firmneſs, or a good condition.

CONSTELLATUM UNGUENTUM. It is an ointment made of earth worms, cleanſed, dried, powdered, and mixed with the fat of bears or bears.

CONSTIPATIO. } OBSTIPATIO, ADSTRICTIO.
CONSTIPATUS. } COSTIVENESS. Dr. Cullen gives this diſorder the name of *obſtipatio.* A perſon is ſaid to be *coſtive*, not only when the excretion from the inteſtines does not daily happen, but alſo when what is diſcharged is too hard to receive its form from the impreſs of the rectum upon it. See OBSTIPATIO.

Hoffman ſays, that *coſtiveneſs* is generally owing to ſpaſms in the inteſtines themſelves, or as propagated by conſent; but various cauſes conduce to this habit, as an inert bile, acidity prevailing greatly in the firſt paſſages, coldneſs of the feet, ſitting much, eſpecially if the body is to be bent forwards, working with vigour, drinking but little, and that after a full meal, &c.

This habit of body is generally attended *with head-ach, vertigo, diſagreeable taſte in the mouth, a diſreliſh of food*, and as it is a ſure ſtep towards chronic complaints, hath, in different perſons, very various effects. In *coſtive* bodies, the moiſture which ſhould be diſcharged with the excrements is abſorbed into the conſtitution, and though a ſtrong perſpiration may diſcharge ſome part of it, yet the groſſer part remains in the blood, which fails not to produce one diſorder or another, as it happens to be at laſt thrown on one or another part.

The *coſtiveneſs, peculiar to ſtudious people*, is much relieved by alkaline ſalts, or the ol. ricini. *Artificers* who ſit much, and work with their bodies leaning forward, are beſt relieved by the ſame.

In *melancholy caſes*, alkaline ſalts anſwer the beſt if long continued, for they leave no effects which tend to render the body *coſtive*.

Women during pregnancy are ſometimes *coſtive* from the preſſure of the child's head againſt the rectum. Early care ſhould be had to prevent an accumulation of fæces, by a due adminiſtration of the milder purges, for rugged ones are to be abſolutely rejected in this caſe.

Old people, from the weakneſs of their muſcles, have hard fæces collected in the rectum: and notwithſtanding they take laxative medicines, which procure a diſcharge of what is thin, the indurated matter ſtill lodges, except manual aſſiſtance is given.

ALOES given in ſmall doſes proves ſufficiently laxative, and this effect is continued longer after its uſe than is obſerved with reſpect to any other medicine; and when flatulencies are very troubleſome, if a little aſſa fœtida is joined, therewith, more conſiderable relief may be expected.

CALOMEL very much prevents other purging medicines from leaving *coſtiveneſs* behind. The extract. colocynthidis compoſ. united with calomel, and corrected by the addition of oleum carui, ſeu aniſi, forms an excellent remedy for relieving, and preventing coſtiveneſs, uſed occaſionally.

Habitual *coſtiveneſs* hath been much leſſened both by the cold and hot baths, alſo by early riſing and walking in the open air.

In the Lond. Med. Obſ. and Inq. vol. iv. are two caſes of *coſtiveneſs*, which reſemble diarrhœas.

CONSTRICTIVA. See STYPTICA.

CONSTRICTOR ALÆ NASI, alſo called *trianguris; depreſſor labii ſuperioris*. Fallopius firſt deſcribed theſe, though Placentinus aſſumes the diſcovery. They riſe fleſhy below the root of the nares, immediately above the gums of the dentes inciſorii, and aſcending tranſverſely, are inſerted into the coats of the alæ naſi, and the ſuperior part of the upper lip.

—— ANI. See SPHINCTER ANI.

—— ISTHMI FAUCIUM. From the uvula two arches run down, and there is a cavity between them, where the tonſils are lodged. The anterior arch goes down to the baſis of the tongue, and is thus called; the other paſſes down the palatum molle, and goes to the pharynx, whence it is diſtinguiſhed by the name of *palato-pharyngæus*.

—— LABIORUM. See SPHINCTER LABIORUM.

—— MUSCULUS. See BUCCINATOR.

—— PALPEBRARUM. See ORBICULARIS PALPEBRARUM.

—— PHARYNGIS INFERIOR. See CRICO-PHARYNGÆI.

—— PHARYNGIS MEDIUS. See HYO-PHARYNGÆUS.

—— PHARYNGIS SUPERIOR. See CEPHALO-PHARYNGÆUS.

—— VESICÆ URINARIÆ. See DETRUSOR URINÆ.

CONSTRICTORES PHARYNGÆI. See PHARYNX.

CONSTRICTORII. Diſeaſes attended with conſtriction.

CONSTRINGENTIA. See ASTRINGENTIA.

CONSUETUDO. CUSTOM. Alſo *hexis*. CUSTOM and HABIT are two terms, uſed by many ſynonymouſly, and indeed the former is often confounded with the latter. By CUSTOM is meant a frequent repetition of the ſame act; by HABIT, the effect that cuſtom has on the mind or body; ſo that one appears to be the cauſe of the other. THE EFFECTS OF CUSTOM AND HABIT IN THE ANIMAL ŒCONOMY, may be reduced to five heads. 1ſt. On the ſimple ſolids. 2nd. On the organs of ſenſe. 3rd. On the moving power. 4th. On the whole nervous power. 5th. On the ſyſtem of blood-veſſels; for an explanation of which, ſee Encyclopædia Britannica, vol. 5. page 620. But the word habit is often made to expreſs conſtitution, as a plethoric habit, &c. means the conſtitution ſuperabundant with blood, &c.

IN MEDICINE this chiefly reſpects the non-naturals, and produces habits which ſometimes are pernicious. *Cuſtom* ſometimes increaſes the efficacy of applications, though ſometimes the contrary happens. When *cuſtom* hath formed an habit that is improper, it is beſt to remedy it by degrees. See Fordyce's Elements, part i. p. 58. &c.

CONSUMMATUM. The French call it *conſommé*. It is a *broth* ſo ſtrong as to concrete into a jelly when cold. Frequent mention is made of it in the French medicinal writers.

CONSUMPTIO. See PHTHISIS.

CONTABESCENTIA. See ATROPHIA.

CONTAGIO vel INFECTIO. CONTAGION, or INFECTION, alſo *aporrhœa*. Of diſorders from theſe cauſes, it is ſaid, ſome require an immediate contact with the bodies of the infected, as in the caſe of the lues venerea, and the ſmall pox, as alſo the meaſles, which require at leaſt an approach within the reach of the *effluvia* from an infected body. In other inſtances the *infection* is ſpread by more general cauſes, ſuch as the air, diet, &c. Of theſe there are three kinds, which differ only in their being more or leſs in quantity, and are all curable by the ſame means, applied in different degrees. Theſe *infectious* effluvia ſpring from either fermenting vegetable fluids, putrifying animal or vegetable bodies, or mineral exhalations. And it is remarkable that each of theſe alike are deſtructive of flame.

It is by the deſtruction of the vital principle in us, that *infection* proves ſo fatal; it is thus that ſome poiſons ſo ſoon deſtroy us.

According to the kind of effluvia and its degree, different diſeaſes are produced, e. g. where mineral exhalations prevail, nervous colics, nervous and intermittent fevers, peripneumonia notha, &c. When putrid ones are diffuſed in the air, ſcurvies, plagues, gangrenes, &c. are the conſequence. Theſe are called *fomites*.

At every inſpiration theſe effluvia are taken into our bodies, and thus produce their ill effects. They are ſwallowed with our food, by which their quantity being increaſed, their power of action is alſo greater: poſſeſſing an aſſimilating property too, no wonder that deſtruction is ſo ſpeedy, as in many inſtances is obſerved. See MIASMA.

In ſhort, ſo ſimilar are the effects of *infection* and poiſon, that they may be conſidered as the ſame, differing only in their modes of communication. See VENENUM.

See on this ſubject Mead on Poiſons, eſſay the fifth; and Shebbeare's Theory and Practice of Phyſic; Cullen's Firſt Lines, vol. i. But there is another diſtinction to be made between the two terms, which appears not altogether uſeleſs. There are ſome diſeaſes, which are acquired, by the particles of morbid matter floating in the atmoſphere, either from that matter being inhaled by the lungs, impregnating what we eat or drink, or abſorbed by the inhaling veſſels of the ſkin, noſe, or fauces; whilſt others are communicated by contact alone: hence the former of theſe ſhould be termed *infectious*, the latter *contagious*, and for this reaſon, *the mode of prevention would be different*: in a country or town where the firſt were rife, quitting thoſe places is abſolutely neceſſary; where the laſt, cautious reſidence in the ſame is ſufficient, avoiding commerce with perſons ſo contaminated, or touching any materials which are capable of retaining the contagious matter, that have by them been uſed or handled. Beſides, in this country, it proves, in caſe of the plague, the ſecurity in drawing lines of circumvallation to prevent its progreſs, for this is agreed to be a contagious diſeaſe. Indeed other modes, from this idea, might be found out to be of great utility under theſe unhappy circumſtances. WALLIS on Health and Diſeaſe.

CONTAGIOSI. Diſorders from infection, or contagious diſeaſes.

CONTEMPERANTIA. See TEMPERANTIA.

CONTENSIO. It ſometimes is uſed to expreſs a tenſion or ſtricture.

CONTENTA. CONTENTS. By these are understood any fluids contained within a solid part of the body.

CONTENTUS. STRETCHED.

CONTINENS FEBRIS. A *continual* or a *continent fever*, which proceeds regularly in the same tenor, without either intermission or remission. This happens rarely, if ever.

CONTINUA FEBRIS. A CONTINUED FEVER, attended with exacerbations, and slight remissions, but no intermission; some use the term *assidua*.

CONTORSIO, from *contorqueo, to turn aside*, CONTORSION. In MEDICINE this word hath various significations. See ILIACA PASSIO; LUXATIO; LUXATION OF THE VERTEBRÆ, and CAPUT.

CONTRA-APERTURA. A COUNTER-OPENING. This is sometimes necessary in wounds made by puncture, or a bullet, &c. to discharge what is contained in them, or to prevent their growing fistulous. The circumstances requiring this procedure are so various, as to demand the sagacity of a surgeon: however, in general the opening is made by passing a trochar, or such like instrument, to the bottom of the wound, directing its point to the nearest skin, and continuing it through, so as to make the old and the new *aperture* one continued passage: or, secondly, by cutting through the skin, &c. directly upon the intruded body, or upon the button of the probe, which may be introduced to the bottom of the wound to direct the incision. See Petit and Heister's Surgery.

CONTRACTURA. CONTRACTURE, called also by Dr. AITKIN, *beriberia*. An immobility of any of the joints, induced by a preternatural *contraction* of some of the muscles destined in a natural state to move them; or from some derangement of the osseous or ligamentous parts about the joint affected.

Dr. Cullen ranks this as a genus of disease in the class locales, and order dyscinesiæ, and defines it, "a continued, rigid contraction, of one or more of the limbs."

He distinguishes two species. 1. CONTRACTURA PRIMARIA, from a rigid *contraction* of muscles, termed also *obstipitas*: which word, with any other annexed, is only one or other variety of contracting; this is the instance known by the name of WRY-NECK, called *torticollis*. Of this species, he forms four varieties. 1st. When the muscles become rigid *from inflammation*. 2d. *From spasm*. 3rd. When contracted, *from the antagonists being paralytic*. 4th. *From irritating acrimony*. 2. CONTRACTURA ARTICULARIS, from rigid joints.

Dr. Aitkin observes, that joint *contraction* (as he terms this disorder) is most frequently symptomatic: and when it depends on muscular *contraction* only, he advises the tepid bath, and deligation, and counteraction by weights, hung in due proportion, to oppose the *contraction*.

CONTRA-FISSURA. CONTRA-FISSURE. See FISSURA.

CONTRAHENTIA. Medicines which shorten and strengthen the fibres. Astringent medicines are generally reckoned the only medicines which do this.

CONTRA INDICATIO. See ANTENDEIXIS.

CONTRALUNARIS. An epithet given by Dietericus to a woman who conceives during the menstrual discharge.

CONTRA-VERMES (Sem.) See SANTONICUM.

CONTRAYERVA. called also *Drakena*, *Cyperus*, *longus odorus & inodorus Peruanus*, *dorstenia*, *bezoardica radix*. COUNTER-POISON. It is the *dorstenia contrayerva*, (called *dorstenia*, by father PLUMIER, in honor of Dr. DORSTEN, a German physician) scapis radicatis, foliis pinnatifido-palmatis, serratis, receptaculis quadrangulis. CLASS, TETANDRIA; ORD. MONOGYNIA; LINNÆI, Gen. Plant. 158.

This root was first brought into Europe about the year 1581, by sir Francis Drake, whence its name *Drakena*. It is the root of a small plant which is found in Peru, and other parts of the Spanish West Indies. There are two kinds, the one *placenta ovali*, the other *angulari & undulata*. That sort which is generally brought to us is about an inch or two long, half an inch thick, full of knots, surrounded on all sides with numerous long tough fibres, most of which are loaded with scaly knobs, of a reddish brown colour on the outside, and pale within.

The tuberous parts of these roots are the strongest, and should be chosen for use. They have an agreeable aromatic smell; a rough, bitter, penetrating taste; and, when chewed, they give out a sweetish kind of acrimony.

They are diaphoretic and antiseptic: of use in low nervous fevers, and those of the malignant kind; though taken freely, they do not produce much heat.

Dr. Cullen says, both this and serpentaria are powerful stimulants, particularly the last, and both have been employed in fevers in which debility prevailed. However he thinks wine may always supersede the stimulant power of these medicines, and that debility is better remedied by the tonic and antiseptic powers of cold, and Peruvian bark, than by any stimulants.

By the assistance of heat, both spirit and water extract all their virtues, but carry little or nothing over with them in distillation; extracts made by inspissating the decoction retain all the virtues of the roots.

The London College directs the following preparation.

Pulvis Contrayervæ *Compositus. Compound Powder of* CONTRAYERVA.

Take of the compound powder of crabs' claws, a pound and a half; of *contrayerva* root, five ounces; mix, and make them into a powder. Pharm. Lond. 1788.

This powder was formerly made up in balls, and called lapis *contrayervæ*. It is excellent in the decline of ardent fevers, and through the whole course of low and nervous ones.

The rad. serp. V. in all cases may be well substituted, for it excels the *contrayerva*. See Lewis's Mat. Med. Neumann's Chem. Works. Raii Hist. and Cullen's Mat. Med.

CONTRAYERVA NOVA, or MEXICAN CONTRAYERVA. It was introduced into Europe after the above sort, and is brought from Guiana, as well as from Mexico. The root is longish, about two fingers thick, externally rough, and of a brownish colour, internally white, with a pith in the middle, of a sweetish aromatic taste, and but little inferior to the sort introduced before it.

—— ALBA.
—— GERMANORUM. } See ASCLEPIAS.
—— VIRGINIANA. See SERPENTARIA VIRGINIANA.

CONTRITIO. See COMMINUTIO.

CONTUSA, from *contundo, to knock together*. *Contusio, contusura, collisio, phlasma*. CONTUSED WOUNDS, CONTUSIONS, or BRUISES. When any part is bruised, one of these two are always consequent, and commonly both happen together; either the small blood-vessels of the *contused* part are broken, and the blood they contained spread about in the adjoining parts; or else without such an effusion of it, these vessels have lost their tone, or active force, and no longer contributing to the circulation, their contents stagnate. In either of these if nature, with or without the assistance of art, does not remove the impediment, an inflammation comes on, followed by an imperfect unkindly suppuration, with putrefaction or gangrene. Beside which, there are peculiar symptoms from the injury done to a nerve, a blood-vessel, or a bone.

In general the symptoms consequent on *bruises* may be reduced to three classes; for,

First, They arise either when the solids are destroyed, and the humour discharged: then those functions are abolished which depend upon a due and determinate motion of the fluids through the sound vessels.

Secondly, The discharged humours, collected either in the natural or preternatural cavities of the body, by their bulk and quantity press upon the adjacent parts, and either totally destroy or at least disturb their respective functions.

Thirdly, The humours, thus discharged, may, by their continuance and stagnation in the cavities, acquire such a degree of acrimony as to corrode and destroy the adjacent parts.

When the internal parts are *bruised*, and the external integuments are entire, or confine the extravasated fluid, the consequence is, 1. An ecchymosis. 2. A spurious aneurism. 3. A sugillation. 4. Ulcers and gangrenes. 5. A caries, 6. A scirrhus, or a cancer.

Boerhaave observes, that *contusions* on fleshy parts may produce suppuration, gangrene, palsy, or a contraction. On a large nerve, a palsy, atrophy, incurable insensibility, and a gangrene in all the parts below the injured part: this peculiarly may follow *contusions* of the spine and its marrow. *Contusions* of the viscera, he justly observes, are often speedily fatal, and no wonder, seeing how tender they are, and how little force may burst their vessels.

Contusions from gun-shot wounds are not so dangerous from the destruction of the injured vessels and the consequences thereof, as from the general concussion that the whole

whole body ſuffers from the air which is violently impelled againſt it; and from this concuſſion it is that moſt of the grievous ſymptoms proceed, which are conſequent on wounds or bruiſes from fire-arms.

In no caſe ſhould we be more cautious of pronouncing the event of any diſaſter than where a concuſſion or a *contuſion* happens; and where both may have occurred, the caution, if poſſible, ſhould be greater.

Bohnius de Renunciat. Vulner. § 2. cap. 1. gives the following caſe from Paaw: A man was ſtruck on the bregma; on examination no fracture was found nor fiſſure, and he continued vigorous, during ten months after, when, being ſeized with a vertigo, he dropped down, and ſoon after died: on opening his cranium, in the place where the blow was received, the bone and membranes of the brain were putrid and fetid. Similar inſtances have occured to others in their practice, and the ſame happening to any other bone, by affecting the marrow, may be as deſtructive as in the cranium. When *bruiſes* are received inwardly, it is not eaſy to judge readily of the extent of injury done by them, and when the caſe becomes more manifeſt, it is too late to attempt relief.

In order to the moſt effectual relief, remedies muſt be uſed that diſſolve coagulated fluids, and that reſtore the tone of the veſſels.

For external uſe, where the ſkin is not much deſtroyed, a mixture of ſharp vinegar, with twice its quantity of water, may be applied frequently by means of linen cloths wrung out of it, and as often as they dry, moiſtened again. If there is much inflammation preſent, the following called EMBROCATIO AMMONIÆ ACETATÆ CUM SAPONE, *acetated ammoniated embrocation with ſoap*, is very uſeful. ℞ Aq. Ammoniæ acetatæ, ſolutionis ſaponis ää ℥. i. m. But where the inflammation has ſubſided, two drams of aqua ammonia pura added to the above is conſidered as very efficacious. Spirituous applications ſhould not be uſed, except where the ſole intention is to ſtrengthen the injured fibres; in ſlighter caſes a ſmall quantity of ſpirit may be mixed with vinegar, and uſed on the firſt reception of the *bruiſe*.

If on account of a tumour or wound a poultice is applied, the common bread poultice is the beſt.

If the *bruiſe* is conſiderable, and particularly if any internal part is affected, bleed as freely as the conſtitution will admit; direct a cooling liquid diet: let clyſters be repeatedly injected, if the lower belly be the ſeat of complaint; and, in all caſes, repeated gentle purging is of the greateſt advantage; of all the purging medicines perhaps none excel the volatile tincture of aloes.

The advantages of the tinct. opii externally as a reſolvent, of Dover's powder, and the anodyne antimonial drops recommended in the article CONCUSSIO, deſerve the ſame attention when *contuſions* happen, and on the ſame principles.

See Bohnius de Renunciat. Vulner. Van Swieten's Commentaries on Boerhaave's Aphoriſms; Tiſſot's Advice to the People; Bilguer's Diſſertation on the Inutility of amputating Limbs, p. 69. 73. Bell's Surgery, vol. v. p. 446.

CONTUSIO. } See CONTUSA.
CONTUSURA. }

CONUS. A CONE. The fruit of the pine, fir, or cedar-tree. Or fruit with a broad baſis, and which gradually diminiſhes to a point. The trees which bear ſuch fruit are called *coniferous*. Dioſcorides ſays that κεδρος is a name of liquid pitch.

CONUS FUSORIUS, alſo called *Pyramis*. A CONE. It is a veſſel reſembling an inverted *cone*, made of braſs or iron, and is uſed for ſeparating reguluſes from their ſcoriæ: for while the fuſed mineral is pouring into the crucible, it is ſtruck with a mallet, in order to produce a tremulous motion in it, by which the heavier parts fall to the bottom.

CONVALLARIA. See LILIUM CONVALLIUM.

—— POLYGONATUM. See POLYGONATUM.

CONVOLUTA SUPERIORA OSSA. See CONCHÆ NARIUM SUPERIORES.

—— INFERIORA. The lower ſhelves of the noſe. See CONCHÆ NARIUM INFERIORES.

CONVOLVULUS. See ILIACA PASSIO. It is alſo the name of a plant, of which botaniſts enumerate nineteen ſpecies with ſcandent ſtalks, and nine with ſtalks that are not ſcandent. See alſo JALAPA, MECOACHANA; TURBITH. The whole plant uſually abounds with a milky juice that is ſtrongly cathartic and cauſtic.

—— COLUBRINUS. See PAREIRA BRAVA.

CONVOLVULUS INDICUS RADICE TUBEROSA EDULI, CORTICE RUBRO. POTATOES. See BATTATAS HISPANICA.

—— MARITIMUS. See BRASSICA MARITIMA.

—— MARITIMUS ZEYLANICUS, &c. See BINTAMBARU ZEYLANENSIBUS.

—— *Cantabrica;—ſpicæ foliis;—linariæ folio*. See CANTABRICA.

—— SOLDANELLA. See BRASSICA MARITIMA.

—— SYRIACUS. See SCAMMONIUM.

—— PERENNIS. See LUPULUS.

CONVULSIO. A CONVULSION, or involuntary contraction of the muſcles, from *convello, to pull* or *haul together*. Called alſo *Hieranoſos*, *diſtenſio nervorum*.

Of *convulſions* there are different ſpecies, as the *epilepſia*, *emproſthotonos*, *opiſthotonos*, *tetanus*, &c. Dr. Cullen places this genus of diſeaſe in the CLASS NEUROSES, and ORD. SPASMI; and defines it "an irregular clonic contraction of the muſcles without ſleep," of which he enumerates nine ſpecies, idiopathic; and five ſymptomatic. See Noſol. Methodicæ Synopſis, p. 216, vol II.

The brain, and its expanſions, the nerves, are the ſeat of theſe diſorders. Primarily, any nervous part is the ſeat, as the ſtomach, and, as frequently as any other, the duodenum, which being irritated by its contents, *convulſions* are the conſequence.

Weakly habits with impure juices are moſt ſubject to theſe affections; thoſe of choleric temper, acute genius, and a delicate turn of mind, are all liable to attacks of this kind.

The *immediate cauſe* of *convulſions* is generally diſtinguiſhed from the immediate cauſe of an epilepſy (which yet is a ſpecies of *convulſion*) by being ſeated differently; or rather the *convulſion* and epilepſy are ſaid to differ thus, a ſpaſm of the coats of the medulla ſpinalis is the immediate cauſe of *convulſions*; in the dura mater, of the *epilepſy*. The *mediate cauſes* are paſſions of the mind, uneaſineſs in the ſtomach and bowels, or other nervous parts; and among the *material cauſes*, are worms, acrid medicines, a repulſion of morbid matter from the ſuperficies of the body inwardly, wounds, diſlocations, &c.

In infants, whoſe diſorders of this kind are ſymptomatic, an acrimony in the contents of the bowels is the general cauſe, though the pain excited by the teeth paſſing through the gums is alſo a frequent one.

Sometimes *convulſions* attack ſuddenly, at others their approach is indicated by certain ſymptoms; ſuch as coldneſs of the feet, or a ſenſe of formication, which alſo ſeizes the os coccygis, and like a cold vapour aſcends through the ſpine of the back; the left hypochondrium is affected with tenſive and flatulent pains, and a coſtiveneſs attends; the urine is thin and pale; tremors and various unuſual ſenſations are perceived, and in different patients other ſymptoms alſo attend, as the prelude to more violent ones. During the fit the motions are violent and involuntary, in ſome continuing longer, in others paſſing off ſooner, and ſooner returning; after the fit there continues in ſome a conſiderable languor; though in others this is not complained of; delirium, ſleepineſs, vomiting, or other ſymptoms ſometimes follow upon the departure of a *convulſive* paroxyſm, and there are cauſes in which little or no ſenſible uneaſineſs is perceived on recovery from it.

Infants while in that ſtate which ſo generally ſubjects them to *convulſive* diſorders, and particularly when diſpoſed thereto, are attended with a cough, vomiting, or diarrhœa; their features are at times diſtorted; a blueneſs appears about their eyes and upper lip, and twitchings or ſtartings are often obſerved, particularly a contraction of the fingers into the palm of the hand, and during the intervals of the fits they are drowſy. As death draws nigh, the *convulſions* are more frequent.

Convulſions, as diſtinguiſhed from an epilepſy, ſhould not be confounded with thoſe that conſtitute the epilepſy, or are accompanied therewith.

Theſe diſorders often degenerate into a melancholy, or take off the patient by inducing an apoplexy.

THE INDICATIONS OF CURE ARE, to correct or to diſcharge the material cauſe, to allay the ſpaſm, and to ſtrengthen the nervous ſyſtem.

In the fit there can be but little done. The only caſes that require immediate aſſiſtance in the fit are, when it is ſo violent as to ſwell the neck, and the face becomes red, and there ſeems to be danger of an apoplexy: alſo when *convulſions* ſeize pregnant women, and labour at the ſame time comes on; in this latter inſtance delivery muſt be haſtened as the only cure.

Dr. Bland thinks that *convulſions* in pregnant women, and

and during labour, have nothing peculiar in their cauſe, from thoſe which happen to women differently ſituated; and though external agents, particularly violent affections of the mind, may ſometimes, as at other periods, excite them; yet this will rarely happen, unleſs there is ſome peculiar vice in the conſtitution, diſpoſing to them: and, from obſervation, he thinks, he is juſtified in ſaying, that the puerperal ſtate is far from favouring them; as women at that time may do and ſuffer, almoſt with impunity, what at any other time would be attended with the moſt ſerious conſequences. But whatever may be the cauſe, he obſerves, there is evidently in the fit, as in the apoplexy, a too rapid and dangerous determination of the blood to the head, which demands the moſt immediate and ſerious attention. To remedy this, blood muſt be immediately drawn, and, if poſſible, from the jugulars. The ſtate of the labour ſhould then be inquired into, and if the child is not too far advanced in the pelvis, it will be right to preſcribe a large ſtimulating clyſter to empty the bowels; and at the ſame time leſſen the determination to the head; this, if not ſufficient for the purpoſe, ſhould be aſſiſted by a few grains of jalap and calomel, or ſome other briſk purge. If the labour is far advanced, the *convulſions* will act upon the fœtus; and if there is no impediment, either from wrong preſentation, or diſproportion of the child to the pelvis, will, in a little time, ſafely expel it. If any obſtacle to delivery is found, the poſition of the child, if faulty, muſt be altered; or we ought to have recourſe to other neceſſary aſſiſtance, in the ſame manner as if *convulſions* were not preſent. In either way the termination of the labour will frequently put an end to the *convulſions*. But if this is too haſtily performed, before the veſſels have been properly emptied, and the rapid motion of the blood in them diminiſhed, there will be danger, from the torrent ruſhing too impetuouſly into the inteſtines or other abdominal viſcera, of inflammation in ſome of thoſe parts, inducing puerperal fever, and oftentimes death. But where the labour is not far advanced, after the exhibition of the clyſter and purgative, thirty drops of the tinct. opii may be given, and repeated, interpoſing occaſionally the clyſter or cathartic, as ſymptoms ſhall indicate. See Dr. Bland's Eſſays on the Treatment of *Convulſions* during Parturition.

Convulſions are ſometimes a ſymptom attending fevers, and may be produced by inanition, as when hæmorrhages, &c. have happened; alſo by repletion; irritation is moſt frequently their cauſe; in theſe caſes relief will moſt readily be procured by means adapted to remove it: the ſame method of relief, as is laſt propoſed when *convulſions* are a ſymptom of fevers, ſhould be attended to when they are cauſed by wounds; here warm oil, or the warmer kind of balſams, applied to the injured part, are often a ſpeedy cure, where no ſtricture in the part remains unrelieved by manual operation: the cauſes of irritation are indeed various, and therefore different means will be required to effect this one end.

Convulſions in children, from teething, require the loſs of blood, particularly if the gums are ſwelled and painful; in this caſe bleeding is the grand ſpecific.

When depletion is the cauſe, cordials muſt immediately be adminiſtered, and a generous nouriſhing diet allowed.

If ſuppreſſed menſes or piles, their return muſt be promoted; here hot and acrid means ſhould be avoided; warm baths, with antiſpaſmodic and gentle anodynes, preferred.

Worms, producing this diſorder, are to be deſtroyed, and the preſent ſymptom relieved, by clyſters of milk, ſweet and oily ſubſtances; calomel may be mixed with rhubarb and valerian; but irritating medicines muſt be ſhunned.

Irritating poiſons cauſe *convulſions*, which generally are fatal: however demulcents and gentle opiates ſhould be tried.

The itch or other morbid humours being repelled, and producing this diſorder, will require abſorbents to correct the primæ viæ; and to relieve from the preſent ſymptom, antiſpaſmodics, with cordials and gentle anodynes, ſhould be uſed.

Other cauſes may produce the ſame complaint; and, as in other inſtances, they muſt be inveſtigated, as the ſureſt way towards relief.

Muſk produces happy effects, if given in doſes from a ſcruple to half a dram, as is inſtanced in a caſe related by Dr. Owen of Salop. See the Lond. Med. Obſ. and Inq. vol. iii. p. 183, &c. The cauſe was a ſhock received from an electric machine; the quantity of muſk which he preſcribed at the firſt, was half a dram every four hours.

Bleeding is only neceſſary in plethoric habits; and Hoffman ſays, that this operation ſhould not be performed until after the fit, for otherwiſe the diſorder will be protracted.

Laxatives are eſſentially neceſſary, as an open belly conduces to prevent and relieve this kind of affliction: of theſe kinds of medicines, rhubarb, manna, and diuretic ſalt, are to be preferred.

Warm bathing, in many caſes of this kind, is followed with happy effects.

Clyſters, in which are from x. to xxx. drops of laudanum, give ſpeedieſt relief, when the inteſtinum rectum is affected with the ſpaſms.

Bliſters, applied upon the part affected, are powerful means of relief. Dr. Whytt relieved a patient who complained of an alternate motion of the muſcles of his belly, by a bliſter applied thereon; and he ſays farther, that, when epilepſies ariſe from an uneaſy ſenſation in the arm or leg, a bliſter applied there is the moſt effectual remedy. And in the *convulſions* peculiar to children, as a drain, a bliſter may be highly uſeful.

Æther, in many inſtances, hath been uſefully applied for the removing of ſpaſmodic complaints.

See Aretæus, Proſper Alpinus's Preſages, Hoffman, Med. Muſ. vol. iii. p. 562. Van Swieten's Com. on Boer. Aph.

CONVULSIO *clonica*, and *tonica*, are diſtinctions made by authors. The *firſt* is when contraction and relaxation alternate with each other; the *laſt* when contraction continues, and is not ſucceeded by relaxation. See SPASMUS CLONICUS, & TONICUS.

—— INDICA. See TETANUS.

—— A NERVI PUNCTURA. See TRISMUS.

—— RAPHANIA,—SOLONIENSIS,—ab Uſtilagine. See RAPHANIA.

—— TONICA. See CONVULSIO CLONICA.

—— UTERI. See ABORTUS.

CONYZA. FLEA-BANE, alſo *danais*. The leaves of this plant are commonly glutinous and ſtrong-ſcented, the cup of the flower generally ſcaly and of a cylindrical form. The flower conſiſts of many florets, which are ſucceeded by ſeeds covered with a downy ſubſtance. See ELICHRYSUM and VIRGA AUREA.

—— ÆTHIOPICA. See ELICHRYSUM.

—— MAJOR VULGARIS. See BACCHARIS.

—— MAS THEOPHRASTI, *conyza* major Dioſc. *pulicaria, virga aurea major foliis glutinoſis et graveolentibus*. GREATER FLEA-BANE.

Boerhaave mentions ten ſpecies, and Dale adds two more.

CONYZA MINOR FLORE GLOBOSO, alſo called *pulicaria, aſter paluſtris* parvo flore globoſo, *conyza* minima, *conyza* mediæ ſpecies flore vix radiato; SMALL FLEA-BANE.

The chief uſe of all the *flea-banes* is to deſtroy fleas and gnats, by burning them ſo as to waſte away in ſmoak.

COOPERTIO. COVERING, CLOATHING; or A SMALL CLOAK, by which the body is defended from the air, the ſame as περιβολαιον, *amictus*. According to HIPPOCRATES, from περιτιθημι, *cooperire, tegere, to cover*, in which ſenſe it is ſeveral times uſed by him. It is applied to the belly, and uterus inveſting the fœtus; and alſo to a medicament, which is placed upon the tooth, involving it like a plaſter, by SCRIBONIUS.

COOPERTORIA, i. e. *Cartilago thyreidea*, called alſo *abicum*. See ASPERA ARTERIA.

COOSTRUM. See DIAPHRAGMA.

COPAIBA,
COPAIFERA OFFICINALIS,
COPAIVA. } See CAPIVI BALSAMUM.

COPAIBÆ INJECTIO. ℞ Balſ. copaibæ ʒ ij. mucilaginis g. arab. ʒ ſs. aquæ calcis ℥ ſs. m. This is an aſtringent injection, proper in gleets, in the latter ſtage of gonorrhœa, and in the fluor albus.

COPAIBÆ cum OLIBANO MISTURA. *Mixture of Capivi with Olibanum.*

℞ Balſami copaibæ ℥ ſs. olibani ʒ ij. mucil. g. Arab. ℥ ſs. mellis deſpumati ℥ i. Aquæ cinnamomi ℥ v. Olibanum prius pulverizetur, & cum balſamo miſceatur, deinde melle, & mucilagine bene concorporentur; et poſtea cinnamomi aqua gradatim addatur. Doſis,

cochlearia larga duo vel tria, bis terve indies. This will be found of great benefit in gleets, leucorrhæa, &c.

COPEIA, COPELLA AMERICANORUM, COPEY, and COPELGA. The name of a tree in Hiſpaniola, in America, whoſe leaf ſerves for paper, and of which the Spaniards there make cards. This tree affords a kind of matter of which a ſort of pitch is made. Raii Hiſt.

COPELLA. See CUPELLA.

COPHOS, κωφος, *deaf*. A ſort of toad mentioned by Nicander. It alſo ſignifies deaf, dumb, or both together. It is alſo uſed to expreſs a dulneſs of any of the ſenſes.

COPHOSIS. DEAFNESS, DUMBNESS, or dullneſs of any of the ſenſes. See DYSECÆA.

COPOS. WEARINESS. A gently-warm bath ſooneſt relieves it; for what is *wearineſs* but an overſtretching or too great a tenſity of the fibres, occaſioned by uſing them too long or too violently? and muſt, upon their being relaxed, go off again. It is for the ſame reaſon that ſleep takes off *wearineſs*.

COPOVICH OCCASSOU. A tree mentioned by De Laet, which grows in the Weſt Indies; the leaves reſemble thoſe of the pear-tree; and the fruit called OUMERY, is like a large pear, and when ripe is eaten as a delicacy. Raii Hiſt.

COPRAGOGUM, from κοπρος, *dung*, and αγω, *to bring away*. The name of a gently-purging electary, mentioned by Rulandus.

COPRIEMETOS, from κοπρος, *dung*, and εμεω, *to vomit*. A perſon who vomits up his excrements.

COPROCRITICA MEDICAMENTA, from κοπρος, *excrement*, and κρινω, *to ſeparate*. See ECCOPROTICA.

COPROSTASIA. A CONSTRICTION of the BELLY.

COPTARION. A medicine in the ſhape of a very ſmall cake. Theſe were directed for diſorders of the aſpera arteria and lungs, and for many other intentions, by the ancients. It is a diminutive from

COPTE, from κοπτω, *to beat or pound*, becauſe it was formed by beating or pounding the ingredients into a paſte. It was the form of a medicine uſed by the ancients, generally made of vegetable ſubſtances, and applied externally, as on the ſtomach, &c. alſo given internally on many occaſions.

COPULA. See LIGAMENTUM.

COQUENTIA MEDICAMENTA. Medicines which promote concoction.

COR. IN CHEMISTRY ſignifies *gold*; and ſometimes an *intenſe fire*. IN BOTANY, it is the *heart* of vegetables, or their pith. See MEDITULLIUM, and alſo CORCULUM.

COR, called alſo by the ancients *cardia*. The HEART. This viſcus conſiſts eſſentially of two cavities, ſerving for two circulations of the blood, one through every part of the body, and one through the lungs. The right ſide of the *heart* is ſimilar to the left, excepting that both the auricle and ventricle have fewer muſcular fibres, and that the auricle receives blood from the venæ cavæ, and the ventricle throws it into the pulmonary artery.

The ſituation of the *heart* is in the middle of the cavity of the thorax, but rather inclining to the left; on each ſide of it lie the lungs, looſe, playing upon the ribs and diaphragm, and attached at their roots to the *heart* by the pulmonary veſſels.

The *heart* is attached, on its lower ſide, to the diaphragm, by the pericardium, which is a membranous bag, incloſing the *heart* and all the parts belonging to it.

The figure of the *heart* is conoid, its baſe is irregular, becauſe of all the large veſſels fixed there. The human *heart* differs from thoſe of quadrupeds, which are round every where; the human rather repreſents half a cone, becauſe the under part which lies upon the diaphragm is flat.

The apex of the *heart* is to the left and forwards, its ſituation varies ſomewhat with the motion of the diaphragm, but that is very little, as it lies upon the tendinous part.

The body of the *heart* is compoſed of two large muſcular cavities, called VENTRICLES, one to the right and forwards, the other to the left and backwards. Winſlow calls them anterior and poſterior.

At the baſis of the *heart* are two muſcular bags, called AURICLES, adjoining to the ventricles; they lie contiguous to one another below; but above they are diſtant, as the aorta and pulmonary artery lie betwixt them. The *right* is larger than the left, and it is very thin. The *left* is pretty thick, unequally ſquare; into which the four pulmonary veins empty themſelves.

The *heart* hath a ſeptum divided into two, called SEPTUM VENTRICULARUM, and AURICULARUM SEPTUM.

The right auricle receives the two venæ cavæ, one at the upper part, the other at the lower; the blood brought thither, by the contraction of the auricle, paſſes into the right ventricle, from thence into the pulmony artery, then through the pulmonary veins, into the left auricle, which propels it into the left ventricle, from whence it is ſent into the aorta, to be diſperſed all over the body, and at laſt is returned by the two cavæ to the right auricle.

The two cavæ go into the middle part of the auricle, each ſomething inclined inwards; the angle between them is partly filled up by the left auricle; there is a tranſverſe ridge upon the ſeptum auricularum, called TUBERCULUM LOWERI, which is placed there to hinder the current of the blood from each cava ruſhing directly againſt each other.

The right auricle hath an appendicle which ſerves to fill up the part between that and the aorta; for the ſame reaſon the left hath an appendage upwards, and to the left ſide, to fill up the ſpace between the pulmonary artery and the left ventricle. The whole of the cavity of the auricles internally is not ſmooth, but compoſed of faſciculi, running from one ſide to the other; this faſciculated texture obtains leſs in the left than in the right auricle; it is moſt obſervable in the appendages of the auricles, which no doubt is with a view to hinder the blood from concreting, as there it is moſt out of the way of the circulation.

Under the tuberculum Loweri, we ſee the FORAMEN OVALE, which runs upwards from the right to the left auricle, and goes through the AURICULARUM SEPTUM, directly oppoſed to the vena cava inferior. After the child is born, and a little grown up, this hole cloſes, though in ſome inſtances, it remains a little open, even through old age. In the fœtus there is a valve which is looſe, but this valve in adults is connected to the ſeptum.

The coronary vein opens into the right auricle, between the orifice of the cava inferior, and the paſſage into the ventricle.

The fibres of the auricle are ſo irregularly diſpoſed as to act as ſphincters, and hinder the regurgitation of the blood.

At the inſertion of the cava inferior, is a valve called VALVULA NOBILIS: it is larger in the fœtus than in the adult; whoſe office is to hinder the blood from flowing back into the vein.

The right ventricle, called *lagares*, on its lower part, lies on the diaphragm; on its upper part, it makes the larger part of the *heart*; this ventricle is thicker than the auricle, and the whole internal ſurface of it is faſciculated. It hath two orifices, one at the lower part, where it receives the blood, and one at the upper part where it expels it: the auricular orifice is ſurrounded by a looſe membrane, which is notched into three parts, called VALVULÆ TRICUSPIDALES, which, though reckoned three, are really but one.

From the edge of the valves we ſee certain fibres continued, called *chordæ tendineæ*, which, collected, make what are called the *columnæ carneæ*, and lead to the internal ſtructure of the *heart*: their uſe is to hinder the valvulæ tricuſpides from being inverted; and the faſciculi are of uſe to churn the blood, and are only in the middle to hinder this fluid from ſtagnating.

The other orifice, which leads into the pulmonary artery juſt at its beginning, is furniſhed with three ſemilunar valves, whoſe looſe floating edges lie towards the artery, whilſt the others are fixed to the ventricle. In order to make theſe valves catch more, each hath a little mamilla in its middle (to fill up the triangular ſpace which is left) called the CORPUS SESAMOIDEUM of Arantius: theſe valves hinder the blood from regurgitating into the *heart*.

The left auricle lies rather on the back part, behind the baſis of the *heart*, and towards the left. It is ſituated below the bifurcation of the trachea and pulmonary artery. It is ſtronger than the other, and is ſmooth internally, except at the little appendicle, becauſe the pulmonary veins being two on each ſide, the blood cannot ſtagnate. There are no valves on the orifices of the pulmonary veins. This auricle is ſtronger than the right, becauſe the left ventricle is ſtronger than the right, and therefore requires more force to open it.

The left ventricle is faſciculated. At the orifice, between the auricle and the ventricle, is a valve, called the VALVULA MITRALIS vel EPISCOPALIS, ſo called from reſembling

reſembling a mitre, which runs from the one to the other; it is fiſſured into two points, which are fixed to the auricles; and hang down looſe into the ventricles. The CHORDEÆ TENDINEÆ, and COLUMNÆ CARNEÆ, are the ſame as in the other, but much ſtronger. The orifice, by which it expels the blood, is ſituated in the middle of the ventricle; ſo the aorta riſes from the middle of the baſis of the *heart*. The larger flap of the valvula mitralis hangs down between the auricle and ventricle; and ſome imagine it ſerves as a valve to both the auricular and arterial orifices; but this is abſurd.

The coronary arteries are two. See CORONARIÆ ARTERIÆ.

The FORAMINA THEBESII are venal orifices, ſaid to open into all the cavities of the *heart*.

The fibres of the *heart* are muſcular; at each of the orifices is a tendinous ring, where the fibres of the ventricles begin, which go downwards to the apex, where they turn in, and run up on the inſide, repreſenting in perſpective a figure of 8. There are ſome fibres common to both ventricles, which, as they compreſs them both, Dr. Hunter thinks is a proof of the ventricles being in action at the ſame time.

According to Lanciſi, the nerves of the *heart* are both numerous and large. In each ſide there are inſerted five pair, viz. from the par vagum, the ſuperior intercoſtal pair, the vertebral pair, the inferior intercoſtal pair, and the phrenic pair. The *heart* hath two motions, *ſyſtole* and *diaſtole*. Harvey, and others ſay, that the ſyſtoles of the two auricles of the *heart*, the two ventricles, and the aorta and pulmonary artery, are reſpectively ſynchronous with each other. But Dr. Nichols, with great probability, thinks that the motion of the auricles are aſynchronous, and that the ventricles and arteries are likewiſe dilated and contracted at different periods of time. As the auricles throw blood into their reſpective ventricles, ſo do the ventricles perform the ſame duty, viz. *the right* throws blood into the pulmonary artery, the left into the *aorta*.

See Winſlow's Anatomy. Haller's Phyſiology.

CORACINE. An epithet for a ſort of paſtil, quoted by Galen from Aſclepiades.

CORACINI LAPIDES. Certain bones found in the head of the

CORACINUS, the CROW-FISH, which is found in the Nile, and other rivers in the Mediterranean ſea.

CORACOBOTANE, from κόραξ, *a crow*, and βοτανη, *a plant*. See LAURUS ALEXANDRINA.

CORACO-BRACHIÆUS (MUSCULUS), from κόραξ, *a crow*, and *brachium*, *an arm*; alſo called *coracoides*, *coracoideus*. It riſes from the point of the coracoid proceſs, and is inſerted internally into the middle part of the os humeri. Riolanus gives it this name, and Arantius firſt took notice of it as belonging to the arm. Winſlow calls it *coracobrachialis*. It hath been called *perforatus Caſſerii*, becauſe this author firſt gave a particular account of it, and becauſe it is perforated in the middle, to give paſſage to a nerve. Spigelius calls it *nonus humeri placentini*.

CORACO-HYOIDÆUS, called alſo *omo-hyoidæus*, *omoplato-hyoidæus*, and *coſto-hyoidæus*. It riſes from the ſuperior part of the uppper coſta of the ſcapula, and is inſerted into the baſis of the os hyoides, to pull it downwards and backwards.

CORACOIDES PROCESSUS. The BEAK-LIKE PROCESS. Its name is from its likeneſs to a crow's beak; called alſo *ſigmoides proceſſus*. It projects from the anterior extremity of the upper coſta of the *ſcapula*, which ſee. This proceſs is a little crooked, with its point inclining forwards: a ligament goes out on its ſuperior part, to connect it to the acromion and clavicle. At the birth of children it is cartilaginous; it is alſo called *anchoralis proceſſus*, *ancoralis*, *ancyroides*, *anchyroides*, *cornicularis proceſſus*, *conchyroides*.

—— MUSCULUS. See CORACO-BRACHIÆUS. It is called *coracoides*, from κόραξ, *a crow*, and εἶδος, *form*, becauſe it proceeds from the proceſs which is formed like a crow's beak.

CORACOIDEUS. See CORACO-BRACHIÆUS.

CORACUM EMPLASTRUM. The name of a plaſter deſcribed by P. Ægineta.

CORALATUM. See MERC. PRÆCIP. RUB.

CORALLINA. Called alſo *Muſcus Marinus*, *Muſcus Maritimus*, *Corallina* Anglica, *Corallina* Alba, SEA CORALLINE, and WHITE WORM-SEED.

It is a marine production, common on rocks and ſhells in ſhallow water, &c. It reſembles a ſmall plant without leaves, conſiſts of ſeveral jointed branches, generally of a greyiſh colour, ſometimes greeniſh, yellowiſh, or reddiſh; of a brittle ſtony ſubſtance, friable betwixt the fingers, and crackling between the teeth. It hath commonly been ſuppoſed a vegetable; but late obſervations give us to believe that it is of animal origin. Its height is about two or three inches.

It ought to be entire, of a ſtrong ſea-ſmell and ſalt taſte. Worms will live in a ſtrong infuſion of it for ſeveral days, notwithſtanding it is given in doſes of ten grains or upwards, even to a dram, as an anthelmintic. By calcination in a ſtrong fire, it becomes true quick-lime. It is alkaline and abſorbent, and conſiſts of the ſame general nature as crabs' claws, and other teſtaceous marine bodies. See Neumann's Chem. Works, Lewis's Mat. Med. Cullen's Mat. Med.

CORALLIUM, CORALIUM, or CORALLUM. CORAL. It is alſo called *lithodendron*, or TREE-STONE; *almarago*, *mergen*, *almargen*, *armolgol*, *boleſis*, *gorganias*.

—— ALBUM RAMOSUM, *Madrepora vulgaris*, *corallium*, officinarum oculatum, and WHITE CORAL.

—— NIGRUM. Alſo called *antiphates*, *lithophyton nigrum*, *pſeudocorallium nigrum*, and BLACK CORAL.

What is uſually ſhewn for black *coral*, is a woody, and not a ſtony plant. See KERATOPHYTON.

The beſt ſort of *white coral* is brought from the Mediterranean, and is not porous, but ſolid.

—— RUBRUM. RED CORAL, called alſo *acme*, *azur*.

This is what hath been chiefly uſed in medicine. It is a hard, brittle, branched ſubſtance, reſembling a plant without leaves, uſually about the thickneſs of a gooſequill, full of knots, ſometimes ſtraight, and ſometimes variouſly bent, both externally and internally of a deep bright red colour. It is found adhering to rocks and other bodies, particularly in the Indian and Mediterranean ſeas, and in the Perſian gulf. It has generally a covering of ſoft fungous matter, in which is a great number of cells, containing a milky liquor. This cortical part is ſeparated eaſily whilſt freſh and ſoft. *Corals* are ſuppoſed now to be of the animal kind.

Red *coral* contains ſome iron; its baſis ſeems to be the ſame calcareous animal earth as that of *corraline* and other animal earths. It is alkaline and abſorbent.

The common teſtacea, coloured with dragon's blood, is ſold for it; but by ſhaking this ſubſtitute in water, the fraud is diſcovered; for the colouring matter being ſeparated, the other becomes white, whilſt red *coral* is ſtill red.

Oil of aniſeeds, white wax, milk, or juice of citrons, all extract the red colour from *coral*.

Many preparations have formerly been made from red *coral*; but as the preſent practice juſtly rejects them, it is only farther obſerved, that chalk, *coral*, or oyſter-ſhells, may be indiſcriminately uſed.

CORALLODENDRON. It reſembles a tree; the leaves are for the moſt part conſiſting of three lobes; the flowers are papilionaceous, and are ſucceeded by knobbed bivalve pods, which contain ſeveral kidney-ſhaped ſeeds.

Boerhaave mentions two ſpecies. A confect made with the flowers is called *caryl*.

Arbor *coral.* alſo called Arbor *coral* ſiliquoſa; *ſiliqua ſilveſtris ſpinoſa*, *arbuſcula corallii*, or *coralloides*, and the THREE-LEAVED AMERICAN CORAL-TREE, with deep red flowers, commonly called in America the BEAN-TREE.

Arbor *coral.* min. or the LESSER THREE-LEAVED AMERICAN CORAL-TREE, with blacker ſeeds and ſpines.

Ray informs us, that the inhabitants of Malabar make ſheaths for their knives and ſwords with the wood; that they uſe the wood with the bark for waſhing of their garments, which they call *ſaraſſas*, and of the flower they make the confection called *caryl*. The powdered leaves, when boiled with the mature cocoa-nut, conſumes venereal buboes, and eaſes pains in the bones. The juice of the leaves, taken with the oil *ſergelim*, mitigates venereal pains.

CORALLOIDES. So called from their likeneſs to coral. See DENTARIA, and CORALLODENDRON.

They are a dry juiceleſs ſubſtance, brittle, ligneous, ramous, and furniſhed with apices: on the apices of the tops of the branches, grow fungous tubercles, which contain many ſmall ſeeds. Boerhaave enumerates nine ſpecies. They are ſaid to be aſtringent, but are not of any note in medicine.

—— FLAVA. A ſort of fungus.

CORALLOIDES FUNGUS, alſo called EROTYLUS. Tournefort uſes it to expreſs a genus of muſhroom; which are thus diſtinguiſhed—they are of a fleſhy, fungous texture, and are branched in the manner of coral. The ſpecies he enumerates are nineteen. They are ſaid to be corroborant and aſtringent, but little notice is taken of them.

CORCHORON. See ANAGALLIS.

CORCULUM, called alſo *cor*. The heart or eſſence of a ſeed, and the primordium of the future plant, attached to and involved in the cotyledon. It conſiſts of the *plumula*, the aſcending ſcaly part, and the *roſtellum*, the deſcending part of the corculum.

CORD. EUR. An abbreviation of Euricii *Cordi* Botanologicon, ſive Colloquium de Herbis.

CORD. An abbreviation of Valerii *Cordi* Hiſtoria Stirpium.

CORDA, or CHORDA. See CHORDEE.

CORDA TYMPANI. The portio dura of the ſeventh pair of nerves: having entered the *tympanum*, it ſends a ſmall branch to the ſtapes, and another more conſiderable one, which runs acroſs the *tympanum* from behind forwards, paſſes between the long leg of the incus, and the handle of the malleus, then goes out at the ſame place where the tendon of the anterior muſcle of the malleus enters.

Dr. Monro thinks, that the *corda tympani* is formed by the ſecond branch of the fifth pair, as well as by the portio dura of the ſeventh.

It is called *chorda tympani*, becauſe it croſſes the tympanum as a cord croſſes a drum-bottom.

CORDÆ WILLISII. See DURA MATER.

CORDE' or CHORDE'. See CHORDEE.

CORDIA SEBESTINA. See SEBESTEN.

CORDIALA. See CARDIACA.

CORDOLIUM. See CARDIALGIA.

CORE. See PUPILLA OCUL.

COREMATA. BRUSHES, or BESOMS; but in P. Egineta it is uſed to ſignify medicines for cleaning the ſkin.

CORIANDRUM. CORIANDER. Probably derived from κορις, *cimex*, a bug; becauſe the green herb, ſeed, and all, ſtinks intolerably like bugs: alſo called *caſſidbott*, *caſſibor*, *corianon*. The CORIANDRUM SATIVUM or CORIANDRUM MAJUS, *fructibus globoſis*. CLASS, PENTANDRIA; ORD. DIGYNIA; LINN. Gen. Plant. 356. This plant is an umbelliferous one, with finely-divided leaves; the lower ones are like parſley; the ſeeds are of a pale yelloviſh-brown colour, they are ſtriated. The plant is a native of Italy, and is cultivated in ſome parts of England. It is annual, flowers in June, and ripens, it is ſaid, in July or Auguſt.

The leaves have a ſmall degree of an aromatic ſmell, mixed with a greater degree of what is offenſive. The ſeeds, when freſh, are alſo diſagreeable, but by drying they become grateful: to the taſte, they are moderately warm and pungent. Notwithſtanding Dioſcorides has aſſerted, that theſe ſeeds, taken in a conſiderable quantity, produce deleterious effects; Dr. Withering ſays, he has known ſix drams of the ſeeds taken at once without any remarkable conſequences. Mathiolus ſays, they are antiſeptic. They are generally uſed as ſtomachic and carminative. Mixed with ſenna in infuſion, they more powerfully correct the odour and taſte than any other aromatic; and are equally powerful in obviating the griping it is very apt to produce. Rectified ſpirit of wine takes up all their virtue, but water only partially extracts it. Diſtilled with water, a ſmall quantity of eſſential oil is obtained, which partakes agreeably of the quality of the ſeeds. Pure ſpirit carries off in evaporation a great part of their flavour. Raii Hiſt. and LEWIS's and CULLEN's Mat. Med.

CORIANON. See CORIANDRUM.

CORIARIUM. See RHUS.

CORIS. See SYMPHYTUM PETRÆUM.

CORIS LUTEA, CORIS LEGITIMA CRETICA. See HYPERICUM SAXATILE.

CORIUM. The ſkin of a beaſt; alſo leather, from whence the buff appearance upon the blood is called CORIACEOUS. See alſo DARTOS.

CORNACHINI PULVIS. See SCAMMONIUM.

CORNEA. A COAT of the EYE, which is alſo called *ſclerotica ceratoides*. It is the firſt coat which is proper to the eye; it is ſtrong, thick, and tendinous; its anterior part is diſtinguiſhed by the name of *cornea tranſparens*, or *cornea lucida*, and the poſterior part is called *cornea opaca*. Some call the tranſparent part *cornea*; and the poſterior part *cornea opaca*, and *ſclerotica*, or *ſclerotis*. The tranſparent part of this coat is elaſtic, the opake part is not. The opake part is made up of ſeveral laminæ cloſely connected, whoſe fibres run in different directions, and form a denſe, compact ſubſtance. The fore part of this coat, bearing a fancied reſemblance to tranſparent horn, takes the name of *cornea*.

The *cornea* conſiſts of two principal laminæ, an external and internal one, each of which is compoſed of thinner laminæ. The ſubſtance of the *cornea* is in ſome degree elaſtic, the better to fit the eye to the different magnitudes and diſtances of objects; it is alſo perforated with many ſmall holes, through which a fluid is ſuppoſed to be conſtantly diſcharged, but which ſoon evaporates.

The *ſclerotica* and *cornea* are furniſhed with arteries, chiefly from a branch of the internal carotid. The nerves proceed chiefly from the ophthalmic branch of the fifth pair.

The *cornea* tranſmits the rays of light into the eye, and produces the firſt refraction of thoſe rays which are neceſſary to viſion.

The natural tranſparency of the *cornea* is liable to be obſcured by inflammation, or by humours affecting it, by abſceſſes and ulcers.

It ſeems more proper to conſider this coat of the eye as the SCLEROTICA, which ſee, and the *cornea* only as its tranſparent part.

CORNESTA. See CORNUMUSA.

CORNI. The CORNEL-TREE. The fruit is moderately cooling and aſtringent. The *ſchagri cottam* is a ſpecies *of cornel* which grows in Malabar, the expreſſed juice of which, drank with ſugar, is cooling and aſtringent.

CORNICULA. An inſtrument of horn, which was uſed by the ancients for the purpoſe of a cupping-glaſs. The broad part was applied to the ſkin, and the oppoſite part ended in a point with a hole in it, through which, by ſucking, the ſkin was raiſed into the inſtrument.

CORNICULARIS PROCESSUS. See CORACOIDES PROCESSUS.

CORNICULATÆ PLANTÆ. Plants which produce many diſtinct horned ſeed-pods, called *ſiliquæ*.

CORNU CERVI. In CHEMISTRY, is the beak of an alembic. It is particularly the HORN of the STAG or HART. Thoſe of the *hart*, or male red deer, are to be underſtood; but thoſe commonly uſed are the male or female of the common fallow deer. See DAMIA.

HART'S-HORN ſhaved gives out to water, by boiling, a ſoft gelatinous matter, inſipid and flavourleſs, in quantity about one-fourth of the weight of the *horn*. This jelly is uſed as a nouriſhing diet, and to obtund acrimony. It is putreſcent, ſo ſhould be mixed with acids, as the juice of lemons, or with wine or ſpice, according to the different circumſtances of the patient. The Edinburgh College directs the following:

JELLY *of* HART'S-HORN.

Boil half a pound of the ſhavings of *hart's-horn*, in ſix pints of water, to a quart: to the ſtrained liquor add one ounce of the juice of lemon, or of Seville orange, four ounces of mountain wine, and half a pound of ſugar, then boil again to a proper conſiſtence.

The *horns* of deer are uſed for obtaining a liquor, ſalt, and oil, denominated, liquor, ſal, and oleum cornu cervi; but there is no obſervable difference betwixt one animal ſubſtance and another for this purpoſe, except that one affords more oil than another: hence the bones of oxen and other animals, the hoofs of horſes, the horns of oxen, ivory, blood, urine, ſoot, the white of eggs, the ſhells of tortoiſes, hair, ſilk, &c. all afford the ſame liquor, ſalt, and oil. See ALCALI.

Hart's-horn is ſaid to be prepared philoſophically, when it is ſuſpended in a ſtill, while diſtilling any ſpirituous liquor; the *horn* being cut into thin ſlices, and placed in the neck of the ſtill, ſo as only to be affected by the vapours: thus it is rendered white and friable. This preparation was accidentally diſcovered at Dreſden, in Saxony, by Caſpar Pantzerus, an apothecary, and native of Pruſſia. At preſent it is boiled till the black part ſeparates, and then the inner white part is dried for uſe. Hoffman orders ſome alkaline ſalt to be put in the water when boiling, to make the black part ſoon ſoft. This proceſs frees the *horns* from their glutinous matter, and thus renders them friable.

By calcination, the earthy part is obtained moſt pure and perfect, in quantity to about half the weight of the *horn*. The London College directs to burn pieces of

hart's-

hart's-horn, till they become perfectly white, then rub them to a very fine powder; it is then called CORNU CERVI CALCINATUM, calcined *hart's-horn*, and is to be powdered and levigated for use. As the intention of this operation is to burn out from the *horns* all that is volatile, and leave only the terreſtrious part, here therefore the heat cannot be too great; for the earth of *hart's-horn* is not, like that of coral and the teſtacea, convertible into quick-lime. The *horns* left after diſtilling the ſpirit, ſalt, and oil, are as proper as freſh ones. The calcined *hart's-horn* is found to be a mixture of calcareous earth and phoſphoric acid, and is the weakeſt of the abſorbents, being the moſt difficult of ſolution in acids. The earth of all bones is the ſame as the earth of *hart's-horn*.

Solutions of this earth in vegetable acids are reſtringent, and it is probable that it only checks fluxes by uniting with acid humours in the primæ viæ. The London College only directs the following decoction:

Decoctum Cornu Cervi vel *Decoctum Album*. DECOCTION *of* HART'S-HORN.

Take of burnt *hart's-horn* prepared, two ounces; gum arabic, ſix drams; diſtilled water, three pints; boil the water away to a quart, and ſtrain it off. This is uſed as a common drink in fevers attended with laxity of the bowels.

Decoctum Cretaceum. CHALK DECOCTION.

Take of *chalk* ſubtily powdered, two ounces; of gum arabic, half an ounce; boil in water three pints to two; pour off the liquor from the heavier parts that fall to the bottom. This may be ſubſtituted for the former.

If a little cochineal is added, it is called DECOCTUM RUBRUM, red decoction.

Theſe decoctions are uſed as common drink in acute diſeaſes, attended with a diarrhœa, and where acrid humours prevail in the primæ viæ, and to this end *chalk* is to be preferred to the calcined *hart's-horn*. See Lewis's Mat. Med. Newmann's Chem. Works.

CORNU UNICORNU. } See UNICORNU.
—— FOSSILE. }

—— CERVINUM. See CORONOPUS.

CORNUA. Horny excreſcences, which ſometimes ariſe on ſome part of the body.

CORNUA UTERI, called alſo *plectenæ*. In comparative anatomy, the *horns* of the *womb*. The *womb* is ſo divided in ſome quadrupeds, as to form *corners* reſembling *horns*.

CORNUMUSA. A RETORT, called alſo *batia*, *corneſta*, *cornuta*.

CORNUS. The CORNELIAN CHERRY. That uſed in medicine is the CORNUS MAS Linn. or *cornus hortenſis*, called alſo CRANEIA. The CORNELIAN CHERRY TREE hath an upright ſtem, riſing 20 feet high, branching and forming a large head, garniſhed with oblong leaves, and ſmall umbels of yellowiſh-green flowers, at the ſides and ends of the branches, appearing early in the ſpring, and ſucceeded by a ſmall red, cherry-like, eatable, acid fruit. They poſſeſs the ſame properties as the CERASUS, which ſee.

CORNUTA. A RETORT. See CORNUMUSA.

CORN. An abbreviation of Jacobi *Cornuti*, M. D. Canadenſium Plantarum, &c. Hiſtoria.

COROCRUM. See FERMENTUM.

COROLLA (from *corona*, *a crown*), one of the ſeven parts of fructification, according to LINNÆUS, who defines it, the bark of the plant preſent in the flower: it is the coloured or painted leaves of the plant, conſiſting of *petala*, and *nectarium*. The corolla of LINNÆUS, Engliſh botaniſts call bloſſon.

CORONA. A CROWN. In botany it is a ſeries of ſmall beards, or rays, in diſcoid flowers.

—— SEMINIS is the appendage to the top of many ſeeds, enabling them to diſperſe, ſerving them as wings. This is either the *calyculus*, formed of the perianthium of the flower; as in the ſcabioſa, knautica, &c. or it is the *pappus* (down), as in the hieracium, ſonchus, &c.

—— CILIARIS. See CILIARE LIGAMENTUM.

—— IMPERIALIS. CROWN IMPERIAL.

It is a bell-ſhaped flower, a fine ornament in gardens. Boerhaave enumerates thirteen ſpecies. In the petals is a juice that is very ſweet, which the Turks uſe as an emetic; but the whole plant is eſteemed poiſonous.

—— REGIA. See MELILOTUS,

—— SOLIS. SUN-FLOWER, called alſo *chimalath*, *chimalati*. This flower is well known as an ornament in gardens. Boerhaave enumerates eighteen ſpecies. It is a native of Peru, and other warm countries of America. It is not known to poſſeſs any valuable medicinal qualities; though ſome take notice of it as heating, and an agreeable food. It produces a reſinous tear which is its moſt active part. A gum alſo flows from it, copiouſly obtained, if the ſeed veſſels are taken when ripe, cut ſmall, and boiled in water. The ſeeds are made into bread.

CORONA SOLIS RAPUNCULI RADICE. The ſpecies is uſed as food in Canada.

—— SOLIS PARVO FLORE, TUBEROSA RADICE. See BATTATAS CANADENSIS.

—— TERRÆ. See HEDERA TERRESTRIS.

CORONALE OS. See OS FRONTIS.

CORONALIS vel ARCUALIS SUTURA. The future upon the crown of the head.

CORONARIA LIGAMENTA. The *coronary ligament* of the radius is a ſort of ligamentary hoop, ſurrounding the circular circumference of the head of that bone, reaching from one ſide of the ſmall lateral ſigmoid, or tranſverſe cavity of the ulna, to the other, in an arch, which is about three fourths of a circle. It is nearly as ſolid as a cartilage. It connects the radius very cloſely to the ulna, yet admits of the pronation, and the ſupination of the arm.

CORONARIA VASA. Veſſels that ſurround the heart like a crown; alſo in the ſtomach. See

CORONARIÆ ARTERIÆ & VENÆ. The CORONARY ARTERIES and VEINS. Thoſe of the heart are alſo called *cardiacæ*. The firſt branches which the aorta ſends off, are the *coronary arteries* of the heart; they appear between the aorta and the pulmonary *artery*, run round the baſis of the heart and to the apex, giving branches chiefly to their reſpective ventricles. They frequently anaſtomoſe both at the baſis and apex. One of theſe runs anteriorly, the other poſteriorly on the heart, and ſometimes there are three. They are loſt in the ſubſtance of the heart.

The *coronary veins* of the heart are diſtributed on its ſurface, much in the ſame manner as the *arteries*; they riſe chiefly from the right auricle, and come out in the angle between the vena cava and the paſſage into the ventricle; one principal branch runs to the apex; the great trunk, to the other parts. Dr. Hunter ſays, that the *coronary vein* of the heart opens into the right auricle, between the orifice of the cava inferior, and the paſſage into the ventricle, and is furniſhed with a ſemilunar valve, to hinder the blood from flowing back.

Mr. C. F. Wolf obſerves, in his paper in the Tranſactions of the Imp. Acad. of Scienc. at St. Peterſburgh, that the great *coronary vein*, and the orifice by which it communicates with the right ſinus of the heart, were known to Galen, but Euſtachius ſeems to have been the firſt who noticed the valve with which this orifice is furniſhed. Since his time, Mr. Wolf ſays, anatomical writers have conſtantly ſpoken of this valve as being of a ſemilunar ſhape, but he aſſerts that its figure is oblong and narrow; and that it is a valve of its own kind, different from any other to be met with in the human body.

The *coronary artery* of the ſtomach riſes from the cœliaca, goes firſt to the left ſide of that organ, a little beyond the ſuperior orifice, round which it throws branches, and alſo to every part of the ſtomach near it: and theſe branches communicate with thoſe which run along the bottom of the ſtomach to the pylorus: afterwards it runs on the right ſide of the ſuperior orifice, along the ſmall curvature of the ſtomach, almoſt to the pylorus, where it communicates with the *arteria* pylorica, and turning towards the ſmall lobe of the liver, it gives off ſome branches to it; then it advances under the ductus venoſus to the left lobe of the liver, in which it is loſt near the beginning of the duct juſt named, having firſt given off ſome ſmall branches to the neighbouring parts of the diaphragm and omentum.

The *coronary vein* of the ſtomach is ſometimes a branch from the vena portæ ventralis, or from its principal branches. It ſometimes ſprings from the ſplenica. The *coronaria ventriculi* is ſo called, becauſe it ſurrounds the upper orifice thereof. It runs along the ſmall arch to the pylorus, and gives out branches to the ſides of the ſtomach.

CORONARIUM LIGAMENTUM. See JEJUN.

CORONARIUS STOMACHICUS. The ramification of the nerves from the eighth pair near the upper orifice of the ſtomach.

CORONE. So the acute proceſs of the lower jaw-bone is called. See alſo PROCESSUS.

CORONILLA INDICA. See INDICUM.

—— MONTANA. See EMERUS MINOR.

CORONOID. See PROCESSUS.

CORONOIDAS APOPHYSIS ULNÆ. It is at the upper end of the *ulna*, prominent, and a little pointed, reſembling a broad ſhort bea'. It is received into the anterior cavity above the pulley, at the lower extremity of the os humeri, when the fore-arm is bent.

CORONOIDAS APOPHYSIS MAXILLÆ. See MAXILLA INFERIOR.

CORONOPUS, from κορωνη, a *carrion crow*, and πους, *foot*, the plant being ſaid to reſemble *a crow's foot*. It is alſo called *cornu cervinum*, *herba ſtella*, *ſtella terræ*, *plantago*, BUCK'S HORN PLANTAIN.

Its flowers and fruit are like thoſe of plantain, but its leaves are deeply cut. Its root is long and ſlender; many of its leaves lie flat on the earth in a circular manner, whence the name *ſtella terræ*, or *ſtar of the earth*. The leaves are downy, long, and narrow; the ſtalk is hoary; the ſeeds are ſmall, and of a dark brown colour. It grows on ſandy places and heaths, and flowers in June.

Its medical virtues are the ſame as thoſe of the other plantains; See PLANTAGO. Botaniſts enumerate five ſpecies.

CORPORA ALBICANTIA. See CEREBRUM.

—— CAVERNOSA PENIS, called alſo *nervea ſpongioſa*. The two bodies, thus named, riſe by two diſtinct crura from the lower part of the oſſa pubis; after which they join, and are continued to the glans. They are ſeparated by a ſeptum, diſpoſed like the teeth of a comb, ſo that any fluid forced into one, diſtends the other. The two crura are connected to the ſymphyſis of the os pubis by the *ligamentum ſuſpenſorium*, which proceeds from the cartilage, and is diffuſed upon the ſheaths of the *corpora cavernoſa*. Towards the upper extremity of the *corpora cavernoſa*, are ſeveral white ligaments, which ſeem to be placed there to hinder the *penis* from being over much diſtended. In the axis of each *corpus cavernoſum*, an artery and a vein run, which enter near the union of the crura, and ramify throughout the ſpongy ſubſtance.

—— FIMBRIATA. A border on the edge of the fornix in the brain is thus named. See FORNIX.

—— LOBOSA. See RENES.

—— OLIVARIA. Two eminences on the medulla oblongata are thus named. Winſlow calls them *corpora olivaria*, which Willis calls

—— PYRAMIDALIA; but theſe are two eminences on the medulla oblongata, near the corpora olivaria. The ſpermatic veſſels have this name given them by ſome.

—— STRIATA. Two prominences in the lateral ventricles of the brain. They got this name, becauſe by ſcraping them with a knife, we meet with a great number of white and aſh-coloured lines alternately diſpoſed, and which are only the tranſverſe ſection of the medullary and cortical laminæ mixed together. See CEREBRUM.

CORPULENTIA. See OBESITAS and POLYSARCIA.

CORPUS CALLOSUM, called alſo CALLUS. If the falx is cut away from the criſta galli, turned backwards, and the two lateral parts of the cerebrum gently ſeparated, we ſee a longitudinal portion of a white convex body, named *corpus calloſum*, which is a middle portion of the medullary ſubſtance of the brain: under the inferior ſinus of the falx, and alſo a little towards each ſide, it is parted from the maſs of the cerebrum, to which it is ſimply contiguous from one end of that ſinus to the other; ſo that at this place the edge of the inſide of this hemiſphere only lies on the *corpus calloſum* much in the ſame manner as the anterior and poſterior lobes lie on the dura mater. Both extremities of this medullary body terminate by a ſmall edge bent tranſverſely downwards. The ſurface of the *corpus calloſum* is covered by the pia mater; along the middle of its ſurface, from one end to the other, there is a kind of raphe, which hath on each ſide a white cord. The *corpus calloſum* covers the two lateral ventricles. See CEREBRUM.

—— GLANDULOSUM. See PROSTATÆ.

—— MUCOSUM. See RETE MUCOSUM.

—— PAMPINIFORME, } The SPERMATIC CHORD.
—— PYRAMIDALE } See SPERMATICA CHORDA.

—— RETICULARE. See RETE MUCOSUM.

—— SESAMOIDEUM. See COR.

CORPUS SPONGIOSUM URETHRÆ. The SPONGY BODY OF THE URETHRA. It is of the ſame ſubſtance as the corpora cavernoſa, and ſurrounds the *urethra*. That part which is next the proſtatæ is thick, but as it runs on it becomes ſmaller, and at the extremity forms the gland. That end next the proſtatæ, becauſe of its bigneſs, is called the bulb of the *urethra*; the other end forms the glans upon the extremities of the corpora cavernoſa.

—— VARICOSUM. See SPERMATICA CHORDA.

CORRAGO. See BORRAGO.

CORÆ. See TEMPORA.

CORRECTIO. CORRECTION. This word, in pharmacy, ſignifies, firſt, that medicines, which operate violently, are corrected by adding ſomething which checks their action. Secondly, when ſome addition leſſens the noxious quality of a medicine. Thirdly, when nauſeous medicines are made more palatable; or thoſe which are apt to gripe by themſelves, have that effect leſſened or prevented.

CORRIGIOLA. See GRAMEN POLYGONUM.

CORROBORANTIA, alſo ROBORANTIA, CORROBORANTS. All ſuch medicines as are ſuited to ſtrengthen the body, and therefore to reſtore the ſtrength when it has been loſt, may come under this head. But Dr. CULLEN thinks, as a general term, it is improper: ſtill as it is employed for medicines which increaſe the tone of the moving fibres, it may be allowable. See, on this ſubject, Conſpectus Medicinæ Theoreticæ Doctoris Gregory de remediis roborantibus. Under this head are placed abſorbents, agglutinants, and aſtringents. Theſe give bulk and firmneſs to the ſolids, which are rendered neceſſary by the continual waſte which the actions of life occaſion. *Abſorbents* remove redundant moiſture, *aſtringents* contract the relaxed fibres, and agglutinants add ſubſtance, where a previous waſte renders a ſupply neceſſary.

CORRODENTIA. CORROSIVES, or corroding medicines, alſo called *cathæretica*. They are thus divided: 1ſt, The MILD, ſuch as burnt alum, the aſhes of green wood, calomel, calx hydrargyri alba, and zincum vitriolatum purificatum. 2, The STRONG, as hydrargyrus nitratus ruber, colcoth. vitr. troch. de minio vigonis. 3d, The STONGEST, as butyr. ant. lap. infern, hydrargyr. muriatus, aqua kali, & acidum vitriolicum. *Corroſives* act by their acrimony, by which they deſtroy not only foreign ſubſtances adhering to animal bodies, but alſo the ſolids themſelves, provided they meet with any moiſture when applied to them; and particularly if ſo confined upon the part, as to have their actions excited by the heat of the body. In the two firſt caſes they are called cathæretics; in the laſt, potential cauſtics. See ESCHAROTICA.

CORROSIO, from *corrodo*, *to eat away*. CORROSION. It is the acting on bodies by means of proper menſtrua, ſo as to produce new combinations, and a change of their form, without converting them to fluids. This depends on the ſame principles as ſolution. The ſubjects are uſually metals; and the modes are either, firſt, by immerſing the body to be *corroded*, in ſome fluid menſtruum, and this is called *corroſion* by immerſion; or, ſecondly, by expoſing it to the action of ſome vapour, and this is called *cementation*. There are other kinds of *corroſion*, as by ſprinkling the ſubject with ſome proper fluid, rubbing it with ſome dry ſubſtance, &c.

CORRUGATOR COITERII Volcherus Coiter firſt took notice of this pair of muſcles. So called from *con* and *rugo* to wrinkle. The *corrugator* ariſes fleſhy from the internal angular proceſs of the os frontis, above the joining of the os naſi, and naſal proceſs of the maxillary bone; from thence, it runs outwards, and a little upwards. It is inſerted into the inner and inferior fleſhy part of the occipito-frontalis muſcle, where it joins with the orbicularis palpebrarum, and extends outwards as far as the middle of the ſupercilliary ridge. When one of theſe muſcles acts, it draws the eye-brow of that ſide towards the other; and makes it project over the inner canthus of the eye: when both act, they pull down the ſkin of the forehead and make it wrinkle particularly between the eye-brows. This muſcle is called by WINSLOW *muſculus ſupercilii*; by DOUGLAS, *frontalis verus muſculus*; and by RIOLAN, *carneſa muſculoſa membrana*.

CORSÆ. See TEMPORA.

CORSOIDES. See AMIANTHUS.

CORTALON. See ERIGERUM.

CORTEX CARDINALIS DE LUGO. The *cort*
Peruv.

Peruv. was thus called, becauſe the cardinal Lugo had teſtimonials of above a thouſand cures performed by it in the year 1653.

CORTEX CARYOPHYLLOIDES. See CASSIA CARYOPHYLLATA.

—— CRASSIOR. See CASSIA LIGNEA.

—— CULILAWAN, alſo called *culilavan*, is a hot aromatic bark found in New Guinea, of ſimilar virtues to the *cortex maſſory*. See CASSIA CARYOPHYLLATA.

—— ELATERII. See THURIS CORTEX.

CORTEX FLAVUS. See FLAVUS CORTEX.

—— MAGELLANICUS. See WINTERANUS CORTEX.

—— MASSORY. It is a warm aromatic bark, found in New Guinea. It is alexipharmic, carminative, and ſtomachic. The inhabitants powder, then mix it with water to anoint their bodies with in cold wet weather. It is alſo uſed againſt pains and gripes.

—— PERUVIANUS. The PERUVIAN BARK; alſo called *cinchona, china chinæ, gannana, gannanaperide, kinkina, chinchina, cina cinæ, kina, kina-kina, magnum Dei donum, quinquina, quina-quina, holquahuilt, cortex patrum, cortex Peruanus, cortex cardinalis de Lugo*, and the JESUIT BARK. The tree from whence it is acquired is called by ſome the ARBOR FEBRIFUGA PERUVIANA, *chilli arbor*. The powder of this *bark* hath been ſold under various names, as *pulvis comitiſſæ, patrum & Jeſuitarum pulv.* BERLIN POWDER, &c. CINCHONA is the practical name in the new London Diſpenſatory.

It is the *bark* of a tree which grows in Peru, according to the account given of it by Mr. Arrot, a ſurgeon, who lived a long time there. It is the cinchona officinalis, or cinchona panicula brachiata, PERUVIAN JESUIT-BARK-TREE, or rather CINCHONA OFFICINALIS *foliis ellipticis ſubtùs pubeſcentibus, corollæ limbo lanato.* CLASS PENTANDRIA; ORD. MONOGYNIA. Lin. Gen. Plant. 228. There are four ſorts of this *bark*, viz. the reddiſh, yellowiſh, whitiſh, and the curling; the two firſt are the beſt, the curling is from young trees. Mr. Condamine ſays, that the tree is call *caſcarilla*, and is very different from the *quinquina*. He alſo aſſerts, that, according to an ancient tradition, the Americans owe the diſcovery of this remedy to the lions, which ſome naturaliſts pretend are ſubject to a kind of intermittent fever, of which they were obſerved to be cured by eating inſtinctively the bark of the cinchona. But it is more generally believed, and with the greateſt probability, that its virtues were diſcovered by the Indians about the year 1500. A lake near a town in Peru was ſurrounded by theſe trees, which were torn up by an earthquake, and falling into the adjacent water, they rendered it bitter. An Indian, urged by his thirſt during a fever under which he laboured, drank of this water, becauſe no other could be had: however, obſerving that he ſoon recovered, he related the caſe, and others were alſo cured. On this, inquiry was made, and to the trees it was found that the water owed its virtue; then it was ſoon diſcovered, that the *bark* alone poſſeſſed the medicinal quality. In 1640, a Spaniſh ſoldier was quartered in an Indian's houſe, and being ſeized with an ague, his landlord, moved with compaſſion, told him of a cure, and with the ſame he cured his companions. At length the vice-queen, wife of the count de Cinchon, then vice-roy of Peru, was ſeized with an intermitting fever; this ſoldier cured her alſo; hence the name CINCHONA and COMITISSA. The counteſs on her recovery diſtributed a large portion of this bark to the Jeſuits, in whoſe hands it greatly increaſed its reputation: hence was it called Jeſuitarum pulvis, and patrum cortex vel pulvis. After this, father de Lugo at a great expence brought a parcel of it to Rome, and diſtributed it among the religious, poor, &c. and from him it received the name of CORT. CARD. DE LUGO. From Rome it was ſpread into France and England, and at length became general. By way of eminence it is called the BARK.

This *bark* is brought in pieces of different ſizes, ſome rolled up in ſhort thick quills, and others flat; the outſide is browniſh, and generally hath a whitiſh moſs ſpread upon it; the inſide is of a yellowiſh, reddiſh, or ruſty iron colour. The beſt ſort is bitter, reſinous breaks cloſe and ſmooth, is friable betwixt the teeth, pulverizes eaſily; when powdered, is of a cinnamon colour, but rather paler; and according to the opinion of ſome, as the ſureſt teſt of its goodneſs, it hath a muſty kind of ſmell; and at the ſame time ſo much of the aromatic, as not to be diſagreeable. The inferior kinds, when broken, appear woody; and in chewing, ſeparate into fibres. That which is called female bark, is redder in the inſide; it is alſo thicker, and on the outſide more white and ſmooth, is weaker to the ſmell and taſte than the above, and, in medical virtue, greatly inferior.

The variety of diſorders, in which the *bark* can be uſed to advantage, may ſeem to entitle it almoſt to the character of an univerſal medicine; in many diſeaſes it is a ſovereign remedy; and every practitioner, in proportion as his knowledge of its qualities increaſes, finds he can ſtill employ it in a larger extent of caſes. It is certainly a bitter, and aſtringent, and has ſome degree of aromatic conjoined; but it is upon the two former qualities its power altogether depends as a tonic. With regard to the ſtomach, it is indiſputable; and it is well known that the ſtate of the ſtomach is readily communicated to the reſt of the ſyſtem: hence it may be diſcovered, where this medicine is likely to be attended with advantage in its application, and where it may be hurtful. In all diſorders where the *bark* is uſeful, other medicines of the aſtringent, or bitter kinds, or combinations of them, have alſo been of ſervice, though not equally with the *bark*, if it is given in ſubſtance; its virtue reſides in the whole of its parts mixt together, none anſwering ſo well, if ſeparated.

Dr. Cullen ſays that the *Peruvian bark* belongs to the claſs of bitters, and along with its bitterneſs has an aromatic acrimony, depending on an eſſential oil preſent; with this it has a ſtypticity and aſtringency, which ſome have thought proper to deny it, but which is ſufficiently evident when, by diſtillation or ſolution, part of the other qualities are extracted; all the common qualities of bitters are aſcribed to the *bark*. I has the ſame effects in the ſtomach, and inteſtines. In a large quantity, he has ſeen it purge, and habitual coſtiveneſs cured by it, which has proceeded from the weakneſs in the alimentary canal, by giving doſes of 3 i. for ſeveral days together, which ſeemed to work a conſiderable change in the ſyſtem. Carried into the blood, little notice has been taken of the diuretic or diaphoretic powers of the *bark*. It is ſuppoſed to ſtrengthen the whole ſyſtem; and, indeed, we may conclude that its virtues chiefly reſide in its tonic powers.

Some are intimidated from the uſe of the *bark*, though manifeſtly indicated, becauſe of their apprehenſions of its aſtringency: for example, in aſthmas it is forbid, though an ague requires it; but it is ſafe in all diſorders, when there is a fair remiſſion of the fever, and the pain that may attend it. The truth is, the *bark* is not very aſtringent; the prejudices on that account have very little foundation. It is ſafely given juſt before the acceſſion of the cold fit in agues; and in general if the pulſe of an adult does not exceed ſeventy ſtrokes in a minute, it is ſafe and uſeful. So far from cauſing obſtructions, it, in many inſtances, reſolves thoſe already formed; in many glandular tumors, in ſcrophulous diſeaſes and venereal phymoſes, &c. this medicine is a powerful remedy; it hath long been given to women, ſucceſsfully, to the quantity of a dram every three hours, two days after delivery, without leſſening the lochia; during the natural flux of the menſes, it hath been frequently adminiſtered without interrupting them; in the confluent ſmall-pox, its uſe does not leſſen the ſpitting: whence it does not ſeem probable, that the *bark* is ſo powerful an aſtringent as to obſtruct either any natural or critical diſcharge; ſo that when on other accounts it is indicated, its adminiſtration is ſafe. If ever injury was derived from its uſe in any caſe in which it is adapted to relieve, a too late, and not too early adminiſtration, muſt be blamed; from its aſtringency it never can endanger.

As a febrifuge, it was firſt and principally celebrated, and in this character it maintains its reputation. In every kind of fever, except the inflammatory, or in their inflammatory ſtage, it is extremely uſeful: in the ardent, if given when they intermit, it effects a cure; in the lower kind its uſe is earlier, and its effects as ſalutary. Almoſt all diſorders which appear in the form of intermittents, yield to its power.

Its antiſeptic power is a diſcovery of later date; but in this reſpect its credit is eſtabliſhed. It, by invigorating the ſolids, and increaſing the craſſamentum of the blood and its adheſion, thus reſiſts a putrid ſtate and diſpoſition in our bodies.

ABSCESSES AND ULCERS that diſcharge a ſanies inſtead of pus, are ſoon reduced to a healing ſtate, ...

ing

ing the *bark*; the ſanious and bloody matter in variolous puſtules ſoon change their appearance on its uſe, and only need be with-held, if the difficulty of breathing ſhould be increaſed by it. The glandular tumors are reſolved by it, and in inflammatory ones it promotes a laudable ſuppuration.

Moſt ſymptoms that attend a STRUMOUS HABIT yield to the efficacy of the *bark*, except when the bones are affected, and pain attends tumors of this kind, from their being ſituated contiguous to tendons and membranes: it then increaſes the uneaſineſs.

It almoſt every caſe from a LAX FIBRE, the *bark* is of ſervice, either as a principal or an auxiliary remedy.

In NERVOUS ASTHMAS, joined with fetids, the *bark* is greatly advantageous, after expectoration hath removed all tenſion in the lungs; and in humoral aſthmas, if there is a ſediment in the urine, a moiſt ſkin, and a weak pulſe, it is both uſeful and ſafe

In many inſtances the EXTERNAL APPLICATION of the *bark* anſwers in a good degree its internal uſe. In the Lond. Med. Obſ. and Inq. vol. ii. are inſtances of cures effected by quilting it in waiſtcoats which were worn next the ſkin.

Again, it ſhould be noticed, that as a judicious uſe of this medicine is of extenſive benefit, ſo an improper one may be productive of as ill effects; for, although it is a febrifuge, its uſe in ardent fevers is during their intermiſſion only; when the fibres are tenſe, its uſe is not required, as to increaſe their firmneſs is its primary effect; conſequently in all diſeaſes ariſing from or attended with tenſe fibres, the *bark* is obviouſly improper. Though the *bark* is a powerful antiſeptic, yet in thoſe gangrenes that are attended with a fulneſs of the pulſe from a ſanguine plethora, it ſhould not be admitted; its excellency is in thoſe mortifications where the blood is poor, and that take their riſe from this poverty.

In all caſes where the *bark* is depended on for the cure, the doſes ſhould be as large, and their repetition as frequent, as the ſtomach will eaſily admit; in moſt caſes its efficacy will be improved by ſome ſuitable auxiliary; as in groſs habits, purging with calomel, rhubarb, or jalap, ſhould precede its uſe; in bilious, and when heat is complained of, nitre ſhould be joined with it; in lax habits with thin and poor blood, aromatics and chalybeates, bitter and warm diaphoretics, greatly aſſiſt it; and if obſtructions are ſuſpected in the abdominal viſcera, the kali acetatum will be a proper adjunct. Of late it hath been much employed in acute rheumatiſms, particularly after the violence of the diſeaſe has been in ſome meaſure moderated by the antiphlogiſtic treatment, or when evident remiſſions take place. Many, however, have recourſe to this medicine in the firſt ſtage of the diſeaſe, and its ſucceſs has been witneſſed in ſome of the London hoſpitals, even whilſt the inflammatory ſymptoms prevailed to a conſiderable degree. In the confluent ſmall-pox, the bark has been recommended to promote the riſing of the puſtules: this opinion, Dr. WOODVILLE ſays, his own experience has taught him to reject; but after the maturation of the puſtules is completed, or where ſymptoms of putreſcency, or a diſſolved ſtate of the blood ſupervenes, the bark cannot be too liberally employed. The other diſeaſes in which the bark is recommended, are gangrenous ſore throats; and indeed almoſt every ſpecies of gangrene, dyſentery, all hæmorrhages of the paſſive kind, likewiſe other increaſed diſcharges, ſome caſes of dropſy, eſpecially when unattended with any particular local affection, ſcrophula, ill-conditioned ulcers, rickets, ſcurvy, ſtates of convaleſcence, certain ſtages of phthiſis pulmonalis, &c. In fine, if we direct our attention to the TONIC POWER of the *bark*, we may almoſt, in all the variety of caſes for which it is recommended, readily determine the propriety or impropriety of its uſe in their different ſtages.

Various are the preparations of the *bark*; but when the ſtomach will bear it, the powder, if very fine, is the moſt agreeable and the moſt uſeful; in caſe of averſion to the powder, the next beſt preparation is the infuſion in cold water, prepared as follows:

INFUSION *of the* BARK.

Take one ounce of bark in fine powder, and twelve ounces of ſoft water; add the water, by a little at a time, continuing to triturate it for about ten minutes in a marble mortar; then let them ſtand together, without ſubjecting them to any heat, for three-quarters of an hour, and ſtrain. The elegance and ſtrength of this preparation is increaſed by the addition of a ſmall quantity of French brandy during the triture. This infuſion is ſooner prepared, is as ſtrong, and more agreeable than the decoction: it may be taken in doſes of two and three ounces.

In boiling, the reſinous matter of the *bark* is haſtily ſeparated by the heat, but is not properly diſſolved by the water: hence in cooling it begins to ſeparate, renders the liquor turbid, and at length falls to the bottom: but when macerated in cold water, the medicinal parts are gradually ſeparated and extracted together, and are retained by the water in a ſtate of perfect ſolution. For weak ſtomachs no preparation excels this.

Dr. Saunders relates the following experiment, in his obſervations on the ſuperior efficacy of the red Peruvian *bark*. A decoction of both red and common Peruvian *bark* was prepared by taking an ounce of each, and boiling them in a pint and half of water, to one pint; the former had greatly the ſuperiority in ſtrength and power. A pint of freſh water was added to each decoction; the boiling ſtill continued till that quantity was evaporated. The decoction of the common Peruvian *bark* ſeemed gradually to loſe its ſenſible qualities, while that of the red *bark* ſtill retained its own. The ſame quantity of water was added as before to each, and the decoction repeated until a gallon of water was exhauſted; at the expiration of which time, the common Peruvian *bark* was rendered almoſt taſteleſs; the red *bark* ſtill retaining nearly its former ſenſible qualities. This experiment proves, that the common practice of boiling the *bark* is hurtful to its powers.

Next to this infuſion in water, an infuſion in Rheniſh wine may be preferred; and the next to it, a tincture drawn with good French brandy. In SCROPHULA, the ſhell-lime-water is a good menſtruum for the *bark*; and in caſes where relaxation ſimply demands the uſe of the *bark*, the lime-water made with ſtone-lime ſhould be preferred.

The diſguſtful taſte of the *bark* is covered by liquorice, or orange-peel, or a ſmall quantity of Winter's bark. In the following electary, mucilage is thought uſeful in covering the taſte, which is made in the following manner, and conſidered an excellent medicine in ſcrophulous caſes, adequate to burnt ſponge. ℞ ſodæ pp. ʒij. pulveris cort. Peruv. ʒi. mucilaginis gum. Arab. q. s. m. The doſe ʒij. two or three times a-day.

The College of London directs two extracts, and two tinctures from the *bark*.

Extractum Corticis *Peruviani* ſeu CINCHONÆ. EXTRACT *of* PERUVIAN BARK.

Take of *Peruvian bark* coarſely powdered, one pound; diſtilled water, twelve pints; boil for an hour or two, and pour off the liquor, which, while hot, will be red and pellucid: but as ſoon as it grows cold, it becomes yellow and turbid; boil the *bark* again in the ſame quantity of water as before, repeating theſe boilings till the liquor remains tranſparent when cold: than evaporate all theſe decoctions, ſtrained and mixed together, to a proper conſiſtence. Ph. Lond. 1788.

This extract is to be prepared under a double form; one of the conſiſtence of a pill; the other hard enough to be reduced to powder.

The extract is not ſo ſtrong of the *bark* as is imagined; beſides, it is hardly poſſible to make it without ſome degree of empyreuma, and the advantage of its form no way compenſates for the expence and trouble in preparing it. Ten grains of the hard extract are computed to be equal to half a dram of the *bark* in powder.

Extractum Corticis *Peruviani* ſeu CINCHONÆ, cum *Reſina*. EXTRACT *of* PERUVIAN BARK *with* RESIN.

Take of *Peruvian bark* coarſely powdered, one pound; rectified ſpirit of wine, four pints; digeſt for four days, and then pour off the tincture; boil the reſiduum in ten pints of diſtilled water, to two; then ſtrain the tincture and decoction ſeparately, evaporating the water from the decoction, and diſtilling off the ſpirit from the tincture, until each begins to be thickened: laſtly, mix the reſinous with the aqueous extract, and make the maſs fit for forming into pills. Pharm. Lond. 1788.

Tinctura Corticis *Peruviani* ſeu CINCHONÆ. TINCTURE *of* PERUVIAN BARK.

Take of the *Peruvian bark*, four ounces; of proof ſpirit of wine, a quart; digeſt with a gentle heat for eight days, and ſtrain. Pharm. Lond. 1788.

This

This is an agreable preparation, but as it is too heating if a large dose is given, it would be better to add twice the quantity of the *bark* to this quantity of spirit, and then the *bark* would be given more plentifully in each dose of tincture.

Tinctura Corticis *Peruviani* seu CINCHONÆ *composita.*
COMPOUND TINCTURE *of* BARK.

Take of *Peruvian bark* in powder, two ounces; exterior peel of Seville oranges, one ounce and an half; Virginian snake-root bruised, three drams; saffron, one dram; cochineal powdered, two scruples; proof spirit of wine, twenty ounces; digest for fourteen days, and strain. This was the tinctura *corticis* Huxhami, and is certainly a good tonic and cordial. Pharm. Lond. 1788.

TINCTURA AMMONIATA CINCHONÆ

Take of *Peruvian bark* in powder, by weight four ounces; compound spirit of ammonia, two pounds; digest them in a close vessel for ten days, and filter it. Pharm. Lond. 1788. See Lewis's Mat. Med. Neumann's Chem. Works. Percival's Essays Med. and Exp. Cullen's Mat. Med.

In the year 1782, Dr. Saunders, physician to Guy's hospital, published his Observations on the Superior Efficacy of the Red *Peruvian Bark*. This publication may be referred to, as not only the first on this subject, but also containing many other important hints respecting the practice of medicine. The following few extracts are here subjoined.

The red *Peruvian bark* is in much larger and thicker pieces than the common *Peruvian bark*. It evidently consists of three different layers. The external is thin, rugged, and frequently covered with a mossy substance, and of a reddish brown colour; the middle is thicker, more compact, and of a darker colour: in this appears chiefly to reside its resinous part, being extremely brittle, and evidently containing a larger quantity of inflammable matter than any other kind of *bark*. The innermost hath a more woody and fibrous appearance, of a brighter red than the former. The entire piece breaks in that brittle manner described by writers on the materia medica, as a proof of the superior excellence of the *bark*. In reducing it to powder, the middle layer, which seems to contain the greatest proportion of resin, will not give way to the pestle so easily as the other layers; this should be particularly attended to when it is used in fine powder. Its flavour is chiefly discoverable, either in powder or solution, is evidently more aromatic, and has a greater degree of bitterness than the common *bark*.

It is highly probable, that it is the *bark* of older trees than that which is called quill *bark*; that it is from the trunks and larger branches of them; and that a more particular care may be taken in collecting and drying it; whence its superior qualities.

The taste and flavour of the red *bark* is more difficultly evolved, and is therefore at first not so obvious, from the closeness of its texture, and from the resinous coat being so well defended, and inclosed between other two layers. It is evidently heavier than any other kind of *bark*, and seems to have been prepared and dried with greater attention, its original appearance and form being better preserved.

The red *bark* is so much warmer than the other, that it would seem to answer all the purposes derived from the union of cordials, aromatics, serpentaria, and the like, so much recommended in the obstinate quartan intermittents of elderly people.

By the testimony of many practitioners, it appears that intermitting fevers are more speedily and effectually cured, either by infusion, decoction, or powder of the red *bark*, than by those of the common *bark*; and this also by smaller doses of the former than of the latter. Dr. Saunders says, that from the numerous trials he hath made with it, in intermitting fevers, and other diseases, he is disposed to conclude that it need be employed only in half the quantity we generally recommend of the other *bark*.

The infusion, decoction, and tincture, made with red *bark*, are considerably stronger than those from the same quantity of common *bark*; and it is said to have afforded more than twice the quantity of extract, than is obtained from the same portion of common *bark*.

In an infusion of the red *bark*, the spirit of vitriol lost its acidity more perfectly than in an infusion of the *bark* before in use. A decoction of the red *bark* keeps perfectly good, during more than a month in the summer season; whilst that of the common *bark* is sensibly changed in a few days. In the decoction of the red *bark*, the powder, which is separated during the cooling of it, remains intimately diffused through the liquor, so that it continues loaded and turbid whilst at rest: in the decoction of the common *bark*, it separates, and easily subsides to the bottom. See also FLAVUS CORTEX.

COSMETORGES. A word invented by Dulæus to express the sensitive soul.

COSMIANA ANTIDOTUS. The name of an antidote in Marcellus Empiricus.

COSMOS. In Hippocrates, it is the order and series of critical days.

COSSI. Tubercles in the face. See VARUS.

COSSUM. A malignant ulcer of the nose, mentioned by Paracelsus.

COSTA PULMONARIA. } See HIERACIUM
—— HERBA PANONICA. } ALPINUM.

COSTÆ. The RIBS. Littleton says, from *consto*, on account of their firmness (as if they were custodes, or guards, to the heart and lungs). The *costæ*, in ANATOMY, are generally twelve on each side, though sometimes there are but eleven, at others thirteen are found: their extremities next the vertebræ are rounder and stronger than those which join the sternum; the upper edges are more round than the lower, which are depressed internally for lodging the intercostal vessels and nerves; this channel is not observable at either extremity, which is a plain direction to perform the operation for the empyema rather towards the sides of the thorax than at either extremity.

The *ribs* are articulated at each extremity, of which the posterior is doubly joined to the vertebræ; for the head is received into the cavities of the two bodies of the vertebræ by ginglymi, and the larger tubercle is articulated to the transverse process of the inferior vertebra by arthrodia, by which means they are properly guarded against luxations.

They are divided into true called *veræ*; and false called *spuriæ*, *illegitimæ*, *mendosæ*, *nothæ*. The true are the seven superior, whose cartilages are joined to the sternum; these *ribs* include the heart, lungs, &c. The false are five inferior, whose cartilages are not joined to the sternum; unto all these the diaphragm is connected; and within them the stomach, liver, spleen, &c. are contained.

The cartilages of the falſe *ribs* are only connected to one another by a membrane which covers them; the two laſt are joined to the vertebræ by a round head, and their cartilaginous extremities are loſt in the interſtices of the muſcles, by both which circumſtances they become more moveable than the other *ribs*.

The upper *rib*, contrary to the reſt, is flat upwards and downwards, that it may not incommode the lungs, and leave room for the ſubclavian veſſels and muſcle.

The anterior extremity of each *rib* is lower than the poſterior; therefore, when elevated, the cavity of the thorax will be increaſed in its diameter backwards and forwards, and the middle part of the ſuperior ridge is lower than the poſterior part; thus, when elevated, the diameter of the thorax will be laterally increaſed.

The *ribs* are but little uſed in ſleep, reſpiration being then carried on by the diaphragm and intercoſtal muſcles.

COSTÆ, in BOTANY. The nerves and leaves, or the long tough ſtrings which run either acroſs or lengthways through them, are called their *ribs*.

COSTALES NERVI. See DORSALES.

COSTO-HYOIDÆUS. See CORACO-HYOIDÆUS.

COSTUS, COSTUS ARABICUS Linnæi, alſo called *coſtus Indicus,—amarus dulcis Orientalis, inpinguedo porci, tſianakua*. SWEET and BITTER COSTUS.

It is a root which is brought from the Eaſt Indies; it is about the ſize of a finger, of a pale greyiſh colour outwardly, and yellow within. In Arabia, a bitter and a ſweet ſort were formerly diſtinguiſhed; but now there is but one ſort known, and is rarely to be met with.

The root of *coſtus* is recommended as being ſtomachic, diaphoretic, and diuretic; it impregnates the urine with a violet ſmell. On evaporating a decoction of this root, almoſt all its ſmell is diſſipated; but a bitter extract is obtained nearly to two thirds of the root. The ſpirituous extract is but ſmall in quantity. Raii Hiſt. Lewis's Mat. Med. See ZEDOARIA.

—— CORTICOSUS. See CANELLA ALBA.

—— HORTORUM MINOR. See AGERATUM.

—— NIGRA. See CINARA.

COSTYLE. The ſocket of the hip-bone. See ACETABULUM.

COTARONIUM. A word coined by Paracelſus. It implies a liquor into which all bodies, and even their elements, may be diſſolved.

COTHON. In Galen it ſignifies a veſſel in which cadmia is burnt.

COTINUS. Among the ancients it ſignified the word *oliva*; but amongſt the moderns, it is the Venetian or RED SUMACH.

COTIS. According to ſome, it is the back part of the head, but others ſay it is the hollow of the neck.

COTONASTER. See SORBUS.

COTONEA. See CYDONIA.

COTONIUM. See BOMBAX.

COTTI VINI. A name of ſome thick and luſcious Italian wines, made ſo by boiling the muſt of the poorer ſorts.

COTULA. See COTYLE, and CYATHUS. Bugs are alſo ſo named, as well as a twelve-ounce meaſure. See CIMEX.

—— FLORE LUTEO RADIATO. See BUPHTHALMUM.

—— FŒTIDA. See CHAMÆMELUM FŒTIDUM.

COTYLA. See COTYLE.

COTYLA, is any deep cavity in a bone, in which any other bone is articulated; but it is generally uſed to expreſs the cavity which receives the head of the thigh-bone. It alſo ſignifies a deep ſinus ſurrounded with large lips, or any cavity like the glene, but deeper.

COTYLE, *Cotyla*, or *Cotula*. Among the ancients it was a drinking cup, or any thing which had a cavity, as the hollow of the hand. Among the Greeks it was a meaſure, and is the ſame as the hemina of the Romans, which held nine or ten ounces. See CYATHUS.

COTYLEDONES. COTYLEDONS. Certain glandular bodies adhering to the chorion of ſome animals, are called *cotyledons*; but no ſuch ſubſtances are obſerved in the human chorion: they are alſo called *acetabula*.

COTYLEDON, (from κοτύλη, *cavity*.) The lateral bibulous, periſhable lobe, or placenta of the ſeed, deſtined to nouriſh the heart, and then fall off. The greater part of ſeeds have two lobes; ſome have more; ſome only one, and others none; hence a diſtinction of all plants into *acotyledones, monocotyledones, dicotyledones, polycotyledones*.

COTYLEDON, alſo called *umbilicus veneris, acetabulum, cotyledon major*, KIDNEY-WORT, NAVEL-WORT, and WALL PENNY-WORT.

Its whole appearance reſembles houſe-leek; the root thick, knotted, and hath many ſmall fibres ſpringing from it. It grows on old ſtone walls and buildings, and flowers in May. The leaves are cooling, aſtringent and diuretic; but are not much uſed. Botaniſts enumerate eleven ſpecies, nine of which are called *African navel-worts*. Raii Hiſt.

COTYLEDON MARINUM. See ANDROSACE.

COTYLEDUM, ALTERUM. See CRASSULA.

COUM. See COLCHICUM.

COUP DE SOLEIL. See ICTUS SOLARIS.

COURADI. See PAIANELI.

COURAP. The modern name for a diſtemper very common in Java and other parts of the Eaſt Indies. It is a ſort of herpes or itch on the arm-pits, groins, breaſt, and face; the itching is almoſt perpetual, and the ſcratching is followed by great pain, and a diſcharge of matter, which makes the linen ſtick ſo faſt to the ſkin, as not eaſily to be ſeparated without tearing off the cruſt. *Courap* is a general name for any ſort of itch, but this diſtemper is thus called by way of eminence. It is ſo contagious that few eſcape it. For the cure, gentle and repeated purging is uſed, and externally the ſublimate in a ſmall quantity is a good topic. See Bontius de Med. Ind.

COURBARIL. The American name of the tree which produces GUM ANIME. This tree is called *excuſta*, the LOCUST-TREE. Alſo *animifera arbor Braſiliana; Braſilienſis arbor ſiliquoſa; cancamum Græcorum; ceratia diphyllos; iétaiba*; COURBARIL. It grows in many parts of the Weſt-Indies.

COURBARIL. RESIN. See ANIME.

COURONDI. It is a tall evergreen tree which grows in the Eaſt Indies; its juice and the kernels of its fruit are aſtringent. Raii Hiſt.

COUROS. So Hippocrates called the child in the womb when perfected there. See CONCEPTIO.

COUROY-MOELLI. A ſhrub growing in ſandy places in the Eaſt Indies: the bark and root boiled in milk are eſteemed as an antidote againſt the poiſon of ſerpents. Raii Hiſt.

COUSCOUS. The African name of a ſort of paſte made of the flour of millet, into which ſome fleſh is infuſed, and when eaten, a ſmall quantity of *lait* is alſo put. It is much uſed as food about the river Senegal.

COUTON. A tree which grows in Candia: it reſembles the walnut-tree. Bauhine calls it *arbor vinifera couton juglandi ſimilis*. When this tree is wounded, an agreeable liquor flows out, which reſembles Orleans wine.

COVALAM, called alſo *cucurbitifera trifolia*, &c. *beli*, ſeu *ſerifole Bengalenſium, capotes, cydonia exotica*.

It is a tall tree, growing in Malabar and in the iſland of Ceylon: its fruit is ſhaped like an apple, the outer rind is thin and green, under it is a woody one, incloſing a viſcid yellowiſh moiſt ſubſtance, of a ſweetiſh acid taſte, in which are long, flat, white ſeeds; it is turgid, with a gummy pellucid juice. This fruit is aſtringent whilſt it is unripe, but when ripe, of a delicious taſte. The bark of the tree ſtrengthens the ſtomach, and relieves in hypochondriac languors. Raii Hiſt.

COUVRE CHEF, LE GRAND. } See RICÆ; DE-
———— CHEF, EN TRIANGLE. } LIGATIO, 5, 7.

COWPERI GLANDULÆ; COWPER'S GLANDS, ſo called, from COWPER the diſcoverer. They are ſmall, hemiſpherical, and compound. One of them is ſituated on each ſide of the urethra, without the corpus ſpongioſum, and acceleratores muſcles, between the bulb and proſtate. Each has an excretory duct, through which a mucous liquor is evacuated upon the internal ſurface of the urethra, for its defence. Whether there be other glands belonging to this part, as ſome authors ſay, it is uncertain. In women, we obſerve, before the hymen, an orifice on each ſide, from Cowper's glands, which lie upon each ſide of the perinæum, and ſerve the ſame purpoſe as in the male. They are called alſo *mucoſæ glandulæ*, and *glandulæ veſiculares*.

COXA. See FEMUR.

COXÆ DOLORES. See ISCHIADICUS MORBUS.

COXÆ OSSA. See OS INNOMINATUM.

COXENDIX. See ISCHIUM, and OS INNOMINATUM.

COYUTENA LUZONIS. See FAGARA MAJOR.

COZTIECZOCOTL. See MACAXOCOTLIFERA.

CRAB YAWS. A name in Jamaica for a kind of

ulcer

ulcer on the soles of the feet, with hard callous lips, so hard that it is difficult to cut them. The ungt. hydrargyri fortius is their cure.

CRADE. In Hippocrates it is the branch of a fig-tree.

CRÆCA MAJOR. See VICIA.

CRÆPALE. Galen says, it is a disorder of the head, produced by excessive drinking of wine; called also CRAPULA.

CRAMBE. A CABBAGE. See BRASSICA.

CRAMBEION. See CICUTA. In Hippocrates it signifies a decoction of cabbage.

CRAMPUS. So Helmont calls the CRAMP. It is a sudden, painful rigidity of a muscle, the pain now and then being excruciating. This complaint is often very troublesome; it is not usually dangerous, though instances have occurred, in which, passing from the limbs to the bowels, the patient hath with difficulty recovered: it principally affects the limbs or neck.

In the Med. Mus. vol. iii. is an instance of a cure effected by drinking a glass of tar-water every night and morning. It hath been advanced by some, that for present relief, the readiest cure is to take hold of a roll of brimstone, which quickly breaks, and thus the patient is eased. But this disease, is either idiopathic, or symptomatic. When of the former class, it affects the legs, thighs, or other parts suddenly, whilst swimming in cold water, or whilst the tibiæ are exposed to the cold night air; or, when the muscles are uneasily situated; the digastric muscles are subject to this complaint; whilst the neck is exposed naked to the cold air, the pain is intolerable, but in a minute or two abates spontaneously, particularly if warmth with friction is applied to the parts, counteracting the contraction of the muscle, by external pressure, or placing the part affected in a situation where extension may be produced.

The sympathetic *cramp* is that which affects the lower extremities, particularly in the cholera morbus, with strong distention and excruciating pain of the calves of the legs; from whence the afflicted moving their legs cry out; and as often as a vomiting supervenes, they are in great torture. After a vomit has been premised of chicken water, twenty drops of liquid laudanum should be administered. If the breast should be affected with this spasm, a *fugitive pleurodyne* arises, but violent, with a fear of suffocation; if the throat, a *spasmodic angina*.

CRANEIA. See CORNUS.

CRANGON, also called *squilla crangon*, and the PRAWN. It is a sea shell-fish affording good nourishment

CRANIUM, called also *calva*, and *calvaria*, *cerebri galea*. The SKULL. It is that part of the head which is covered with hair; besides the os frontis, it consists of the two parietalia, the two temporal, the occiput, the os ethmoides, and os sphenoides. See CAPUT. As to its medicinal virtues, they differ not from those of other bones.

CRANTERES. See SAPIENTIÆ DENTES.

CRAPULA. See CRÆPALE. It is also a SURFEIT. A disorder from something taken into the stomach, and occasioning a sickness, or at least a loathing of that to which the disorder was owing, though sometimes it signifies a plethora, from indolence, and full but improper feeding, in which case perspiration is defective, and eruptions form themselves in the skin: this though more properly is the *cholera accidentalis*. See CHOLERA MORBUS.

A *surfeit* from animal food, as muscles, putrid flesh, &c. is best remedied by the use of vegetable acids, which may be taken diluted with water, a vomit being premised, and this, even though a vomiting and purging both attend.

When an excess of feeding is the cause, the primæ viæ being evacuated, and the nature of the plethora attended to, that the load may be properly evacuated, the indication of cure will be, to recover the perspiratory discharge; consistent with which, diuretics may be used: but the increase of any other evacuation would interfere with the principal design.

CRASIS, from κεραννυμι, *to mix*. The temper of the blood peculiar to every constitution.

CRASPEDON. See HYPOSTAPHYLE.

CRASSA ARTERIA. See AORTA.

—— MENINX. See DURA MATER.

—— INTESTINA. See INTESTINA.

CRASSAMENTUM. So the red globules in the blood are called: in the due proportion of which, consists the health and life of a man. See CALIDUM INNATUM.

CRASSENA. A term of Paracelsus, by which he would signify certain saline, putrefactive, and corrosive particles, which produce ulcers and tumors of various forms.

CRASSULA, called also *faba crassa*, *faba inversa*, *sedum*, *telephium*, *fabaria*, *anacampseros*, *cotyledum alterum*, *scrophularia media vel tertia*, *acetabulum alterum*. COMMON ORPINE, or LIVE-LONG. The sort used in medicine is the SEDUM TELEPHIUM, Linn.

It is a plant with unbranched stalks, which are clothed with thick, fleshy, oval leaves, but producing no leaves immediately from the root: the flowers stand in form of umbels on the top of the stalk, and are followed each by three, or four, or six pods full of small seeds: the root is irregular and knobby. It is indigenous in England, and perennial.

Common orpine, with the leaves slightly or not at all serrated, grows in hedges and shady grounds, hath reddish or whitish pentapetalous flowers. The leaves are anti-inflammatory, but their power seems too inconsiderable for a place in practice.

CRASSULA MINOR. See SEDUM.

CRATÆGUS. The WILD SERVICE-TREE.

—— ALPINUS. The WHITE BOAM-TREE. See ARIA.

—— OXYCANTHA. See SPINA ALBA.

CRATÆOGONUM. See MELAMPYRUM.

CRATEVÆ SIUM. See NASTURTIUM AQUATICUM.

CRATIBULA. } The iron bars or grate which covers
CRATICULA. } the ash-hole in chemical furnaces.

CRATICULARIS. from *craticula*, *a gridiron*. Bread broiled on the hearth or on a gridiron.

CRATON. See CATAPUTIA MINOR.

CREA. See TIBIA.

CREBER. *Frequent*. It is applied to respiration, and to the pulse, when the intervals, betwixt each inspiration, or each pulsation of the artery, are short.

CREMASTER, from κρεμαω, *suspendo*, *to suspend*. These muscles are also called *suspensorii testium*. Dr. Hunter says, they arise from the inside of Poupart's ligament on each side, run down to the perforation where the seminal cord comes out, and being expanded over it, make part of the tunica vaginalis communis. The course of this muscle being very oblique, makes the spermatic cord seem much more so than it really is. Their use is to draw up and suspend the testes.

CREMER. The name of a distemper endemial in Hungary, which seems to be a sort of crapula. It is cured by drinking a small quantity of any cordial water.

CREMNOI. The lips of ULCERS, also the *labiæ pudendæ*, from κρημνος, *a precipice*, or *shelving place*.

CREMOR, χυμος, or χυλος. It is the expressed juice of any grain; also the strained juice of any grain, particularly of barley boiled till it be so soft as to pass through a strainer (see PTISANA); and lastly, it is the cream of milk, or expressed water of barley. See CHYLUS.

—— CALC. VIV. The cream or flour of quick-lime is the pinguious substance floating on the top of new-made lime-water, which, when taken off and dried, becomes insipid.

CREMOR LITHARGYRI ACETAT. See PLUMBUM, N°. 6.

CRENATUM, or *crenated*, (from *crena*, *a notch*.) Having the edge cut with angular or circular incisures, not inclining to either extremity. When the edge of a leaf is cut into segments of small circles, instead of angular teeth, it is said to be *obtusely crenate*; when the larger segments have smaller ones upon them, the leaf is then said to be *doubly crenate*: the same term is applied to the *corolla*, and *nectarium*, in some cases.

CREPATIO. } In pharmacy, is the cracking or
CREPATURA. } bursting of any seed in boiling, and this is to be understood when seeds are directed to be boiled *ad crepaturam*. See also HERNIA SCROTALIS.

CREPINUM. See TARTARUM.

CREPITA ÆTAS. See ÆTAS.

CREPITATIO. See DECREPITATIO.

CREPITUS, or crackling of the joints

This may happen either from a defect of synovia, or a disposition of cretaceous matter, as in the gout. Mr Sharp recommends, in order to the cure, a frequent use of fomentations, rubbing the joint with the ungt. hydrargyri, and to administer purges now and then.

A dis-

A discharge of air from the anus, when attended with a noise, is thus called.

CREPITUS LUPI. See LYCOPERDON VULGARE.

CRESPINUS. See BERBERIS.

CRESPULUM. See BUPHTHALMUM.

CRESSIO. See NASTURTIUM AQUATICUM.

CRETA. CHALK. Kentman mentions fifteen sorts; but the only one now used in medicine is the white *chalk*.

—— ALBA. So called because the best was formerly found in Crete, now Candia: it is also called *terra Creta*, and *creta candida*. It is also named *glisomargo*.

It is now found in most parts of the world. It is a pure white mineral calcareous earth, of different degrees of hardness; it crumbles between the fingers, and stains them white; also readily diffuses itself in water, and as soon subsides again; it sticks to the tongue without any astringency. It is met with both in the form of stones and in powder.

The best is that which is perfectly white, soft, close, and solid, equal and uniform when broken, free from sand and other bodies, and rather agreeable than insipid to the taste. Many other earths are of a similar nature; but this being the purest, is preferred.

It does not dissolve in the vitriolic acid, but readily in all others, even totally in vinegar. The vitriolic acid precipitates it from all other acids, and forms with it a selenites. It is convertible into quick-lime; with borax it melts into a transparent glass. The solutions of it in acids are bitter.

Chalk is employed as a remedy against the heart-burn, and other disorders that have acidity in the primæ viæ for their cause. Dr. Slare asserts from experiments, that it absorbs acids sooner, and more powerfully, than crabs'-eyes, calcined harts-horn, or coral. Some use it when finely powdered, to sprinkle on erysipelatous inflammations. When *chalk* is saturated with an acid, it is said to become subastringent, otherwise it hath no such property; hence *chalk*, given when acidity prevails in the stomach, sometimes produces costiveness; this though is much doubted by Cullen and others. Two drams for a dose, and repeated at proper intervals, have often effected a speedy cure, both in a diarrhœa and a dysentery; but this effect was owing to its absorbing those acrid juices whose stimuli caused the morbid excretion. When milk turns sour on the stomach, a scruple of *chalk* may be given with each half pint. When on any account a free use of *chalk* is required, if the belly is inclined to costiveness, laxative medicines should now and then be taken, otherwise concretions will be formed in the bowels, or the mouths of the lacteals will be clogged, and a marasmus may be the consequence.

Chalk should be finely powdered, and separated from its grosser parts by elutriation. Boerhaave prefers it to the C. c. c. for making the white decoction with. Bates formerly used to boil half a pound of *chalk* in three pints of water to a quart, after which he just permitted the grosser parts to fall, and poured off the yet turbid fluid for use. And the London College directs the following:

CHALK MIXTURE, *Mistura Cretacea, formerly called* JULEPUM E CRETA.

Take of the whitest *chalk* prepared, one ounce; of double refined sugar, six drams; of gum arabic, finely powdered, two ounces; of distilled water, a quart: mix. Pharm. Lond. 1788.

See Dale, Lewis's Mat. Med. Dict. of Chem. Neumann's Chem. Works, Cullen's Mat. Med.

Besides these the following are often used:

CRETÆ UNGUENTUM COMPOSITUM. *Compound Ointment of Chalk*; vel CERATUM NEUTRALE, *Neutral Cerate*, of Kirkland.

℞. Cretæ pp. aceti distillati, olei olivæ ää ℥ iv. emplastri lithargyri ℥ 8. aq. lithargyri acetati ℥ ss. The chalk and vinegar are to be mixed together, and over a slow fire, incorporated with the litharge plaster, and oil, when sufficiently, the water of acetated litharge is to be added. This is allowed to be an efficacious remedy, when applied to inflamed parts and ulcers, and is much employed in practice.

Decoctum e CRETA. See CORNU CERVI.

Pulvis e CRETA *Compositus.* } See BOLUS.
Pulvis e CRETA *Comp. cum Opio.* }

The two last supply the place of the pulvis e bolo compositus, and pulvis e bolo compositus cum opio, of the old London Pharmacopœia.

CRETA NIGRA. BLACK CHALK, called also *humus nigra pictoria*.

—— RUBRA. See OCHRA.

—— SELENUSIA, called also *terra selenusia*. The best is of a shining white friable appearance, and readily diluted with a fluid. It is drying and astringent.

CRETA CIMOLIA. TOBACCO-PIPE-CLAY. } See CI-
—— FULLONICA. } MOLIA ALBA.

CRETHMON. See CRITHMUM.

CREVIS. See ASTACUS FLUVIATILIS.

CRIBRATIO, CRIBRATION, or SEARCING. In pharmacy, it is the passing of powders and pulps through sieve.

CRIBRIFORME Os. } from *cribrum*, *sieve*. See
CRIBROSUM Os. } ETHMOIDES OS.

CRISELASIA. The driving a ring or circle. Driving a hoop was one of the ancient gymnastics: this hoop was as high as the breast of the person who used it. It was commended for rendering the limbs pliable, and for strengthening the nerves.

CRICO-ARYTÆNOIDÆI MUSCULI, from κρικος, *a ring*, αρυταινα, *a funnel*, and ειδος *forma*. Muscles of the larynx, whose office is to open the glottis. They rise from the cricoid cartilage, and are inserted into the arytænoid.

—— ARYTÆNOIDES LATERALES. They lie laterally upon the upper edge of the cricoid cartilage, and are inserted into the lower part of the side of the arytænoid. They serve to dilate the glottis.

—— ARYTÆNOIDES POSTICI. They lie upon the back part of the cricoid cartilage, and are inserted into that knob which stands on the back part of the basis of the arytænoid cartilage, near the angle of the basis, one on each side. They open the larynx, and are called by Casserius, *par cucullare*.

—— PHARYNGÆI. These muscles arise from the lower part of the side of the cricoid cartilage. They seem to be appendices of the *thyro-pharyngæi*, shewing no other marks of distinction but these insertions, and a small difference in direction, because as they run backward they descend a little; for this reason, Winslow says, he hath sometimes looked on them as one, and called them *thyro-crico-pharyngæi*. The lowest of these muscular fibres, he says, make a complete circle backwards, between the two sides of the basis of the cartilago cricoides; this circle is the beginning of the œsophagus, and has been thought by some to form a distinct muscle, called œsophagus. Sometimes there is another fasciculus of fibres detached from the thyro-pharyngæus, and inserted laterally in the thyroid gland, for which reason I call it musculus *thyro-adenoidæus*.

Innes calls it the *constrictor pharyngis inferior*; and describes it as follows. It arises from the side of the thyroid cartilage, near the attachment of the sterno-hyoidæus and thyro-hyoidæus muscles, and from the *cricoid* cartilage, near the *crico-thyroidæus*. This muscle is the largest of the three, and is inserted into the white line, where it joins with its fellow, the superior fibres running obliquely upwards, covering nearly one half of the middle constrictor, and terminating in a point; the inferior fibres run more transversely, and cover the beginning of the œsophagus. Their use is to compress that part of the pharynx which they cover, and to raise it with the larynx a little upwards. See PHARYNX.

—— THYROIDÆI. Certain muscles of the larynx, which shut up the glottis. They rise from the anterior and lateral part of the *cricoid* cartilage, and are inserted into the lower edge of the thyroid cartilage. Some call these *crico-thyroidæus anticus*.

CRICOIDES, also CYMBOLARIS CARTILAGO; κρικος, *a ring*, and ειδος, *a form*. The name of the *annularis cartilago*, annular cartilage belonging to the larynx, which it encompasses. See ASPERA ARTERIA.

CRICOS, κρικος, *a ring* or *circle*. So Hippocrates calls the annular cartilages, which form the aspera arteria.

CRIDONES. Worms which breed in the skin. See CRINONES.

CRIMNODES, from κριμνον, *bran*. An epithet for urine, which deposits a *branny* sediment.

CRIMNON. Dioscorides describes it as being a coarse sort of meal produced from zea and wheat, of which they make pulse. Galen says, that κριμνα are the largest particles

ticles of torrefied barley, which have eſcaped due contuſion in the mill.

CRINATUM, from κρινον, *a lily*. An epithet of a *thymiama*, or ſuffumigation, mentioned in P. Ægineta.

CRINEDONES. } See CAPILLARES VERMICULI.
CRINES. }

CRINIS. See CAPILLUS.

CRINITUS, from *crinis*, *a hair*. Hairy, or having long hair, or beards reſembling hair, as in phlegm crinitum, applicable alſo to *frondi*.

CRINOMYRON, from κρινον, a *lily*, and μυρον, *an ointment*. OINTMENT OF LILIES, conſiſting of *lilies* and ſome other aromatics. It was alſo called *Ægyptium album*, and *ſuſinum*.

CRINON. A *lily*.

CRINONES, called alſo *comedones*, *crinones*. Ambroſe Paré deſcribes this diſeaſe as follows: "The mention of dracunculi calls to my memory another kind of abſceſs, altogether as rare. This our Frenchmen name *crinones*, I think, *a crinibus*, i. e. from *hairs*. It chiefly troubles children, and pricks their back like thorns. They toſs up and down, being not able to take any reſt. This diſeaſe ariſeth from *ſmall hairs*, which are ſcarce of a pin's length, but thoſe thick and ſtrong. It is cured with a fomentation of water more than warm, after which you muſt preſently apply an ointment made of honey and wheaten flour; for ſo, theſe *hairs* lying under the ſkin are allured and drawn forth; and being thus drawn, they muſt be plucked out with ſmall mullets." See Edinb. Med. Comment. vol. ix. p. 64.

In the Hiſtory of the Royal Medical Society at Paris, for the year 1776, is a paper as follows, on this ſubject, by Monſ. Baſſignet. "This diſeaſe, which is ſaid to be peculiar to the town of Seyne and its neighbourhood, attacks almoſt all the new-born children. Authors call it *crinons*, or comedons. In the place itſelf it is called *cées*, a corruption of *ceddés*, a provincial word that ſignifies *a briſtle*. It appears in many caſes within twelve hours, in others not till a month after birth, and ſometimes, though rarely, at a more advanced age, of even twelve or more years. The ſymptoms are deſcribed to be *a violent itching, which is increaſed by the heat of the bed, and prevents ſleep; a continual agitation; incapability of ſucking, the child's tongue not being able to accommodate itſelf to the nipple*; and laſtly, *a hoarſeneſs, and gradual extinction of the voice*. Of all theſe ſymptoms *the laſt is conſidered as the moſt certain*, ſo that by the weakneſs of the child's cries, and the alteration in its voice, the degree of the diſorder is to be judged of. As ſoon as it is obſerved, they proceed to the cure, which conſiſts of frictions by women of the country, who are ſo accuſtomed to this diſeaſe, that they ſeldom call in either a phyſician or a ſurgeon. Theſe frictions are made on different parts of the body, according to the three ſtates of the diſeaſe, which are ſometimes diſtinct, at others complicated. *In the firſt*, to a diminution of voice is joined an inability to ſuck. This, we are told, requires frictions at the upper part of the ſternum, neck, cheeks, and about the jaws, and temples. If the child's tongue is at liberty, and yet he is ſtill unable to ſeize the nipple, his arms or fingers at the ſame time feeling tenſe, this is the *ſecond ſtate* of the diſeaſe, and requires frictions on the fore-arm. The *third* is known only by the change in the voice, and is cured by rubbing the arms, ſhoulders, back, and calves of the legs. The mode of friction is as follows: the woman wets her hand with ſaliva, and rubs the ſkin of one of the child's arms, for inſtance, along the tenſor muſcles, till ſhe feels a conſiderable roughneſs. She then quits this arm and begins with the other, rubbing always in ſmall circles, and conſtantly in the ſame direction. Nothing particular is obſerved in the ſkin previous to theſe frictions. Some of the moſt experienced women, however, ſpeak of a ſort of tenſion which gives way to rubbing. In many caſes where this practice hath been neglected, the child, it is ſaid, has been carried off by convulſions or diarrhœa. In ſome ſubjects a ſpecies of dark, rough hairs, not longer than the tenth of an inch, and in others, little ſubſtances reſembling very fine red hair, not quite ſo rough as the former, and furniſhed with a minute bulb at their extremity, appear on the ſkin, and terminate the diſeaſe. This circumſtance it is that gives name to the diſeaſe. To what is above ſaid, a caſe is related of a girl ten years old, who, after having been for ſome time ill, and taking different medicines, at length tried frictions as above deſcribed, and theſe brought out a prodigious quantity of dark-coloured, rough hairs, after which ſhe got well."

Mr. Loppy, in his Tractatus de Morbis Cutaneis, treats on this diſeaſe. See the London Medical Journal, vol. ii. p. 289, &c. See alſo BOVINA AFFECTIO.

CRIOGENES. An epithet for certain troches mentioned by Paulus Ægineta, and which he commends for cleanſing ſordid ulcers.

CRIOMYXUS. An epithet for perſons abounding with mucus in the noſe.

CRIPSORCHIS, from κριπτω, *to hide*, ορχις, *a teſticle*. See TESTES and PARORCHIDIUM.

CRISIMOS. CRITICAL.

CRISIS, from κρινω, *to indicate*, alſo *criterion*. The termination or change of a diſeaſe either by recovery or death.

Hippocrates firſt eſtabliſhed the doctrine of *criſes*, and *critical* days, which were 3, 5, 7, 9, 11, 14, 17, 21. The reaſon why in his time this exactneſs happened was, becauſe phyſicians committed fevers to themſelves, and did nothing to diſturb the procedure of nature, ſo that the diſorder always kept the ſame type. A *criſis* only reſpects acute diſeaſes, and more particularly continual fevers. Now the phyſician is called in to give ſome aſſiſtance, *critical* days are not a ſubject of attention, the type of the diſorder, or the *criſis*, being accelerated or retarded by what is adminiſtered.

Aſclepiades and Celſus deny that diſeaſes have their *critical* days; and Langius ſays, "if a *criſis* is to be expected, medicine is ſuperfluous."

The word *criſis* is not confined to this ſignification; for ſometimes it means the excretion of ſomething noxious from the body, or the ſecretion of the noxious humours in a fever; for the word κρινω, ſignifies alſo *to ſeparate*, or as it were to paſs through a ſieve, &c.

Thoſe who obſerve *critical* days, conſider CRUDITY as that ſtate of the morbid matter wherein it is unfit for a regular ſeparation from the ſounder juices; CONCOCTION, as that work upon the morbid matter by the power of nature, or aſſiſtance of art, which renders it fit for ſeparation from the healthy part of our fluids, and to be thrown out of our bodies; CRISIS is the actual diſcharge of the morbid matter, whether brought on by the power of nature, or by medical aid; and the CRITICAL DAY is the time that this diſcharge happens.

Perhaps the fallacy of this may be ſeen into, by adverting to the article CONCOCTION, already noticed.

In favour of this ſubject, ſee Hippocrates, Galen, P. Ægineta, and Fernelius; on the other ſide, ſee Aſclepiades, Celſus, Langius, and Faber.

CRISPATURA, CRISPATURE, CURLING. In medicine it is a ſpaſmodic contraction of the membranes and fibres.

CRISPINUS. See BERBERIS.

CRISTA. The name of a tubercle about the anus and pudenda. Tubercles of this ſort are ſo called on account of their form. The cauſe and cure are the ſame as the *condyloma*. See alſo PROCESSUS.

CRISTÆ CLITORIDIS. See NYMPHÆ.

CRISTA GALLI. In anatomy, it is an eminence riſing from the upper part of the *os ethmoides*, to which the beginning of the falciform proceſs is attached. It is called *criſta galli*, from its ſuppoſed reſemblance to the *comb* of a *cock*. See ETHMOIDES OS.

CRISTA PAVONIS. See POINCIANA flore pulcherrimo.

CRISTA PAVONIS CORONILLÆ FOLIO. See BRASILIUM LIGNUM.

CRITERION. See CRISIS.

CRITHAMUM. See CRITHMUM.

CRITHE. BARLEY; and, from its ſimilitude, a ſort of tubercle on the eye-lid is thus named; this tumor is called alſo a STYE. By Aetius, *grando*; it is a hard ſcirrhous immoveable STIAN in the interior part of the eye-lid, containing a pellucid body. When ſmall it is ſeated on the edge of the eye-lid, but when large it ſpreads further. When the ſtians do not ſuppurate, they become wens. They are apt to diſappear and return. If there is inflammation, endeavour to ſuppurate it with the white bread poultice: if it is hard, deſtroy it with a mixture of equal parts of hog's lard and quickſilver. If the lower eye-lid is affected, the tumor is more frequent on its inſide, and then is beſt if diſſected, or to make way for it outwardly by applying a cauſtic on the ſkin juſt upon it. See St. Yves on Diſorders of the Eyes. Alſo HORDEOLUM and CHALAZA.

CRITHMUM, called alſo *fœniculum marinum majus*, *herba Sancti Petri*, *cauponga*, *critmum*, CRETHMON, *paſpier*, *baticula*, *crithamum*, *batis*, *fœniculum maritimum minus*, *crithmum marinum*; SAMPIRE, and SAMPHIRE.

It grows wild on rocks, and in maritime places; the leaves reſemble thoſe of fennel, but the ſegments are thicker and ſhorter; to the taſte they are warm and bitter, to the ſmell ſomewhat like ſmallage. They are aperient and diuretic. Their chief uſe is as a pickle.

CRITICA SIGNA. Thoſe ſigns which are taken from the criſis of a diſeaſe, as to recovery or death.

CRITICI. CRITICAL FEVERS. Thoſe which terminate with a lateritious ſediment in the urine.

CRITICI DIES, called *internuncii*. Critical days. See CRISIS.

CRITMUM. See CRITHMUM.

CROCIDE CONFECTIO. The name of a confect commended by Nicolaus Myrepſus for the colic.

CROCINUM. OIL of SAFFRON. It is mentioned by Dioſcorides as conſiſting of olive oil, myrrh, and a ſmall quantity of *ſaffron*.

CROCODES. An epithet for certain troches in P. Ægineta.

CROCODILION. See CARLINA, ERYNGIUM, ECHINOPUS MAJOR.

CROCODILUS TERRESTRIS. See SCINCUS.

CROCOMAGMA. Dioſcorides informs us, that it is prepared of the ungt. crocinum, and ſpices preſſed and made into troches, called alſo *Ecmagma*.

CROCUS. SAFFRON; called *crocus* ſativus, *crocum*, *crocus* autumnalis ſativus; becauſe of its golden colour the chemiſts call it *aroma philoſophorum*, by contraction *aroph*; others have called it *ſanguis Herculis*, *aurum vegetabile*, *anima pulmonum*, and *Jovis flos*. For its extraordinary efficacy in ſome diſeaſes, it is entitled *rex vegetabilium*, and *panacea vegetabilis*; from its power of exciting laughter it hath the appellation of *hortus lætitiæ*, and from its cheering effects, *medicina triſtitiæ*. Beſides theſe, various other names are to be met with in different authors. Its name of *ſaffron* is from the Arabian word *zaffaran*, or *zahafaran*.

Saffron is a bulbous-rooted plant; its leaves are ſhaped like thoſe of graſs; the flower is of a purpliſh blue colour, cut deep into ſix ſegments; in the middle of the flower, among the ſtamina, ariſes a piſtil, which is divided at the top into three fleſhy filaments; the upper part of theſe filaments is of a deep orange-red colour, and are the *ſaffron* of the ſhops. The plant is perennial; the flowers blow in September, and October. Boerhaave enumerates twenty-eight ſpecies. The officinal *crocus* is the CROCUS SATIVUS, vel CROCUS *ſpatha univalvi radicali corollæ tubo longiſſimo*. CLASS, TRIANDRIA; ORD. MONOGYNIA. LINN. Gen. Plant. 55.

The filaments of the *ſaffron* flowers are carefully ſeparated, and moderately dried in a kiln, and when no farther manufactured are ſold under the name *ſaffron* in the hay. But the greateſt part of this article is, after being dried to a certain degree, preſſed into thin cakes.

It is cultivated in France, Spain, Auſtria, Hungary, &c. but the beſt is produced in England, and is now indiſputably aſcertained to be a native of this country. It may be diſtinguiſhed from all others by the greater breadth of its blades; the beſt is in long broad filaments, of a deep red colour, without any yellow parts, moderately dry, yet flexible and ſoft to the touch, difficultly pulverized, of a ſtrong and agreeable ſmell, eſpecially at a diſtance; affecting the eyes ſo as to draw tears from them; of a pungent and ſomewhat bitteriſh taſte; it readily impregnates the hand with its ſmell, and ſtains the moiſt hand with a deep yellow colour.

As a medicine it has been eſteemed an agreeable aromatic, of a warm pungent bitteriſh taſte; alſo an anodyne, antiſpaſmodic, cordial, and attenuant. Boerhaave ranks it among narcotic poiſons, and in caſe of an imprudent doſe being taken, he orders a vomit and acidulated draughts. It has been called a very powerful emenagogue, and in this intention ſaid to require caution in its uſe, as ſome patients are more extraordinarily affected by it than others; in diſorders of the lungs it hath been ſo eſteemed as to obtain the name of anima pulmonum. In coughs it is highly commended; and Camerarius ſays, that a ſcruple of *ſaffron*, with half a grain of muſk, is of conſiderable efficacy in aſthmas. Notwithſtanding all which, Dr. Cullen affirms, very frequent experiments in practice do not at all ſupport the opinions commonly entertained of it; he has given it in large doſes without producing any ſenſible effects, hardly, in any degree, increaſing the frequency of the pulſe; and as anodyne or antiſpaſmodic, he ſcarcely obſerved its operation. In one or two inſtances he had ſome reaſon to believe in its emenagogue power, but in others not at all, though repeatedly employed in large doſes. And though the Doctor has given it in every ſhape, and in larger doſes than authors ever propoſed, he ſtill has not diſcovered in it any conſiderable power or virtue. Indeed though the ſenſible qualities of this medicine are pretty conſiderable, it appears to poſſeſs no other power than that of a weak aromatic. In this medicine very little confidence is at preſent placed; though it enters into ſeveral officinal compoſitions, more for its colour perhaps than its conſequence.

Rectified ſpirit of wine, proof ſpirit, wine, vinegar, and water, all extract the whole virtue and colour of *ſaffron*. About three parts in four of the *ſaffron* are taken up by each of theſe menſtrua; and what remains undiſſolved, is inodorous, inſipid, and of a pale clay colour.

Tinctures drawn by acid liquors ſoon loſe their fine colour; the watery and the vinous tinctures ſoon fade, and participate part of the diſſolved *ſaffron*; but thoſe made with proof or rectified ſpirit will keep good during many years.

In diſtillation, water is ſtrongly impregnated with its flavour; and if the quantiy of *ſaffron* is large, a ſmall portion of a fragrant and very pungent eſſential oil may be collected, which, according to Vogel, amounts to about a dram and a half from ſixteen ounces. The remaining decoction, inſpiſſated to an extract, retains all the virtues of the *ſaffron*, except the cordial one. The ſpiritous extract retains much of the cordial quality.

The dearneſs of *ſaffron* ſubjects it to many artifices, by which it is adulterated; but the beſt method of avoiding them is to purchaſe only the ſort called hay-*ſaffron*.

The London College directs the following preparation from *ſaffron*:

Syrupus Croci. SYRUP OF SAFFRON.

Take of *ſaffron*, one ounce; boiling diſtilled water, two pints; macerate the *ſaffron* with the water for two hours, in a veſſel cloſe ſtopped; and to the ſtrained liquor add, of double refined ſugar, ſufficient to make a ſyrup. Pharm. Lond. 1788.

See Lewis's Mat. Med. Raii Hiſt. Plant. Neumann's Chem. Works. Cullen's Mat. Med.

CROCUS ANTIMONII. See ANTIMONIUM. N° 4, 5, 6.

—— INDICUS. See CURCUMA.

—— MARTIS APERIENS, and ASTRINGENS. See EXTRACTUM MARTIS under FERRUM and ANTIMONIUM. N° 12.

—— METALLORUM. See ANTIMONIUM. N° 4.

—— SARACENICUS. Baſtard *ſaffron*. See CARTHAMUS.

CROMMYON, or CROMYON. An ONION. See CEPA.

CROMMYOXYREGMIA. Acid and fœtid eructations reſembling the taſte of onions.

CROTAPHI. See TEMPORA.

CROTAPHITES. See TEMPORALIS MUSC. from κρόταφος, *tempus*, *temple*, *pars capitis*, or κρότος, *to beat* as the pulſe.

CROTAPHIUM. A pain in the head near the temples.

CROTAPHOS. See CEPHALALGIA.

CROTON. According to Foeſius, it ſignifies in Hippocrates, the bronchia of the lungs expectorated; a name alſo of the ſeeds from whence the ol. ricini is taken. See CATAPUTIA.

CROTON BENZOE. See BENZOINUM.

—— CASCARILLA. See THURIS CORTEX.

CROTONE. A fungous excreſcence on trees; but, by a metaphor, it is applied to excreſcences and fungous tumors on the periоſteum.

CROUSMATA. This word is met with in Myrepſus, and is tranſlated by *deſluxions*, *rheums*: but Fuchſius thinks it ſhould be read, ῥεύματα.

CRUCIALIA, LIGAMENTA. They riſe from the inſide of each condyle, and are attached to the femur. They give ſtrength to the joint, and limit its motion.

CRUCIALIS INCISIO. An inciſion in the form of a croſs.

CRUCIALIS GALLII SPECIES. See CRUCIATA VULGARIS.

CRUCIATA

CRUCIATA. CROSS-WORT. So called becauſe its leaves are diſpoſed in the form of a croſs. Boerhaave divides the ſpecies into ſpicated and verticulated.

CRUCIATA VULGARIS; alſo named *crucialis*; *cruciata hirſuta*, *crucialis gallii ſpecies*, *gallium latifolium flore luteo*, MUG-WEED and CROSS-WORT.

The roots are ſlender and creeping, the branches hairy, about a foot high; at the joints of the ſtalk are placed four round pointed leaves that are hairy, and have foot-ſtalks; the flowers are ſmall and yellow, each followed by two ſmall round black ſeeds. It grows in hedges, and the ſides of fields, and flowers in July. The leaves and tops are commended for promoting expectoration. Raii Hiſt.

CRUCIBULUM, alſo called, *tigillum*, *catinus fuſorius*, *albot*, *alkaza*, *alkozeal*, or CRUCIBLE. It is an earthen veſſel, made for enduring the greateſt degree of heat, generally wider above than below, and of a round, or triangular figure. Calcined bones are equal, if not ſuperior, to any other materials for making them; ſome are made of equal parts of the beſt potter's clay dried, of plumoſe alum, and of baſtard talc, finely powdered, formed into a paſte with whey, and then baked as other pottery wares. Chalk cut into the form of a *crucible*, then ſteeped in linſeed oil for twenty-four hours, anſwers many purpoſes very well; ſome uſe the powder of common tiles, and an equal quantity of chalk; theſe are mixed with linſeed oil, and then baked. They may be either made of earth, black lead, forged iron, or platina; Chaptal ſays, they ought to ſupport the ſtrongeſt heat without melting, and be capable of reſiſting the attacks of all ſuch agents as are expoſed to heat in veſſels of this kind. Thoſe crucibles which poſſeſs the greateſt degree of perfection, are made in Heſſe, or Holland. Thoſe made of platina unite the moſt excellent properties. They are nearly infuſible, and at the ſame time indeſtructible by fire. M. Achard, and M. Morveau have made them by firſt fuſing platina with arſenic: at firſt though it remains brittle, but in proportion as the arſenic is driven off by the continuance of heat, it becomes more ductile. Theſe chemiſts, by melting it a ſecond time in moulds, formed crucibles. Various other materials, and modes of combining them, may be ſeen in POTT's Diſſertation on *Crucibles*, and in the Dict of Chem. CHAPTAL's, and LAVOISIER's Elements of Chemiſtry.

CRUDITAS. CRUDITY. It is applied to unripe fruits, to raw fleſh, undigeſted ſubſtances in the ſtomach, humours in the body which are unprepared for expulſion, and to the excrements. See CRISIS.

CRUENTA SUTURA. BLOODY SUTURE; when the lips of a wound are brought together by means of a ligature made with a curved needle.

CRUNION. The name of a diuretic compound medicine deſcribed by Actius.

CRUOR. Blood extravaſated and congealed, from κρυος, *frigus*. Sometimes it means the BLOOD in general, and ſometimes the venal only.

CRUPINA. See CALCITRAPA.

CRURA CLITORIDIS. See CLITORIS.

—— MEDULLÆ OBLONGATÆ. The two largeſt legs, or roots, of the medulla oblongata, which proceed from the cerebrum. See CEREBRUM.

CRURÆUS, CRUREUS, or CRURALIS, from *crus*, *a leg*. The *crureus*, the vaſtus externus, and vaſtus internus, may be conſidered as one muſcle. See VASTUS INTERNUS.

The *crureus* muſcle covers almoſt all the fore-ſide of the os femoris, between the two vaſti. The tendons of the *crureus* rectus anterior, and of the two vaſti, unite into one, and are inſerted into the ſide of the patella, in the edge of the ligament of that bone, and in the adjacent lateral part of the head of the tibia. They extend the leg.

CRURALES ARTERIÆ. The CRURAL ARTERIES.

The external iliac arteries paſs out of the belly under the inguinal glands, and there take the name of *crural*; they run over the heads of each os femoris, turn under the crural vein, preſently after paſſing out of the abdomen; here they are not covered with any muſcles, but preſently plunge betwixt the ſartorius, vaſtus internus, and triceps muſcles, and are covered by them all the way to the lower part of the thigh. A little above the internal condyle of the os femoris they perforate the tendon of the triceps, and run to the poſterior part of the thigh, down the ham, and there take the name of *popliteæ*. In the courſe of theſe arteries, they give out the *pudicæ externæ* and other branches to the different muſcles of the thigh.

CRURALIS NERVUS. The nerve which paſſes from the loin into the thigh is thus called. The ſecond lumbar nerve joins the third, and that again communicating with the fourth, they produce this *crural* nerve (ſee LUMBARES), which paſſing under Poupart's ligament, runs on the forepart of the thigh upon the iliacus internus muſcle; it diſperſes itſelf into many branches, one of the principal of which accompanies the vena ſaphena all the way to the ankle.

CRURALIS VENA, called alſo *iſchiac*. The external iliac vein, going out from under the ligamentum Fallopii, on the inſide of the iliac artery, is there called *crural*. About an inch below its paſſing out of the abdomen, it ſends off a large branch, called the *ſaphena*; after which it ſinks in between the muſcles, and is diſtributed to all the inner parts of the lower extremity, accompanying the *crural* artery to the toes. In its deſcent down the thigh, it runs behind the *crural* artery: when it hath arrived into the lower part of the thigh, its ſituation is between the *crural* artery, and the inner condyle of the os femoris, and juſt above the ham it takes the name of *poplitea*.

CRUREUS. See CRURÆUS.

CRUS. The LEG. It includes the whole of the lower extremities from the os innominatum to the toes, viz. the thigh, *leg*, and foot. It ſometimes ſignifies only *femur*, the thigh, and by ſome it is alſo confined to that part between the knee and ankle.

CRUSTA. The ſhell of a lobſter, crab, cray-fiſh, prawn, or ſhrimp; alſo the name of a ſcab, or ſcurf, upon a diſeaſed part, or an eſchar; or a ſort of cruſt or cream which coagulates on the ſuperficies of any liquor, as upon blood, urine, or upon fermentable liquors during one ſtage of their fermentation.

CRUSTA LACTEA. See ACHOR.

CRUSTACEA. } And μαλακοστρακα, are animals which
CRUSTATA. } have the external parts firm and hard, but contain a fleſhy ſoft ſubſtance within; or, which being covered with ſlender cruſts or ſhells, are deſtitute of bones internally; which have their heads furniſhed with horns and other appendages: they have eight feet obliquely bent, and two arms called claws, notched like a forceps. Pliny comprehends all cruſtaceous animals under the name of CRABS. Linnæus claſſes them among inſects without wings, under the generical name of CRABS.

Dr. Cullen takes notice in general of the lobſter, crab, prawn, and ſhrimp only, of which he ſays the two former hardly differ in any quality from one another: and from the ſmall proportion of volatile alkali that is obtained from their entire ſubſtance, or extract, he concludes they contain leſs of animal ſubſtance than the fleſh of quadrupeds, birds, or even the amphibia. With reſpect to them as aliment, they are much of the nature of moſt fiſhes; approaching to the nature of many, in being without oil, or having it in a very ſmall proportion, and therefore affording leſs nouriſhment. They appear to be more difficult of digeſtion than moſt fiſhes. Mat. Med.

CRUSTULA. See ECCHYMOSIS.

CRUSTUMINA PYRA. PEARS much admired by the Romans, and mentioned by Columella, lib. v. c. x. Rhodius takes it to be the bergamot pear, but from its hiſtory his notion ſeems not probable.

CRUSTUMINATUM. A ſort of rob made of the juice of apples and pears, boiled up with honey and rain-water. Aetius gives directions for making it.

CRUX CERVI. See CERVUS.

CRYMODES, from κρυος, *cold*. An epithet for a fever wherein the external parts are *cold*.

CRYOXA. Erotian ſays it is a kind of pot-herb.

CRYPTÆ, from κρυπτω, *to hide*. Hollow places, like cavities, containing ſome fluid. See FOLLICULUS.

CRYPTOGAMIA. From κρυπτος, and γαμος, concealed nuptials. The 24th of Linnæus's claſſes of plants. They are ſo called from the obſcurity of their manner of impregnation. Their parts of generation are obſcure. They comprehend vegetables whoſe fructification is concealed, or at leaſt too minute to be obſerved by the naked eye. The *moſſes*, *muſhrooms*, *flags*, and *ferns* are of this ſort. In ſome of them, as in the fern, the ſeeds are found on the back of the leaves of the plant.

CRYPTOPYICA. ISCHURIA. A ſuppreſſion of urine,

urine, from a retraction of the penis within the body. See ISCHURIA, 4th ſpecies.

CRYPSORCHIS. A retraction, or retroceſſion, of one of the teſticles.

CRYSTALLI. See CRYSTALLINÆ.

CRYSTALLI TARTARI. See TARTARUM.

CRYSTALLINA. The CRYSTALLINE HUMOUR of the EYE; from κρυσταλλος *ice*; which comes from κρυος, *cold*, and σηλλομαι, *to grow together*, called alſo *cryſtallinus humor*. *Diſcoides* from its reſembling a diſk or quoit of the Romans.

Immediately behind the aqueous humour, is ſituated the *cryſtalline*; it is tranſparent, of the colour of cryſtal, and therefore is thus called. It is ſituated between the aqueous and vitreous humours, its anterior part being oppoſite to, and very near the pupil; its poſterior part is lodged in a cavity, formed for its reception in the middle and fore-part of the vitreous humour: the figure of the *cryſtalline* is that of a lens, convex on both ſides, but rather more ſo poſteriorly. The *cryſtalline* is the leaſt, but of the moſt firm conſiſtence, of the three humours of the eye. It is more firm in the middle than in the ſides; and, in time, is apt to change both in its conſiſtence and colour, growing ſtill more firm, and becoming yellowiſh. It is inveſted with a denſe, firm membrane, which is rather looſely connected to it; it is perfectly tranſparent, but when injected, appears furniſhed with an immenſe quantity of blood-veſſels. In the fœtus there appears a branch of the artery that paſſes through the axis of the optic nerve, which comes through the vitreous humour, and ramifies through the capſula of the *cryſtalline* in a radiated manner; this is much larger in the fœtus, and ſtronger than in adults; theſe branches go to the tips of the proceſſus ciliaris, and are there imperceptible. The *cryſtalline humour* is membranous, and conſiſts of many coats incloſed in one another, the whole of which are contained in a capſula, formed by a continuation of the covering of the vitreous humour. This capſula is called ARANEA, which ſee. The *cryſtalline humour* produces a ſecond refraction of the rays of light; the firſt refraction, which is produced by the cornea and the aqueous humour not being ſufficient to bring them to a focus at the retina.

CRYSTALLINÆ. CRYSTALLINES. Alſo CRYSTALLI. The Italian phyſicians call them *taroli*. They are puſtules filled with water, tranſparent, and on that account receive their name. They are ſometimes about the ſize of a lupin, and break out all over the body. But, when they attend a gonorrhœa, they are conſidered as one of the moſt troubleſome ſymptoms. They are lodged on the prepuce without pain, and though cauſed by coition, have nothing of infection attending them. The cauſe is ſuppoſed to be a contuſion of the lymphatic veſſels in the part affected. Dr. Cockburn, who hath deſcribed this caſe, recommends for the cure a mixture of three parts of lime-water, and two of rectified ſpirit of wine, to be uſed warm, as a lotion, three times a day.

CRYSTALLINÆ MANUS. In Hippocrates, are hands ſo cold as to ſeem frozen.

CRYSTALLINUM. See ARSENICUM ALBUM.

CRYSTALLINUS HUMOR. See CRYSTALLINA.

CRYSTALLION. See PSYLLIUM.

CRYSTALLIZATIO. CRYSTALLIZATION. The parts of all bodies which take the ſolid ſtate are diſpoſed to arrange themſelves in ſuch a manner, as to produce ſome regular geometrical figure in the ſolid. This property is called CRYSTALLIZATION, and the regularly-figured bodies we call CRYSTALS. In this proceſs the integrant parts of a ſolid body, ſeparated from each other by the intervention of a fluid, are made to exert the mutual attraction of aggregation, ſo as to coaleſce, and produce a ſolid maſs.—When the particles of a body are only ſeparated by caloric, and the ſubſtance is thereby retained in the liquid ſtate, all that is neceſſary for making it cryſtallize, is to remove a part of the caloric, which is lodged between its particles, or in other words to cool it. If this refrigeration be ſlow, and the body be at the ſame time left at reſt, its particles aſſume a regular arrangement; and cryſtallization, properly ſo called, takes place; but if the refrigeration is made rapidly, or if the liquor be agitated at the moment of its paſſage to the concrete ſtate, the cryſtallization is irregular, and confuſed. The ſame phænomena occur with watery ſolutions, or rather in thoſe made partly in water, and partly by caloric. So long as there remains a ſufficiency of water and caloric to keep the particles of the body aſunder beyond the ſphere of their mutual attraction, the ſalt remains in a fluid ſtate; but whenever either caloric or water is not preſent in a ſufficient quantity, and the attraction of the particles for each other becomes ſuperior to the power which keeps them aſunder, the ſalt recovers its concrete form, and the cryſtals produced are more regular in proportion as the evaporation has been ſlower, and more tranquilly performed.

To diſpoſe a ſubſtance to cryſtallization, it is neceſſary in the firſt place, to reduce it to the moſt complete ſtate of diviſion. This may be effected either by ſolution, or by an operation merely mechanical. Solution may be effected either by the means of water or fire. The ſolution of ſalts is generally performed in the firſt liquid, that of metals by means of the ſecond; and their ſolution is not complete, until a degree of heat is applied, of ſufficient intenſity, to convert them into the ſtate of gas. In order that the form of a cryſtal may be regular, three circumſtances are required; TIME, a SUFFICIENT SPACE, and REPOSE. TIME cauſes the ſuperabundant fluid to be ſlowly diſſipated, and brings the integral parts by inſenſible gradation nearer each other, and without any ſudden ſhock. Theſe integral parts, therefore, unite accordingly to their conſtant laws, and form a regular cryſtal. For this reaſon it is that ſlow evaporation is recommended by all good chemiſts. SPACE, or ſufficient room, is likewiſe a condition neceſſary for obtaining regular cryſtallization. If nature be reſtrained in her operations, the product of her labour will exhibit ſymptoms of this ſtate of conſtraint. It may be aſſerted that nature performs her productions according to all the circumſtances which may influence her operations. A ſtate of repoſe in the fluid is likewiſe neceſſary to obtain very regular forms: uninterrupted agitation oppoſes all ſymmetrical arrangement; and in this caſe the cryſtallization obtained will be confuſed and indeterminate.

This term however is moſt commonly applied to bodies of the ſaline kind; and their ſeparating in regular figures from the water, or other fluid in which they are diſſolved, is called their cryſtallization. This word is never applied to the freezing of water, or to the conſolidation of metals, after they have been melted, yet it might certainly with as much juſtice to theſe ſubſtances as any others. Though this is accounted one of the proceſſes of chemiſtry, it is truly a proceſs of nature, which the chemiſt can only prepare for, leaving the operation in her hands. All the alcaline ſalts are excluded from this operation, for fixed ones never aſſume this form, and the volatile fly off before a pellicle can be diſcovered. Some of the neutral kind, particularly thoſe of which certain metallic bodies are the baſis, are as incapable of *cryſtallization* as any other ſort of ſalt, except ſome other ſubſtance be added, with which the water hath a greater affinity. Different ſalts alſo require different quantities of water to diſſolve them; hence, if a mixture of two ſalts be diſſolved in one fluid, they will begin to ſeparate at different times of the evaporation: upon this foundation ſalts are freed not only from their impurities, but alſo from one another; that which requires the moſt water to diſſolve in, ſhooting firſt.

All ſalts when diſſolved in ſuch a quantity of water as is not ſufficient to keep them in that ſtate, and prevent their coaleſcence, do form themſelves into ſimilar figures of a peculiar kind, each according to its ſpecies. The nature of ſaturation, and the variation of the ſolvent power of hot and cold water, which are principles on which this operation depends, ſee in the article SOLUTION and MENSTRUUM. The end of *cryſtallization* is, to render the ſalts pure and diſtinguiſhable, as well by freeing them from feculence, and giving them their proper form, as by ſeparating each kind from every other.

The manner of *cryſtallizing* ſalts is, to make a ſaturate ſolution of them in boiling water (hot water diſſolves more ſalt than it can ſuſpend when cold); then put the ſolution into a proper veſſel, and let it ſtand ſtill in a cool place till the *cryſtals* are formed; this requires ſome days. When *cryſtals* are formed, the remaining ſolution, called the mothers, muſt be poured off, and what the *cryſtals* retain muſt be drained from them, which is done on a paper, then dried; the mothers may be evaporated to dryneſs, or kept for the ſame purpoſe again.

If ſalts are diſſolved in too much water, evaporate ſlowly until the ſalts ſhew a diſpoſition to concrete, even from the hot water, by forming a pellicle on the ſurface. If large, and the moſt perfect *cryſtals* are required, remove the ſolution from the fire before the pellicle appears; otherwiſe

otherwiſe the ſuddenneſs of the *cryſtallization* will diminiſh the perfection of the *cryſtals*. In this caſe evaporate until ſome drops of the liquor, let fall on a cold glazed plate, diſcover cryſtalline filaments; where this mark of ſufficient exhalation appears, remove the veſſel from the fire into a leſs warm, but not cold place; cover it with a cloth, to prevent the acceſs of cold air, and thus leave it till *cryſtals* are formed. If the ſalt is pure, no more is neceſſary; but if not, filtration will be required, previous to the ſolution being left for the ſeparation of its contents.

In *cryſtallizing* large quantities, ſticks are placed acroſs in the veſſels, on which the ſalts forming, are taken out in a more perfect figure, and with leſs trouble, than when they adhere in thicker concretions to the ſides and bottoms of the veſſels.

Sudden cooling, or ſhaking the veſſel, will either of them prevent the ſalts from being properly and regularly formed.

Care ſhould be taken that the ſubſtances of the veſſels are ſuch as not to endanger corroſion.

The figures of ſalts cannot be deſtroyed; for if they are comminuted ever ſo ſmall, yet upon *re-cryſtallization*, they form themſelves again into their proper ſhapes. *Common ſalt* diſcovers quadrilateral pyramids, with ſquare baſes, or nearly cubes. *Sugar* diſcovers the ſame pyramids with oblong and rectangular baſes. *Alum* hath ſix ſides ſupported with an hexagonal baſe. *Cryſtals of vitriol* reſemble iſicles, among which are ſome polygons. *Sal ammoniac* reſembles the branches of a tree, or feathers. *Salt of hart's horn*, a quiver of arrows. *Glauber's ſalt*, both ſea-ſalt and vitriol. *Nitre* appears in priſmatical columns, or hexagonal priſms. *Salt of tin* repreſents a ſtar, its lines radiating from the centre to the circumference.

Salts retain in *cryſtallization* a portion of water, and on this their *cryſtalline* form ſeems much to depend. *Nitre* contains about one-twentieth of its weight of water; *alum* one-ſixth; *ſea-ſalt* one-fourth; *borax*, *green vitriol*, and the *bitter purging ſalts*, from one-third to one-half.

Rectified ſpirit of wine diſſolves ſome ſalts, aſſiſts the *cryſtallization* of others, and is neceſſary for ſeparating any oily matters therefrom.

See Chaptal; Fourcroy; Lavoiſier's Elements of Chemiſtry; the Encyclopædia Britannica; Boerhaave's Chemiſtry; Dictionary of Chemiſtry; and Neumann's Chemical Works.

CRYSTALLUM MINERALE. See SAL PRUNELLÆ, under NITRUM.

CRYSTALLUS PHILOSOPHORUM. See AZOTH.

CRYSTALLOIDES TUNICA. See ARANEA.

CRYTHE. A hard, ſcirrhous, immoveable ſtian in the interior part of the eye-lid, containing a pellucid body. See CHALAZA, CRITHE-HORDEOLUM.

CTEIS. See PUBIS OSSA.

CTENES, the plural of Cteis, implies thoſe teeth which are called *inciſores*.

CTESIPHONTIS MALAGMA. A plaſter deſcribed by Celſus.

CUBARIS. See ASELLI.

CUBEBÆ. CUBEBS, alſo called *piper caudatum*; by Actuarius, *compeba*, and by Myrepſus, *compiper*. PIPER CUBEBA, vel PIPER *foliis oblique ovatis, f. oblongis venoſis acutis, ſpica ſolitaria pedunculata oppoſiti folia, fructibus pedicellatis*, LINN. The cubeb tree is alſo the *Baccifera arbor Braſilienſis fructu piper recipiente*. The berries are dried, of an aſh-brown colour, generally wrinkled, greatly reſembling pepper, but furniſhed each with a ſlender ſtalk. They are brought from Java, and other different parts of the Eaſt Indies. They are a warm ſpice, agreeable to the ſmell, and ſomewhat pungent to the taſte. *Their qualities reſemble thoſe of pepper, but are much milder.* Diſtilled with water, they yield a ſmall quantity of eſſential oil, which poſſeſſes moſt of their virtue. An extract made with rectified ſpirit of wine abounds with all their virtues, for the odorous principle does not exhale with ſpirit.

Chuſe ſuch as are ſound, large, ſmooth, plump, and heavy; for if they are wrinkled, they have been gathered before they were ripe. See Raii Hiſt. Neumann's Chem. Works Lewis's Mat. Med.

CUBEBIS. See FAGARA MAJOR.

CUBIFORME OS. See CUBOIDES OS.

CUBITALIS NERVUS. See CERVICALES. Cheſelden deſcribes the *cubital nerves* as being two in each arm; the upper paſſing over the upper extuberance of the os humeri, runs on to the thumb and the three next fingers by its branches, which ſpread when it approaches the thumb; the inferior, which paſſes under the inner extuberance of the os humeri, and runs on to the ring and little fingers.

CUBITALIS vel ULNARIS ARTERIA. The *cubital*, or *ulnar artery*, parting from the radical about a finger's breadth below the bend of the arm, ſinks in between the ulna and the upper parts of the pronator teres, perforates the palmaris longus and radiæus internus; near the carpus it lies juſt under the integuments, is continued on the inſide of the os piſiforme, runs before the annular ligaments acroſs the palm, and forms an arch which anaſtomoſes with that of the radial; whence theſe arteries go to the finger and thumb, one running on each of the fingers. In its courſe it ſends off various branches.

—— MUSCULUS. See ANCONÆUS MUSCULUS.

—— EXTERNA & INTERNA, VENA. See BASILICA VENA.

CUBITI PROFUNDA VENA. Sometimes from one and ſometimes from another of the branches called mediana, a branch goes out on the inſide of the fore-arm, which is thus named.

CUBITUS, alſo *cybitos*; *elene*; from *cubando*, becauſe the ancients uſed to lie down on that part at their meals. See ULNA. It is alſo a *cubit* meaſure. In BOTANY, it is the ninth degree in the Linnæan ſcale for meaſuring plants; from the elbow to the extremity of the middle finger; ſeventeen Pariſian inches; or a foot and an half Engliſh. So the ſtalks of plants are named cubitalis, bicubitalis, &c. according to their height.

CUBOIDES, os, from κυβος, *a cube*, and ειδος, *forma*. Called alſo *cyboides*; *varium os*; *cubiforme*, *quadratum*, *grandinoſum*, *teſſera*, *multiforme*. This bone is ſituated immediately before the os calcis; on its fore-ſide it ſuſtains the os metatarſi of the little toe, and that toe next to it. The oſſification of this bone is ſcarce begun at the birth.

CUCOS. The kernel of the fruit of a ſpecies of palm tree; the fruit is the ſize of a cherry.

CUCULATUM MAJUS. BRANDY, or SPIRIT of WINE.

CUCULLA, } called alſo *trapezius*,
CUCULLARIS MUSCULUS, } *trapezia*, ariſes by a ſtrong round tendon, from the lower part of the protuberance in the middle of the os occipitis behind; and by a thin membranous tendon, which covers part of the ſplenius and complexus *muſcles*, from the rough curved line that extends from the protuberance towards the maſtoid proceſs of the temporal bone; runs down along the nape of the neck, where it ſeems to ariſe from its fellow, and covers the ſpinous proceſſes of the ſuperior vertebræ of the neck, but ariſes from the ſpinous proceſſes of the two inferior, and from the ſpinous proceſſes of all the vertebræ of the back, adhering tendinous to its fellow the whole length of its origin. It is inſerted, fleſhy, into the poſterior half of the clavicle, tendinous and fleſhy into the acromion, and into almoſt all the ſpine of the ſcapula. ITS USE is to move the ſcapula, according to the three directions of its fibres; for the *upper deſcending fibres* draw it obliquely upwards; the *middle tranſverſe ſtraight fibres* draw it directly backwards, and the *inferior aſcending fibres* draw it obliquely downwards and backwards. Where it is inſeparably united to its fellow in the nape of the neck, it is named *ligamentum colli*, or *nuchæ*. Innes. It is obſerved by Douglas, that Galen divides this *muſcle* into two, viz. the ſuperior and the inferior. The firſt he calls the *trapezia*; and to the ſecond, later anatomiſts have given the name of *cucullæ*, from whence they are both commonly named *cucullares*. Its upper part, from the os occipitis to the ſpinal proceſs of the laſt vertebra colli, is inſeparably united to its fellow of the other ſide.

CUCULLATA. See SANICULA.

CUCULLATI FLORES. CUCULLATE FLOWERS. See FLOS LABIATUS.

CUCULLUS. See CUCUPHA, and EPITHEMA.

CUCUMERARIA. } See MOMORDICA.
CUCUMERINA INDICA. }

CUCUMIS. The CUCUMBER. The *cucumber* hath a flower conſiſting of one leaf, which is bell-ſhaped, and expanded toward the top, and cut into many ſegments, of which ſome are male, others female. The beſt fruit is long, and of a deep green. This plant is annual and raiſed from ſeed, the beſt of which is long, thick, and with a thin rind.

CUCUMIS AGRESTIS, called alſo *cucumis aſininus*, *elaterium* offic. *boubalios*, *guarerba orba*. The WILD or SQUIRTING CUCUMBER. The fruit from whence the elaterium of the ſhops is obtained, is the MOMORDICA ELATERIUM, or MOMORDICA *pomis hiſpidis*, *cirrhis nullis*. LINN. CLASS, MONŒCIA; ORD. SYNGENESIA. LINN. Gen. Plant. 1090. This fruit is watery, hairy, and almoſt of an oval ſhape, about two inches in length: when ripe, it burſts on being touched, and throws out with violence its whitiſh juice and black ſeeds. It is ſown in our gardens annually, but is found wild in many other countries. From the circumſtance of its burſting with violence, the Greeks call it *elaterion*, which ſignifies the elaſtic power of the air, derived from ἐλαύνω, *to ſtake*, or *exagitate*; and from hence it is called the *ſquirting cucumber*. Elaterion alſo ſignifies any purging medicine, particularly thoſe that act with violence, as does the juice of *wild cucumber*: whence another reaſon for calling it by this name. All the parts of the *wild cucumber* are bitter and ſtrongly purgative; the fruit is the moſt ſo, and the root more active than the leaves. The juice of the fruit hath an unpleaſant ſmell, and a durable nauſeous bitter taſte: on ſtanding a few hours, it ſeparates into a thick part which falls to the bottom, and a thin watery fluid, which floats above. The dried juice, or fæculæ of the fruit, known in the ſhops by the name *Elaterium*, is the only part now medicinally employed, and has been diſtinguiſhed into white and black elaterium; the firſt is prepared of the juice which iſſues ſpontaneouſly, the latter from that which is obtained from expreſſion. It is a ſtrong, irritating, but ſlow cathartic, and often operates likewiſe upwards; it remarkably raiſes the pulſe, and ſeems to excite a feveriſh ſtate for a time; it is therefore only uſed in cold phlegmatic conſtitutions, as in dropſies; in which diſeaſe it was much employed by Sydenham, and Liſter. See Sydenham's Works, with notes by Dr. Wallis. Liſteri Exercitationes Medicinales de Hydrope. It is undoubtedly the moſt violent purgative in the materia medica, and ought therefore to be adminiſtered with great caution, and only where the milder cathartics have proved ineffectual. The doſe is from half a grain to three grains: the moſt prudent and effectual mode of exhibition in dropſies is by repeating it in ſmall doſes, at ſhort intervals; it is moſtly uſed to quicken other purgatives. Four grains of extract of gentian, and quarter of a grain of elaterium, formed into a pill, and repeated every two hours, till it operates ſufficiently by ſtool, and given every third, or fourth day is ſaid to have been efficacious in reducing dropſical ſwellings, and affording an opportunity for the exhibition of tonics.

The London College directs the following method of preparing elaterium:

Slit ripe *wild cucumbers*, and paſs the juice, very gently preſſed through a very fine hair ſieve, into a glazed veſſel; ſet it by ſome hours, till its thicker part ſhall have ſubſided; then pour off the thin part of the juice, and draw away the reſt by ſtraining; let the thicker part which remains be covered over with a linen cloth, and dried by a gentle heat. Pharm. Lond. 1788.

Care ſhould be taken not to preſs the *cucumber*, ſo as to force out any of the pulpy part; for thus the preparation will be proportionably weakened. An extract made with wine from the roots is equally uſeful with this fæcula, called elaterium.

Elaterium is mentioned as a purging medicine by Hippocrates; ſometimes it occaſions great uneaſineſs in the bowels, if too large a doſe is given: in which caſe acids and mucilages are the proper antidotes. See Raii Hiſt. Lewis's Mat. Med.

CUCUMIS ÆGYPTIUS. CHATE, or EGYPTIAN CUCUMBER. It is more white, ſoft, and round than our garden *cucumber*, but of ſimilar qualities.

—— CANADENSIS. See SICYOS.

—— COLOCYNTHIS. See COLOCYNTHIS.

—— HORTENSIS, *Cucum.* vulgaris, *cucumis* ſativus, or GARDEN CUCUMBER.

The ſeeds of this ſpecies are the only part uſed in medicine. They have uſually been preſcribed in a mixture of equal portions of the ſeeds of the CITRULLUS, citrul, or water-melon; CUCURBITA, or gourd; and PEPO, or pompion, under the general name of the GREATER COLD SEEDS. The ſeeds of all theſe plants are ſimilar in their medical properties. The fruit of the *cucumber* is not very nutritious, becauſe perhaps it is employed in its unripe ſtate, though it makes a conſiderable part of the aliment of many perſons in warm climates, and ſeaſons, and its aqueous, cooling, and acecſcent quality renders it very proper for ſummer aliment, and an agreeable food in hot, bilious diſpoſitions. From the firmneſs of its texture, it is often retained long in the ſtomach, occaſioning acidity and flatulence; hence it ſhould be accompanied with ſome of the condiments. Formerly the ſeeds were beat into an emulſion with other ingredients, but now are rarely called for in practice, the almond emulſion ſuperſeding their uſe.

CUCUMIS PUNICUS CORDI. See MOMORDICA.

CUCUPHA, called alſo *cucullus*, *pileolus*, *birrethus*, *pileus*, *byrethrum*, *byrethrus*. An ODORIFEROUS CAP for the head. It is made like what is called the *ſkull-cap* for children, of either ſilk or linen; it is double, and between its ſides are put cephalic aromatic drugs in powder; ſometimes they are mixed with cotton, to keep them equally diſperſed; theſe ſpices are alſo ſprinkled with ſome ſuitable eſſential oil, or ſpirit, or vinegar; then the *cap* being ſewed round it edges, it is placed next the head, and another over it. When to half of the ſkull, or only to a particular part, it is to be applied, it is called a *ſemi-cucupha*. The ingredients ſhould be renewed when their virtue is worn off. The proportions of the ſpecies are uſually as follow: of *roots*, an ounce; of *leaves*, two or three hand-fulls; of *flowers*, two or three pugils; of *gums*, one or two drams; of *powders*, one ounce; the whole rarely exceeds four ounces. *Cucuphæ* act by the exhalations from the ſpices they contain. They are apt to render the patient diſagreeably ſenſible of all changes of weather. See EPITHEMA.

CUCURBITA, *Cucurbita* lagenaria, Linn. The GOURD. It is a large fruit, growing on a plant: its ſeed is one of the four cold ſeeds mentioned in the article CUCUMIS. Likewiſe a glaſs veſſel with a round belly and a long neck, about ſix inches diameter, and firmly cloſed. It is alſo called *bocia*, *botus*, *botia*, *botus barbatus*, and *ovum ſublimatorium*.

—— A CUPPING-GLASS. See CUCURBITULA.

Alſo a CUCURBIT, called alſo *alkara*, *alcara*, *kymia*, *abelchera*. A chemical veſſel, ſo called from its reſemblance to a gourd; for it gradually ariſes from a wide bottom and terminates in a ſmall neck. Some call it *vas urinale*, becauſe it is ſhaped like a glaſs in which urine is inſpected; though ſome are ſhallow and wide-mouthed. It is uſed in diſtillation, with a head, &c. and then it conſtitutes a ſort of alembic: it is alſo uſed in digeſtions, with a blind alembic fitted to it.

Cucurbits are made of glaſs, earthen ware, or of metals, according to the reſpective uſes in which they are engaged: the earthen ones are called *canthari ſigulini*; the copper ones are lined with tin, and are called *veſicæ diſtillatoriæ*.

The broader the bottom, and the narrower and longer the neck, the more difficultly its contents are diſtilled, ſo that the leſs obedient any ſubject is to the fire, the narrower the bottom and the ſhorter the neck ſhould be, and vice verſa.

It is a blind *cucurbit*, when another ſmall *cucurbit* is placed on with its neck in the neck of the larger. The leſſer are called ſeparatory *cucurbits*. If its belly is ſpherical, and its neck long and cylindrical, it is called *Matracium*, a MATRASS or a BOLT-HEAD.

The length of the neck is ſuch, that ſcarce any of the liquor aſcends to its mouth, the cold external air repelling it before it arrives there, and it falls again to the bottom of the veſſel. Thus the digeſtions of menſtruums, with the ſubſtances to be reſolved in them, are conveniently carried on without any loſs. They are uſed for macerating, and digeſting various ingredients in proper menſtrua: they are alſo uſed as receivers, and take different names from their different ſhapes. Beſides theſe advantages, the long-necked *cucurbits* are ſingularly uſeful in ſeparating pure alkaline and volatile ſpirits and ſalts from water, oil, and volatile earth.

Cucurbits are more uſed for digeſting and ſubliming, than for diſtilling. See Dict. of Chem.

CUCURBITA CITRULLUS. See CITRULLUS.

CUCURBITACEÆ. (Cucurbita, a gourd.) The forty-fifth order in Linnæus's fragments of a natural method, and the thirty-fourth of his natural orders.

CUCURBITIFERA MALABARIENSIS, &c. See NUX VOMICA.

CUCURBITIFERA TRIFOLIA INDICA FRUCTUS PULPA CYDONII ÆMULA. See COVALAM.

CUCURBITULA, alſo called *cucurbita*. A CUPPING-GLASS. Formerly this inſtrument was made of horn,

horn, or ſome kind of metal. It is of great antiquity, being mentioned by Hippocrates. Different names have been given to them, according as they were uſed with or without ſcarifications, as leves, arentes, ſiccatæ, &c. The ancients had them with narrow mouths, for drawing more forcibly, and with wider mouths for drawing more gently.

Dry cupping is when the glaſſes are uſed without ſcarifying. *Sanguineous* or *wet*, is when ſcarifications are made.

The preſent mode of applying a *cupping-glaſs* is to expel the air by heat, which is done by having ſpirit of wine in a lamp to which is affixed a ſpout, through which ſome cotton wick is drawn, impregnated with the ſpirit: this is ſet on fire, then put within the cupping glaſs, which is inſtantaneouſly applied to the part, and adheres with a ſtrong attraction. The uſe of dry *cupping* is to invite a humour to the place where the glaſs is applied, in order to remove it from another. The operation ſhould be repeated until the part becomes red, and is in pain.

When ſcarification is uſed with *cupping*, the part ſhould firſt be dry-*cupped* until it appears red; then make the inciſions with the ſcarificator. If ſcarifications are to be made in ſeveral parts, begin below and proceed upwards, or the blood will incommode the operator. The ſcarifications made, the air muſt be excluded from the glaſs by burning ſomething in it, as above mentioned, and then applying it. The preſſure of the external air preſſes the glaſs forcibly to the ſkin; and the glaſs, being emptied of its air by the fire introduced in it, powerfully attracts the blood. The operation ended, wipe the part with a ſponge dipped in warm water; and to ſtop the bleeding, a little ſpirit of wine may be applied by dipping a linen rag therein, and applying it over the ſcarifications.

This operation does not ſeem to be neceſſary, except when blood cannot be obtained by opening a vein in the uſual manner. Celſus, lib. ii. cap. 11, ſays, that "*cupping* is needful when the body is to be relieved in ſome acute diſorder, and yet the ſtrength does not admit of a loſs of blood from the veins." It is true, that the ſlow diſcharge of blood by *cupping* does not leſſen the vital heat ſo much as the ſame quantity of blood does when ſuddenly taken away by opening a vein; but in ſuch caſes, as Celſus ſuppoſes, other more eligible means of relief may be made uſe of with leſs fatigue to the already enfeebled patient, and more to his advantage.

The blood extracted by ſcarification and *cupping*, Hoffman ſays he often examined, and found to be the ſame with that from the veins; if ſo, there appears no other advantage from *cupping* than what ariſes from opening a vein, except what may happen from the ſlow diſcharge of the blood in the firſt method of extracting it, and the relief of the part only, when the complaint is local.

Some extol *cupping* in apoplexies, epilepſies, and ſome kind of convulſions, becauſe they ſay that the ſpaſms are increaſed by the ſpeedier diſcharge of blood which is the conſequence of phlebotomy. The taking away blood by this mode is chiefly to relieve ſome part locally affected, or in weak conſtitutions, or torpid habits, where the general mode is unneceſſary, or might produce too debilitating effects.

See Cœlius Aurelianus, Celſus, Morgagni, Hoffman, Haller, Bell's Surgery, vol. i. p. 154, &c. White's Surgery, p. 180.

CUDU PARITI. A ſhrub which grows in Malabar: it flowers all the year long. The leaves are anodyne when externally applied. The fruit checks a dyſentery. Raii Hiſt.

CUEMA vel CYEMA. See CONCEPTIO and EMBRYON.

CULBICIO. A ſort of ſtrangury, or rather heat of urine. See DYSURIA.

CULEUS, or CULLEUS. A Roman meaſure containing twenty *amphoræ*; the largeſt liquid meaſure among the Romans; ſometimes it ſignifies a leather ſack.

CULI FLOS. See CARDAMINES.

CULILAVAN. See CORTEX CULLITLAWAN.

CULINARIUS SAL. The *culinary* or *alimentary ſalt*. It is generally called COMMON SALT, becauſe of common uſe in culinary preparations; but the ſea-*ſalt* ſeems, from its univerſality in the world, to be more properly the common *ſalt*. Sea-*ſalt* conſiſts of this culinary *ſalt*, and the *ſalt* uſually called Epſom *ſalt*, or *ſalt* cath. amar. When *ſea*-water, or a ſolution of the *ſal* gem. is evaporated, the firſt cryſtals that are formed are the *culinary ſalt*, which when ſeparated from the remaining brine, and the evaporation is continued, the ſucceeding cryſtals are not of the *culinary* kind, but the bitter purging *ſalt* of the ſhops. The conſtituents of the *culinary ſalt* are, the ſpirit uſually called *acidum muriaticum*, and a mineral alkaline *ſalt*. See MARINUM SAL.

CULILTLAWAN. See CORT. CULITLAWAN

CULLEUS. See CULEUS.

CULMEN. } The STALK or BLADE of CORN or
CULMUS. } GRASS. Culmiferous plants have a ſmooth jointed ſtalk, are uſually hollow, and at each joint wrapped about with ſingle, narrow, ſharp-pointed leaves; and their ſeeds are in chaffy huſks, as wheat, barley, &c.

In graſſes and corns, the *culmus* or ſtalk correſponds to the caudex or trunk of trees; ſo that it generally denotes that part between the root and the ear or panicle: but botaniſts differ in their diſtribution of plants into culmiferous. Alſo the ſtubble of corn, remaining after the ears are cut off, is ſo called.

CULMINIÆ, from *culmen* the top, the twenty-fifth order in Linnæus's fragments of a natural method.

CULTER. The third lobe of the liver. See AURIGA.

CULUS. See ANUS.

CUMANA, called alſo *gacirma*. An Indian tree, like that of the mulberry-tree. Its wood is ſo hard that it ſtrikes fire like a flint.

CUMBULU, called alſo *nux Malabarica unctuoſa flore cucullato*. A tall tree growing in Malabar, the root of which is uſed in a decoction with rice, for common drink in fevers.

CUMINOIDES. WILD CUMIN. Called alſo *cuminum ſylveſtre, paſtinaca tenuifolia Cretica, and daucus odoratus Creticus*.

This plant grows in Crete; the ſeeds only are in uſe; they are carminative. Raii Hiſt.

CUMINUM. CUMIN. According to Miller, this name is derived from κυειν, *to bring forth*; becauſe it is ſaid to be efficacious in curing ſterility. It is alſo called *cyminum* and *fœniculum orientale*. It is the CUMINUM CYMINUM, or CUMINUM ÆGYPTIACUM SATIVUM, *ſemine longiore*. CLASS, PENTANDRIA; ORD. DIGYNIA. LINN. Gen. Plant. 351.

This plant reſembles fennel, but is much ſmaller; produces longiſh, ſlender, plano-convex ſeeds, of a browniſh colour, with yelloviſh ſtriæ. It is annual, a native of Egypt and Ethiopia; is cultivated in Sicily and Malta, from whence it is brought to us.

Theſe ſeeds are bitteriſh to the taſte, and warm; have an aromatic but diſagreeable flavour. Water takes up much of their ſmell by infuſion, but not much of their taſte. Diſtilled with water, they afford a pungent oil, which partakes much of the flavour of the ſeeds. Rectified ſpirit extracts their whole virtue; the ſpirituous extract is very warm, moderately pungent, and not a little nauſeous.

Theſe ſeeds are carminative and ſtomachic, and poſſeſs theſe powers equally, if not ſuperiorly to moſt of thoſe of the umbelliferous claſs: but they are rather too ungrateful. Externally they are diſcutient and antiſeptic.

The London College directs the following preparations, in which theſe ſeeds are a part:

Cataplaſma Cumini. CATAPLASM *of* CUMIN, formerly *Theriaca Londinenſis*.

Take of *cumin* ſeeds, one pound; bay berries, the leaves of water-germander dried, Virginia ſnake-root, of each, three ounces; of cloves, one ounce: with honey equal to thrice the weight of the ſpecies powdered, make a cataplaſm. Ph. Lond. 1788. This was applied to mortified parts, as an antiſeptic, but is now ſeldom uſed.

Emplaſtrum Cumini. CUMIN PLASTER.

Take of Burgundy pitch, three pounds; yellow wax, *cumin* ſeeds, carraway ſeeds, and bay berries, of each, three ounces. The pitch and wax being melted together, ſprinkle into them the reſt, reduced to powder, and ſtir all well together. Ph. Lond. 1788. See Miller's Dict. Lewis's Mat. Med. Raii Hiſt. This is conſidered as a ſuitable application to encyſted and other tumors, which ſuppurate imperfectly.

CUMINUM ÆTHIOPICUM. See AMMI VERUM.

—— PRATENSE. See CARUM.

That called SILIQUOSUM is the CODDED WILD CUMIN. It grows in Spain, flowers in May, and produces the ſame effects, medicinally, as the poppy.

CUMINUM SYLVESTRE. See CUMINOIDES.

CUNEALIS SUTURA. The future by which the os ſphænoides, or cuneiforme, is joined to the os frontis.

CUNEIFORME Os. From *cuneus, a wedge*, called alſo *clavicula, cuzilla, Chalceideum os, Baſilare os.* A name of the *os ſphænoides*, from its being wedged between the other bones. Alſo the third bone of the firſt row in the wriſt. It is called ſo from its appearing like a wedge ſticking between the two rows. See CARPUS.

—— OS EXTERNUM, or *Chalceideum externum* of the tarſus. At its poſterior edge it joins the os naviculare and os cuboides; it ſupports the metatarſal bone of the toe next the little one, and that next the great one and of the middle toe. The *os cuneiforme* medium vel minimum is ſtill more wedge-like than the former; it ſuſtains the metatarſal bone of the toe next to the great one. The os *cuneiforme* internum vel maximum ſuſtains the os metatarſi of the great toe. All theſe are cartilaginous at the birth of children. Theſe bones are alſo called *chalceidea officula.*

CUNILA SATIVA. See SATUREIA SATIVA.

CUP. HORT. CATH. and Hort. Cath. Cup. An abbreviation of Franciſci Cupani Hortus Catholicus.

CUP. HORT. CATH. SUP. Hort. Catholic. Supplementum Primum.

CUP. HORT. CATH. A. Supplementum Alterum ad Hort. Cathol.

CUPELLA, called alſo *capella, copella, catellus cinereus, cineritium, patella docimaſtica*, or *teſta probatrix, exploratrix*, or *docimaſtica.* A CUPEL or TEST.

Theſe are veſſels uſed for ſeparating baſer metals from gold or ſilver; they are made of earth, and are hollowed like flat cups, from which reſemblance they have been named: they reſiſt every degree of fire that is needful to keep any metal in fuſion; they alſo retain theſe metals when fuſed. The aſhes of bones or of plants, that have been calcined, are the propereſt for making them; though Cramer prefers thoſe made with plaiſter: which-ever of theſe materials are choſen, they muſt be perfectly calcined, then levigated, after which, they muſt be formed into a paſte, and moulded into their proper form, and burnt in a potter's furnace. See various directions concerning them in the Dict. of Chem.

CUPEROSA. COPPERAS.

CUPHOS. LIGHT. When applied to aliments, it imports their being eaſily digeſted; when to diſtempers, that they are mild.

CUPRESSUS, called alſo *cyparifſus, cypreſſus.* The CYPRESS-TREE. The CUPRESSUS SEMPERVIRENS, Linn. It is a tall ever-green-tree, native of the warmer climates, bearing male and female flowers on the ſame branches; the leaves are ſlender, and ſo are the branches, which ſpread forming a cone, the apex of which is the top of the tree; the fruit is a kind of nut, called GALBULÆ, *galbuli, glabulæ*, as large as a walnut, and aſtringent. The flowers have an agreeable odour, and have been uſed in conjunction with ſome other ingredients for making an oil by infuſion with olive oil, which was named *oleum cyprinum.*

There are three ſpecies of this tree.

CUPRESSINUM. CYPRESS WINE. See CEDRINUM.

CUPRI AMMONIATI AQUA, *olim.* AQUA SAPPHIRINA, called COLLYRIUM CŒRULEUM.

Take of *lime-water*, one pint; ſal ammoniac, one dram; let them ſtand together in a copper veſſel, until the ammonia is ſaturated. Phar. Lond. 1788.

CUPRI PREPARATIONES. *Preparations of copper.* See ÆRIS FLOS.

CUPRI RUBIGO. See ÆRUGO ÆRIS.

CUPRUM. See Æs. Of the preparations of copper, there are different compoſitions formed, chiefly uſed for injection, of which ſome ſpecimens are here recited.

CUPRI AMMONIATI LIQUOR. *Liquor of ammoniated Copper.*

℞ Calcis cupri ʒ j. aq. ammoniæ ʒ ij. Theſe are to be digeſted without heat, till the copper is diſſolved.

CUPRI AMMONIATI CALX. *Calx of ammoniated Copper.*

℞ Cupr. vitriolat. q. v. ſolvatur in aquæ diſtillatæ, q. ſ. et adjiciatur kali præparati portio propria, donec cuprum ad vaſis imum deſcendat; deinde bene lavetur, et ſiccetur.

CUPRI ACETATI INJECTIO. *Injection of acetated Copper.*

℞ Æruginis g. x. olei amygdal. ʒ iv. m. Triturationе ſolvatur in oleo ærugo.

CUPRI AMMONIATI INJECTIO. *Injection of ammoniated Copper.*

℞ Liquor. cupri ammoniati g. xx. aq. roſæ ʒ iv. m.

CUPRI VITRIOLATI INJECTIO. *Injection of vitriolated Copper.*

℞ Cupri vitriolati g. iv. aquæ diſtillatæ ʒ iv. m.

Theſe injections, being of the aſtringent claſs, are calculated for the latter ſtage of gonorrhæa. The ammoniated one is conſidered by Mr. Foot, and recommended as a remedy preferable to all others of this nature. Practitioners ſhould be cautious in the uſe of aſtringents: they ſhould be firſt introduced in very ſmall quantity, and have them gradually increaſed: indeed, till the inflammation is conſiderably abated, they are ſcarcely at all admiſſible, for much miſchief has been done by their too early adminiſtration. The following has been highly uſeful in that ſymptom called phimoſis, which has been ſupported by ulcerations within the prepuce.

CUPRI VITRIOLATI COMPOSITA INJECTIO. *Compound Injection of vitriolated Copper.*

℞ Cupri vitriolati g. vj. aquæ diſtillatæ ʒ iv. aquæ lithargyri acetati g. xx. m. Cupro vitriolato prius ſoluto, adjiciatur lithargyrum acetatum, et inter præputium, et glandem penis injiciatur, & pro ratione effectus caute repetatur.

CUPRI VITRIOLATI PILULÆ. *Pills of vitriolated Copper.*

℞ Cupri vitriolati g. xx. Olibani, extract. cinchonæ, ää ʒ ij. ſyr. ſacch. q. ſ. ut fiant pilulæ quadraginta. Doſis, ab una ad quatuor indies. Theſe are calculated to remove gleets, and ſometimes become of advantage in the latter ſtage of gonorrhæa.

CUPRI VITRIOLATI CAMPHORATA AQUA, vel AQUA CAMPHORATA BATANEA. *Camphorated water of vitriolated Copper.*

℞ Cupri vitriolati, bol. gallici. ää ʒ ſs. camphoræ ʒ j. aquæ ferventis ℔ iv. Adjiciatur aqua ingredientibus aliis, et quando frigida fiat, per chartam colatur. This in a diluted ſtate is chiefly employed as an eye-water; but it may be ſerviceable, applied to foul ulcers.

CUPRUM AMMONIACUM. AMMONIACAL COPPER. Phar. Edin.

Take of pureſt blue vitriol, two parts; volatile alkali of ſal ammoniac, three parts: rub them briſkly in a glaſs mortar, till the effervescence is finiſhed, and they run calmly into a violet-coloured maſs, which is to be rolled up in a piece of bibulous paper, and exſiccated, firſt upon a chalk-ſtone, and afterwards with a gentle heat, then put up for uſe in a cloſe vial; this is a very active medicine, uſed for the ſame purpoſes and in the ſame manner as VITRIOLUM CŒRULEUM, which ſee.

CUR. POST. An abbreviation of curæ poſteriores.

CURA AVENACEA. A decoction of oats and ſuccory roots, in which a little nitre and ſugar were diſſolved, was formerly uſed in fevers, and was thus named.

CURCAS. See RICINOIDES, under CATAPUTIA MINOR.

CURCUMA. TURMERIC; alſo called *crocus Indicus, terra marita, cyperi genus ex India, cannacorus radice crocea, manjella, kua, cypira, kaha*, and by the Indians *borri-borri*: the Portugueſe call it *ſaffran de terra*; the name *curcuma* is Arabian: the Arabians call every root of a ſaffron colour by this name, *curcuma.* There are two ſpecies, the long and the round-rooted, but the firſt is the beſt, and the ſort in uſe. It is the CURCUMA LONGA, or CURCUMA INDICA *foliis lanceolatis, nervis lateralibus numeroſiſſimis.* CLASS, MONANDRIA; ORD. MONOGYNIA. LINN. Gen. Plant. 6. INDIAN LONG-ROOTED TURMERIC.

The root is the only part in uſe; it is ſmall, tuberous, and knotty; it is brought from the Eaſt Indies; externally it is greyiſh-coloured, but internally it is of a deep lively yellow, which tends to red: a longiſh and a round ſort is mentioned by ſome authors; but the firſt only is brought to us.

It hath a ſlight aromatic and bitteriſh taſte, and ſomewhat diſagreeable ſmell. It gives out its virtues both to water and to ſpirit. By diſtillation with water, a ſmall quantity of eſſential oil is obtained; and from the remaining decoction a bitter extract is formed by evapo-

ration. The ſpirituous extract retains nearly the whole virtue of the root.

It has been thought a powerful remedy in obſtructions of the viſcera, particularly the abdominal; and alſo much uſed in icteric and uterine diſorders. The doſe may be from a ſcruple to a dram. Though the uſe of this root has been particularly recommended by ſeveral practical writers, in the jaundice, or other viſceral obſtructions, it is now very rarely uſed. The powder is often mixed with yellow peas, ground fine: the roots ſhould be choſen of the largeſt ſize, freſh, compact, heavy, not eaſy to break, of a lightiſh yellow without, and a deep reddiſh yellow within.

It is chiefly conſumed by the dyers. See Lewis's Mat. Med. Neumann's Chem. Works.

CURIMENTOS. So the Portugueſe call ſome pains in the limbs, which are relieved by a warm bath made with an aſtringent bark, produced in the Brazils.

CURMI. Dioſcorides ſays it is a drink made of barley, which is uſed inſtead of wine: ſuch a liquor is uſed in Iberia and Britain, which is prepared of wheat: this is ale.

CURSUMA, or CURTUMA. See CHELIDONIUM MINUS.

CURTA. See COLOBOMATA.

CURURU. See BUFO.

CURURU APE. A ſcandent tree which grows in Brazil, and bears pods with ſeeds like beans: theſe ſeeds deſtroy fiſh.

CURUTU PALA. A ſhrub which grows in Malabar. The bark of the root boiled in water cures a diarrhœa; boiled and taken with it, cures a dyſentery.

CUSCUTA, called alſo *caſſutha*, *cuſcuta* major, *caſſuta*, *epithimum*, DODDER, and DODDER of THYME. The CUSCUTA EUROPÆA, Linn. It is of the number of plants called paraſitical; it hath no leaves, grows on *thyme*, and conſiſts of a number of ſlender juicy filaments, producing here and there ſmall heads of white or reddiſh flowers, which are followed by roundiſh capſules full of minute ſeeds. A large kind, known by the name of HELL-WEED, is common in heaths, upon furzes, nettles, &c. this *hell-weed* deſtroys the vegetables which afford it nouriſhment, whence its name; it is alſo called *diaboli inteſtina*, the DEVIL'S GUTS.

Dodders are ſuppoſed to partake of the virtues of the plant on which they grow. They are hardly known in practice, but recommended as reſolvents, deterſives, and diuretics.

Dodders are found on almoſt all plants. Raii Hiſt.

CUSPIDATUS. POINTED, (from cuſpis a point or ſpear). In botany, the term regards the apex only, when the leaves have the apex ſharp like a ſpear, or terminating in a briſtly point. Some of the teeth are called *cuſpidati*. See CANINI DENTES.

CUSPIS. Properly the point of a ſpear; but it is applied to the *glans penis*. It is alſo the name of a bandage.

CUSTOS OCULI. An inſtrument to preſerve the eye in an operation.

CUTAMBULI. A name of a ſort of worms either under the ſkin or upon it, which by their creeping cauſe uneaſineſs and pain.

CUTANEUS MUSCULUS. See PLATYSMA MYOIDES.

CUTANEUM OSSIS COCCYGIS LIGAMENTUM. It goes out anteriorly from the extremity of the os coccygis; is ſlender, and divides into two portions at the orifice of the anus, which run into the membrana adipoſa, are inſerted in the ſkin on each ſide of the anus by a kind of expanſion, and continue to divaricate: they are loſt on the two ſides of the perinæum.

CUTANEUS. See SPHINCTER ANI. There is alſo a nerve ſo called. See CERVICALES.

CUTANEUS INTERNUS NERVUS. It riſes from the union of the ſeventh cervical, and firſt dorſal pairs, runs over the other brachial nerves, and paſſes down on the inſide of the arm, between the muſcles and integuments; it divides into two branches, which accompany one another as far as the inner condyle on one ſide of the vena baſilica, being covered by the ramus medianus of that vein; then runs down towards the wriſt, where it ſpreads, and on the beginning of the palm of the hand. The other branch paſſes backward along the integuments, and down to the little finger.

CUTCH. See TERRA JAPONICA.

CUTICULA. The SCARF-SKIN. The Greeks call it *epidermis*, becauſe it is placed upon the true ſkin as a covering. It is as large as the true ſkin, and more compact; it is full of pores for the evacuation of what tranſpires through it from the body, though the beſt glaſſes do not enable us to diſcern them: it hath neither blood-veſſels nor nerves; therefore it is void of ſenſe. Dr. Hunter ſays, it is an organized body, though its organization cannot be demonſtrated. Leuwenhoeck aſſerts much with reſpect to the pores which he ſays he diſcovered in it; but to what he hath ſaid, it ſufficeth to refer the reader.

The integuments, or the univerſal covering of the body, are the *cuticle*, the rete mucoſum, the cutis, and the membrana cellularis; beſides theſe, the old anatomiſts reckon the membrana communis muſculorum, which is not now reckoned in the number; and the panniculus carnoſus, which is only found in brutes. The rete mucoſum is added by the moderns.

The whole ſurface of the ſkin is covered by the rete mucoſum, and the rete mucoſum with the *cuticle*, ſo that the *cuticle* is the moſt external.

The *cuticle* does not, in general, extend ſo far as the ſkin does, though upon the belly it ſtretches conſiderably, without loſing its thickneſs. Its origin is obſcure, and its generation ſurpriſingly ſudden. Friction looſens it, but ſoon a new ſtratum ariſes.

The *cuticle* is continued, not only over all the external parts of the body, but alſo in all the cavities thereof, where the air can arrive; as in the mouth, œſophagus, aſpera arteria, inteſtines, &c. where it is called the *epithelium*; in theſe places there is no *cutis*, but there are innumerable papillæ. No nerves nor veſſels can be demonſtrated to exiſt in it.

In examining the pores, the *cuticle* ſeems to inſinuate itſelf into them, to complete the excretory tubes of the cutaneous glands. The foſſulæ of the hairs have likewiſe the ſame productions of the *cuticle*, and it ſeems to give a ſort of coat to the hairs themſelves.

The beſt method of ſeparating the *cuticle* for examination is to macerate it in water.

The *cuticle* is a medium betwixt the ſkin and the ſubjects of feeling, and moderates the impreſſions, which, without it, would be too painful. It alſo moderates the perſpiration, which, without it, would be too copious.

The colour of the cutis differs in different perſons, and alſo in different parts of the ſame perſon; but it is owing to the difference in the rete mucoſum that complexions are ſo oppoſite to one another. See the Obſervations of Dr. Monro of Edinburgh on the Epidermis, in the Edinburgh Med. Eſſays.

In the ſecond volume of the Medical Muſeum, is a remarkable inſtance of a young man loſing the uſe of his hands, by the *cuticle* there being thickened and hardened in an extraordinary degree. He was a dyer, and by frequently cleaning braſs wire in the mixture which is uſed for dying Saxon colours, which conſiſts of the oil of vitriol, tartar, alum, &c. this complaint was gradually produced. His hands were quite ſtiff from the hardneſs of the *cuticle* on their palms, and on the inſide of the fingers; the *cuticle* there appeared like parchment full of chaps; and on endeavouring to ſtraighten the fingers by force, blood ſtarted from every joint. As the acid ſeemed to contribute much to the diſeaſe, the following emollient liniment was ordered. ℞ ol. olivar. ℥ ii. aq. kali, ℥ ii. m. f. linim. With this he rubbed his hands frequently, particularly before going to bed; and to prevent the liniment from being too ſoon rubbed off, he wore gloves. In about four days the ſkin ſeemed a little ſoftened, and his fingers did not ſuffer ſo much by endeavouring to ſtretch them out. He complained that the liniment occaſioned much ſmarting, whence the following was directed with a view to abate the acrimony of the alkaline ſalt; ℞ ol. olivar. ℥ ii. aq. kali, ℥ i. vitel. ovorum, No. ii. f. linim. This, uſed as the other, in three days was leſs troubleſome, and produced further evidence of relief: the hardened *cuticle* began to peel off, and a new flexible one appeared underneath; many of the chaps were healed, and he began to have ſome uſe of his fingers. He continued the laſt preſcribed liniment about two months; and then, to prevent a relapſe, he uſed the following. ℞ axung. porcin. ℥ ii. vitellum unius ovi, ol. lavend. gut. v. m. f. liniment. With this he rubbed his hands every night at bed-time; and on continuing it about a month, he obtained a perfect cure. Except three doſes of purging phyſic, he took nothing inwardly as a medicine, during the cure.

CUTICULARIS MEMBRANA. See DURA MATER.

CUTICULOSUS. See SPHINCTER ANI.

CUTILIÆ. Certain cold fountains in Italy, mentioned by Celſus and Pliny, which were uſed in baths.

CUTIO. See ASELLI.

CUTIS. The SKIN. It is called by HERODOTUS, *anthrope*. It is a ſtrong, thick, univerſal covering of the external parts of the body, immediately above the adipoſe membrane. It is compoſed of a cloſe texture of fibres of various kinds, and alſo of veins and arteries, variouſly diſpoſed: where there are large orifices, it terminates by being gradually loſt. Its inner ſurface is moulded upon the outer ſurface of the membrana adipoſa, whoſe membranous part being produced, forms the *ſkin*.

The *ſkin*, on its outſide, is unequal: this is occaſioned by the miliary glands, and the bulbs of the hair. It is naturally contracted; but when it is ſwelled, it is ſmooth. Upon its ſurface we obſerve the papillæ pyramidales, which are longer in ſome parts than in others, as in the fingers, where they are called villi, and appear in rows, each having two ranks contiguous; theſe are the organs of touch. Oppoſite to the joints, the *ſkin* is formed into plicæ, to admit of a free motion. Its whole ſurface, outwardly, is covered with the rete mucoſum, and the cuticle.

The *ſkin* is thickeſt between the ſhoulders, and on the back part of the neck. Dr. Hunter ſays, that when the *ſkin* is once deſtroyed, it is never regenerated, but the edges ſtretch conſiderably to form a covering: after that, a cicatrix, which is hardened fleſh, completes the healing.

The outer ſurface is furniſhed with ſmall eminences, called *papillæ pyramidales*, and the inner ſurface with the miliary glands. Fewer papillæ appear on the *ſkin* of the belly than elſewhere; the anterior portion of it is not only thinner and more compact than the poſterior, but it hath this likewiſe peculiar to it, that it may naturally be very much increaſed in breadth, to an extraordinary degree, without loſing any of its thickneſs, in proportion to what it gains in breadth; and it is generally more difficult to pierce the *ſkin* on the belly with pointed inſtruments, than on the back.

Though the beſt glaſſes cannot aſſiſt us to ſee pores in the cuticle, the naked eye can diſcern them in the *ſkin*, which is the ſeat of many diſeaſes: and on theſe Dr. Turner has profeſſedly writ. See his Diſeaſes of the *Skin*.

CUTT. See TERRA JAPONICA.

CYAMOS ÆGYPTIACUS. See FABA ÆGYPTIACA.

CYAMUS. See FABA. It alſo ſignifies a wood-louſe in the form of a bean. See ASELLI.

—— ORIENTALIS major moſchatus, i. e. SWEET-SULTAN, or SULTAN-FLOWER, is ſomewhat cordial.

CYAR. Properly, the eye of a needle; but it is uſed to ſignify the orifice of the internal ear See AURIS.

CYASMA. Brown ſpots in the lips, forehead, and hands of pregnant woman.

CYATHISCUS, from κυαθος, *a cup*. The hollow part of a probe, formed in the ſhape of a ſmall ſpoon, as in an ear-picker.

CYATHUS, κυαθος, *a cup*, from the verb χεω, *to pour out*. It was a common meaſure among the Greeks and Romans, both of the liquid and dry kind. It was equal to an ounce, or the twelfth part of a pint. The *ſextans* was two ounces; the *quadrans*, three ounces; the *triens*, four ounces; theſe three were ſo named, from the portion of a pint they contained, being the ſixth, the fourth, and the third part of a pint, or twelve ounces; the *quincunx*, five ounces; the *ſemis*, ſix ounces; the *ſeptunx*, ſeven ounces; the *bes*, eight ounces; the *dodrans*, nine ounces; the *dextans*, ten ounces; the *deunx*, eleven ounces; the *as*, *ſextarius*, or *cotula*, twelve ounces. The *cyathus* was made with a handle like our punch-ladle. The Roman topers were uſed to drink as many *cyathi* as there were Muſes, nine; alſo as many as there were letters in their patron's name. Thus, they had modes of drinking, ſimilar to the modern health-drinking, or toaſting. Pliny ſays, that the *cyathus* of the Greeks weighed ten drams, and Galen ſays the ſame; though elſewhere he ſays, that a *cyathus* contains twelve drams of oil, thirteen drams and one ſcruple of wine, water, or vinegar, and eighteen drams of honey. Galen ſays, that, among the Veterinarii, the *cyathus* contained two ounces.

The modern *cyathus* is ℥ j. ß.

CYBITOS. See CUBITUS.

CYBOIDES. See CUBOIDES.

CYCAS CIRCINALIS ſeu INDICA. See PALMA JAPONICA.

CYCEON, from κυκαω, *to mix*; alſo *cinnum* or *cinnus*. It is a mixture, of the conſiſtence of pap, made with wine, honey, flour, and cheeſe. This name was given to ſome ptiſans; alſo a kind of ſallad in which cheeſe was mixed. See alſo ŒNUS ANTHINOS.

CYCIMA. See LITHARGYRUM.

CYCLAMEN.
—— EUROPÆUM.
CYCLAMENUS.
} See ARTHANITA.

CYCLISCUS, from κυκλος, *a circle*. See *Trochiſci*. alſo an inſtrument formerly uſed in the operation of the trepan.

CYCLOPION. The white of the eye from κυκλοω, *to ſurround*, and ωψ, the *eye*. See ADNATA.

CYCLOS A CIRCLE. See BUCCÆ and ORBITA.

CYCLUS METASYNCRITICUS. It is a long protracted courſe of remedies, perſiſted in with a view of reſtoring the particles of the body to ſuch a ſtate as is neceſſary to health.

CYCNARION. A collyrium mentioned by Galen and P. Ægineta. It was ſo called becauſe its colour reſembled that of a ſwan.

CYDAR. See STANNUM.

CYDONATUM. A preparation of quinces with an addition of aromatics, deſcribed by P. Ægineta.

CYDONIA. The QUINCE-TREE Alſo called *cotonea*, *mala cotonea majora et minora*, *malus cydonia*. It is the PYRUS CYDONIA, or PYRUS CYDONIA SYLVESTRIS, *fol. integerrimis, floribus ſolitariis*. CLASS, ICOSANDRIA; ORD. PENTAGYNIA. LINN. Gen. Plant. 626. The WILD QUINCE-TREE.

Botaniſts enumerate five ſpecies.

The *quince-tree* is low, a native of the rocky banks of the Danube, and is common in our gardens. Its fruit reſembles in ſhape ſome ſorts of round pears; it hath an agreeable and ſtrong ſmell, an auſtere acid taſte; its expreſſed juice, taken in ſmall quantities, is cooling, reſtringent, and ſtomachic, is uſeful in nauſeas, vomitings, nidorous eructations, and ſome kind of alvine fluxes; by boiling, it loſes its aſtringency. The ſeeds abound with a mucilaginous ſubſtance, which they give out to boiling water. One dram of them makes ſix ounces of mucilage, about the conſiſtency of the white of egg; this has been recommended in aphthous affections, and excoriations of the mouth and fauces; though, that of the ſimple gums appears more efficacious. It is the moſt agreeable of all the mucilages, but is apt to become mouldy in a ſhort time.

The London College directs the following:

Mucilago Seminis CYDONII MALI. *Mucilage of* QUINCE SEED.

Take of *quince* ſeed, a dram; diſtilled water, eight ounces; boil with a gentle fire, till the water thickens; then ſtrain through a linen cloth.

Formerly a ſyrup was made of the juice of the fruit, and a conſerve, called MARMALADE, *jelly*, *mixa cydoniorum*, or *diacydonium*; but it is now an article in the confectioners' buſineſs only. See Lewis's Mat. Med. Raii Hiſt.

CYDONIA EXOTICA. See COVALAM.

CYEMA. See CUEMA.

CYGNUS REGINÆ, A collyrium deſcribed by Actius.

CYLICHNE. A ſmall veſſel or box for holding medicines; a GALLIPOT, or PILL-BOX.

CYLINDRUS. The CYLINDER. A tube, equal in diameter from top to bottom. The fruits of plants are termed cylindrical, when they reſemble a column. Martyn ſays, it is applied to ſtems, and ſome leaves, which are round, that is, without angles; but many times longer than they are thick. But this is more properly expreſſed by Columnar, becauſe they are not of the ſame diameter from top to bottom. The term is applied to the calyx, to the ſtyle, and to the ſpike; ſo is it to maſſes of plaſter. See MAGDALEONES.

CYLLOS, from κυλλοω, *to make lame*. In Hippocrates, it is one affected with a kind of luxation which bends outwards, and is hollowed inward. Such a defect in the tibia is called *cylloſis*, and the perſon to whom it belongs is called, by the Latins, *varus*, or *Blæſſus*, and is oppoſed to *valgus*.

CYLLOSIS. See CYLLOS.

CYMA,

CYMA, from κυμα, *fœtus*. It properly ſignifies a ſprout or tender ſhoot, particularly of the cabbage. LINNÆUS explains it to be an aggregate flower, compoſed of ſeveral florets, ſitting on a receptacle, producing all the primary peduncles from the ſame point, but having the partial peduncles ſcattered or irregular; all faſtigiate, or forming a flat ſurface at top. The cyme, is either naked or with bractes. Flowers diſpoſed in a cyme, are called cymoſe flowers: hence Cymoſæ, the ſixty-third of Linnæus's natural orders in Philoſophia Botanica.

CYMBÆ Os. See SCAPHOIDES Os.

CYMBALARIA. alſo called *Linaria*. IVY-LEAVED TOAD-FLAX, or IVY-WORT. It grows on old walls in Italy and Switzerland. It hath the ſame virtues as the navel-wort. See ANDROSACES.

CYMBOLARIS CARTILAGO. See CARTILAGO CRICOIDES.

CYMBIFORME, from *cymba, a boat*. See SCAPHOIDES.

CYMIA. See CARORA.

CYMINUM. See CUMINUM.

CYMOSÆ. See CYMA.

CYNANCHE. See ANGINA.

——— ANGINOSA. } The MUCOUS QUINSY.

——— GANGRÆNOSA, PHARYNGÆA, MALIGNA, ULCEROSA. See ANGINA.

—— ŒSOPHAGÆA. See ANGINA, No. 4, and PHARYNGÆA CYNANCHE.

—— PAROTIDÆA, alſo *angina externa*, MUMPS. It is a ſpecies of quinſy, and called alſo *catarrhus bellinſulanus, aurles, orcillons, oſſervazioni*. Dr. Cullen names it *cynanche parotidæa*; which he defines a cynanche, with a conſiderable external ſwelling of the parotid, and maxillary glands; reſpiration, and deglutition being ſcarcely impeded; attended for the moſt part with a mild inflammatory fever. This name was given to a diſorder which manifeſted itſelf by a ſlight fever, ſoon after the appearance of which, the face, the neck, and particularly the throat, were conſiderably ſwelled, and of a ſomewhat deeper colour than a damaſk roſe, but the tumor rarely extended to the eyes. This ſwelling was chiefly external, and ſometimes ſo increaſed in a few days, as to obliterate the features; and yet this quick and extraordinary diſtenſion of the parts was rarely attended with pain.

This diſorder was of the inflammatory kind; it chiefly affected the young and the poor; it was very rarely mortal, and ſeldom terminated in an abſceſs, but gave way to general antiphlogiſtic methods.

Sometimes the tumor ſubſided in three or four days, and from the face was tranſlated in men to the teſticles; but this circumſtance required no alteration from the general method of cure, nor did the ſwelling in the teſticles ever ſuppurate.

The patients bore bleeding, purging, and nitrous medicines very well. In ſome a thickneſs and hardneſs remained upon the parotid and maxillary glands, after the patient was very well in all other reſpects; theſe yielded to ſome doſes of calomel, with gentle purging, the affected part being kept warm, and the patient continued to a ſuitable regimen. Sometimes a mild mercurial ointment was uſeful. See Gooch's Caſes and Remarks, p. 74—76, and Appendix to the ſame, p. 13, &c. Cullen's Firſt Lines, edit. 4. vol. i. p. 303.

—— PHARYNGÆA. See ANGINA, No. 4, and PHARYNGÆA CYNANCHE.

—— STRIDULA. See SUFFOCATIO STRIDULA.

—— TONSILLARIS. See ANGINA.

—— TRACHEALIS. See SUFFOCATIO STRIDULA.

CYNANCHICA MEDICAMENTA. Medicines appropriated to the cynanche.

CYNANTHEMIS. See CHAMÆMELUM FŒTIDUM.

CYNANTHROPIA, from κυων, *a dog*, and ανθρωπος, *a man*. A kind of melancholy delirium, in which the perſons affected believe they are changed into dogs, and in conſequence thereof endeavour to act like them. Or, according to ſome, the *hydrophobia*.

CYNARA SCOLYMUS. See CINARA.

CYNCHNIS. A ſmall veſſel to hold medicines in.

CYNICUS. CANINE. Certain convulſions, called *cynic ſpaſms*. See SARDONICUS RISUS.

CYNIPHES, in Helmont, ſignifies FLIES or GNATS.

CYNNIA. See CARORA.

CYNOBOTANE. See CHAMÆMELUM FŒTIDUM.

CYNOCOCTONUM. See ACONITUM.

CYNOCOPRUS, from κυων, *a dog*, and κοπρος, *dung*. See ALBUM GRÆCUM.

CYNOCRAMBE. See MERCURIALIS. SYLV. and HIPPOMANES.

CYNOCTONUM. See ACONITUM.

CYNOCYTIS. See CYNOSBATOS.

CYNODECTOS. Bitten by a mad dog.

CYNODES. CANINE.

CYNODESMION, from κυων, *membrum virile, the yard of a man*, and δεω, *to tie*. A ligature by which the prepuce is bound upon the glands. Sometimes it ſignifies the lower part of the prepuce.

CYNODONTES, from κυων, *a dog*, and οδους, *a tooth*. See CANINI DENTES.

CYNOGLOSSUM. HOUND'S-TONGUE. Botaniſts enumerate nine ſpecies.

CYNOGLOSSUM MAJ. VULG. *Canina Lingua*. GREATER HOUND'S-TONGUE. It is the CYNOGLOSSUM OFFICINALE. Linn.

It is a biennial plant; produces, the firſt year, large, ſoft, tongue-ſhaped, long, pointed leaves: the ſecond year, a thick branched ſtalk, with pointed leaves joined to it, without pedicles: on the tops of the branches are dark purple flowers, which are followed by four flat ſeeds: the root is oblong, and of a dark brown or blackiſh colour on the outſide, but white within. It grows in ſhady places, and flowers in June.

The roots have a rank, but not very ſtrong ſmell, like thoſe of the narcotic plants, which in drying is moſtly diſſipated; but thoſe that happen to grow on dry ground have very little ſmell.

The medical effects, if any, are very little known.

CYNOLOPHA. Pollux calls theſe certain aſperities of the vertebræ, and beginning of the ſpine of the back.

CYNOLYSSA. See LYSSA, and HYDROPHOBIA.

CYNOMORON. See HIPPOMANES.

CYNOMOJA. See PSYLLIUM.

CYNOPTICON. See DACNERON.

CYNOREXIA. See BOULIMUS.

CYNORRHODON. } from κυων, *a dog*, and ῥοδον, *a*
CYNOSBATOS. } *roſe*. Alſo called *caninus ſentis, canirubus, cynocytis, roſa ſylveſtris vulgaris, roſa ſylveſtris inodora*. It is the ROSA CANINA, *germinibus ovatis, pedunculiſque glabris, caule petioliſque aculeatis*. CLASS, ICOSANDRIA; ORD. POLYGYNIA. LINN. Gen. Plant. 631. The DOG-ROSE, WILD BRIAR, or HIP-TREE. It is one of the largeſt plants of the roſe-kind, a native of Britain, grows wild in hedges, and flowers in June. The fruit contains a four-ſweetiſh pulp, which is made into a conſerve, as follows:

Conſerva Cynoſbati. *Conſerve of the* HIP.

Take of the pulp of ripe *hips*, one pound; of double refined ſugar, twenty ounces; mix them into a conſerve.

The *hips* are to be ſplit, and the hairy ſeeds carefully picked out; and then, when the fruit is mellowed by ſtanding a few days, it muſt be paſſed through a hair ſieve, and to the pulp the ſugar muſt be added. Ph. Lond. 1788. If this caution is not obſerved in pulping the fruit, the rough prickly matter encloſing the ſeeds, may be retained in the conſerve; a ſmall portion of which will occaſion uneaſineſs at the ſtomach, an itching about the anus, and ſometimes vomiting. Though formerly it was ordered in large doſes, to correct acrid bile, ſharp urine, heat in the ſtomach, and eſteemed uſeful in many diſorders, as dropſies, calculous complaints, dyſenteries, hæmorrhages, &c. it is now conſidered as a pleaſant, cooling reſtringent, agreeable to the taſte, and principally uſed as a vehicle to more efficacious remedies. There is alſo a reddiſh-green, ſpongy, hairy excreſcence, made by ſmall ichneumon flies, on the ſtalks of this tree, called *bedeguar*, which is ſaid to be poſſeſſed of, and celebrated for its aſtringent power; but it is yet not ſufficiently tried with us, to ſpeak with great certainty.

CYNOSORCHIS. See ORCHIS.

CYON. See CANIS. Alſo the inferior parts of the penis and prepuce. See PENIS.

CYOPHORIA, from κυημα *the fœtus*, and φερω, *to carry*. See GESTATIO.

CYPARISSUS. See CUPRESSUS.

CYPERI GENUS EX INDIA. See CURCUMA.

CYPEROIDIS GRAMEN and CYPERI. See GRAMEN CYPEROIDES.

CYPERUS. A plant with graſs-like leaves, and triangular ſtalks, bearing tufts of flowers on their top, which are followed by a triangular ſeed.

—— LONGUS, Linn. CYPERUS ODORATUS *radice longa. Cyperus* panicula ſparſa ſpecioſa. The ordinary ſweet *cyperus*, or ENGLISH GALANGALE. It hath a long ſlender root, crooked and knotted, on the outſide of a blackiſh-brown colour, and white within; it grows in marſhy places, and thoſe in England are as good as the foreign ones.

The root hath an agreeable aromatic ſmell, and a bitteriſh taſte; both water and ſpirit take up its virtues; by diſtillation a very ſmall quantity of eſſential oil is obtained. This long root is ſomewhat aromatic, but moſt noticed for its aſtringency.

—— ROTUNDUS. CYP. CRETICUS, vel SYRIACUS. ROUND-ROOTED CYPERUS. This plant hath ſeveral roundiſh roots, about the ſize of wallnuts, connected by fibres, rough, and ruſty-coloured on the outſide, of a yellow white within. It is a native of the Eaſt Indies, and grows wild in ſome other countries. The roots have the ſame ſmell and taſte as the long ſort have. This ſort is moſt noted for its aroma, but they may be uſed indifferently. Raii Hiſt.

—— AMERICANUS. See SANCTÆ HELENÆ RADIX.

—— LONGUS ODORUS, &c. See CONTRAYERVA.

—— NILOTICUS vel *Syriacus*. See PAPYRUS.

CYPHI. A compoſition of ſixteen ingredients, ſuch as honey, raiſins, cardamom ſeeds, &c. It was much uſed in the Egyptian ſacrifices, and hence the troches, called *trochiſci cyphos*.

CYPHOMA. } From κυφόω, *to bend*. A kind of gib-
CYPHOSIS. } boſity, an incurvature of the ſpine of the back, when the vertebræ incline preternaturally outwards.

CYPIRA. See CURCUMA.

CYPRESSUS. } See CUPRESSUS.
CYPRINUM OL. }

CYPRINUS. See CARPIO.

CYPRUS. } See LIGUSTRUM INDICUM.
CYPRUS DIOSCORI PLINII. }

CYPSELE, or CYPSELIS. See CERUMEN AURIS.

CYRÆNIA. In Rulandus, it ſignifies the fæces of ſaffron infuſed in oil.

CYRBASIA. Properly the *tiara*, or cap, worn by the Perſian monarchs. Hippocrates uſes this word in his Treatiſe of the Diſeaſes of Women, in deſcribing a ſort of covering which he directs for the breaſts.

CYREBIA. The huſks of barley, or of other corn, which fall off while they are torrefying, or when ſoaked in water.

CYRENAICUS SAL. See AMMONIACUS SAL.

—— SUCCUS. It is applied to the juice of the laſerpitium of the ancients, from the country where it moſt flouriſhed, by Scribonius Largus, Paulus Ægineta, and ſome others, and by Sanctorius: it is alſo taken notice of by the ſame name, in his Aphoriſms. See ASA FŒTIDA.

CYRONES. See PHTHIRIASIS.

CYRSEON. See ANUS.

CYRTOIDES. } GIBBOSITAS. Any preterna-
CYRTOMA. } tural tumor or gibboſity, from κυρτός, *hump-backed*. In Vogel's Noſology, it ſignifies a particular flatulent tumor of the belly.

CYRTONOSUS. See RACHITIS.

CYSSAROS, κυσός, the *breech*. The ANUS, or RECTUM.

CYSSOTIS. See PROCTALGIA.

CYSTEOLITHOS, from κύστις, *the bladder*, and λίθος, *a ſtone*. See CALCULUS.

CYSTICÆ ARTERIÆ. The *cyſtic arteries*. The hepatic artery advances behind the ductus hepaticus towards the veſicula fellis, to which it gives two principal branches. Theſe are called *arteriæ cyſticæ*. See HEPAT. ARTERIA.

CYSTICÆ VENÆ. A branch from the vena portæ ventralis. They run along the veſicula fellis, from its neck to the bottom; and as they are often only two in number, they are called *cyſticæ gemellæ*.

CYSTIRRHAGIA. Diſcharge of the blood from the urinary bladder. It is always a ſymptomatic diſorder.

CYSTICAPNOS AFRICANA SCANDENS. See FUMARIA ALBA.

CYSTICUS DUCTUS, or DUCTUS VESICULARIS. The neck of the gall-bladder is formed by the contraction of its ſmall extremity, and this neck bending afterwards, produces a narrow canal called the *ductus*, and *meatus cyſticus*. It conveys the gall from the gall-bladder to the duodenum.

CYSTICA ISCHURIA. See ISCHURIA. Var. 3d ſpecies.

CYSTIDES. Encyſted tumors, and thoſe whoſe ſubſtance is included in a membrane.

CYSTIS. A BAG. It is applied to any receptacle of morbid humours, κύστις, *a bag*. See CAPSULA. Alſo to the VESICA URINARIA which ſee. Hence a number of the complaints of the bladder are derived from this term compounded with ſome other word, as *cyſtitis*, cyſtocele, cyſtorrhæa, &c. &c.

CYSTINX. A ſmall bladder.

CYSTITIS, CYSTIPHLOGIA. See INFLAMMATIO VESICÆ.

CYSTOLITHICA ISCHURIA. A ſuppreſſion of urine from a ſtone in the bladder.
CYSTOPHLEGICA. A ſuppreſſion of urine from a palſy in the bladder. } See ISCHURIA. Var. 3d. ſpecies.

CYSTOCELE. A hernia formed by the protruſion of the urinary bladder.

—— VAGINALIS. See COLPOCELE.

CYSTOPTOSIS. The inner membrane of the bladder protruding through the urethra.

CYSTOPHLEGMATICA ISCHURIA. A ſuppreſſion of urine from abundance of mucus in the bladder.
CYSTOSPASTICA. A ſuppreſſion of urine from a ſpaſm in the ſphincter of the bladder.
CYSTOTHROMBOIDES. A ſuppreſſion of urine from grumous blood in the bladder.
CYSTOSPYICA. A ſuppreſſion of urine from purulent matter in the bladder.
CYSTOPROCTICA. A ſuppreſſion of urine from pain in the bladder, cauſed by indurated fæces, wind, inflammation, abſceſs, &c. in the rectum. } See ISCHURIA. Var. of the 3d. ſpecies.

CYSTOTOMIA. A cutting of the bladder in the operation for the ſtone. See LITHOTOMIA.

CYTHION. A collyrium mentioned by Celſus.

CYTINIFORME. } Generally ſignify the flower of
CYTINUS. } the true pomegranate; but ſometimes uſed to ſignify the cups of flowers which expand after the ſame manner.

CYTINUS HYPOCISTIS. See HYPOCISTIS.

CYTISO-GENISTA. See GENISTA,—*ſcoparia*, &c. ſee CAPPARIS.

CYTISUS ALPINUS, alſo called *anagyris non fœtida*. BEAN TREFOIL TREE. The leaves are ſaid to cool and diſcuſs; a decoction of them is diuretic.

—— SPINOSUS, alſo called *aſphalathus*, &c. *acacia altera trifolia*, cytiſoſpartium aculeatum. TREFOIL ACACIA. Its juice is aſtringent.

—— SCOPARIUS VULGARIS. See GENISTA.

CYZICENUS. An epithet of a plaſter deſcribed by Galen, and commended for ulcers and wounds of the nervous parts.

D.

DAM

D. See VITRIOLUM.

DABURI. See ACHIOTL.

DACETON, from δακνω, *to bite*. An epithet for ſuch animals as hurt by biting.

DACHEL. See DACTYLUS.

DACNERON, from δακνω, *to bite*, BITING. An epithet for a collyrium in Trallian, alſo called *oxydorcia*, and *cynopticon*.

DACRYDIUM. See DIAGRIDIUM.

DACRYODES, from δακρυ, *a tear*. In Hippocrates it is a fanious ulcer.

DACRYOMA. A coalition of one or more of the puncta lacrymalia.

DACRYOPŒOS. An epithet for ſuch things as cauſe the tears to flow, ſuch as onions, &c.

DACTYLETUS. See HERMODACTYLUS.

DACTYLETHRA. A machine ſhaped like a finger, and introduced into the ſtomach to excite a vomiting

DACTYLION. WEB-FINGERED.

DACTYLIOS. See TROCHISCI.

DACTYLON RADICE REPENTE. See GRAMEN DACTYLON.

DACTYLOTHECE. So Paré calls an inſtrument which he uſed in ſome caſes of injury done to the fingers.

DACTYLUS. DATE. The fruit of the dactylus palmula, which ſee; and alſo DIGITUS.

—— PALMULA, called alſo *palma major*, *parma dactylifera*, *dachel*, the GREAT PALM-TREE, or DATE-TREE. It is cultivated in the ſouthern parts of Europe; its fruit is oblong, larger than an acorn, and includes a ſtone. The beſt *dates* come from Tunis. Chuſe thoſe that are ſoft, large and not much wrinkled, of a reddiſh-yellow colour on the outſide, and a whitiſh membrane between the fleſh and the ſtone. They are moderately aſtringent, yet are eaten as food in Africa. GALEN uſed to call the beſt dates in Syria *caryoti*.

DÆDALUS. QUICKSILVER. See ARG. VIVUM.

DÆDION *tædula*. A diminutive of *dais*, *tæda* a TORCH. It is a kind of peſſary.

DÆMONIS. ORDURE.

DÆMONOMANIA, alſo *dæmonia*. The melancholy which is ſuppoſed to ariſe from poſſeſſions of demons, &c.

DAIS. See TÆDA.

DAITIDES. Galen ſays it means great torches; but by a metaphor it ſignifies heads of garlic. See ALLIUM.

DALE. An abbreviation of Sam. Dalei, M. L. PHARMACOLOGIA.

DALECHAMP. LUGD. An abbreviation of Hiſtoria Generalis Plantarum Dalechampio elaborata.

DALIGTHRON. A name of the *thalictrum*. See SOPHIA.

DAMA. FALLOW-DEER. This is a ſpecies of the cervus, in the order of pecora, in the Linnæan Syſtem, called *cervus dama*, and alſo *platyceros cervus*. This animal lives entirely on vegetables and water, and its ſalts are not highly exalted; nor is it much inclined to putreſcency. The veniſon of a *deer* killed when cool differs much from that of one heated with exerciſe. The fibres of the firſt are harder, the fleſh more tough, and leſs eaſily ſoluble in the ſtomach. But from the nature of its œconomy, from its wild, and exerciſed ſtate, and from being generally killed in the blood, it is an alkaleſcent, ſapid animal, conſidered as a very great delicacy, and,

DAU

though an exerciſed animal, of eaſy digeſtion. Its fleſh approaches very near to that of ſheep, though undoubtedly it is more ſapid and alkaleſcent. This is the *deer* with which we are beſt acquainted, and as moſt known under the name of veniſon. MEDICINAL VIRTUES have been attributed to different parts. The *recent blood*, drank immediately from the veins, hath been ſaid to remove vertigo; the *gall* to be deterſive, and take away films from the eyes; the *liver* hath been recommended in diarrhœa; the *horns* are uſed exactly in the ſame intentions as thoſe of the ſtag, and the *fat* or *ſuet* agrees perfectly with that of the ſame animal.

DAMASCENA PRUNA NOSTRATA. See PRUNUS DAMASCENA.

DAMASCENÆ PASSULÆ, vel UVÆ. See VITIS.

DAMASONICUM. }
DAMASONIUM. } See DORIA.
DAMESONIUM. }

DAMNATA TERRA. See CAPUT MORTUUM.

DANAIS. See CONYZA.

DAPHNE. In BOTANY, it is a genus of the octandria monogynia, of which Linnæus ſupplies ten ſpecies. It is alſo a name for the BAY-TREE. See LAURUS ALEXANDRINA.

—— GNIDIUM. See THYMELEA MONSPELIACA.

—— LAUREOLA. See LAUREOLA MAS.

—— MEZEREUM. See LAUREOLA FŒMINA.

DAPHNELÆON, from δαφνη, *the bay-tree*, and ελαιον, *oil*. The OIL OF BAY-BERRIES. See LAURUS VULGARIS.

DAPHNITIS. A name for the beſt pieces of *caſſia*.

DAPHNOIDES. See LAUREOLA MAS.

DARATOS. See PANIS.

DARCHEM. A name of the beſt *cinnamon*.

DARSINI. See CINNAMOMUM.

DARSIS, from δερω, *to excoriate*. Where the ſkin is divided and ſituated by the ſculpel from the parts which are ſituated underneath, when ſome parts are to be ſeparated, the phraſe Κατα δαρσιν was uſed.

DARTA. See HERPES and PRURITUS.

DARTOS, from δερμα, *leather*, or *a pelt*. *Dartos*, a Greek name derived from its raw or excoriated appearance, and not from its uſe in contracting the ſcrotum. See Warner on the Teſticles, p. 2. One of the coats, which form the ſcrotum, is called the *dartos* muſcle, alſo *corium*; but Dr. Hunter ſays that no ſuch muſcle can be found; and Albinus takes no notice of it in his table. See SCROTUM.

DAS. See TÆDA.

DASYMMA, from δασυς, *rough*. See TRACHOMA.

DASYS. Denſe, thick, cloſe, or rough. An epithet for a tongue that is parched in a fever. Applied to reſpiration, it ſignifies a breathing as if the lungs had not room to expand. Thoſe who labour under this denſity of breathing are called *cerchodes*.

DATURA, and DATYRA. See STRAMONIUM.

DAUCITES VINUM. Wine in which are the ſeeds of daucus.

DAUCUS. The CARROT, called alſo *carota*, ſuppoſed to be derived from *cara*. Boerhaave reckons up ſeven ſpecies.

—— ALSATICUS. See OREOSELINUM PRATENSE.

DAUCUS ANNUUS MINOR. See CAUCALIS.

—— VULGARIS, called alſo *daucus ſylveſtris, paſtinaca tenuifolia, ſtaphilinus Græcorum vel ſylveſtris.* WILD CARROT, or BIRD'S-NEST. This is the ſort, the ſeeds of which are uſed in medicine. It is the DAUCUS CAROTA, or DAUCUS SYLVESTRIS, *ſeminibus hiſpidis, petiolis ſubtus nerveſis.* CLASS, PENTANDRIA; ORD. DIGYNIA. Linn. Gen. Plant. 333.

DAUCUS CRETICUS, called alſo *myrrhis annua, daucus* foliis fœniculi tenuiſſimis, CANDY CARROT, or CARROT of CRETE. It is the ATHAMANTA CRETENSIS of Linn.

That which is called *carret* of *Crete*, is often brought from Germany, &c. The beſt is large, freſh, ſound, and of an acrid taſte.

The WILD CARROT is common in many uncultivated parts of England, and flowers in June: in its cultivated ſtate, this is the well known garden carrot. Carrots appear to contain from experiment a large proportion of ſaccharine matter, and conſequently afford much nouriſhment, if well boiled; if otherwiſe, or eaten raw, they are very difficult of digeſtion, and paſs through the bowels without ſuffering any conſiderable change. Raw carrots have been given to children as an anthelmintic, probably, on this account: in calculous complaints, the expreſſed juice, or decoction of the roots, has been recommended; and likewiſe, as gargles for infants in aphthous affections, or excoriations of the mouth: to cancerous and putrid ſores, and alſo, to phagedænic ulcers, cataplaſms of ſcraped carrot have been found uſeful, as they mitigate the pain, and abate the ſtench of ſuch as are foul and cancerous. See DAUCUS SATIVUS. The ſeeds are ſimilar in their taſte and ſmell to thoſe of the Cretan *carret*, but weaker; however they are ſubſtituted for them, and, if infuſed in ale or wine, they give out all their virtues, which are diuretic, antiſcorbutic, carminative, and lithontriptic. Half a pound of the ſeeds may be infuſed in five or ſix gallons of ale, and a pint of the clear liquor may be drank three times a day. The ſeeds of the *wild carrot* have in many inſtances been uſeful in the ſtone and gravel, particularly in the latter, when accompanied with great pain and coffee-coloured or bloody urine. The ſeeds ſhould be gathered in Auguſt. They ſeem to be forcing, but not dangerous. Half an ounce of the ſeeds may be put to half a pint of boiling water, and the infuſion drank with ſugar and milk, inſtead of tea, for breakfaſt, and again in the afternoon. Gouty people, who are afflicted with the gravel, are much relieved by it. Some experience relief from this infuſion in a few days; others are longer, even to twelve months, before they perceive any ſenſible effect from it, but after that have been happily rewarded for their perſeverance: though Dr. CULLEN ſays, that the ſeed has been employed for a conſiderable time, in large quantities, in calculous caſes, without any remarkable diuretic power being manifeſted.

—— SATIVUS, called alſo *buſelinum.* The COMMON GARDEN-CARROT. This root is in frequent uſe, and though it will not yield any grained ſugar, it affords a great deal of a ſweet, and melligenous juice which gives a ſtrong mark of its nutritious quality. When boiled, it affords a tender, and not very flatulent food. The roots, when ſcraped ſmall, and made up into a poultice, take off the diſagreeable ſmell which attend ulcerated cancers. The raw *carrot* may be ſcraped or grated, then made into a cataplaſm with cold water, and applied to any kind of fetid ulcers; or *carrots* may be boiled a ſufficient time, till they become ſoft enough to maſh up into a pulp. Turnips prepared the ſame way are ſaid to anſwer the ſame purpoſe. They are both to be applied immediately to the ulcer, without the intervention of lint, or any other ſubſtance. See Lond. Med. Obſ. and Inq. vol. iv. p. 183, 358, &c. Lewis's Mat. Med.

—— MACEDON. See APIUM MACEDONICUM.

—— MONTANUS. See OREOSELINUM, APII FOLIO, &c.

—— ODORATUS CRETICUS, &c. See CUMINOIDES.

—— PEREGRINUS. See SELINUM MONTAN.

—— PETROSELINI vel CORIANDRI FOLIO. See BUNIUM.

—— SELENOIDES. See OREOSELINUM.

DAULONTAS FRUTEX. An American ſhrub, which Lemery ſays poſſeſſes the properties of camomile, and its berries relieve in aſthmas, &c.

DAUPHINY SAL. See GLAUBERI SAL.

DAURA. See HELLEBORUM NIGRUM.

DAVERIDON. OIL OF SPIKE. See LAVENDULA LATIFOLIA.

DEARTICULATIO. See DIARTHROSIS.

DEASCIATIO. See APOSCEPARNISMUS.

DE BOOT. An abbreviation of Anſelmi Boetii de Boot Gemmarum & Lapidum Hiſtoria, &c.

DEC. The abbreviation of decad.

DEBILITATES. Diſeaſes from deficiency, as blindneſs, want of appetite, &c.

DEBUS. So Paracelſus calls a medicine which is given againſt anger.

DECAMYRON. In Oribaſius it is a compoſition made of ten aromatics.

DECAGYNIA, (*δεκα, decem, ten,* and *γυνη, mulier, a woman*). TEN-STYLED; the name of one of the orders of Linnæus's artificial ſyſtem, comprehending thoſe flowers which have ten ſtyles, conſidered as the female organs of generation. This occurs only in the claſs,

DECANDRIA (a *δεκα, decem,* and *ανηρ, vir*). The name of the tenth claſs of Linnæus's artificial ſyſtem, comprehending all hermaphrodite flowers with ten ſtamens or filaments in each flower, and one ſtyle. It is alſo the name of an order in the claſſes, *monadelphia, diadelphia, gynandria* and *diœcia.*

DECANTATIO. DECANTATION. Pouring gently the clear liquor off from a ſediment. See DEPURATIO.

DECIDENTIA. It is an epithet affixed to ſome acute diſeaſes, which are protracted beyond fourteen days, to the twentieth, nay ſometimes to the fortieth day, hence diſeaſes are called acute per decidentiam, or ex decidentia. See alſo CATAPTOSIS.

DECIDUA, (from the Latin, *de, from,* and *cado to fall*). FALLING, fading once in the year. Thoſe things that fall away, as leaves off trees. In BOTANY, *deciduous* plants are ſuch as caſt their leaves in winter, and the term is applicable to trees, ſhrubs, and herbaceous vegetables. From this Dr. Hunter calls the ſpongy *chorion* by the names *decidua* and *caduca*, both which words ſignify falling off. See ABORSUS. Dr. Hamilton obſerves that the membranes (ſpeaking of thoſe which contain the fœtus during pregnancy) conſiſt, externally, of two layers of the ſpongy chorion, called *decidua* and *decidua reflexa*; internally, of the true chorion and the amnion. They form a pretty ſtrong bag, commencing at the edge of the cake, going round the whole circumference, and lining the internal ſurface of the womb. The membrana *decidua*, or that lamella of the ſpongy falſe chorion, which is in immediate contact with the uterus, is originally very thick and ſpongy, and exceedingly vaſcular, particularly where it approaches the placenta. At firſt it is looſely, as it were, ſpread over the ovum; and the intervening ſpace is filled with a quantity of gelatinous ſubſtance. It gradually becomes more and more attenuated by ſtretching, and approaches nearer to the interior lamella of the *decidua*, called *decidua reflexa*: and about the fifth month the two layers come in contact, and adhere ſo as to become apparently one membrane. The *decidua reflexa*, in its ſtructure and appearance, is ſimilar to the former, being rough, fleecy, and vaſcular, on its external ſurface; internally, ſmoother, and perforated with a number of ſmall foramina, which are the orifices of veſſels that open into this internal ſurface. In advanced geſtation it adheres intimately to the former membrane, and is with difficulty ſeparated when the double *decidua* comes off entire; but the outer lamella more commonly adheres to the uterus after the placenta and other membranes are expelled, and is afterwards caſt off with the cleanſings. The *decidua reflexa* becomes thicker, and more vaſcular, as it approaches to the placenta; and is then blended with its ſubſtance, conſtituting the cellular or maternal part of the cake, as it is termed by Dr. Hunter. The other or more internal part belongs to the fœtus, and is ſtyled the fœtal part of the placenta. The double *decidua* is opake in compariſon of the other membranes; the blood-veſſels are derived from the uterus, and can be readily traced into it. Dr. Hunter ſuppoſes that the double *decidua* lines the uterus nearly in the ſame manner as the peritonæum does the cavity of the abdomen, and that the ovum is incloſed within its duplicature, as within a double night-cap. On this ſuppoſition, the ovum muſt be placed on the outſide of this membrane; which is not very readily to be comprehended, unleſs we adopt ſignor Scarpa's opinion, and ſuppoſe it to be originally entirely compoſed of an inſpiſſated coagulable lymph.

Dr.

Dr. Ruyſch called this exterior coat the *tunica filamentoſa*; more modern authors, the FALSE OR SPONGY CHORION. But Dr. Hunter found the ſpongy chorion to conſiſt of two diſtinct layers: that which lines the uterus, he ſtyles membrana caduca, or *decidua*, becauſe it is caſt off after delivery; the portion which covers the ovum, *decidua reflexa*, becauſe it is reflected from the uterus upon the ovum, forming the connecting medium between them. The portion which covers the ovum is a complete membrane, like the true chorion and amnios; but that which immediately lines the uterus is imperfect or deficient, being perforated with three foramina, viz. two ſmall ones, correſponding with the inſertion of the tubes at the fundus uteri; and a larger ragged perforation oppoſite to the orifice of the womb. See Dr. Hamilton's Outlines; Dr. Hunter on the Gravid Uterus.

DECIMANA. An erratic kind of fever which returns every tenth day.

DECLINATIO. It is when a diſeaſe abates. See alſo LUXATIO.

DECLIVIS. See OBLIQUUS DESCENDENS.

DECOCTA. It is a water that hath been boiled, and is cooled by the help of ſnow. DECOCTA alſo ſignifies decoctions, boiling different ingredients in water, and adminiſtering the decanted liquor, when cold, to patients in a variety of caſes, viz. DECOCTUM *ſalani lignoſi* vel *dulcamaræ*;—*bardanæ*;—*hellebori albi*;—*hordei cum gummi*;—*lobeliæ*;—*Luſitanicum*;—*mezerei*;—*quercus*;—*ſaponariæ*;—*ſarſaparillæ*;—*ulmi*, &c.

DECOCTUM ALBUM. See CORNU CERVI.

—— CAMPECHENSE. See CAMPECH. LIGNUM.

—— NITROSUM. See NITRUM, No. 15.

—— RUBRUM. See CORNU CERVI.

DECOCTIO. See COCTIO.

DECOLORES. Diſeaſes which diſagreeably change the colour of the ſkin.

DECREPITATIO, vel CREPITATIO. The crackling noiſe, which common ſalt makes when ſubjected to the fire.

DECURTATUS PULSUS. A weak or a deficient pulſe. If it fails, and revives by turns, it is called *decurtatus reciprocus*.

DECUSSORIUM. An inſtrument to depreſs the dura mater after trepanning, quia decutit membranam, or from its extremity being grooved, decuſſatim.

DECOLATIO. It is when a part of the cranium is cut off with the teguments, in a wound of the head.

DEFECTIVI, ſynonymous with *adynamiæ*.

DEFECTIO ANIMI. See LIPOTHYMIA.

DEFENSIVA. See CARDIACA.

DEFENSIVUM. An epithet for ſome ſurgical topics which repel.

DEFERENTIA VASA. Immediately beneath the tunica albuginea are lodged the teſticles, the tubuli of which run on to form the epididymis; when becoming larger, they unite and form the *vaſa deferentia*, which aſcend in the ſpermatic cord behind the blood-veſſels, and having got through the abdominal rings, are reflected downwards, and paſſing on the back of the bladder, between that and the ureter, go on the inſide of the veſicula ſeminalis, to its anterior end, where they unite with the veſicula; and from the union of theſe with veſiculæ ſeminales, two ducts are formed and continued, which gradually approaching each other, they become contiguous at the notch, in the baſis of the proſtate gland, and terminate in a ſmall duct on each ſide of the caput gallinaginis, in the urethra. At a diſtance from the veſiculæ ſeminales, the *vas deferens* is hardly capable of admitting an hog's briſtle; but as it approaches the veſiculæ, it grows larger both externally and internally, and becomes cellular and tortuous. The uſe of theſe veſſels is to contain the ſperm ſecreted from the blood, and to carry it into the ſpermatic veſſels.

DEFIXUS. Impotent with reſpect to venereal deſires.

DEFLAGRATIO. See CALCINATIO.

DEFLUXIO, from *defluo, to flow down*. A defluxion. The flowing down of humours upon any inferior part, as in a catarrh, &c.

DEFORMATIONES. Diſtortions of particular parts, and other deformities.

DEFORMES. Synonymous with *cachexiæ*. It ſignifies diſeaſes occaſioning external deformity of the body.

DEFRUTUM, from *defervendo*. See MUSTUM.

DEGLUTITIO, from *deglutio, to ſwallow*. The act of SWALLOWING. In *ſwallowing*, the morſel is collected on the upper ſurface of the tongue, is ſqueezed againſt the bony palate, and then carries the palatum molle backward and upward; the pharynx meets it, the tongue keeps cloſe up to the palatum molle, the rimula of the larynx is ſhut, and the bolus is forced down the œſophagus.

INCAPABILITY OF SWALLOWING, called *acatapoſis*; or a difficulty, named *dyſphagia* or *aglutitio*, may be cauſed, 1ſt, *by ulcers of the œſophagus*, in which caſe there will be frequent vomiting of blood, and other kinds of matter; 2dly, *a ſcirrhous bronchocele*; 3dly, *a thickening of the mucus in the œſophagus*; 4thly, *indurations of the œſophagus*; 5thly, *a fungus in the œſophagus*; 6thly, *a ſacculus formed by ſome hard ſubſtance lodging a little time in the œſophagus, and weakening its coats*; 7thly, *by ſpaſms*; 8thly, *foreign bodies ſticking in their paſſage to the ſtomach*; 9thly, *tumors preſſing againſt the ſide of the œſophagus*.

Mr. Warner relates a ſingular caſe of difficult *ſwallowing*, in which the œſophagus, beſides being otherways diſeaſed, was ulcerated in its internal ſurface. Though a ſimilar one may no more admit of a cure than that which he relates, yet its inſertion here may extend the advantage he propoſed in firſt publiſhing it, viz. to enable others to form a juſt prognoſtic, though not an agreeable one; and alſo prevent the adminiſtering of many uſeleſs applications, in a caſe that does not admit of much relief. The caſe is as follows: a young woman, aged twenty-five, was admitted into Guy's Hoſpital, on account of a difficulty in *ſwallowing*, with which ſhe had been afflicted for ſome months; there was not any thing appeared outwardly, that could lead to the diſcovery of the malady, but ſhe complained of a particular tightneſs in *ſwallowing*, juſt below the back part of the cricoid cartilage. The part affected was too low to be looked into; but it was eaſily diſcovered by conveying down the throat a bit of ſponge, faſtened upon whale-bone, and dipt in ſweet oil, which, though very ſmall, could not be made to paſs beyond it. She at length became incapable of taking any nouriſhment, and died ſoon after. After death, her neck was opened, and upon taking out the œſophagus, it appeared conſiderably thickened, about an inch in length, juſt below the cricoid cartilage. Upon opening the œſophagus lengthways, its coats appeared ſo contracted in the diſeaſed part, as to be only juſt capable of admitting a paſſage to a common probe. The internal coat of the œſophagus was in part ulcerated, and beſmeared with matter. All the adjacent parts were ſound and well.

When a bronchocele is the cauſe, whatever its ſtate be, as it admits of but little relief, or none, there is no palliating the difficulty of ſwallowing cauſed by it, further than that of which the bronchocele admits.

Hoffman takes notice of difficulty of *ſwallowing* from a thickening of the mucus in the œſophagus. He ſays, a mucous matter not unfrequently concretes, during the night, in the fauces and gullet, and is afterwards with difficulty brought up. This proceeds, not from the aſpera arteria, or the pharynx, or the pituitary tunic of the noſe, but from the glands of the œſophagus itſelf, irritated by acrid, acid, or hot exhalations from the ſtomach. In ſuch caſes, he obſerves, that warm aromatics, and ſpirituous medicines, muſt neceſſarily do harm, by further inſpiſſating the lymph, and rendering the humours in this part more acrid. He recommends diluents and mineral waters as the principal remedies; and relates a caſe, in which a cure was effected by abſtinence from a more generous diet, and the uſe of a ſoft and ſlender one; drinking the Egra waters, omitting ſuppers, and taking a doſe of a nitrous powder in a draught of cold water, at bed-time.

Indurations happening in any part of the œſophagus, is amongſt the cauſes of a difficulty of *ſwallowing*; an inſtance of which is already noticed. Theſe tumors rarely admit of relief. In the London Medical Journal, vol. iii p. 157. is the following caſe extracted from the Hiſtory of the Royal Medical Society in Paris, for the year 1776. A young lady, aged ſixteen years, after being troubled for about three months with a ſpaſmodic cough, began to have a difficulty of *ſwallowing*, which increaſed ſo faſt, that after a very ſhort time ſhe became incapable of taking any nouriſhment by the mouth; ſo that, for the ſpace of three months, life was ſupported ſolely by clyſters. Mercurial and other frictions were employed, but without any effect. At length M. Macquart reflecting on the caſe, and conjecturing that an encyſted tumor exiſted in the œſophagus, and that it might probably be

now in a ſtate of ſuppuration, he reſolved to adminiſter ſome ſubſtance, which, by its weight, might occaſion a rupture of the ſac. For this purpoſe, he preſcribed an ounce of crude mercury, mixed with the yolk of eggs, to be ſwallowed every three hours. This remedy was taken; and the patient, ſoon after ſhe had ſwallowed the ſecond doſe, brought up a conſiderable quantity of pus. From this moment, ſhe was able to ſwallow broth; and by proper care recovered. When ſcrophulous indurations happen about the œſophagus, the ungt. hydrargyri, rubbed on the neck over the induration, or ſmall doſes of calomel, have often been of ſingular efficacy, eſpecially if uſed early after the attack of the diſorder. If the caſe is of more conſiderable duration, the mercurials ſhould be given, ſo as to excite and ſupport a moderate ptyaliſm for ſome time.

In the London Medical Obſervations and Inquiries, vol. iii. p. 85. is the hiſtory, &c. of a caſe, in which *deglutition* was obſtructed, from a preternatural dilatation of a bag formed in the pharynx. This inſtance was produced by a cherry-ſtone lodging in the throat, which was returned three days afterwards by a fit of coughing; the part where it had lodged gradually gave way, and retained a part of the food which was taken at each meal; this circumſtance increaſing, no aliment at length could paſs into the ſtomach, but all returned without cauſing either pain or ſickneſs. It is propoſed, if a ſimilar caſe ſhould occur, to paſs a tube into the œſophagus; and, through it, to inject a due quantity of broth; by which, life may be continued many years, and the enlargement of the ſac, from the food preſſing into it, will be thus totally prevented.

DEGLUTITION PREVENTED BY SPASMS. See ŒSOPHAGUS.

TUMORS PRESSING AGAINST THE SIDES OF THE ŒSOPHAGUS. When theſe cauſe a difficulty of *ſwallowing*, relief can only depend on the diſſolution or extirpation of ſuch tumors: if theſe cannot be effected, whatever can be thought of to palliate, may be tried.

FOREIGN BODIES STICKING IN THE PASSAGE to the ſtomach, is no unfrequent cauſe of this diſorder; to remove which, is the chief intention of cure. Many are the contrivances for theſe ends; but it would often be better to leave the caſe to nature than to deal roughly with a part ſo irritable as the œſophagus is, as it is often neceſſary to bring back the ſubject *ſwallowed*. If the ſubſtance can be reached with the fingers, or with the forceps, attempts to extract it may be made. When pins, fiſh-bones, or ſuch-like bodies, ſtick acroſs the gullet, ſome adviſe to paſs a crotchet (a wire with its end turned up like a hook) below theſe bodies, and then to turn it ſo as to bring them up with it. Pins, and ſuch-like ſharp bodies, when they have ſtuck in the throat, have been returned by *ſwallowing* a piece of tough meat tied to a ſtrong thread, and then pulled up again. If the detained body may more ſafely be puſhed down, puſh it on by means of the *probang*; that is, a flexible piece of whale bone, with a piece of ſponge ſecured to its end. It hath frequently happened, that though indigeſtible bodies have been *ſwallowed*, no inconvenience hath ariſen therefrom. If the bodies cannot be eaſily moved up or down, endeavours ſhould not be continued long, leſt the œſophagus ſhould become inflamed. Whilſt other means are uſed, it is recommended that the patient ſhould frequently *ſwallow* ſome ſoftening liquid, as barley water, or milk and water, or ſuch like; and if he cannot *ſwallow*, an aſſiſtant may now and then inject the like through a crooked tube that will reach into the gullet: thus, not only abatement of inflammation is ſecured, but if, when the injection is uſed, it be ſomewhat forcibly puſhed, it proves more ſucceſsful in looſening the obſtruction, than all attempts with inſtruments. When endeavours fail, and the body is left in the part, treat the patient as if labouring under an inflammatory diſeaſe; bleed, direct a low diet, apply a poultice round the patient's neck: the ſame treatment will be required, if an inflammation takes place in the part, though the obſtructing body be removed. A proper degree of agitation hath ſometimes ſucceeded in removing the obſtructing body, better than inſtruments. Thus, a blow on the back hath often forced up a ſubſtance that ſtuck in the gullet: but *this is ſtill more proper and efficacious, when the ſubſtance falls into the wind-pipe*; in this caſe, vomiting and ſneezing are to be excited. *Pins, which have ſtuck in the gullet*, have been diſcharged by riding on a horſe or in a carriage. *If the gullet is ſtrongly contracted*, ſo that the patient cannot *ſwallow*, he may be ſupported by means of clyſters until relief is obtained. *If there is danger of ſuffocation*, the operation of bronchotomy may be had recourſe to. *If an indigeſtible* ſubſtance is forced into the ſtomach, the patient ſhould live on a mild, ſmooth diet, conſiſting chiefly of farinaceous matters, as puddings, ſoups, &c. carefully avoiding all irritating and heating things; and thus proceed until the required relief is obtained.

In the London Medical Obſervations and Inquiries, vol. iii. p. 7. is an account of a quill being ſwallowed, and extracted by means of a probang, with a thread or two paſſing from one end to the other, and faſtened to the ſponges which were connected with each end of this inſtrument.

In the Medical Muſeum, vol. ii. are ſeveral inſtances related of different bodies ſticking in the œſophagus, and the methods by which patients were relieved. In the ſame volume it is obſerved, that many bodies, whoſe bulk and figure permit them to paſs eaſily through the inteſtines, are not much to be dreaded when they arrive at the ſtomach, though they have paſſed the œſophagus with difficulty. Pieces of money of various ſizes have paſſed by the anus in a few days: pieces of lead, as bullets, &c. have done the ſame, though ſometimes they have been detained for years.

In the London Medical Tranſactions, vol. iii. p. 30. is an account of a crown-piece which a man ſwallowed; ſome time after, and on another account, an emetic was given him, but without any effect with reſpect to the crown-piece: but ſome weeks after, he was taken with a ſickneſs and vomited ſeveral times, and in vomiting, brought up the crown-piece without any pain, after its lying in his ſtomach from the 12th of March, 1771, to the 26th of November, 1772.

See Warner's Caſes in Surgery. Medical Muſeum, vol. ii. Haller's Phyſiology. London Med. Tranſ. vol. i. p. 165. ii. p. 90. iii. p. 30. Percival's Eſſays Med. & Exp. vol. ii. p. 141. Gooch's Caſes, vol. ii. p. 108. Lewis's Tranſlation of Hoffman's Practice of Medicine, vol. ii. p. 147, &c. London Med. Obſ. and Inq. vol. ii. p. 7, &c. 85, &c. Med. Communications, vol. i. p. 157. 242. White's Surgery, 296.

DEGMOS, from δακω, *to bite*. A biting pain in the orifice of the ſtomach, ſuch as is perceived in the heart-burn, &c.

DEHEB or DEHEBEE. See AURUM.

DEHENE. See SANGUIS.

DEHENEZ. See VITRIOLUM CŒRULEUM.

DEJECTIO. A diſcharge of the excrements by ſtool. On prognoſtics from this evacuation, ſee Proſper Alpinus's Preſages.

DEJECTORIA. See PURGANTIA.

DEINOSIS, from δεινοω, *to exaggerate*. EXAGGERATION. Hippocrates uſes this word with reſpect to the ſupercilia, where it imports their being enlarged.

DELACRYMATIVA, DELACRYMATIVES. Medicines which dry the eyes by firſt diſcharging tears; ſuch are onions, &c.

DELAPSIO, from *delabor, to ſlip down*. See PROLAPSUS.

DELATIO. See INDICATIO.

DELETERIOS, from δηλεω, *to injure*. Pernicious, or extremely noxious. It is an epithet affixed to poiſons.

DELIGATIO, from *de* and *ligo, to tie*. The APPLICATION OF BANDAGES. The principal BANDAGES are:

1. The UNITING BANDAGE, or *ſpica deſcendens*, uſed in rectilinear wounds, made with a double-headed roller, with a longitudinal ſlit in the middle, of three or four inches long. After dreſſing the wound, compreſſes ſhould be applied on each ſide of it, ſo as to preſs from the bottom to the lips of the wound, before the roller is applied, which roller by having one head paſſed through the ſlit, an opportunity will be given of drawing the lips of the wound together. The whole muſt be managed ſo that the *bandage* may act equally. Where wounds are ſtitched, this *bandage* ſupports the ſtitches, and prevents their tearing.

2. The RETENTIVE BANDAGE. It is uſually the ſingle-headed roller. It ſhould be applied, firſt on one ſide oppoſite to the wound, and brought round, ſo as to bring the lips of the wound cloſer. The contrary manner ſeparates the lips.

3. The EXPULSIVE BANDAGE. It is a ſingle-headed roller. It ſhould be applied by making the preſſure gradually

dually leſs, by ſmall and even edgings, from the bottom of the wound to its orifices.

4. The TAILED BANDAGE. It is a linen cloth two or three times folded, and long enough to wrap, at leaſt once and a half round the limb to which it is applied, and broad enough to ſpread farther than the injury extends. At each end, two notches are to be cut, deep enough to admit of the *bandage*'s wrapping cloſe about the limb; the notches ſhould be at equal diſtances, and, if the cloth is folded twice, each end will have nine ſlips, called tails: the two ends being alike ſlit, it is the eighteen-tailed *bandage*. In many caſes, this *bandage* is more commodious than the roller, as it admits of viewing the limb, and dreſſing the wound without moving.

5. The TRIANGULAR BANDAGE. It is generally a handkerchief doubled into that form. In common caſes it is uſed on the head, alſo as a ſupport to the teſticles when ſwelled, &c. called by the French *couvre-chef en triangle*.

6. The NODOSE BANDAGE, called SCAPHA. It is a double-headed roller, made of a fillet four yards long, and about an inch and a half broad; it muſt be reverſed two or three times, ſo as to form a knot upon the part which is to be compreſſed; as when an hæmorrhage from a wound is to be ſtopped, or for ſecuring the compreſs after bleeding any part of the head.

7. The QUADRANGULAR BANDAGE is about three feet ſquare, or a little longer than broad. The French call it *le grand couvre-chef*.

8. The REFLEX BANDAGE. See CAPELINA.

There are variety of other *bandages*; but the occaſion, and the genius of the ſurgeon, will generally beſt ſuggeſt, in particular caſes, what mode of applying the *bandage* will be the moſt proper.

Beſides the above-named, there are the CIRCULAR or ANNULAR, that is, when the upper rounds come exactly over the under. The OBTUSE, or ASCIA, *ſimple bandage*; the French call it DOLOIRES; it is when the rounds aſcend or deſcend upon each other in the form of a ſcrew. The REPENT; the French call it RAMPANT; it is when the *bandage* is applied to the part affected, in rounds, ſeparate, and at a little diſtance from each other. The REFLEX or REFLECTED: the French call it RENVERSEE; it is when the *bandage* muſt be inverted, and turn back, as in thoſe applied to the legs, and where the part is of different thickneſſes. The EXPELLENT, or EXPULSIVE BANDAGE, is when it is applied to the legs to repel a ſwelling there, in which caſe it is applied firſt to the feet, and rolled upwards. The SCAPULARIA, SCAPULARY, and NAPKIN, is a piece of cloth four or ſix fingers broad, with a ſlit in the middle to paſs the head through, and long enough to reach from the bottom of the ſternum over the ſhoulders, and down the back, as low as the ſternum is before. For the SPICA INGUINALIS,——INGUINALIS DUPLEX,——SIMPLEX, ſee SPICA. SPICA DESCENDENS, ſee DELIGATIO. The STELLA, SUSPENSOR, MONOCULUS, DISCRIMEN, DIVIDENS FASCIA, EPIDESMUS, FOSSA AMYNTÆ, HABENA, HEMICERAUNIOS, AURIGA, CHIASTOS, CHIASTE, CIRCUS QUADRUPLEX, may be found under their reſpective heads. For *monophthalmus*, ſee MONOCULUS. For *circulus*, and *plinthius laqueus*, ſee CIRCUS QUDRUPLEX. And for a variety of other ſorts beſides, ſee FASCIA, and HEISTER'S SURGERY, vol. ii. Tables 37, 38.

However, notwithſtanding the variety of directions, which may be given concerning bandages, they all fall ſhort of enabling a perſon dexterouſly to apply them: ſeeing them applied, and alſo being exerciſed in the application, are eſſentially neceſſary. See figures of *bandages*, and directions, as circumſtantial as words perhaps can expreſs, in Heiſter's Surgery. Pott's Works. Bell's Surgery, vol. vi. p. 469.

DELIQUATIO. See SOLUTIO.

DELIQUIUM, from *delinquo, to ſwoon*. See LIPOTHYMIA, and alſo SOLUTIO.

DELIRIUM, from *deliro, to rave*, or *talk idly*. It is termed alſo, *alienatio mentis, paranoiæ, dementia*, ſometimes *emotio*. When the ideas excited in the mind do no not correſpond to the external objects, but are produced by the change induced on the common ſenſory, the patient is ſaid to be *delirious*. The Greeks call it *paraphreneſis*; when ſlight, it is named *leros*. In the Engliſh there is no word for it, except LIGHT-HEADED be admitted.

In *madneſs*, reaſon is deſtroyed; in *fooliſhneſs*, which the Greeks call *moroſis*, reaſon is defective; and in a *delirium*, reaſon is vitiated.

The *paraphreneſis*, or *delirium*, differs from madneſs, in not being perpetual, which happens in *deliriums* without a fever.

Galen ſays, that *deliriums* are cauſed by the heat and acrimony of the fluid, but principally by yellow bile. See his book de Sympt. Cauſ. lib. ii. Many other writers ſay that the bile is the cauſe. Dr. Shebbeare, in his Theory and Practice of Phyſic, attributes this diſorder to either an exceſs, or a defect of vital heat. As to preſages from *deliriums*, in theſe and many other caſes, no great danger is to be apprehended, whilſt the pulſe, the appetite, and reſpiration, are favourable.

DELIRIUM MANIACUM. See MANIA.

—— MELANCHOLICUM. See MELANCHOLIA.

DELOCATIO. See LUXATIO.

DELOTICOS (from δηλος, *manifeſtum*). INDICATIVE: (a δηλεω) uſed in this ſenſe by HIPPOCRATES, in his Aphoriſms; hence by this term are pointed out thoſe ſigns, commonly called diagnoſtics. See DIAGNOSIS.

DELPHINIUM PLATANI FOLIO. } See STAPHIS
—— STAPHIS AGRIA. } AGRIA.

DELPHYS. See UTERUS.

DELTA. The name of the letter D in the Greek; alſo the external pudendum muliebre.

DELTOIDES MUSC. The deltoid muſcles, from Δ, the Greek D, and ειδος, *likeneſs*. Some call theſe muſcles *triangulares*, others name them *humerales*. They riſe from the anterior edges of the extremities of the clavicles, which join the acromions; from the acromions, and from the ſpines of the ſcapulæ; and are inſerted into the middle of each os humeri reſpectively. They move the arm forward, upward, and backward.

DEMENTIA. See VESANIA, and DELIRIUM.

DEMETRIAS. See CEREALIA.

DEMOCRATIS THERIACA. A theriaca deſcribed by Aetius.

DEMOTIVUS LAPSUS. SUDDEN DEATH.

DEMULCENTIA MEDICAMENTA. DEMULCENT MEDICINES. They are ſuch medicines as ſheath the acrimony of the humours, and ſo render them mild. Dr. CULLEN ſays, they are ſuch as are ſuited to correct acrids, or to obviate the irritations ariſing, or which might ariſe from them. Emollients are alſo *demulcents*; for they both obtund ſharp humours, and ſoften rigid fibres. See EMOLLIENTIA.

Demulcents are of two kinds, viz. *general*, which involve all kinds of acrids indiſcriminately; or *ſpecifical*, obtunding only a particular kind of acrimony.

The general ſort are, 1ſt, All oily bodies obtained by the expreſſion of fruits, or formed by boiling certain ingredients in water; the oil diſtilled from wax, and all animal fats. 2dly, All inſipid inodorous plants that yield no oil, taken in the form of emulſions, infuſions, decoction, &c. 3dly, All ſeeds from which an oil may be expreſſed. 4thly, The viſcid inſipid gums. 5thly, All the ſucculent and concreſcent parts of ſound animals (except the bile and urine), and all their glutinous parts.

The ſpecific demulcents, 1ſt, All terreſtrial abſorbents, which take up acids, and prevent their effects as ſuch; beſides theſe, the teſtaceæ, corals, crabs' eyes, iron filings, &c. by theſe the muriated quickſilver, and ſuch like poiſons, may be weakened or deſtroyed. 2dly, All acids, with reſpect to alcalies. 3dly, All alcalies with regard to acids. 4thly, Ardent ſpirits, with regard to acids.

DENARIUS. See AUREUS.

DEND. An abbreviation of *dendrographia*.

DENDR. An abbreviation of dendrographia, or dendrologia, a deſcription of, or diſcourſe on trees, from δενδρον, *arbor, a tree*, and γραφη, *ſcriptura, ſeu ſcriptus, ſermo*.

DENDROIDES. Plants that reſemble trees; they are alſo called *arboreſcens*.

DENDROLIBANUS. See ROSMARINUS.

DENDROMALACHE. See MALVA ROSEA folio ſubrotundo.

DENODATIO. See DISSOLUTIO.

DENS. A TOOTH. The *teeth* are uſually ſixteen in each jaw; they are divided *into the body above the gum*, and the *root*, or *fang*, which is within the ſocket of the jaw; the neck is the line of diviſion between the root and the body. They are made up of a bony ſubſtance and an enamel.

The enamel covers only the body of the *tooth*, that part which is out of the gums, as far as to its neck; it is not bone, for it is not vaſcular, nor capable of being injected: for, if animals are fed with madder, the

body part of the *tooth* will be injected, but the enamel will remain unaltered; or steep the enamel in a weak acid, and it will all become a powder; whereas when bone is thus steeped, a soft elastic part remains.

Each root is hollow, for the admission of vessels and nerves to pass into the substance of the *teeth*, but these cavities grow less as we advance in years.

Ossification begins in the body of a *tooth*, and is continued to the root, and there are as many points of ossification as there are tubercles in the *tooth*. The long part of the *tooth* is the hardest part in the body, except the enamel with covers the *teeth*. Mr. John Hunter suspects that the *teeth*, when full grown, are not simply bone. He observes, that bones are tinged with the colouring matter of madder when they are complete and perfectly grown, if the animal is fed for a time with this root; and *teeth*, whilst growing, receive this tinge, but not when they are perfected; in all other bones this red colour is in time carried out of them by absorption; and they return to their original colour: but when a *tooth* hath had this colour given to it, which must be while it is growing, when it is perfected it never loses it; which shews their want of the absorbent system, and therefore, most likely, of the vascular also. The rickets do not affect the *teeth*; for we never find them grow soft like the other bones, but they remain perfectly hard: lastly, in old age, the other bones become brittle, and waste, but never the teeth.

The *teeth* are divided into three classes, viz. the INCISORES, CANINI, and MOLARES. The *incisores*, called also *dentes lactei*, and *dentes riserii*, are the four anterior *teeth* in each jaw; they appear the first. The *canini*, or *dentes oculares*, are one on each side of the incisores, in each jaw. The *molares* are five on each side of both jaws: Cicero calls them *genuini*. Sometimes, before twenty years of age, and sometimes at five or six and twenty, the last of the grinders appear, and are called *dentes sapientiæ* and *dentes genuini*. Mr. John Hunter divides and names them as follows; viz. from the symphysis of the jaw on each side, are two INCISORES, which see. One CUSPIDATUS. See CANINI DENTES. Two BICUSPIDES. See MOLARES. And three MOLARES, the last of which is the *sapientiæ dens*. See MOLARES.

The *incisores*, *canini*, and the *two first of the grinders*, are formed at the birth, and are those *teeth* which are shed. They usually cut or appear about the seventh month, and are shed about the seventh year. *The secondary teeth* are formed in sockets of their own, which are situated below the other socket. The *three dentes molares* on each side do not come through the gums until all the first set of *teeth* are shed; then they come through with the second set, and are never shed. Some people never have the *dentes sapientiæ*. At three years of age, or thereabout, a child hath its first set of *teeth*, which are twenty.

There are generally as many protuberances on the body of the *teeth* as there are roots; but these latter sometimes grow together; at other times they are divaricated, especially on the upper jaw, where, not having a sufficient depth, because of the maxillary sinus, they spread and are extracted with greater difficulty than those on the lower jaw.

The *fifth pair of nerves* supply the *teeth* with branches, which are wrapt up with the blood-vessels by means of a membrane, and running under the *teeth*, enter into their cavities. From an attention to the fifth pair of nerves, and the parts to which they are distributed, many of the phænomena attendant on disorders of the *teeth* may be accounted for. Mr. Moss observes, in his Essay on the Management of Children, &c. that the *teeth*, when a child is born, are lodged in the sockets in the jaw-bones, and are covered with, and enveloped by a thin membrane that is very irritable, and sensible of pain, viz. the periosteum of the *teeth*; so that when the *teeth* begin to grow, and emerge from their recesses, or sockets, they must necessarily distend, perforate, and force their way through this membrane, which, when upon the full stretch, from its sensibility, gives great pain, and occasions fevers, startings, and all the symptoms which happen during the time of breeding the *teeth*. As soon as this membrane is completely divided in that part by the *tooth* or *teeth*, which then happen to be rising, the child is relieved for the present, from the fever and other complaints, but which are subject to return upon the successive rising of the other *teeth*.

Disorders in the *teeth* depend chiefly on a caries in them; an inflammation in the membrane which cover their root, &c. and a defluxion of humours on the said membrane. When a *tooth* is carious, it often occasions a fetid breath; and the air passing into, or any warm or cold substance touching it, pain is excited: relief is often obtained by filling the carious part with mastich; but the best method is to extract the *tooth*.—In case of an inflammation in the membrane which spreads itself about the roots of the *teeth*, bleeding or purging, according to the state of the constitution, will be needful; warm barley-water may also be held in the mouth, and such other general methods may be used, as are are found to be useful in other inflammatory disorders.—When a defluxion of humours gives rise to complaints in the *teeth*, purging will be peculiarly useful; blisters may be applied behind the ears or on the back, and horse-radish or pellitory root may be held between the gums and cheeks, to excite a discharge of saliva. Besides these general causes, a morbid quality induced into the general habit may give rise to disorders in the *teeth*, as happens in scorbutic and venereal patients, in which cases, the method of cure will consist in freeing the constitution from these kinds of complaints.

The tartareous crust which is secreted from the blood and lodged on the *teeth*, is speedily removed by touching it with acidum muriaticum, and then washing it off with water.

On the *teeth*, and their disorders, see Mr. John Hunter's Natural History of the Human *Teeth*; Eustachius de *Dentibus*; Hoffman de *Dent.* eorum Morb. & Cura; Hurlock on Breeding of *Teeth*; Moss on the Management of Children; Bell's Surgery, vol. iv. p. 191, &c. White's Surgery, p 280.

DENS CABALLINUS. See HYOSCYAMUS.

—— CANIS. DOG'S TOOTH. Boerhaave mentions five species. The flower is shaped like that of a lily: the root is long, fleshy, and formed somewhat like the *tooth* of a dog: the leaves resemble those of the cyclamen. The dried roots are commended as anthelmintic, but are not used with us.

—— LEONIS, also called *taraxacum*, *taraxacon*, *caput monachi*, *urinaria*, *hieracium alpinum*, *hedypnois*, PISS-A-BED, and DANDELION. It is the LEONTODON TARAXACUM, *calyce squamis inferne reflexis, foliis runcinatis denticulatis lævibus*. CLASS, SYNGENESIA; ORD. POLYGAMIA ÆQUALIS. LINN. Gen. Plant. 912. It is a low plant, with long, narrow, deeply indented leaves, lying on the ground; among which arises a single, naked, hollow pedicle, bearing a large, yellow, flosculous flower; the flower is followed by small seeds, covered with a tuft of long down: the root is oblong, slender, yellowish, or brownish on the outside, and white within. It is perennial, common in uncultivated places, and flowers from April to the end of summer.

The roots, stalks and leaves, abound with a milky juice, that is bitterish, but of no particular flavour. They are mildly detergent, and aperient, but more powerful than the cichoreum sylvestre. Boerhaave highly commends them as a resolvent. But the more immediate and sensible operation of this plant is to loosen the belly, and promote urine, which it does without heating; and has been considered by some, as highly efficacious in removing biliary obstructions. MURRAY says, that this plant resolves viscid humours, opens obstructed vessels, and is a remedy for various eruptive complaints: and BERGIUS considers it as an effective hepatic deobstruent, recommending it in hypochondriasis and jaundice. He says, it is a most excellent medicine in diseases of the liver, boiled in whey, or formed into broths and apozems. It has also been useful in dropsies, pulmonic tubercles, and some cutaneous disorders. It is given, plant and root, boiled in decoctions; or its expressed juice may be administered, from one ounce to four, three or four times a day. The plant should always be used fresh; for even extracts of it, as well as the roots and leaves, lose much of their power by keeping. It may also be taken as part of diet, and eat fresh. The young leaves blanched have much the taste of endive, and make an excellent addition to sallads in the spring. The roots are roasted, and used at Gottingen, by the poorer sort of people, for coffee, from which a decoction of them thus prepared can hardly be distinguished.

Boerhaave takes notice of twelve species. See Raii Hist. Lewis's Mat. Med. It is also a name of the *auricula muris*, and some other plants.

DENSITAS. DENSITY. It is that property in any body,

body, which is oppoſite to rarity, whereby it contains ſuch a quantity of matter under ſuch a bulk. But in medical writings, *denſeneſs* ſometimes means frequency, and is applied to the pulſe, and to reſpiration.

DENTAGRA, from *dens, a tooth*, and ἀγρα, *a ſeizure*. It is uſed both to ſignify the gout in the *teeth* (ſee ARTHROTIS), and an inſtrument for drawing them, called alſo *dentaſpago, dentiducum, dentoducum, odontagogos*.

DENTALE. See DENTALIUM.

DENTALE VIRIDE STRIATUM. See ENTALIUM.

DENTALIS LAPIS. It is the tartareous matter which is formed about the teeth in the likeneſs of a ſtone.

DENTALIUM, alſo called *dentale, autalis, tubulus dentalis*, and TOOTH-SHELL. It is the ſhell of a ſmall ſea-fiſh; it is oblong, ſlender, and of a whitiſh, greeniſh, or reddiſh colour, about two inches long, ſtriated, and marked with two or three bands about it. As a medicine, the oyſter-ſhell may be ſubſtituted for it.

DENTARIA, called alſo *coralloides, ſeptifolia*, SETFOIL-TOOTHWORT, and CORAL-WORT. This plant hath a long pod, full of round ſeeds; when this pod is ripe, its valves are twiſted into a ſpiral form, and diſcharge the ſeeds with violence: the root is ſquamous, fleſhy, and denticulated. It flowers in April: the root is drying and aſtringent.

DENTARIA. See PLUMBAGO.

DENTASPAGO. See DENTAGRA.

DENTATA. So the ſecond vertebra of the neck is called. It is remarkable for its proceſs, which is called proceſſus dentatus, which plays in the hollow of the anterior arch of the vertebra above it (called Atlas). From the ſides of the proceſſus dentatus, the ligaments go off to attach it to the Atlas; and from its point, a ſtrong one is ſent out to the os occipitis. It expreſſes DENTATED. In BOTANY, a *dentated* leaf, alſo called *denticulatum*, is a leaf having ſpreading points or teeth, remote from each other, about the edge.

DENTATUS PROCESSUS. See ATLAS.

DENTELLARIA. See PLUMBAGO.

DENTES COLUMELLARES. In Varro and Pliny, they are the ſame as Varro elſewhere calls *dentes canini*.

—— GENUINI. Cicero calls the *molares* thus; but they are the *teeth* called *ſapientiæ*.

—— LACTEI. See INCISORES.

—— OCULARES. EYE-TEETH. See DENS.

They are thus named, becauſe that extracting them is ſuppoſed to injure the eyes.

—— RISORII. See INCISORES.

DENTICULATA. See *Mochatellina foliis fumariæ bulboſæ*.

DENTICULATUM. See DENTATA.

DENTIDUCUM. See DENTAGRA.

DENTIFRICIUM, from *dentes fricare, to rub the teeth*. DENTIFRICE, called alſo *odontotrimma*. Medicines for cleaning the teeth. There are many preparations contrived for this purpoſe, chiefly conſiſting of ſcuttle-fiſh bone, cream of tartar, bole, bark, myrrh, ſalt, and ſoot, all which may be uſed in powder, or mixed up with honey. But the moſt effectual *dentifrices* are the mineral acids, the beſt of which is the *acidum muriaticum*; next is the *acidum vitriolicum*. But the acidum nitroſum ſhould never be uſed, for it deſtroys the enamel of the teeth.

DENTILLARIA. See PLUMBAGO.

DENTISCALPIUM. } Alſo called ODONTOGLY-
DENTISCALPRA. } PHON. An inſtrument for ſcraping off the cruſt which is formed on foul teeth. In Oribaſius, it is an inſtrument for ſeparating the gums from the teeth.

DENTITIO, alſo called *odontiaſis, odontophya*. DENTITION, or breeding of teeth. Sauvages, in his ſyſtem of Noſology, makes this a ſpecies of odontalgia. Cullen makes *dentitio* ſynonymous with *odaxiſmos*; but does not admit it as a diſeaſe. Hippocrates uſes the word principally with reſpect to the gums, when the teeth are forcing a paſſage through them.

Children often ſuffer much uneaſineſs from the cutting of their *teeth*. Yet *teething* is not properly a diſeaſe. Whatever dangerous ſymptoms may occaſionally attend this proceſs of nature, they are owing to ſome accidental diſorder attendant on the child. Plenitude is generally the morbid habit, which is productive of fatal conſequences during *dentition*. In this caſe, bleeding, and a frequent repetition of ſolutives, muſt be uſed. If a morbid acrimony in the blood is attendant, the pain will be increaſed, which accompanies this ſtate; in which caſe, alteratives, adapted to the caſe, muſt be preſcribed.

If there is much fever and a *tooth* is ready to cut, an inciſion may be made in the gum, to remove its tenſion.

A troubleſome cough is often an attendant on *teething*; in which caſe, a plaſter of Burgundy pitch, applied to the nape of the neck, is of conſiderable ſervice. A freſh one may be applied when the firſt begins not to adhere.

Dr. Withers obſerves in his Treatiſe on the Aſthma, p. 301, 302, that, "If a child has a diſeaſe in his breaſt, the cutting of a *tooth*, as it often excites pain, fever, and general irritability, will be found commonly to increaſe it. But this affords no proof why a cough and ſhortneſs of breath, with a pulmonary obſtructions in the lungs, ſhould be thought a neceſſary attendant on *teething*. According to the beſt of my obſervations, it is an indiſputable fact, that healthful children cut their *teeth* without a cough; and, when in others a cough attends *teething*, it is in general an accidental circumſtance, proceeding from a local complaint in the breaſt, and is not merely ſymptomatic of the cutting of a *tooth*. The violence of the cough, the riſing of the phlegm from the lungs, inflammations, pulmonary obſtructions, and ulcerations, which have followed, and been proved by diſſection, have fully convinced me of the truth of the above aſſertion. I ſhould not have dwelt at all on this fact, if I had not obſerved that the notion, which I am endeavouring to refute, is pernicious to ſociety, and productive of fatal conſequences. For, when we ſay that a cough, with ſhortneſs of breath, is a common ſymptom of *teething*, we unite the two complaints together under one idea; and as we conſider *teething* as natural and neceſſary, the other being united with it and regarded only as an effect, falls in under the ſame general idea, and conſequently is too often ſuppoſed to require no particular treatment; by which means it is neglected, and in many inſtances proves fatal.

When children are vigorous, they cut their *teeth* earlier; weakly children, particularly thoſe that are diſpoſed to the rickets, are later before their *teeth* appear. Mr. J. Hunter ſays, that weakneſs and diſeaſe in the body does not affect the *teeth*.

A ſlavering, or a diarrhœa, are favourable ſymptoms during the time of cutting the *teeth*. Children attended with theſe ſymptoms are rarely diſturbed with any of the violent diſorders, ſuch as convulſions, &c. See Hurlock's Treatiſe on *Dentition*. Mr. John Hunter's Nat. Hiſt. of the Human *Teeth*.

Hoffman obſerves, that the *teeth* appear in ſome in the ſeventh month, in others later, as in the ninth, or even the twelfth, the fore *teeth* are generally cut firſt, from the friction of the nipple; next, the eye *teeth*; and, laſtly, the grinders. In ſome, this proceſs gives but little uneaſineſs; in others, it is accompanied with very troubleſome ſymptoms. In difficult *dentition*, the child is preternaturally hot, cries immoderately, ſtarts in his ſleep, often applies his hand to his mouth, ſucks with eagerneſs, and even bites the nipple. The gums ſwell and look whitiſh and reddiſh; the ſaliva is copiouſly diſcharged, and often hangs viſcid from the mouth; the belly either coſtive or over looſe. Sometimes acute fevers, convulſive and epileptic motions, diſtortions of the jaws, and other violent ſymptoms are joined, different in different ſubjects, according to the difficulty of the eruption of the *teeth*, or the ſenſibility of the child. Amongſt the prognoſtics, he ſays, that thoſe who are plethoric, ſleepy, coſtive, alſo thoſe who are ſeized in *dentition* with a cough, who are of great ſenſibility, or an hereditary paſſionate diſpoſition, have the moſt to fear. Hippocrates obſerves, that thoſe who are attacked by the acute fever, eſcape convulſions; and that the *teething* is eaſieſt in winter. The principal indications of cure are, to abate the pain and inflammation; and to ſoften and relax the gums. If the belly is not naturally lax, it ſhould be kept ſo. A ſpontaneous looſeneſs is ſalutary, and ſhould not be checked; if it is, convulſions and other threatening ſymptoms are then much more apt to ſucceed.

Moſs, in his Eſſay on the Management of Children, &c. remarks, that the time of cutting the firſt *teeth* is uncertain; it ſometimes happens in the third or fourth month; at others, not until the ſixteenth or eighteenth; but that, in general, it is about the ſeventh or ninth. He adds, that there are TWO STAGES OR PERIODS OF TEETHING, which it becomes needful to attend to: the firſt is the time of breeding, and the ſecond the time of cutting the *teeth*. The FIRST, or BREEDING THE TEETH, *commonly begins about the third or fourth month:*

it

it may be known by a copious diſcharge of ſaliva from the child's mouth taking place; its being pleaſed with having its gums rubbed with a finger, or other harder ſubſtance; its becoming more fretful, &c. If now there is great heat, thirſt, fever, a dulneſs and drowſineſs, with frequent ſtartings when aſleep, it will be neceſſary to procure a few ſtools, and to keep the bowels lax, if they are not already ſo; if a looſeneſs at this time attends, though it is ſomewhat ſevere, it ſhould not be checked. The griping, which ſometimes accompanies this looſeneſs, is generally abated by the uſe of a little magneſia. When the drowſineſs, ſtarting, and feveriſhneſs above named come on, bleeding with leeches will be ſingularly uſeful. Two leeches may be applied to the feet, every, or every other day, until theſe ſymptoms abate. During the thirſt, if the children crave ſweetened drinks, liquorice may be boiled in the water which is given, as it does not increaſe this troubleſome ſymptom. After the bleeding, bliſters behind the ears, or on the back, are not to be omitted. The antimonial emetics ſhould be repeated now and then until the fever is removed. Should convulſions come on, the above treatment will be alſo well adapted to relieve. A diſcreet uſe of anodynes is an important addition in this inſtance. THE SECOND STAGE OR PERIOD OF TEETHING is that of cutting the *teeth*. This uſually begins about the ſeventh or ninth month: in this, the ſymptoms and management are in general the ſame as thoſe of the firſt period. And it may be noted, that a child, who a little before was pleaſed with having his gums rubbed, will now ſeldom ſuffer any thing hard to touch them; for when a *tooth* is upon the point of coming through the gum, the gum is exceeding ſore, and ſenſible of pain from the ſlighteſt touch. It may be known that a *tooth* is near cutting, when the gum, in one particular part where the *tooth* or *teeth* may be expected to come, appears fuller and more diſtended than uſual, and than the other parts of the gums are; the gum in that part looks red and inflamed the bottom or baſe, but is paler or whiter at its point or edge; and when the *tooth* is very near cutting, the edge of the gum ſeems as if it had a flat white bliſter upon it, and appears thicker and broader than the edges of the gums are in other places: at this time, if any alarming ſymptoms come on, cutting the gum over the edge of the approaching *tooth* will be a ſpeedy and often an effectual means of relief. Sometimes, though, in cutting the gums, the ſymptoms abate, the *tooth* does not appear until ſome days, or perhaps weeks after; nay, ſometimes the gum heals, and the former uneaſy ſymptoms return; which, for their relief require the cutting to be repeated, and that ſeveral times before the *tooth* will completely appear. It is a miſtaken notion, that repeated cutting the gum renders it harder: for the contrary happens; on which, ſee Mr. John Hunter's Practical Treatiſe on the Diſeaſes of the *Teeth*, p. 121. Bell's Surgery, vol. iv. p. 191. White's Surgery, p. 280, &c.

DENTO. One whoſe teeth are prominent to a great degree, or who is full-mouthed.

DENTODUCUM. See DENTAGRA.

DENUDATIO. DENUDATION. It is ſpoken of bones that are laid bare by the fleſh being torn off them.

DEOBSTRUENTIA (*de*, priv. and *obſtruo, to obſtruct.*) DEOBSTRUENTS. DEOPPILATIVA. See APERIENTIA.

DEPART. See DISCESSUS. It is alſo called *quartatio*, which ſee.

DEPASCENS ULCUS. See PHAGEDÆNA.

DEPERDITIO. See ABORTUS.

DEPETIGO. See PRURITUS.

DEPHLEGMATIO. Vinous ſpirits are ſaid to be dephlegmated, or rectified, when well freed from their watery parts.

DEPILATORIUM. DEPILATORY. Medicines which take off the hair, ſuch as quick-lime, orpiment, &c. There are three kinds of *depilatory* medicines; 1. The *pſilothra*, or *depilatoria*, by way of eminence; 2. Thoſe which thin the hair; and, 3. Thoſe which are corroſive, and extirpate the hair.

DEPILIS. See ALOPECIA.

DEPOT LAITEUX. See LYMPHÆ DUCTUS.

DEPLUMATIO. An affection of the eye-lids, with a callous tumor, which cauſes the hair to fall off. Actius ſays, it is a diſorder of the eye, conſiſting of a *madaroſis* and *ſclerophthalmia*.

DEPREHENSIO. See CATALEPSIS.

DEPRESSIO. A DEPRESSION. In ſurgery this word generally ſignifies particularly a ſinking inwards of ſome part of the ſkull, which happens from an external violence by which the bone is fractured. This injury by ſome is named *impreſſio, introceſſio*.

In this caſe, the ſame ſymptoms may attend, as are obſerved in an extravaſation within the ſkull, and are cauſed by the ſame means, viz. mechanical preſſure; they differ widely from thoſe of a concuſſion of the brain. See CONCUSSIO, EXTRAVASATIO, CEREBRI COMPRESSIO.

Dr. Hunter ſeems to think, that it is almoſt impoſſible to raiſe a *depreſſion* of this kind, becauſe the fracture is more extenſive in the inſide than the outer one, and the ſpiculæ can never be brought exactly to fit each other. However, as according to Hildanus and Van der Weil, ſome ſkulls have been ſo ſoft as to be *depreſſed* without being fractured, ſucceſs may be expected at leaſt in ſome caſes: and where the bones are ſoft and yielding, they may be raiſed by means of a ſtring faſtened to an adheſive plaſter, which may be applied to the *depreſſion*, after ſhaving the part. But after all, if their elevation was eaſily practicable, it would be unwarrantable, in general, to be contented with mere elevation; for all the ills attending and ſucceeding ſimple fractures are more likely to happen from *depreſſed* pieces of bone; therefore, removing the *depreſſed* pieces, is the only proper intention to be purſued.

DEPRESSOR, alſo *Deprimens*, from *deprimere, to pull*, or *draw down*. IN ANATOMY, a name applied to ſeveral muſcles, becauſe they *depreſs* the parts they are faſtened to.

—— ANGULI ORIS. A name given by Albinus to the *depreſſor labiorum communis*. It riſes from the outer part of the lower edge of the lower jaw, at the ſide of the chin, and is continued outwardly, to the greater zygomaticus, to the naſalis of the upper *lip*, and thence into the outer part of the orbicularis, where it ſurrounds the upper lip at the corner of the *mouth*. It extends and joins the elevator of the corner of the *mouth*.

—— EPIGLOTTIDIS. It riſes from the ligament on the thyroid cartilage on its fore part on each ſide, and is inſerted in the *epiglottis*, near its baſis, on each ſide.

—— LABIORUM COMMUNIS. See DEPRESSOR ANGULI ORIS.

—— LABII SUPERIORIS, called alſo *triangularis, conſtrictor alæ naſi*. It riſes from the ſockets of the inciſores, runs to the ſuperior part of the *upper lip*, and ſome fibres to the noſe.

—— OCULI, called alſo *humilis rectus inferior, deprimens muſculus inferior*. It riſes tendinous from the back part of the ſocket, cohering in ſome meaſure with the covering of the *optic* nerves, and is inſerted into the fore part of the ſclerotica, after running under the *eye*.

—— SUPERCILII. See CORRUGATOR Coiterii.

DEPRESSORES ALÆ NASI. The *depreſſors* of the wings of the noſe. They ariſe from the upper jaw-bone outwardly, where the gums cover the ſockets of the dentes inciſores and canini, and are inſerted into the root of the *wing of the noſe*, advancing up the ſide of the *wing* a little way: they pull the *alæ* downwards.

—— COSTARUM. They are ſo ſimilar to the levatores longiores, as to need no farther deſcription, only (as their name imports) their office is the reverſe of the other.

—— LABII INFERIORIS, alſo called *quadrati*. They ariſe fleſhy on each ſide of the chin, march obliquely, and croſſing each other, terminate together in the whole edge of the *lip*, where it grows red.

—— MAXILLÆ INFERIORIS. See PLATYSMA MYOIDES.

DEPRESSORIUM. An inſtrument which is uſed for depreſſing the dura mater after the operation of the trepan.

DEPRIMENS. See DEPRESSOR, alſo DEPRESSOR OCULI.

DEPURATIO. DEPURATION, *clarificatio*, aut *deſpumatio*, vel *rectificatio*. It is the freeing of any fluid from all heterogeneous matter or feculence, and rendering it more tranſparent. This operation is of three kinds: 1ſt, DECANTATION, which can only take place where a difference is in the ſpecific gravities of what conſtitutes the mixture; whence that which is the heavieſt falls to the bottom, and the lighter part is ſeparated from it by the decantation or pouring off. When oils are to be ſeparated from water, which are obtained by diſtilling, or indeed from other fluids, a *tritorium*, or ſeparatory

plaſs, is uſed. 2dly, DESPUMATION; this is performed by adding the whites of eggs, or other ſuch viſcid matter, to the fluid, to be clarified, and, after a perfect commixture, making them coagulate by means of heat, and thus carrying to the ſurface all the heterogeneous matter; the impurities are then, with the concreted viſcid matter, ſeparated with a ſpoon. This is alſo called CLARIFICATION. 3dly, FILTRATION, PERCOLATION, or COLATURE; it is performed by paſſing, without preſſure, the fluid to be purified through ſtrainers of linen, flannel, or paper, which retaining the feculence, permits only the clearer fluid to paſs through. Though in filtration, a ſoft, porous paper is folded in the ſhape of a funnel, then placed into one; into which ſome of the liquor is to be poured, which is to paſs through the paper; this paper is called filtering paper.

When flannel is uſed, it is commonly formed into a cone, called HIPPOCRATES' SLEEVE, and its baſe is hung on three props, with the cone downwards; it is then filled with the liquor, which gradually drops from the apex: it is generally uſed when the matter muſt be paſſed through whilſt hot.

When paper is uſed for filtering through, it muſt be ſupported by fitting it to a funnel, or by laying it on a linen ſtrainer, in a ſieve, or other ſuch like convenience. When paper is fitted to a funnel, ſtraws ſhould be placed here and there betwixt them.

Diſtillation and ſublimation are practiſed in the caſe of ſpirits and ſalts, with a view to *depuration*, and the operation is called in theſe caſes RECTIFICATION.

DEPURATORIA FEBRIS. DEPURATORY FEVER. A name given by Sydenham to a fever which prevailed in the years 1661 and 1664. He called it *depuratory*, becauſe he obſerved, that nature regulated all the ſymptoms in ſuch a manner as to fit the febrile matter for expulſion in a certain time, either by a copious ſweat, or a free perſpiration. See Sydenham's Works, with notes, by Dr. Wallis.

DERAS. Δερας, *a ſheep-ſkin*. The title of a book in chemiſtry, treating of the art of tranſmuting baſe metals into gold. It is written on ſheep-ſkins; hence alſo DERMA.

DERBIA. See IMPETIGINES.

DERMA, δερμα. See DERAS.

DERIVATIO. DERIVATION. In MEDICINE it is when a humour which cannot conveniently be evacuated at the part affected, is attracted from thence, and diſcharged elſewhere; thus, a bliſter is applied to the neck to draw away the humour from the eyes.

The doctrine of *derivation* and *revulſion* ſo much talked of by the ancients is, in their ſenſe of theſe terms, wholly exploded. By REVULSION they meant the driving back of the fluids from one part to another. The only rational meaning that the word revulſion, as here applied, can have, is the preventing too great an afflux of humours to any part, either by contracting the area of the veſſels, or diminiſhing the quantity of what flows from them; the firſt of theſe intentions is anſwered by the application of repellents to the part, the laſt by bleeding and other evacuations.

DERMATOIDES, from δερμα, a *ſkin* or *leather*, and ειδος, *likeneſs*. See DURA MATER.

DERTRON. See ABDOMEN, OMENTUM, and INTESTINA.

DESCENSIO. } It is ſpoken of the gentle and mode-
DESCENSUS. } rate motion of the body, or of the humours downwards. The chemiſts call it *diſtillatio per deſcenſum* when the fire is applied to the top and all round the veſſel, whoſe orifice is at the bottom, and the vapours conſequently driven there. Liquifying ſalts by expoſing them to the air, as in making the aq. kali, is alſo a ſort of diſtillatio per *deſcenſum*.

DESCENSORIUM. See BOTUS.

DESESSIO. Celſus uſes this word for fitting on a cloſe-ſtool. *Deſurrectio* is uſed in the ſame ſenſe.

DESICCATIO. DRYING. The chemiſts alſo refer it (though improperly) to calcination.

DESICCATIVUM. DESICCATIVE, from *deſicco, to dry*. See EPULOTICA.

DESIDIA OBLIVIO. See LETHARGUS, under CAROS.

DESIPIENTIA. See PHRENITIS.

DESME, from δεω, *to tie, or bind*. This word occurs in Moſchion. See MANIPULUS.

DESMIDION. It is a diminutive of *deſme*, ſo ſignifies a ſmall handful.

DESMOS. In Hippoc. de Fract. this word ſignifies an affection of the joint after a luxation, in the manner of a tye or ligature, whereby the joints are rendered incapable of bending or ſtretching out. It proceeds from inflammation.

DESPUMATIO, from *deſpumo, to ſcum*. See DEPURATIO.

DESQUAMATIO, from *de*, privative, and *ſquama, the ſcale of a fiſh*. To take off ſcales. Sometimes it ſignifies the ſame as *abraſio*. By a metaphor it is applied to a foul bone, the laminæ of which riſe like *ſcales*. But this is more properly termed EXFOLIATIO, which ſee.—When the ſcarf ſkin peels off after ſome eruptive complaint this proceſs is named Deſquamatio.

DESQUAMATORIUM. An epithet of a trepan, called alſo *exfoliatorium*, for abrading part of the cranium.

DESTILLATIO. See DISTILLATIO.

DESUDATIO. See EPHIDROSIS.—It is alſo a profuſe ſweat ſucceeded by an eruption of puſtules, called *ſudamina, hydroa, Boa:* or HEAT PIMPLES.

DESURRECTIO. See DESESSIO.

DETENTIO. See CATALEPSIS.

DETERGENS, from *detergeo, to wipe off*. DETERGING. See ABSTERGENTIA. *Detergents* differ only in degree of efficacy from vulneraries. They have more ſubtil parts, and ſo are more fit to mix with, attenuate, and wear away the contents of abſceſſes and ulcerations, and ſuch viſcid humours as adhere to and obſtruct the veſſels.

DETERIORATIO. DETERIORATION. The impairing or rendering a thing worſe; it is the oppoſite of melioration.

DETERSORIUM. The apartments at baths where the ſweat was ſcraped off.

DETERSORIUS. See ABSTERSIVUS.

DETONATIO. DETONATION, from *detono, to make a great noiſe*. In CHEMISTRY it is that noiſe and exploſion which any ſubſtance makes upon the application of fire to it. It is alſo called *fulminatio*; but *detonation* is a leſs degree of thundering noiſe; it is a cracking noiſe, and leſs explofive than the fulminating noiſe. See CALCINATIO, by *Detonation*. As nitre is the cauſe of moſt exploſions, the word *detonation* hath been appropriated chiefly to the inflammation of the acid of this ſalt with bodies containing phlogiſton; and it is frequently given to thoſe inflammations of nitrous acid, which are not accompanied with exploſion. See Dict. of Chem.

DETRACTIO. See CATHÆRESIS.

DETRAHENS QUADRATUS. See PLATYSMA MYOIDES.

DETRACTOR AURIS. See ABDUCTOR AURIS.—

DETRITIO. See RHACOSIS. In a general ſenſe it is taken for *trituratio*, from *detero, to rub off*.

DETRUSOR URINÆ, from *detrudere, to thruſt*, or *ſqueeze out of*. Douglas divides the muſcular covering of the bladder into two diſtinct muſcles; the longitudinal fibres he calls the *detruſor urinæ*, which he deſcribes as ariſing from the proſtate gland going round the fundus, and being loſt in the gland again; the oblique fibres he calls *conſtrictor veſicæ urinariæ*, and deſcribes it as running obliquely under the other. But Dr. Hunter ſays, it is plain that there are no other regular muſcles, and this diſtinction is merely artificial.

DEUNX. See CYATHUS.

DEURENS FEBRIS. See ARDENS FEBRIS.

DEUSTIO. See ENCAUSIS.

DEUTERIA, } from δευτερος, *ſecundus*. A poor
DEUTERINAS, } kind of wine, which the Latins call LORA. Alſo *adheſion of the placenta*.

DEUTERION. See SECUNDINA.

DEVALGATUS. See BLÆSUS.

DEXAMENE. Any receptacle, but particularly the *labrum* or *ſolium*, that is, a deep baſon in which bathers might ſwim. It was alſo called COLYMBETHRA and EMBASIS.

DEXTANS. See CYATHUS.

DIA, δια. The beginning of ſeveral terms in medicine: and when the name of any thing begins with theſe three letters they ſignify compoſition, and the word with which they are compounded is the chief thing in the compoſition; of which a variety of inſtances may be ſeen in the ſucceeding pages.

DIABACANU, from *bacanon*, a principal ingredient in it. An hepatic remedy mentioned by Trallian.

DIABEBOS. The ANKLE-BONES. Hippocrates uſes this word. See ASTRAGALUS.

DIABESASA, from διὰ and βεσασα, *wild rue*. The name of a preparation, in which *rue* forms a part.

DIABETES, from διαβαινω, *to paſs off or through*; ſome call it DIARRHŒA URINOSA; DIARROIA EX OURE; DIPSACOS; DIURESIS; HYDROPS AD MATULAM; PROFLUVIUM URINÆ. That diſorder in which what is drank ſuddenly paſſes off, and is evacuated almoſt crude. Or it is an exceſſive diſcharge of crude urine, exceeding the quantity drank. Boerhaave, in his Inſtitutes, ſays, it is a frequent copious diſcharge of lacteous urine, in conjunction with an extraordinary thinneſs of the humours.

Dr. Cullen places this genus of diſeaſe in the claſs neuroſes, and order ſpaſmi: which he defines a chronic profuſion of urine, for the moſt part preternatural, made in immoderate quantity. He notices two ſpecies, 1ſt, DIABETES MELLITUS, when the urine hath the colour, odour, and taſte of honey. 2d. *Diabetes inſipidus*, when the urine is limpid, and not ſweet. Dr. Home defines it to be an extraordinary increaſe of the urine as to its quantity, and that of a ſweetiſh taſte; attended with perpetual thirſt, and a dry ſkin, which for the moſt part is alſo ſcaly.

Lommius ſays that the ſeat of this diſorder is in the kidnies; but this does not appear to be the caſe, and ſome difficulty attends the aſcertaining it.

Youth is ſcarcely ever attacked with this diſorder: its moſt frequent ſubjects are thoſe in the decline of life, who have been ſubject to a liberal uſe of wine in their youth, and who are alſo employed in the more violent kinds of buſineſs.

The cauſes are generally ſaid to be a relaxation of the renal duct; too great a tenuity of the fluids; or obſtructed perſpiration: but perhaps, on maturer conſideration, a defect of vital heat, and the concurrence of ſuch accidents as determine the ſerum to the kidnies, are the real cauſes. The diſcharge is not a truly urinous one, no more than that through the ſkin in a hectic fever is of a truly perſpirable kind.

Beſides the frequent and too copious diſcharge of urine, it is generally inſipid, though ſometimes a ſweetneſs both to the ſmell and taſte is obſerved in it: thirſt, an hectic heat, a weak but quick pulſe, a gradual waſting of the fleſh, and, after ſome time, an anaſarcous tumidneſs comes on. Dr. Liſter obſerves that it is ſlow in its approach; that in the beginning the mouth is dry, the ſaliva white and frothy, and an unuſual heat is perceived in the bowels. If by accident the urine is ſuddenly checked, there follows a ſwelling of the loins, ſcrotum, legs and feet; and what urine is diſcharged paſſes off with pain, and thus death is ſoon uſhered in.

The ſweetneſs of the urine (which ſymptom is not conſtant, but generally when it does attend, only appears towards the end of the diſeaſe, or when death ſeems near at hand,) is owing to the chyle paſſing unaltered into it, which, as Dr. Morton obſerves, gives a ſweetneſs to the matter expectorated in the laſt ſtage of a phthiſis.

When recent, and the conſtitution of the patient not much injured, a cure is ſometimes effected; but if of long ſtanding, and there is a debilitated or otherwiſe diſordered habit, no hope of relief can be encouraged.

The general indications of cure, are, 1. *To increaſe the craſſamentum of the blood*; and 2. *To divert* or *reſtrain the preternatural diſcharge*.

The diet ſhould be the ſame as in an hectic fever, viz. animal ſubſtances, ſuch as broth made of beef, ſhell-fiſh, milk often, and in ſmall quantities; jellies; barley-water, in which the root of comfrey is boiled, and lime-water, may be the common drink.

Moderate exerciſe on horſeback, and dry friction of the whole body, aſſiſt in promoting perſpiration; and which, when excited, peculiarly tends to divert the diſcharge through the kidnies.

When unquenched lime is mixed with the ſerum of blood, it generates thoſe ſalts that are neceſſary to the true urinary diſcharge; and if lime-water is drank as freely as the thirſt requires it, its efficacy exceeds that of Briſtol water in the cure of a *diabetes*, notwithſtanding the latter is eſteemed as a ſpecific: but, in order to this advantage from lime-water, it muſt be drank while the heat continues which it poſſeſſes from the lime being quenched in the water.

At proper intervals, during the uſe of lime-water, as above directed, the acidum vitrioli dilutum; cort. Peruv; limat. ferri; and whatever can improve the craſis of the blood, may alſo be adminiſtered.

A flannel ſhirt may be worn to ſolicit a diſcharge through the ſkin. The tincture of cantharides is ſaid by Dr. Morton to be a ſpecific in this complaint. Others prefer the ſerum aluminoſum, made as ſtrong as the ſtomach will bear it, and direct half a pint to be taken night and morning. With others, the vitr. cœrul. gr. ſs. given twice a day, diſſolved in any agreeable liquor, is moſt depended on. When the means firſt propoſed are unſucceſsful, recourſe may be had to theſe, or ſuch other means as experience may ſuggeſt. Rhubarb is found to be of ſingular advantage; and from the ſucceſs which follows on the uſe of antiſpaſmodics, joined with other means, a ſpaſm in the ducts, through which ſome other excretions are conveyed, rather than an irritation in the kidnies, may be a principal cauſe of this malady.

See Aretæus, Lommius, Boerhaave, Liſter, Shebbeare's Theory and Practice of Phyſic, Lond. Med. Obſ. and Inq. vol. iii. p. 274, &c. vol. v. p. 298. Cullen's Firſt Lines, vol. iv. Wallis's Sydenham.

DR. GOTTLIEB RICHTER, profeſſor of medicine at Goettingen, ſays, according to his experience, that a diabetes is occaſioned by a ſtimulus which acts upon the kidneys, when the particular irritation cannot be diſcovered, nor removed: to counteract its action upon the kidneys by antiſpaſmodics and ſedatives, is the proper remedy. In proof of which he refers to Dr. WHYTT and M'CORMIC, who ſaw it originate from gouty matter, and SYDENHAM from healing an old ulcer. STELLER, who cured a patient with bark and opium; DOBSON by warm baths; M'CORMICK by Dover's powder: BRISBANE, who affirms almond emulſion to be of great uſe in ſuch caſes. Dr. Richter ſays alſo, that tincture of cantharides and bark, have been variouſly uſed with advantage againſt diabetes, and ſuppoſes, that the firſt acted by carrying off irritation as in the chincough; the ſecond, by allaying irritation, as in agues. But notwithſtanding theſe, he depends upon his own experience, and gives ſome cures in ſupport of this opinion: one caſe, which ſucceeded a bilious fever, wherein the pulſe was ſmall, tenſe, irritated, and quick, attended with an uneaſy ſenſation and fulneſs in the region of the ſtomach; all the complaints growing worſe towards evening, was cured by a vomit, by which a very great quantity of bilious ſtuff was evacuated. A ſecond, wherein ſome ſcorbutic ſymptoms appeared, was conquered by wort. A third and fourth, for which no preciſe cauſe could be diſcovered, yielded to tartar emetic and valerian in the firſt caſe; in the ſecond, to ipecacuanha, which occaſioned vomiting; and as often as the patient vomited, the diſeaſe diſappeared for twenty-four hours; but beſides theſe medicines above ſpoken of, he ſtrongly recommends camphor in emulſion. See Medical and Surgical Obſervations, Edinburgh, 1794.

DIABOLUS METALLORUM. See STANNUM.

DIABOLI INTESTINA. See CUSCUTA.

DIABOTANUM, from βοτανη, *an herb*. The name of a plaſter prepared of herbs.

DIABROSIS, from διαβιβρωσκω, *to eat through*. See ANASTOMOSIS, and ANABROSIS.

DIACADMIAS. The name of a plaſter, whoſe baſis is cadmia.

DIACALAMINTHES. The name of an antidote whoſe baſis is calamint.

DIACARCINON, from καρκινος, *a crab*, or *cray-fiſh*. The name of an antidote prepared of theſe kinds of fiſh.

DIACARYON, from καρυον, a *walnut*. See JUGLANS.

DIACASSIA. See CASSIA FISTULARIS.

DIACASTORIUM, from καστορεον, *caſtor*. A name of an antidote whoſe baſis is caſtor.

DACATHOLICON, from διὰ, *of*, and καθολικος, *univerſal*. See CATHOLICON.

DIACEPTATESSON. A name given by Van Helmont to a purging preparation of antimony. It is alſo a term in Paracelſus; he ſeems to mean a vomit excited by quickſilver. According to ſome, this word ſignifies quickſilver diſſolved in alcaheſt.

DIACENOS, from κενος, *empty, void*. An epithet of porous bodies, ſuch as ſponge, pumice-ſtone, &c.

DIACENTAURION. See CHAMÆDRYS.

DIACENTETON. The name of a collyrium in Celſus. It is ſo called from κερας, *a horn*, becauſe burnt hartſhorn is a principal ingredient.

DIACHALASIS, from διαχαλαω, *to be relaxed*. This word was formerly uſed to ſignify the opening of the ſutures of the cranium.

DIA-

DIACHALCITIS. The name of a plaſter whoſe baſis is the calcitis.

DIACHEIRISMOS, from χειρ, *a hand*. It is any manual operation.

DIACHELIDONIUM, from χελιδων. A SWALLOW. A preparation of ſwallows.

DIACHETON. See ASPALATHUS.

DIACHOREMA. } All ſorts of excretions from the
DIACHORESIS. } body, but more properly and frequently thoſe by ſtool. See DISTRIBUTIO.

DIACHRISTA, from χριω, *to anoint*. In P. Ægineta it ſignifies medicines that are applied to the fauces, palate, uvula, and tongue, to abſterge phlegm.

DIACHRYSU, διαχρυσου, from χρυσος, *gold*. The name of a plaſter mentioned by Galen, which was uſed when limbs were fractured.

DIACHYLON, from δια, *ex*, and χυλος, *a juice*. An emollient digeſtive plaſter made of certain juices. This name is given to very different compoſitions for plaſters, and is now the empſ. lithargyri of the London Diſpenſatory. See EMPLASTRUM COMMUNE.

DIACHYSIS, from χυω, *to fuſe* or *melt*. See FUSIO.

DIACHYTICA. See DISCUTIENTIA, and DISSOLVENTIA.

DIACHYTOS. An epithet of wine prepared of grapes, that have been dried ſeven days, and were preſſed on the eighth.

DIACINEMA, διακινεω, *dimoveo*, to *thruſt* or *put aſide*. See LUXATIO.

DIACLYSMA, from κλυζω, *to waſh out*, or *rinſe*. See GARGARISMA.

DIACOCCYMELON, from κοκκυμηλον, *a plum*. See DIAPRUNUM.

DIACOCHLACON, from κοχλακες, *flints*. An epithet of milk in which red-hot flints have been extinguiſhed. Such milk is ſudorific.

DIACODIUM, from δια, *ex*, and κωδια, a *poppy head*. See PAPAVER ALBUM.

DIACOLOCYNTHIDOS PILULÆ. Alex. Tralian's compoſition which bears this name is called pil. de nitro in the Auguſtan Diſpenſatory: they conſiſt of aloes, colocynth, nitre, &c.

DIACOLOCYNTHIS, from *colocynth*, which is the chief ingredient in the preparation.

DIACOMERON. The name of an antidote in Myrepſus.

DIACOPE, from διακοπτω, *to cut through*. A deep cut or wound, or the cutting off any part.

DIACOPRÆGIA, from κοπρος, *dung* and αιξ, *a goat*. A preparation with *goat's dung* againſt diſorders of the parotids and ſpleen.

DIACRISIS, from διακρινω, *to judge* or *diſtinguiſh*. The judging of diſeaſes and ſymptoms.

DIACROCIUM. The elect. de ovo; PLATERUS de curat. Febrium Peſtilentialium, Tom. 2 C. 2.

DIACROCU, διακροκου, from κροκος, *ſaffron*. The name of a dry collyrium in P. Ægineta, in which is *ſaffron*.

DIACURCUMA, from *curcuma*. A word which Fuchſius thinks Meſue uſed for *ſaffron*. A name of ſeveral antidotes in Myrepſus, of which *ſaffron* is an ingredient.

DIACYDONIUM. MARMALADE of QUINCES. See CYDONIA.

DIADAPHNIDON, from Δαφνις, the *bay-tree*; *bayberry*. The name of a drawing plaſter prepared of *bayberries*; with intent to extract, or move pus. Celſ. lib. 5. chap. 19.

DIADELPHIA, from δι, twice, and αδελφος a brother. The name of the ſeventeenth claſs, in Linnæus artificial ſyſtem, comprehending thoſe plants which bear hermaphrodite flowers, with two ſets of united ſtamens. This is a natural claſs with papilionaceous, or pea-flowers, and leguminous fruits. The orders are founded on the number of ſtamens, and ten being the predominating number in this claſs, the ORDER *decandria* is much the largeſt. The regular diſpoſition of the ſtamens, in this order, is, nine united in one brotherhood, the lower broad part of the filament ſheathing the germ, and the tenth ſingle; but in almoſt twenty genera, the ten ſtamens are connected into one body at bottom.

DIADEXIS, }
DIADOCHE, } See METASTASIS.

DIADOSIS, from διαδιδωμι, *to diſtribute* or *diſſipate*. In medicinal authors it ſignifies to remit, though ſometimes it means the diſtribution of the aliment over all the body.

DIÆRESIS, from διαιρεω, *to divide* or *ſeparate*. It is taken generally, from Galen, to be a SOLUTION of CONTINUITY, of which he forms four ſpecies, wounding, contuſion, eroſion, rapture; it is now uſed in this ſenſe from whatever cauſe the ſolution ariſes.

DIÆRETICA, from διαιρεω, *to divide*. Corroſive medicines.

DIÆTA, DIETA, alſo DIATERETICA. DIET. When ſtrict, and regular, the Greek ſnamed it *cathefſecos*. Though Diet is often confined to what we eat and drink, yet Galen and moſt other medical writers include in it the whole of what are called the non-naturals. On this ſubject, ſee Galen, whoſe work is the baſis of what hath been written ſince his day; ſee Hoffman, Arbuthnot, Mackenzie, and others, on the non-naturals.

DIÆTETICA. See PHARMACEUTICE.

DIAGLAUCIUM. The name of a collyrium recommended by Scrib. Largus. It is thus named from *Glaucium*, which, according to Dioſcorides, is the juice of the *papaver ſpinoſum*.

DIAGNOSIS, from διαγινωσκω, *to diſcern* or *diſtinguiſh*, alſo DIGNOTIO. It is the knowledge, by ſigns, of things preſent, and appertaineth therefore as well to a ſtate of health, as diſeaſe. But it is now generally confined to the latter, therefore by Diagnoſtics, are underſtood the ſigns of diſeaſes, by which they may be known. They are of two kinds, viz. the *adjunct*, and *pathognomonic*; the *firſt* are common to ſeveral diſeaſes, and ſerve only to point out the difference between diſeaſes of the ſame ſpecies; the *latter* are thoſe which always attend the diſeaſe, and diſtinguiſh it from all others

DIAGRYDIUM, alſo DIACRYDIUM. A preparation of ſcammony. The ordinary way of doing which, in order to correct it, was by baking the ſcammony in a quince: from whence its name, quaſi διακρυδια, *lacrymula*, becauſe, among phyſicians, the juice iſſuing from the wounded root of the ſcammony tree, was called *lacryma ſcammonii*. Some make it receive the fumes of lighted ſulphur; hence *diagrydium ſulphuratum*. Some incorporate it with a quantity of ſpiritus vitrioli roſati, ſufficient to make a ſort of liquid paſte, which is afterwards ſet to dry in the ſun or by a gentle fire; hence *diagrydium roſatum*. But theſe modes are conſidered now as of no conſequence as correctors. See SCAMMONIUM.—

DIAHERMODACTYLU. A purging medicine, of which hermodactyls form the baſis.

DIAHEXAPALA, or DIAHEXAPTE. See LAURUS ALEXAND.

DIAION. The name of a paſtil in Myrepſus. Violets are its chief ingredient.

DIAIREOS. An antidote in Myrepſus, in which is orris root.

DIALACCA. An antidote in Myrepſus, in which is the lacca.

DIALAGOU. The name of a medicine, in which is the dung of a hare.

DIALEPSIS, from διαλαμβανω, *to interpoſe*, or from διαλειπω, *to leave a ſpace between*. To intermit. See APOLEPSIS.

DIALIBANON. A name of ſeveral medicines in which frankincenſe is an ingredient.

DIALOES. A compoſition in which is aloes.

DIALTHÆA. The name of an ointment in Myrepſus, from which the ointment of althæa ſeems to have been taken.

DIALYSIS, from διαλυω, *to diſſolve*, or *render languid*, alſo *diſſolutio*. A *diſſolution* of the ſtrength, or a weakneſs of the limbs. It is alſo applied by Hippocrates to the agent cauſing the debility, particularly the winds, hence νοτοι διαλυσεις, auſtri diſſolventes. Beſides it is expreſſive of a diſcontinuity or diviſion of a part.

DIALYTICA. A ſolution of continuity, as in fractures, wounds, &c.

DIAMARENATUM. It is a confection of acid cherries, called *amarenæ*, reduced to a pulp, paſſed through a ſieve, then mixed with ſugar, and alſo ſome aromatics. See Schroder. Pharmacopœia medico-chymica. Lib. 4. p. 41.

DIAMARGARITON. An antidote in which pearls are the chief ingredient.

DIAMASCIEN. See ÆRIS PLOS.

DIAMASSEMA, from διαμασσομαι, *to chew*. A maſticatory.

DIAMBRÆ PIL. See AROMAT. PILULÆ.

—— SPECIES, (called *ſpecies aromatica*, now *pulvis aromaticus*.) The preſcription is originally Meſue's, and had

had its name from the ambergriſe which was in the compoſition. See AROMATICÆ SPECIES.

DIAMELON. The name of a compoſition in which are quinces.

DIAMNES. An involuntary diſcharge of urine, and that inſenſibly. This word is uſed by Joh. Anglicus: called alſo *diapne*.

DIAMORON, a preparation of mulberries, and honey.

DIAMOSCHU. The name of an antidote in which is muſk.

DIAMOTOSIS, from μῶλος, *lint*. See CARRASUS.

DIANA, in chemiſtry, is the *ſilver* of the philoſophers. It is alſo a name of *ſilver*. See ARGENTUM.

DIANANCASMOS, from ἀναγκη, *force* or *neceſſity*. The forcible reſtitution of a luxated part into its proper place. Hippocrates calls an inſtrument thus, which is intended for reſtoring a diſtorted ſpine.

DIANDRIA. The ſecond claſs of Linnæus's artificial ſyſtem, comprehending all hermaphrodite flowers, which have two ſtamina. It includes 3 ORDERS; MONOGYNIA, in which are 32 genera; DIGYNIA, 1 genus; and TRIGYNIA, of which there is only 1 genus.

DIANTHON. The name of an antidote in Galen, which is thus made:

℞ Flor roriſm. ʒ i. roſar. R. & rad. glycyr. ää ʒ vi. caryoph. arom. ſpic. nard. nuc. muſch. rad. galangal. cort. cinnam. rad. zedoar. lign. aloes ſem. card. min. ſem. anethi, ſem. aniſi, & macis. ää ℈ iv. m.

DIANTHUS CARYOPHILLUS. See CARYOPHILLUS RUBER.

DIAOPORON, from ὀπωρα, *autumnal fruit*. A compoſition in which are quinces, medlars, and ſervices.

DIAPASMA. See CATAPASMA.

DIAPEDESIS, from διὰ, *through*, and πηδαω, *to leap*. The tranſudation of blood through the coats of an artery. See ANASTOMOSIS.

DIAPENCIA. See ALCHIMILLA.

DIAPENSIA. See SANICULA MAS.

DIAPENTE from διὰ and πεντε, *quinque*. A compoſition ſo called becauſe it conſiſts of five ingredients. It is thus made:

℞ Rad. gentian. Ariſtol. Long. vel Rot. Raſ. Eboris; bac. laur. & myrrh. ää p. æq. m. f. pulv.

Meſue is ſaid to be its author, but Vegetius deſcribes it before. It is now chiefly uſed by Farriers.

DIAPEPEREON. An antidote mentioned in Galen.

DIAPHÆNICON. The name of an electary for purging off phlegm, &c.

DIAPHILEDONU. The name of an antidote in Myrepſus.

DIAPHLYXIS, from διαφλυω, *to moiſten*. In Galen's Exegeſis it is expounded by effuſions or ebullitions.

DIAPHONE. See PERSPIRATIO.

DIAPHŒNICON, from φοινιξ, *a date*. A medicine made of dates.

DIAPHORA, from διαφερω, *to differ*. DIFFERENCE. In medicine it comprehends the characteriſtic marks and ſigns which diſtinguiſh one diſeaſe from another. It alſo ſignifies a corruption of food in the ſtomach; and then is an inſtance of DYSPEPSIA, which ſee.

DIAPHORESIS, from διαφορεω, of διὰ, *through*, and φερω, *to carry*. See PERSPIRATIO.

DIAPHORETICA. DIAPHORETICS. Medicines which promote perſpiration. *Diaphoretics*, called alſo perſpiratives, differ from *ſudorifics*: the former only increaſe the inſenſible perſpiration; the latter excite a ſenſible diſcharge through the ſkin, which is called ſweat. See SUDORIFICA.

One half of a ſudorific is generally a due doſe for a diaphoretic.

Hoffman obſerves that *diaphoretics* are the beſt edulcorants, or ſweeteners of the blood and humours.

DIAPHRAGMA. The *diaphragm*, from διαφραγω vel διαφραττω, *to make a partition*, or *incloſure*, of διὰ, *through*, and φραγω, *to cloſe*; becauſe it divides the cavity of the thorax from that of the abdomen. MIDRIFF. It is alſo called DIAZOMA, DISSEPTUM, HYPOZOMA, SEPTUM TRANSVERSUM, CINETUS, SUCCINGENS MEMBRANA. Cœlius Aurelianus calls it the DISCRIMEN *thoracis & ventris*, becauſe it ſeparates the thorax from the belly. Pliny calls it the PRÆCORDIA, becauſe it ſtands, (he ſays,) like a wall, to defend the heart. Hippocrates, with many of the ancients, call it φρενες; they alſo gave the name of *diaphragma* to the ſtrait place of the fauces, between the mouth and the œſophagus, terming it by way of diſtinction the *diaphragma* by the œſophagus. Galen and Rufus Epheſius call the cartilaginous partition between the noſtrils, the *diaphragm* of the noſe. But the only part which is now called *diaphragma*, is that which ſeparates the thorax from the belly.

The *diaphragm* is compoſed of two muſcles; the ſmall one riſes by two tendons, called *cruræ*, from the ſecond lumbar vertebra, and receives a ſlip from the firſt vertebra of the loins, and from the ligament which joins the laſt rib to the vertebra, the two cruræ then run upwards and grow fleſhy. The large muſcle riſes from the inſide of the margin of the thorax, all round, from the falſe ribs to the xiphoid cartilage; its fibres ſhoot forwards, and form that triangular appearance called the *centrum tendineſum*, or *centrum nervoum*. Winſlow calls it the middle aponeuroſis, or aponeurotic plane of the *diaphragm:* Meſſrs. Le Gare and de Bordeu call it CENTRE *phrenique*. It is alſo called *Coeſtrum*. There is a notch between the cruræ of the leſſer muſcle, where the aorta paſſes. In the larger muſcle are two holes, one in the tendinous part, for the vena cava, which is ſituated there, becauſe, as the tendon is not capable of being contracted, the circulation will not be interrupted: the other hole is for the œſophagus, and is ſituated in the fleſhy part; which ſeems to be for this reaſon, that, as the *diaphragm* in its action preſſeth on the ſtomach, it might cauſe an evacuation of its contents, unleſs at the ſame time it was to ſerve as a ſphincter to the œſophagus, by reducing its cavity from an oval figure to a narrow ſlit; wherefore the *diaphragm* acts in this caſe as an antagoniſt to the abdominal muſcles, which contradicts that opinion, that vomiting is occaſioned by their joint action. From conſidering the attachment of the *diaphragm*, it will be ſeen that its action will be to render itſelf flat, and thereby to enlarge the cavity of the thorax; but if we regard it as acting round the viſcera as round a pully, we may conceive how it both depreſſes the viſcera, and raiſes the ribs; at the ſame time, ſtill more enlarging the cavity of the thorax. The veins are large, and go directly to the vena cava. The arteries are ſometimes immediately from the aorta, and ſometimes from the cœliac; a few twigs are received alſo from the lumbals and adipoſe. The nerves are from the plexus cervicalis on each ſide, and from the ſecond pair of the vertebræ.

In inſpiration, the *diaphragm* deſcends towards the belly; this is its proper motion, which, as a muſcle, is contraction. In expiration, it is relaxed and drawn upwards, forming a concavo-convex figure, the concave ſide being towards the belly. It aſſiſts in the expulſion of the excrements and fœtus. It is in perpetual motion, and ſeems to have other and more important uſes in our conſtitution, than as yet are clearly ſeen into. See Berdoe's Enquiry, p. 27 and 126. It is alſo a name of the SEPTUM SCROTI. See SCROTUM.

DIAPHRAGMATICÆ ARTERIÆ. The DIAPHRAGMATIC ARTERIES. They are alſo called PHRENICÆ ARTERIÆ. As ſoon as the aorta gets through the *diaphragm*, it ſends off two arteries thereto; though ſometimes the *diaphragmatic arteries* are branches of the cœliac, and ſometimes the right *diaphragmatic artery* riſes from the lumbar artery. The *diaphragmatic arteries* generally appear on the under ſide of the *diaphragm*, very rarely on the upper; they give ſmall branches to the glandulæ renales, and to the fat which lies on the kidneys; theſe latter are called adipoſæ. Beſides theſe capital *diaphragmatic arteries*, there are other leſſer ones from the intercoſtales, mammariæ internæ, mediaſtinæ, pericardiæ, and cœliacæ.

—— VENÆ, The *diaphragmatic veins*, alſo called PHRENICÆ VENÆ. They ſpring from the vena cava inferior, juſt as it deſcends through the *diaphragm:* they appear generally on the lower ſide of the *diaphragm*. The left branch runs much upon the pericardium.

—— SUPERIORES VENÆ. The upper diaphragmatic veins, alſo called PERICARDIO-DIAPHRAGMATICÆ VENÆ. The right comes anteriorly from the root of the bifurcation, near the mediaſtina, and is ſpread about the pericardium: the left from the left ſubclavian.

DIAPHRAGMITIS. INFLAMMATION of the DIAPHRAGM. See PARAPHRENITIS.

DIAPHTHORA, from φθειρω, *corrumpo, to corrupt*. In Hippocrates it ſignifies the corruption of the fœtus. See ABORSUS.

DIAPHYLACTICOS, from φυλασσω, *to keep*. See PROPHYLACE.

DIAPHYSIS, from διαφυω, *interna ſcor*, to grow between. An inſterſtice, a partition, or whatever intervenes

between things. Galen explains it to be a nervous and cartilaginous protuberance in the middle of the joining of the os tibiæ with the os femoris, which enters that large sinus, and makes a separation between the lower heads and processes of the os femoris, which are inserted into the sinus of the os tibiæ. This substance only appears in recent subjects. In other places, the *diaphysis* is spoken of as a cavity, chink, &c. for the reception of some other part.

DIAPISSELÆON. A composition in which is liquid pitch as a chief ingredient.

DIAPLASIS, from πλασσω, *to form*, or from διαπλασσω, *to put together*, or *fashion*. CONFORMATION. It signifies the replacing a luxated or fractured bone as near as may be to its proper situation.

DIAPLASMA, from διαπλασσω, *to smear over*. An unction or fomentation applied all over the body.

DIAPNE. See DIAMNES.

DIAPNOE, from διαπνεω, *to perspire*, from δια, *through*, and πνεω, *to breathe*. See PERSPIRATIO.

DIAPOREMA, from διαπορεω, *to be in doubt*. ANXIETY, heat, and restless tossing about the body, in distempers. See ALYSMOS.

DIAPRASIUM, from πρασιον, a composition in which *horehound* is one of the ingredients.

DIAPRUNUM, also called DIACOCCYMELON. The name of two compositions in which are prunes: both are purging electaries. The elect. e sennâ is used in their stead.

DIAPSORICUM. The name of a collyrium in Marcellus Empiricus.

DIAPTERNES, from πτερνα, *the heel*. A medicine made of the heels of animals and cheese.

DIAPTEROSIS, from πτερον, *a feather*. The cleaning of the ears with a feather.

DIAPYEMA, from πυον, *pus*. See ABSCESSUS.

DIAPYEMATA. } See SUPPURANTIA.
DIAPYETICA. }

DIARRHODOMELI. The name of a composition of scammony, juice of roses, &c.

DIARIA FEBRIS. See EPHEMERA.

DIAROMATICUM. A medicine composed of aromatics.

DIARRHAGE. A fracture, in particular of the temple bones.

DIARRHODON. A name of many compositions in which roses are an ingredient.

DIARRHŒA, from διαῤῥεω, *to flow through*; δια, *through*, and ῥεω, *to flow*; ALVI FLUXUS. It is when the intestines are solicited to a too frequent discharge of their contents, called also *hypexodes*; *perturbatio alvi*. Dr. Cullen places this genus of disease in the class neuroses, and order spasmi, which he defines a frequent purging; the disease not contagious, and unattended with any primary febrile affection. Of this he forms six species. 1st. *Diarrhœa crapulosa*; STERCOROSA, seu VULGARIS; when the excrements are more fluid and more copious than is natural. 2. *Diarrhœa biliosa*; when yellow fæces are copiously discharged. 3. *Diarrhœa mucosa*, called also *leucorrhois*; DIARRHŒA *lactantium*; —*serosa*; —*pituitaria*; —*vel pituitosa*; —CŒLIACA *mucosa*; —*diarrhœa chylosa*; —Dysenteria a catharticis; —*parisiaca*; in which, either from acrid materials taken into the stomach, or from cold applied particularly to the feet, there is a copious dejection of mucus. 4. *Diarrhœa cœliaca*, called also *cœliaca chylosa*; *cœliaca lactea*; when a milky liquid like chyle passes downwards.—5. *Diarrhœa lienteria*, called also *lienteria spontanea*; when the aliment soon passes through, and but little altered. 6. *Diarrhœa hepatorrhœa*; also—*cholerica*; —*intestinalis*; when the discharge is bloody-coloured serum, and not attended with pain. If attended with pain, it is sometimes called a colic.—When the evacuations are fluid, but partly indigested, it is called CŒLIACA PASSIO.—When the aliment is carried through the bowels, and ejected in an indigested state, or nearly so, the disorder is called LIENTERIA. These are only different degrees of the same disorder.

Those who have been rendered weak or irritable by a hot season or sultry clime, or by being exposed to a putrid vapour, are peculiarly liable to this disease.

The *immediate cause is irritation in the intestines*; but the causes of this preternatural irritation are numerous: the most frequent are an *undue use of purgatives*; *acidity*, or *putrescency of the aliments*; *acrid bile*; *pus secreted from abscesses, and carried to the intestines*; *a laxity of the glands of the intestines*; *obstructed perspiration*; *putrid vapours*; *a translation of the morbid matter of other diseases to the intestines*; *passions of the mind*, &c.

Whatever other symptoms occasionally attend a *diarrhœa*, besides a too copious and too frequent discharge of the intestines, they are not proper to it, but are accidental. The loss of appetite, and of strength, are consequences of the excessive evacuations, or of some other attending disorder: sickness, pain, &c. which in many cases attend, are rather conjuncts with, than constituents of this morbid excretion. The discharges are various in different patients, and also in the same at different times. *If there is a defluxe of watery humours*, the looseness is most urgent by night and after sleep; if *a disorder in the mesentery* or *stomach is the cause*, the discharges are mucous, and made chiefly in the day. *An offending bile*, when too freely emptied into the intestines, disturbs in the night more than in the day. In violent cases, skins appear in the stools, like the coats of the intestines; these are pieces of the epithelium, which lines the rectum, &c. and, in this disorder, is thickened and separated, then cast out of the body.

While the patient's strength is but little affected by a *diarrhœa*, it may be generally looked on as a salutary rather than morbid evacuation; but sometimes, if neglected, or ill-treated, a dysentery is the consequence, and the cure is difficult. When passions are the cause, the cure is also tedious. Fevers sometime terminate in *diarrhœas*, in which case, if they abate in a day or two, their effects are salutary; but if they continue, they sometimes prove fatal. When a looseness abates and returns, accompanied with a fever, it is generally troublesome, and sometimes much danger attends it. Copious as well as frequent discharges subject the patient to fainting. If a spontaneous vomiting comes on upon a long-continued purging, it proves generally a cure. Bilious discharges cease on the accession of deafness; as, on the contrary, a deafness often hath its solution upon the discharge of bile. Acid eructations, which do not begin with the disorder, but come on afterwards, are favourable indications. The loss of appetite, and hiccoughing, are bad. A moist skin, and a sediment in the urine, are symptoms of the most favourable kind.

WITH REGARD TO THE CURE; the diet may be preparations of rice; and the white decoction may be the common drink, or camomile tea.

When unattended with pain, fever, or other violent symptoms, the stomach may be cleared with a few grains of ipecac. and, after it, a draught may be given of the tinct. rhab.

If any further assistance seems necessary, *whatever kind of symptoms attend*, a perspiration excited by such small doses of ipecac. pulv. as will not solicit the stomach to a discharge, seems to be a specific. To children it may be given in a clyster, which must be repeated three or four times a day, each containing eight or ten grains of this powder. Adults may take two or three grains in a powder or draught, and repeat it two or three times a day, as the case may require.

A suppression of the evacuations by means of astringents, or of opiates, before the pulse fails, is improper; but the ipecac. may be used at all times with safety and advantage; a warm bath, or any other external method of promoting perspiration, contributes much to the assistance of the ipecacuanha. To this end, opiates are the best internal aids; but when their use is forbid, the baths; or flannels, wrung out of warm water, may be wrapped round the legs and thighs, and the patient at the same time duly guarded from cold.

When a DIARRHŒA *is chronical*, moderate exercise in a dry warm air is beneficial. Sydenham commends riding on a horse; but a carriage is more proper, as it defends more from the moisture of the atmosphere, and strengthens the bowels in a greater degree: in this case, besides small doses of pulv. ipec. aromatics and chalybeats should be administered; and a moderate use of diuretics, in some instances, is useful.

If a tenesmus is troublesome, ℞ Enem. ex amyl. ℥ vi. cum. tinct. opii gut. xx. ad xxx. vel spt. vin. Gallic. ℥ i. m. & repet. pro re nata.

When obstructed perspiration is the cause, the stools are usually serous; in this case, bleeding sometimes is required, before other means can be used with proper advantage.

When an acrid bile produces a DIARRHŒA, a few grains of nitre will be a neceſſary addition in each doſe that is given, to reſtrain the diſcharges.

When a DIARRHŒA *attacks child-bed women*, it is a threatening ſymptom, and, if it continues above two or three days, is very dangerous. In this ſituation, a clyſter with ſtarch and tincture of opium ſhould be injected, and immediately after it the columbo-root may be given by way of infuſion in boiling water; a tea-cupful after each evacuation. It is ſafe and efficacious, like the ipecac. *whether a fever attends or not*; and, like it, may be adminiſtered in thoſe early ſtages in which aſtringents are often forbid.

When grief or other paſſions gave riſe to this diſorder, the cure is difficult; the affections of the mind are a check to perſpiration, and powerfully counteract every means of exciting it. In ſuch a caſe, the feet muſt be kept warm, vomits and purges omitted, except very mild ones, and antiſpaſmodics, with moderate doſes of opium, muſt be perſiſted in for the cure. Small doſes of the tinct. opii, in draughts of valerian tea, will be proper.

The DIARRHŒA *which attends infants during dentition*, is much relieved by the following: ℞ Pulv. rad. columb. ℈ i. ad ʒ i. magneſ. alb. ℈ ii. ad ʒ ii, aq. menth. ʒ iv. m. detur cochl. parv. 2da, vel 4ta, vel 6ta quaq. hora.

Aſtringents are only indicated when the exorbitant diſcharges endanger life; and when theſe are admitted, logwood and its preparations are to be preferred. The *cort. ſimaroub.* is ſingularly efficacious; the *biſtort* and *tormentil roots* are powerfully ſo; but *alum*, ſo uſeful in hæmorrhages, which has been thought not to be of great advantage here, is recommended ſtrongly to be tried by Dr. Cullen.

If flatulencies are very troubleſome, the following bolus may be repeated every three or four hours. ℞ Extr. lign. Campech. ℈ i. pulv. cort. eluther. gr. x. fyr. q. ſ. bol.

In *ſcorbutic*, *arthritic*, and *other diſeaſed habits*, a *diarrhœa* is often a conſequence of the peculiar acrimony of the humours affecting the inteſtines: in which caſes, to correct the morbid quality of the fluids, or to remove them to a leſs dangerous ſituation, will conſtitute the cure. Here regard muſt be had to the original diſorder.

Infants that have not the breaſt, are ſometimes ſo diſordered by watery ſtools attended with gripes, that all the uſual methods of relief are but vain endeavours; when this happens, *a freſh breaſt will as rarely fail to cure, and therefore ſhould not be neglected.* The ſtools attending theſe tender patients are ſometimes green as well as watery, and generally uſher in convulſions. The eaſieſt and moſt effectual management is to give *three*, *four*, or *ſix drops of the vin. ant. or more, if neceſſary, to provoke a vomiting, and repeat it every four, ſix, or twelve hours*, until the colour and conſiſtence of the ſtools are amended. While the ſtools are ſour and green, three or four drops of aq. kali may be given at proper intervals, or the mixture above preſcribed, with magneſ. alb. and r. columb.

See Aretæus, Lommius, Wallis's Sydenham, Fordyce's Elements, part ii. Dr. Pye's Obſervations on the Uſe of Ipecac. in the Lond. Med. Obſ. and Inq. vol. i. Cullen's Firſt Lines, vol. iv.

DIARRHŒA CARNOSA. See DYSENTERIA.
—— CHOLERICA. See CHOLERA MORBUS.
—— LACTANTIUM.
—— PITUITARIA vel PITUITOSA. } h. s. DIARRHŒA MUCOSA. } See DIARRHŒA.
—— SEROSA.
—— STERCOROSA. See DIARRHŒA CRAPULOSA.
—— URINOSA. See DIABETES.
—— VULGARIS. See DIARRHŒA CRAPULOSA.

DIARROIA EX OURE. See DIABETES.

DIARROXÆ, from διαῤῥωξ, *fiſſus*. The interſtices betwixt the circumvolutions of bandages.

DIARTHROSIS, from δια, *per*, and ἀρθρον, *a joint*. It is that ſpecies of articulation which is moveable, alſo called *abarticulatio*, *dearticulatio*, *genou*, *adarticulatio*. Different authors vary in their diviſion thereof, but Dr. Hunter reckons it to conſiſt of three ſpecies: 1ſt, The *enarthroſis*, or ball and ſocket, which is, when a large head is received into a deep cavity, as the head of the femur into the acetabulum of the os innominatum, and is conſidered as a ſynonym with *genou*. 2dly, *Arthrodia*, which is, when a round head is received into a ſuperficial cavity. Theſe two kinds admit of a motion on all ſides. 3dly, The *ginglymus*, called alſo *cardo*, *cardinamentum*, becauſe it reſembles the motion of an hinge. There are properly but two ſpecies of this ſort of articulation. The firſt is confined to flexion and extenſion. WINSLOW calls this the *angular ginglymus*. IN THIS SORT, either each bone receives partly, and partly is received by the other, as in the articulation of the humerus with the ulna, or many eminences in one bone are received into as many cavities in the other. THE SECOND is adapted only to ſmall turns towards each ſide; hence WINSLOW calls it a *lateral ginglymus*; it is either *ſingle*, as in the articulation of the firſt vertebra of the neck, with the apophyſis dentiformis of the ſecond; or *double*, that is, in two different parts of the bone, as in the articulation of the ulna with the radius.

DIASAPONIUM. An ointment in which ſoap is a principal ingredient.

DIASATYRION. An electary, in which is ſatyrion.

DIASCILLION. So M. Empiricus calls the vinegar and oxymel of ſquills.

DIASCINCI. A name for mithridate. See CONFECTIO DAMOCRATIS.

DIASCORDIUM. So called from the ſcordium in it. It was called *electr. e ſcordio*. Hieronymus Fracaſtorius firſt preſcribed it; ſince named *Fracaſtorii confectio*; though it is now rejected from the London Pharmacopœia, 1788.

DIASENA. It is an antidote in Myrepſus, containing ſena; but is very different from the pulv. e ſen. now in uſe.

DIASERICOS. A compoſition in which ſilk is an ingredient.

DIASMYRNON, or DIASMYRNES. A name of ſeveral collyria, in which are myrrh, σμυρνα, called alſo EUELPIDIUM and ATHENIPPON.

DIASOSTICA, from σωζω, *to preſerve*. See PROPHYLACE.

DIASPERMATON. A name of two malagmas which are compounded of ſeeds.

DIASPHAGE. An INTERSTICE. Hippocrates expreſſes by it the interval betwixt two branches of a vein.

DIASPHYXIS, from σφιζω, *to ſtrike*. The pulſation of an artery.

DIASTASIS, from διαστημι, *to ſeparate*. It ſignifies the diſtance betwixt the fractured ends of bones receding from each other, alſo the interſtice which is naturally betwixt the radius and the ulna. Sometimes it ſignifies that diſtenſion of the muſcles which happens in convulſions. When this word is applied to the ſtomach, it means an effort to vomit; and when uſed with reſpect to the pulſe, it is the ſame as diaſtole. Some ſignify by it a *luxation*.

DIASTEATON, from στεαρ, *fat*. The name of an ointment, in which are the *fats* of a ſtag, ſwine, gooſe, and hen.

DIASTOLE, from διαστελλω, *to ſtretch*. In ANATOMY, it imports the dilatation of the heart, auricles, and arteries. This is in contradiſtinction to SYSTOLE, by which is underſtood their contraction. In the *diaſtole*, the artery is enlarged both in length and breadth. In the *ſyſtole*, the elaſtic coats of the arteries act by reſtoring themſelves, aſſiſted by the action of their muſcular fibres. The *diaſtole* is performed almoſt inſtantaneouſly, the ſyſtole more gradually, inſomuch, that the latter employs two-thirds more than the former. When the heart begins to vibrate, the *diaſtole* is the firſt motion. Kirkland's Med. Surgery, vol i. p. 306. It has been ſaid, that the heart had only two motions, that of dilatation, and contraction, expreſſed by the terms, DIASTOLE, and SYSTOLE; but it hath probably a third, or ſubſultory motion, by which the blood is projected forward from the ventricles of the heart, into the large veſſels.

DIASTOMOTRIS. It is uſually joined with μυλη, a *probe*. See SPECULUM.

DIASTREMMA. } from διαστρεφω, *to diſtort, or turn*
DIASTROPHE. } *aſide*. A diſtortion of the limbs.

DIASULPHURIS EMPLASTRUM. This is a preſcription of Rulandus's, but it contains only a very ſmall proportion of ſulphur, with wax, &c.

DIATAMARON. See ANTIMOROS.

DIATASIS, from διατεινω, *to ſtretch out*. The extenſion of a fractured limb, in order to its reduction.

DIATECOLITHU. An antidote in which is the lapis Judaicus, which is called τηκολιθος.

DIATERETICA. See DIÆTA.

DIATES-

DIATESSARON, δια, *ex*, and τεσσαρες, *four*. A compound ſo called becauſe made of four ingredients, viz. gentian, bay-berries, myrrh, and the root of birth-wort, in equal quantities.

DIATETTIGON. The name of an antidote, in which are graſs-hoppers.

DIATHESIS, from διατιθημι, *to diſpoſe*. An affection or a diſpoſition, as when the blood is inclined to ſome faulty ſtate. Hence the term, often made uſe of in medicine, *inflammatory diatheſis*, that is, when the vaſcular ſyſtem, and the ſanguinary fluid, are in an inflammatory ſtate, or ſo diſpoſed, as readily to become ſo, by any accidental cauſe. See HEXIS.

DIATRAGACANTHI SPECIES. See GUM. TRAGACANTHA.

DIATRINSANTALON. A confect in which is the wood called ſanders.

DIATRION PIPEREON SPECIES. A powder preſcribed by Galen, which chiefly conſiſts of peppers.

DIATRITARII. } An abſtinence during three days
DIATRITOS. } was one of the points in practice by which the firſt methodic phyſicians diſtinguiſhed themſelves from others. This term of three days they call *diatritos*, and not the abſtinence itſelf; and from this circumſtance, the methodics had the name of *diatritarii*. On the third day they gave ſuch medicines as they thought of importance, and not before. Cœlius Aurelianus gives the name *diatritos* not only to the ſpace of three days, but to the third day in particular.

DIAULOS, from δις, *twice*, and αυλη, *a ſtation*. A kind of exerciſe in which the perſon runs a ſtraight courſe forwards and back again.

DIAZOMA, from δια, and ζωννυμι, *to ſurround*. See DIAPHRAGMA.

DIAZOSTER. A name of the twelfth vertebra of the back. It is ſo called from ζωστηρ, *the belt*, which lies upon it.

DICENTETON. The name of a collyrium deſcribed by P. Ægineta.

DICHALCON. A weight equal to one-third of an obolus.

DICHASTERES. See INCISORES.

DICHOPHYIA. It is a diſtemper of the hairs, when they ſplit or grow forked; from διχα, *double*, and φυω, *to grow*.

DICHOTOPHYLLON. See CERATOPHYLLUM.

DICOCTA. Water firſt heated, then cooled with ſnow.

DICOTYLEDONES. See COTYLEDON.

DICRÆUS. See BIFIDUS.

DICROTUS, or BIS-FERIENS, from δις, *twice*, and πρυω, *to ſtrike*. An appellation of a pulſe, where one ſtroke (when the artery hath not been perfectly dilated) is perceived, as if the preceding ſtroke had been intercepted, ſimilar to what appears from hammers ſtriking the anvil, and afterwards rebounding. Dr. Solano firſt obſerved it, and it is conſidered as a certain ſign of an approaching critical hæmorrhage from the noſe. It is alſo called a REBOUNDING PULSE.

DICTAMNITES. A wine medicated with dittany.

DICTAMNUS ALBUS, called alſo *fraxinella*, WHITE or BASTARD DITTANY. Boerhaave mentions three ſpecies. It is a plant with leaves reſembling thoſe of the aſh-tree, but much ſmaller, and more juicy. On the tops of the ſtalks, are long ſpikes of purpliſh and white flowers, which are followed by pods with black ſeeds in them. It is perennial, and grows wild on the mountains in France, Italy, and Germany. It is the DICTAMNUS ALBUS, vel DICTAMNUS FLORE ALBO, *foliis pinnatis, caule ſimplici*. LINN. SUPP. p. 232. CLASS, DECANDRIA; ORD. MONOGYNIA.

The roots are whitiſh; their cortical part, freed from the pith and ſmall fibres, is dried and rolled up, and in this form is brought to England. The young roots, which are about the ſize of a quill, are the beſt. When freſh, they have an agreeable ſmell, which is all diſſipated in drying: they are conſiderably bitter; and this quality is taken up both by water and by ſpirit; and on inſpiſſating the tincture, remains in the extract. Formerly this medicine was in much eſteem, and conſidered very efficacious in conquering uterine, and other viſceral obſtructions, and alſo in deſtroying worms. But it had fallen almoſt entirely into diſuſe, till brought again into practice by baron Stoerck, and recommended in tertian intermittents; againſt worms, particularly that ſpecies called lumbrici; and menſtrual ſuppreſſions. A ſcruple of the powder was given twice a day, which may be gradually increaſed to ʒ i. From twenty to fifty drops of the following tincture were ſucceſsfully preſcribed in epilepſies, given two or three times a day. ℞ Dictamni albi recentis ℥ ij. ſp. vini rect. ℥ xiv. digere. In chlorotic patients, the root, mixed with ſteel, has been ſaid to be efficacious. However, notwithſtanding what has been aſſerted, and though it is allowed to be a medicine of conſiderable power, it is not of any conſequence in preſent practice.

DICTAMNUS CRETICUS, } called alſo *origanum Creti-*
—— VERUS. } *cum, onitis*, DITTANY of CANDY, or of CRETE, ORIGANY, or CANDY WILD MARJORAM. It is the *origanum dictamnus*, Linn. It is a ſmall ſhrubby plant, with ſquare ſtalks, and roundiſh leaves, that are covered with a thick white down; the flowers are in ſpikes of a purpliſh colour. The flowery tops were formerly brought from Crete, and indeed are ſomewhat ſtronger than ours; but in their ſtead, thoſe of our own country are now always uſed. It is perennial, a native of ſtony grounds in Greece, and the iſland of Candy. It bears the ordinary winters of our clime. Thoſe we have from abroad, however ſuperior, whilſt freſh, to our own produce, are hardly ſo good when we receive them.

Whilſt the leaves are in perfection, they are warm and aromatic, have an agreeable ſmell, and a hot biting taſte, reſembling that of the thymus citratus. The garden pennyroyal is of the ſame quality, but not quite ſo ſtrong, though in general far better than the *dittany* which we receive from abroad. Both water and ſpirit take up the virtues of this plant. If a large quantity is diſtilled at once with water, a ſmall portion of eſſential oil is obtained, which is of a yellowiſh colour, of an highly pungent, aromatic taſte and ſmell; it congeals in the cold into the appearance of camphor; the remaining decoction, when inſpiſſated, is a bitteriſh, diſagreeable maſs, but deſtitute of the flavour and warmth of the herb: the ſpirituous extract poſſeſſes all its virtues. See Neumann's Chem. Works; Lewis's Mat. Med.

DICTYOIDES, from δικτυον, *a net*, and ειδος, *form*. NET-LIKE. See RETE MIRABILE.

DIDYME. See BIFOLIUM.

DIDYMÆA. The name of a cataplaſm mentioned by Galen.

DIDYMI. See GEMINUS, TESTES, and CEREBELLUM.

DIDYNAMIA, (δις, *bis, twice*, and δυναμις, *potentia, power*.) LINNÆUS's fourteenth claſs, comprehending thoſe plants which have hermaphrodite flowers, with four ſtamens, in two pairs, of different lengths, the outer pair longer, the middle pair ſhorter, and converging. Theſe flowers have one piſtil, and the corolla is irregular. LINNÆUS has divided this claſs into two orders, GYMNOSPERMIA, and ANGIOSPERMIA.

DIECBOLION. A medicine cauſing abortion: hence DIECBOLICA.

DIELECTRON. The name of a troche, in which is amber (ηλεκτρον).

DIEMEAC. } Terms in Paracelſus. They ſignify a
DIENER. } kind of ſpirit, which, he ſays, reſides in ſtones.

DIETA. See DIÆTA.

DIEXODOS, from δια, and εξοδος, *a way by which any thing paſſes*, alſo DIODOS. In Hippocrates, it is the deſcent or paſſage of the excrements by the anus.

DIFFLATIO. See PERSPIRATIO.

DIGASTRICUS, from δις, *twice*, or *double*, and γαστηρ, *a belly*. See BIVENTER.

DIGESTIO. DIGESTION. IN SURGERY, it is the diſpoſing an ulcer or wound to ſuppuration, by the application of proper remedies.

IN PHARMACY, it is the ſubjecting of bodies, included in proper veſſels, to the action of a gentle heat. The term *digeſtion* is often uſed for maceration; and in this caſe, the proceſs is without heat: where this circumſtance is not expreſſed, *digeſtion* always implies the uſe of heat. In ſome caſes, *digeſtion* is uſed to produce a change in one ſingle body, as in hydrargyrus nitratus ruber, in others, to promote ſolutions, or other combinations. Circulation is a mode of *digeſting*: the veſſels generally uſed are matraſſes, or Florence wine flaſks, either of which may be converted into circulatory veſſels; alſo by inverting the neck of one into the neck of the other. The operation is generally performed in a ſand-bath, by which the degrees of heat may be regulated according to the intention of the operator. This heat

never

never arifes fo as to make the matter boil. *Digeftion* is ufed for making tinctures, wines, elixirs, &c.

In the animal œconomy, it is the converfion of aliment into chyle, and then into blood. By digestion, the fpecific differences of all fubftances are abolifhed; the blood, formed from different kinds of aliment, whether ufed fingly, or together, does not fenfibly differ in its properties, provided that the organ of *digeftion* be fufficiently powerful to convert them into blood. *Digeftion* in the ftomach alone is capable of converting our food into chyle, and the power of animal *digeftion* can alone aflimilate it into our own nature.

When the aliment is converted into chyle by being digefted in the ftomach, it is carried into the duodenum, where mixing with the bile, the nutritious parts are feparated, and the reft is conveyed through the inteftines, to be caft out as excrement. The thinner part of the chyle being feparated from the grofs, is conveyed by the lacteal veffels into the receptacle of the chyle, and thence into the left fubclavian vein, where it begins its circulation with the blood.

Boerhaave obferves, that many caufes concur in the proportion of *digeftion*; as the aids of cookery; the action of maftication; the mixture of faliva with what we eat, and of other juices in the œfophagus and ftomach; the motion of the diaphragm and abdominal mufcles; and, laftly, in the duodenum, the mixture of bile, and the pancreatic juice.

Haller denies that any kind of fermentation takes place in the ftomach in order to *digeftion*; and feems to attribute the greateft effects, in order to the diffolution of our aliment, to the feparation of the air therein contained, and the action of the bile.

From the experiments of Reaumur, and Pere Bertier, it appears, that the ftomachs of granivorous animals *digeft* their contents partly by trituration, and of carnivorous ones principally by folution in a proper fluid. Thefe are further confirmed by Mr. John Hunter, in his late publication on *Digeftion* of the Stomach after Death, which fee. See alfo Haller's Phyfiology, and Shebbeare's Theory and Practice of Phyfic.

Fordyce, in his Gulftonian Lectures, after defcribing the ftructure of the organs of digeftion; the matters applied to the food in thofe organs: then pointing out, that the fubftances employed for food, had, all and every one of them, the fame elements exactly, and each of them, all the elements neceffary for the formation of chyle, that is, all the elements that are actually found in chyle, viz. *a part* which is fluid, and contained in the lacteals, but coagulates on extravafation:—a *fecond*, which confifts of a fluid coagulable by heat, and in all its properties that have been obferved, is confonant to the ferum of blood; and a *third* formed of globules, which render the whole white and opaque; fays, that it was therefore only neceffary, that thefe elements fhould be feparated from one another, and recombined, in order for its formation.—That the action of the ftomach, duodenum, and perhaps jejunum, together with the fluids applied, induced in the matter employed for food, one operation, by which its elements were difunited, and re-united in a new manner, and into a new matter; which matter, although it might be mixed with other fubftances, was in itfelf always the fame in all its properties, and that this matter was, by a new operation induced by the action of the duodenum, and the fluids it met with there, to have its elements again difunited and re-united, fo as to form the eflential parts of the chyle, which therefore could not be influenced in the fmalleft degree by the food; and that thefe three eflential parts of the chyle were always the fame, and therefore, when converted into blood, the blood, *a fortiori*, could not in the fmalleft degree be influenced by the food. And moreover, fuppofe a fufficient quantity of food was employed, and the organs of digeftion were fufficiently powerful in their action, and the fluids applied were properly added, a fufficient quantity of blood would be formed, and that too large a quantity of food did not produce too large a quantity of blood. Hence then, according to him, digestion is performed on fubftances containing all the elements of chyle, by thefe fubftances thrown into the ftomach and other organs of digeftion, having their elements feparated from one another, by the powers of the ftomach, and thefe organs acting upon them, occafioning in them a decompofition, and recombination of their elements into a new fubftance.

DIGESTIVUM, Sal Sylvii. See Marinum sal.

DIGITALIS. Purple fox-glove, called alfo *aralda*, digitalis purpurea, or digitalis *calycinis foliolis ovatis acutis, corollis obtufis, labio fuperiore integro*. CLASS, didynamia; ORD. angiospermia. Linn. Gen. Plant. 758. Boerhaave mentions eleven fpecies. It is a hairy plant with ferrated leaves; a thick angular ftalk, on which are numerous purple tubulous flowers (which are compared with the finger of a glove) hanging downwards, in a row along one fide, each on a fhort pedicle; the flower is followed by an oblong pointed capfule, full of fmall angular feeds. It is biennial; grows wild in woods and on heaths, and flowers in June, July, and Auguft. It grows only in gravelly foils.

The leaves are bitterifh and naufeous to the tafte; they give out their virtue both to water and to fpirit. Dr. Hulfe recommends an ointment made of it by boiling in butter, for dreffing ferophulous ulcers with; he at the fame time directs gentle purging two or three times a week.

Dr. Withering confiders this as one of the moft certain diuretics in the whole materia materia. The leaves are the part in ufe; of which from one to three grains in powder may be given to an adult twice a day, alone, fometimes united with aromatics, and fometimes formed into pills with foap and gum ammoniac: and indeed the dofe may be gradually increafed; but four grains is generally a fufficient dofe in dropfical cafes. Or a dram of the dried leaves may be infufed in half a pint of boiling water, for four hours, adding to the ftrained liquor an ounce of any fpirituous water: two table-fpoonfuls, or an ounce, given twice a day, is a medium dofe for an adult; if the patient be ftronger than ufual, or the fymptoms very urgent, this dofe may be given once in eight hours; and on the contrary, in many inftances half an ounce will be fufficient. When this medicine is difpofed to purge, opium may be advantageoufly joined with it; for if it purges, it fails of fuccefs, according to the doctor's account: but when the bowels are too tardy, jalap may be given with it at the fame time. Neither of thefe additions interferes with its diuretic effect. But it muft be here obferved, that it feldom fucceeds in men of *great natural ftrength, of tenfe fibre, warm fkin, florid complexion*, or *in thofe with a tight, cordy pulfe*. If the belly in afcites *be tenfe, hard*, and *circumfcribed*, or *the limbs in anafarca folid*, and *refifting*, there is little hope. On the contrary, *if the pulfe be feeble*, or *intermitting*, *the countenance pale, the lips livid, the fkin cold, the fwoln belly foft* and *fluctuating, the anafarcous limbs readily pitting with preffure of the finger*, we may expect the diuretic effects to follow in a kindly manner. Of the digitalis there is an ointment made, unguentum digitalis, in the fame manner, and applied to the fame ufes, as that of cicutæ; the ingredients are equal parts of the digitalis purpureæ, recently gathered, and hog's lard For the procefs, fee Cicuta. See his Pamphlet of the Digitalis Purpurea, publifhed at Birmingham, 1785, which ought to be perufed with attention, by thofe who adminifter this remedy. Indeed Dr. Cullen was of opinion, that it ought to be in the hands of every practitioner of phyfic. It is alfo a name of the sesamum orientale. See Sesamum verum.

Digitalis minima. See Gratiola.

DIGITUM. A fort of contracture, by which the joint of a finger is fixed; and a pain, with waffing of a joint of the finger. See alfo *paronychia*.

DIGITORUM TENSOR. See Extensor digitorum communis.

DIGITUS. A finger. In the hands and feet of men there are commonly five. In the hands, they have particular names. The firft, which is oppofite to, and thicker than the reft, is called αντιχειρ, *antichelr*, and Pollex; the *fecond*, index, δειχτης, *lichanis*, alfo salutaris; the *third* μεσος, *medius*, and longissimus; the *fourth*. παραμεσος, *parameſos*, and fometimes annularis; and the *fifth*, minimus, auricularis, μικρος. The Greeks called the firft, or thume, αντιχειρ, becaufe it was alone as powerful as the other four fingers, from αντι, *againſt*, and χειρ, *the hand*; and the Latins, pollex, from *pollendo*, for the fame reafon. The fecond, or fore finger, δειχτης, *index*, becaufe, by pointing, difcoveries are made, or indications given; and salutaris, becaufe being applied to the mouth, it caufes filence,

than

than which nothing was conſidered more ſalutary. The third, μεσος, MEDIUS, and LONGISSIMUS, THE MIDDLE FINGER, from its ſituation and length. The fourth, παραμεσος, becauſe it was next to the middle finger; and ANNULARIS, from wearing rings upon it, hence called RING-FINGER. The fifth, AURICULARIS, becauſe of its uſe in clearing the ear, and MINIMUS, μικρος, from its ſize, LITTLE FINGER. The toes have no names. The thumb and the four *fingers* are each compoſed of three bones; thoſe of the *fingers* are formed alike, but thoſe of the thumb are much thicker and ſtronger, in proportion to their length, than thoſe of the *fingers*; which is a neceſſary contrivance, as they counteract all the four *fingers*. The firſt joint of the *fingers* is arthrodia, the two laſt are ginglymus. The different parts or bones of the *fingers* are called *phalanges*; the firſt phalanx is the largeſt, and the laſt the leaſt. See PHALANX. DIGITUS, among the Latins, ſtands alſo for a meaſure, ſimilar to dactylus among the Greeks; the ſmalleſt meaſure, by which the diſtances of ſpace or time were meaſured, ſimilar to our JOT. However, at the preſent day, it ſeems to be a meaſure taken from the breadth of the finger, properly three fourths of an inch, and equivalent to four grains of barley laid breadth-wiſe, ſo as to touch one another.

DIGLOSSON, from δις, *bis*, and γλωσσα, *a tongue*. A name of the *laurus Alexandrina*, becauſe that above its leaf there grows another leſſer leaf, reſembling a tongue.

DIGNOTIO. See DIAGNOSIS.

DIGYNIA, (δις, *bis*, γυνη, *mulier*.) The name of an order in LINNÆUS's artificial ſyſtem, comprehending thoſe plants which have two *piſtilla* to a flower. This order is the ſecond, in the firſt thirteen claſſes, except the ninth.

DIHÆMETON, from αιμα, *blood*. The name of an antidote, in which is the blood of many different animals.

DIHALON, from αλς, *ſalt*. A plaſter prepared of ſalt and nitre, and adapted to foul ulcers.

DIIPETES. See SEMEN.

DIKALEGI. TIN. See STANNUM.

DILATATIO, alſo *diſtenſio*. A DILATATION. Sometimes it is uſed for diaſtole.

DILATATORES ALARUM NASI. DILATORS of the NOSTRILS. They are ſmall, thin muſcles, having a double order of fibres decuſſating each other. They riſe from the interior and inferior parts of the oſſa narium, and are ſoon inſerted into the ſuperior parts of the alæ. They pull up the alæ, and dilate the noſtrils.

DILATATORIUM. A ſurgical inſtrument for dilating any part.

DILATIO. See PERSPIRATIO.

DILL. CAT. GISS. An abbreviation of Johannis Jacobi Dillenii Catalog. Plant. ſpont. circ. Giſſam naſcent.

DILL. H. MUSC. An abbreviation of Johannis Jacobi Dillenii Hiſtoria Muſcorum.

DILUENTIA. DILUENTS. They are whatſoever, on being mixed with a fluid, renders its parts more fluid. They produce their effect by dividing each part into ſmaller parts, ſimply mixing therewith; in which caſe, the *diluent* muſt be a fluid, more fluid than that with which it is mixed, and muſt retain its fluidity after mixture. Theſe three properties are in water only; and the diluting property of water is increaſed only by fire. "This, ſays Dr. CULLEN, is the preciſe idea of diluents, and if it is applied to ſubſtances, which by other means increaſe the fluidity of the blood, it ſeems to be very improperly employed." Mat. Med. vol. i.

DILUTUM. DILUTED. See alſo INFUSUM.

DILYTÆA. In Myrepſus, it is the fat of ſome animal, but of what, is unknown.

DINICA, from δινεω, *to turn round*. Medicines againſt a vertigo.

DINOS. See VERTIGO.

DIOBOGON. See SCRUPULUS.

DIOCRES. The name of a paſtil in Myrepſus.

DIODOS. See DIEXODOS.

DICŒCIA, (δις, *bis*, and οικος, *domus*.) PLANTA. A plant which has no hermaphrodite flower, but in which male flower is upon one plant, and the female flower upon another. It is the twenty-ſecond of Linnæus's claſſes.

DICŒNANTHES, An epithem in Trallian againſt the cholera morbus.

DIOGMUS. See PALPITATIO CORDIS.

DIONIS COLLYRIUM. A collyrium in Oribaſius, ſo called from Dion its author.

DIONYSIA. The name of a plaſter for abſceſſes, invented by Hera the Cappadocian. It is alſo call *Dionyſianum emplr*

DIONYSIAS. See ANDROSÆMUM.,

DIONYSISCI. HORNED. Certain bony eminences near the temples; or rather the people with thoſe prominences; from *Dionyſius*, a name of Bacchus, who is deſcribed often with horns.

DIONYSIUS. See LEPIDIUM.

DIONYSOS. The name of a collyrium in Aetius. P. Ægineta hath one like it which he names collyrium *malabathrinum*, and *ifotheon*.

DIOPORON, from οπωρα, *autumnal fruit*. The name of a medicine in Cœl. Aurelianus. It was uſed againſt the quinſy.

DIOPTRA, from διοπτομαι, *to ſee through*. An inſtrument for dilating any natural cavity, the better to ſee its ſtate, ſuch as the ſpeculum uteri, &c.

DIOPTRISMOS. The operation which conſiſts in dilating the natural paſſages with a dioptra.

DIOROBON. A medicine in which are vetches (οροβος).

DIORRHOSIS, or DIOROSIS, from ορος, ὀρρος, *ſerum*. A converſion of the humours into ſerum and water.

DIORTHOSIS, from ορθος, *right*, or from διορθοω, *to direct*. A reſtitution of a fractured limb into its natural ſituation.

DIOSCOR. An abbreviation of Pedacii Dioſcoridis Opera Græce & Latine, Interpretatione Jani Antonii Saraceni Lugdunæi Medici.

DIOSCURI. See PAROTIDES.

DIOTA. The name of a wooden cup, which was lined with aromatics, to give a flavour to the liquor that was drank out of it.

DIOXELÆUM. A malagma, in which was oil and vinegar.

DIOXUS. The name of a collyrium in Marcellus Empiricus, in which is vinegar.

DIOSPYROS. See GUAJACANA.

DIPCADI. See BULBUS VOMITORIUS.

DIPCÆA. See CIRCÆA.

DIPHRYGES, or DISPHRYGES. SCURF.

There are three kinds; 1ſt, Metallic, produced only in Cyprus: it is found in the mud of a pool, whence it is taken and dried in the ſun, then burnt; whence the name, from δις, *twice*, and φρυγω, *to torrify*, it being as it were twice roaſted. 2d, The droſs in working copper. 3d, Pyrites calcined to redneſs.

DIPLOE, from διπλοος, *double*, called alſo *meditullium*. It is the ſoft part between the two tables of the bones of the ſkull. Some ſay, the two tables of the ſkull themſelves.

DIPLOMA. The written inſtrument which gives authority for men to practiſe as phyſicians, from διπλοω, *to fold*. A DOUBLE VESSEL. To boil in *diplomate* is to ſet one veſſel, containing the ingredients intended to be acted upon, in another larger veſſel full of water, and to this latter veſſel the fire is applied.

DIPLOPIA. Διπλοον, *duplex*, and οψις, *viſus*. A depravity of ſight, by which the ſame objects appear double, multiplied, or often repeated. That ſymptom is almoſt always of ſhort duration, and we bear it freely, as in experiments, whether in that caſe looking with one, or both eyes. So long as the object is not within the diſtance of diſtinct viſion, two images oppoſite to one foramen, or aperture, and having fallen upon the eye, are not united in the retina, but in diſtinct places; and therefore they have not the optic point as a centre, whence the image appears double. The optic portion is a circular point in the bottom of the eye, whoſe centre the optic axis occupies; but as often as we look at any object with both eyes, ſo often, unleſs there ſhould be ſome defect in the organs, we ſo turn the eyes that each axis of the eye concurs in the ſame point of the object; and we have been taught by long habit, our ſenſe of touching chiefly directing us, that a double image anſwers to one object, when ſo often as an image falls upon the optic point, ſo often we judge that object ſingle, but if a double image ſhould fall upon the ſame eye, and not concur in the optic point, then the ſame object appears to us to be ſeen in two different places, and therefore to us it appears double. Dr. Cullen makes it a variety of the ſecond ſpecies of PSEUDO-BLEPSIS, which he calls MUTANS, in which objects appear, by ſome means or

other, changed from what they really are: and the diplopia is that which varies according to the variety of the remote cauſe, of which he enumerates, from SAUVAGES, ten ſpecies. See Noſologia Methodica Sauvageſii, & Culleni. Wallis's Noſologia Meth. Oculorum, with notes.

DIPNOOS, from δις, *bis, double*, and πνεω, *to breathe*. An epithet of wounds which penetrate into ſome cavity, or quite through a part, or that have two orifices.

DIPSACON. See ASPALATHUS.

DIPSACOS, } from δψα, *thirſt*. See DIABETES.
DIPSACUS. }

DIPSAS. DRY EARTH. Alſo the name of a ſerpent, whoſe bite cauſes thirſt. The ſerpent is alſo called *cauſus*.

DIPSETICUS. An epithet for ſuch things as cauſe thirſt.

DIPYRENON, from δις, *bis, double*, and πυρηνα, *a berry* or *kernel*, or the end of a probe reſembling a *berry*. Alſo the name of a probe, with two buttons on one end. It is mentioned by Cœlius Aurelianus.

DIPYRITES, or DIPYROS, from δις, *twice*, and πυρ, *fire*. BREAD TWICE BAKED. Hippocrates recommends it in dropſies.

DIRADIATIO. See ACTINOBOLISMUS.

DIRECTOR, from *dirigo, to direct*. An hollow inſtrument for guiding an inciſion-knife

DIRECTORES PENIS. See ERECTORES PENIS.

DIRINGA. A name, in the iſle of Java, for the SWEET-SCENTED FLAG. See CALAMUS AROMATICUS.

DISCESSUS. A chemical term, which the French call *depart*, or *linquart*; it ſignifies, in general, any ſeparation of two bodies before united: but it is particularly applied to the ſeparation of gold from ſilver by the acidum nitroſum, where the ſilver is diſſolved, but the gold left untouched.

DISCOIDES, from δισκος, *diſcus*, the *quoit* uſed in the Roman games, and ειδος, *a form*. See CRYSTALLINA.

DISCRETA PURGATIVA. In Fallopius it is that ſort of purging which evacuates a particular humour.

DISCRIMEN. It is a ſmall roller, about twelve feet long, and two fingers breadth broad, rolled up with one head, and uſed after bleeding in the forehead, as follows: The bandage is held with the left thumb upon a compreſs, ſo that about a foot hangs below the forehead; then the *roller* is carried round the temples and occiput in the circular direction; after this, the part which hangs down is to be carried over the head to the occiput, and there having rolled it ſeveral times about the head, it is to be ſecured. It is a term alſo applied to the *diaphragma*.

DISCIFORME. See PATELLA.

DISCUS. A DISK. It is a body employed in the gymnaſtic art, but not eaſy to ſay what. IN BOTANY, the whole ſurface of a leaf; *ſupinus*, the upper, *pronus*, the under ſurface; DISK, of a flower, is the central part in radiate compound flowers conſiſting generally of regular corollules, or florets; it is applied to other aggregate flowers, when the florets, towards the middle, differ from thoſe in the circumference, as in umbels.

DISCUSSIO. See PERSPIRATIO.

DISCUSSORIA, } DISCUTIENTS, by DIOSCO-
DISCUTIENTIA. } RIDES called alſo *diachytica*. They are ſuch medicines as by their ſubtilty diſſolve a ſtagnating fluid, and diſſipate the ſame without an external ſolution of continuity. Such *diſcutients* as alſo mollify are to be preferred, of which kind are opium and camphor. Suppurants diſcuſs, and *diſcutients* ſuppurate. Oils, and what ſtops the pores, may be applied when ſuppuration is aimed at, but they are improper when the deſign is to *diſcuſs*. But diſcutients are ſuppoſed to diſpel hardneſs or tumor. The operation of ſuch medicines ſeem to be of different kinds, and therefore the general term ſhould if poſſible be avoided. CULLEN'S Mat. Med. vol. i.

DISLOCATIO, from *diſſico*, or from δι *vel* δις, *ex, out of*, and *locus, a place*, to put out of its place. See LUXATIO.

DISPENSATORIUM. DISPENSATORY. The place, or ſhop, where medicines are prepared; but more frequently a book treating of the compoſition of remedies; called alſo *antidotarium*.

DISPHRYGES. See DIPHRYGES.

DISRUPTIO. A ſpecies of violent puncture which penetrates the ſkin to the fleſh.

DISSECTIO, from δι *vel* δις, *per, through*, and *ſeco, to cut*. DISSECTION. The cutting up a body, with a view of examining the ſtructure of the parts. See ANATOMIA.

DISSEPIMENTUM. It is the thin ſeptum which divides the ſeveral cells in the fruit of plants. See CAPSULA.

DISSEPTUM. See DIAPHRAGMA.

DISSOLVENTIA, by DIOSCORIDES called DIACHYTICA. Medicines, which diſſolve concretions in the body, are thus called. In CHEMISTRY, *diſſolvents* are *menſtrua*.

DISSOLUTIO, *denudatio*. DISSOLUTION. A *ſyncthymia*, or *ſyncope*, is thus named: ſo is death. Solution of continuity, or diſcontinuity; and thus it is ſynonymous with *dialyſis*.

DYSOPIA, δυς, *difficulter*, and οψις, *viſus*, is ſuch a depravity of ſight, that objects cannot be ſeen diſtinctly but in a certain light, or at a certain diſtance, or in particular poſitions, of which Dr. Cullen enumerates five ſpecies; 1ſt,—*Tenebrarum*, in which objects can only be ſeen in a ſtrong light. 2d,—*Luminis*, in which objects cannot be ſeen but in an obſcure light. 3d,—*Diſtantorum*, in which objects at a great diſtance cannot be perceived. 4th,—*Proximorum*, in which objects very near cannot be ſeen. 5th,—*Lateralis*, in which objects cannot be ſeen unleſs ſituated in an oblique poſition. See Culleni Noſologia Methodic. edit. 4.

DISSOLUTUS MORBUS. See DYSENTERIA.

DISTA. See DYOTA.

DISTENTIO. DISTENSION. It ſignifies ſimply *dilatatio*, *pandiculatio*, or *convulſio*, as nervous diſtenſion almoſt always implies.

DISTICHIA, or DISTICHIASIS, from δις, *bis, double*, and στιχος, *a row* or *order*. See DISTRICHIASIS.

DISTICHUM. That ſpecies of barley which hath only two rows of grains.

DISTILLATIO. DISTILLATION; alſo DESTILLATIO, *alſacta*, *cataſtagmos*, *cataſtalagmos*. Sometimes it ſignifies the ſame as *defluxio*, or *catarrhus*.

In PHARMACY it is the ſeparation of the more volatile from the more ſolid parts of any ſubſtance by means of heat. Or it is the condenſing and collecting the lighter parts of bodies, previouſly rarefied by heat. Re-diſtilling a fluid ſeveral times from freſh parcels of the ſame kind is called *cohobatio*; but no advantage is derived from this practice. When *diſtillation* is repeated, in order to purify or ſeparate the matter diſtilled from ſome parts not required, it is called *rectificatio*. *Diſtillation* with an alembic or a common ſtill is called *per aſcenſum*, becauſe the vapours riſe and are condenſed in the upper part of the veſſel: thus all *diſtillations* may be performed, that require no greater heat than boiling water. When a heat greater than boiling water is required, retorts may be uſed: from their ſhape, the volatile parts of what is diſtilled in them can only eſcape through the ſide, whence this is called *per latus*. When the heat is to be applied above the bodies to be diſtilled, ſo that the lighter parts are forced downwards into a veſſel placed for their reception, it is called *per deſcenſum*: this method is now never uſed. When the volatile parts that are rarefied by *diſtillation* are in a dry form when collected, this operation is called *ſublimatio*. When no more heat is applied than is neceſſary juſt to raiſe a vapour, which when condenſed only falls in drops, it is called a cold *diſtillation*: roſes and other things valued only for their flavour, and which do not admit of drying, are commodiouſly *diſtilled* this way; and the dry cake, left after *diſtilling* roſes, is better for making a decoction or ſyrup than after any other management: in this kind for *diſtillation*, the ſubject ſhould neither be bruiſed nor have water or any other thing added to it: they ſhould be gathered with the morning-dew upon them: a retort and receiver placed in a ſand-bath is the beſt apparatus in this caſe. The worm ſtill is moſt frequently uſed now for diſtilling; it is called alſo the HOT STILL, becauſe it is worked with a fire which makes the materials boil; it communicates with a leaden ſpiral tube (called the *worm*), which is placed in a tub filled with water (called the *refrigeratory*); in this worm the vapours are condenſed, and run out in the form of a ſmall ſtream into whatever veſſel is placed to receive it.

The end of *diſtilling* is the ſeparation of ſome bodies from thoſe with which they were mixed; as in obtaining vinous ſpirits, eſſential oils, volatile ſpirits, &c. or for the more ſpeedy or effectual combination of ſuch bodies as require a boiling heat, as in the caſe of the ſpt. ætheris nitroſi.

As a principal article in *diſtillation* is to apply no more heat to the ſubject than is juſt neceſſary to accompliſh our intention, retorts are ſometimes uſed, and are placed on an open fire, on ſand-baths, or in water-baths, in order the more certainly to adjuſt the heat to the degree of volatility

tility which the ſubject to be *diſtilled* poſſeſſes. In *diſtilling* waters, whether for uſing, or obtaining eſſential oils, the menſtruum ſhould be attended to, as well as the heat to be applied; for as ſome eſſential oils require the full heat of boiling water, they cannot be raiſed by the uſe of ſpirit of wine: this happens in *diſtilling* of cinnamon, and ſome other ponderous oils.

Retorts are proper when the ſubject to be *diſtilled* would corrode the metal of a ſtill, as in the obtaining of any mineral acid, or preparing other corroſive matters. Earthen veſſels are ſometimes uſed, and, on ſome few occaſions, iron ones. But as to theſe, and many other obſervations on this ſubject, they are fully noticed under the articles where an attention to them may be required.

DISTILLATIO per DESCENSUM. See DESCENSIO.

DISTORSIO, DISTORTIO. It is applied to the eyes, when a perſon ſeems to turn them from the object he would look at, which is called *ſquinting*. See STRABILISMUS. It alſo ſignifies the bending of a bone preternaturally to one ſide. See Bell's Surgery, vol. vi. p. 281.

DISTORTIO SPINÆ, vel VERTEBRARUM. This diſeaſe in the *ſpine* is manifeſt by its becoming more or leſs curved, and by a loſs of the uſe, generally, of the lower limbs. It is ſometimes called the *curved ſpine*. Mr. Pott is the firſt who hath favoured the world with any juſt idea either of its nature or cure. In one of his publications he calls it a kind of palſy in the lower limbs; in another he ſpeaks of it as a uſeleſs ſtate of them. From his account of this diſorder, it hath a ſcrophulous origin; but as its moſt ſtriking ſymptoms are from the caries, which takes place in the bodies of ſome of the vertebræ, may it not be properly termed the STRUMOUS SPINAL CARIES? Mr. Bell, in his Surgery, vol. vi. p. 294. calls it *diſtortion of the ſpine*.

In this diſeaſe, there is a total or partial abolition of the power of uſing, and ſometimes of even moving the limbs, generally only the lower, but ſometimes the upper, or both, in conſequence of a diſeaſe in the *ſpine*, which is firſt manifeſted by a curvature taking place in ſome part of it. To this diſtemper, both ſexes, and all ages, are equally liable, though the majority of theſe patients are infants or young children.

When the attack is made on an infant of only one or two years old, the true cauſe is rarely diſcovered until ſome time after the effect has taken place; the nurſe or parents ſuppoſe that the child is weakly, or hath been hurt at its birth. When, on the attack, the patient hath been uſed to walk, the loſs of the uſe of his legs is gradual, though not in general very ſlow. At firſt he ſhews ſigns of being ſoon tired; he is languid, liſtleſs, and unwilling to move much, or at all briſkly; ſoon after this he is obſerved frequently to trip and ſtumble, although there is no impediment in his way; whenever he attemps to move quickly, he finds that his legs involuntarily croſs each other, by which he is frequently thrown down ſuddenly, and that without ſtumbling; upon endeavouring to ſtand ſtill and erect, even for a few minutes, his knees give way, and bear forward. When the diſtemper is a little farther advanced, it will be found that he cannot, without much difficulty, direct either of his feet preciſely to any exact point: on attempting to do ſo, they ſuddenly interſect, and very ſoon after, both thighs and legs loſe much of their natural ſenſibility, and become perfectly uſeleſs. When an adult is thus affected, the progreſs of the diſtemper is much the ſame, but rather quicker. Arrived at this ſtate, whatever be the age or ſex of the patient, complaint is made of twitching and frequent pains in the thighs, particularly when in bed, and of uneaſy ſenſation at the pit of the ſtomach; when he ſits on a chair or a ſtool, his legs are almoſt always found acroſs each other, and drawn up under the ſeat; in a little time after theſe particulars have been obſerved, the power of walking is totally loſt.

The true curvature is invariably uniform in being from within outwards. This curve of the *ſpine* varies in ſituation, extent and degree, being either in the neck, back, or, more rarely, in the upper part of the loins; ſometimes comprehending one vertebra only, ſometimes two, three, or more; by which the curve becomes neceſſarily more or leſs extenſive; but whatever variety theſe circumſtances may admit, the lower limbs moſt frequently feel the effect; ſometimes the arms only are paralytic, as it is called; and a few inſtances have occurred, in which both legs and arms were alike affected. The effect is alſo different in different ſubjects; ſome are rendered totally and abſolutely incapable of walking in any manner, or with any help, and that very early in the courſe of the diſeaſe, that is, ſoon after the appearance of the curvature; others can move with the help of crutches, or by graſping their thighs juſt above the knees with their hands; ſome can ſit in an erect poſture or in a chair, without much trouble or fatigue, whilſt others are incapable of doing ſo, at leaſt for any length of time; ſome have ſuch a degree of motion in their legs or thighs, as to enable them to turn and move for their own convenience in bed; others have not that benefit, and are obliged to lie until they are moved by another.

When a naturally weak infant is the ſubject, the curvature is in the vertebræ of the back; it is not unfrequently productive of additional deformity, by gradually rendering the whole back what is vulgarly called *humped*; and by alterations which all the bones of the thorax ſometimes undergo in reſpect to ſituation, in conſequence of the flexure and weakneſs of the *ſpine*, by which, ſuch perſons are juſtly ſaid to be ſhortened in their ſtature; but in all caſes, where this effect has been gradually produced, to whatever degree the deformity may extend, or however the alteration made in the diſpoſition of the ribs and ſternum, may contribute to ſuch deformity; yet I think that it will always be found, that the curvature of the *ſpine* appeared firſt, and, if I may ſo ſay, ſingly, and that all the reſt are conſequential.

The general health of the patient does not ſeem, at firſt, to be materially, if at all, affected; but when the diſeaſe has continued ſome time, and the curvature thereby increaſed, many inconveniences and complaints come on, viz. *When the incurvation is in the neck*, and to a conſiderable degree, by affecting ſeveral vertebræ, the child finds it inconvenient and painful to ſupport its head, and is always deſirous of laying it on a table or pillow, or any thing to take off the weight.—*When in the dorſal vertebræ*, there is a difficulty of breathing, loſs of appetite, indigeſtion, dry cough, quick pulſe, a diſpoſition early to an hectic pain, and what they all call tightneſs at the ſtomach, obſtinate conſtipations, or purgings, involuntary flux of urine and fæces, &c. with the addition of what are called nervous complaints, ſome of which are cauſed by the alterations made in the form of the cavity of the thorax, others ſeem to ariſe from impreſſions made on the abdominal viſcera.

An adult, in a caſe where no violence hath been committed, or *received*, uſually complains, that his firſt intimation is a ſenſe of weakneſs in his back-bone, accompanied with what he calls a heavy dull kind of pain, attended with ſuch a laſſitude as renders a ſmall degree of exerciſe fatiguing; that this is ſoon followed by an unuſual ſenſe of coldneſs in his thighs, not accountable for from the weather, or any cauſe that can produce a diminution of their ſenſibility; that in a little time more, his limbs are affected with an unuſual ſenſibility, alſo are frequently convulſed by involuntary twitchings, particularly troubleſome in the night; that ſoon after this, he not only becomes incapable of walking, but that his power either of retaining or diſcharging his urine or fæces are conſiderably impaired, and his penis becomes incapable of erection. The adult as well as the child complains conſtantly of a tightneſs and pain at his ſtomach, and he finds all the offices of his digeſtive and reſpiratory organs much impeded.

The loſs of motion in the limbs, which generally accompanies a diſtorted ſpine, is ſuppoſed to proceed from the ſaid diſtortion. Until the curvature is diſcovered, it generally paſſes for a nervous complaint; but when the ſtate of the vertebræ hath been adverted to, recourſe is almoſt always had to ſome previous violence, to account for it, ſome blow, fall, or other accident, which is ſuppoſed to have hurt the back, or deranged the *ſpine*. In ſome few inſtances, theſe exertions may have been ſuch, as might be allowed to have been equal to the effect; but in the majority, theſe are ſo far from being the caſe, that if they are admitted to have any ſhare at all in it, ſome prediſpoſing cauſe, at leaſt, muſt be looked for, in which conſiſts the very eſſence of the diſeaſe. From many conſiderations reſpecting this ſubject, it appears, that when we attribute the whole of this miſchief to the mere accidental curvature of the *ſpine*, in conſequence of violence, we miſtake an effect for a cauſe; and that previous both to the paralytic ſtate of the legs, and to the alteration of the figure of the back-bone, *there is a prediſpoſing cauſe of both, conſiſting in a diſtempered ſtate of the ligaments and bones, where the curve ſoon after makes its appearance.* THE PRIMARY AND SOLE CAUSE OF THE MISCHIEF,

MISCHIEF *is a diſtempered ſtate of the parts compoſing*, or *in immediate connection with the ſpine, tending to, and moſt frequently ending in a caries of the body or bodies of one or more of the vertebræ*; from this proceed all the ills, whether general or local, apparent or concealed; this cauſes the ill health of the patient, and in time the curvature. The helpleſs ſtate of the limbs is only one conſequence of ſeveral proceeding from the ſame cauſe.

It has been ſuppoſed that there is a diſlocation of the vertebræ, but there is no diſplacement of them with regard to each other; the *ſpine* bends forward, only becauſe the rotten bone or bones, intervening between the ſound ones, give way, being unable in ſuch a ſtate to bear the parts above. *From every circumſtance in the living, and appearance in the dead, it is evident that the complaint ariſes from what is commonly called a ſcrofulous indiſpoſition affecting the parts that compoſe the ſpine, or thoſe in its immediate vicinity*: this morbid affection ſhews itſelf in a variety of forms; but they are always ſuch as ſooner or later determine the true nature of the diſtemper. Sometimes each of the diſtempered ſtates of theſe parts is accompanied by a greater or leſſer degree of deformity and crookedneſs of the *ſpine*, without any apparent diſeaſe of the bones compoſing it; ſometimes the deformity is attended with eroſion or caries of the body or bodies of ſome of the vertebræ; and ſometimes the ſame bones are found to be carious, without any crookedneſs or alteration of figure. It may not be amiſs to remark, that *ſtrumous tubercles in the lungs, and a diſtempered ſtate of ſome of the abdominal viſcera, often make a part of the attendants.*

It is further to be obſerved, that when theſe complaints are not attended with an alteration of the figure of the back-bone, neither the real ſeat, nor true nature of the diſtemper are pointed out by the general ſymptoms, and conſequently that they frequently are unknown, at leaſt while the patient lives.—When the ligaments and cartilages of the *ſpine* become the ſeat of the diſorder, without any affection of the vertebræ, it ſometimes happens that the whole *ſpine*, from the loweſt vertebra of the neck downwards, gives way laterally, forming one great curve to one ſide; and ſometimes a more irregular figure, and attended with many marks of ill health.—The attack is ſometimes on the bodies of ſome of the vertebræ; and when this is the caſe, ulceration and eroſion of the bones is the conſequence; this eroſion or caries of the bones often produces the curvature peculiar to this diſeaſe, by waſting the body of each vertebra that is affected; and then the ſpinal proceſſes of the diſtempered vertebræ protuberate behind in conſequence of their fore parts falling down as above noticed.—When the attack is made upon the dorſal vertebræ, the ſternum and ribs, for want of proper ſupport, neceſſarily give way, and other deformity, additional to the curve, is produced.—As to the caſes of carious *ſpine* without curvature, it ſometimes happens that internal abſceſſes and collections of matter are formed near the *ſpine*; this matter affecting the *ſpine*, and alſo making its way outward, produces what are called pſoas, abſceſſes, &c. and deſtroy the patient; the real and immediate cauſe of death in theſe inſtances is rarely known until the body is examined. The uſeleſs ſtate of the limbs is by no means a conſequence of the altered figure of the *ſpine*, or of the diſpoſition of the bones with regard to each other, *but merely of the caries: of this truth there needs no other proof than what may be drawn from the cure of a large and extenſive curvature, in which three or more vertebræ were concerned; in this, the deformity always remains unaltered and unalterable, notwithſtanding the patient recovers both health and limbs.*

From diſſections it has appeared that, in this diſeaſe, either there is a defect of oſſific matter, or a caries of ſome of the vertebræ.

Mr. Pott obſerves, that, in compliance with cuſtom, he hath called this diſeaſe *a palſy*; but that notwithſtanding the limbs be rendered almoſt totally uſeleſs, yet there are ſome eſſential circumſtances in which this affection differs from a common nervous palſy: the legs and thighs are rendered unfit for all the purpoſes of loco-motion, and have loſt much of their natural ſenſibility; but notwithſtanding this, they have neither the flabby feel which a truly paralytic limb has, nor have they that ſeeming looſeneſs at the joints, nor that total incapacity of reſiſtance which allows the latter to be twiſted in almoſt all directions: on the contrary, in this diſeaſe, the joints have frequently a conſiderable degree of ſtiffneſs, particularly the ancles, by which ſtiffneſs the feet of children are generally pointed downwards; and they are prevented from ſetting them flat on the ground. In the true paralyſis, from whatever cauſe, the muſcles of the affected limb are ſoft, flabby, and unreſiſting, and incapable of being put into even a tonic ſtate; the limb itſelf may be placed in almoſt any poſition or poſture; and if it be lifted up, and then let go, it falls down, and it is not in the power of the patient to prevent, or even to retard its fall: the joints are perfectly and eaſily moveable in any direction; if the affection be of the lower limbs, neither hips, nor knees, nor ankles, have any degree of rigidity or ſtiffneſs, but permit the limb to be turned or twiſted in almoſt any manner. But in caſes of uſeleſs limbs from the ſame cauſe as that of the curved *ſpine*, the muſcles are extenuated and leſſened in ſize; they are rigid, and always in a tonic ſtate, by which the knees and ancles acquire a ſtiffneſs not very eaſy to overcome; by means of this ſtiffneſs, mixed with a kind of ſpaſm, the legs of the patient are either conſtantly kept ſtretched out ſtraight, in which caſe, conſiderable force is required to bend the knees, or they are by the action of the ſtronger muſcles drawn acroſs each other, in ſuch a manner as to require as much to ſeparate them. When the leg is in a ſtraight poſition, the extenſor muſcles act ſo powerfully as to require a conſiderable degree of force to bend the joints of the knees; and when they have been bent, the legs are immediately and ſtrongly drawn up, with the heels towards the buttocks: by the rigidity of the ancle joints, added to the ſpaſmodic action of the gaſtrocnemii muſcles, the patient's toes are pointed downwards in ſuch a manner as to render *it impoſſible for him to put his feet flat on the ground, which makes one of the deciſive characters of this diſtemper.* Thus the marks of diſtinction, between this diſeaſe and the palſy, are ſufficiently ſtrong to ſhew the impropriety of confounding them.

The reſtoration of the *ſpine* to its natural figure depends much on the early adminiſtration of the help propoſed; though the diſtemper may be ſo far cured, as that the patient may recover the uſe of his limbs, yet ſuch an alteration may have taken place in the bodies of the vertebræ, as to render it impoſſible for the *ſpine* to become ſtraight again; and, if from inattention, from length of time, or from any other circumſtances, it happens that the bodies of the vertebræ become completely carious, and the intervening cartilages are deſtroyed, no aſſiſtance is to be expected from the propoſed remedies. According to the obſervations made on the uſual effect of the diſcharge produced by art for the removal of this diſorder, after the diſcharge hath continued for ſome time, the patient begins to feel better health, he gradually recovers his appetite, gets refreſhing ſleep, hath a more quiet and leſs hectical pulſe; but the chief relief is from having got rid of that diſtreſſing ſenſation of tightneſs about the ſtomach; in a little time more, a degree of warmth, and a ſenſibility is felt in the thighs, to which the patient hath been a ſtranger for ſome time; and generally much about the ſame time the power of retaining and diſcharging the urine and fæces begins to be in ſome degree exerted.—The firſt return of the power of motion in the limbs is rather diſagreeable, the motion being involuntary and of the ſpaſmodic kind, principally in the night, and generally attended with a ſenſe of pain in all the muſcles concerned. At this point of amendment, if it may be ſo called, it is no uncommon thing, eſpecially in bad caſes, for the patient to ſtand ſome time without making any further progreſs; this in adults occaſions impatience, and in parents deſpair; but in the milder kind of caſes, the power of voluntary motion generally ſoon follows the involuntary. The knees and ankles by degrees loſe their ſtiffneſs, and the relaxation of the latter *enables the patient to ſet his feet flat upon the ground, a certain mark that the power of walking will ſoon follow*; but thoſe joints having loſt their rigidity, become exceedingly weak, and are not for ſome time capable of ſerving the purpoſe of progreſſion. The firſt voluntary motions are weak, not conſtantly performable, nor even every day, and liable to great variation, from a number of accidental circumſtances, both external and internal. The firſt attempts to walk are feeble, irregular and unſteady, and bear every mark of nervous and muſcular debility. The patient requires much help; and his ſteps, with the beſt ſupport, will be irregular and unſteady; but when they have arrived at this, no inſtance hath occurred, in which the full power of walking was not ſoon attained. When the patient can juſt walk, either with crutches, or between two ſupporters, he is generally troubled to reſiſt or

overcome

overcome the more powerful action of the ſtronger muſcles of the thighs over the weaker, by which his legs are frequently brought involuntarily acroſs each other, and he is ſuddenly thrown down. Adults find aſſiſtance in crutches, by laying hold of the chairs, tables, &c. but for children, a go-cart is the beſt; it ſhould reach up to the arm-pit, and ſhould encloſe the whole body; this takes off all inconvenient weight from the legs; at the ſame time enables the child to move them as much as it pleaſes. Or the inſtrument of Mr. Jones ſhould be worn, which in all caſes would be ſerviceable, and in many, a perfect cure, as it acts by taking off the ſuperincumbent weight from the diſeaſed vertebræ. See his Eſſay on Crookedneſs, with a variety of cures therein inſerted.

While the curvature of the *ſpine* remains undiſcovered or unattended to, the caſe is generally ſuppoſed to be nervous, and nervous medicines, ſo called, are as generally adminiſtered; but without any advantage. When the caſe is known, recourſe is too frequently had to ſteel ſtays, ſwings, ſcrew chairs, &c. to reſtore the *ſpine* to its natural figure; but ſtill the patient grows unhealthy, and languiſhing under a variety of complaints, dies in an exhauſted, emaciated ſtate. The remedy for this dreadful diſeaſe conſiſts merely in procuring a large diſcharge of matter by ſuppuration, from underneath the membrana adipoſa on each ſide of the curvature, and in maintaining ſuch diſcharge until the patient ſhall have perfectly recovered the uſe of his legs. They who have been experimentally acquainted with the very wonderful effects of purulent drains, made from the immediate neighbourhood of diſeaſed parts, will not be much ſurpriſed at this particular one; and will immediately ſee how ſuch kind of diſcharge, made and continued from the diſtempered part, checks the further progreſs of the caries, gives nature an opportunity of exerting her own powers, of throwing off the diſeaſed parts, and of producing by incarnation an union of the bones, now rendered ſound, and thereby eſtabliſhing a cure. It matters not by what means the diſcharge is procured, provided it be large, and from a ſufficient depth.

WITH REGARD TO THE CURE, an eſchar is to be made on each ſide of the curved part of the *ſpine* with a cauſtic; the eſchar ſhould be of an oval ſhape, about an inch and a quarter in length, and three quarters o fan inch in breadth, at the broadeſt part. Apply each cauſtic near the ſide of the curvature, ſo as to leave the portion of the ſkin covering the ſpinal proceſſes of the protruded bones, entire and unhurt, and ſo large, that the ſores upon the ſeparation of the eſchars may eaſily hold each three or four peas in the caſe of the ſmalleſt curvature, but in large curves, at leaſt as many more. A few days after applying the cauſtics, the ſloughs begin to looſen: it is then proper to cut out all the middle, and put into each a large kidney-bean; when the bottoms of the ſores are become clean in ſuppuration, ſprinkle now and then a ſmall quantity of finely-powdered cantharides on them, by which the ſores are prevented from contracting, the diſcharge is increaſed, and poſſibly other benefit is obtained. The iſſues ſhould be kept open until the cure is complete; that is, until the patient has not only the perfect uſe of the limbs, but alſo the general health. By means of this diſcharge, the eroding caries is firſt checked, then ſtopped; in conſequence of which, an incarnation takes place, and the cartilages between the bodies of the vertebræ having been previouſly deſtroyed, the bones become united with each other, and form a kind of anchyloſis. No degree of benefit or relief, nor any the ſmalleſt tendency towards a cure, is to be expected until the caries be ſtopped, and the rotten bones have begun to incarn; the larger the quantity of bones concerned, and the greater the degree of waſte committed by the caries, the greater muſt be the length of time required for the correction of it, and for reſtoring to a ſound ſtate ſo large a quantity of diſtempered parts; and vice verſa. Nothing can be more uncertain than the time required to accompliſh a cure: ſometimes it is perfected in two months, and at others it requires two years; and in this laſt, two thirds of the time hath paſſed without any ſenſible amendment.

The diſcharge by means of the iſſues is all that is requiſite for the cure; but yet this is no reaſon why every aſſiſting means ſhould not be applied at the ſame time in order to expedite it, ſuch as the bark, cold bathing, frictions, &c.

In the courſe of lecturing in the year 1781, Mr. Pott obſerved, that it ſeems to be one of the few things that one may reaſon upon à priori, viz. that the whole train of the various ſymptoms of this diſeaſe are derived originally from a conſtitutional prediſpoſing cauſe; for, whenever, in a curvature of the *ſpine*, the diſcharge begins to have any effect, the leſſer ſymptoms, if they may be ſo called, as pain in the ſtomach, tightneſs acroſs the breaſt, incapacity of holding the urine or fæces, all give way before the removal of the lameneſs from the curve begins to take place.

Laſtly. If it is conſidered, that the primary cauſe of the curved *ſpine* and all its ſymptoms preceding, attending, and conſequent, is a morbid ſtate of the *ſpine* and of the parts connected with it, the following inference will be allowed, viz. by an early and proper attention, the temporary lameneſs, permanent deformity, and fatality, may be prevented. As it is found that iſſues are capable of effecting a perfect cure, even after a caries hath taken place, and *that* to a conſiderable degree, *is it not reaſonable to conclude, that the ſame means, made uſe of in due time, might prove preventive?* In many habits, iſſues would be beneficial, independent of this diſorder; infants and young children of ſtrumous habits are the ſubjects who are moſt liable to this diſtemper; and they are in general more ſerved by artificial drains than any other perſons.

It is to be obſerved, a curvature of the *ſpine* may take place from the *mollities oſſium*, the rickets, and from the various cauſes of caries. An aneuriſm often produces a caries in the bones; ſo an aneuriſm near a vertebra may render it carious; the venereal diſeaſe ſometimes attacks the vertebræ, and renders them carious. The ſcrofula, attacking the lymphatics and glands about the *ſpine*, is ſaid to be the conſtant cauſe of the curved *ſpine* above noticed, in which the curvature is angular; the angular protuberance ariſes immediately from the caries of the vertebra or vertebræ, and is attended with a uſeleſs ſtate of one or more of the extremities; but may not any cauſe, that produces a caries in the vertebræ, occaſion the angular inſtead of the curved appearance of the *ſpine?* and when the carious vertebra happens, ſo as that it is nearly deſtroyed, may not all the ſame ſymptoms proceed from ſuch deſtruction of the vertebra or vertebræ, though the cauſes of the caries were various?

See Remarks on that Kind of Palſy of the Lower Limbs, which is frequently found to accompany a Curvature of the *Spine*, and is ſuppoſed to be cauſed by it, by Percival Pott, F. R. S. &c. 1779; Farther Remarks on the uſeleſs State of the lower Limbs, in conſequence of a Curvature of the *Spine*, &c. by Percival Pott, F. R. S. &c. 1782; Jones's Eſſay on Crookedneſs; Select Caſes of the Diſorder commonly called the Paralyſis of the lower Extremities, by John Jebb, M. D. &c. Edit. 2; Bell's Surgery; London Med. Journal, vol vi. p. 358.

DISTORTOR ORIS MUSCULUS. See ZYGOMATICUS MINOR muſc.

DISTRACTIO. In chemiſtry, it is a forcible diviſion of ſubſtances from each other which were before united, either by ſeparation or calcination.

DISTRIBUTIO. DISTRIBUTION. It ſometimes implies diviſion. In MEDICINE, it relates to the nutritious juices, and is the ſame as *anadoſis*, the diſtribution of aliment over the body; or to the excrements, and is the ſame as DIACHORESIS, or DIACHOREMA.

DISTRICHIASIS, from δὶς, *bis*, *double*, and θρὶξ, *a hair*, alſo *diſtichia*, *diſtichiaſis*. A diſeaſe of the eye-lid, which conſiſts in its having a double row of hairs, or at the leaſt ſupernumerary ones. Galen. Aetius. See TRICHIASIS.

DISTRIX. The hair growing ſmaller and ſmaller.

DIURESIS, from διὰ, *by*, and οὖρον, *urine*. An excretion of urine. It alſo ſignifies a DIABETES.

DIURETICÆ. DIURETICS, from διὰ, *by*, and οὖρον, *urine*. Medicines which are ſuited to promote the ſecretion, and provoke the diſcharge of urine, which is to be done, either by increaſing the quantity of water in the maſs of blood; and *that* remaining the ſame, by introducing a matter that may be a ſtimulus to the kidneys;—in the application of which, we are to obſerve, that if a medicine is deſigned to paſs off by urine, walking gently in a cool air will aſſiſt it; but ſweating or conſiderable warmth directs it to the ſkin, or at leaſt reſtrains its efficacy. *Diuretics* of the ſaline kind are *diuretic* or perſpirative according as the body is kept cool or warm. But how ſome things paſs off by urine ſo immediately after being taken into the ſtomach, is ſtill a matter of

diſpute. Diuretic medicines are very numerous; but ſtill in their operation, they are very uncertain with reſpect to the *firſt intention*.

The increaſe of drink has been always conſidered as the chief of diuretics, becauſe it increaſes the quantity of water in the blood, conſequently promotes a proportional increaſe in the quantity of urine ſecreted: and if water is impregnated with ſaline matters, it paſſes more certainly to the kidneys, than if taken perfectly inſipid. Thus water impregnated with vegetable acids is not only more grateful than barley water and common gruel; but is more powerfully diuretic; which power will be ſomewhat increaſed by having it ſweetened with ſugar, or honey, for theſe increaſe even the virtues of other diuretics. To *anſwer the ſecond*, various are the remedies propoſed, for the particulars of which we ſhall refer our readers to the authors on the Materia Medica, particularly Dr. CULLEN. A great variety of medicines, which really poſſeſs very different powers, have been conſidered, with reſpect to their operation, as *diuretics*, which appears from the different claſſes that come under this denomination; the chief of which remove impediments to, rather than promote the diſcharge of urine.

The following have been uſed with a view to promote the diſcharge of urine.

1. *Cordial nervous medicines*. Theſe accelerate the motion of the blood when too languid, and increaſe its fluidity, and thus increaſe this diſcharge.

2. *Emollient balſamics*. Theſe relax and lubricate, ſo obtain a paſſage for what is too bulky.

3. *Subſtances conſiſting of ſalts and mucilages*. Theſe guard againſt ſtricture in the veſſels, and at the ſame time fit the matter to be diſcharged for a more eaſy exclusion.

4. *Detergent balſamics*. Theſe rareſy and ſcour away viſcous or fabulous matters which obſtruct the paſſages.

5. *Alkaline and lixivious ſalts*. Theſe keep the fluids at leaſt in a due ſtate of tenuity for being excreted.

6. *Acid and nitrous ſalts*. Theſe determine the ſerum to the kidneys, if not counteracted by heat.

7. *Antiſpaſmodics*. Theſe relieve by taking off a ſtricture in the kidneys. Theſe medicines cannot be admitted as diuretics, but may on particular occaſions be applied to as uſeful auxiliaries.

See Hoffman's Med. Rad. Syſt. Alexander's Exper. Eſſays, p. 149, &c.

DIURETICUS SAL. DIURETIC SALT, alſo called *ſal Sennerti, tartarus regeneratus*, and *arcanum tartari, foliata terra, eſſentiale ſal*. It is a fixed vegetable alkaline *ſalt* ſaturated with the acetous acid, and evaporated to dryneſs: when the proceſs is carried no farther, it is of a browniſh colour, and appears ſomewhat oily, and it is called *tart. regen.* When it is purified to perfect whiteneſs, it is called *ſal diureticus*.

Sal Diureticus. DIURETIC SALT, *now called*, KALI ACETATUM, *acetated Kali*.

Take of kali, one pound; boil it with four or five pints of diſtilled vinegar over a gentle fire: when the fermentation ceaſes, add more diſtilled vinegar, and when the fermentation ſubſides, add more vinegar; and proceed thus until, the vinegar being nearly all evaporated, freſh vinegar will not excite any fermentation; which uſually happens when about ten quarts have been uſed: then gently evaporate to dryneſs. The *ſalt* left will be impure, which is to be melted for a time with a gentle heat, then diſſolved in water, and filtered through paper. If the melting hath been duly performed, the filtered liquor will be colourleſs; if otherwiſe, of a brown colour. Laſtly, the water is to be evaporated with a very gentle heat in a ſhallow glaſs veſſel, the *ſalt* as it dries being frequently ſtirred, that the humidity may the ſooner be diſcharged; which ſhould be kept in a veſſel cloſe ſtopped, or it will diſſolve by the moiſture of the air. If on diſſolving a little of it in water, or the ſpirit of wine, any faeces are obſerved in either of theſe liquids, the whole muſt be diſſolved in ſpirit, filtered, and evaporated again. Ph. Lond. 1788.

In order to ſucceſs in this proceſs, care muſt be had perfectly *to ſaturate the ſalt with the acid*, duly to calcine it afterwards, and at laſt to dry it without heating it too much. For the firſt, make the finiſhing trial, when the liquid is almoſt evaporated away, by dipping a coloured paper into it, as directed in the article, SPT. MINDER. The degree of calcination may be judged of, by dropping a little in water, and obſerving when it begins to part with its blackneſs readily; if, after this, the calcination is continued, the *ſalt* will be browniſh. In the laſt drying, care muſt be taken not to melt it; for thus its whiteneſs will be leſſened, and dregs will fall on diſſolving it in ſpirit.

The only uſe of redering this *ſalt* white by depriving it of its oil, is that it may reſt more eaſily on weak ſtomachs; but if the proceſs above was carried on no farther than to ſaturate the alkaline *ſalt*, then the evaporation of the liquor being performed in a water-bath, the oily part of the *ſalt* would not have an empyreumatic flavour, ſo as to become offenſive; the remaining trouble of the above method would be ſpared, and a medicine in all caſes as good would be obtained.

Dr. Lewis directs the *ſalt* of tartar to be diſſolved in cold water, and filtered, and then to ſaturate this ſolution with diſtilled vinegar: after which the evaporation is to be made over a very gentle fire, ſo that the liquor may not boil, until a pellicle appears on its ſurface, after which the reſt of the proceſs muſt be finiſhed in a water-bath; the pellicle as it whitens muſt be taken off, and the reſt kept continually ſtirring until the whole is taken away in the form of a white ſcum, which may be dried in an oven.

In making of this *ſalt*, care ſhould be taken to uſe a pure alkaline *ſalt*, in which no neutral one is mixed: though, after all poſſible care in preparing the kali acetatum, a bare mixture of the ſalt of tartar with vinegar, to a point of ſaturation, without evaporation, or any other procedure, is very little if at all inferior.

The doſes of this *ſalt* will be according to the intention had in preſcribing it. From ten to twenty grains, it is a mild, cooling aperient and deobſtruent; from twenty to thirty, an alterative diuretic; from a dram to half an ounce, it is purgative. When this *ſalt* is given as a purgative, the patient is neither griped nor weakened by it; and as it is diuretic too, it is a peculiarly proper purgative in dropſies. The fixed alkaline ſalts are more diuretic; but when feveriſhneſs forbids their uſe, the kali acetatum very well ſupplies their place. In the jaundice and other complaints in which chalybeate medicines are indicated, but are from accidents forbid, this ſalt may be given to advantage, and then preparations of ſteel may be perfiſted in. See Lewis's Mat. Med. Neumann's Chem. Works.

DIURNUS. An epithet of diſeaſes whoſe exacerbations are in the day-time.

DIUTURNUS. When applied to diſeaſes it ſignifies chronical.

DIVERSORIUM. See RECEPTACULUM CHYLI.

DIVERTALLUM. Paracelſus ſays it is whatever is generated of elements.

DIVIDENS FASCIA. The name of a bandage for the neck.

DIVINUM OLEUM. See LATERITIUM OLEUM.

DIVINUS. A pompous epithet for many compoſitions, given on account of their ſuppoſed excellencies.

DIVINUS LAPIS. It is the name of a preparation made by fuſing alum, ſalt-petre, and Cyprian vitriol together, and then, while fluid, adding a ſmall portion of camphor.

DIVULSIO URINÆ. An irregular ſeparation of urine, in which the ſediment is divided, ragged, and uneven.

DOCHME. A meaſure among the Greeks, of four fingers' breadth.

DOCIMASTICA. See CUPELLA.

DOCIMASTICE. The docimaſtic art is the art of examining foſſils, in order to diſcover what metals, &c. they contain.

DOCTILETUS. Paracelſus names it as a medicine for the cancer; but he does not explain what it is.

DOD. An abbreviation of Remberti Dodonæi Stirpium Hiſtoriæ Pemptades ſex.

DODECADACTYLON, from δώδεκα, *twelve*, and δάκτυλος, *finger's length*. See DUODENUM.

DODECANDRIA, (from δώδεκα, *twelve*, and ἀνὴρ *huſband*). The eleventh of Linnæus's claſſes of plants. It comprehends thoſe plants which produce hermaphrodite flowers, and have from twelve to nineteen ſtamina, both numbers incluſive. In this claſs there are five orders, 1 MONOGYNIA—25 *Genera*;—2 DIGYNIA—2 *Genera*;—3 TRIGYNIA—5 *Genera*;—4 PENTAGYNIA—1 *Genus*;—5 DODECAGYNIA—1 *Genus*.

DODECAPHARMACUM. See APOSTOLORUM UNGUENTUM.

DODECATHEON. The name of an antidote which conſiſts of twelve ſimples. It is deſcribed by P. Ægineta; alſo of the SANICULA.

DODRA. A kind of potion among the ancients, made, of nine ingredients.

DODRANS. See CYATHUS.

It is the name alſo of a meaſure of nine inches, and a weight of ten ounces.

DŒDYX. See COCHLEARIA.

DOGGA. An Arabic term for the PARONYCHIA.

DOG-AND-DUCK WATERS. This ſpring is ſituated in Surry, about half a mile from Weſtminſter bridge. Of ſolid contents got from this water, they appear different, at different times. Dr. HALES got, from one gallon, 324 Grains;—Dr. FOTHERGILL, 200;—Dr. RUTTY, only 96. Of this about $\frac{1}{4}$ part is an earth, which, Dr. Rutty ſays, is ſoluble in acids; but does not calcine to lime: the ſalt is vitriolated magneſia and ſea ſalt mixed together. Drank from one to three pints, it generally purges briſkly. See AQUÆ CATHARTIC ÆAMARÆ.

DOGMA, from δοκεω, *to be of opinion*. It is a principle, maxim, tenet, or ſettled opinion, with regard to matters of faith, or philoſophy. In *medicine*, a ſentiment founded on *eſtabliſhed principles*, from whatever baſes they were formed. Hence,

DOGMATICUS. DOGMATIST. A ſect of ancient phyſicians, of which Hippocrates was the firſt. They laid down definitions, and diviſions; reducing diſeaſes to certain genera, and thoſe genera to ſpecies, and furniſhing remedies for them all; ſuppoſing principles, drawing concluſions, and applying thoſe principles and concluſions to particular diſeaſes under conſideration: hence were they called LOGICI, Logicians, from their uſing the rules of logic in their profeſſions, and ſtood contradiſtinguiſhed from the Empirici and Methodici.

DOLICHOS. *Long* or *prolix*. It is alſo a pod or kidney-bean. See PHASEOLUS ZURRATENSIS.

DOLOIRES. See DELIGATIO.

DOLOR. PAIN, alſo *algema*. As the brain is the ſeat of ſenſation, ſo it is of *pain*. Boerhaave and moſt other authors on this ſubject aſſign a ſtretching of the nerves as the only immediate cauſe of *pain*: but as the nerves do not appear to conſiſt of fibres, this cauſe of *pain* does not ſeem to be well founded; nor indeed will it be eaſy to treat this ſubject clearly, but in proportion as the means of ſenſation are underſtood. See the articles CEREBRUM, NERVI, and SYMPATHIA.

Many kinds of *pain* are met with in authors: ſuch as a *gravitative pain*, in which there is a ſenſe of weight on the part affected, which is always ſome fleſhy one, as the liver, &c.—a *pulſative pain*: this, Galen ſays, always ſucceeds ſome remarkable inflammation in the containing parts, and is obſerved in abſceſſes while ſuppurating:—a *tenſive pain*, which is alſo called a *diſtending pain*; it is excited by the diſtenſion of ſome nervous, muſcular, or membranous part, from either ſome humour, or from flatulence:—an *acute pain* is when great *pain* is attended with quick and lively ſenſations:—a *dull pain* is when a kind of numbneſs is as much complained of as the *pain* is.

The mediate and more remote cauſes of *pain* are generally obvious; and when ſo, the cure will conſiſt for the moſt part in removing them; for though, in many inſtances, the chief complaint is very diſtant from the ſeat of theſe cauſes; yet their removal is the proper method of relief: the reſpective methods of affecting which are intimated in each diſorder included in the rank of painful ones. Perhaps, all *pains* may be included with irritation, in thoſe that have ſpaſm or inflammation for their ſource.

When *pain is owing to inflammation*, the pulſe is quicker than in a natural ſtate, generally full, hard, and tenſe; the *pain* is equal, throbbing, and unremitting.—*If a ſpaſm is the cauſe*, the pulſe is rarely affected: at intervals the *pain* abates, and then returns with ſome degree of aggravation; gentle motion ſometimes abates, or even cures, in ſome inſtances; but in inflammatory caſes, no ſuch effects are ever experienced. See Dr. Lobb's Treatiſe of Painful Diſtempers.

The *pains* ſo frequently attendant on child-bed women, called after-*pains* (from their happening only after delivery) are often occaſioned by ſcooping with the hand, to fetch away coagulated blood, which is a needleſs endeavour. When no improper treatment in delivering the ſecundines can be ſuſpected, *the irritability of the uterus alone* is to be conſidered as the cauſe. Care ſhould be taken not to confound theſe after-*pains* with, or miſtake the *pains* attending puerperal fevers, or the colic. After-*pains* come by fits, and ſoon go off, but return at different intervals, which are longer each day, and after two or three days uſually ceaſe, though ſometimes they continue ſeven or eight: notwithſtanding theſe *pains*, the lochia flow properly, and generally more abundantly after the ceſſation of each fit; this does not happen in colicky complaints, nor is the belly ſo free from tumefaction when the puerperal fever is attendant.

As theſe pains are of the ſpaſmodic kind, anodynes and gentle opiates, with frequent draughts of warm caudle, chamomile tea, &c. are all that are required in order to their relief. See the authors recommended under the article PUERPERILIS FEBRIS.

Pain forms, with ſome noſologiſts, a claſs of diſeaſes, under the denomination PAINFUL DISEASES, becauſe pain is the characteriſtic ſymptom, and conſtant concomitant of ſuch complaint, as Gout, Rheumatiſm, Colic, &c. &c. and theſe all ariſe either from *Irritation*, *Spaſm*, or *Diſtenſion*; but moſt commonly from the former often inducing the two ſubſequent affections.

Among the various cauſes of *pain*, a ſingular one is related in the third vol. of the Lond. Med. Obſ. and Inq. p. 241, &c. Some perſons who had taken cold during their being ſalivated, were afflicted with *pains* which reſiſted all the uſual methods of relief; at length the author of the narrative referred to the ſuggeſted cauſe, and by exciting a freſh ſalivation, the *pains* abated; the ſpitting was kept up a little while, and permitted to abate with ſome caution, and thus the cures were completed.

DOLORES, } Painful diſeaſes.
DOLOROSI. }

DOLOROSI EXTRINSECI. Painful diſeaſes of the limbs.

—— INTRINSECI. Painful diſeaſes of the internal parts.

DOMESTICUS, DOMESTIC. In ZOOLOGY, it ſignifies animals that are fed at home, in diſtinction from thoſe called WILD. In BOTANY, it ſignifies cultivated. In PHARMACY, ſome medicines are thus named, which are managed in a family without the direction of a phyſician.

DOMINICUM SERPENTUM. See BOICININGA.

DORCAS. See CAPRA ALPINA, and CAPREOLUS.

DOREA. See HEMERALOPS.

DORIA. } Alſo called *Lobelii*
DORIA NARBONENSIUM. } DAMESONIUM, *damaſonium Mathioli*, ALISMA, DAMASONICUM, JACOBÆA pratenſis. DORIA'S WOUND-WORT.

It grows on the banks of rivers, flowers in July and Auguſt, is commended as a vulnerary, but not in much uſe.

DORIA, HERBA. See VIRGA AUREA.

DORIDIS HUMOR. See AQUA MARINA.

DORIS. See ANCHUSA.

DORONICUM. LEOPARD'S-BANE.

—— AUSTRIACUM, GERMANICUM. See ARNICA MONTANA.

—— ROMANUM, alſo called *doronicum* radice ſcorpii, *doron*. vulg. *graphoy*, *aconitum pardalianches minus*, BROAD-LEAVED LEOPARD'S-BANE, ROMAN LEOPARD'S-BANE, and WOLF'S-BANE. It is the DORONICUM PARDALIANCHES, Linn.

It is a native of the Alps; cultivated in our gardens; hath heart-ſhaped leaves, and roots that are knotted, and reſemble a ſcorpion's tail. It flowers in June and July. The roots are ſweetiſh to the taſte, and ſlightly aromatic. Some extol it in epilepſies; but it is not noted at preſent in our practice. Some think it is the *duronego* of the Arabians.

DORSALES NERVI. The nerves, which paſs out from the vertebræ of the back, are thus named. Theſe *dorſal* nerves, as ſoon as they paſs from the vertebræ, ſend out two branches anteriorly, which contribute to form the intercoſtal, called *coſtales*; and ſend ſeveral twigs backwards to the muſcles. The *dorſal* nerves go to the internal and external intercoſtal muſcles, running on the under ſide of the ribs; thoſe that go to the true ribs, reach as far as the ſternum; thoſe that go to the ſpurious ribs, are diſperſed on the muſcles of the belly. The firſt *dorſal* nerve goes to the axilla, to join the cervical; the laſt is diffuſed over the tranſverſalis and obliqui interni; and at the ſpine of the os ilium, it throws a branch out, to be a cutaneous nerve on the hip.

DORSTENIA, } See CONTRAYERVA.
DORSTINEA. }

DORSUM. The BACK. Moſt etymologiſts ſay, from *deorſum*, becauſe it bends downwards; called alſo *antiſternon*, *metaphrenon*; but this laſt appellation properly means the part between the ſhoulders.

What

What is commonly called a gibbofity, is a preternatural incurvation of the fpine of the back, either to the poſterior or to the lateral parts. It generally happens from external cauſes, as blows, tight ſtays, &c. GOUEY, in his Surgery, gives an inſtance from a preternatural contraction of the muſcles of the belly. A relaxation of the ligaments of the vertebræ may alſo be the cauſe. See Heiſter's Inſt. of Surgery, alſo DISTORTIO SPINÆ.

DORYCNIUM. See CISTUS.

DOTHIEN. See FURUNCULUS.

DOUCHE LA. See DUCCIA; and STILLICIDIUM.

DOVERI PULVIS. See *Pulv. Ipecac. Comp.* under IPECACUANHA.

DRABA, called alſo *lepidium Arabis*; ARABIAN MUSTARD, and TURKEY CRESSES. The ſeeds ſerve as pepper in ſeaſonings, but are not noted as a medicine.

DRACHMA. Among the Greeks this was the name of a coin; alſo of a weight, which they divided into ſix oboli. The Romans reckoned eight drams to an ounce, and twelve ounces to a pound; our apothecaries' weights, which are now uſed.

DRACO, called *draco* herba, *tarachon*, *tarchon*, *dracunculus hortenſis*, *abrotanum lili-folio*, TARRAGON.

The leaves of this herb reſemble thoſe of hyſſop; the flowers grow on the top of the plant, and appear like thoſe of ſouthernwood. It is planted in gardens, and flowers in July and Auguſt. The leaves have a ſtrong ſcent, ſomewhat like fennel; they are warm and ſtomachic, but not much noticed in medicine. See Miller's Bot. Off.

DRACO ARBOR IND. SILIQ. See ANGSANA.

—— FIGENS. The name of an anti-epileptic powder extolled by Dolæus.

—— SYLVESTRIS. See PTARMICA.

DRACONTHEMA, from δρακων, *a dragon*, and αιμα, *blood*. See SANGUIS DRACONIS.

DRACONTIA. See DRACONTIUM.

—— MINOR. See ARUM.

—— MAGRA. See DRACUNCULI.

DRACONTIDES. A name given, as Rufus Epheſius informs us, to ſome veins proceeding directly from the heart.

DRACONTIUM, alſo called *dracunculus polyphyllus*, dracuntium, *Colubrina*, *Dracontia*, *Erva de Sancta Maria*, *Gigarus*; *ſerpentaria*, *arum polyphyllum*, DRAGON'S, and MANY-LEAVED ARUM. It is the ARUM DRACUNCULUS, Linn.

It is a plant with ſmooth gloſſy leaves, ſet on long pedicles; the ſtem is ſingle, thick, whitiſh, and variegated with purple ſtreaks; on the top is a long ſheath, including a dark-coloured piſtil, like that of *arum*, but larger, which is ſucceeded by a cluſter of red berries. The root is large, rather round, externally inclining to yellow, and internally white. It is perennial; a native of the ſouthern parts of Europe.

Its botanic characters are the ſame as thoſe of *arum*, and its medical virtues ſo ſimilar, that each may be ſubſtituted for the other. It is only uſeful whilſt freſh, and the ſame pharmaceutic management, as directed for *arum*, is proper for this. See ARUM.

DRACUNCULUS HORTENSIS. See DRACO.

DRACUNCULI, from δρακων, *a ſerpent*. GUINEA WORMS, called alſo *capillares vermiculi*, TAPE-WORM, and SOLITARY-WORM. The Arabians call it *Medinenſis* vel *medena Vena*. They ſtyled it *Vena*, becauſe they doubted its being a living animal, and *Medinenſis* from the frequency of its appearance at Medina. Hence AVICENNA treats of it among abſceſſes. LE CLERC, and many others miſtake them for the BOVINA AFFECTIO, which ſee; but AETIUS ſeparates them; and ALBUCASIS hath two chapters which diſtinguiſh them.

Dr. Frend ſays, that Aetius is the firſt who gives an account of theſe worms; but Plutarch quotes Agatharchides for an account of them, who writ long before Aetius. Plutarch calls them δρακοντια μακρα.

They are common in both the Indies, in moſt parts of Africa, in Switzerland, Genoa, and many other hot countries.

"This *worm* reſembles a common *worm*, but is often much larger: it is commonly found in the legs, but ſometimes it is in the muſcular part of the arms. Theſe *worms* are bred in Ethiopia and India, principally affecting children; and their generation is not unlike that of the broad *worms* of the belly; hence their name TAPE-WORM. While they move under the ſkin they create no trouble; but in length of time the place near the dracunculus ſuppurates, and the animal puts forth its head. If it be drawn, it excites conſiderable uneaſineſs, eſpecially if drawn ſo forcibly as to break it; for the part left within creates intolerable pain." Aetius in Tetrabib. 4. ſerm. 2. cap. 85. Paulus Ægineta mentions them as being always ſeated in the muſcular parts of the thighs, legs, and arms; and he ſays, that ſometimes they are met with in the ſides of children. Avicenna ſays, that theſe *worms* are from ten to fifteen palms long. Albucaſis mentions one of twenty palms. In the ſixth vol. of the Edinb. Med. Eſſays, mention is made of one that was three yards and a half in length.

In ſome inſtances, beſides the pain which theſe *worms* occaſion, a fever is alſo a conſequence.

Kempfer obſerves, that theſe *worms* prevail moſt when the weather is hotteſt; and he attributes their production to ſtagnant rain-water, which is ſo much drank in hot countries.

Dr. Towne, in his Treatiſe on the Diſeaſes of the Weſt Indies, deſcribes this *worm* as being long, white, round, and reſembling round tape or bobbing. This deſcription is juſt.

Nothing need be done until a tumor comes on; and then the beſt method is to promote ſuppuration: as ſoon as the tumor is open, the head of the *worm* appears, which being tied by a thread, may be ſecured on a roll of linen ſpread with ſticking plaſter, and as the worm appears, it may be rolled round this linen, until the whole is extracted; after which, the treatment will be only as in common caſes. During the time that this *worm* is coming out, the greateſt care is neceſſary that it may not be broken, for the conſequence of ſuch an accident are tedious ulcers in the whole length of the part which is poſſeſſed of the remaining *worm*. A daily uſe of aloes, or of any other anthelmintic, is convenient, during the extraction of the *worm*, as ſuch means are obſerved to haſten its expulſion.

DRACUNCULUS. See DRACO; DRACONTIUM.

—— PRATENSIS. See PTARMICA.

—— POLYPHYLLUS. See DRACONTIUM.

DRAGACANTHA. } See GUM TRAGACANTHÆ.
DRAGANTUM. }

DRAGMA. See MANIPULUS.

DRAGMIS. See PUGILLUS.

DRAKENA RADIX. See RAD. CONTRAYERVA.

DRANGÆA. A name of ſeveral antidotes. See TRAGÆA.

DRANK. See ÆGYLOPS.

DRAPTA. DILACERATED.

DRASTICOS, from δραω, *to act, effect* or *perform*. DRASTIC, *active*. It is an epithet beſtowed on medicines of quick action, and powerful operation, and commonly applied to emetics and cathartics of a violent quality.

DRESDENSIS PULVIS. It is an oleoſaccharum, in which is the oil of cinnamon.

DRIFF. So Helmont calls Butler's ſtone, or ſome ſuch preparation, which is alſo named *periapton*, *ſalutis magneticum*. It is ſaid to cure diſeaſes by a touch of it with the lips and tongue.

DRIMYLEON, from δριμυς, *eager, ſhrewd*, and λεων, *a lion*; alſo *drimymoros*. This was a term of reproach beſtowed by Menodotus, the empiric, upon the phyſicians of his time, who profeſſed to govern their practice by reaſon.

DRIMYMOROS, from δριμυς, *eager* or *ſhrewd*, and μωρος, *a fool*. See DRIMYLEON.

DRIMYPHAGIA, from δριμυς, *acrid*, and φαγω, *to eat*. The eating of acrid ſubſtances.

DROMA. The name of a plaſter deſcribed by Myrepſus.

DROPACES. }
DROPACISMUS. } See CEROPISSUS.
DROPAX. }

DROSATUM, i. e. Roſatum. Wine made of roſes infuſed, or any other compoſition, where roſes make the chief ingredient.

DROSERON. The name of an ointment in Myrepſus.

DROSIOBETANON. See BETONICA.

DROSOMELI. See MANNA.

DRUPAS. See OLEA.

DRYOPTERIS. See POLYPODIUM TENERUM MINUS.

DRYPA. See OLEA.

DUBEL COLEPH. A compoſition of coral and amber.

DUBE-

DUBELECH. The cavity of an apoſtem, with manifeſt ſolution of continuity.

DUBLETUS. See ABSCESSUS.

DUCCIA, } Barbarous terms for a drop. They
DUCIA. } ſimply alſo that ſpecies of bathing which we call pumping, and the French *la douche*. Baccius, in his Treatiſe of Baths, lib. ii. gives rules for this kind of bathing. See alſo Le Dran's Obſervations, p. 310.

DUCIS HOLSATIÆ SAL. See NITRUM. No. 6.

DUCTUS, from *duco, to lead*. A DUCT or CANAL. This word is frequently applied to parts of the body through which particular fluids are conveyed.

—— ARTERIOSUS. It is found only in the fœtus, and very young children: it ariſes from the aorta deſcendens, immediately below the left ſubclavian artery. In adults it is cloſed up, and appears like a ſhort ligament adhering by one end to the aorta, and by the other to the pulmonary artery, ſo that in reality it deſerves no other name than that of *ligamentum arterioſum*.

—— AURIS PALATINUS. See TUBA EUSTACHIANA.

—— AD NASUM. See ANTRUM GENÆ.

—— NIGRI. On ſeparating the cryſtalline and vitreous humours from their adhelions to the ciliary proceſſes, part of the black pigment, which is on the choroides chiefly, is left lying in black radiated lines, which are thus named.

—— STENONIS. See SALIVAL. DUCT. STEN.

—— THORACICUS. THORACIC DUCT. PECQUET diſcovered and demonſtrated it, at Paris, 1651, 1652. It is a thin tranſparent canal, which runs up from the receptaculum chyli, along the ſpina dorſi, between the vena azygos and aorta, as high as the fifth vertebra of the back, or higher; from thence it paſſes behind the aorta, towards the left ſide, and aſcends behind the left ſubclavian vein, where it terminates in ſome ſubjects by a kind of veſicula; in others by ſeveral branches united together, and opens into the back ſide of the ſubclavian vein near the outſide of the internal jugular. It is furniſhed with many ſemilunar valves turned upwards. Its opening into the ſubclavian vein in the human body is, in the place of valves, covered by ſeveral pelliculæ, ſo diſpoſed as to permit the entrance of the chyle into the vein, and hinder the blood from running into the *duct*. It is ſometimes double, one lying on each ſide; and ſometimes it is accompanied with appendices, called *pampiniformes*. Any compreſſion upon this duct will occaſion atrophy, and death; as it prevents the fluids by which the animal is to be nouriſhed from entering the courſe of circulation in a ſufficient quantity, if not totally. See MONRO's OSTEOLOGY.

—— VENOSUS. In a fœtus, as the vena cava paſſes the liver, it gives off the *ductus venoſus*, which communicates with the ſinus of the vena portæ, and in the adults becomes a flat ligament.

—— WHARTONI. The inferior ſalival duct is thus named from his deſcribing it.

DUDAIM. See MANDRAGORA.

DUELLA. A weight of eight ſcruples.

DUENECH. See ANTIMONIUM.

DUENEZ. FILINGS of STEEL. See LIMATURÆ FERRI, under FERRUM,

DULCACIDUM. Any preparation that is ſweet and tart.

DULCAMARA. See SOLANUM LIGNOSUM.

DULCEDO SATURNI, i. e. Ceruſſa. See PLUMBUM, No. 1.

—— VENERIS. See CLITORIS.

DULCIS RADIX. See GLYCIRRHIZA.

DULECH. A term uſed by Paracelſus and Helmont for a ſort of ſpongy ſtone generated in the body.

DULWICH-WATERS. This well is ſituated in the county of Surry, about four miles ſouth-eaſt of London-bridge. The water is clear, obſcurely brackiſh, and taſtes a little bitter in the throat. A gallon at one time yielded two, at another, three drams of ſolid matter, containing a ſmall portion of calcareous earth, and a vitriolated magneſia, mixed with a portion of marine ſalt. From one to three pints in a morning is a doſe. See AQUÆ CATHARTICÆ AMARÆ.

DUMUS. A BUSH. *Buſhes* ſend out branches from near their roots; hence are diſtinguiſhed from trees, whoſe ſtem riſes conſiderably before any branches are ſent out. *Dumus* is a *buſh*, ſuch as the thorn; and *rubus* is alſo a *buſh*, but ſuch as the briar.

DUOBUS, SAL DE. See NITRUM. No. 6.

DUODENALIS ARTERIA, alſo called *inteſtinalis*. As ſoon as the gaſtrica dextra hath paſſed behind the ſtomach, it ſends out the duodenal artery (which ſometimes comes from the trunk of the hepatica): it runs along the *duodenum*, on the ſide next the pancreas, to both which it furniſhes branches, and alſo to the neighbouring part of the ſtomach.

DUODENALIS VENA. A branch from the vena portæ ventralis, called *inteſtinalis*; it is diſtributed chiefly in the *duodenum*, but ſends ſome branches to the pancreas. A branch of the gaſtrica is alſo thus called. The hæmorrhoidalis interna gives a branch of this name to the *duodenum*.

DUODENUM, from *duodeni, twelve*. This inteſtine is thus named from a ſuppoſition that its length does not exceed the breadth of twelve fingers: and if meaſured with the ends of the fingers, it is about the matter: alſo called *dodecadactylon, ecphyſis, portorarium*. It begins at the right orifice of the ſtomach behind the liver; runs backward, and obliquely downward; then turns a ſecond time towards the right kidney, to which it is attached by the cellular membrane, from thence paſſes between the kidney and liver, acroſs the ſpine about the laſt vertebra of the back; it comes out on the left ſide, behind the root of the meſentery; as ſoon as it arrives at the meſentery, it forms the *jejunum*. It is the wideſt and ſhorteſt of the ſmall inteſtines; indeed it is a ſort of ſuccedaneous ſtomach, and is by ſome called *ventriculus ſuccenturiatus*. Its extremity, next to the jejunum, is fixed in a courſe almoſt perpendicular upwards. It is not entirely covered with the peritoneum, nor is it furbelowed on the meſentery (for thereby it would have dragged the ſtomach down), but is attached to the neighbouring parts. Its outer coat is furniſhed with more cellular membranes than any of the other ſmall inteſtines; the villi in its inſide are thicker than in the ſtomach, and its texture is like a fungus, and not like hairs, as it is uſually repreſented in figures. As its form is much like that of the ſtomach, ſo is its uſe of the ſame nature: it is furniſhed with liquors peculiar to itſelf, ſince not only a large number of ſmall glands, diſcovered by Brunnerus, which diſcharge a menſtruous lymph, are ſituated in it; but alſo becauſe the pancreatic juice, mixing with the bile, accompliſhes the farther elaboration and rectification of the chyle: thus the digeſtion of the aliment, begun in the ſtomach, is further elaborated in the *duodenum*. For its arteries and veins, ſee DUODENALIS ARTERIA & VENA. Its nerves are the middle plexus of the ſemilunar ganglion, and ſome filaments of the plexus ſtomachicus and hepaticus. The *duodenum* is connected with the œſophagus by the ſame coats, and hence they communicate with the coat which ſurrounds the fauces and the mouth. Like the ſtomach, the *duodenum* hath a connection with almoſt all the body by the nerves.

Of ſuch importance is the *duodenum*, that by Sylvius it is aſſerted *to be the ſeat of almoſt all the diſorders in the phyſician's province*: Helmont agrees with him; and indeed the more this inteſtine is underſtood, the greater appearance there ſeems to be of reality in their thoughts.

In the circulation, no morbid matter can be ſaid to be produced; in the ſtomach and *duodenum*, a ſtagnation, and conſequent degeneracy, may be, and often is produced: if the bile ſtagnates in the *duodenum*, it ſoon acquires a morbid quality, and occaſions great anxiety, with other afflictive ſymptoms. Other juices, by too long delay there, acquire a morbid acrimony alſo. From this ſource, viz. *the morbid contents of the duodenum*, it is eaſy to trace many diſorders. The truth of this is farther confirmed, by the ſucceſs of emetics, and of gentle purgatives, in the cure of many chronic complaints. When morbid matter in the *duodenum* is the ſuſpected cauſe of any illneſs, emetics ſhould not be omitted. The reaſon why emetics are inſiſted on, is, becauſe the ſtomach and the *duodenum* have a glandulous coat over their nervous one; whereas, in the other inteſtines, the nervous coat lies more immediately expoſed to the action of purging medicines, which often paſs the ſtomach and *duodenum*, without much affecting their nervous coat. Or if emetics are not ventured on as ſuch, the action of purges may be quickened by a ſmall addition of the antimonial wine, or of tartarized antimony. See Monro's Obſervations on the Inteſtines, in the Edinb. Eſſays, and Fred. Hoffman on the *duodenum*.

DUPLICANA. See TERTIANA DUPLEX.

DUPONDIUM. A weight equal to four drams.

DURA MATER, alſo called *cuticularis membrana craſſa meninx*, to diſtinguiſh it from the *meninx tenuis* or

pia mater (see PIA MATER); which two membranes are called *meninges*, or *matres*, from being the ſuppoſed ſource of al lthe other membranes, alſo *omenta*, *tilamides*.

The *dura mater*, to which *dermatoides* is uſed as an epithet, from its ſkin or leather-like appearance, lies contiguous to the inſide of the ſkull every where: its ſubſtance is very compact; it is white, and gliſtening like a tendon, and by ſome divided into two lamellæ, by others into more. The external ſurface of this membrane is analogous to the internal ſurface of the perioſteum in all parts of the body; it adheres more firmly to the cranium at the ſutures than elſewhere, becauſe of the veſſels which run in theſe, and in the proceſſes which are thrown out. The inner ſurface of the *dura mater* is in general a ſmooth membrane, and lies looſe upon the pia mater, except at the ſinuſes, where they are attached by means of the veins which come out from the pia mater, and ſinking into the *dura mater*, form the ſinuſes. The proceſſes of the *dura mater* are divided into the external and the internal. The true external are thoſe that line the foramina, which, when they get out, are loſt in the pericranium; but when the proceſſes of the *dura mater* are mentioned, without particularifing them, the internal ones are to be underſtood. The longitudinal, or the PROCESSUS FALCIFORMIS, falciform proceſs, named alſo *falx* (from its ſhape being like that of a ſickle) begins at the CRISTA GALLI; runs thence in the direction of the ſagittal ſuture, to the middle of the os occipitis, dividing the cerebrum into two hemiſpheres; it there forms two tranſverſe proceſſes which lie between the two poſterior lobes of the cerebrum and cerebellum. The glands of the *dura mater*, ſpoken of by ſome old anatomiſts, are never met with by the moderns. The ſinuſes of the *dura mater* are venal, though their ſtructure and form differ from veins; every ſection is triangular, and their ſhape like a priſm. The veins are every where pouring their blood into theſe ſinuſes from all parts of the brain, and there are ſeveral cords going acroſs them, which, from their diſcoverer, are called CHORDÆ WILLISII. The orifices of the veins of the pia mater into the ſinuſes, are in a direction contrary to the courſe of the blood in the ſinuſes. The principal ſinus runs along the proceſſes. The longitudinal ſinus begins ſmall at the criſta galli, becomes larger as it proceeds, and running on to the os occipitis, forms the two tranſverſe ſinuſes, which paſſing out of the cranium, between the os temporis, and the os occipitis, forms the internal jugular veins. Juſt at the angle where the longitudinal ſinus divides into the two tranſverſe, the fourth ſinus, called TORCULAR HEROPHILI, opens, which is formed by the vena magna Galeni. The *dura mater* appears more red than the tendons, becauſe of the arteries which go to the brain, and which play upon its ſurface before they penetrate it. The arteries go from ſide to ſide, but do not open into the ſinuſes, as ſome have aſſerted. Wherever an artery runs upon the *dura mater*, it is accompanied with one or more veins, which contribute to make the ſulci on the cranium, as well as the arteries. Its principal uſes are as a covering for the brain; it alſo ſerves as an inner perioſteum. The uſe of the proceſſes is to connect the bones, and the uſe of the ſinuſes is to return the blood freely.

The *dura mater*, when expoſed in a living animal, is ſeen to have a pulſation correſponding to that of the arteries, and is owing to the ſyſtole and diaſtole of the arteries of the pia mater. When the *dura mater* is laid bare, it commonly ſloughs like a tendon; in ſome caſes it is oſſified. The brain is ſometimes protruded through the bregma in children, and the *dura mater* ſerves for a bag for the rupture. Gooch, in his Med. Obſ. gives an inſtance of a fractured ſkull; in which caſe, a fluid being perceived under the *dura mater*, in order to its diſcharge, this membrane was cut through with the ſciſſors from one ear to the other, and the patient recovered.

The nerves are from the trunk of the fifth pair, and from the common trunk of the eighth pair. The arteries from the carotids, called,

DURÆ MATRIS ARTERIÆ, and *meningeæ*. The DURA-MATRAL ARTERIES. The external carotid *artery* ſends a branch through the ſpinal hole of the os ſphenoidale, which is the middle *artery* of the *dura mater*, and is called, by way of eminence, the *artery* of the *dura mater*. It is divided into many branches, which are diſperſed through the ſubſtance of the external lamina as high as the falx, where theſe ramifications communicate with their fellows on the other ſide. The impreſſions of this *artery* are ſeen on the inſide of the parietal bones; the anterior and lower angle of which, inſtead of a ſimple impreſſion, contain a canal for the paſſage of a trunk of this *artery*; on which account, ſeveral accidents happen in fractures of the ſkull. The external carotid ſends off another branch through the ſuperior orbitary fiſſure, to the dura mater, called its anterior *artery*. The carotid and the vertebrals ſend it branches. Winſlow calls the firſt mentioned of theſe *arteries*, *ſphæno-ſpinalis*. Dr. Hunter ſays, the dura-matral *artery* proceeds from the inferior maxillary *artery*, and paſſes through a hole in the petrous part of the temporal bone.

DURATUS. HARDENED; but Scrib. Largus expreſſes by it, *macerated*.

DURONEGO. BROAD-LEAVED LEOPARD'S-BANE. See DORONICUM ROMANUM.

DUTRAY. See STRAMONIUM.

DYAMASSIEN. See *ÆRIS FLOS*.

DYNAMIS, from δυναμαι, *to be able*. It is the faculty or power from whence an action proceeds. Galen often uſes this word for a compoſition of a medicine, ſometimes particularly of an approved one.

DYOTA, alſo DISTA. A PELICAN, or circulating veſſel, with two ears, reſembling in ſhape a man ſtanding with his arms bent outward, and his hands on his ſides.

DYSÆSTHAESIA, from δυς, *difficulty*, and αισθανομαι, *to feel*, or *perceive*. A DULNESS OF SENSATION, or FAULTY SENSE. Under this term, Dr. CULLEN forms his firſt order of his fourth claſs LOCALES; though, in the enumeration of the ſpecies, he has not adhered cloſely to the definition. See his Notologiæ Methodicæ Synopſis. Cl. 4th, Ord. 1ſt, p. 302. Diſeaſes of this order are ſynonymous with *hallucinationes*, according to Dr. CULLEN, and are conſidered as complaints, whoſe principal ſymptom is a depraved or erroneous imagination. He defines them, The ſenſes depraved or deſtroyed from ſome defect, or fault of the external organs. *Privativi* come alſo under this head.

DYSALTHES, from δυς, *difficulty*, and αλθω, *to cure*, difficult of cure.

DYSANAGOGOS. An epithet for tough viſcid matter, which is difficultly expectorated.

DYSCATAPOTIA. A difficulty of ſwallowing, which Dr. Mead thinks a more proper term than that uſed in canine madneſs, called HYDROPHOBIA, as it is more particularly deſcriptive of the affection under which the unhappy patients labour.

DYSCINESIA, from δυς, *bad*, and κινω, *to move*. Difficulty of motion. Alſo faulty or defective organs: alſo termed *intemperies*. This is the third order of Dr. Cullen's claſs locales—defined, Motions impeded or depraved from the fault of the organs.

DYSCRASIA. DYSCRACY. An ill temperament or habit of the blood and humours, as in the jaundice and the like.

DYSCRITOS, from δυς, *difficult*, and κρισις *a criſis*. Difficult to be brought to a criſis, or brought to an imperfect criſis.

DYSECCŒA, from δυς, *difficult*, and ακουω, *to hear*. DEAFNESS, called alſo *cophoſis*. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order dyſæſtheſiæ, which he defines, Hearing diminiſhed or aboliſhed. He points out two ſpecies; 1. *Dyſecœa organica*, from a fault in the organs by which ſound is tranſmitted into the internal ear. 2. *Dyſecœa atonica*, in which there is no manifeſt fault in the organs for tranſmitting ſound into the internal ear. See SURDITAS.

DYSELCES, from δυς, *difficult*, and ελκος, *an ulcer*. An epithet for ſuch perſons whoſe ulcers are difficult to heal.

DYSEMETI, from δυς, *difficult*, and εμεω, *to vomit*. Thoſe who vomit with difficulty.

DYSENTERIA, from δυς, *difficulty*, or *evil*, or *diſeaſe*, and εντερα, *the inteſtines*. A DYSENTERY. It is called *diarrhœa carnoſa* and *diſſolutus morbus*, often the BLOODY-FLUX, becaute blood ſometimes appears in the ſtools; but this is not always a ſymptom, nor eſſential to the diſeaſe. Dr. Akenſide calls the *dyſentery* a rheumatiſm in the bowels, and ſays, that a *dyſentery* and rheumatiſm are the ſame. The Latins name this diſorder *tormina*. Cœlius Aurelianus calls this diſorder a rheumatiſm of the belly, and ſays it is preceed either by a diarrhœa, a cholera morbus, or a tumor of the belly. Dr. Cullen defines it a contagious fever, in which the patient has frequent mucous, or bloody ſtools, accompanied with much griping, and followed by a teneſmus, the alvine faces being for the moſt part retained. The ſtools, though

frequent,

frequent, are generally ſmall in quantity; the matter voided is chiefly mucus; ſometimes mixed with blood. At the ſame time, the natural fæces ſeldom appear, and when they do, their form is generally compact and hardened. He places this diſeaſe in the claſs pyrexiæ, and order profluviæ. There is but one ſpecies, which varies its name from different circumſtances, e. g. *dyſenteria caſtrenſis*, from happening in a camp, becauſe there it is apt to affect the ſoldiers, on account of their being more expoſed to the night air, which aggravates the diſeaſe. *Dyſenteria verminoſa*, from being occaſionally accompanied with worms. *Dyſenteria carnoſa*, when fleſhy or ſebaceous lumps were diſcharged. *Dyſenteria intermittens*, when accompanied with an intermittent fever. *Dyſenteria alba*, when the ſtools had no blood in them. *Dyſenteria miliaria*, when accompanied with miliary eruptions. All others are ſymptomatic.

In ſome inſtances, this diſeaſe is acute, but more frequently of a chronic kind.

According to different authors, the *dyſentery* is divided into many ſpecies; but with reſpect to the cure, the beſt method of conſidering it is as follows: a diarrhœa is conſtituted a *dyſentery* by the gripes, ſlimy ſtools, teneſmus, &c. it may be attended with inflammatory, putrid, or other ſymptoms, or may be totally free from them: ſimply then the diarrhœa, attended with pain, is a *dyſentery*, and all other ſymptoms are accidental; and though requiring ſome difference in the method of cure, they do not conſtitute different *dyſenteries*. For different ſpecies, conſult Dr. Zimmerman

When the ſmall inteſtines are the ſeat of the diſeaſe, and blood is diſcharged, it is more intimately mixed with the ſtools than when the ſeat is in the larger: when the lower inteſtines are principally affected, an hiccough is a frequent ſymptom. The pain being above or below the navel, generally indicates the ſeat of the diſeaſe; if below, the ſtools ſoon follow the returns of pain; and the ſeat is in the greater or lower inteſtines; if above, and the ſtools do not quickly follow the pain, the ſmall inteſtines are chiefly affected. When the ſeat is in the rectum, the excrements, and the abraſions of the part, are ſeparately voided; but as the malady is higher, the abraſions and excrements are more mixed in the diſcharges.

The plethoric, bilious, and thoſe of irregular life, are the moſt ſubject to a *dyſentery*.

The primary cauſes are an error in the non-naturals, particularly the air and diet. HIPPOCRATES obſerves, that *dyſenteries* rage moſt in thoſe ſummers which ſucceed very cold and dry winters, followed with a rainy ſpring: that a rainy winter and a dry ſpring alſo produce them. BONTIUS remarks, that the hotteſt ſeaſon hath the moſt natural tendency to produce them; and that about Auguſt or September, when the cold nights ſucceed the heat of the day, this diſtemper rages the moſt. This remark of Bontius's is the moſt applicable to what happens in our camps, where the ſoldiers are expoſed to damps in their night watches, as well as to cold and damp grounds, where generally they are ſituated. This obſtructs perſpiration; and as the bowels are more or leſs weak, nature ſeeks her relief in their diſcharges, and the conſtitution is proportionably harraſſed. A putrid air particularly offends the bowels, and irritates them to inordinate diſcharges; and putrid aliment is no leſs miſchievous. Fruit, and fermentative liquors, too freely uſed, are often productive of this diſorder.

The antecedent cauſe is generally, if not always, a ſuppreſſion of ſome other excretion; and for the moſt part this is that of perſpiration.

The remote cauſe is conſidered to be a ſpecific contagion, and *the proximate*, or at leaſt the chief part of the proximate cauſe (on an attention to which the cure in a great meaſure depends), conſiſts in a preternatural conſtriction of the colon, occaſioning at the ſame time thoſe ſpaſmodic efforts which are felt in ſevere gripings, and which efforts, propagated downwards to the rectum, occaſion theſe frequent mucous ſtools and teneſmus. See Wallis's Sydenh. vol. i. p. 226.

By ſome, *the immediate cauſe* is thought to be a ſtimulus applied to the inteſtines. The bile and pancreatic juice becoming acrid, or too abundant, irritate and excite to proportionably frequent ejections. Purges adminiſtered when the irritability of the bowels is preternaturally increaſed, or aliments that are acrid, or become ſo, may alſo ſolicit to this morbid evacuation, and produce the painful ſymptoms uſually attendant on it. Sydenham, who deſcribes this diſorder well, calls it a fever of a peculiar kind, and ſays, that it is cauſed by the morbid matter turning particularly on the inteſtines, and that the meſeraic arteries convey it there from the blood.

The diagnoſtics, according to Sydenham's celebrated deſcription, are as follow: "The patient is attacked with a chilneſs and ſhaking, which is immediately ſucceeded by a heat of the whole body; ſoon after this, gripes and ſtools follow: it is indeed often not preceded by a fever; but the gripes attack firſt, and the ſtools ſoon ſucceed. Intolerable gripings, and a painful deſcent, as it were, of the bowels, accompany every evacuation. The diſcharges are chiefly mucous, except now and then an excrementitious one intervenes without any conſiderable pain. The mucous ſtools are generally ſtreaked with blood; but ſometimes no appearance thereof is ſeen throughout the diſeaſe: nevertheleſs if the ſtools are frequent, mucous, and accompanied with gripings, the diſtemper may as juſtly be entitled a *dyſentery*, as if blood was diſcharged along with them. If the patient is in the vigour of life, or hath been treated with cardiacs, a fever ariſes, and the tongue is covered with a thick, white mucus; and if he hath been much heated, it is black and dry: great loſs of ſtrength, a lowneſs of ſpirit, and all the ſigns of an ill-conditioned fever, are joined with it. This diſeaſe is attended with extreme pain and ſickneſs, greatly endangering life, if unſkilfully treated; for when the ſpirits are much exhauſted, and the vital heat diminiſhed by frequent ſtools, before the matter can be expelled from the blood, a coldneſs of the extremities enſues, and there is danger of death, even within the periods of acute diſeaſes. But if the patient eſcapes for this time, ſeveral ſymptoms of a different kind ſucceed. Sometimes in the progreſs of the diſeaſe, inſtead of the ſanguineous filaments, which are uſually mixed with the ſtools in the beginning, a large quantity of pure blood, unmixed with mucus, is voided at every ſtool; which, as it manifeſts an eroſion of ſome of the larger veſſels of the inteſtines, it threatens death. Sometimes an incurable gangrene ſeizes the inteſtines, which is cauſed by a violent inflammation excited by the afflux of hot acrid matter to the affected parts. At the decline of the diſeaſe, aphthæ frequently affect the internal parts of the mouth, eſpecially if the patient hath been kept hot for a long time, and the evacuation of the matter hath been checked by aſtringents; the fuel of the diſeaſe not having been firſt carried off by cathartics: theſe aphthæ generally foreſhow imminent death. If the patient ſurvives the foregoing ſymptoms, and the diſeaſe proves laſting, the inteſtines at length ſeem to be affected ſucceſſively downwards, till it be driven to the rectum, and ends in a teneſmus; upon which the natural ſtools occaſion great pain in the bowels, the fæces, in their paſſage through them, abrading the ſmall guts; whereas the mucous ſtools only offend the rectum during the time that the matter is made and diſcharged. Though this diſeaſe is often mortal in grown perſons, and eſpecially in the aged, it is nevertheleſs very gentle in children, who have it ſometimes for ſeveral months without any inconvenience, provided the cure of it be left to nature." Thus far Sydenham.

To the ſymptoms enumerated by Sydenham, many others might be named, which occaſionally attend: but as the principal differences in this diſorder may be included in what are called the inflammatory, putrid, and malignant kinds, it may ſuffice juſt to deſcribe their general appearances.

DYSENTERIA INFLAMMATORIA. The INFLAMMATORY DYSENTERY approaches with a violent fever, and a hard pulſe, which in other *dyſenteries* is generally ſmall, and that (only in the progreſs of the ſickneſs), becomes full; an almoſt continued and intolerable pain in the belly, which increaſes on the part being touched, and ſtill more after vomiting; ſtools very inconſiderable with reſpect to quantity; a head-ach, red face, and ſometimes a diſtended belly.

DYSENTERIA PUTRIDA. A PUTRID DYSENTERY diſcovers itſelf by a bitterneſs in the mouth, which appears directly on the firſt attack; a vomiting of bilious matter, which is ſometimes alſo mingled with worms; a ſhivering that returns in the courſe of the diſorder; the ſlightneſs of the fever, the paleneſs of the countenance, and the variegated colour of the excrements.

DYSENTERIA MALIGNA. A MALIGNANT DYSENTERY is attended in the beginning, or whenever any other kind degenerates into it, a ſudden weakneſs, great anxiety about the pit of the ſtomach, heavineſs in the head, an heavy, oppreſſed, deadly aſpect, frequent ſlight convul-

convulſions, a weak voice, frequent fainting, ſometimes miliary eruptions, petechiæ, aphthæ, ſickneſs, and a very weak pulſe.

The *dyſentery* ſhould be diſtinguiſhed from a diarrhœa, a cholera morbus, a flux from the piles, an abſceſs of the inteſtines, and other diſcharges therefrom.

The gripes, ſo troubleſome, and a *pathognomonic ſymptom*, are owing to the irritation in the part affected; this irritation continuing, the *mucus* and *lymph* are diſcharged, and by being mixed with air, give that ſlimy, frothy appearance to the ſtools; and, in time, the mucus being too much abraded, a teneſmus is produced.—*The blood in the ſtools* happens from the rupture or enlargement of the mouths of ſome ſmall veſſels, and is leſs mixed with excrement, according as the diſcharge of it is lower in the inteſtines; and more intimately mixed therewith, as the affected veſſels lie in or nearer to the ſmall inteſtines.—*The aphthæ* are produced by an abſorption of morbid matter from the bowels.—*The ſuety-like matter*, and *ſkins in the ſtools*, are thus occaſioned: the mucus, &c. being diſcharged, the villous coat becomes abraded, and ſo paſſes off in thoſe appearances; or it may be only the epithelium which is continued on the inner ſurface of the inteſtines, which, when ſeparated, becomes thick as when raiſed on the ſkin by a bliſter, and ſo ejected.

Sydenham ſays, that a *dyſentery*, when ill treated, is apt to affect the patient more or leſs for ſome years after.

In general the prognoſtics are taken from the intenſeneſs of the ſymptoms, the colour and ſmell of the ſtools, the ſtrength of the patient, and the length of the diſorder's continuance. *It is never without danger*, and *never to be ſlightly regarded*, for nature alone contributes very little to its cure. There is always danger of a mortification of the bowels, until the diſeaſe gives way. When the excrements are of various colours, and of an ill ſcent, there are ulcers in the inteſtines, and then the danger is increaſed. If blood appears on the firſt day, or any thing that cauſes irritation, the danger is great. When the fever is urgent, when the cauſe is contagious, the patient already reduced by previous ſickneſs, or attended at preſent with any other diſorder, the danger is proportionably enhanced. An hiccough, delirium, the pain and thirſt ceaſing at once, the excrements paſſing involuntarily, convulſions, coldneſs of the extremities, ſigns of ulceration in the inteſtines, vomiting with hiccough, are among the mortal ſymptoms.

Scarce any diſeaſe requires more care and ſkill in order to a rational cure, than this; and as danger is almoſt a conſtant attendant, every caution for prevention will be as needful, as preſcriptions for the cure. Thoſe then who are in warm climes ſhould carefully avoid the coldneſs of the evenings, and the chilling dews which ſucceed the ſultry days; thoſe who are confined in jails, in camps, &c. ſhould avoid the vapours from putrid fæces; and if any diſorder of this, or of any putrid kind is prevalent, the bark may be taken at proper intervals. If there is any ſuſpicion of the diſeaſe approaching, an emetic ſhould be given immediately; a warm ſudorific ſhould ſucceed; and, in the morning, a doſe of ſome gentle purgative (rhubarb excepted) may be given, to promote a gentle motion downward.

When the diſorder is manifeſt, and irritation is the immediate cauſe, the direct indications are, *to correct* or *evacuate the offending matter*, and *to allay the irritation excited by it*. As to accidental ſymptoms, and thoſe peculiarities that diſtinguiſh this diſeaſe into different ſpecies, an attendance to their general nature muſt lead to the particular treatment required on their account.

Peculiar attention is required reſpecting the non-naturals; the air ſhould be kept as pure as poſſible, and moderately warm; cleanlineſs is abſolutely neceſſary, whence the excrements ſhould be immediately removed, the linen, and every thing about the patient, frequently changed. The diet may be of rice, ſalop, panada, the broth of lean meat acidulated with lemon or orange juice, jelly of animal ſubſtances with cinnamon. Dr. Rutherford extols the following: Boil a few hands-full of wheat-flour, tied up in a tight rag, until it is as hard as ſtarch, which it will be in ſix or eight hours: of this two or three table ſpoons-full, when grated, may be boiled in milk and water, enough to make it into a pap: this may be made agreeable to the palate with ſugar, &c. and uſed both for the general food, and for the ſubſtance of clyſters, which in this diſorder are frequently required. For drink, milk and water, butter-milk, the white decoction, or what is ſtill preferable, a decoction of mallows in milk and water, may be freely uſed.

Agreeable to the indications above mentioned, it was uſual with Sydenham, and ſome other judicious practitioners, whoſe ſucceſs juſtified their proceeding, to begin the cure, if called in early after the firſt attack, by a gentle emetic, and copious draughts of ſome thin fluid, to cleanſe the ſtomach; and clyſters of the ſame were frequently injected, that the irritating cauſe might be leſſened, if not wholly carried away from the ſeat of the diſorder.

Sydenham ordered bleeding if the ſymptoms required it; then directed a large quantity of whey to be drank, and that cold; and clyſters of the ſame, but of a proper heat, to be repeated until the gripes were abated: theſe were adminiſtered warm. After this, the patient was put in bed, and a ſweat promoted. When the patient was greatly exhauſted, endeavours were uſed to check the evacuation. Dr. Robinſon (ſee his Theory of Phyſic and Diſeaſes) begins with an emetic of ipecac. after its operation, he gives a cordial draught, with about five drops of the tinct. opii, and repeats the ſame every four hours, or after each evacuation downwards; and now and then he propoſes a clyſter of red wine and diaſcordium. Both theſe phyſicians proceed, with reſpect to a *dyſentery*, with the ſame views as in a cholera morbus, which ſeems only to differ in its ſeat from this diſorder. It may here be added, that diluting drinks taken plentifully are often ſo beneficial in the beginning, as to render any other medicine unneceſſary: they may be drank cold or warm as moſt agreeable to the patient. As to other remedies, their uſe is indicated by the nature of attending ſymptoms, only being required, as circumſtances not eſſential to the diſeaſe occur. The principal are as follow:

BLEEDING. In the inflammatory kind, this operation is neceſſary; but when there is no manifeſt inflammation, nor obvious tendency thereto, it cannot be with propriety propoſed. When the loſs of blood is proper, *the pulſe will be found full, ſtrong*, and *hard*.

NITRE. When *the heat of thirſt is great, if the patient is of a choleric or bilious habit*, ſmall doſes of nitre will be uſeful: when the fever is conſiderable, and the ſymptoms of inflammation attend, *antiphlogiſtics are needful remedies*, and the nitre may be given with two or three grains of ipecac. and ther. Androm. one ſcruple, made into a bolus, with the balſ. Locatel.

OL. RICIN. Dr. Akenſide reſolves the whole virtue of the ipecac. in this diſeaſe to its *relaxing the coats of the inteſtines*, and *mitigating the gripes:* theſe effects are as powerfully produced, if not more ſo, by this oil. In the beginning of this diſorder, whether it be of the inflammatory or bilious kind, it excels all other purges.

PURGATIVES. In every kind of *dyſentery*, purging medicines ſhould only be ſuch as evacuate the contents of the bowels; and the ol. ricin. may be ſuited by proper additions to every ſpecies; a ſmall portion of ANTIMONIUM TARTARISATUM mixed with CRYSTALL. TART. TAMARINDS, and ſuch like, may be given; though towards the end of the cure, ſome ſay, RHUBARB may be allowed with advantage.

SWEATING. In all the ſpecies of this diſorder, this evacuation is deficient and difficultly promoted; but when excited, conduces greatly to the cure. In the malignant kind of *dyſentery*, perſpiration muſt be promoted by means the moſt effectual, in conjunction with cordials. The firſt paſſages being well cleared, ſmall doſes of ANTIM. TARTAR. with the PULV. IPECAC. ſhould be repeated ſo as not to excite purging or vomiting, and may be aſſiſted in their operation by the pores, with ſuch other means as the circumſtances of the patient may require. OPIATES are generally the beſt auxiliaries in this caſe; and a vapour-bath, or wrapping the legs and thighs in flannels wrung out of warm water, greatly expedite this intention.

IPECACUANHA. Dr. Akenſide aſſerts the propriety of this remedy in every form, ſtate, and degree of this diſeaſe; and that the more its uſe is experienced, the more its merits are eſtabliſhed. Its virtues are owing to its relaxing and ſedative quality, and determining the fluids to the ſurface; one or two grains ſhould be repeated every four or ſix hours, more or leſs, according as the ſymptoms require it, or as the ſtomach will retain it.

DIURETICS, in ſome inſtances, have been uſeful; but are not to be attempted, except where all other means fail, or when they have been efficacious in former inſtances.

ASTRINGENTS. They are uſeful when, after numerous evacuations, the ſtrength fails. Among theſe, alum

is not found ſo uſeful as it is in hæmorrhages, and is rarely preſcribed. THE CORT. SIMAROUB. removes this complaint without the uſual inconveniences of aſtringents. Two drams may be boiled in a pint and quarter of water to a pint; and two ounces of the ſtrained liquor may be taken three or four times a day. The LIGN. CAMPECH. is alſo uſeful, and in ſome reſpects to be preferred to moſt other medicines of its claſs; for where aſtringents are required, it may be ſafely uſed, whether fever or inflammation attend or not. From a ſcruple to a dram of the extract hath been given at a doſe, and frequently repeated. In general the following method of adminiſtering it is to be approved of:

℞ Extract. lign. Campech. ʒ ii. f. pil. xx. cujus cap. iii. vel iv. quarta vel ſexta quaque hora cum ℥ ii. decoct. ſimaroubæ. *Theſe medicines ought to be given with caution; and ſcarce ever exhibited till the cloſe of the complaint; nor however till the inteſtines have been ſufficiently evacuated, and the morbid matter removed by emetics, aperients, or naufeatives: for, given early in the diſeaſe, they are productive of great miſchiefs.*

The teneſmus, when troubleſome, may be relieved by clyſters of ſtarch.

CORT. ELUTHERIÆ. In ſome inſtances where the ipecac. failed, or diſagreed, this medicine hath been attended with the deſired ſucceſs; and to reſtore the tone of the inteſtines after the abatement of the diſorder, this bark is generally to be preferred to the Peruvian.

The VITRUM ANTIMON. CERAT. given from gr. ii. ad x. and a gentle opiate after it, is generally eſteemed as a ſpecific. It may be repeated two or three times a day, or oftener if required, and the ſtomach retains it.

The RAD. COLUMBÆ is particularly uſeful in the bilious and putrid *dyſentery*, and may be uſed in the diarrhœa, which ſee.

The NUX VOMICA. Dr. Hagſtroom, a Swediſh phyſician, recollecting the ſuppoſition of ſome celebrated profeſſors, that the epidemic *dyſentery* is an hæmorrhage of the inteſtines brought on by animalculæ, he was led to imagine that nux vomica, which is known to be fatal to large animals, might alſo prove equally deſtructive to theſe animalculæ. The auſtere taſte of this ſubſtance confirmed him in his ideas on this ſubject, and knowing that it might be taken in ſmall doſes without danger, he ventured to try its effects. He began by cleanſing the bowels with rhubarb and cream of tartar, after which he preſcribed a ſcruple of nux vomica, in powder, to be taken once a day. The good effects of this remedy exceeded his expectations. The ſucceſs which followed the uſe of this medicine was equal, whether uſed in thoſe *dyſenteries* which followed putrid fevers, or thoſe in which no ſuch fever had preceded. In many inſtances a cure was effected in three or four days. This medicine ſeemed to have a better effect when taken in warm water or beer, than when ſwallowed in either of theſe liquors cold. See the Lond. Med. Journ. vol. iii. p. 189.

Thoſe with whom a *dyſentery* is fatal are carried off by the mortification in their bowels, to which regard ſhould always be had throughout the cure.

GOETTLIEB RICHTER, in his medical and ſurgical obſervations, ſays, that the dyſentery does not at all depend upon bilious, corrupt acrimonies in the inteſtines: that it cannot be at all cured by emetics, and ſtill leſs by purgatives; but that it is a rheumatic or catarrhous affection of the inteſtines, particularly of the great guts, and that the proper remedies for the diſeaſe are ſedatives, and diaphoretics. That in three epidemical dyſenteries, wherein he made careful and accurate obſervations, he was fully convinced, that the bilious character which it often aſſumed, was merely accidental, and acceſſory. And he produces ſeveral arguments from facts, to prove that bilious acrimonies, which were evident in many, were not the cauſe of the diſeaſe, but rather the effect of irritation in the bowels, which produced an increaſed ſecretion of bile, occaſioned by a ſtimulus, and that they had no farther eſſential influence on the principal diſeaſe.

From hence then, he depended upon opium and antimony for performing a cure, which they effected by allaying pain and irritation, and raiſing a gentle diaphoreſis. Nay, he aſſerts, that by the uſe of opium, the bilious ſymptoms diſappeared, and the patient was cured without evacuation: *ventricular*, or *inteſtinal, he muſt mean, I preſume.* He does not totally reject vomits and purgatives; but if there are indications for them at the beginning of the diſeaſe, he adminiſters them. For vomits evacuate the bile, and acceſſory irritations diminiſh the ſpaſm in the inteſtines, and promote a gentle perſpiration; for which purpoſe, he prefers ipecacuanha to emetic tartar—to clear the inteſtines, manna; but more particularly CALOMEL, which upon experience, he found, operated more powerfully, and more gently than other purgatives. Beſides, ſo far from encreaſing the pains in the bowels, like other purging medicines, it frequently diminiſhed them remarkably.—Rhubarb, he conſiders, as a very dangerous medicine in this diſeaſe; though after it is gone, he approves of it as a ſtrengthener of the ſtomach and inteſtines. In caſes of conſiderable degrees of fever, the antimon. tartariſat. in ſmall doſes was given, with ſal ammoniac, or Mindererus' ſpirit.—When inconſiderable, tinct. thebaic, with vin. antim. Huxami, or extr. opii, and ipecacuanha. But in order to cure the diſeaſe radically, the uſe of opium muſt be continued, and emetics given at intervals, if neceſſary. A ſoft pulſe, and moiſt ſkin, are the chief ſigns of the good effects of opium, and of a certain amendment. Warm fomentations to the abdomen; and frictions, with volatile camphorated liniment, were uſeful; but if there was a fixed pain in the belly, or they were conſtant, a bliſter on the abdomen produced the beſt effects. In caſes where the evacuations were very fetid, and the patient much debilitated, the *arnica* did wonders; and when a lientery remained after the diſeaſe, the columbo exceeded all other remedies.

See Sydenham on the *Dyſentery*, with notes by Dr. Wallis. Among the ancients, Alex. Trallian, Aretæus, Cœlius Aurelianus, and Celſus may be conſulted; but among the lateſt authors, and where improvements on predeceſſors may be expected, ſee Baker on the *Dyſentery*; Akenſide's Comment; Zimmermann's Treatiſe; and Dr. Wilſon on the *Dyſentery*; Cullen's Firſt Lines, vol. iii. p. 101. edit. 4. Moſeley on the *Dyſentery* of the Weſt Indies: alſo the Lond. Med. Journ. vol. ii. p. 86. vol. vii. p. 337; Goettlieb Richter's work above quoted.

DYSENTERIA CATHARTICIS, } i.e. Diarrhœa mucoſa.
DYSENTERIA PARISIACA, } See DIARRHŒA.

There are many ſympathetic *dyſenteries.*

DYSEPULOTOS, } from δυς, *difficulty*, and ουλη,
DYSEPULOTICUS. } a *cicatrix*, or δυς, *difficulty*, and ουλοω, *to cicatrize.* An epithet for an ulcer which is difficult to heal.

DYSHÆMORRHOIS. Suppreſſion of the bleeding piles.

DYSHELCES, from δυς, *male*, and ἑλκος, *ulcers.* One who hath ulcers difficult of cure.

DYSIATOS, from δυς, *difficulty*, and ιαομαι, *to heal* or *cure.* Difficult of cure.

DYSLOCHIA. Suppreſſion of the lochia. See LOCHIA.

DYSMENORRHŒA. Difficult or painful menſtruation. See MENSES DEFICIENTES.

DYSODES, from δυς, *bad*, and οζω, *to ſmell.* An ill ſmell, FOETID. Fœſius ſays, that in Hippocrates we are to underſtand by this word, a *fœtid* diſorder of the ſmall inteſtines. It is alſo the name of a malagma for the pleuriſy, and of an acopon, which Galen and Paulus deſcribes. Sauvages, and ſome other noſologiſts, form a genus of diſorder which they name dyſodia, and define it to be ſtinking exhalations from the whole body, or from a particular part, e. g. *ſtinking ſweat, ſtinking breath, ſtinking feet*, &c.

Dr. Percival takes notice of a kind of STINKING BREATH, (*dyſodes* pulmonica) to which perſons with a narrow cheſt and ſcorbutic habit are peculiarly incident. He obſerves, that it ſeems to originate from a want of power to make a full expiration, by which too much perſpirable matter is retained, and corrupted by ſtagnation in the veſicles of the lungs. In ſuch caſes he hath found the moſt ſalutary effects from the uſe of myrrh and fixed air, internally adminiſtered. Theſe antiſeptic ſubſtances are probably carried to the lungs, and diſcharged together with the offenſive vapour, which correct, at the ſame time that they invigorate the ſmalleſt ramifications of the bronchiæ.

DYSOPIA, δυς, *bad*, οψις, *ſight.* DIFFICULT SIGHT, called alſo *paroraſis.* Dr. Cullen places this genus of diſeaſe in the claſs locales and order dyſæſtheſiæ, which he defines, depraved viſion, ſo that objects cannot be ſeen, except in a certain degree of light, or at a certain diſtance, or in a certain poſition. He diſtinguiſhes five ſpecies. 1. *Dyſopia tenebrarum*, alſo *amblyopia crepuſcularis*; when a great light is required for diſtinct viſion. 2. *Dyſopia luminis*, alſo *amblyopia meridiana*, when

ſight is moſt diſtinct in an obſcure light. 3. *Dyſopia*, called alſo *amblyopia diſſitorum*, when objects muſt be very near to be ſeen. 4 *Dyſopia amblyopia*, called alſo *proximorum*, when objects cannot be ſeen diſtinctly, if very near. 5. *Dyſopia lateralis*, alſo called *amblyopia luſcorum*, when objects are beſt diſcerned by a ſide view.

DYSOREXIA, from δυς, *bad*, and ορεξις, *appetite*. A BAD APPETITE. Alſo a WRONG APPETITE, as when the appetite is exceſſive, or requires unuſual food, &c. it is ſynonymous with *hyperæſthieſis*, and *morboſitates*,—*privativi*. This is the ſecond order of Dr. Cullen's fourth claſs LOCALES,—which he divides into two ſections, *appetitus erronei*, and, *deficientes*;—Synop. Noſol. Meth. See ANOREXIA; he alſo places *morbi pathetici* as ſynonymous, p. 318, 324.

DYSPEPSIA, from δυς, *difficult*, or *bad*, and πεπτω, *to concöct*. DIFFICULTY of, or rather DEPRAVED DIGESTION. See APEPSIA.

DYSPHAGIA. Dr. Cullen ranks this under his CLASS LOCALES, and ORD. DYSCINESIÆ, and defines it, impeded deglutition unattended with inflammatory affection, or injured reſpiration. See DEGLUTITIO.

DYSPERMATISMUS, δυς, *difficulter*, and σπερματιζω, *semino*, alſo called *ageneſia*. Dr. Cullen places this genus of diſeaſe in the claſs locales and order epiſchetis, which he defines, a flow, impeded emiſſion, in coition, of the ſemen virile, inſufficient for the purpoſe of generation. He obſerves eight ſpecies. 1. *Dyſpermatiſmus urethralis*, when the fault is in the urethra. 2. *Dyſpermatiſmus nodoſus*, when a tumor is formed in the corpus cavernoſus penis. 3. *Dyſpermatiſmus præputialis*, when the impediment is from a ſtraitneſs of the orifice of the prepuce. 4. *Dyſpermatiſmus mucoſus*, when the urethra is obſtructed by a too viſcid mucus. 5. *Dyſpermatiſmus hypertonicus*, when there is an exceſs of erection of the penis. 6. *Dyſpermatiſmus epilepticus*, from epileptic fits coming on during coition. 7. *Dyſpermatiſmus ephractodes*, from a want of vigour in the genitals. 8. *Dyſpermatiſmus reflluus*, in which there is no emiſſion of ſemen, on account of theſe men being thrown back into the urinary bladder. See STERILITAS.

DYSPHONIA, from δυς, *difficulty*, and φωνη, the *voice*. A difficulty of ſpeech.

DYSPNŒA; alſo *Dyſpnoon*. DIFFICULT BREATHING, from δυς, *difficulty*, and πνεω, *to breathe*. Dr. Cullen places this genus of diſeaſe in the claſs neuroſes, and order ſpaſmi; and defines it to be a conſtant *difficulty* of *breathing*, without a ſenſe of ſtraitneſs in the breaſt, but rather that of fullneſs and obſtruction there; a cough frequently attending through the whole courſe of the diſeaſe. He diſtinguiſhes eight ſpecies. 1. *Dyſpnœa catarrhalis*, when with a cough there are copious diſcharges of viſcid mucus, called alſo *aſthma catarrhale*;—*pneumodes*;—*pneumonicum*;—*pituitoſum*;—*amphineuma*. 2. *Dyſpnœa ſicca*, when there is a cough without any conſiderable diſcharge. 3. *Dyſpnœa aerea*, when the cough is much encreaſed by ſlight changes of the weather. 4. *Dyſpnœa terrea*, when earthy or calculous matters are ſpit up. 5. *Dyſpnœa aquoſa*, when there is a ſcarcity of uriſe, and œdematous feet, without any ſymptoms of a dropſy in the cheſt. 6. *Dyſpnœa pinguedinoſa*, from corpulency. 7. *Dyſpnœa thoracica*, when parts ſurrounding the cheſt are injured, from ill formation of the cheſt, called alſo *aſthma a gibbo*. 8. *Dyſpnœa extrinſeca*, from manifeſt external cauſes, called alſo *aſthma pulverulentorum*,—*metallicum*. It is ſpoken of by many as a ſpecies of aſthma, but much difficulty attends ſuch a view of it, and as much in affording relief. If reſpiration be only thick and quick, without the other ſymptoms, it is called *dyſpnœa*. To this place belong ſeveral of the ſpecies of the ORTHOPNŒA, to which the reader is referred.

It is a ſpaſm affecting the vital functions. SAUVAGES defines it a diſeaſe whoſe principal ſymptom is a ſhortneſs of breathing, with chronic indiſpoſition, not intermitting, and without ſigns of hydrothorax or empyema.

The moſt uſual cauſes of *dyſpnœa* are, phlegm lodged in the bronchia, or the too ſtrong conſtriction of the bronchia themſelves, which prevents the eaſy ingreſs of the air into the lungs.

Noſologiſts enumerate many ſpecies of this diſeaſe: Sauvages no leſs than twenty-two, but moſt of them are ſymptomatic; and few, if any of them, admit of more effectual remedies, than ſuch as mitigate their violence; in order to which, it is adviſable to moderate the plethora in the lungs, and avoid all hurry of reſpiration.

Sometimes naufeating emetics are good expectorants in this caſe, eſpecially if given in ſmall doſes. Gum ammoniacum, and aſſa fœtida, may be uſed. Bliſters are often beneficial. Iſſues may be formed in the thigh. In ſome caſes theſe have their uſe, but in too many inſtances aſſiſtance fails.

DYSPNOON. See DYSPNŒA.

DYSRACHITIS. The name of a plaſter in Galen.

DYSTHERAPEUTOS, from δυς, *difficulty*, and θεραπευω, *to heal*. Difficult to heal.

DYSTOCHIA, from δυς, *difficult*, and τικτω, *to bring forth young*. Difficulty in labour or child-birth.

DYSTŒCHIASIS, from δυς, *bad*, and στοιχος, *order*. An irregular diſpoſition of the hairs in the eyelids.

DYSURIA. DYSURY, from δυς, *painful*, and ουρον, *urine*. A DIFFICULTY OF VOIDING THE URINE. It is called *ſtillicidium*, *ardor urinæ*, *culbicio*, obſtruction, heat, and difficulty of voiding urine, and *ſtranguria*, STRANGURY.

A total ſuppreſſion is called ISCHURIA, which ſee. A partial ſuppreſſion is called *dyſuria*, and may be with or without heat. When there are frequent painful, or uneaſy urgings to diſcharge the urine, and it paſſes off only by drops, or in very ſmall quantities, it is called a *ſtrangury*. When a ſenſe of pain or heat attends the diſcharge of urine, it then paſſes with difficulty, and is diſtinguiſhed by the name *ardor urinæ*, HEAT OF URINE.

The *dyſuria* is acute and chronic. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order epiſcheſes, and defines it, a painful, and by ſome means, impeded emiſſion of urine. He diſtinguiſhes ſix ſpecies. 1. *Dyſuria ardens*, when the urine ſcalds in paſſing off, and there is not any evident diſorder in the bladder. 2. *Dyſuria ſpaſmodica*, when a ſpaſm affects the parts which communicate with the bladder. 3. *Dyſuria compreſſionis*, from parts contiguous preſſing the bladder. 4. *Dyſuria phlogiſtica*, when the parts about the bladder are in inflamed. 5. *Dyſuria irritata*, when there are the ſigns of a ſtone in the bladder. 6. *Dyſuria mucoſa*, when there is a copious excretion of mucus; alſo called *gluſ*; *veſicæ morbus rarus*, *catarrhus*; *chylaria*, when the mucous urine is whitiſh; *pyuria*,—*pyuria arthritica*;—*viſcida*.

The cauſes are various: as caruncles in the urethra;—a ſtone in the neck of the bladder, or in the urethra;—ſpaſm, or inflammation in the neck of the bladder or urethra:—acrimony in the urine, abrading the mucus from the bladder, or the urethra;—the venereal diſeaſe, and the ſcurvy, often produce this diſorder;—an ulcer in theſe parts, and a defect in the diſcharge of mucus for lubricating the urinary paſſages. The chronic *dyſury* hath generally for its cauſe a rheumatic, arthritic, ſcorbutic, or other morbid humour fixing itſelf in the villous coat of the bladder, near its neck, and in the urethra.

The diagnoſtic ſigns of a *dyſury* ſometimes ſo much reſemble thoſe of a ſtone in the bladder, that ſome difficulty attends the diſtinguiſhing of them, eſpecially when the *dyſury* is of the chronic kind. However, in general, *the difficulty of diſcharging urine is unattended with pain or heat, except during the endeavours to void it, or its actual paſſing off, and for a ſhort time, the pain perceived afterwards is in the glans, a circumſtance not ſo particularly attendant in the ſtone*; in the chronic *dyſury*, *bloody urine is more frequently cauſed by exerciſe, and voided in large quantities after vigorous motions, than happens in the ſtone*.

Heat of urine is not from an increaſe of the natural heat thereof, but from its coming in contact with the inner coat of the bladder, or of the urethra; its acrimony abrades the mucus from theſe parts, or their mucus is too ſparingly ſupplied, when the acrimony of the urine irritates them too much, and excites the ſenſe of heat and pain. And if the heat of urine proceeds from acrimony in the urine, it will be known by the high colour and thinneſs of the urine, or elſe a mixture of unuſual matter.

The different kinds of *dyſuries* ſhould be diſtinguiſhed from each other; and they from the ſtone in the bladder, or urethra, from the iſchuria, and from the piles.

The *dyſury* is not a dangerous diſorder, but it is both troubleſome and difficult to cure, particularly in the aged. Whenever it happens, if it continues long, it ulcerates the bladder and its neck.

IN ORDER TO THE CURE, the particular cauſe muſt be diſcovered.

When the application of bliſters cauſes a ſtrangury, waſh the bliſtered part with warm milk and water when dreſſed.

When

When an acrimony in the juices is the cauſe, if it is venereal, give anti-venereals; if ſcorbutic, give antiſcorbutics, &c. If the pulſe admit of it, bleed; given lenient cooling laxatives, ſuch as caſſia, tamarinds, the ol. ricini, or draughts of oil and manna. It is uſual to give nitre, but a ſolution of true gum arabic is by far more uſeful: an ounce of it ſhould be taken in a day. Camphor, and ſmall doſes of laudanum, are often of great ſervice. Spt. ætheris nitroſi, may be taken in each draught of common drink, or the following draught and clyſter may occaſionally be adminiſtered.

℞ Tinct. opii gr. xx. ſpt. æth. nit. gr. xxx. ol. amygd. ʒ ii. aq. font. ℥ i. ſs. m. f. hauſt.

℞ Balſ. Peruv. ʒ i. ſs. in vitel. ovi ſolut. tinct. opii ʒ i. & ʒ ii. ol. oliv. ℥ ii. decoct. per enemate ℥ viii. m. f. enem. A ſemicupium is often of uſe.

The patient ſhould drink plentifully of a ſolution of gum arabic, or ſalop, of whey, or of a decoction of marſhmallow root.

When the pain is violent, let the mucilage of gum-arabic, or ſome oily matter, be injected into the urethra before diſcharging the urine.

Where inflammation in the urethra is the cauſe, as happens in blenorrhagia virulenta, the PULVIS REFRIGERANS of Falck, though an inelegant compoſition, has been ſtrongly recommended; it is alſo called PULVIS NITRI COMPOSITUS, and made by mixing two ounces of nitre, with two drams of red ſulphurated quickſilver, and one ſcruple of calomel. The doſe, ʒ ſs. vel ϑ ij. night and morning.

When there is much ſtrangury, the following infuſion and electary are of great uſe. Take of gum arabic,—tragacanth,—ſtarch,—cryſtals of tartar, and tincture of Tolu, of each ℥ i. conſerve of hips ℥ ij. and mix theſe well with ſimple ſyrup: the quantity of a large nutmeg may be taken three or four times a day. This is called the ELECTARIUM GUMMOSUM. The infuſion, called INFUSUM LINI, is made of linſeed 1 ounce; liquorice root ſliced, 2 drams; boiling water, 2 pints. Theſe are ordered to ſtand in a moderate heat for ſome hours, that the mucilage of the ſeed may be completely diſſolved, which alſo ſhould be now and then ſtirred. An ounce of gum arabic, added to this, would increaſe its efficacy. A wine glaſs or two of this may be taken very frequently in the day.

If there are caruncles in the urethra, bougies ſhould be carefully introduced therein, and repeated as required.

In the chronic *Dyſury*, after other means fail, a ſalivation excited by the uſe of mercury hath ſucceeded; and an iſſue in the inſide of one thigh, a little above the knee, prevents the return, or at leaſt renders relapſes very moderate. When the patient is too weakly to admit of ſalivation, a doſe of the uva urſi may be taken every morning, and after it half a pint of lime-water, mixed with a ſtrong decoction of the great water-dock root.

Dr. Percival obſerves, that there is a ſpecies of chronic *dyſury*, to which perſons of an arthritic or ſcorbutic habit, and who have paſſed the meridian of life, are peculiarly incident. It is often miſtaken for the ſtone, and aggravated by the uſe of lithontriptics. He adds, that it hath many ſymptoms in common with that diſorder, ſuch as frequent and urgent calls to make water; pain at each extremity of the urethra; a mucous diſcharge, teneſmus, and ſometimes a ſuppreſſion of urine. But the patients who labour under it feel no uneaſy weight in the perinæum, and always void their water with much leſs difficulty, in an erect, than in a horizontal poſture. The complaint, alſo, may be further diſtinguiſhed from the ſtone by having ſhorter intervals of eaſe; by more frequently injuring the retentive power of the bladder, and by occaſioning no ſudden interruption to the ſtream of urine in the abſence of pain. It ſeems to ariſe from an acrid defluxion on the coat of the bladder, which is thereby rendered ſo exquiſitely ſenſible, that the ſtimulus of the urine becomes almoſt intolerable, and very frequent efforts are excited to expel it: theſe efforts, however, ſhould be reſtrained as much as poſſible, becauſe they tend to increaſe the pain and irritation of the bladder, and to prevent the complete diſcharge of its contents; for that organ cannot effectually contract itſelf without a due degree of previous diſtenſion. Of all the remedies which Dr. Percival tried, he ſays, that mercury was the moſt ſucceſsful; it ſeldom failed to afford relief, and generally produced a cure, if adminiſtered with perſeverence and in ſufficient quantity. According to the urgency of the caſe, one, two, or three ſcruples of the ungt. hydrargyri fort. ſhould be rubbed into the thighs every night, till a ſlight ptyaliſm enſues: the ſymptoms for the moſt part abate before the ſpitting comes on; and after it has continued a while, they diſappear entirely. Sometimes, in ſlighter caſes, the doctor gives half a grain of calomel, with two grains of James's fever powder, twice every day; and this ſmall doſe of mercury, if duly continued, may ſuffice to effect a cure, without producing any ſalivation, or even ſoreneſs of the mouth. See Lond. Med. Journ. vol. iv. p. 69.

Violent heat in the urinary paſſages of women has been cured by the uſe of the bark.

See the authors under the article ISCHURIA, Biſs's Eſſays, Lobb on painful Diſtempers, Gooch's Caſes and Remarks, vol. ii.

E.

EAU DE LUCE. See Sps. AMMONIÆ SUCCINATUS, under ALCALI.

EBEL. The feed of fage, or of juniper.

EBESMECH, A name in Langius for QUICKSILVER. See ARGENT. VIVUM.

EBISCUS. See ALTHEA.

EBRIECATUM. By this term Paracelfus expreffes the partial lofs of reafon, as it happens in drunkennefs; and by the addition of the word CŒLESTE, that kind of enthufiafm which is affected by many heathen prieffs, &c.

EBRIETAS. DRUNKENNESS. Spirituous liquors render the fibres rigid, and increafe our natural vigour: but this effect is fleeting. If they are often repeated, or otherways too freely ufed, their excefs of action enervates the conftitution; the appetite fails, and digeftion is too feebly carried on; confequently due fupplies not being conveyed to the blood, the fpirits fail, and a general feeblenefs enfues. Add to this, that fpirituous liquors create a morbid acrimony in the blood, and gradually coagulate its thinner parts, whence a fcirrhous liver and obftructed mefenteric glands.

When from a frequent or exceffive ufe of fpirituous liquors the ftomach lofes its fenfibility, the faline and faponaceous medicines fhould be ufed; and after them, the waters at Bath may finifh the cure. When this excefs produces relaxation in the ftomach, pituitous, and often bilious humours, too much abound in this organ; here emetics fhould be ufed; rhubarb and aloetic purges now and then repeated; then bitters, bark, and chalybeates, joined with moderate exercife, bid faireft for reftoring ftrength.

When the over-night's potation is too liberal, a quantity of cold water fhould be placed at the bed-fide, and as reftleffnefs comes with heat, a dryneſs of the tongue, &c. this water fhould be drank as freely as the thirft requires it: thus, by degrees, a perfpiration is produced, and the moft effectual relief obtained. The fucceeding day, abftemioufnefs is very requifite; and fuch a mode of regimen fhould be purfued, as is conſiſtent with the peculiar nature of the conftitution, viz. in a man of a ftrong, healthful, plethoric habit, drinking plentifully of thin, warm, diluting liquids, in which fmall portions of nitre may be diffolved, or mixed with vegetable acids, keeping in bed, and promoting perfpiration, will be highly ufeful. *On the contrary*, to fuch as are weak, delicate, and relaxed, befides abftinence from folid diet, riding on horfeback, or fome other gentle exercife in the pure air, will be of the moft fervice; a glafs or two of generous wine, or fome cordial, may be taken, or fuch other means purfued, as are calculated to invigorate the fyftem, and keep up an increafed ftate of inſenſible perfpiration, &c. See WALLIS, on Health and Difeafe.

Fermented vegetable fpirits are alone the cauſe of drunkennefs, and vinegar is an antidote; whence, in cafe of what is called being *dead drunk*, a draught of ſtrong vinegar will relieve, or recover therefrom, fooner than any other means; but in fuch a cafe, let the perfon be ſeated with his head elevated. After he is a little roufed, give warm water with vinegar, acidum vitriolicum dilutum, or fps. ætheris nitroſi, to drink. Frequently apply a ſponge dipped in vinegar to the mouth and noſe; an emetic that operates with ſpeed will alſo have its uſefulneſs; a clyſter, and, after it, a purging draught may be adminiſtered; and then attempt to promote a gentle ſweat.

EBSHAMENSIS SAL. See CATH. SAL.

EBULUS, alſo called *chamæacte*, *ſambucus humilis*, *ſambucus herbacea*, WALL-WORT, DANE-WORT, and DWARF ELDER. It is the SAMBUCUS EBULUS, Linn.

It is an herbaceous plant, dying to the ground in winter, with longer leaves than thoſe of the *elder*-tree, and nine leaves on one rib. It grows wild in many parts of England, flowers in July, and produces ripe black berries in the beginning of September.

Its virtues are the ſame as thoſe of the common *elder*, but ſomewhat more efficacious. It is a powerful hydragogue, and in ſmaller doſes a powerful reſolvent and deobſtruent. See Cullen's Mat. Med. Wallis's Sydenham.

EBUR. See SPODIUM ARABUM.

EBUR FOSSILE. See UNICORNU.

ECBOLION, from ἐκβάλλω, *to caſt out*. See DIECBOLION, hence diecbolica.

ECBRASMATA, from ἐκβράσσω, *to caſt out*, or from βράζω, *to be very hot*. Fiery puſtules on the ſurface of the body, alſo called *ecchymata*, *ardentes pupulæ*.

ECBRASMUS. See FERMENTATIO.

ECBYRSOMATA, from βύρσα, *a ſkin*. Protuberances of the bones at the joints, which appear through the ſkin.

ECCATHARTICA, from καθαίρω, *to purge*. According to Gorræus, *eccathartics* are remedies which, applied to the ſkin, open the pores; but in general they are underſtood to be deobſtruents: ſometimes expectorants are thus called, and ſo are purgatives.

ECCHYLOMA, from χυλὸς, *a juice*. See EXTRACTUM.

ECCHYMATA. See ECBRASMATA.

ECCHYMOMA ARTERIOSUM. The falſe aneuriſm. See ANEURISMA.

ECCRYSIS, from ἔκκρισις, *to flow out*. It means an excretion, expulſion, or removal of any excrementitious or morbific matter from the body, either by the bowels, or any other convenient paſſages. It is alſo taken for the excreted matter itſelf.—It is ſimilar to APOCRISIS, which alſo, according to HIPPOCRATES, is applied to the contagious effluvia of the air, or to a certain morbid quality, impreſſed upon the air by exhalation, called miaſma.

ECCYMOSIS, } from ἐκχύω, *to pour out*, or from ἐξ,
ECCHYMOMA, } *without*, and χυμὸς, *juice*, called alſo *exſuccatio*. Sometimes *cruſtula* is applied in this ſenſe; and alſo *ſugillatio*, which ſee. It is an effuſion of humours from their reſpective veſſels, under the integuments; or, as Paulus Ægineta ſays, "When the fleſh is bruiſed by the violent colliſion of any object, and its ſmall veins broken, the blood is gradually diſcharged from them." This blood, when collected under the ſkin is called an *ecchymoſis*; the ſkin in the mean time remaining entire, ſometimes a tumor is formed by it, which is ſoft and livid, and generally without pain. If the quantity of blood is not conſiderable, it is uſually reſorbed; if much, it ſuppurates: it rarely happens that any further inconvenience follows: though in caſe of a very bad habit of body, a mortification may be the reſult, and in ſuch caſe, a regard muſt be had thereto. Dr. Cullen places this genus of diſeaſe in the claſs, LOCALES, and order TUMORES, and defines it, a diffuſed tumor, a little elevated, growing blue, or black. The cauſes

are preſſure or bruiſes, then called *ſtigmata*, blood-letting, either from the orifice in the ſkin ſliding over that of the vein, or from the vein being cut through. Livid or black ſpots are ſometimes a ſymptom of the ſcurvy: when it is round and ſmall, it is named *thrombus*; when more diffuſed, *ecchymoſis*. According to the different cauſes, ſo ſhould an ecchymoſis be diſtinguiſhed; as when happening from blows, bleeding, or other external injuries; or from the ſcurvy, or other internal cauſes:—it ſhould not be miſtaken for a ſpurious aneuriſm.

In ſlight caſes, compreſſes dipped in vinegar or in water, ſo ſtrongly impregnated with ſalt, as to ſuſpend an egg, frequently applied and kept upon the part, is all that can be neceſſary for a cure. If it tends to ſuppurate, it muſt be treated as an abſceſs. If the quantity of coagulated blood be conſiderable, diſcharge it by as many inciſions as are requiſite for that purpoſe; then treat it as an approaching mortification. See Bell's, White's, and Heiſter's Surgery. Van Swieten's Commentaries on Boerhaave's Aphoriſms, ſect. 324, 1151.

ECCLYSIS, from ἐκλύω, *to bend*, or *turn aſide*. See LUXATIO.

ECCOPE, from κόπτω, *to cut*, or ἐκκόπτω, *to cut off*. The cutting off of any part.

ECCOPEUS, from κόπτω, *to cut*. An ancient inſtrument, of the ſame uſe as the modern raſpatory.

ECCOPROTICA, from κόπρος, *dung*. Alſo *coprocritica*. Mild aperients, or gently purging medicines which promote the natural evacuation by ſtool.

ECCRINOLOGICA, from ἐκκρίνω, *to ſecrete*, or *ſeparate*. That part of medicine which relates to the doctrine of excretions.

ECDORA, from δέρω, *to excoriate*. See EXCORIATIO, and particularly uſed by P. Aegineta, for an *excoriation* of the urethra.

ECHECOLLON, from κόλλα, *glue*. A glutinous topic.

ECHETROSIS. See BRYONIA ALBA.

ECHINIDES. In Hippocrates it is mentioned as what he uſed for purging the womb.

ECHINATA SEMINA, } Such ſeeds of plants as
ECHINATE SEEDS. } are prickly and rough are thus named, from ἐχῖνος, *echinus*, *a hedge-hog*.

ECHINOPHORA. See CAUCALIS.

ECHINOPHTHALMIA, from ἐχῖνος, a *hedge-hog*, and ὀφθαλμία, an *inflammation of the eye*. An inflammation of the hairy part of the eye-lids. I ſuppoſe that the term is diſtinguiſhed thus, becauſe the *eye-lid* is ſet with hairs, as the echinus with prickles.

ECHINOPUS, called alſo *crocodilion*, *acanthalruca*, *ſcabioſa carduifolia*, *ſphærocephala elatior*, GLOBE THISTLE. It is raiſed in our gardens. The root and ſeeds are moderately diuretic; but are not in uſe. Boerhaave mentions five ſpecies.

ECHINUS. IN BOTANY, thoſe plants or parts of plants which are beſet very cloſely with ſpines, like a hedge-hog, termed echinated. The prickly head or cover of the ſeed is alſo thus named. It is alſo the name for the hedge-hog, which is likewiſe called *acanthion*.

—— MARINUS. The SEA HEDGE-HOG or URCHIN. See AMYGDALOIDES.

ECHOS. See TINNITUS AURIUM.

ECHYSIS. See LIPOTHYMIA.

ECLAMPSIA TYPHODES. See RAPHANIA.

ECLAMPSIS, from λάμπω, *to ſhine*. It is a flaſhing light, or thoſe ſparklings which ſtrike the eyes of epileptic patients. Cœlius Aurelianus calls them *circuli ignei*, *ſcintillations* or *fiery circles*. Though only a ſymptom of the epilepſy, Hippocrates puts it for the *epilepſy* itſelf. But Dr. CULLEN places it as a ſynonyme with epilepſia, and ſays, "that VOGEL and SAUVAGES will diſtinguiſh an eclampſia as an acute diſeaſe, from epilepſy which they conſider a chronic one; but as it is very difficult every where to place accurate limits between acute and chronic diſeaſes; and as the eclampſia of SAUVAGES will exactly agree for the moſt part, as well in the cauſes as ſymptoms, with epilepſy, I could by no means arrange it different in genus from epilepſy."

ECLECTICA MEDICINA, from ἐκλέγω, *to elect*. ARCHIGENUS, and ſome others, ſelected from all other ſects what appeared to them to be the beſt and moſt rational; hence they were called *eclectics*, and their medicine, *eclectic medicine*.

ECLECTOS, }
ECLEGMA, } from λείχω, *to lick*. See LINCTUS.
ECLEICTOS, }

ECLYSIS. An univerſal faintneſs.

ECMAGMA. See CROCOMAGMA.

ECNEPHIAS, of ἐκ, *from*, νέφος, *a cloud*. A ſtormy wind breaking out of a cloud.

ECPEPIESMENOS, from ἐκπιέζω, *to depreſs* or *preſs outward*. An epithet for ulcers with protuberating lips.

ECPHRACTICA, from ἐκ, and φράσσω, *to obſtruct*. Deobſtruent medicines.

ECPHRAXIS, from ἐκ, and φράσσω, *to obſtruct*. An opening of the pores.

ECPHYAS, from ἐκ, and φύω, *to produce*. An appendix, or *excreſcence*. Some give to the *appendicula vermiformis* this name.

ECPHYSESIS, from ἐκ, and φυσάω, *to breathe*. A quick expulſion of the air out of the lungs.

ECPHYSE. Flatus from the bladder through the urethra, and from the womb through the vagina.

ECPHYSIS, from ἐκ, and φύω, *to produce*. See APOPHYSIS, alſo DUODENUM.

ECPIESMA, } from ἐκ, and πιέζω, *to preſs*. The ſame
ECPYESMA, } as *magma*. Alſo the juice that is preſſed out from the plants of which the magma is made. It is alſo a kind of fracture of the cranium, in which the bones are ſhattered, and *preſs* inwardly, affecting the membranes of the brain.

ECPIESMOS, from ἐκ, and πιέζω, *to preſs*. In general it implies expreſſion, but it is alſo the name of a diſorder of the eye, which conſiſts in a great prominence of the entire globe, thruſt, as it were, almoſt out of the orbit by an afflux of humours.

It is alſo a true *exophthalmia* produced by ſtrong exertions, by which the eyes are ſo far preſſed out as to remain prominent. Protuberances of the eyes, happening from the effects of labour from child-bed pains, are often cured by the ſucceeding diſcharges and lochia. It is therefore neceſſary that we ſhould endeavour to aſſiſt theſe. Wallis's Noſologia Oculorum.

ECPLEROMA, from πλήρω, *to fill*. In Hippocrates, they are hard balls of leather, or other ſubſtances, adapted to *fill* the arm-pits, while by the help of the heels, placed againſt the balls, and repreſſing the ſame, the luxated os humeri is reduced into its place.

ECPLEXIS, from ἐκπλήσσω, *to terrify* or *aſtoniſh*. A ſtupor or aſtoniſhment, from ſudden external accidents.

ECPNEUMATOSIS, } from ἐκ, and πνέω, *to breathe*.
ECPNŒA. } See EXPIRATIO.

ECPTOMA, from ἐκπίπτω, *to fall out*. The excluſion of the ſecundines; and ſpeaking of corrupt parts, it ſignifies a falling off. See alſo LUXATIO; HERNIA SCROTALIS; and PROCIDENTIA UTERI.

ECPYEMA. By Hippocrates it is underſtood a copious collection of pus, from ſome tumor, particularly an inflammatory one having ſuppurated, a vomica or abſceſs with ſuppuration. It comes from the verb ἐκπυάσμαι, vel ἐκπύω, *in pus vertor*, *to be turned into pus*. Hence medicines abounding with maturating or ſuppuratory powers, were called by Galen ἐκπυητικὰ, vel ἐκπυοποιὰ. EMPYEMA was uſed by the ancients in this diffuſe ſenſe, but the moderns confine it to a diſeaſe of the cheſt. See EMPYEMA.

ECPYSIS. See EXCRESCENTIA.

ECREUELLES. See SCROFULA.

ECREXIS, ῥήγνυμι, *to break*. A RUPTURE. Hippocrates expreſſes by it a *rupture* or laceration of the womb. See HERNIA, and HERNIA UTERI.

ECRISIS. See SEMEN.

ECROE, from ἐκρέω, *to flow*. An efflux, or the courſe by which any humour, which requires purging, is evacuated. The ſame as *exerrheuſis*, *exerrhoſis*, *exerrhyſis*.

ECRYTHMUS, from ἐξ, *ex*, and ῥυθμὸς, *harmony*. See ARYTHMUS.

ECSARCOMA, from σὰρξ, *fleſh*. A fleſhy excreſcence.

ECSTASIS, from ἐξίστημαι, *to be out of one's ſenſes*. An ECSTASY, alſo EXTASIS. It is conſidered as a ſpecies of catalepſy, with this difference, the CATALEPTIC has no perception of what paſſes during the paroxyſm; nor any remembrance thereof when it is over; the ECSTATIC remembers the ideas perfectly which he conceived during its continuance. In HIPPOCRATES it ſignifies a delirium; and Dr. CULLEN ranks it as a ſpecies of apoplexy. *Apoplexia mentalis*, ariſing from affections of the mind.

ECSTROPHIUS, from ἐκστρέφω, *to invert*. An epithet for any medicine that makes the blind piles appear outwardly,

ECTASIS, from τεινω, *to extend*. An extenſion of the ſkin, the reverſe to wrinkling.

ECTEXIS, from τηκω, *to liquefy* or *conſume*. See EMACIATIO.

ECTHELYNSIS, from εκθηλυνω, *to render effeminate*. SOFTNESS. It is applied to the ſkin and fleſh when lax and ſoft, and to bandages when not ſufficiently tight.

ECTHLIMMA, from εκθλιβω, *to daſh* or *preſs out againſt*. An ulceration cauſed by preſſure on the ſkin.

ECTHLIPSIS, from εκθλιβω, *to daſh* or *preſs out againſt*. ELISION or EXPRESSION. It is ſpoken of ſwelled eyes, when they dart forth ſparks of light.

ECTHYMA, from εκθυω, *to break out*. See PUSTULA.

ECTILLOTICA, from εκτιλλω, *to pull out*. Medicines which conſume tubercles and corns, or which aſſiſt in pulling off ſuperfluous hairs from any part.

ECTOME, from εκ, *out*, and τεμνω, *to cut*. EXCISION or EXTIRPATION. See AMPUTATIO.

ECTOPIÆ. PROTRUSIONS or MISPLACED PARTS. As when a part of the body is moved from its proper ſeat, and forms a tumour. This is the fourth CLASS of Dr. Cullens LOCALES, and ſeventh ORDER, in which he includes HERNIA, PROLAPSUS, and LUXATIO. Synopſis Noſol. Method. Vol. 2. p. 366.

ECTOPOCYSTICA, ISCHURIA. A ſuppreſſion of urine from a rupture of the bladder. See ISCHURIA. Var. 3d. ſpecies

ECTOMON. See HELLEBORUS NIGER.

ECTRIMMA, from εκτριβω, of τριβω, *to rub*. An ATTRITION or GALLING. In Hippocrates it is an exulceration of the ſkin about the os ſacrum.

ECTROPE, from εκτρεπω, *to divert, pervert*, or *invert*, It is any duct by which the humours are diverted and drawn off. In P. Æ.ineta it is the ſame as

ECTROPIUM. When the eye lids are ſo inverted or retracted, or turned outward, that their interior red ſkin becomes prominent, and the eyes cannot ſufficiently be covered by them. It is alſo called *everſio*; but by the Greeks, *ectropium*. Hence it may properly enough be termed a turning outward, or an everſion of the eye-lids. When this misfortune happens in the ſuperior eye-lid, in conſequence of its reſemblance to a hare's eye, it is called by the Greeks, *lagophthalmus*, or *lagophthalmia*, *hare's eye*. Galen, in his Definit. Med. makes *ectropium* an everſion of the eye-lids in general. But according to Paulus Ægineta, lib. vi. cap. 12. the *ectropium* is peculiar to the under eye-lid, and lagophthalmus to the upper. Some, juſtly enough, diſtinguiſhed between the *ectropium* and lagophthalmus, the latter of which is, when the ſuperior eye-lid is not everted, but only, like a hare's eye, retracted by any cauſe, ſo that it cannot ſufficiently cover the eye. The like misfortune often happens in the lower eye lid, without any degree of everſion, though few have noticed this ſymptom. Hence it may be conſidered as a ſpecies of *ectropium*.

Sometimes this diſorder is unaccompanied with any other, but often an inflammation of the eye, a *ſarcoma*, or an *encanthis* attends it. When it appears alone, it is cauſed by cicatrices after wounds, exulcerations, burns, and imprudent uſe of aſtringents, or from the protuberance of the internal fleſhy parts. In old people, a relaxation of the orbicular muſcle ſometimes cauſes it in the lower eye-lid.

If the eye-lid is greatly diſtorted and contracted, or if the diſorder hath been of long continuance, a remedy is rarely to be expected.

When a cicatrix is the cauſe, endeavour to ſoften it by a frequent application of the ſteams of warm water, the egg-liquor mentioned in the article ANCHYLOSIS, &c. At night proper compreſſes may be applied to bring the eye-lids together, and keep them ſo.

When a contraction of the eye-lid is the cauſe, if emollients and compreſſes fail, an inciſion in the form of a creſcent may be made at a ſmall diſtance from the eye-laſhes; in the upper eye-lid the points of the inciſion ſhould be downwards, and in the under eye-lid upwards; thus the ſkin will be lengthened: the number of inciſions may be one or more, according to the degree of the contraction; if more than one is required, make the reſt parallel to the firſt, and at a ſmall diſtance from it. When the neceſſary inciſions are made, ſtretch the ſkin, and lay compreſſes of lint upon it; but at the ſecond dreſſing, ſpread the lint with ſome digeſtive ointment to encourage the fleſh riſing betwixt the inciſions; and ſlips of ſticking plaſter may be uſed to keep the upper and lower eye-lids cloſe until the inciſions are healed.

If an inflammation produces fungous fleſh, firſt allay the inflammation, then gradually conſume the fungus with the mildeſt eſcharotics.

In old age, a relaxation of the orbicular muſcle ſometimes produces this complaint; in this caſe, relief muſt be attempted by ſpirituous and ſtrengthening applications.

Tumors in the orbit are ſometimes the cauſe, and when not of a cancerous kind, the cure will depend on their extirpation. Ware's Remarks on the Ophthalmy, &c. See BLEPHAROPTOSIS.

Galen, Celſus, P. Ægineta, Keckius's Diſ. on the *Ectropium*, Heiſter's Surgery, Lond. Med. Obſ. and Inq. vol. iv. p. 371. Warner's Caſes in Surgery, p. 34. and Monſ. St. Yves on the Diſorders of the Eyes. Bell's Surgery, vol. iii. p. 287. Wallis's Sauvages's Noſology of the Eyes, p. 13. White's Surgery, p. 248.

ECTROSIS, from εκτιτρωσκω, *to miſcarry*. See ABORSUS.

ECTROTICA, } from the ſame. Medicines which
ECTYROTICA, } cauſe miſcarriage.

ECTYLOTICA. So Horſtius calls medicines that deſtroy calloſities.

ECZEMA, } from ζεω, *to boil*, or *to be hot*. See
ECZESMA, } PUSTULA.

EDELPHUS. So Paracelſus calls one who makes prognoſtics from the nature of the elements.

EDENTULUS. WITHOUT TEETH.

EDERA TRIFOLIA, See TOXICODENDRON.

EDES. EDETS. See AMBER.

EDESSENUM PELARIUM. The name of a collyrium in Actius.

EDIC. EDICH. or EDIR. See FERRUM.

EDINBURGENSIS PULVIS. EDINBURGH POWDER. See ANTIMONIUM.

EDRA. A fractured bone, in which, beſide the fracture, there is an impreſſion from the inſtrument by which it was broken.

EDULCORANTIA. By this term ſuch medicines are meant, as are ſuppoſed to correct the blood, called by many *ſweetening*. And if the word is allowed to have any preciſe meaning, it muſt be conſidered as ſimilar to ALTERANTIA.

EDULCORATIO. Sweetening with ſugar or honey. But IN CHEMISTRY, it is the rendering preparations ſweet, *that is*, mild, by depriving them of their acrimony: this is done by repeated affuſions of water; thus the acid and other ſaline ſubſtances are waſhed from them. See CALCINATIO by *detonation*.

EFFERVESCENTIA. EFFERVESCENCE. It ſignifies a ſlight degree of ebullition in liquors expoſed to a due degree of heat. The chemiſts apply it to that ebullition which is excited by mixing an acid and alkali together: if the *effervеſcence* produces heat, they call it a hot *effervеſcence*; if cold, a cold *effervеſcence*.

Some confound it with fermentation; but Boerhaave judiciouſly limits fermentation to that commotion in vegetable juices which produces a vinous or an acetous liquor, and calls thoſe ebullitions, that are produced by the mixture of bodies, *effervеſcencies*.

EFFIDES. See PLUMBUM.

EFFILA. See LENTICULÆ.

EFFLORATIO, or EFFLORESCENTIA. See EXANTHEMATA.

EFFLUVIA. Minute particles which exhale from bodies. By theſe effluvia from morbid bodies, contagion is propagated. See CONTAGIO.

EFFŒTE, from *ex* and *fœtus*. BARREN, childleſs. But figuratively, it is any thing that is ſo decayed as to have loſt its virtue.

EFFRACTURA. A ſpecies of fracture of the cranium when the bone is broken and much depreſſed by a blow.

EGESTIO. EXCRETION. Generally uſed with reſpect to evacuations by ſtool.

EJACULANTIA. } The veſſels which re-
EJACULATORIA VASA. } ceive the ſeminal matter elaborated in the teſticles, and convey it to the penis. Theſe are the *epididymis*, the *deferentia vaſa*, the *veſiculæ ſeminales*, and the *proſtatæ*.

EILAMIDES, from ειλεω, *to involve*. See DURA MATER.

EILEMA, from ειλεω, *to form convolutions*. In Hip. de Flatib. it ſignifies painful convolutions of the inteſtines, from flatulence. Sometimes it ſignifies a covering. Vo-

gel

gel says it is a fixed pain in the guts, as if a nail was driven in.

EILEON, from ειλεω, *to wind*. See ILEUM INTESTINUM.

EILEOS, from ειλεω, *to form convolutions*. See ILIACA PASSIO.

EISBOLE, from εις, *into*, and βαλλω, *to cast*. It signifies ſtrictly an INJECTION, but is uſed to expreſs the acceſs of a diſtemper, or of a particular paroxyſm.

EISPNOE, from εις, *in*, and πνεω, *to breathe*. See INSPIRATIO.

EL. BOT. An abbreviation of elements of botany.

ELA-CALLI. An Eaſt Indian ſhrub, whoſe juice is an excellent cathartic in dropſies. Raii Hiſt.

ELÆAGNUS. See MYRTUS BRABANTICA, and OLEASTER.

ELÆOMELI, from ελαιον, *oil*, and μελι, *honey*. In Syria this oil is prepared from the buds of a certain tree, though ſome ſay from the trunk; it is ſweet, thicker than honey, and of a purging quality. See Dioſ. lib. i. c. 37.

ELÆOSACCHARUM, from ελαιον, *oil*, and σακχαρ, *ſugar*. A mixture of eſſential oil with ſugar is thus named in pharmacy. This oil requires at leaſt eight or ten times its quantity of ſugar, which ſhould be well rubbed with it, and kept cloſe in a phial. In the eſſential oil of vegetables reſide moſt of the virtues that are communicated to water, or to vinous ſpirit by diſtillation; hence, if a proper quantity of water or of vinous ſpirit be added to theſe elæoſaccharums, a water is immediately produced, of ſimilar efficacy with a diſtilled water.

ELAMBICATIO. A method of analyzing mineral waters, to inveſtigate their virtues.

ELANULA. See ALUMEN.

ELAPHICON, } See PASTINACA SYLVESTRIS.
ELAPHOBOSCUM. }

ELAPHOBOSCON. See SISARUM.

ELAPHOPILA. See CERVUS.

ELAPS. A ſerpent whoſe bite produces a diſorder like the iliac paſſion.

ELAQUIR. RED VITRIOL. This is brought from Germany, but of no great uſe among us. It is ſuppoſed to be the green vitriol calcined by a ſubterranean heat. Dr. Brown, in his Travels, tells us, that at Friburg in Germany, they take the ore out of which brimſtone has been melted, and burn it again in the open air; then putting it into a large vat, they pour water upon it ſo as to imbibe and drink in the vitriol. This water is afterwards boiled to a ſufficient ſtrength, and let out into coolers; where ſticks are ſet in it, as in making ſugar-candy; the pureſt cryſtallized vitriol ſticks to the wood, and the reſt to the ſides, and bottoms of the veſſels.

ELAS MARIS. See PLUMBUM USTUM.

ELASIS. See ELASTICITAS.

ELASMA, from ελαυνω, *to impel*. A lamina or plate of any kind. But it is uſed to expreſs a clyſter-pipe. See ENEMA.

ELASTICITAS, ELASIS, ELATER. ELASTICITY, from ελαυνω, *to impel*, or repel.

It is the property in bodies by which they reſtore themſelves *ſpontaneouſly* to the figure and dimenſions which they had loſt by the action of ſome other body applied to them.

ELATE. So the ancients call the vagina which incloſes the flowers and rudiments of the fruit of the great palm-tree.

ELATE THELEIA. See ABIES.

ELATER. See ELASTICITAS.

ELATERII CORT. See THURIS CORTEX.

ELATERIUM. See THURIS CORTEX; and alſo, beſides its application to the wild cucumber, and its preparations, (ſee CUCUMIS AGRESTIS,) it is often uſed in Hippocrates to expreſs an internal application of a digeſtive or a detergent nature.

ELATHERIA. See THURIS CORTEX.

ELATINUM OLEUM. The name of an oil in Dioſcorides.

ELCOS. See CATAGMA.

ELCOSIS. Numerous, or large chronic ulcers, carious, fœtid, and attended with a ſlow fever.

ELECTARIUM. An ELECTARY. *Electaries* are of the ſame conſiſtence and materials as boluſſes; and in chronic diſeaſes, where the exactneſs of doſes is not neceſſary, and the long continuance of the medicine requires the conciſeſt form, this is better than boluſes, powders, or draughts. *Electaries* for keeping in the ſhops require a care to avoid ſuch things as will deſtroy one another by being combined: *aſtringents* and *agglutinants* ſpoil by being mixed with *ſugar*; *alkalies* and *acids* will ferment if they lie together; naſeous, bitter ingredients, are improper for this form; ſteel, antimony, and æthiops mineral, becauſe of their colour, are beſt made up in pills; but the colour of cinnabar is improved by mixture with the conſerve of roſes or hips. The conſiſtence of *electaries* ſhould be ſuch as neither candies nor ferments. When ſoft they are called *opiata*.

Extemporaneous *electaries* ſhould not exceed two or three ounces, half of which is conſerve; but this is not a fixed rule; for the conſideration of how much of the medicine can conveniently be given for one doſe, is ſometimes to be attended to: when the ingredients are ungrateful, they are beſt to take if mixed up with mucilage and a ſolution of liquorice juice. See Lemery's Univerſal Pharmacopœia.

ELECTARIUM ALTERANS. ALTERATIVE ELECTARY. ℞ Antimonii p p. hydrargyri cum ſulph. gummi guaiaci ää ʒſs. electarii ſennæ comp. ʒ j. ſyr. ſimp. q. ſ. ut fiat electarium; doſis ʒ j. vel ʒ ij. bis de die. In chronic eruptions of the ſkin, this is given, with ſome of the alterative decoctions, or diet drinks.

ELECTIO. ELECTION. That part of pharmacy which conſiſts in a knowledge of the various ſimples which compoſe the materia medica, and directs the choice of drugs, diſtinguiſhing the good from the bad.

ELECTRODES, from ελεκτρον, *amber*. An epithet for ſtools which ſhine like amber.

ELECTRON, } AMBER. See SUCCINUM. It is alſo
ELECTRUM. } a mixture of gold with a fifth part ſilver.

ELECTRUM MINERALE. The tincture of metals is made of tin and copper, to which ſome add gold, and double its quantity of martial regulus of antimony, melted together; from theſe there reſults a metallic maſs, to which ſome chemiſts have given the name of *electrum minerale*. This maſs is powdered and detonated with nitre and charcoal to a kind of ſcoria; then it is powdered again whilſt hot, and then digeſted in ſpirit of wine, whence a tincture is obtained of a fine red colour. This tincture is a deobſtruent.

ELECTUARIUM è SENNA. See SENNA.

ELELISPHACOS. See SALVIA.

ELEMBROT. See ALEMBROTH.

ELEMENTUM. ELEMENT, quaſi elicimentum, quod omnia ex iis *elicita* et extracta. Thus is called a ſimple body, from whence any thing is firſt conſtituted, and into which it may intimately be reſolved; the parts of which are not of a different nature, but homogeneous. EMPEDOCLES, and ARISTOTLE acknowledged as *elements*, *air*, *earth*, *fire*, and *water*, which opinion has been well received for many ages, but now proved fallacious. PARACELSUS, with other chemiſts, conſidered *earth*, *ſalt*, *ſulphur*, and *mercury* in the ſame ſenſe, but theſe are allowed to be incomprehenſible, and the theory built on experiments made on metallic ſubſtances. Principles which cannot be ſubdivided by art are called elements or firſt principles; and the principles made up of theſe, ſecondary principles. Some writers carry this order much farther; but it muſt be confeſſed, no means have yet been deviſed to ſhew unequivocally, whether any ſuch ſubordination of principles exiſts. We may indeed diſcover the component parts of bodies, but we know nothing of their arrangement. Hence it is ſaid that this term ought not to be uſed, but as an expreſſion denoting the laſt term of our analytical reſults. GALEN ſays, that the element of any thing is the ſmalleſt and moſt minute part of that thing whoſe element it is. But the word elements, in a figurative ſenſe, is uſed for the principles, and foundations of any art or ſcience, as Euclid's elements, the elements of chemiſtry, elements of medicine, &c. &c. &c.

ELEMI, } called alſo *Icicariba*; *icica*. GUM ELE-
ELEMNI, } MI.

It is a dry reſinous ſubſtance; the beſt is brought from the Eaſt Indies and Æthiopia; an inferior ſort is the produce of a kind of olive-tree in the Spaniſh Weſt Indies; the AMYRIS ELEMIFERA. Linn. The elemi tree is alſo called *myrobalanus Zeylanicus*; *elemnifera Curaſſavica arbor*; *kækuria*. What we have from the Eaſt is wrapped in flag leaves; is ſoftiſh, ſomewhat tranſparent; of a pale whitiſh yellow colour, inclining to green; inflammable, and of an agreeable flavour when melting; to the taſte it is bitteriſh; it diſſolves totally in rectified ſpirit of wine; by diſtillation with water, about one ounce of eſſential oil is obtained from ſixteen of the gum.

Its chief uſe is as a digeſtive in the form of an ointment: the London College gives the following preſcription, in which it is the chief ingredient.

Unguentum Elemi. OINTMENT *of* ELEMI.

Take of tried mutton ſuet, freſh, two pounds; of gum *elemi*, one pound; of common turpentine, ten ounces. Melt the gum with the ſuet; and all being removed from the fire, add forthwith the turpentine, and, while the mixture is fluid, ſtrain it.

Arcæus was its firſt preſcriber, and from him it was formerly called *linimentum* vel *balſamum Arcæi*. See Lewis's Mat. Med. Neumann's Chem. Works. When to this two ounces of olive oil is added, it has been called *unguentum elemi compoſitum*. It is the beſt of the terebinthinate applications in uſe for encouraging a good digeſtion in ulcers. If to half a pound of this ointment is added one dram of ærugo æris, it is then called *unguentum elemi cum ærugine*. It is made by gradually ſtirring it into the elemi ointment whilſt in a melted ſtate. This remedy has been long in uſe as a ſtimulant to foul ulcers.

ELEMNIFERA CURASSAVICA ARBOR. See ELEMI.

ELENGI. A tall tree which grows in Malabar, and bears fragrant flowers, eſteemed for their cordial quality.

ELEOSELINUM, from ἐλος, *a fen*, and σελινον, *parſley*. See APIUM.

ELEPHANTIA. A ſort of anaſarca.

ELEPHANTIA ARABUM. According to ſome it is the *elephantiaſis*, when the feet are ſwelled and hard. In Dr. Cullen's Noſology, it is ſynonymous with *elephantiaſis*.

ELEPHANTIASIS, called alſo *elephas*; *Lazari morbus vel malum*; *Phœnicius morbus*. It is generally ranked as a ſpecies of leproſy; ſee LEPRA ARABUM. Some ſay it is the higheſt degree of ſkin diſeaſes: and others diſtinguiſh it from the leproſy by having its ſeat in the fleſh, whilſt the leproſy only affects the ſkin, or, at the moſt, the integuments. This diſorder receives its name from its affecting the legs ſo as to make them reſemble thoſe of an elephant.

Dr. Cullen places this genus of diſeaſe in the claſs cachexiæ, and order impetigines, and defines it a contagious diſeaſe, wherein the ſkin is thick, wrinkled, rough, and unctuous, diveſted of its hair; the extremities inſenſible, with reſpect to feeling; the face diſfigured with hard tumors, called *tubera*; the voice hoarſe and naſal. In different parts of the ſkin ſometimes ariſe fungi, having the appearance of mulberries, or raſpberries.

Dr. Towne aſſures us, that negroes are very commonly the ſubjects of this diſorder, and that it bears a great affinity to the beſt account we have of the lepra of the Arabians. He ſays thoſe are the moſt ſubject to it, who, after ſevere acute fevers, long continued intermittents, or other tedious illneſſes, are either much expoſed to the inclemency of rainy ſeaſons, and the cold dews of the evening, or who are conſtrained to ſubſiſt on bad diet.

On the firſt attack the patient complains of ſhiverings; theſe continue a few hours, and are ſucceeded by a pain in the head, back, and loins; a nauſea and vomiting ſoon follow, with pain in one of the inguinal glands (never in both): a ſevere fever follows; the gland reddens, becomes hard, but ſeldom ſuppurates; a red ſtreak runs down the thigh, from the ſwelled gland to the leg, almoſt an inch broad, and of a fleſh colour; this ſtreak ſoon ſwells, and then the fever abates, and the matter is thrown upon the leg by an imperfect criſis. By degrees the leg is more and more tumified, and the veins are formed into large varices, which are very apparent from the knee downward to the toes. After this, the ſkin grows rugged and unequal, a ſcaly ſubſtance ſoon forms itſelf on it, with fiſſures here and there. Theſe ſcales do not dry off, but are daily protruded forward, until the leg is greatly enlarged. Though this ſcaly ſubſtance appears harſh and inſenſible, if it is very ſuperficially touched with the point of a lancet, the blood freely oozes out. Notwithſtanding the monſtrous ſize of the diſeaſed leg, the appetite remains good, and in all other reſpects the patient is healthy: many of them continue thus for twenty years or more, and make no other complaint than what the enormous ſize of the leg occaſions. It rarely happens that both legs are affected. White people are afflicted with this diſorder when ſubjected to the ſame circumſtances that are the apparent cauſe in blacks.

This diſeaſe is infectious, and often found to be hereditary.

The cure is uncertain: however, after cleanſing the firſt paſſages, warm perſpiratives may be mixed with antimonials, and adminiſtered with the bark. The diet and other helps ſhould all conduce to increaſe the vis vitæ. Mercury is ſaid by ſome to be injurious; but the experience of others manifeſts its uſefulneſs, when joined with the above-named remedies.

Aretæus deſcribes the *elephantiaſis* with great accuracy. Towne is particular in the account of it. See Turner alſo in his Diſeaſes of the ſkin, and Brook's Practice of Phyſic.

In the Lond. Med. Tranſ. vol. i. p. 23, &c. is inſerted a deſcription of the *elephantiaſis*, as it appears in Madeira, and alſo the method which in one inſtance was attended with ſucceſs. In this country the diſorder appears at firſt in the form of tubercles on any or all parts of the body; in time they ulcerate: if they happen on the beard or eye-brows, the hairs there fall off, but this does not happen on the head. The legs ſwell, and are hard; white ſcales cover them, and fiſſures appear here and there, though in ſome inſtances the legs are emaciated and full of ulcers. Many other very diſagreeable ſymptoms are obſerved in different patients.

None are obſerved to receive this diſorder from others by contact, but generally the children of the diſeaſed are ſubject to it.

The bark, with the following embrocation and bliſtering, proved curative, after mercurials and antimonials failed.

Applicet. Empl. *Epiſp. Nuch.*

℞ Cort. peruv. pulv. ℥ i. ſs. cort. rad. faſſafr. pulv. ℥ſs. ſyr. q. ſ. f. electar. cap. q. n. m. major bis in die.

℞ Spt. vini tenuior. ℥ viii. lixiv. tart. ℥ i. ſpt. ſal. ammon. ʒ ii. m. f. embroc. cum qua inung. partes affect. mane nocteque.

ELEPHANTINUM EMPL. A plaſter deſcribed in Oribaſius. Celſus deſcribes one of the ſame name, but very different in qualities.

ELEPHAS. IN CHEMISTRY it ſignifies *fortis aqua*. In BOTANY it is a plant which Parkinſon calls ſcordio affinis elephas columnæ. In ZOOLOGY it is the large animal called an *elephant*. In NOSOLOGY it is the diſorder called *elephantiaſis*.

ELERSNA. See MOLYBDÆNA.

ELETTARI. See CARDAMOMUM.

—— PRIMUM. See AMOMUM.

ELUTHERIA. See THURIS CORTEX.

ELEVATIO. See SUBLIMATIO.

ELEVATOR AURICULÆ. This muſcle ariſes from the external termination of the frontal muſcle, it being formed of diverſe fleſhy fibres covering the temporal muſcle; and being thin and membranous, is carried over it; then growing narrower, is inſerted into the upper part of the ear, bringing it upward and forward.

—— LABII INFERIORIS MUSCULUS. See LEVATOR LABII INFERIORIS.

—— LABII SUPERIORIS. See LEVATOR LABII SUPERIORIS.

—— LABIORUM. See LEVATOR COMMUNIS.

—— NASI ALARUM. Theſe muſcles ariſe from the top of the bone of the noſe near the lachrymal cavity, with a ſharp and fleſhy beginning, and falling down towards its ſides in a triangular figure, not much unlike the Greek letter Δ, run downwards the length of the bone, and are inſerted broad and fleſhy into the naſi alæ.

—— OCULI; alſo called *ſuperbus, attollens*, and *rectus ſuperior*. This muſcle riſes from the bottom of the ſocket near the hole, which gives a paſſage to the optic nerve; then paſſing over the upper part of the globe of the eye, is inſerted into the ſuperior and anterior part of the ſclerotica.

—— PALPEBRÆ SUPERIORIS. See LEVATOR PALP. SUPER.

ELEVATORES ANI. See LEVATORES ANI.

ELEVATORIUM. An ELEVATOR. From *eleve, to raiſe up*. An inſtrument to raiſe a depreſſion in the ſkull.

ELHANNE ARABUM. See LIGUSTRUM INDICUM.

ELICHRYSON, } HELYCHRYSON. *Helychryſum*,
ELICHRYSUM. } from ἡλιος, *the ſun*, and χρυσος, *gold*. GOLDYLOCKS.

Boerhaave

Boerhaave enumerates nineteen ſpecies. It is a ſmall, ſhrubby, downy plant, clothed with long very narrow leaves, producing on the tops of the branches ſeveral ſmall round heads, of bright yellow ſcaly flowers. It is a native of the ſouthern parts of France. It flowers in May and June, and holds its leaves all the winter.

ELICHRYSUM, *Coma aurea*, called alſo *linaria aurea*, *linoſyris*, *nupcarum*, *virga aurea*, *conyza*, elichryſum latifolia, *gnaphalium luteum*, and GERMAN GOLDYLOCKS. It is cultivated in gardens, and flowers in May. The flowers are diuretic.

Conyza Æthiopica. AFRICAN SHRUBBY GOLDYLOCKS.

ELICHRYSUM, called alſo *chryſocome*, *coma aurea*, GOLDEN MAIDEN-HAIR, GOLDEN STOECHAS, GOLDEN, or YELLOW CASIDONY, GOLDYLOCKS.

The flowers, naturally dry and firm, retain their figure and gloſſy yellow colour for years. Both the flowers and leaves, if rubbed a little, ſmell ſtrongly, and have a flavour of the muſk kind. To the taſte they are warm, pungent, bitteriſh, and aſtringent. Water takes up their flavour in diſtillation; and, by infuſion, rectified ſpirit does the ſame. It is not much uſed in medicine, although it is eſteemed as being aſtringent and corroborant. See Lewis's Mat. Med. or Neumann's Chem. Works.

—— MONTANUM. See GNAPHALIUM MONTANUM.

ELIDRION. Rulandus ſays, it is maſtich, or mercury, or rapontic, or a mixture of ſilver, braſs, and gold.

ELIGII MORBUS. See FISTULA.

ELEGMA. See LINCTUS.

ELIQUATIO, ELIQUATION, from *eliquo*, *to melt down*. This is an operation, by which a more fuſible ſubſtance is ſeparated from one leſs fuſible, by means of a heat ſufficiently intenſe to melt the former, but not the latter. Thus an allay of copper and lead may be ſeparated by applying a heat, which ſhall melt the lead, but not the copper.

ELITHROIDES. See TESTES.

ELIXIR, ſometimes, according to Lemery, called *enchiloma*. An *elixir* is only a compound tincture. This word is from the Arabic, in which language *al-ecſir*, or *al-ekſir*, ſignifies *chemiſtry*; hence *elixir*, a medicine prepared by the chemical art, is appropriated by way of eminence to a tincture extracted by a proper menſtruum from many ingredients. An *elixir* is more ſaturated than a tincture, hence not ſo clear.

ELIXIR ALOES. } VITRIOLICUM. See ALOES.
—— PROPRIETATIS. }
—— MYRRHÆ COMP. } See MYRRHA.
—— UTERINUM. }

ELIXIS, from λειχω, *to lick*. See LINCTUS.

ELIXIVIATIO. ELIXIVIATION. The operation by which a fixed ſalt is extracted from the aſhes of vegetables, by an affuſion of water.

ELIZ. See ÆRIS FLOS.

ELLEBORINE. See HELLEBORUS NIGER HORTEN. &c.

ELLEBORUS. See HELLEBORUS.

ELLOBOS. An epithet for ſuch ſeeds or fruits as are in pods or lobes.

ELLYCHNION, } from λυχνος, *a lamp*. The WICK
ELLYCHNIOTOS, } of a LAMP or CANDLE. Theſe were made of different materials, ſome of the papyrus, ſome of the fruit of the ricinus, &c. Theſe wicks were uſed by the ancients inſtead of lint.

ELMINTHES. See VERMES.

ELOANX. See AURIPIGMENTUM.

ELODES. This is a ſpecies of TRITÆOPHYA, or REMITTENT fever, of the inflammatory kind, which uſually terminates in fourteen, or twenty-one days; it is epidemic, though not contagious; and from the beginning of the diſeaſe, through its courſe, profuſe ſweating attends.

ELOGIUM. See RENUNCIATIO.

ELOME. See AURIPIGMENTUM.

ELONGATIO, from *elongo*, *to lengthen out*. See LUXATIO.

ELOPHOBOSCUM. See CARA BRASILIENSIBUS.

ELOPITINUM. See VITRIOLUM.

ELIPIS. The SCORIA of SILVER.

ELTZ. See ÆRIS FLOS.

ELUTHARIA, } See THURIS CORTEX.
ELUTHERIA. }

ELUTRIATIO. ELUTRIATION, from *elutro*, *to decant*. This is an operation performed by waſhing ſolid ſubſtances with water, ſtirring them well together, and haſtily pouring off the water, while the lighter part remains ſuſpended in the agitated fluid, that it may thereby be ſeparated from the heavier part. By this operation, metallic ores are cleanſed from earth, ſtones, and other lighter unmetallic parts adhering to them.

ELUVIES. In Pechlinus it imports the humour diſcharged in a *fluor albus*

ELUXATIO. See LUXATIO.

ELYMAGEOSTIS, } See PANICUM.
ELYMOS. }

ELYTHROIDES or *Elithroides*, from ελυθρον, *vagina*, *a ſheath*, and ειδος, *form*. So the *tunica vaginalis* of the teſtes is called. See TESTES.

ELYTROCELE, ελυτροκηλη, *vagina*, and κηλη, *hernia*. See HERNIA VAGINALIS.

ELYTRON, from ελυω, *to involve*, or *cover*, a covering or ſheath. Hippocrates calls the membranes which involve the ſpinal marrow, ελυτρα.

ELZIMAR. See ÆRIS FLOS.

EMACIANTES. Diſeaſes that occaſion a waſting of the whole body.

EMACIATIO. A falling away of the fleſh, called alſo *ectexis*.

EMANSIO. Etmuller uſes this word inſtead of *ſuppreſſio*, when ſpeaking of ſuppreſſed menſes. *Emanſio menſium* is the retention or abſence of the menſes beyond their uſual period of appearing. See MENSES DEFICIENTES.

EMARGINATO. EMARGINATE. To cleanſe a wound of the ſcurf, &c. about its edge.

EMARGINATUS, (*e*, *from*, and *margo*, *margin*). Deficient in its margin: when applied to the apex of a leaf, it ſignifies terminating in a notch, the margin being diſcontinued, or broken.

EMASCULATIS. See MALAXISSATUS.

EMBAMMA, vel *bamma*, from βαπτω, *to immerge*, or *dip*, alſo *apobamma*. A ſauce or pickle to dip victuals in. Muſtard is a kind of *embamma*. Alſo a ſlight tincture, and applied to water in which hot iron hath been quenched.

EMBAPHION. A CRUET for containing embammas.

EMBASIS, from εν, and βαινω, *to go*. See DEXAMENE.

EMBELG, } See MYROBALANI EMBLICI.
EMBLEG. }

EMBOLE, from εμβαλλω, *to put in*. The reduction or ſetting of a diſlocated bone. See LUXATIO.

EMBORISMA. See ANEURISMA.

EMBOTUM. A funnel conveying fumes into any orifice of the body.

EMBREGMA, } from εμβρεχω, *to moiſten*, *ſprinkle*,
EMBROCATIO, } or *ſoak in*. EMBROCATION, called *emplaſium*, *embroche*, alſo *cataclyſmus*, which ſee. It is an external application in a fluid form, uſually prepared of volatile and ſpirituous ingredients, and moſtly uſed to relieve pains, numbneſs, or palſies. See LOTIO.

EMBROCHE, from εμβρεχω, *to make wet*. See EMBROCATIO; alſo FOTUS.

EMBRONTETOS, from βροντη, *thunder*, one *thunder-ſtruck*. See alſo APOPLECTICI.

EMBRYON. An EMBRIO, from εν, *in*, and βρυω, *to pullulate*, or *bud forth*. Thus the child in the womb is called, becauſe it buds forth in the internal parts. So Hippocrates calls the child in the womb when in its third ſtage, that is, before it is a complete child. See CONCEPTIO.

Galen ſays, that the Greeks did not call the fœtus under two months old by the name of *embryon*, but named it *cuema*; but others ſay, it is *embryon* during the whole time of its being in the womb. Homer applies the term *embryon* to the fœtus of brutes; and Theophraſtus does the ſame with reſpect to the ſeeds of plants, and they are followed in the ſame by all the moderns.

EMBRYONATUM. See ANTIMONIUM, No. 15.

EMBRYONUM BALS. vel SPT. It is a preſcription of Bates; but in point of excellency, it is exceeded by a mixture of the ſpirituous aniſeed water, and ſimple cinnamon water in equal parts.

EMBRYOTHLASTES, from εμβρυον, *a fœtus*, and θλαω, *to break*. An inſtrument to break the bones of a fœtus, in order to its more eaſy delivery. It is alſo a CROTCHET for extracting a fœtus. See EMBRYULCIA.

EMBRYOTOMIA. EMBRIOTOMY. From εμβρυον, *a fœtus*, and τεμνω, *to cut*. It is a cutting of the child whilſt in the womb, in order to its eaſier delivery.

EMBRYULCUS. It is when embryotomy is made uſe of for delivering a child from the womb.

EMBRYULCIA, from ἐμβρυον, *a fœtus*, and ἑλκω, *to draw*. An hook for the extraction of a child when labour is difficult. In the preſent practice of midwifry, as circumſtances vary, the *fœtus* is drawn away from the uterus by the BLUNT HOOK, the STRAIGHT FORCEPS, the CURVED FORCEPS, or the CROTCHET; the latter of theſe wounds, and ſo generally kills the child; but its delivery is only expedited and facilitated by the other three.

The BLUNT HOOK is uſed when the child preſents with its breech, and the pains are not ſufficient for effecting its delivery. In this caſe, the hook is carefully to be fixed in the groin of the child, and as the pains return, nature muſt be aſſiſted by gently pulling with the hook; but if much ſtrength is required, it is ſtill better to leave the delivery to the uſual aſſiſtance of the hands only with the labour-pains, becauſe the hook may diſlocate or break the thigh of the child. When the hook is uſed, it ſhould be taken away as ſoon as the finger can be fixed in the child's groin, for thus the danger is much leſſened.

The CROTCHETS are uſed in the ſame manner as the forceps, except that the crotchet, having a hook at its point, is forced into the part to which it is applied.

The STRAIT FORCEPS are uſed for bringing the head of the child forward, when by reaſon of its ſize, or the want of pains, it cannot otherwiſe be protruded; but much care ſhould be had in uſing them. They are never neceſſary whilſt the head is above the brim of the pelvis, and indeed very rarely when it hath deſcended lower. Dr. Hunter abſolutely forbids their uſe, if they can poſſibly be avoided, and that conſiſtent with the ſafety of the child; for if time is allowed, the parts will diſate, and the head will be moulded ſo as to paſs with the leaſt poſſible violence.

The forceps, as improved by Smellie, are the beſt; he reduced their length, to prevent their being uſed before the head is ſufficiently low. They ſhould not be applied before the ears can be felt, and before uſing them, the following rules ſhould be obſerved.

1. The external parts ſhould be ſufficiently dilated.

2. The exact ſituation of the child's head ſhould be known; and this is beſt diſcovered by feeling one ear.

3. A finger ſhould be in the os internum to guide the forceps, leſt a part of the uterus itſelf ſhould be included in them. When the finger cannot be thus introduced, great care is required in paſſing the forceps along the ſide of the child's head.

4. The blades of the forceps ſhould be well greaſed before they are introduced.

5. If poſſible, apply the blades over the child's ears, for thus they are placed on the narroweſt part of the head: when this cannot be done, fix one before one ear, and the other behind the oppoſite one.

6. The forceps ſhould be paſſed up in the direction of a line, that would be ſuppoſed to paſs through betwixt the navel and the ſcrobiculus cordis; at the ſame time keeping the handles as far back as the perineum will eaſily admit. When the forceps are ſecure, pull them from blade to blade, for otherwiſe they are apt to ſlip off.

7. The handles ſhould be tied tight before the operator begins to pull downwards with them; and when the two blades are locked, the lock ſhould be about an inch from the child's head.

8. As the child's head advances, the operator ſhould alternately reſt and pull while the perinæum is on the ſtretch, and until the vertex is brought from under the os pubis; then the handles of the forceps being gradually raiſed towards the mother's belly, and the pulling repeated with caution, whilſt with one hand the perinæum is ſupported, the forehead will be freed from it. The forceps are now to be taken away, and the delivery finiſhed as is uſual, with the hands alone.

The different caſes in which theſe forceps are required, may be ſeen under the article PRÆSENTATIO.

The LONG CURVED FORCEPS. They were invented by Smellie, with a view to ſaving the life of the child, when, the body being delivered, the head could not be brought away in the uſual manner. In this caſe, the crotchet was formerly uſed. Theſe forceps are longer than the ſtraight ones, becauſe they are applied when the head of the child is above the brim of the pelvis; but as it can very rarely happen that where the buttocks have paſſed (eſpecially when doubled, as in breech preſentations) the head will be detained; theſe inſtruments will hardly ever be required. Indeed when the head is ſeparated from the body, and left in the uterus, if the pelvis is much diſtorted, the long curved forceps may ſometimes be preferable to the ſtraight ones; but in this caſe, if the ſize of the head is leſſened by emptying it of part of the brain, the delivery may generally be effected by one hand and one crotchet. Notwithſtanding the advantages propoſed by the uſe of the foregoing inſtruments, in ſome caſes they are unavailing: it is then adviſed, to open the head by the uſe of the STOP-SCISSORS; a large pair of ſciſſors, with a ſtop put on the outward edge of each blade, about the middle; the inner edge of which are blunted downwards. Theſe contrivances are, firſt, to ſtop the ſciſſors before they are expanded in a proper ſituation, and to prevent cutting the vagina or uterus, in occaſionally cloſing them. See Præſentatio, Caſe 19; and the others where the head preſents, which will ſhew the utility of theſe inſtruments more clearly.

EMBULA. A PIPE.

EMUBLARCHI SUFFUMIGIUM. A SUFFUMIGATION deſcribed by Actius.

EMERUS, alſo called *colutea ſcorpioides major*, and *ſenna, ſcorpium, colutea humilis, colutea ſcorpioides humilis, colutea ſiliquoſa minor, coronilla montana*, and LESSER SCORPION SENNA.

It grows on hilly places; its leaves are purging, and poor people ſometimes gather and uſe them on that account.

—— AMERICANUS. See INDICUM.

EMESIA, EMESMA, and EMETOS, from ἐμεω, *to vomit*. The action of *vomiting*.

EMETICA, EMETIC, from ἐμεω, *to vomit*, called alſo *ano-cathartica, vomitoria*; medicines which excite vomiting. The benefit of *emetics* ariſes from their evacuating power, and not only clears the ſtomach, but the upper parts of the inteſtines; hence their uſe, in caſe of poiſonous or other offenſive materials being lodged in the ſtomach; beſides, from the ſhock which they give to the general frame, they are highly uſeful; they alſo evacuate bile, and prevent ſtagnations happening in the ſyſtem of the vena portarum, which often lay the foundation of the moſt obſtinate complaints; nor is the compreſſion alone which they give, confined to the liver, but the whole abdominal viſcera experiences the good effects, as alſo thoſe of the thorax; they clear the inteſtines downwards; and alſo excite the force of the circulation in every part of the ſyſtem, and determine the fluids to the ſurface of the body, from all which circumſtances much general utility may be derived in practice.

Medicines of this kind act by irritation, the effect of which is a conatus naturæ to expel ſomething obnoxious; hence a cathartic in an over doſe often proves emetic.

When *emetics* are adminiſtered, if bleeding is required, it ſhould be firſt performed. If the patient is coſtive, or if he hath a ſerous plethora, purging ſhould precede the uſe of emetics, eſpecially in children. Fat people ſhould take *emetics* on an empty ſtomach, after uſing briſk exerciſe, about noon; and thin people ſhould take them about an hour or two after eating.

During the operation of an *emetic*, the perſon ſhould ſit with his knees advanced towards his breaſt, for thus the diſcharges will be much more eaſy. Though drinking freely generally aſſiſts the operation of theſe medicines; yet if two or three draughts do not come up, the throat ſhould be tickled with a feather, or a few grains of white vitriol may be ſwallowed, becauſe by drinking more, the ſtomach may be ſo diſtended as not to be able to eject its contents.

In all feveriſh paroxyſms, inflammations of the ſtomach, ſpaſms in the ſtomach from anger, hyſterics, &c. congeſtions of blood in the upper parts; if on any account an *emetic* is indicated, bleeding ſhould precede, and the plethora be removed.

A decoction of the bulbous roots of common daffodil is one of the gentleſt *emetics* in the materia medica. Horſe-radiſh and muſtard are diuretics as well as gentle *emetics*, and as they diſcharge only the contents of the ſtomach, their uſe is the ſafer in caſes which do not admit of more active ones. A tea-ſpoon-ful of the flour of muſtard may be added to each pint of warm water, and repeated as required.

In venereal diſorders, the hydrargyrus vitriolat. has been thought the moſt proper. In old chronic complaints, antimonial *emetics* are to be preferred, as they are attenuating and deobſtruent. In maniac caſes, antimonials are never to be omitted. When poiſons are ſwallowed, the zincum vitriolatum purificatum is the beſt adapted for ſpeedy relief.

The uſefulneſs of *emetics* extends very far into medical practice.

practice. When the menſes are exceſſive from any obſtruction in the returning veſſels, an *emetic* may procure relief; and when the menſes are ſuppreſſed, *emetics* powerfully aſſiſt in reſtoring their due courſe, if taken a little before the time of their uſual return. The head-ach attending youth at the age of puberty is much relieved by this diſcharge. The vomiting, which ſo frequently is attendant during pregnancy, is much relieved by frequent ſmall doſes of the pulv. ipecac. Two, and from that to ſix grains, may be now and then given, to reſtrain the frequency and violence of theſe diſcharges; and the ſtrainings in conſequence of the ipec. is far leſs than thoſe that are natural.

Thoſe who are violently ſtrained by *emetics*, thoſe who have ruptures, or aneuriſms, as alſo thoſe whoſe viſcera are unſound, ſhould be cautious in the uſe of theſe Herculean remedies.

An opiate ſhould generally ſucceed an *emetic*; and when theſe evacuants are too powerful, or operate more than is required, opiates greatly reduce their efficacy; common ſalt given in the gruel will turn the operation of *emetics* downwards; a ſpoonful of brandy ſometimes ſucceeds in checking their action; mild oils, grateful acids, and aromatics, are alſo efficacious helps.

On the ſubject of *emetics*, Dr. Fothergill's Inaugural Diſſertation (a tranſlation of which is in that edition of his works publiſhed by Dr Lettſom) may be read with conſiderable advantages. In this publication, beſides the many occaſional remarks on other important ſubjects, the doctor very advantageouſly dwells, 1. On the action of vomiting, and the various means uſed to excite it; he attends to *emetics* with reſpect to their ſtrength or different power on the ſtomach. 2. The uſe of *emetics* conſidered as ſtimulants. 3. The uſe of *emetics* as evacuants. 4. The uſes of *emetics*, ariſing from their mechanical force: this laſt diviſion he concludes with obſervations on ſome diſeaſes in which *emetics* may be hurtful. In the courſe of his remarks under the above diviſions, moſt diſeaſes are noticed which are benefited by *emetics* operating in any one of thoſe modes. But ſuch is the importance of every part of his performance, that to ſelect would leave too much; it is therefore thought beſt, after a general information of its contents, to urge the peruſal of the work itſelf on every inquirer into the ſubject.

EMETICUM MITE. The mild emetic of Boerhaave is made by deflagrating one part of crude antimony with two of nitre. By this proceſs, not only all the ſulphur, but much of the phlogiſton of the regulus, is conſumed; it is therefore *mild*.

EMETICUM VINUM. See ANTIMONIALE VINUM.

EMETOCATHARTICUM. A medicine which operates both by vomit and ſtool.

EMISSARIUM. An EMISSARY. In medicine, it is any orifice of the body, whether natural or morbid, out of which any thing is emitted.

EMMENAGOGA, EMMENAGOGUES, from εμμηνια, the *menſtrual diſcharges*, and αγω, *to draw*, *lead*, or *force*, called alſo *menagoga*; medicines ſuited to promote the menſtrual flux in women; or to excite and reſtore it, when retained or ſuppreſſed. Though there is ſuch a power in medicine, cannot abſolutely be denied; yet, ſhould the term be cautiouſly admitted; for Dr. CULLEN ſays, that he is of opinion, that in an hundred inſtances, it has been employed without reaſon. Some medicines ranked under this claſs produce their effect by *leſſening irritations*, others *by their ſtimuli*; and *a third kind*, by conducing to fill the body with healthy fluids. When ſpaſms in the veſſels cauſe obſtructions of the catamenia, the *fœtid* gums and plants may be of ſervice; ſuch particularly, as *rue*, *caſtor*, *ſabine*, *aſafœtida*.

The ſtimulating kinds ſhould not be given, except the body is full of good blood and juices; for as they urge to an excretion, they cauſe a diſcharge of what cannot be ſpared until then. With reſpect to the third kind, there is great uncertainty; few, if any of this claſs, having been found to anſwer the expectation of the practitioner; indeed, ſo little ſo, that one cannot almoſt in any caſe of amenorrhœa, with much confidence promiſe ſucceſs. The general doctrine at preſent ſtands, that the medicines which are to be employed in both the ſtates of amenorrhœa, are chiefly thoſe, which ſtrengthen, and increaſe the action of the veſſels of the uterus. Hence *iron* and *its preparations*, alſo *mercury*, on theſe accounts, have been generally eſteemed powerful medicines of this claſs. *Aloes* are alſo enumerated among menagogues; but its power here chiefly ariſes from ſtimulating the rectum, and from hence, communicating its action to the uterine veſſels.

EMMENIA, from μην, a *month*. See MENSES.

EMMOTOS. from μοτος, *lint*. An epithet for perſons, parts of the body, or diſorders, that require *lint* for the cure.

EMODIA. A STUPOR of the TEETH.

EMOLLIENTIA. EMOLLIENTS, called alſo *malacticos*. Medicines which diminiſh the force of cohelion in our ſimple ſolids, and therefore ſoften and diminiſh the hardneſs and rigidity of the parts to which they are applied. They not only relax and ſupple the ſolids; but alſo ſheath and ſoften the aſperity of the fluids. When externally applied, they are termed *emollientia*, internally adminiſtered, *demulcentia* ſeems to be their propereſt appellation. See DEMULCENTIA. Dr. Cullen ſays, that *emollients* act upon the parts to which they are immediately applied, either by being inſinuated into the ſubſtance of the ſolid; and thereby diminiſhing the denſity of the whole of the mixt; they diminiſh its force of coheſion; or by being inſinuated into the interſtices of dry particles, they diminiſh the friction, that might otherwiſe occur, and thereby render the whole more flexible. The former ſeems to be the operation of water, the latter of oil.

Emollient topics are formed of water, oily, and mucilaginous ſubſtances. Water, particularly, when aſſiſted by a moderate heat, is plentifully abſorbed from the whole ſurface of our body; it powerfully relaxes and dilutes, being miſcible with almoſt every animal fluid. Oil relaxes and obtunds what is acrid; and mucilage alſo ſheathes ſharp humours. In compoſitions of this kind, the aqueous part ſhould be freely allowed; for the mucilages require to be largely diluted; gentle friction on the part increaſes their efficacy, and, as to the heat with which they are applied, it ſhould not exceed what produces a pleaſing ſenſation. From the relaxing quality of *emollient* topics, and their ſheathing of acrimony, it is that they are good ſedative applications, when pain from tenſion, or from irritation, is excited: from the ſympathy of the nerves, their efficacy is conveyed alſo to diſtant and deep-ſeated parts; and thus it is, that the warm bath proves ſo powerful a ſedative. From the ſame principles theſe applications rank with antiſpaſmodics. *Emollients*, by relaxing the fibres, and increaſing the congeſtion of fluids, promote ſuppuration; and laſtly, the heat with which they are applied, concurs with their other effects to rank them with the tribe of ſeptics; their oily parts particularly diſpoſe them to a putrid acrid acrimony. See Aikin's Obſervations on the external Uſe of Preparations of lead, p. 29, &c.

EMOTIO. When this word is uſed with reſpect to the mind, and in a medical ſenſe, it ſignifies a *delirium*; when relative to ſome bone, a *luxation* is to be underſtood.

EMPALEMENT. See CALYX.

EMPASMA, from πασσω, *to ſprinkle upon*. See CATAPASMA.

EMPEROS. MUTILATED.

EMPETRUM. See ALYPUM.

—— THYMELÆÆ FOLIIS, alſo called *ſanamunda*, and SEA-HEATH SPURGE. This ſort grows on the coaſt of Andaluſia: it flowers in February. A dram of the root purges ſtrongly. About Gibraltar it is called *burhalaga*, but is there only uſed to heat their ovens with.

EMPHRACTICA, from φραττω, *to obſtruct*. Such topics as ſtop the pores when applied to the ſkin; alſo named *emplaſtica*. EMPLATTOMENA.

EMPHRAGMA, from φραττω, *to obſtruct*. An IMPEDIMENT, or OBSTRUCTION. Thus Hippocrates calls the parts of a child which preſent in an unnatural poſture, becauſe they *obſtruct* the birth.

EMPHYSEMA, from φυσαω, *to inflate*, ſometimes called *inflatio*; and ſometimes ſignifies *leucophlegmatia*. It is any flatulent tumor; but by it is generally underſtood a ſoft tumor ariſing from air being admitted into the cellular membrane. In Hippocrates it ſignifies an *inflation* of the belly, and ſometimes a *tumor* in general. When ruptures or tumors are of the flatulent kind, they are called PHYSOCELE. Dr. Cullen means by the word *pneumatoſis*, which is his general name for this diſeaſe, the ſwelling formed by air or elſe flatus or rarefied fluids. He places it in the claſs cachexiæ and order intumeſcentiæ, and defines it, a tenſe, elaſtic tumor of the body, making, on preſſure under the hand, a crackling noiſe. The ſpecies are, 1. *Pneumatoſis ſpontanea*; that is, when it happens without manifeſt cauſe. 2. *Pneumatoſis traumatica*, when from a wound in the thorax. 3. *Pneumatoſis venenata*,

venenata, when from the ſwallowing, or external application of poiſon. 4. *Pneumatoſis hyſterica*, when accompanied with hyſterics.

The moſt frequent cauſe of this diſorder is the piercing of the pleura, and wounding the lungs by the pointed fragments of broken ribs; though it ſometimes happens that an *emphyſema* is produced in the lungs by lacerations therein, without any injury having happened to the pleura: putridity is alſo a cauſe, as is ſeen in mortifications of the external parts, and in many inſtances of putrid fevers. Putridity raiſes the air, both in vegetable and animal ſubſtances, from a fixt to an elaſtic ſtate. It never happens from pointed inſtruments, as the blood inſtantly ſtops the paſſages.

An *emphyſema* is manifeſt by a ſoft puffy ſwelling, in which caſe the ſkin appears gloſſy, the tumor gives way on preſſure, but, that removed, it inſtantly returns; a crackling is perceived on ſtroking the *emphyſematous* part. When the lungs are wounded, a troubleſome cough attends, and the matter expectorated is mixed with blood; ſometimes air eſcapes from the lungs into the cavity of the breaſt, and not being diſcharged outwardly through the pleura, &c. it occaſions great difficulty of breathing, anxiety, a ſenſe of ſuffocation, ſtupor, a livid colour in the face; and if relief is not ſpeedily obtained, the patient dies. The air detained in any part of the cellular membrane may produce a mortification there.

When theſe kind of tumors happen in putrid diſorders, fomentations may be applied to them, made with equal parts of ſharp vinegar and rectified ſpirit of wine; but when a wound is the cauſe, if the breathing is quick and laborious, bleed, and repeat the operation as often as this ſymptom renders it neceſſary. Punctures, or rather ſmall inciſions, may be made into the cellular membrane, with a lancet, or in different parts of the body; the air will thus be excluded, if gentle preſſure is alſo made on the tumor: when the air is thus evacuated, a compreſs may be dipped in vinegar, and applied over the part where the wound is ſuppoſed to be; a tight bandage may ſecure it, and the patient ſhould be directed to lie on the injured ſide, to prevent a freſh afflux of air. Nitre, and pectoral emulſions, may be given to prevent internal ſuppurations. When the air is detained in the cavity of the breaſt, Mr. Hewſon propoſes to diſcharge it by a ſmall opening made with a knife on the fore-part of the cheſt, which, if on the right-ſide, muſt be between the fifth and ſixth ribs, becauſe there the integuments are thin; but if on the left-ſide, the opening muſt be betwixt the ſeventh and eighth, or betwixt the eighth and ninth ribs, the better to avoid wounding the pericardium. See Le Dran's Obſ. No. 29; James's Med. Dict. Art. *Fracture*; and London Medical Obſervations and Inquiries, vol. ii. p. 17, &c. vol. iii. p. 28—36, 372—399. White's Surgery, p. 78.

EMPIRICA SECTA. The EMPIRIC SECT. It was begun by SERAPION, of Alexandria, ſome ſay, HERACLEON, &c. about 278 years before the birth of Chriſt. Theſe were a ſet of phyſicians, who conducted themſelves wholly by their own experience, without ſtudying phyſic in a regular way. See Celſus de Medicina, p. 3, 8, 8vo, Lugd. Bat. 1746. Hence

EMPIRICUS. An EMPIRIC, from πειρα, *to experience*, or εμπειρα, *to try, in a good ſenſe*, is applied to practitioners, who found their practice on experience, and pay little regard to theory, but ſuch only, as is founded incontrovertibly on facts, totally freed from all ſpeculative ideas. *In a bad ſenſe*, it is an appellation beſtowed on a ſet of quacks, who, without knowledge, pretend to perform miracles by ſome deſperate noſtrums, careleſs of the deſtruction they create, and labour only to pillage their unfortunate patients, generally at the expence of their health, and too often of their lives. For the difference between the *empiric* and *dogmatiſt*. See Percival's Eſſays Med. and Exp. vol. i.

EMPLASTICA, from εμπλασσω, *to obſtruct*, or *ſpread upon*. See EMPRACTICA.

EMPLASTRUM, from εμπλασσω, *to obſtruct*, or *ſpread upon*. PLASTER.

Plaſters are compoſitions for external uſe; they do not poſſeſs much medical virtue, and are chiefly employed to make retentive dreſſings, or to keep the parts to which they are applied warm and tight. This they do more equally and ſteadily than a bandage of linen can, eſpecially if there is no ſwelling. They are compoſed of oily and unctuous ſubſtances, united with powders, into ſuch a conſiſtence, that the compound may remain firm in the cold without ſticking to the fingers; that it may be ſoft and pliable in a ſmall heat; and that by the warmth of the human body, it may be ſo tenacious, as readily to adhere. When a *plaſter* is ſoftened to the conſiſtence of ſtiff honey, it is called CERATE;—when ſoftened ſo as to ſpread eaſily whilſt cold, yet not to run with the heat of the body, an OINTMENT;—and if betwixt the conſiſtence of an ointment, and oil, a LINIMENT.

Calces of lead boiled with expreſſed oils unite with them into a *plaſter* of a good conſiſtence, and are a proper baſis for ſeveral other *plaſters*. *Plaſters* may alſo be made of reſins, gummy reſins, &c. without wax, eſpecially in extemporaneous preſcription: but for officinals, theſe compoſitions are leſs proper, as they ſoon grow too ſoft in keeping, and fall flat in a warm air.

As ſome difference is obſerved in the hardneſs of a *plaſter* for the breaſt or ſtomach, and one that is to be applied to the limbs, the following proportions are generally obſerved. For a ſoft *plaſter*, take one ounce of expreſſed oil, one ounce of wax, and half an ounce of any powder; for an harder, add an ounce more of wax, and half an ounce of powder.

EMPL. ADHÆSIVUM NIGRUM. The BLACK STICKING PLASTER, called alſo the LADY'S COURT PLASTER, and the CHICHESTER PLASTER.

Diſſolve twelve ounces of the gum Benjamin, in twelve ounces of rectified ſpirit of wine, and ſtrain the ſolution. In a ſeparate veſſel diſſolve a pound of the beſt iſinglaſs in five pints of pure water, then ſtrain the ſolution. Mix theſe ſolutions together, and let them ſtand in a narrow veſſel, that the groſſer parts may ſubſide: when the clear liquor is cold, it will form a jelly; ſo, when ſpread, it muſt be near the fire to melt. This quantity ſuffices for ſpreading on ten yards of half-yard-wide ſilk; in order to which, the ſilk muſt be ſtretched in a frame, then the mixture may be ſpread on it with a ſponge or bruſh: this muſt be done with the warmth of a fire. As each ſpreading dries, it muſt be repeated to the tenth or twelfth time; after which touch it lightly with the bruſh to give it a gloſs.

Its uſe is too generally known to need any thing further being ſaid, than to propoſe an eaſy ſubſtitute, which is as follows: diſſolve a pound and a quarter of fine iſinglaſs in five pints of water; and before it cools ſpread it on ſilk, in the ſame manner as above directed.

EMPLASTRUM ad CONTUSA BOERHAVII. ℞ Bryoniæ in farinam redactæ ℥ ij. florum ſulph. ℥ i. hydrargyri cum ſulphure ʒ iii. galbani puri, & l. a. ſolutæ ℥ iv. emplaſtr. de meliloto ℥ iv. ol. chamæmeli q. s. ut fiat emplaſtrum. The three laſt ingredients are to be melted together, and the powder ſtirred in. Modern practice adopts this, only making uſe of the emplaſtrum cereæ compoſitum, inſtead of that of melilot; and one ounce of olive oil in the place of that of chamomile; and practitioners find it a beneficial application, particularly in ſcrophulous indurations.

—— ANODYNUM. Take four pounds of common *plaſter*, melt it over a gentle fire, with an ounce and a half of common black pitch. When this is ſpread, mix with each ounce weight of it half a dram of opium, and the ſame quantity of camphor in fine powder. This compoſition is very efficacious in relieving old pains.

—— ATTRAHENS. See EMPLASTRUM CERÆ, under CERA.

—— VESICATORIUM. See CANTHARIDES.

—— CUMINI. See CUMINUM.

—— COMMUNE. The COMMON PLASTER, formerly called *diachylon*, now *lithargyri emplaſtrum*, *plaſter* of *litharge*.

Take of olive oil, one gallon; of litharge finely powdered, five pounds; boil them together with about a quart of water over a gentle fire, continually ſtirring, till the oil and the litharge are united, and acquire the due conſiſtence of a *plaſter*; and if the water is waſted before the operation is over, more water (previouſly made hot) muſt be poured on.

As ſoon as the mixture is warm, begin to ſtir it; in about four hours the boiling will be completed; but to aſcertain this, drop a little on a tile to cool, by which you will eaſily diſcover whether the litharge is diſſolved or not; the boiling muſt be continued very gently, or the *plaſter* will be black, or perhaps boil over ſuddenly. If water ſhould be added that is not very hot, the *plaſter* would explode with violence and be waſted: this accident will happen with hot water, if the *plaſter* is very hot. If the compoſition proves diſcoloured, the addition

of

of a little white lead and oil will improve it; but if it is expected to be very white, nothing but a true olive oil will do.

EMPLASTRUM NIGRUM Domini Sharp, seu Emplastrum Cerussæ.

℞ Olei olivarum ℥ xij. ceræ flavæ ℥ ij. ſs. ceruſſæ ℥ x. Let the oil and wax be melted together, the ceruſs added, and the whole boiled to the conſiſtence of a plaſter. Sharp uſed this as an application to diſeaſed knees. Dr. Kirkland uſes a plaſter of red lead, and oil boiled to a dark brown colour, for the ſame purpoſe.

EMPLASTRUM STIMULANS, ſeu—ammoniæ, stimulant plaster, or plaster of ammonia. ℞ Saponis ʒ ij. empl. lithargyri ℥ ſs. ammoniæ muriatæ ℥ i. Let the ſoap and litharge plaſter be melted together, and when nearly cold, the muriated ammonia, in fine powder, be ſtirred in. This plaſter muſt be made at the time of application, elſe the volatile part, ſet at liberty by the decompoſition of the muriated ammonia, will fly off, and fruſtrate the intent of the remedy. In delicate and irritable ſkins, the quantity of the ammonia may be leſſened, otherwiſe the plaſter may perhaps bliſter the part. In chronic enlargement of the joints, or cold tumors; in ſome ſcrophulous affections of the knee or elbow joints; but particularly in thoſe gelatinous ſwellings, which frequently form on the olecranon, it has been of ſingular ſervice; and this it is ſuppoſed to do by ſtimulating the abſorbents, and increaſing their power of action.

—— Saponis. ℞ Saponis ʒ ij. emplaſtr. lithargyri ℔ iij. Let theſe be melted together, and boiled to a proper conſiſtence. This is a mild diſcutient, and to tumors of various kinds, is conſidered as an uſeful application; but, as *ſoap* is much more advantageouſly uſed in liquid forms, the practitioner will rarely be induced to apply it in that of a ſolid one.

Emplastrum Stomachicum. Stomach plaster. Now called *emplaſtrum ladani compoſit. compound plaſter* of *ladanum*.

Take of ſoft labdanum, three ounces; of frankincenſe, one ounce; cinnamon and expreſſed oil of mace, of each half an ounce; of eſſential oil of mint, one dram: add to the frankincenſe, melted firſt, the labdanum a little heated, till it becomes ſoft, and then the oil of mace; afterwards mix in the cinnamon with the oil of mint, and beat them together in a maſs, in a warm mortar, and keep it in a veſſel well cloſed.

Theſe *plaſters* ſhould be frequently renewed to produce any effect, and ſhould be applied on the five lower ribs of the left ſide, towards the back. This plaſter ſhould be kept in a cloſe veſſel, on account of the volatility of part of the ingredients. It is of uſe, beſides what is ſpecified by its title, to promote the ſuppuration of indolent tumors.

EMPLATTOMENA. See Emphractica.

EMPNEUMATOSIS, from ἐμπνεω, *to blow into*, or *inflate*. An inflation of the ſtomach, the womb, or other parts.

EMPORIUM. See Cerebrum.

EMPRION, from πριων, *to ſaw*. Saw-like. A kind of pulſe mentioned by Galen, in which the artery is unequally diſtended in different parts.

EMPROSTHOTONOS, from ἐμπροσθεν, *forwards*, or *before*, and τεινω, *to bend*, or *ſtretch*. It is when the body is bent forward and confined ſo by a ſpaſmodic contraction. Celſus, lib. iv. cap. 3. ſays, it is a convulſive ſtiffneſs of the neck, by which the chin is fixed on the breaſt. See Tetanus.

EMPTYSIS, from πτυω, *to ſpit out*. Spitting of blood: ſo Aretæus calls this diſcharge, when it comes only from the mouth, fauces, and parts adjacent.

EMPYEMA, from ἐν, *within*, and πυον, *pus* or *matter*. The ancients called all internal ſuppurations *empyema*; ſee ecpyema. But at preſent this name is confined to a collection of purulent *matter* lying looſe in the cavity of the breaſt, and lodging on the diaphragm. Dr. Cullen conſiders it, as a conſequence of pneumonia, and ſays, its ſymptoms are, a remiſſion of pain after a pleuriſy has terminated in ſuppuration, often after a vomica; whilſt difficulty of breathing, cough, uneaſineſs in lying down, and hectic fever, continue; frequently attended with a ſenſation of ſome fluid fluctuating in the breaſt, and ſigns of an hydrothorax.

Aretæus, lib. i. de Cauſ. & Sign. Morb. Chron. cap. 9. ſays, "They who have purulent abſceſſes in the cavities of the body, whether within the thorax or below the diaphragm, if the pus be diſcharged upwards, are called ἐμπυοι (*empyi*), if downwards, *apoſtomatici*. And if there be a ſuppuration in the thorax, and the pus be diſcharged through the lungs, it is called ἐμπυον." But the moderns account it only an *empyema* when purulent matter floats upon the diaphragm. If matter is lodged on both ſides of the breaſt, there are two *empyemas*. Dr. Cullen conſiders the *empyema*, not as an original diſeaſe, but as a mode of terminating one.

The pus, that forms an *empyema*, may be from an abſceſs in the lungs, pleura, mediaſtinum, pericardium, or diaphragm; or perhaps from that inflammatory exudation, or inſpiſſated ſerum, which, Dr. Hunter obſerves, is formed into a kind of pus, and is often found in large quantities in the cavities of the breaſt, belly, &c. Wounds in the breaſt may alſo evacuate their matter into his cavity, and prove a cauſe of this diſeaſe. And Le Dran informs us that he met with inſtances of abſceſſes in the liver making a way through the diaphragm, and emptying themſelves into the breaſt. From Sauvages may be collected ſix varieties, although they are not always capable of being diſtinguiſhed, viz. empyema *a peripneumonia*;—*vomica*;—*pleuræ*;—*mediaſtini*;—*diaphragmatis*:—*interoſtales*.

When any fluid matter is collected in the cavity of the breaſt, it may be known by the following ſigns; *the breathing is ſhort and laborious; expiration is more difficult than inſpiration; the patient perceives a fluctuation when particular motions are performed; ſometimes there is an enlargement of the cavity of the thorax, and an œdematous fullneſs of the ſkin and fleſh of one ſide of the cheſt, or both*, according as the matter is lodged in one or both ſides; *a dry cough*; when the matter is on one ſide only, *the patient cannot lie on the other; a ſlow fever, heat at the extremities of the fingers, hollowneſs of the eyes*, &c. but as to the kind of matter which is lodged here, it can only be known by the nature of the diſorder which preceded an accumulation, from the preceding and concomitant ſymptoms. The matter may be blood or pus, and the latter of theſe may be ſuſpected when there hath been an inflammatory diſorder of the lungs, pleura, or other parts in the breaſt, attended with ſymptoms of ſuppuration, and particularly if thick clammy ſweating attend.

If the matter of an *empyema* is not ſpeedily expectorated, the patient dies of a conſumption, with an hectic fever, which is always exaſperated at night.—If the mediaſtinum is corroded through, upon opening the thorax a ſudden ſuffocation often enſues.—If the *empyema* is of long ſtanding, the ſtrength decayed, a colliquative diarrhœa comes on, with a waſting of the body; the operation, inſtead of relieving, haſtens the death of the patient.—When this diſorder is merely local, the operation may ſucceed; but if the habit is ſtrumous, or otherwiſe unſound; if fever, coughing, thirſt, and other ſymptoms, are either numerous or conſiderable in their degree, there is but ſmall hope of recovery. The operation is alſo ineffectual, if the lungs adhere to the pleura, or if the matter lodged on the diaphragm was emptied from a cyſt.

The chirurgical method by which relief is obtained, is called the operation for the empyema. The fluids to be voided by this operation is matter. In this caſe, therefore, only the aſſiſtance of a ſurgeon is required. For blood will be gradually abſorbed, as declared by Mr. Sharp, Mr. Pott, and other eminent practitioners, it need not be removed by any artificial opening. Gooch gives a caſe in his Med. Obſ. of air in the thorax producing the ſymptoms of an *empyema*; it paſſed through an ulcer in the lungs, but the ulcer healing, the air was evacuated by the operation for the *empyema*, and a complete cure was effected.

The manner of operating is to fix on the part for the perforation; then, with a knife or a trochar, a paſſage may be formed for the offending matter. Whether an opening is made by means of a knife or a trochar, as Albinus hath obſerved, that the diaphragm on the right ſide aſcends higher into the thorax than on the left, it may be proper to pierce on the right ſide *between the third and fourth ſpurious ribs*; but on the left, *between the ſecond and third*; and *at about half or two thirds of the diſtance from the ſternum to the vertebra*; for here the muſcles are thinneſt, the artery is concealed under the rib, and the diaphragm at a due diſtance. Matter lodged in both cavities of the thorax require that the operation be performed on each ſide. See Hippocrates, Galen, Aretæus, Boerhaave, with Van Swieten's Comments, Le Dran's

Operations, Sharp's Operations, Heiſter's Surgery, Bell's Surgery, vol. ii. p. 383. Kirkland's Med. Surgery, vol. ii. p. 175. Pearſon's Principles of Surgery, vol. i. p. 94. White's Surgery, p. 303.

EMPYEMATA. So the ancients called *ſuppurating medicines*; for they named an internal collection of pus, *empyema*.

EMPYI. Purulent or ſuppurated, or thoſe who have purulent abſceſſes internally.

EMPYREUMA, from εμπυριω, *to kindle*, denotes a certain ignition or dry adventitious heat, ſuch as things burnt receive: hence in CHEMISTRY it is the offenſive ſmell and taſte which diſtilled waters, or other ſubſtances, receive from being too much expoſed to the fire.

EMPYREUMATICA OLEA. EMPYREUMATIC OILS. Theſe are *oils* both of the animal and vegetable kinds, which are diſtilled with a heat greater than that of boiling water; for thus they receive a burnt ſmell. Some ſpeak of theſe *oils* as being of one diſtinct claſs, but they have nothing in common, except that they are half burnt, they diſſolve more or leſs in rectified ſpirit of wine, are acrid, by repeated diſtillations they may be rendered volatile, and almoſt free from their diſagreeable ſmell. They are conſidered as powerful antiſpaſmodics; that however in chief uſe is the *oleum* DIPPELII ANIMALE.

EMPYROS. One labouring under a fever.

EMULGENS. EMULGENT, ſtroking or milking out. It is applied to the arteries and veins which go from the aorta and vena cava to the kidnies. According to the ancients, *they ſtrained, and*, as it were, *milked the ſerum through the kidnies*.

EMULGENTES ARTERIÆ & VENÆ. See RENALES ARTERIÆ & VENÆ.

EMULSIO, from *emulceo, to ſtroke*, or *cheriſh*; or from *emulgeo, to milk out gently by the hand*. Medicines of any kind, made in a form reſembling milk, uſed to be called EMULSIONS; though now the College of Phyſicians of London have rejected that term, and ſupplied it with LAC. But generally they are made from farinaceous ſeeds, which are beat up with ſome fluid, by which their oily parts are intimately blended with it. Their uſe is chiefly for common drink in acute diſorders. This form is perhaps the beſt for adminiſtering camphor. For the *emulſ. com.* or *lac. amyg.*—*emulſ. abſorb.* &—*camphorat.* ſee AMYGDALÆ DULCES.

EMUNCTORIUM. An EMUNCTORY, from *emungo, to clean, wipe away*, or *draw off*. The paſſages in the body, by which ſuperfluous matters are evacuated, are called *emunctories*. The glands are alſo thus named. Particularly (*according to the ancients*) thoſe which received the excrements from the noble parts, as the parotides from the brain, the axillary glands from the heart, and the inguinal from the liver.

ENÆMOS, from αιμα, *blood*. So Hippocrates and Galen call ſuch topical medicines as are appropriated to bleeding wounds.

ENÆOREMA, from αιωρεω, *to exalt*, αιωρημα, *ſublime*. It is the pendulous ſubſtance which floats in the middle of the urine, called alſo *ſublimamentum*, *Nubecula ſuſpenſa*, *ſublimatio urinæ*.

ENARGES, from αργης, *white*, or *evident*. Hippocrates applied this as an epithet to dreams.

ENARICYMON. See ARYCIMON.

ENARTHROSIS, from εν, and αρθρον, a *joint*. See DIARTHROSIS.

ENCHANTHIS, from εν, *in*, and κανθος, *an angle of the eye*. This diſorder is an encyſted tumor on its inner angle. At the firſt a tubercle appears on the caruncula lacrymalis, or on the creſcent-like red cuticle adjacent to it; afterwards this tumor extends over the pupil of the eye; when this happens the tears continually trickle down the cheeks, the ſight is impaired, the countenance deformed, and the eyes inflamed.

When it is of a mild nature it may be deſtroyed by gentle eſcharotics; while this method of cure is proceeding, the belly ſhould be kept lax, and an iſſue in the arm, or a perpetual bliſter between the ſhoulders ſhould be continued.

When this tumor is of a malignant kind, it is attended with pain, is of a livid hue, and often becomes cancerous. If it is manifeſtly cancerous, palliatives only are to be uſed; but if not, diſſect the whole tumor and its cyſt; in doing which raiſe it with the forceps, the better to avoid cutting either the eye or the caruncle: if the latter is hurt, the tears will ever after run down the cheek; it is therefore ſafer to leave a little of the luxuriant fleſh, and to deſtroy it afterwards with a cauſtic. See ECTROPIUM, and Heiſter's Surgery, White's Surgery, p. 231.

ENCARDION, from καρδια, *the heart*. See MEDITULLIUM.

ENCARDIUM PREMNU. The heart and marrow of the trunk; but DIOSCORIDES improperly calls the tender medullary ſubſtance which grows on the tops of the great palm-tree thus; THEOPHRASTUS, *encephalus*.

ENCATALEPSIS. See CATALEPSIS.

ENCATHISMA, from εγκαθημαι, *to ſit in*. See SEMICUPIUM.

ENCAUMA, from εν, and καιω, *to burn*. The ſcoria of ſilver is thus named, ſo is the mark left by a burn, alſo a puſtule which is produced by a burn.

A ſuperficial ulceration on the eye is thus called. AETIUS ſays, that thoſe ulcerations on the eyes which ariſe from defluxions of humours receive different names; as when one is formed on the pupil, covering a great part of it, and is of a bluiſh colour, it is called *caligo*: when an ulcer is not ſo wide, but is deeper, and alſo ſeated in the pupil, it is called *nubecula*: when the ſurface of the pupil appears rough, and of an aſh colour, an *epicauma* is ſaid to be formed, and when after a fever an ulcer is formed, with a ſordid cruſt, and is ſeated either on the pupil or the white part of the eye, it is called an *encauma*, which, when fixed in the pupil, ſuch an eroſion of the coats of the eye happens, as in the end is the deſtruction of all its humours. In the beginning of theſe caſes relief is ſometimes obtained by keeping the bowels lax. White's Surgery, p. 229.

ENCAUSIS. A BURN or SCALD; or rather the inflammation cauſed by a burn or ſcald. It is alſo that action of heat upon the body, which external cauſes occaſion, either the power of the ſun, fire, or more vehement affections, &c. It is a ſynonym with *deuſtio*. It is alſo the HEART-BURN, with thirſt. In Dr. Cullen's Noſology it is ſynonymous with erythema and ambuſtio.

ENCAUSTUM CŒRULEUM. See COBALTUM.

ENCEPHALON, from εν, *within*, and κεφαλη, the *head*. The *encephalon* includes the dura and pia mater, the cerebrum, the cerebellum, and the medulla oblongata.

ENCEPHALOCELE. See HERNIA CEREBRI.

ENCEPHALUS. See CEREBRUM, and ENCARDIUM PREMNU.

ENCERIS, from κηρος, *wax*. Bits of wax found in plaſters as they cool.

ENCHARAXIS, from χαρασσω, *to ſcarify*. See SCARIFICATIO.

ENCHEIRESIS, from χειρ, *the hand*. Galen uſes this word as part of the title to one of his works which treats of diſſection. The word imports the manual treatment of any ſubject.

ENCHILOMA. See ELIXIR.

ENCHONDROS, from χονδρος, which ſignifies both *a grain*, and *a cartilage*. Hence implies both granulated and cartilaginous.

ENCHORIOS, from εν, and χωρα, a *region* or *country* See ENDEMIUS.

ENCHRISTA. Liquid medicines for anointing any part with it.

ENCHUSA. See ANCHUSA.

ENCHYMA, from εγχεω, *to infuſe*. INFUSION, or a ſanguine plethora.

ENCHYMATA. Liquid medicines to be infuſed into the eyes, ears, &c.

ENCHYMOMA, from εγχεω, *I pour in*. In the writings of the ancient phyſicians, it is a word by which they expreſs that ſudden effuſion of blood into the cutaneous veſſels, which ariſes from joy, anger, or ſhame; and in this laſt inſtance, is what is uſually called BLUSHING. Dr. HUNTER ſays, it is a nervous affection.

ENCHYMOSIS. BLUSHING; alſo an extravaſation of blood which makes the part appear livid. Thus, *but improperly*, it is ſynonymous with *ecchymoſis*.

ENCHYSA. See ANCHUSA.

ENCHYTOS. An epithet for any thing infuſed into any cavity of the body.

ENCLYSMA. See ENEMA.

ENCŒLIA, from εν, *in*, and κοιλια, *the belly*. All the contents of the abdomen.

ENCOLPISMOS. An uterine injection.

ENCOPE, from εν, *in*, and κοπτω, *to cut*. An inciſion, and, *figuratively*, an impediment.

ENCRANION, from εν, *in*, and κρανιον, *ſkull*. See CEREBELLUM.

ENCRIS. A ſort of cake made of fine meal, boiled in oil, then ſweetened with honey.

ENCYMON, from ἐγκυω, *to conceive* Pregnant with child.

ENCYSTIS. See NÆVUS.

ENDEDINEMENOS, from ἰδινεω, *to turn round like a vortex*. An epithet for the eyes which perpetually turn in their orbitt.

ENDEIXIS. See INDICATIO.

ENDEMIAS, or ENDEMIUS, from ἐν, and δημος, *people*, called alſo ENCHORIOS, *popularis*. A term applicable to common diſeaſes, where the inhabitants living in one country are liable to be affected with them, from a cauſe, common and familiar to that country, viz. intermittents in the marſhes of Eſſex, and fens in Cambridgeſhire. It is put in oppoſition to EPIDEMICUS, which ſee.

ENDESIS, from δεω, *to tie*. A LIGATURE, band, or connexion.

ENDICA. Rulandus ſays, it is the fæces at the bottom. It is alſo called *moſe hazuania*.

ENDIVIA, called alſo *intybus ſcariola, ſeriola, cichoreum, latifolium*, ENDIVE. This plant is in common uſe in our kitchens: it very much reſembles ſuccory both in its appearance and virtues.

ENDIVIA ERECTA LUTEA NAPIFOLIA. See LAMPSANA.

—— VULGARIS. A name of ſeveral ſpecies of cichoreum.

ENELLAGMENOS, from ἐναλλαττω, of ἀλλαττω, *to change*. An epithet applied to the joints of the vertebræ, becauſe of their alternate or mutual receptions and inſertion.

ENEMA. A CLYSTER. From ἐνιημι, *injicio, to inject*; alſo ENCLYSMA, *catalyma*. The words *enema, catacliſmo*, and *lotio*, are equivalent to each other, and ſignify any liquid medicine injected into the anus. With us, *clyſters* are injected by means of a bladder and pipes, called *eluſma, fiſtula, auliſcos*; from whence *fiſtula armata, pipe*, and *bladder*; but in many other countries a ſyringe is always uſed, by which the liquor is farther thrown up into the bowels.

The quantity of liquor uſed in each *clyſter*, will vary according to the age of the patient and intention propoſed. *For infants*, two ounces at the moſt ſuffices; *a child of ſix years old*, from four to ſix ounces; *a youth of fourteen years*, from ſix to eight ounces; and *to an adult*, from ten ounces to a pint.

In diarrhœas, and all diſorders where the inteſtines are weak, alſo whenever the *clyſter* is to be retained, the quantity for an adult ſhould not exceed ſix or eight ounces.

In ardent fevers, and *inflammation of the bowels*, they anſwer the end of a fomentation, and ſhould be adminiſtered from a pint to a quart.—*In putrid fevers*, it is one way of expediting a quantity of proper acid and antiſeptic medicines into the conſtitution, particularly fixed air. Nouriſhment may be conveyed by *clyſters*, when from ſome complaint of the mouth, throat, or ſtomach, nothing can be conveyed that way: many have been thus ſupported during ſeveral months.

Clyſters ſhould never be either hot or cold when uſed; but ſo warm that they may be eaſily ſuffered on the back of the hand; then their effect in the inteſtines will be the moſt agreeable.

When a *clyſter* is intended only for emptying the inteſtines, half an ounce of common ſalt is a better addition than any quantity of the other purging medicines.

It is a practice with many to mix oil in reſtringent *clyſters*, but as it counteracts the intention of the preſcriber, it ſhould always be omitted in them.

When a very powerful ſtimulus is required in purging *clyſters*, it is moſt ſafe to mix emetics with them, and of theſe the vin. antimon. ſhould be preferred.

ENEMA EX AMYLO. See AMYLUM.

ENEOS. *Vain, empty*, or *uſeleſs*. The Greeks call thoſe who are unable to perform the common offices of life, ſuch as dumb, deaf, &c. ἐνεοι.

ENERGIA, from ἐργον, *a work*. ENERGY. By this is meant *force, vigour, efficacy*.

ENERVATIO. It is an equivocal term, ſignifying aponeuroſis or debilitation.

ENFLURE DES JAMBES. See LYMPHÆ DUCTUS.

ENFONDE. See CASSADA.

ENGER. See INDICUM.

ENGISOMA, from ἐγγίζω, *to draw near*. An inſtrument formerly uſed about fractures of the cranium. Alſo a fracture of the cranium, in the middle of which the bone preſſes upon the membrane of the brain, and makes the appearance of γυφοι, *the caves of a houſe*.

ENGOMPHOSIS. See GOMPHOMA.

ENGONIOS, from γονια, *an angle*. Hippocrates expreſſes by it the bending of the arm at a right angle.

ENGORGEMENT LAITEUX. See LYMPHÆ DUCTUS.

ENHÆMON. The name of a plaſter in Myrepſus.

ENIXA. A WOMAN IN CHILD-BED.

ENIXUM. The chemiſts apply this word to a third kind of ſalts, which are formed of acid and alkali: Galen calls them the third, but at preſent they are known by the name of neutral. See NEUTRI.

—— PARACELSI SAL. It is the caput mortuum of the ſpirit of nitre, joined with vitriolic acid. It is much the ſame as kali vitriolatum.

ENNEANDRIA, from ἐννεα, *novem*, and ἀνηρ *maritus*; the ninth claſs of the LINNEAN ſyſtem, comprehending ſuch hermaphrodite flowers as have nine ſtamina. The orders are three, MONOGYNIA, TRIGYNIA, and HEXAGYNIA.

ENNEAPHARMACOS, from ἐννεα, *nine*, and φαρμακον, *a medicine*. A compoſition of nine ſimple ingredients. It is alſo the name of a peſſary mentioned by Galen and Ægineta; and likewiſe of the antidotus Heraclidis, and of ſeveral plaſters mentioned by Aetius, and Celſus.

ENNEAPHYLLUM, from ἐννεα, *nine*, and φυλλον, *a leaf*. See HELLEBORUS NIGER HORTENSIS, &c.

ENOCHDIANUS. In Paracelſus it is one who equals Enoch in longevity.

ENOC DIANA VITA. A VERY LONG LIFE.

ENRYTHMOS. See ARYTHMUS.

ENS. An ENTITY or thing really exiſting. In Paracelſus *ens* imports the power, virtue, and efficacy, which a thing exerts upon our bodies.

ENS PARVUM SAPIENTIUM. It is ſoap made by mixing fixt alkaline ſalt with diſtilled vegetable oil. The ſalt muſt be quite hot when mixed with the oil, for the leaſt portion of water prevents their union: after their combination they are to be placed ſome time in a ſubterraneous place. A ſmall quantity of the ſalt remaining on the ſurface of the oil will attract water, and prevent the ſucceſs of the proceſs.

—— PRIMUM SALIUM. See CIRCULATUM.

—— —— SOLARE. See ANTIMONIUM.

—— VENERIS. See FLOR. MARTIALES under FERRUM.

ENSIFORMIS, from *enſis, a ſword*, and *forma, a form*, CARTILAGO. The SWORD-LIKE CARTILAGE, called alſo *xiphoides*; and by Hippocrates *chondros*; ſometimes it is biſurcated at the end, and is then called *fercula* or *furcella inferior*. It is called alſo *mucronatum os*; but more properly *mucronata cartilago*. This is the cartilage at the bottom of the *ſternum*; but the ancients oft give the name of *enſiformis* to the whole breaſt-bone. Dr. Hunter obſerves, that "if this cartilage ſhould be preſſed inwardly by a blow, it will occaſion vomitings and violent pains, by preſſing againſt the pylorus; in this caſe, it would be proper to lay it bare, and elevate it; but the diaphragm ariſing partly from it would probably diſplace it." From the form, or from accidents in this cartilage, many diſeaſes ariſe, as a cough, pain in ſtooping, difficult breathing, &c. That theſe ſhould happen will not appear wonderful, when we conſider that the diaphragm is attached to it, and that the great lobe of the liver and the ſtomach lay immediately under it.

ENSTACTON, from ἐναζω, *to diſtil*. INSTILLATIONS. The name of a liquid collyrium in Galen, which Ægineta calls ſtacticon.

ENTALE. See VAS.

ENTALI. FOSSIL ALUM.

ENTATICA MEDICAMENTA. Medicines that provoke venery. Cœlius Aurelianus calls them *ſatyrica*.

ENTATICON. The name of a plaſter in P. Ægineta.

ENTERA. So Hippocrates calls the bags in which were incloſed medicines for fomentations.

ENTERADENES, from ἐντερον, *an inteſtine*, and ἀδην, *a gland*. The INTESTINAL GLANDS. See INTESTINA.

ENTERENCHYTÆ, from ἐντερα, *the viſcera*, and ἐγχυω, *to infuſe*. Inſtruments for adminiſtering clyſters.

ENTERITIS. See INFLAMMATIO INTESTINORUM.

ENTERITIS MESENTERICA. See INFLAMMATIO MESENTERII.

ENTEROCELE, from εντερον, *an inteſtine*, and κηλη *a rupture*. See HERNIA SCROTALIS.

—— OVULARIS. A rupture of the inteſtines through the foramen ovale.

ENTERO-EPIPLOCELE, from εντερον, *an inteſtine*, and επιπλοον, *the omentum*; and κηλη, *a tumor*. It is when both the omentum and inteſtines protrude through the integuments of the belly.

ENTERO-HYDROCELE, from εντερον, *an inteſtine*, υδωρ, *water*, and κηλη, *an hernia*. A dropſy of the ſcrotum, with a defcent of the inteſtine.

ENTEROMPHALOS, from εντερον, *an inteſtine*, and ομφαλος, *the navel*. A rupture of the inteſtine at the navel. This ſeldom happens but to women in labour, or from labour.

ENTERON, from εντος, *within*. INTERNAL and INTESTINE. But in Hippocrates Epid. 6. § 4. ap. 3. *enteron* ſignifies ſimply the COLON.

ENTERORAPHE. A SUTURE of the INTESTINES.

ENTEROSCHEOCELE, from εντερον, *an inteſtine*, οσχεον, *the ſcrotum*, and κηλη, *an hernia*. See HERNIA SCROTALIS.

ENTHEMATA, εντιθημι, *to put in*. Medicines applied immediately to recent wounds, in order to prevent an inflammation and ſtop an hæmorrhage.

ENTHETOS, from εντιθημι, *to put in*. Any thing introduced, but particularly ſuch as are put up the noſe to prevent an hæmorrhage there.

ENTHLASIS. A contuſion with the impreſſion of the inſtrument by which it happened; called alſo *illiſio*.

ENTHUSIASMUS. A FANATIC STROKE; it is when a perſon is engaged in religious affairs, he loſes his reaſon, &c. in an ecſtacy ſees ſtrange ſights, or hears the noiſe of muſical inſtruments, &c.

ENTRICHOMA, from εν, and τριχωμα, *the hair*. The edge of the eye-lid on which the hairs grow.

ENTRIMMA, from εντριβω, of εν, and τριβω, *to rub, grate*, or *triturate*. See INTRITUM.

ENTROCHUS. An oblong ſtone nearly as thick as a man's finger, from one to two inches long; bluiſh coloured, and made up of joints, as ſo many rings. They are found frequently in clay pits. Sometimes the joints are found looſe, then they are called *trochitæ*. It is a part of the arm of a ſtar-fiſh, or ſome ſuch like ſea-animal, that is petrified. It is always hardened with ſparry matter, and like it, is diuretic. A *trochite*, when found ſeparate, is as broad as a ſix-pence, with a hole in the centre, and of different thickneſſes; the colour is bluiſh or greyiſh, and when broke, it is gloſſy and ſhining.

ENTROPIUM. Introverſion of the eye-lid. See TRICHIA.

ENTYPOSIS, from εντυπωω, *to make an impreſſion*, of τυπος, *a type*, or *image formed by impreſſion*. The acetabulum of the humerus. It is not uſed by any phyſical writer, but mentioned by Jul. Pol.

ENUCLEATIO. The taking a kernel out of a nut.

ENULA, called alſo *inula*, enula campana, *heleneum*, *aſter*, — *omnium maximus*. SCAB-WORT, and ELECAMPANE. Platerus calls it *aroma Germanicum*.

Miller enumerates thirty ſpecies; and Boerhaave makes it a ſpecies of *aſter*. It is the INULA HELENIUM, or INULA *foliis amplexicaulibus ovatis rugoſis, ſubtus tomentoſis, calycum ſquamis ovatis*. CL. SYNGENESIA; ORD. POLYGAMIA SUPERFLUA. LINN. Gen. Plant. 956. It is a large plant, with long, wrinkled leaves that are ſerrated; of a pale green colour above, and hoary underneath; the flowers are yellow, and of the diſcous kind, and are followed by oblong ſeeds, winged with down; the roots are ſhort and thick, unctuous to the touch; brown or blackiſh on the outſide, and whitiſh within. It is perennial, grows wild in moiſt rich ſoils, and flowers in June.

The freſh roots have a weak but not very grateful ſmell; when perfectly dried, they are more grateful: when chewed, they diſcover at the firſt a kind of rancid glutinous taſte, quickly ſucceeded by an aromatic bitterneſs, which by degrees becomes more pungent. They are diaphoretic, diuretic, and ſtomachic; if taken freely they looſen the belly; they powerfully attenuate viſcid humours, and aſſiſt expectoration in coughs and humoural aſthmas. The ancients had an high opinion of its virtues, and from its ſenſible, and chemical qualities it promiſes to be a medicine of ſome efficacy. It is now chiefly recommended where the digeſtion is impaired, in pulmonic affections, and uterine obſtructions. But Dr. Cullen, notwithſtanding its allowed qualities, ſays, ſtill he is at a loſs to determine what are its peculiar virtues.

The ſpirituous extract is the moſt active preparation, but the watery is far more abundant in the quantity which is obtained from theſe roots, and ſo little inferior in its virtues, as to deſerve the preference for general uſe. Neumann obtained from an ounce of the dry root, by means of water, ſix drams and a half of extract, but by means of ſpirit, only two drams and a half. Much of the aromatic warmth and bitterneſs of theſe roots, reſide in the more fixed parts, which do not exhale in the heat of boiling water; they are therefore well preſerved in the watery extract. In diſtillation with water, an eſſential oil ariſes which concretes into white flakes, and partly into an unctuous maſs like ſoftiſh wax. Thirty ounces of roots afford about a dram of this oil. Geoffroy the younger, obſerves, that this oil reſides in the exterior part of the root near the bark. When this concrete oil is but newly diſtilled, it is ſtrongly poſſeſſed of the flavour of *elecampane*, but it ſoon loſes all its ſmell by keeping.

Extract. ENUL. CAMP.

Boil *elecampane* roots in water; preſs and ſtrain the decoction, and ſet it by to ſettle; then pour off the clear, and boil it down to a conſiſtence of pills, taking care to prevent its burning towards the end of the operation. The doſe may be from ℈ i. to ʒ i. in a lax ſtate of the fibres of the ſtomach, and in ſome diſorders of the breaſt.

The doſe of the root may be to two drams. In infuſion, one dram of the root, and from ʒ ij. to ℥ ſs. in decoction is ſaid to be the doſe uſually given.

The rad. *enul.* c. condit. is prepared in the ſame manner as the ERINGO ROOT. See ERYNGIUM.

See Raii Hiſt. Lewis's Mat. Med. Neuman's Chem. Works. Cullen's Mat. Med.

ENULON, from εν, and ουλον, *the gums*. See GINGIVÆ.

ENUR. That vapour of water of which ſtones are generated.

ENURESIS. See URINA, *incontinence of*.

ENYPOSAPROS, from εν, *within*, υπω, a prepoſition, which in compoſition is a diminutive one, and σαπρος, *putrid*. An epithet uſed to the ſpit of hepatic patients.

ENYSTRON, from ενυω, *to perfect*. See ABOMASUM.

EON. The whole compaſs of the eye.

EPACMASTIC. See ACMASTICOS.

EPAGOGION. A name in Dioſcorides for the prepuce. See PRÆPUTIUM.

EPANADIDONTES PURETI. Fevers, whoſe heat is not biting to the touch in the beginning, but becomes more and more ſo in the advance.

EPANADIPLOSIS, from διπλοος, *reduplication*. The reduplication of a fit of a ſemitertian fever; that is, the renewal of a cold fit before the hot fit is ended.

EPANASTASIS. A TUMOR or TUBERCLE.

EPANCYLOTUS, from αγκυλος, *crooked, winding*. A ſort of bandage, in Oribaſius.

EPANTHESMA, or EPANTHISMA, from ανθος, *a flower*. An EFFLORESCENCE. See EXANTHEMATA.

EPAOIDAI. See AMULETA.

EPAPHÆRESIS, from επι, importing a repetition, and αφαιρησις, *a removal*. In Galen it is uſed to expreſs a repeated evacuation by bleeding.

EPARGEMOS. An epithet for a perſon affected with that diſorder of the eyes called *argemon*.

EPARMA, } from αιρω, *to elevate*. Any kind of tu-
EPARSIS. } mor, but frequently applied to the parotis.

EPAROTH. See BOTRYS MEXICANA.

EPENCRANIS. A name of the *cerebellum*.

EPERLANUS. Called alſo *viola marina*. The SMELT, This fiſh receives its firſt name from its pearl colour, and the ſecond from its violet-like ſmell. It is very nouriſhing, and as eaſy to digeſt.

EPHEBÆON. See PUBIS OSSA.

It is the name of an inſtrument for reducing luxations.

EPHEDRANA. See CLUNES.

EPHELCIS, from ελκος, *an ulcer*. The cruſt of an ulcer, or a ſmall abraſion, or bloody fragment coughed up.

EPHELIDES, from επι, and ηλιος, *the ſun*. SUNBURNING, (called *æſtates*, alſo *lentigines*, *lenticulæ*, becauſe of their ſize and colour reſembling a lentil-ſeed.)

FRECKLE,

FRECKLES, TAN, MORPHEW, which ſeem only to differ in degree, are yellowiſh coloured ſpots, ſpread over the face, neck, and hands; brought on by heat or ſudden change of the weather;—they affect people of fine complexions, and with red hair, more than others, in thoſe parts expoſed to the ſun: in winter they generally diſappear. Juice of lemons, mixed with ſugar, and borax, finely powdered, and digeſted for eight days, forms an uſeful compoſition for their removal. HOMBERG alſo recommends bullock's gall mixed with alum, and after the alum has precipitated, expoſed three or four months in the ſun in a cloſe vial, as one of the beſt remedies for clearing the ſkin from theſe appearances. Of the VITILIGO, or *Morphew*, SAUVAGES enumerates four, and of the EPHELIS, ſix ſpecies. Noſologia Methodica, vol. i. p. 127, 128.

EPHEM. GERM. An abbreviation of Ephemerides Medico-phyſicæ Germaniæ.

EPHEMERA, from ἡμέρα, *a day*, A DIARY FEVER, or fever of one day's continuance only: *diaria febris*. It is an inſtance of ſynocha. It ſhews itſelf in the following manner. The heat of the body is moderate, ſuch as attends an exceſs of wine, or what occurs in paſſion. The pulſe is ſomewhat full and quick, but ſoft and regular. The urine undergoes little or no change, neither is the complaint preceded by any loathing of victuals, yawning, or propenſity to ſleep, or horror—it comes on ſuddenly, unattended with any violent ſymptoms, ſuch as pain of the head, and ſtomach, nauſea, burning heat, inquietude of the body, or ſuch like. The diſorder ſometimes goes off without any apparent evacuation; but oftener by a free perſpiration, or at moſt by a pleaſant moderate ſweat. It generally ariſes from evident cauſes—ſuch as watching—ſolicitude, ſorrow, anger, inebriation, fatigue, heat of the ſun, want, or ſuch like—it for the moſt part terminates in one day, and at the fartheſt in two or three days. —Nature commonly effects a cure: a phyſician is ſeldom called in:—abſtinence from food—warm watery drink—and reſt, are all that is requiſite for the cure. See LOMMII Obſervat. Medic. SAUVAGESII Noſologia.

—— DICHOMENE. It is a kind of febris erratica.

EPHEMERIDES. Helmont calls thoſe diſeaſes thus which ſeize the patient at particular times of the moon, *ephemerides ægrotorum*, the *almanacs of the ſick*.

EPHEMERON. See HERMODACTYLUS.

EPHESIUM. The name of a plaſter deſcribed in Celſus.

EPHIALTES, or EPIALTES, from ἐφάλλομαι, *to leap upon*. See INCUBO.

EPHIALTIA. See PÆONIA.

EPHIDROSIS, from ἐφίδρωω, *to break out into a ſweat*. Called alſo *hydropedeſis*. This is what the Latins call *defudatio* and *mador*. Dr. Cullen places this genus of diſeaſe in the CLASS, LOCALES; and ORD. APOCENOSES; which he defines a preternatural evacuation of ſweat, one ſpecies of which he only conſiders as idiopathic, *ephidroſis ſpontanea*. The reſt are ſymptomatic, of which he enumerates nineteen varieties—SEVEN, according to the diſeaſes which they accompany; viz. *febrile—febricoſe—hectic—exanthematic—ſyncoptic—ſcorbutic—ſaburral*; ELEVEN, from the nature of the ſweat; *lacteal—mealeous—vinous—green—black—pale yellow—urinous—bloody—bluiſh—acid—arenous*;—and one from the part whence the ſweat is effuſed, viz. *lateral*. The idiopathic ephidroſis is moſt frequently the reſult of debility. SAUVAGES has three or four times obſerved men who were afflicted violently with night ſweats, that continued for months, without any fever; which brought on emaciation, debility, and loſs of appetite: theſe were cured by cathartics, the mineral waters, ſtyled acidulæ, and milk; but amongſt boys the diſeaſe uſed to continue a long time. See CULLEN's Synopſis, and SAUVAGES' Noſolog. Methodica.

EPHIPPIUM, a SADDLE. See SELLA TURCICA; it is called *ephippium*, from its reſemblance to a ſaddle.

EPHODES, from ἐπί, and ὁδός, *a-way*. In Hippocrates it hath three ſignifications; 1. The ducts or paſſages by which the recrements of the body are evacuated. 2. The periodical attack of a fever, from the common uſe of it to expreſs the attack of thieves. 3. The acceſs of ſimilar or diſſimilar things which may be uſeful or hurtful to the body.

EPIALOS. An epithet of a fever, from ἤπιος, *gentle*, ἅλς, *the ſea*; becauſe the ſea while undiſturbed is gentle, and this kind of fever gently heats the patient. Galen defines it to be a fever in which the patient labours under a preternatural heat, and a coldneſs at the ſame time. The ancient Latins call it *quercera*. Heſychius ſays, that the cold ſhivering preceding a fever was thus named. Some reckon it among the varieties of tertian fever.

EPIALTES, } See INCUBO.
EPIBOLE. }

EPICANTHIDES. See CANTHI.

EPICARPIUM, from ἐπί, *upon*, and καρπός, *the wriſt*. See CATAPLASMA.

EPICAUMA, from καίω, *to burn*. See ENCAUMA.

EPICERASTICA, from κεράννυμι, *to mix*, or *attemperate*. Medicines that obtund acrimony, and eaſe troubleſome ſenſations.

EPICHOLOS, from χολή, *bile*. BILIOUS.

EPICHORDIS, from χορδή, *an inteſtine*. From ἐπί, *upon*, and χορδή, *a gut*. See MESENTERIUM.

EPICHORIOS, from ἐπί, *upon*, and χώρα, *a region*. See EPIDEMIUS.

EPICŒLIS. The UPPER EYE-LID.

EPICOLICÆ REGIONES. From ἐπί, *ſuper*, and κοιλος, *hollow*. The lateral or lumbal regions. Theſe parts of the body which are adjacent to the colon.

EPICRANIUM. See OCCIPITO-FRONTALIS.

EPICRASIS. A critical evacuation of bad humours, an attemperation of bad ones. When a cure is performed in the alterative way, it is called *per epicraſin*.

EPICTENION, from ἐπί, *above*, and κτείς, *pubes*. The part above the pubes. Alſo the fine lint which hangs about where flax is dreſſing.

EPICYEMA, from κύω, *to conceive*, alſo EPIGONON. In Hippocrates it is a FŒTUS; alſo a MOLE.

EPICYESIS, from κύω, *to conceive*. See SUPERFŒTATIO.

EPIDEMICA AQUA. See ALEXITER. Aq. ſp.

EPIDEMIUS, from ἐπί, *upon*, and δῆμος, *the people*. EPIDEMICAL, alſo EPICHORIOS; *pandemius*, *popularis*, *regionalis morbus*. An epithet of diſeaſes which at certain times are popular, and attack many people at the ſame time. A diſeaſe which appears, and generally prevails, then for a time diſappears, is alſo called *epidemical*. See Obſ. on Epidemic Diſorders, &c. by James Sims, M. D. Dr. Wallis's Sydenham.

EPIDERIS. See CLITORIS.

EPIDERMIS, from ἐπί, *upon*, and δέρμα, *the ſkin*. See CUTICULA.

EPIDESMUS, from δέω, *to bind*. A bandage by which ſplints, bolſters, &c. are ſecured.

EPIDIDYMIS, from ἐπί, *upon*, and διδύμος, *a teſticle*. The *epididymis* may be reckoned a kind of teſtis acceſſorius. HIPPOCRATES called it *paraſtatæ*. It is a body, on the upper part of the teſticles, which is formed of a continuation of the tubes that conſtitute the teſticles; the continuance of the *epididymis* upwards forms the *vaſa deferentia*. See TESTES.

—— DISTENSA. See SPERMATOCELE.

EPIDOSIS. Preternatural enlargement of the parts.

EPIDROME, from ἐπί, *upon*, and δρόμος, *to run*. An afflux of humours; as it happens when a ligature is made on any part.

EPIGASTRICÆ ARTERIÆ. The EPIGASTRIC ARTERIES.

The external iliac artery divides into two branches at the ligamentum Poupartii; one of them is the *epigaſtric*, which runs to the inſide of the rectus abdominis, at whoſe upper part it communicates with the internal mammary. Dr. Hunter obſerves, that in the operation for the femoral rupture, we riſque cutting the *epigaſtrica* if we cut upwards and outwards; and if upwards and inwards, the ſpermatic is in danger, as the hernial ſac lies in the angle between the two.

—— VENÆ. The EPIGASTRIC VEINS.

The external iliac veins, a little before their going out of the belly, ſend off from the inſide the *epigaſtric veins* from whence branches run to the neighbouring glands and up the muſculi recti abdominis, and then advancing, join the mammaria.

EPIGASTRIUM, from ἐπί, *upon*, or *above*, and γαστὴρ, *the ſtomach*. The upper fore-part of the belly is thus called. It reaches from the pit of the ſtomach to an imaginary line above the navel, ſuppoſed to be drawn from one extremity of the laſt of the falſe ribs to the other. Its ſides are called hypochondria, and are covered by the falſe ribs, betwixt which lies the *epigaſtrium*.

EPIGENEMA, from ἐπιγίνομαι, *to generate over and*

above, or *anew*. Sometimes it ſignifies a ſymptom, at others any thing grown over another, as when the ſaliva is thickened, and forms a fur on the tongue.

EPIGINOMENA, from επιγινομαι, *to ſucceed*, or *ſupervene*. Galen ſays, they are thoſe ſymptoms which naturally ſucceed or may be expected in the progreſs of a diſeaſe; but Fœſius ſays they are new acceſſions of ſome other affection to diſeaſes, which never happens but in ſtubborn and malignant diſeaſes. See EPIPHÆNOMENA.

EPIGLOSSUM. See LAURUS ALEXANDRINA.

EPIGLOTTIS, from επι, *above*, and γλωττα, the aperture of the larynx. See ASPERA ARTERIA.

EPIGLOTTUM. An inſtrument mentioned by Paracelſus, for elevating the eye-lids.

EPIGLOUTIS, } from επι, *above*, and γλουτος, *the but-*
EPIGLUTIS, } *tock*. The ſuperior part of the buttock.

EPIGONATIS, from επι, *upon*, and γονυ, *a knee*. See PATELLA.

EPIGONON. See EPICYEMA.

EPIGOUNIDES. The muſcles inſerted into the knees.

EPILENTIA, } from επιλαμβανω, *to ſeize, invade*, or
EPILEPSIA, } *oppreſs*. The EPILEPSY. It is alſo called *abas*, ſometimes by CONSTANTINE, *morbus caducus, interlunius morbus, magnus morbus, morbus attonitus*, and by ſome, *analepſia*; PARACELSUS coined the word *catalentia* to expreſs this diſeaſe. The Portugueſe call it *cabrello*; HIPPOCRATES, *eclampſis*; FALLING SICKNESS, becauſe the patient falls ſuddenly to the ground; *heracleios, heracleius*, the great, or *herculean diſeaſe*, on account of its violence, and the difficulty in conquering it; *morbus ſacer*, or ſacred diſeaſe, becauſe it affects the mind, and moſt noble parts of a rational creature; divine diſeaſe, either becauſe it requires ſomething more than human for its cure, or becauſe it was thought to be ſent from heaven as a curſe upon earth; *morbus infantilis*, and *puerilis*, becauſe it happens moſt frequently to infants and children; *comiſſe*, and *comitialis morbus*, becauſe people were frequently ſeized with this diſorder whilſt in the aſſemblies called *comitia*.

Dr. Cullen places this genus of diſeaſe in the CLASS, NEUROSES, and ORD. SPASMI; which he defines, a convulſion of the muſcles, attended with a loſs of ſenſe, terminating in a ſtate of inſenſibility, and ſeeming ſleep. He diſtinguiſhes three ſpecies; 1. *Epilepſia* cerebralis, when it ariſes ſuddenly without any manifeſt cauſe; no uneaſineſs preceding, except ſometimes a giddineſs, or loſs of ſight. 2. *Epilepſia* ſympathica, when it ariſes without any manifeſt cauſe; but is preceded by a particular ſenſation called aura epileptica, ariſing from ſome part of the body which goes upwards to the head. 3. *Epilepſia* occaſionalis, when it ariſes from manifeſt irritation, and ceaſes on the removal of that morbid cauſe.

An *epilepſy* is a violent, involuntary, or convulſive contraction of the nerves, membranous, and muſcular parts of the whole body, attended with an abolition of ſenſe, and drawing its origin from a ſpaſmodic ſtricture of the membranes ſurrounding the brain, the ſpinal marrow, and the nerves; whence the vital principle is impetuouſly conveyed into the organs of motion, but in a leſſer quantity into thoſe which ſubſerve the purpoſes of ſenſation.

Weakly and pampered children are the moſt ſubject to this diſorder; men more than women.

The cauſes are various; the principal and immediate one is a ſpaſmodic ſtricture in the dura mater, and its continuation over the ſpinal marrow and nerves; but as the ſecondary and remote cauſes are very various, ſo there ariſe different ſpecies, and denominations of epileptic fits. When the cauſe is in the brain itſelf, it is called an idiopathic *epilepſy*; when in other parts it is called ſymptomatic.

The idiopathic *epilepſy* hath for its ſecondary cauſes external violence, as blows, bony protuberances ariſing internally in the baſis of the ſkull, or in the lateral, or the falciform ſinuſes; from this cauſe the diſorder is chronical; an obſtruction of the jugular veins, or of the ſinuſes of the dura mater, eſpecially the falciform ſinus, from polypous concretions or other matters, the paſſions of the mind, an ill conformation of the brain, &c.

A ſymptomatic *epilepſy* hath for its ſecondary cauſes, cachectic and hypochondriac habits; flatulencies proceeding from the ſtomach and bowels; ſpaſms of the inteſtines; irregular ſecretions and excretions; the acrid matter of eruptive and other diſeaſes tranſlated to the brain; pains that are violent and attended with ſpaſms in the nervous parts; ſtones paſſing through the ureters cauſe a ſymptomatic *epilepſy* which hath obtained the name of the nephritic *epilepſy*; worms, poiſons, &c.

Among the primary cauſes of *epilepſies* are whatever can impair the general vigour of the conſtitution, and particularly that injures the nervous ſyſtem.

To form a more diſtinct idea of the ætiology of an *epilepſy*, it ſhould be obſerved how different the circulation of blood through the brain is carried on from what it is in the reſt of the body. As ſoon as the arteries enter the head, they loſe their ſtronger coat, and conſiſt of a thin membrane only, which is deſtitute of ſenſation and motion; they are emptied into the venous ſinuſes in the dura mater; thence the blood is conveyed into the jugular veins, &c. to the heart again. The ſtructure of the dura mater ſhould be attended to, and its other peculiarities. To this end, ſee Baglivi de Fibra Motrice, lib. i.

The diagnoſtics vary much in different people; ſome are ſuddenly ſeized, others have a train of ſymptoms foreboding the attack, ſuch as wearineſs, an oppreſſive pain in the head, interrupted ſleep, a languid pulſe, a pale countenance, ſtupor and drowſineſs, an unuſual dread and terror, a ringing in the ears, palpitation of the heart, inflation of the præcordia, diſturbed reſpiration, rumbling in the bowels, a diſcharge of fetid ſtools, coldneſs in the joints, and a copious diſcharge of urine.—*Some* alſo perceive a kind of cold vapour gradually aſcending from the extremities to the heart and brain. Whether more or leſs of theſe ſymptoms precede the attack, or none of them attend, the fit approaches ſuddenly, and as it were unexpectedly; the patient falls down on his back to the ground; the thumbs are firmly fixed on the palms of the hands; the eyes are diſtorted, and the white part of them only appears; all ſenſation, both internally and externally, is deſtroyed; there is a frothing at the mouth with a hiſſing noiſe, the tongue is often lacerated by the teeth, and the joints are ſeized with a violent trembling.—*In ſome* there are many ridiculous and diſagreeable diſtortions and geſticulations;—in others, inſtead of convulſive motion, there is a highly rigid ſpaſm in all the members, by which they are ſo fixed that no force can move them. *In infants*, the penis is erected;—*in young men*, the ſeed is ejected, and ſometimes the urine is diſcharged to a conſiderable diſtance, and this, as well as the diſcharges by ſtool are involuntary. At length theſe ſymptoms remit; the patient ſeems to have a ſort of reſpite at intervals, but the eye-lids remain immoveable; the teeth grind upon each other, the tongue hangs out of the mouth; when the paroxyſm ceaſes, the patient is entirely ignorant of every thing that happens during it; he rolls on the ground, his countenance appears ſad, he begins to yawn, and ſtretches himſelf with a kind of violent efforts; he riſes and walks ſlowly, ſeems uneaſy, and the veins of his forehead appear diſtended.—*Some* are ſo affected after their recovery, that for a time they know not their moſt familiar friends;—*others* are more or leſs affected with ſome of the ſymptoms that precede the attack of the fit. *In ſome*, the returns are regularly periodical; *in others*, irregular and uncertain. By frequent returns of this diſorder, the patient grows dejected, is indolent, ſubject to a vertigo and trembling if he looks upward, becomes liable to ſudden anger from trifles; and many other unhappy attendants gradually gain upon him.

The *epilepſy* ſhould be diſtinguiſhed from the apoplexy, convulſions, and hyſterics.

That kind of *epilepſy* which reſembles a ſleep is more dangerous than that in which convulſive motions happen. The hereditary kind is rarely cured, and when the diſorder is chronical or habitual, ſucceſs is not to be depended upon. When the approach of puberty, or the eruption of the menſes does not remove an *epilepſy* in women, nor delivery of the firſt child, an hereditary cauſe may be ſuſpected, but a cure is not to be expected; cauſed by frights, they are never cured, or ſo rarely as to afford but little hope; for when the patient ſeems recovered, trifles are productive of a relapſe. When the fit approaches during ſleep, the danger is greater. Hippocrates aſſerts, that boys are relieved from this diſorder about their ſeventh, fourteenth, or ſeventeenth year. There is ſome hope of a cure when the caſe is not inveterate or hereditary, when the caſe is in the primæ viæ, or ſome diſorder tranſlated to the nervous ſyſtem. GOETTLIEB RICHTER ſays, that in all ſpaſmodic diſeaſes, and ſurely in epilepſy, the diſeaſe often continues from cuſtom alone, after the original

ginal cauſe has long ceaſed to act; that, frequently, every thing depends upon nature being made to diſcontinue this cuſtom for a time, ſo that ſhe may forget the diſeaſe;—that every thing depends entirely on ſeveral ſucceſſive attacks being prevented, in order to ſucceed in hindering it from ever returning. I know of no medicine which will ſo certainly prevent an epileptic fit, as a vomit given an hour before the attack. But this can only be had recourſe to when we foreſee the fit, i. e. when the diſeaſe is periodical; when the fit comes on at certain times, and when the attack is always preceded by a forewarning. In the epilepſia nocturna, a doſe of ipecacuanha may be given at bed time. In proof of this opinion, he mentions two caſes treated ſucceſsfully by this mode. Indeed, to him they appear ſo fully ſatisfactory, that he has thought unneceſſary to mention more; add to this, that he has no doubt, but the ſame method of cure would, in ſimilar circumſtances, be equally effectual in other ſpaſmodic nervous attacks.—*See his Obſervations, Medical and Surgical*, under the article EPILEPSY.

From the variety of cauſes, and the nature of ſome of them, it is difficult to ſtate the indications and method of cure. However, with Dr. Smith, we may propoſe, 1. *To prevent an impending paroxyſm.* 2. *To ſhorten a preſent one.* 3. *To guard againſt future attacks.* THE FIRST OF THESE INTENTIONS is anſwered in plethoric habits by ſuitable evacuations and antiſpaſmodics, as nitre, opium, muſk, &c. in languid conſtitutions, by warm, nervous medicines, as caſtor, valerian, camphor, fetid gums, volatile ſalts, the bark, chalybeates, &c. Cheyne ſays, that the *epilepſy* differs but little, otherwiſe than in the degree, from the hypochondriac and hyſteric fits, and obſerves, that when the former abates, it ends in hypochondriac or hyſteric diſorders, and when the latter is violent, they terminated in *epilepſies:* he therefore urges to a free uſe of vomits, bitters, and ſteel. THE SECOND INTENTION calls for the uſe of ſinapiſms or bliſters if the fits are long; but before theſe are applied, or when the fits are ſhort, endeavour to force open the mouth by means of a wedge thruſt between the teeth: when the jaws are ſeparated as far as the patient can eaſily admit of in health, the fit will generally be removed; and in caſes where the patient hath due notice of its approach, he may prevent the fits by introducing the wedge into his mouth. When the fits are preceded by peculiar ſenſations in the toes, feet, or legs, a bandage applied tight below the knee will often prevent the paroxyſm; or wherever theſe ſenſations are felt, let a bandage be applied there, and continued from thence upwards. Inſtances of abſolute cures have occurred by cutting down to the part in which thoſe peculiar feelings were firſt perceived. See an inſtance in the Edinb. Med. Eſſays, vol. iv. and ſee the article SESAMOIDEA. Cœlius Aurelianus prefers the blowing of ſtrong vinegar up the noſtrils, to volatile ſalts. THE THIRD INTENTION requires, if poſſible, that the cauſe be known, in order to its being removed; but unhappily in ſome inſtances it cannot be diſcovered; and in ſome, if it could, no remedy could be applied. However, in ſome caſes, the cauſe hath been clearly diſcerned, and in others, cures have been effected where the cauſe was only gueſſed at; whence there is encouragement for endeavours under very doubtful circumſtances. Among the means of cure, and what is extolled as a ſpecific, is the flores cardam. given to a dram, three or four times a day. See CARDAMINE.

In the Medical Commentaries of Edinburgh we have accounts of *epilepſies* having being relieved and cured by flowers of zinc, (ſee GOETTLIEB RICHTER'S Obſervations, Medical and Surgical, p. 147.) ſtramonium, white vitriol, pilulæ cœruleæ, pills conſiſting of the cuprum ammoniacum mixed up with bread; and bleeding. See vol. i. p. 5, 7. Dividing the cartilaginous or griſtly ſubſtance of the ear with a knife, not extremely ſharp, and thick at the back, ſo that the diviſion may be large, has been ſucceſsful; procuring and promoting at the ſame time a copious evacuation, as long continued as poſſible. WALLIS on Health, &c.

An iſſue kept open in the vertex hath been curative in ſome inſtances, and in all caſes concurs with evacuants in general in removing the plethora, which often, by compreſſing and irritating, is the cauſe of the diſorder.—When contuſions or fractures of the ſkull, or a fragment of it, preſs upon the brain;—when a caries in the bones of the ſkull, from the lues venerea or other diſorder, is the cauſe of *epilepſies*, the part muſt be trepanned.—When the *epilepſy* is ſymptomatic, the original diſeaſe removed the ſymptomatic of courſe will alſo be cured. In ſome inſtances a few large doſes of aſſa fœtida hath effectually relieved;—in others, four or five drops of the tinct. opii, every morning and night, hath had the ſame effect;—a milk diet continued for three or four months hath ſucceeded; and various other particulars are mentioned in practical authors, from which the like advantages have been reaped. In general, beſides proper evacuations duly repeated, warm nervous medicines, and the bark will be the moſt to be depended on, with iſſues in the inſide of the thigh, a little above the knee; and if the returns are periodical, or ſeem to be influenced by the moon, attend to its changes, and, after an emetic, let the bowels be emptied by a gentle ſolutive, and the patient be directed to avoid whatever he obſerved to produce or increaſe his fits. Valerian and the bark, mixed in equal quantities, may be taken to ʒ i. or ʒ i. ſs. three times a day. Muſk from gr. x. to ʒ ſs. twice a day. See Hippocrates, Celſus, Cœlius Aurelianus, Aretæus, Hoffmann, Boerhaave; and among the beſt authors on this ſubject, ſee Threlfal's and Lyſon's Eſſays on the ſame; Cullen's Firſt Lines, vol. iii. edit. 4.

EPIMELIS. See AMAMELIS.

EPIMORIOS, from μερος, *to divide.* SUPER-PARTIAL. In Galen it is an epithet of the difference of pulſe with reſpect to their inequality of the time they keep in beating.

EPIMULIS. See PATELLA.

EPINEUCOS, from νευω, *to nod*, or *incline.* It is an epithet of a pulſe which beats unequally in different parts of the artery. It is alſo called *perineuces.* Galen ſays, it is familiar in hectics.

EPINEPHELOS. from νεφελη, *a cloud.* CLOUDY. An epithet applied to the enæorema in the urine, which appears like a cloud.

EPINOTION, from επι, *upon*, and νωτος, *the ſhoulder*, the SHOULDER-BLADE. See SCAPULA.

EPINYCTIS, from επι, *on*, and νυξ, *night.* It is a kind of puſtule which riſes in the night, whence its name. SAUVAGES deſcribes this complaint, puſtules of a black-iſh-red colour, crowding together, three or four lines in diameter, affecting the legs for the moſt part, and very frequently painful, chiefly in the night. He enumerates two ſpecies;—*vulgaris*;—*prurigineſa.* Celſus ſays, this puſtule is of a bad kind, of a whitiſh or ſomewhat livid colour, with a violent inflammation round it. Theſe tumors affect the hands, arms, and thighs. The ancients rank them with the *terminthus*, which is rather leſs. Some deſcribe them as of a duſky red colour, and ſometimes of a livid and pale colour, with great inflammation and pain. In a few days they are ſaid to burſt and gleet, and ſeparate away in a ſlough. It appears to be a kind of furunculus. When it is opened, there is an efflux of ſanies, and an ulcer is found therein. The pain is more violent than is in proportion to its magnitude, for it is ſcarcely ſo large as a bean. Paulus and Aetius ſay, it creates no great pain in the day-time, but that it is troubleſome in the night. Celſus recommends that in this, and all other kinds of puſtules, the patient walks much, abſtains from all acrid food, and is very ſparing in his diet. SAUVAGES recommends bleeding, a cooling diet, antiphlogiſtic, cathartic, emollient gruels; at the ſame time, the application of cataplaſms of mallow flowers, line-ſeed, and ſuch like.

EPIOS. MILD, GENTLE. An epithet which Hippocrates beſtows on mild epidemic fevers.

EPIPACTIS. Dioſcorides mentions this plant, and Boerhaave takes it to be the *helleborine latifolia montana.*

EPIPAROXYSMUS. It is when the patient ſuffers more exacerbations than are uſual in a fever.

EPIPASMA. See CATAPLASMA.

EPIPASTON. See CATAPASMA.

EPIPECHY, from επι, *above*, and πηχυς, *the cubit.* The part of the arm above the cubit.

EPIPEPHYCOS, from επι, *upon*, and φυω, *to grow.* See ADNATA.

EPIPHÆNOMENA, from επι, importing *addition*, and φαινομενον, *a phenomenon* or *ſymptom.* Thoſe adventitious ſymptoms which do not appear till the diſeaſe is found, and ſeem to be the ſame as *epiginomena.*

EPIPHLEBOS, from επι, and φλεψ, *a vein.* One whoſe veins are prominent.

EPIPHLOGISMA, from επι, and φλογιζω, *to inflame*, of φλοξ, *a flame.* A violent inflammation, attended with pain,

pain, tumor, and redneſs. Alſo a name which Hippocrates gives to the SHINGLE'S. See ERYSIPELAS. Likewiſe a burning heat in any part.

EPIPHORA, from ἐπιφέρω, *to carry with a force.* In a medical ſenſe, it is an impetuous flux of humours, eſpecially an inflammatory one of the blood, to the whole ſurface of the body, or to any part thereof, but more particularly it is when tears trickle down from the eyes, in conſequence of obſtructed puncta lachrymalia, or an inflammatory influx of the humours upon the eyes.

The *epiphora* or WATERY EYE, alſo called *rheuma, lippitudo, oculus lachrymans,* and MOON-EYE, it is when the tears do not paſs the puncta lachrymalia, but run down the cheek. Some confound this with the fiſtula lachrymalis, becauſe in both the tears run down the cheeks; but in the fiſtula lachrymalis there is pus mixed with the tears. Whatever prevents the tears from paſſing through the puncta lachrymalia and naſal duct, produces an *epiphora*; as FIRST, *any tumors*, as the cicanthis in the great angle of the eye. SECONDLY, *any accident*, as a wound, burn, &c. cloſing up the puncta lachrymalia. THIRDLY, *deſtruction of the naſal duct.* FOURTHLY, *a polypus of the noſe.* FIFTHLY, *a fiſtula lachrymalis.* SIXTHLY, *an inverſion of the eye-lid.* See ENTROPIUM. LASTLY, *an eroſion, or other defect* of the caruncula lachrymalis.

Dr. Cullen places the *epiphora*, or *watery eyes*, as a genus of diſeaſe in the CLASS, LOCALES, and ORD. APOCENOSES, and defines it, a flux of the lachrymal humour, and ſays, of all the ſpecies recited by SAUVAGES, only one, *epiphora frigida*, can be eſteemed idiopathic; the reſt are ſymptomatic; of which there are twelve varieties.

When this diſorder exiſts, it is more eaſy to diſcern, than it is to diſcover the cauſe.

When the cauſe is a humour in the angle of the eye, a polypus in the noſe, a diſtortion in the eye-lids, and a fiſtula lachrymalis, they muſt be removed.—When a conglutination of the puncta lachrymalia is the cauſe, we are to examine whether their ducts are totally conglutinated, or it is only their mouths that are covered; for if it is after a burn, or from a cicatrix after a wound, &c. a cure is hardly to be hoped for; but if only a cuticle covers the duct, a perforation may be made with a needle, and then a hog's briſtle, or ſilver wire may be oiled, and paſſed through, and continued till the part is healed.—If the cauſe is a total want of the caruncula lachrymalis, a cure cannot be performed, becauſe that gland cannot be reſtored. Mr. WARE, in ſpeaking of the epiphora, ſays, it may be occaſioned either by a more copious ſecretion of tears, than the puncta lachrymalia are capable to abſorb; or, which is more commonly the cauſe, by an obſtruction in the lachrymal canal: whence the tears are prevented from paſſing freely from the eye into the noſe. It is the opinion of ſome anatomiſts, not only that part of the tears tranſudes through the pores of conjunctiva and cornea; but their quantity is increaſed, and that their acrimony is abated, by the ſecretions of the caruncula lachrymalis, and the glandulæ Meibomii. When therefore a morbid epiphora is produced by too copious a ſecretion of tears, its cauſe is uſually an inflammation in the membranes of the eye. *This, though, is ſymptomatic*, the cure conſequently accompliſhed by the removal of the inflammation, and by giving ſtrength to the parts affected, by the uſe of mild aſtringents, either cold water alone, or mixed with ſmall proportions of white vitriol or verjuice. But when it originates from an obſtruction in the ducts, leading from the puncta lachrymalia into the lachrymal ſac, *a caſe which rarely occurs*, the tears fall over the cheeks, and the ſac is conſtantly empty. *Preſſure therefore on the ſac can produce no regurgitation, either of the tears or mucus, into the eye.* The cure is performed by introducing a probe of a ſuitable ſize, through the puncta of the obſtructed ducts, into the ſac; and this operation muſt be repeated daily, till the obſtruction is removed. The part, though, in which the obſtruction *moſt commonly lies*, is in the ſac itſelf; then *the tears, mixed ſometimes with mucus, flow back into the eye, through the puncta, when preſſure is made upon the ſac.* Now the cauſes producing an obſtruction to the paſſage of the tears, are either a *thickening of the membrane lining the ſac;—a lodgment of inſpiſſated mucus in the inferior portion of the cavity, or a ſpaſmodic action in that part, which has by ſome been called the ſphincter of the ſac.*—Theſe three cauſes not only take place ſeparately, but ſometimes exiſt together, and they mutually tend to increaſe each other. This mucus, ſecreted by the membrane which lines the lachrymal ſac in its natural ſtate, is perfectly limpid, and mixing with the tears, paſſes into the noſe; but when this membrane is diſeaſed, it often happens, that the mucus ſecreted by it is thickened; in conſequence of which, it becomes incapable of paſſing through the ſac, and the tears by its lodgment are prevented from purſuing their regular courſe; their deſcent being probably ſtill further interrupted by a ſpaſmodic action in the inferior part of the ſac, ſuppoſed to form a ſphincter. Of the various remedies which have been propoſed for the cure, Mr. Ware approves moſt of MONSIEUR AVEL'S, recommended firſt in the year 1712; which conſiſted in firſt paſſing a probe, and afterwards injecting a liquor through the puncta lachrymalia, in order to clear away the matter which obſtructed the lachrymal paſſage. Mr. Ware adopted this plan, which in ſeveral cures were attended with ſucceſs, which he proſecuted in the following manner. He had a ſmall ſilver ſyringe, with pipes fitted to it of various ſizes, much ſhorter than that which is repreſented in plate 37, vol. iii. of Bell's Surgery; they were a little arched towards the point, for the convenience of being introduced into the punctum lachrymale with moſt eaſe; of theſe he uſed the *largeſt that could be introduced* without giving pain; and through that, he injected water. Warm water is to be preferred, on account of its relaxing, *and perhaps diſſolving*, and antiſpaſmodic power, contributing to take off any ſpaſms, that may have been excited at the inferior part of the lachrymal ſac, and *diluting the viſcid mucus.* In introducing the pipe, he found it convenient to ſtand either behind the patient, or on the ſide oppoſite to that of the diſeaſed eye, and always high enough to give him a full command of the patient's head. The ſyringe being held in the right hand, the eye-lid was drawn downward, and a little outward, with the fore-finger of the left hand. This brought the inferior punctum fully within the ſight of the operator, and placed it in a poſition very convenient for admitting the point of the pipe. When the pipe was introduced, the finger was removed from the lower lid, and applied as accurately as poſſible over the ſuperior punctum, to prevent the liquor from eſcaping through it; and with this finger, the lachrymal ſac was occaſionally compreſſed, to aſſiſt the determination of the liquor downwards to the noſe. See Ware on the Epiphora or Watery Eye; Hieſter's Surgery, Brook's Practice of Phyſic, White's Surgery, p. 233, and Dr. Wallis's Notulogia Oculorum.

EPIPHYLLOSPERMOPHERÆ PLANTÆ. EPIPHYLLOSPERMIFEROUS PLANTS, of ἐπι, *upon*, φυλλον, *a leaf*, σπερμα, *ſeed*, and φερω, *to bear.* They are ſuch as bear their ſeeds on the back of their leaves, as do all capillary plants.

EPIPHYSIS, from ἐπιφυω, *to grow to*, or *upon.* Called alſo *additamentum, appendix.* It is a ſmall bone annexed to the larger by means of an intervening cartilage; this cartilage is only obſervable in growing ſubjects, for in adults it cannot be diſtinguiſhed from the bone. Epiphyſes being of a larger diameter than the bone they belong to, ſerve to render the articulation more firm; and the muſcles inſerted into them, act with greater force, as their axes are farther removed from the centre of motion. *Epiphyſes* are ſometimes ſeparated from the head of the bone, and miſtaken for a luxation, or a fracture. See SYMPHYSIS.

EPIPLASMA. See CATAPLASMA. Alſo a name for an application of wheat meal, boiled in hydrelæum, to wounds.

EPIPLOCELE, from ἐπιπλοον, *the omentum*, and κηλη, *a rupture*, called alſo *hernia omentalis.* An HERNIA, or, *rupture of the omentum.* It is when the omentum protrudes through the openings in the integuments of the belly. Mr. Sharpe ſays, in the fifth chapter of his Operations, that ſometimes ſo large a quantity of the omentum hath fallen into the ſcrotum, as by drawing the ſtomach and bowels downwards hath excited vomiting, inflammation, and the ſame train of ſymptoms as happen in the bubonocele; and that when this happens, it is neceſſary to open the ſcrotum, in which the operation and proceſs will be the ſame as in the bubonocele. It is neceſſary alſo that the rings of the muſcles ſhould be dilated; or otherwiſe, though ſome of the mortified part of the omentum is removed, the reſt cannot well be returned, ſo will gangrene. But except an inflammation, &c. are actually commenced, this method is not to be attempted.

EPIPLO-

EPIPLOICÆ. APPENDICULÆ. The peritoneal coat of the inteſtines ſends out ſome proceſſes like little epiploons, to which Winſlow gives this name.

EPIPLOICA ARTERIA. See SPLENICA ARTERIA.

—— DEXTRA VENA. It is a branch from the trunk of the meſaraica major which goes to the omentum.

—— SINISTRA VENA. It ariſes from the ſplenica at the ſmall extremity of the pancreas, and is ramified on the omentum all the way to the colon, where it communicates with the hæmorrhoidalis interna.

EPIPLOITIS. See PERITONITIS OMENTALIS, and PUERPERILIS FEBRIS.

EPIPLOOCOMISTES, from ἐπίπλοον, *the call*, and κομίζω, *to carry*, as if it was a burden. It ſeems to be only a term of railliery, from ἐπίπλοον, *the omentum*, and κομίζομαι, *to poſſeſs* or *have*.

An epithet for thoſe who have a large epiploon, in compariſon of brutes. Veſalius underſtands it of one who hath a preternaturally large epiploon. Or it may be applied to one labouring under an epiplocele.

EPIPLOOMPHALON, from ἐπίπλοον, the *omentum*, and ὀμφαλὸς, the *navel*. See HERNIA UMBILICALIS.

EPIPLOON, from ἐπιπλέω, *to run over*, becauſe it ſeems to float upon the guts. See OMENTUM.

EPIPLOSCHEOCELE. See HERNIA SCROTALIS.

EPIPOLÆUS. SLIGHT, GENTLE. Hippocrates applies it to diſorders that are no way dangerous.

EPIPOLASIS. A redundance and fluctuation. In chemiſtry it is when what is ſublimed aſcends only to the ſurface and there ſettles.

EPIPOROMA, from ἐπιπωρόω, *to harden*. It is any indurated tumor in the joints. See TOPHUS.

EPISARCIDIUM, from σὰρξ, *fleſh*. See ANASARCA.

EPISCHESIS, from ἰσχω, *to ſtop, retain*. See EPISTASIS.

EPISCHION, from ἐπὶ, *upon*, and ἰσχίον, *iſchium*. See OSSA PUBIS.

EPISCOPALES VALVULÆ. See COR.

EPISEION. See PUBIS OSSA.

EPISEMASIA. See ANNOTATIO.

EPISPASMOS, from ἐπισπάω, *to attract*. In Hippocrates, according to ſome, it is inſpiration: but others ſay it is a more quick inſpiration than uſual.

EPISPASTICA, from ἐπισπάω, *to draw*. Medicines which draw the fluids more copiouſly into the parts to which they are applied, and therefore, ſtrictly a term of the ſame meaning as attrahentia; but as the effect of the epiſpaſtica is commonly that of exciting bliſters, the term is often employed for that of veſicatoria and veſicantia. What the ancients called *epiſpaſtics*, were ſuch external applications as only rubified the ſkin; and according to the different degree of effect, received different names; the ſlighteſt were called *phœnigmoi*, the next were *ſinapiſmi*, the next were *veſicatorii*, and the ſtrongeſt were *cauſtici*. The London College hath changed the name of bliſtering plaſter from veſicatorium to emplaſtrum cantharidis. See CATAPLASMA.

EPISPASTICUM MEDICAMENTUM. A dry medicine prepared for the cure of malignant ulcers by inſperſion.

EPISPHÆRIA, from σφαῖρα, *a ſphere*. The brain, being ſomewhat of that ſhape. According to ſome, it is the windings of the exterior ſubſtance of the brain; others ſay, it is the winding veſſels on the ſurface thereof.

EPISTAPHYLINI. See STAPHYLINI.

EPISTASIS. According to Hippocrates, it is the ſame with *epiſcheſis*, a ſuppreſſion of proper excretions; it alſo means the ſuperficies of urine, called *inſidentia*, and is oppoſed to the *upoſtaſis*, *ſubſidentia*, or ſediment in urine.

EPISTAXIS, ἐπιστάζω, *inſtillo*. See HÆMORRHAGIA.

EPISTHOTONOS. See TETANUS.

EPISTOMION. A STOPPER for a BOTTLE, &c. Alſo a vent-hole of a furnace called a REGISTER.

EPISTROPHÆUS, from ἐπὶ, *upon*, and στρέφω, *to turn*. The firſt vertebra of the neck; ſo ſome (though improperly) call the ſecond. It is alſo written *epiſtrophea*, and *epiſtrophis*.

EPITASIS. In Hippocrates, it is the beginning and increaſe of the fit.

EPITEDEUMA. The way of living which a perſon preſcribes to himſelf. Cœlius Aurelianus calls it *vitæ affectiones*; and Celſus, *vita propoſita*.

EPITHELIUM. See CUTICULA, and PROLABIUM.

EPITHEMA, from ἐπὶ, *upon*, and τίθημι, *to cover*, *to lay upon* or *apply*. A LID or COVER; but it is alſo uſed to ſignify a topical medicine. *Epithems* are, 1. liquid; and when applied warm, are ſometimes called fomentations or embrocations. 2. Dry, or ſolid. Theſe are medicated powders ſewed up in cloths, called *ſacculus*, *ſaccus*, *cucupha*, *cucullus*, *frontale*, *ſcutum*, *lectulus*, and *pulvinar*. 3. Thoſe of the ſoft or poultice kind, as ſinapiſms, and other kinds of poultices. Turner confines the name of *epithem* to liquids in which rags are dipped, to be applied to the part affected. See Gaubius de Formulis Medicamentorum.

EPITHESIS. In ſurgery, it is the ſtraightening of crooked limbs by means of inſtruments.

EPITHYMBRUM. A ſpecies of moſs growing on the thymbra, or winter-ſavory.

EPITHYMUM. See CUSCUTA.

EPOCHETEUSIS. A derivation of the juices to other parts.

EPOMIS, i. e. ACROMION, from ἐπὶ, *upon*, and ὦμος, *ſhoulder*. See SCAPULA.

EPOMPHALUM, from ἐπὶ, *upon*, and ὀμφαλὸς, the *navel*. Any application to the navel.

EPODE, } from ἐπὶ, *over*, and ᾠδὴ, *a ſong*. The
EPODOS, } method of curing diſtempers by incantations.

EPOSCHION. The tendril of a plant.

EPOMPHALION, from ἐπὶ, *upon*, and ὀμφαλὸς, *the navel*. A medicine which purges by being applied to the region of the navel.

EPOSILINGA. SCALES of IRON.

EPSOMENSIS AQUA. EPSOM WATER.

This water has been long in repute, and was the firſt *water* from whence a bitter purging ſalt was acquired. It is one of the moſt noted purging *waters* in Europe; and its medicinal powers are contained in the ſalt which bears its name. The ſpring of this *water* is ſituated near *Epſom*, in Surry. There are different accounts of the products of this *water* reſpecting the quantity of its ſolid contents.

From one gallon was procured by
- Dr. Liſter, 1½ ounce.
- Dr. Rutty, 1 ounce, and in ſome ſeaſons only half the quantity.
- Dr. Lucas, only 5 drams and 1 ſcruple.

Of this ſolid matter Dr. Allen alleged that ⅛ was an earth, or inſoluble matter; but Dr. Rutty ſays, that he found a much leſs proportion of it, and that it was of a calcareous nature. The ſalt is moſtly a vitriolated magneſia, or vitriolated abſorbent earth. Dr. Lucas ſays, that if the natural ſalt of this well be diſſolved in diſtilled water, and that evaporated, it ſhoots into cryſtals, like Glauber's ſalt, and that there remains a bittern which will not cryſtallize. Dr. Rutty affirms, that it requires at leaſt twenty-four times its own weight of water entirely to diſſolve it, though the factitious Epſom ſalt diſſolves readily in little more than an equal weight of water.

EPSOMENSIS SAL. See CATHARTICUS SAL.

EPULIS, from ἐπὶ, *upon*, ὑλὰ, the *gums*.

VOGEL deſcribes it, "a tubercle on the gums without inflammation."—Of theſe there are two ſpecies; one without pain, the other is troubleſome, and often degenerates into a cancer. They are of different ſizes, ſome having a broad baſis, and others a ſlender neck, by which they are united to the *gums*.

The beſt method of cure is totally to extirpate them: when they have a ſmall neck, or root, they may be twitched off with a thread. When the baſis is broad, deſtroy it with the aqua kali, or a ſolution of ſal ammoniac. If theſe mild corroſives fail, it is better to uſe the knife than to hazard the danger which attends the ſtronger ones.

After the humour is extirpated, waſh the mouth with red wine, or oxycrate with alum; and when the blood ceaſes to flow, uſe a mixture of the honey of roſes with oil of myrrh. See Turner's Surgery, vol. i. p. 210. Heiſter's Surgery.

EPULOTICA, from ὑλὴ, a *cicatrix*, ἐπιλύω, is *to cicatrize*. EPULOTIC. *Cicatriſantia*; *deſiccativa*; *apulotica*. Topical medicines which dry up humidity, repreſs fungous fleſh, and diſpoſe wounds or ulcers to be covered with ſkin, are ranked under this name. Dry lint, gentle compreſs, and the cerate with lap. calam. are the general applications. With regard to inducing a cicatrice, or new ſkin upon wounds and ulcers, Dr. CULLEN ſays, it is extremely doubtful if ſuch a power in any medicine exiſts; the propriety of the term therefore may be juſtly queſtioned.

EQUI CLIBANUS. In chemiſtry it is the heat of horſe-dung.

EQUINA FRASA. See FABA MINOR.

EQUINOX. See ÆQUINOCTIUM.

EQUI VENTER. See VENTER.

EQUITATIO. RIDING. Nothing ſtrengthens the viſcera and inteſtines more than this ſpecies of exerciſe, which ſhould be taken when the bowels are in their moſt empty ſtate, or when the buſineſs of digeſtion is ſomewhat advanced. Its uſe ariſes from the repeated gentle agitation given to theſe parts, which are calculated to *remove viſceral obſtructions, promote the circulation of the blood, clear away viſcidities from the bowels, determine the fluids to the ſurface of the body*, and *increaſe perſpiration*. Dr. Huxham had ſo high an opinion of this remedy, that he ſays, where tedious courſes of medicines have failed, in ſome chronic diſeaſes, riding only has performed a cure: hence adviſes, when a patient can ſit on horſe-back, that he ſhould have daily recourſe to this exerciſe.

ERAWAY. See CATAPUTIA.

EREBINTHUS. See CICER.

ERECTOR CLITORIDIS. See CLITORIDIS MUSCULUS.

ERECTORES PENIS. Theſe muſcles, ariſing from the inſide of the tuberoſity of the iſchium, are loſt in the crura, where they unite. They are alſo called *directores penis*; and Spigelius calls them *collaterales penis*, from their collateral order of fibres.

EREGMOS, from ἐαγνυμι, *to break*. It is any leguminous fruit decorticated and broken into pieces. Fœhus ſays, it is bean meal.

ERETHISMOS, from ἐρεθιζω, *to excite, irritate*, In general, medicinally uſed, it ſignifies every thing irritating, comprehending all things which by any means weakens the vires vitæ, and thus deſtroys the vital heat; or impedes critical efforts, whether they may be *acrid* or *vicious humours in the body*; or other things which are præternatural, as *worms, calculi*, &c. or things external, as *watchings, anger, grief*, &c. Thus is it expounded by GALEN. Hence things of this ſort are, σημεια ἐρεθιστικα, *ſigna irritantia*. The term *erethiſm*, therefore, means, whatever is an obſtacle to nature, in a general ſenſe. In particular, it ſignifies an irritation of the belly, from thin acrimonious humours, and their diſcharge in liquid ſtools.

ERETRIA TERRA. ERETRIAN EARTH, alſo named *canabil*. It is a very peculiar kind of alkaline bole; once in great uſe as an aſtringent and ſudorific. DIOSCORIDES and GALEN deſcribe two kinds, white and grey: the latter was in the higheſt eſtimation. The ancients eſteemed it a great medicine, and were very careful in their mode of preparing it, by frequent waſhing it for uſe. Though unknown to the preſent practice, ſome think, from its highly alkaline quality, it might be worthy of being brought into uſe again. It is dug up in the Negropont, near ancient Eretria, where it might be readily procured.

EREUGMOS. An ERUCTATION.

EREUMENA URA. Urine that aſſumes a cloudy conſiſtence in the middle.

EREUXIS. ERUCTATION.

ERGALIA. That part of alchemy that explains the inſtruments thereof.

ERGASIMA. See MYRRHA.

ERGASTERIUM, from ἐργον, a *work*. A LABORATORY. In particular, it is that part of a furnace, in which the copel, alembic, retort, &c. containing the matter to be acted on, is repoſited.

ERGOT. So the French call a diſeaſe, which reſembles one in England, which is cauſed by eating bad corn.

ERICA, alſo called *erite*, COMMON HEATH, HEATHER, LING. Boerhaave mentions eight ſpecies, but others add ſtill more. The flower is of a curious ſtructure, and a decoction of them is commended as a ſolvent for the ſtone; five ounces of it are to be drank every night and morning. See Raii Hiſt.

ERICERUM. The name of ſeveral collyria in Aetius, ſo called from *erica, heath*, which is an ingredient.

ERIGERUM. SIMPSON, and GROUNDSEL, called alſo in MYREPSUS, *cortalon*. It is a low plant, and too generally known to require a deſcription. The ſpecies uſed in medicine is the SENECIO VULGARIS, Linn. It is an annual plant, but may be found at all times of the year. The juice of the leaves are a powerful emetic. An infuſion of them, or their expreſſed juice, may be given. Some maniacs find that a tea-cup full of the juice will operate with them as an emetic when other means fail, and thus they remove ſlight attacks of their diſorder. See Lewis's Mat. Med. and for their ſingular power externally applied, Edin. Med. Eſſays, vol. ii. art. 5.

ERINEAS. See FICUS SATIVA.

ERIX. See JECUR.

ERIZAMBA. See ASPHODELUS LUTEUS.

ERODINIUM. See PROGNOSIS.

EROTION. See MELISSA.

EROTOMANIA. That ſort of melancholy to which lovers are ſubject. See MELANCHOLIA.

EROTYLUS. See CORALLOIDES FUNGUS.

ERPES. See HERPES.

ERRANA, } ERRATIC FEVERS, irregular TERTI-
ERRATICA. } ANS or QUARTANS.

ERRHINÆ. STERNUTATORIA. ERRHINES, from ῥις, the *noſe*, called *naſale*, CAPUT PURGIA, which laſt is a barbarous term, uſed by ſome to ſignify ſuch remedies as purge the head. Theſe are either errhines, or maſticatories. *Errhines* are the name which Galen gives to *ſternutatories*; they are ſubſtances, which, if ſnuffed up the noſe, promote a diſcharge of mucus therefrom. At preſent the milder ſorts are diſtinguiſhed by the name of *errhines*, and the ſtronger by that of *ſternutatories*, becauſe they excite a ſneezing By the uſe of this kind of medicines, the megrims, ophthalmia, and tooth-ach have been cured by this violent operation; but their practice appears hazardous. Beſides the general ſhock that *ſneezing* gives to the whole body, it tends to remove the remoteſt obſtructions; hence its uſe extends to lethargies, epilepſies, palſies, apoplexies, head-achs, vertigoes, catarrhs, gutta ſerena, &c. The action of *ſneezing* ſeems to be more extenſively uſeful by its general ſhock than that of vomiting; but it ſhould ever be obſerved, that if there is any kind of plethora in the habit, that ſhould be removed before *ſternutatories* ſhould be adminiſtered. See CULLEN's Mat. Medica.

ERRIPSIS, from ῥιπτω, *to precipitate*. When ſpoken with reſpect to the body, it ſignifies a loſs of ſtrength.

ERODENTIA. See ESCHAROTICA.

ERROR LOCI. Boerhaave is ſaid to have introduced this term, from the opinion that the veſſels were of different ſizes for the circulation of blood, ſerum, and lymph, and that when the larger-ſized globules were forced into the leſſer veſſels by an *error of place* they were obſtructed. But this opinion does not ſeem well grounded. See ARTERIA.

ERUCA. ROCKET: called alſo *euzomon*. Boerhaave mentions ſeven ſpecies. This kind of plant reſembles muſtard in appearance, but is diſtinguiſhed by the ſmoothneſs of its leaves, and its diſagreeable ſmell. The ſeeds have a pungent taſte, ſomewhat like that of muſtard, but weaker. The ſort uſed in medicine is the *braſſica eruca*, Linn. It is alſo a term for MUSTARD. See SINAPI.

—— SATIVA, called alſo *eruca latifolia alba, erucæ major ſativa*. GARDEN-ROCKET. The roots have a hot biting taſte, and the ſeeds have the ſame qualities. The herb is eaten as a ſallad, and is ſomewhat warming and diuretic, but is not in uſe as a medicine.

—— SYLVESTRIS, called alſo *eruca ſylv. major, erucæ tenuifolia*, &c. WILD ROCKET.

—— LATIFOLIA LUTEA. See BARBAREA.

—— SILIQUA CAULI OPPRESSA. HEDGE MUSTARD. See ERYSIMUM.

ERUTHEMATA. Red fiery tumors which ariſe from an inflammation, as in eryſipelas.

ERVA DE SANCTA MARIA. See DRACONTIUM.

ERVILIA. See OCHRUS.

ERVUM, called alſo *orobus, orobrychis peregrina*. The BITTER VETCH. It is the ERVUM ERVILIA, Linn. This plant grows up two feet in height, its leaves and flowers are like thoſe of the tare in their ſhape, but are leſs, and of a white colour; theſe flowers are ſucceeded by pods which contain two or three large, round, whitiſh ſeeds. It is a native of France, Italy, and ſome other of the warm parts of Europe, The ſeeds have a farinaceous, diſagreeable, bitter taſte, are nephritic, powerfully diuretic, and if mixed with honey, are expectorant.

—— LENS. See LENS.

ERYNGIUM. ERYNGO. Boerhaave reckons eleven ſpecies, and Dale enumerates ſtill more. It is alſo called *eringus*, eryng. maritimum, *inguinalis, ætherea herba, aſter atticus, hyophthalmos, crocodilion, iringus*, SEA-HOLLY and ERYNGO. It is the ERYNGIUM MARITIMUM,

RITIMUM, or ERYNGIUM *foliis radicalibus ſubrotundis, plicatis, ſpinoſis, capitulis pedunculatis, paleis tricuſpidatis.* CLASS, PENTANDRIA; ORD. DIGYNIA, Gen. Plant. LINN. 324. This is ſuppoſed to be the ἠρυγγιον, of DIOSCORIDES who with other ancient writers ſpeak highly of its medicinal efficacy.

It is a bluiſh branched plant, with mallow-like, thick, prickly leaves, angular or jagged about the edges; the flowers are white; the roots are ſlender and long, brown on the out-ſide, and white within. It is perennial, grows plentifully on ſome of our ſandy and gravelly ſhores: it flowers in July.

The root has an agreeable ſweet taſte, which on chewing is followed by a light aromatic pungency. It is putreſcent, and a mean betwixt animal and vegetable food. Freely uſed, it is aperient, diuretic and antiſcorbutic. It has been extolled as an aphrodiſiac, but obtains now very little credit; and ſeldom uſed but as a ſweet meat; and more fit for diet than as a medicine.

The candied roots, bought at the confectioners', are an ingredient in ARTIFICIAL ASSES MILK which is thus made:

Take of candied *eryngo* root one ounce; pearl barley, half an ounce; liquorice root, three drams; boil them in two pints of water to one pint, to which add a pint of new milk from the cow; boil them gently together, then ſtrain for uſe. Half a pint ſhould be drank three times a day.

ERYSIMUM, called alſo *iris, camelina, chamæplion, verbena fœmina, eruca ſiliqua cauli oppreſſa.* HEDGE-MUSTARD. It is the ERYSIMUM OFFICINALE, Linn.

It is an hairy plant, with oblong narrow leaves, tough branched ſtalks; bearing numerous ſmall yellow flowers; which are followed by ſhort roundiſh pods full of ſmall reddiſh brown ſeeds. It is annual, common in waſte places, and flowers in July.

This plant is not in much eſteem; it has been employed in the cure of hoarſeneſs, in the ſame manner as horſe-radiſh, (ſee RAPHANUS RUSTICANUS); and perhaps has the advantage over the other ſiliquoſe plants, as having leſs acrimony, which allows it to be more freely and frequently uſed. Cullen's Mat. Med. The leaves are herbaceous to the taſte; the flowers are attenuant, expectorant, and diuretic; the ſeeds reſemble in their qualities thoſe of muſtard, but are much weaker: their acrimony is extracted totally by water, and partially by ſpirit. Water is ſtrongly impregnated with them in diſtillation. STAHL highly commends the active parts of this plant in ſcirrho-cancerous tumors. It is alſo a name of *Sophia.*

—— ALLIARIA. See ALLIARIA.

—— LATIFOLIUM, alſo called *ſinapi ſilveſtre*, &c. BROAD-LEAVED HEDGE-MUSTARD. Its virtues are ſimilar to thoſe of the other kind. Raii Hiſt.

—— THEOPHRASTI. See FAGOPYRUM.

ERYSIPELACEA, } Called alſo *Antonii ſancti ignis*;
ERYSIPELAS. } *ignis ſacer*; *brunus*; *herpes ferus*; *ignis Perſicus.* Authors vary in their derivation of this word. Conſtantine and Martinius derive it from ερυω, *to draw*, πιλας *prope, the neighbouring parts.* Pollux calls the word ερυθρομελαν, from ερυθρος, *red*, and μελας, *black*, from its variety of colours. And this name ſeems to be from the colours which this diſorder induces in the parts it affects. Hippocrates calls this diſorder επιφλογισμα; the Latins call it *ignis ſacer* when it is of the ulcerated kind: it is alſo called *zoſter, zona, macula lata*; the GIRDLE; SHINGLES: in Switzerland it is called the *violet*: ſome name it *the roſe*, from its red colour. GALEN and CELSUS name the eryſipelatous inflammation *phygethlon.* The common Engliſh term is SAINT ANTHONY'S FIRE.

The *true ſpecies* is acute and inflammatory.

Dr. Cullen places this genus of diſeaſe in the CLASS, PYREXIÆ; and ORD. EXANTHEMATICÆ, which he defines, an inflammatory fever of two or three days, attended with ſomnolency commonly, often with delirium. In ſome part of the ſkin, moſt frequently on the face, there is an erythematous inflammation. See PHLOGOSIS, ERYTHEMA. He diſtinguiſhes two ſpecies, 1. *Eryſipelas veſiculoſum*, an erythema with a ſpreading redneſs occupying a broad ſpace, which in ſome of its parts run into large bliſters. This comprehends the ERYSIPELAS; *roſa*; *typhodes*; *peſtilens*; *contagioſum*; FEBRIS *eryſipelatoſa* of Sydenham;—an erythema conſiſting of many pimples occupying particular parts of the trunk of the body, and running forthwith into phlyctenæ, or ſmall bliſters. This comprehends the ERYSIPELAS *zoſter*;—*zona*, ſhingles; ZONA IGNEA of Hoffman; HERPES ZOSTER. When ſymptomatic—ERYSIPELAS *a veneno.* The term eryſipelas has been applied by medical writers to the erythematous inflammation, as well as the eryſipelatous fever; but SAUVAGES properly uſes the term vitium cutaneum, becauſe where only a ſymptomatic fever attends, he would have it called erythema; an eryſipelas, only, when that exanthematic fever, which an erythema follows; and this will be found a neceſſary practical diſtinction, which Dr. CULLEN has judiciouſly adopted. 2. *Eryſipelas phlyctænodes.*

This diſorder may be on any part of the body; but the face is moſt frequently affected, the arm next, and then the feet and other parts. The ſeat of the true ſpecies is in the ſurface of the ſkin; Heiſter ſays in the ſcarf-ſkin and fat contiguous thereto, and the internal membranes.

Autumn, or when hot weather is ſucceeded by cold and wet, are the ſeaſons which favour this diſeaſe, and in which it moſt frequently happens. The ſanguine and plethoric, young people, and pregnant women, are the moſt ſubject to it. Thoſe who have once been affected are very liable to future attacks.

The cauſes are in general the ſame as thoſe which produce other kinds of inflammations; but *chiefly ſudden cold ſucceeding a great heat or ſweat, obſtructed perſpiration*, and an *acrimonious blood.* TISSOT ſays that it reſults from two cauſes: 1ſt. *An acrid humour*, which is commonly bilious, *diffuſed through the maſs of blood*: of this opinion were Hippocrates and Galen. 2dly, *The humours not being duly diſcharged by perſpiration.* MAGANISE, in his Doctrine of Inflammations, obſerves that a glutinous humour is ſupplied by the ſebaceous glands, to preſerve the ſenſibility of the ſkin and keep it moiſt, by checking, in ſome meaſure, the egreſs of the fluid which goes off through its pores; this glutinous humour being wanting in an *eryſipelas*, the ſkin is dry and parched, becauſe the erethiſm of the veſſels is but ſmall, and the morbific humours, having nothing in their way to retard their egreſs, exhale through the expiring veſſels of the ſkin; and that it is by the want of this glutinous humor that an *eryſipelas* differs from any other inflammation of the ſanguine or phlegmonic kind. From the want of a tumor ſomewhat ſimilar to the ſebaceous, it is, that other membranes are the ſeat alſo of an *eryſipelatous* inflammation.

The diagnoſtics of this diſeaſe are well deſcribed by Tiſſot. It begins with a violent ſhivering, which is ſucceeded by a burning heat, a vehement head-ach, ſickneſs, or reaching to vomit, which continues till the *eryſipelas* appears, which ſometimes does not happen till the ſecond or third day; the fever then abates, and the ſickneſs goes off; though frequently a leſs degree of ſickneſs, or loathing, and of fever remaining during the whole time of the increaſe of the diſeaſe. When the inflammation and eruption happen in the face, the head-ach continues until the decline of the diſeaſe; the eye-lids ſwell, the eyes cloſe, and the patient hath no eaſe. It often paſſes from one cheek to the other, and extends ſucceſſively over the forehead, neck, and nape of the neck, under which circumſtance the diſeaſe is of a more than ordinary duration. Sometimes alſo, when it exiſts in a high degree, the fever continues, the brain is oppreſſed and obſtructed, the patient raves, and his caſe becomes exceeding dangerous. A violent *eryſipelas* in the neck brings on a quinſey, which is very grievous, and often fatal. When it attacks the leg, the whole of it is ſwelled up, and the heat and irritation from it is extended up to the thigh. Whenever the tumor is conſiderable, the part it ſeizes is covered with ſmall puſtules, filled with a clear watery humour, reſembling thoſe which appear after a burn: theſe afterwards dry and ſcale off. Sometimes, when this diſtemper affects the face, the humour which iſſues out of theſe puſtules is thick and gluey, and forms a thick ſcurf and ſcab nearly reſembling thoſe of ſucking children, and they continue faſt on the face many days before they fall off. When the diſeaſe is violent, it continues eight, ten, or twelve days at the ſame height, and is at laſt terminated by a very plentiful ſweat, that may ſometimes be predicted by a reſtleſſneſs, attended with ſhivering and a little anxiety of ſome hours duration. In the progreſs of the diſeaſe, the whole ſkin, and even the inſide of the mouth is very dry.

An *eryſipelas* rarely comes to ſuppuration; when it does the ſuppuration is always unkindly, and much diſpoſed to degenerate into an ulcer. Sometimes a malignant kind of *eryſipelas* is epidemical, and then it often terminates in

a gangrene. This diſtemper often ſhifts its ſituation, it ſometimes retires ſuddenly; but the patient is uneaſy and diſordered; he hath a propenſity to vomit, with a ſenſible anxiety and heat; the *eryſipelas* appears again in a different part, and the patient feels himſelf quite relieved from the preceding ſymptoms. But if, inſtead of re-appearing on ſome other part of the ſurface, the humour is thrown upon the brain, or the breaſt, he dies within a few hours; and theſe fatal changes and tranſlations ſometimes occur without the leaſt reaſon or colour for aſcribing them either to any error of the patient, or his phyſician. If the humours have been transferred to the brain, the patient immediately becomes delirious, with a highly-flushed viſage, and very quick ſparkling eyes; ſoon after he proves frantic and goes off in a lethargy. If the lungs are attacked, the anxiety and heat are inexpreſſible. There are ſome conſtitutions ſubject to a very frequent, and, as it were, an habitual *eryſipelas*: if it often affects the face, it is generally repeated on the ſame ſide of it, and that eye is at length conſiderably weakened by it.

Sydenham reckons the ESSERA (which ſee) a ſpecies of *eryſipelas*.

The *eryſipelas* ſhould be diſtinguiſhed from the plague, and from inflammations of different kinds that happen on the ſkin.

As to the prognoſtics, many of them may be noted from the diagnoſtics above related: when it approaches ſuddenly, but with little diſturbance, and attacks a perſon with a good habit, and when no nervous, membranous, or principal parts are affected, there is but little to be apprehended from it. Sometimes a convulſive diſeaſe, as an aſthma, colic, &c. hath been relieved by the approach of an *eryſipelas*. Danger is very conſiderable when this diſorder is deeply ſeated, fixed on a ſenſible part, and the habit of body but indifferent: in ſome bad habits this diſorder leaves behind it a ſwelling in the foot, or ankle, or both, which is both troubleſome and difficult to remove; by bad management it is eaſily and ſoon rendered fatal; frequent returns denote a diſordered liver or gall-bladder; when it is ſeated in the face, a drowſineſs often attends it, in which caſe there is danger of a phrenitis, or of a mortal lethargy; when it ſeizes the breaſts, particularly of women in child-bed, or who give ſuck, an abſceſs is the conſequence for the moſt part: if the noſtrils and mouth are dry, and the patient is drowſy, an inflammation of the brain is to be ſuſpected; it is generally fatal within the ſeventh day, when the patient dies; and they who are often ſeized with it, at laſt die of it.

IN ORDER TO THE CURE, the diet ſhould be thin and perſpirative; roaſted apples may be eaten freely: the drink may be whey, barley-water, ſmall beer, water-gruel; or if the pulſe ſinks, ſmall negus may be allowed. The patient ſhould keep out of the bed during ſome hours in the day. But equal care ſhould be taken to guard againſt the extremes of heat and cold; our firſt endeavour by medicine ſhould be to remove this diſorder by reſolution. In the lighter caſes, perſpiration may be kept up with frequent draughts of camomile or of elder-flower tea, acidulated with the ſpt. ſeb. Di. Clutton, or with other cooling perſpiratives. If the face and head be affected, gentle but repeated purging is to be directed; they ſhould alſo be continued until all danger ſeems to be alleviated. But if the pulſe is ſtrong and hard, bleed, and repeat it as the fever and ſtrength of the patient indicate; in this caſe, beſides nitre and other cooling perſpiratives, the bowels may be kept ſoluble by means of whey, prepared by turning cow's milk with cream of tartar, tamarinds, &c. Dr. FREIND obſerves that when the head is affected, purges are the ſpecifics; but it may be added, that in ſuch like caſes ſinapiſms may be applied with ſingular advantage to the ſoles of the feet.

From an admiſſion of cold air the *eryſipelatous* matter is ſometimes ſtruck inwardly; when this happens, bleed immediately, apply bliſters on the ſides of the neck, one on the part from whence the inflammation receded, and ſinapiſms to the feet; at the ſame time forget not to adminiſter a purge, and to repeat the like as the caſe may require.

When the pulſe is low, cordials and the warmer perſpiratives ſhould accompany the uſe of bliſters.

When an eryſipelas attacks, or *is repelled to the lungs*, the only chance of life is to divert it therefrom, and fix it on the external parts: in this caſe, beſides the fever, pain in the breaſt, and other violent ſymptoms, the patient frequently faints; and what is worſe, he rarely ſurvives his ſufferings.

Bliſters are often uſeful, but ſhould be applied as directed under emp. veſicat. mitior. in the article CANTHARIDES, which ſee.

In the wandering kinds of this diſorder, give half an ounce of the rob. ſambuc. four times a day with five or ſix grains of the kali vitriolat. in each doſe; every third day give a cooling purge, place the patient every evening in a pediluve, and after it apply ſinapiſms to the feet.

From the nature of this diſeaſe, and from the peculiarities in the ſkins of different perſons, much caution is required in the application of external remedies. When the ſcarf-ſkin is raiſed in bliſters, and the ſerum begins to tranſude, then apply abſorbing external medicines, ſuch as chalk finely powdered, or a thin rag may be ſpread over the inflamed part, and the chalk or fine flower ſprinkled upon the rag; or, inſtead of theſe, flannels wrung out of a decoction of elder and camomile flowers may be applied as often as they grow cool. Among liquids, Goulard's ſaturnine water is one of the beſt applications, and may ſafely be uſed in every caſe where a reſolution of the inflammation is the aim. See alſo SECALE.

If, notwithſtanding all endeavours to diſcuſs, *the ſymptoms of a ſuppuration ſtill prevail*, encourage them by applying the common white bread poultice, with ſaffron mixed in it.

If a gangrene is threatened, beſides the inward uſe of camphor and the bark, ſpirituous and ſtrengthening applications ſhould be employed externally, ſuch as mixtures of lime-water with camphorated ſpirit, or camphorated ſpirit mixed with tincture of myrrh, or an infuſion of the bark.

It may be obſerved here, that the *eryſipelas* is not always of the phlegmonic but ſometimes of the nervous or low kind. It ſometimes appears with a redneſs in the ſkin; a kind of puffineſs inſtead of a ſwelling; the pain is more acute, but the throbbing of the veſſels leſs; no circumſcribed tumour, but the parts are more inflamed; at the decline of the diſeaſe the redneſs of the ſkin becomes of a purple hue; it is very liable to terminate in a mortification; the habit from the firſt, and throughout, is very irritable, and the ſtrength depreſſed. It generally attacks the heart and præcordia, and is accompanied with cardialgia, itching, inflammation of the ſkin, painful exulcerations, and ſmall lucid puſtules.

It is true, in ſome ſtrong habits, both a phlegmonous and the low *eryſipelatous* inflammation attend together, in which caſe, a moderate bleeding may ſometimes have its uſe, but ſhould be cautiouſly admitted. If the low *eryſipelatous* inflammation attacks, and the patient labours under great depreſſion of ſtrength, irritability, &c. we muſt ſupport him with wine, and keep up his ſtrength by the ſame; when bliſters ariſe, it happens from the ſalts of the watery parts of the blood being thrown out upon the ſurface and there ſtimulating; in this caſe the bark may be freely given, from ʒ vj. to ʒ i. or more if the ſtomach will bear it, in twenty-four hours. When the puſtules are all out (and not before) and ripened, ſnip the bliſters, and drink up the fluid with ſoft rag, then apply the ung. ſperm. ceti; or ung. lapid. calamin. See Wallis's Sydenham, Heiſter's Inſt. of Surgery, p. i. lib. iv. c. vi. p. 290. Mageniſe on Inflammations. Cullen's Firſt Lines, edit. 4. vol. ii. Kirkland's Medical Surgery, vol. i. p. 329, 404. Pearſon's Principles of Surgery, vol. i. p. 173. and White's Surgery, p. 12.

ERYSIPELAS BULLATUM, and INFLAMMATORIUM. See ŒDEMA ERYSIPELATOIDES.

—— CURANS ARBOR. See MALLEAMOTHE.

—— INFANTORUM. *Eryſipelas of infants.* This diſorder ſeems to be firſt noticed by Dr. Underwood, who, in his Treatiſe on the Diſeaſes of Children, calls it Anomalous Inflammation; though in treating of it he ſays infants are liable to a kind of *eryſipelatous* inflammation.

It never appears, I think, later than the month, but moſt frequently ſhews itſelf a few days after birth. It attacks the moſt robuſt as well as delicate children, and in an inſtantaneous manner: the progreſs is rapid; the ſkin turns of a purpliſh hue; and ſoon becomes exceedingly hard.

The milder ſpecies of it appears often on the fingers and hands, or the feet and ankles, and ſometimes upon or near the joints, forming matter in a very ſhort time. The more violent kind is almoſt always ſeated about the pubis, and extends upwards on the belly, and down the thighs and legs; though I have two or three times ſeen it begin in the neck. The ſwelling is but moderate, but

after

after becoming hard, the parts turn purple, livid, and very often ſphacelate; eſpecially in boys, when it falls on the ſcrotum. The penis ſwells, and the prepuce puts on that kind of emphyſematous appearance, which it has in children, when a ſtone is ſticking in the urethra.

Various means have been made uſe of without ſucceſs; though for a time ſome benefit was received from ſaturnine fomentations and poultices, applied on the very firſt appearance of the inflammation: but it ſoon ſpread, and a gangrene preſently came on; or, where matter had been formed, the tender infant ſunk under the diſcharge. It is now ſome years ſince I propoſed making trial of the bark, to which ſometimes a little confectio aromatica has been added; from which time ſeveral have recovered. Dr. Garthſhore has lately tried the application of linen compreſſes wrung out of camphorated ſpirit of wine, in the place of the vegeto-mineral water, which has proved very ſucceſsful in ſeveral inſtances; nevertheleſs, the greateſt number of infants attacked with this diſorder, ſtill ſink under its violence, and many of them in a very few days.

ERYSIPELAS PULMONIS LOMMII, See INFLAMMATIO CORDIS.

—— CONTAGIOSUM. } h. s. ERYSIPELAS VESICULOSUM. See ERYSIPELAS.
—— PESTILENS.

—— PHLYCTÆNODES. } The SHINGLES. See ERYSIPELAS.
—— ZOSTER & ZONA.

ERYSIPELATOIDES, from ερυσιπελας, *an eryſipelas*, and ειδος, *likeneſs*. It is a tumor reſembling the *eryſipelas*, or a ſpurious *eryſipelas*, called ŒDEMA ERYSIPELATOIDES.

ERYSISCEPTRUM. See ASPALATHUS.

ERYTHEMA. See INFLAMMATIO.—Sp. 2. *Phlogoſis Erythema.*

—— A FRIGORE. See PERNIO.

—— AMBUSTIO. The ſame as combuſtura, or rather the inflammation cauſed by burns or ſcalds.

—— GANGRÆNOSUM. See CARBUNCULUS.

ERYTHRION. The name of an amalgama in P. Ægineta.

ERYTHRODANUM. See RUBIA TINCTORUM.

ERYTHROEIDES, from ερυθρος, *red*, and ειδος, *form*. See TESTES.

ERYTHROXYLON. See POINCIANA.

ESAPHE, from ισαφαω, *to feel with the fingers*. The touch of feeling the mouth of the womb, to know its ſtate.

ESCAPATLI. A ſpecies of SENA.

ESCHARA, vel ESCURA. An ESCHAR or CRUST. In SURGERY it is a hard cruſt, or a ſcab upon the fleſh, formed by the application of a red-hot iron, a cauſtic, or ſome ſharp humour of the body. Alſo a SLOUGH, formed on a wound or ulcer, and is an inſtance of mortification. Likewiſe the name of a ſub-marine plant which reſembles a net or cobweb, called *frondipora*; *porus reticulatus*. Boerhaave mentions three ſpecies. Their virtues are ſimilar to thoſe of coral; but none of them obtain in practice.

ESCHAROPEPA. In Hippocrates it is a term for roaſted barley-meal.

ESCHAROTICA, from ισχαροω, *to burn into a cruſt*. ESCHAROTICS, called alſo, *erodentia*, *cauſtica*, *cauteria*. Subſtances which diſſolve the ſolid matter of the human body; and they are indicated in all thoſe caſes in which either a portion of the ſolid matter is to be taken away, or when the texture of it is to be deſtroyed, ſo as it may fall off either ſpontaneouſly, or by mechanical means, may be eaſily ſeparated from the other parts.

CAUSTICA, *cauſtics*, and *eſcharotics*, differ only in degree, both being what deſtroys any fleſhy part to which they are applied on living bodies. Van Helmont firſt aſſerted their inefficacy on dead bodies; and Dr. Petit of Paris confirmed it. Theſe kinds of applications do not act upon the body from any innate power in themſelves, but only as actuated by the heat and moiſture of the circulating fluids which are found to be ſo eſſential to their action, that on the dead body they produce no alteration: they firſt heat the fluids in the part to which they are applied, and rarify them ſo as to burſt their veſſels; then the finer parts flying off, the part is left dry, and incruſted.

CAUTERIA, *Cauſtics*, or *cauteries*, are diſtinguiſhed into *actual* and *potential*. *The actual* is real fire, that is, an iron made red-hot, called by Celſus, *ferramenta candentia*; but theſe, on account of their terrifying appearance, as well as the pain which they occaſion, are now laid aſide. Theſe act on the ſolids. The *potential* are thoſe which do not act with immediate burning, but only as the body is diſpoſed to favour their action. The chief of theſe are what were called CAUSTICUM *lunare*,—*commune fortius*,—*antimoniale*—*lapis infernalis*; now named argentum nitratum, calx e kali puro, antimonium muriatum. They act by the acrid ſalts which they contain.

Their uſe, beſides that of deſtroying excreſcences, &c. is to open large abſceſſes where there is danger of cutting ſome adjacent veſſel, or when the knife appears horrid to the patient. In this caſe, the common milder *cauſtic* generally ſuffices, and may be thus applied; lay a piece of ſticking-plaſter on the ſoft part of the abſceſs, having previouſly cut a hole in it, nearly as big as the eſchar is to be made; then in the hole of the plaſter lay the *cauſtic*, which muſt be ſecured by another piece of ſticking plaſter: when the ſkin is not inflamed, the *cauſtic* very often occaſions little or no pain. When the *cauſtic* hath produced its effect, an opening may be made through it for the diſcharge of the pus, but the reſt may digeſt away. When iſſues are made by *cauſtics*, or bones laid bare by them, the eſchar muſt be cut out immediately, or the next day, leſt new fleſh ſhould fill up the part which is opened. To lay a bone bare, or to make an iſſue, let the *cauſtic* lay on *about four hours*; to deſtroy a large gland, lay it *on ſix hours*; but to open an abſceſs, it may remain two or three hours, according to the thickneſs of the ſkin, though generally, when the effect of the *cauſtic* is completed, the part on which it is applied ceaſes to be uneaſy.

When a large fungus is to be deſtroyed by a *cauſtic*, the method deſcribed in the Edinb. Med. Eſſays ſeems moſt eligible; it is as follows: the lap. infern. was applied to a tumor on the coats of the teſtis: after the ſeparation of the *eſchar*, the lap. infern. & ol. vitr. were alternately uſed, by rubbing the part firſt with the lap. infern. then in leſs than a minute after, with a fir ſtick dipped in the ol. vitr. which inſtantly removed the pain occaſioned by the lap. infernalis; at each dreſſing, this alternate application of theſe oppoſite *cauſtics* was repeated, till as much was waſted as was then thought convenient; the moiſture was abſorbed by an armed probe, and a digeſtive applied. This method prevents the continuance of pain, and is not productive of any degree of inflammation; it is alſo recommended for the removal of ſcirrhus, or any other kind of tumor that admits of a *cauſtic* being made uſe of.

Mr. John Hunter recommends a mixture of opium with *cauſtics*, in order to leſſen the pain which they occaſion. See CAUSTICUM OPIATUM. White's Sugery, p. 188.

ESCARPE. See FASCIA.

ESCHEL. It is an imperfect zaffer. See COBALTUM.

ESCORZONERA. See SCORZONERA.

ESCULUS. A ſpecies of oak is thus named.

ESCURA, See ESCHARA.

ESDRÆ ANTIDOTUS. An antidote deſcribed by P. Ægineta.

ESEBON. See MARINUM SAL.

ESOCHE, from εσεχω, *to protuberate*. A tubercle within the anus; from εσω, *within*, and εχω, *to have*.

ESPHLASIS, from εσφλαω, *to recede inwards*. A receſſion of a part inwards from ſome violent outward impreſſion.

ESSATUM POTENTIALE. The medicinal power or virtue which reſides in vegetables and minerals.

—— VINUM. Spirit of wine impregnated with the medicinal virtues of vegetables.

ESSENTIA. The ESSENCE of any thing. From philoſophy this word hath been transferred to chemiſtry, where it ſeems ſtrictly to import the diſtinguiſhing part of medicinal ſimples, ſeparated from all other parts of the body which contained it.

—— ABIETIS. See ABIES.

—— NEROLI. See AURANTIUM.

ESSENTIALE SAL. See DIURETICUS SAL.

ESSENTIALIS. ESSENTIAL. It is an epithet for ſalts procured from vegetable juices by cryſtallization. How theſe ſalts are procured, ſee ACETOSA. When the viſcous juices of vegetables are uſed in this proceſs, as thoſe of comfrey, &c. the ſalt cannot be obtained without a previous fermentation to diſſolve their tenacity. Juices that contain an oil or a balſam will not eaſily yield

their ſalt, for oils and balſams prevent the cryſtallization of the ſalts. Theſe ſalts are never alcaline, though by burning they are convertible into an alcaline.

The oils peculiar to different vegetables are alſo called *eſſential*.

Some fevers are called *eſſential* or *idiopathic* by way of diſtinction from the ſymptomatic.

ESSENTIALIS SAL, ESSENTIAL SALT. This name is given to all concrete ſaline ſubſtances, which preſerve the ſmell, taſte, and all other principal qualities of bodies from which they were obtained, which bodies are only vegetable and animal. The uſual method of preparing them, is by evaporating, to almoſt the conſiſtence of a ſyrup, the liquors containing the *eſſential ſalt*, viz. the expreſſed and depurated juices and ſtrong decoctions, and by keeping them in a cold place. The cryſtals which ſhoot from theſe liquors may be depurated by diſ ſolving them in water, filtrating, evaporating, and cryſtallizing.

Very often the ſalts thus obtained from animal and vegetable matters are nothing but vitriolated tartar, vitriolated natron, nitre, common ſalt, and other ſuch neutral ſalts, which ought not to be conſidered as the *eſſential ſalts* of the ſubſtances from which they are extracted: thoſe only are the *eſſential ſalts*, in the combination of which we find oily parts, which cannot be ſeparated from them, unleſs the ſalt be decompoſed. See ESSENTIALIS and ESSENTIAL SALT in the Dict. of Chemiſtry.

ESSERA. The CHRONICAL NETTLE-RASH. It is called *eſſere*, *ſera*, and *ſara*, by the Arabians; Sydenham calls it a BASTARD or SCORBUTIC ERYSIPELAS; and this, he ſays, is with or without ulcerations. What PLINY calls zoſter, and others call zona, he reckons a ſpecies of this diſorder: ſome name it the NETTLE-SPRING, from its reſemblance to the eruptions excited by the ſtinging of nettles. Dr. CULLEN ſays, there is a diſeaſe among the Engliſh called the NETTLE-RASH, which by ſome is conſidered as the *urticaria*. But the NETTLE-RASH, as deſcribed by Dr. HEBERDEN in the London Med. Tranſact. and ſuch as Cullen hath often ſeen, is totally different from the urticaria of noſologiſts, in as much as that it is chronical without fever, may be numbered with the diſorders in the order impetigines.

The *eſſera* is a ſpecies of tumor not mentioned by the Greeks nor Latins. It is a chronical diſorder, and is ſeated in the ſkin.

Some people are affected with it only when the weather is froſty, others only in the hotteſt months. Perſons of all ages and of both ſexes are ſubject by it.

In ſome patients this diſorder takes its riſe from cauſes which prove curative in others. SENNERTUS ſays, the cauſe is in the ſerum. Dr. HEBERDEN intimates, that whatever it is which produces the itching and tubercles in the ſkin, when muſcles, &c. diſagree with thoſe that eat them, it is the ſame cauſe which produces the *eſſera*.

This diſorder appears in the ſkin in the form of ſmall white hard tubercles; ſometimes there are very broad tumours, and long ones alſo, ſuch as appear after being ſtruck with the laſh of a whip; an intolerable itching attends them, and generally the ſkin is inflamed and very red in the ſpaces betwixt the eruptions. The elevations appear ſuddenly, they ſeldom continue long, and are apt to diſappear from one part and appear again in another. No part of the body is exempt from this complaint. When many of the tubercles appear together, the part ſeems ſwelled. In ſome inſtances this diſorder totally diſappears in a few days, in others it hath continued many months, and even years, diſappearing at times, but returning after very ſhort intervals. For the moſt part the itching is the only inconvenience, and this indeed is ſometimes ſo great as to deprive the patient of his ſleep; but ſome patients complain of ſickneſs, head-ach, or other troubleſome ſymptoms during the preſence of the eruptions, whilſt others are only thus affected on their ſuddenly ſinking in.

SERAPIO ſays, there are two ſpecies of *eſſera*, but his diſtinctions do not ſeem well grounded.

The *eſſera* ſhould be diſtinguiſhed from that ſpecies of itch which appears in the form of dry pimples at the firſt, but ſoon after have a thin ſerum lodged on their apex, in the manner of a ſmall veſicle. Some confound the *eſſera* with the epinyctides, but the latter hath alſo a thin humour which oozes from them.

No danger attends this complaint, either as to life or health, any farther than the itching may hinder ſleep.

As to the cure, the only indication is to allay the itching; how to anſwer this is difficult to ſay, becauſe of the different effect which follows from the application of the ſame remedy in a variety of caſes. In ſhort, this diſorder ſeems to ſtand without any rational preſcription for its cure. Rubbing the parts with parſley juice has been ſaid to be of uſe in taking off the itching. When it has been of ſome continuance, I have ſeen diuretics of ſervice; now and then, interpoſing purgatives of the ſaline kind, which have ſucceeded a doſe of calomel given at bed time. See Sennertus, Wallis's Sydenham, and Dr. William Heberden's Remarks on the *Nettle Raſh*, in the ſecond volume of the Lond. Med. Tranſ.

ESTHIOMENOS, *ἐσθιω, to eat*, from *ἐσθιομαι, to eat*. EATING, CORRODING. An inflammation in the ſkin, attended with a ſharp humour, more properly the herpes exedens. It is indeed any inveterate ulcer.

ESULA, vel EZULA. SPURGE. There are many ſpecies of plants which bear this name, for which, beſides what are here inſerted, there are others which rank under the article *tithymalus*.

—— INDICA, called alſo *tithymalus orientalis arboreſcens, triquetrus ſpinoſus*, and *talukghaha*. The plant that produces the *bogia gum* differs not from this ſpecies of *eſula*; but, as Sydenham obſerves, there are two ſpecies of gamboge, one collected from a plant called *cambodia*, and the beſt ſort from the *codampulli*.

The *ſpurges* generally agree in their containing a milky juice, which is violently emetic and cathartic; and, if applied to the ſkin, corroſive.

—— MAJOR, alſo called *tithymalus paluſtris fruticoſus, tithymalus magnus multicaulis*, GREAT MARSH SPURGE, and GERMAN SPURGE; alſo the GARDEN SPURGE.

—— MARINA. See TITHYMALUS MARITIMUS.

—— MINOR, alſo called *pityuſa, tithymalus foliis pini tithymalo cypariſſæ ſimilis*, and PINE SPURGE. Some have named it the COUNTRYMAN'S RHUBARB.

—— SOLISEQUA. The SUN SPURGE. See TITHYMALUS HELIOSCOPUS.

ETESIÆ. Certain annual winds. Pliny ſays, that the *Aquilones*, north-eaſt winds, are called *Prodromi*, and that they blow eight days before the dog-ſtar riſes. He alſo obſerves, that the *Eteſian winds* (theſe are the ſame north-eaſt winds) ſet in two days after the dog-ſtar riſes, and continue forty days. Proſper Alpinus informs us, that the *Eteſian winds* blow in Egypt when the ſun enters Cancer, and blow almoſt all June, July, and Auguſt; and that at the riſing of theſe winds, the Nile riſes, and the peſtilence ceaſes. The ſouth wind brings the peſtilence there; and theſe winds they call *Campſin*, from *Campſis, a general*, who, with his whole army, was ſuffocated in the ſands which were driven upon them by theſe winds.

ETHEL. It imports both fire and blackneſs. In chemiſtry, the words *ethel, terra alba, ſulphur album, fumus albus, almagra, auripigmentum*, and *magneſia*, all mean the ſame thing.

ETHER. See ÆTHER.

ETHICA. See HECTICA.

ETHMOIDES, os, from *ἠθμος, ſtrainer*, or *ſieve*; *εἰδος, a form*; called alſo *cribriforme os*; *cribroſum os*; *coliforme os*; *foraminulentum ſpongioſum os*. This bone is placed between the two orbits of the eyes, where there is a notch left for its inſertion. The cribriform lamella is the internal plain, thin, horizontal plate, which hath a ſuperior middle eminence called *criſta galli*, to which the beginning of the falciform proceſs is attached; round the *criſta galli*, except at the hind part, this lamella is pierced obliquely by many ſmall foramina, through which the filaments of the olfactory nerves paſs. From the middle of the cribriform lamella, the naſal lamella riſes extremely thin, but at its anterior extremity it becomes thicker. At a little diſtance from each ſide of this lamella, a cellular bony ſubſtance is obſervable; the figure of the cells is uncertain, they communicate with the frontal ſinuſes, and with the cavity of the noſe, and are the external lateral portion of the ethmoid bone; their outward poſterior ſurface is ſmooth, hence called *os planum*; it makes a part of the orbit. The *oſſa ſpongioſa*, or *turbinata ſuperiora*, are ſituated at the inferior part of the cellulæ; their figure is oblong, and they are ſharp at their extremities.

The cribriform lamella is the body, as it were, of the ethmoid

ethmoid bone; and it is ſo thin, that it may eaſily be puſhed through by a probe: when it is hurt, the accident is uſually fatal.

ETRON. See HYPOGASTRIUM.

ETYTHOXYLUM BRASILIANUM. See BRASILIUM LIGNUM.

EUANASPHALTOS, from εὖ, *eaſe*, and ἀνασφάλλω, *to recover ſtrength*. One who is ſoon reſtored.

EUANTHEMON. See CHAMÆMELUM.

EUAPHION, from εὖ, *eaſe*, and ἁφὴ, *the touch*. A medicine for the hæmorrhoids. Galen takes notice of it. It hath its name from its gentleneſs.

EUCARISTOS. An epithet for an antidote in N. Myrepſus.

EUCHROON. A plaſter mentioned by S. Largus.

EUCOILIA. See CERASUS.

EUELPIDIUM. A liquid collyrium. See DIASMYRNON.

EUELPISTI. A plaſter deſcribed in S. Largus.

EUEMBOLOS, from εὖ, *well*, ἐν, *in*, and βάλλω, *to caſt*. One expert at ſetting of bones.

EUEMETI, from εὖ, importing *facility*, and ἐμέω, *to vomit*. Thoſe who vomit with eaſe.

EUERES, from εὖ, *well*, and ἐρετμὸς, *an oar*, Eaſy to be rowed. But Hippocrates uſes naval terms, and applies this word to inſtruments. In his book de Medico, it ſignifies *ready* or *handy*.

EUEXIA, from εὖ, *well*, and ἕξις, *a habit*. A good habit of body.

EUGEOS, from εὖ, *well*, and γῆ, *the earth*. See UTERUS, and HYMEN.

EULE. A worm, properly that is bred in ulcers.

EULOGIUM. In Foreſtus from Rhaſes, it ſignifies an exanthematous diſorder, the ſmall-pox, or the meaſles.

EUNUCHION. See LACTUCA. It is ſaid to be thus called becauſe Venus laid upon a bed of them after the death of Adonis, to reſtrain her venereal inclinations.

EUONYMO ADFINIS OCCIDENTALIS. See GUAIACUM.

EUONYMUS, alſo called *tetragonia*, *fuſanus*, *fuſaria*, PRICKWOOD, and the SPINDLE-TREE. Boerhaave enumerates four ſpecies, and Miller reckons up ten. In France and Germany, the wood is made into ſpindles, whence the names *fuſanus* and *fuſaria*. The fruit is emetic and cathartic, and if powdered, and ſprinkled in the hair, it kills lice. Raii Hiſt. See alſo SIMAROUBA.

EUPATORIUM, alſo called *hepatorium*, *cannabinum*, WATER HEMP, WATER AGRIMONY, DUTCH AGRIMONY, and COMMON HEMP AGRIMONY. See AGRIMONIA. The *eupatorium* uſed in medicine, is the EUPATORIUM CANNABINUM, Linn. It is a plant in much uſe in Holland, but not in England; it is found on the ſides of ditches and rivers; is acrid and bitter to the taſte; the leaves are ſtrengthening and aperient. Boerhaave ſays, that the turf-diggers uſe it againſt foul ulcers, the ſcurvy, and ſwelling of the feet, to which they are very ſubject. The root is cathartic. Two ounces of the freſh juice, or a dram of the extract, is a doſe. Raii Hiſt. It is alſo the name for a ſpecies of *Baccharis*.

—— ARABUM. See BIDENS.

—— GRÆCORUM. } See AGRIMONIA.
—— VERUM & VETERUM. }

—— MESSUE. See AGERATUM.

EUPEPSIA, from εὖ, *good*, and πέπτω, *to digeſt*. GOOD DIGESTION.

EUPETATON. See LAUREOLA MAS.

EUPHORBIA PALUSTRIS. See TITHYMALUS.

EUPHORBIA, εὖ, *well*, and φορέω, *to feed*; ſo named by king Juba, who firſt found it out, in honour of Euphorbus his phyſician; called alſo *ſchadida-calli*, *ſcadidacalli*, *tithymalus aizoides fruticoſus*, &c. The EUPHORBIUM PLANT, BURN. THORNY PLANT, SPURGE. EUPHORBIA OFFICINARUM, *aculeata*, *nuda*, *multangularis*, *aculeis geminatis*, LINN. Gen. Plant. 609. CLASS, DODECANDRIA; ORD. TRIGYNIA. It is a prickly lacteſcent ſhrub; from it the gummy, reſinous, concrete juice, called GUM EUPHORBIUM, exudes. This gum is brought from Barbary in drops, or tears, of an irregular form, ſome of which when broken, contain little twigs, and other vegetable matters. The tears are generally very eaſy to break; they are of a gold colour outwardly, and white within; they conſiſt of equal parts of reſinous and gummy matter; their acrimony reſides in the reſin.

The ſpirituous tinctures are exceſſive fiery, and when inſpiſſated they are ſtill more ſo. The watery infuſion and extract are bitteriſh, having only a ſlight though durable acrimony. Neither ſpirit nor water carries over any thing from this gum by diſtillation.

This drug is too acrid for internal uſe; it is a part in the compoſition of ſome ſtimulating plaſters which are uſed in palſies and ſome other diſorders. There are two compoſitions as plaſters, formed in the following manner.

EMPLASTRUM EUPHORBII. ℞ Picis burgundicæ ℥ iv. euphorbii ʒ ſs. terebinthinæ vulgaris q. s. pici burgundicæ liquefactæ adjiciantur euphorbium bene in pulverem redactum, & terebinthinæ portio, adeo ut inſpiſſitudinem propriam abeant. This is a powerful ſtimulant, well calculated to relieve diſeaſes of the hip joint, in their early ſtage.

EMPLASTRUM EX EUPHORBIO. ℞ Emplaſtri lithargyri ℔ ij. ſs. euphorbii bene pulverizati ℥ iij. picis burgundicæ ℥ ſs. euphorbium c. olei paululo in mortario teratur, poſtea, alia, prius liquefacta, adjiciantur. This is highly recommended for promoting the ſuppuration of ſluggiſh ulcers. Some have uſed it as an errhine, but it is too active for ſuch a medicine, for in very ſmall quantities it is liable to be very violent; the fine duſt which riſes in powdering, affects the operator's head and throat violently. Cullen's Mat. Med.

In the ſecond vol. of the Med. Muſ. is an inſtance of a perſon, who, through miſtake, ſwallowed ſome of the tincture of *euphorbium*, and was relieved by frequent draughts of water and olive oil, and a ſmall quantity of camphor. The ſymptoms produced by the *euphorbium* were a burning pain in the mouth, throat, and ſtomach, with a violent ſuffocation.

EUPHORIA, from εὖ, *well*, and φέρω, *to bear*. The eaſy bearing of a diſorder, or the operation of a medicine.

EUPHRAGIA, } called alſo *euphroſyne*, *ocularia*, EYE-
EUPHRASIA, } BRIGHT. It is the EUPHRASIA OFFICINALIS, Linn. Boerhaave mentions three ſpecies. It is an herb with little, oval, ſerrated leaves, ſet in pairs without pedicles; the flowers appear on the top of the ſtalks; they are white outwardly, but inwardly they are ſtreaked with purple and yellow. It is annual, grows wild in uncultivated grounds, and flowers from July to September.

It is a very mild corroborant, is ſlightly aſtringent, and hath been much extolled againſt diſorders in the eyes. Both ſpirit and water extract its virtues. Some take an infuſion of it, others uſe the powder in the manner of ſnuff, in caſes of dim-ſightedneſs. The following preparation, called PULV. HELIDÆI, hath been held in great repute. ℞ *Euphraſiæ* ℥ ii. macis, ʒ ſs. m. f. pulv. cap. ʒ i. ad. ʒ iii.

EUPHRASIÆ AFFINIS. BRAZIL SILIQUOSÆ. See CAA-ATAYA BRASILIENSIS.

EUPHROSYNE. See EUPHRASIA.

EUPORISTA, } from εὖ, *eaſy*, and πορέω, *to afford*.
EUPORISTON, } Medicines eaſily prepared.

EURYTHMIA, from εὖ, *juſt*, and ῥυθμὸς, *order* and *harmony*, properly in muſic. It imports dexterity in handling inſtruments; alſo the proper order of the pulſe, *eurythmus*. See ARYTHMUS.

EUROPEE. See VERONICA.

EUSARCHUS, εὖ, *bene*, and σαρξ, *caro*. WELL-FLESHED.

EUTHESIA. Galen explains it to be an innate ſtrong habit of body.

EUTHYPOROS, from εὐθὺς, *ſtraight*. An epithet of extenſion made with a view to reduce a broken limb.

EUZOMON. See ERUCA.

EVACUANTIA, from *evacuo*, *to evacuate*. Medicines ſuited to promote the natural excretions; or, in any other way to draw fluids out of the body. Theſe produce their effects by general principles, which capacitate them for other effects, according to the ſkill of the adminiſtrator, and not by a particular power of ſelecting bad humours from the good. The good and the bad are mixed in the body, and are evacuated in the ſame proportions.

EVACUATIO. See EXCRETA, and RETENTA.

EVACUATORII. Diſeaſes attended with increaſed diſcharges.

EVAPORATIO. EVAPORATION, called alſo *anathymiaſis*. It is a diſſipation of the finer parts of any fluid by means of the ſun or fire. Chemical *evaporation* is always carried on by heat, yet cold and winds cauſe water to evaporate. The hardeſt ice is not exempt from *evaporation*.

IN PHARMACY, ſome ſolid bodies are recovered from their ſtate

ſtate of ſolution by *evaporation* with heat. This proceſs is applicable to all thoſe ſubſtances which are leſs volatile than the menſtruum, or which will not exhale by the heat requiſite for the *evaporation* of the fluid, as ſolutions of alkaline ſalts, and the inodorous parts of vegetables and animals from water, and reſinous and odorous bodies in ſpirit of wine, as the tincture of mint made with ſpirit of wine, which, when ſeparated from the ſpirit by *evaporation*, leaves a reſin rich with the properties of the herb. See Dict. of Chem.

EVERRICULUM. In Paré, it is a ſort of ſpoon uſed to clear the bladder from gravel, &c. after lithotomy.

EVERSIO. See ECTROPIUM.

EVISTIOLA. In Paracelſus it ſeems to import a leprous diſorder in the nape of the neck.

EXACERBANTES. REMITTING FEVERS.

EXACERBATIO, called alſo *exoreſcentia*. See PAROXYSMUS.

EXACINATA. Fruits which have their ſtones taken out. See ACINUS.

EXÆMA, ἐξ, *ex*, and αἱμα, *ſanguis, exanguis*. A total privation of blood. Hence *exæmos* differs from thoſe called *leiphaimoi*.

EXÆRESIS, from ἐξ, *out of*, or *away*, and αἱρω, *to remove*. It is that part of ſurgery, which conſiſts of removing ſuperfluities.

EXALMA, from ἐξαλλω, *to leap out*. Hippocrates applies it to the ſtarting of the vertebræ out of their places.

EXALTATIO. EXALTATION. In CHEMISTRY, it ſignifies an operation by which a ſubſtance is raiſed to a greater degree of virtue. Of *exaltation* there are two kinds: firſt, *maturation*, which is effected by digeſtion, fermentation, and projection. Secondly, *gradation*, ſee GRADATIO. *Exaltation* is alſo defined a micro-chronic ſubtilization, by which a thing by a gradual diſſolution is tranſpoſed into a pure and more exalted degree of its virtue, and this is effected by circulation and ablution. Rulandus.

EXAMBLOMA, or EXAMBLOSIS. See ABORTUS.

EXANASTOMOSIS. See ANASTOMOSIS.

EXANG. The abbreviation of *Exanguis*. See EXÆMA. The bones and cartilages which are nouriſhed with a humour of their own nature, endowed with lentor and whiteneſs, are alſo called *exangues*.

EXANIA. The ſame as *procidentia*; alſo in particular, the bearing down of the anus.

EXANIMATIO. *Lipothymia*, or death.

EXANTHEMATA, from ἐξανθιω, to ſpring forth like a flower; called alſo *efflorатio*, and *efflorеſcentia*, *epantheſma* or *epanthiſma*. PUSTULES or ERUPTIONS. Eruptive fevers; any kind of *eruptions* that elevate the ſkin.

EXANTHROPIA. According to Wedelius, it is the third degree of melancholy.

EXANTHEMATA SEROSA. See PEMPHIGUS.

EXARMA, from ἐξαιρομαι, *to be elevated*. An elevated tumor.

EXARSIO, a hot intemperature, ſuch as happens in hectic fevers.

EXARTHREMA, from ἐξ, *out of*, and ἀρθρον, *a joint*. See LUXATIO.

EXARTHROS. An epithet for a perſon whoſe joints are large and prominent.

EXASPERATIO. EXASPERATION. Beſides its ſignifying the increaſe of a diſorder, it is alſo a rendering the ſkin rough.

EXCATHISMA. See SEMICUPIUM.

EXCIPIENS. In preſcriptions, that is called the excipient, which receives the other ingredients, and gives them a proper form; as officinal electaries, conſerves, robs, &c.

EXCIPULUM. In chemiſtry it is a receiver. See AMPULLA.

EXCISIO. See AMPUTATIO.

EXCLUSORIUM. A medicine which cauſes abortion.

EXCORIATIS, } EXCORIATURE, or ABRASION
EXCORIATURA. } of the ſkin, called alſo *ecdora*.

EXCREMENTUM. An EXCREMENT, from *excerno, to divide, part*, or *ſeparate*. It is whatever requires to be diſcharged out of the body.

EXCRESCENTIA, from *ex* and *creſco, an excreſcence*. It is any thing which grows peternaturally upon any part of the body, called alſo *cephyas, ecpyſis*.

EXCRETA & RETENTA. THINGS CAST OUT OF THE BODY, and THOSE THAT ARE RETAINED. The natural *excretions* do not ſo directly imply and abſolutely regard life, as they indirectly regard health, and the exercite of all the functions of life. The artificial evacuations from the circulating fluids are of blood, ſerum, and lymph; and theſe are made according as the plethora is of the ſanguine or ſerous kind: *by bleeding*, the red blood and the vital heat are diminiſhed; by purges, vomits, diuretics, &c. *the ſerous diſcharges* are made; and by perſpiration *the lymph* is evacuated.

The ſecretions are beſt performed in a regular ſtate of health; hence in diſeaſes, all turbulent ſymptoms ſhould be allayed with the greateſt ſpeed. And as the degree of heat in the conſtitution is that on which regular ſecretions chiefly depend, its exceſs or diminution demands our firſt attention, that its ſtate may be reduced as near as may be to the ſtandard of health.

EXCUTIA VENTRICULI. A bruſh made of ſoft briſtles, fixed in a flexible braſs wire, with ſilk or flaxen thread wrapped round it. When it is uſed, the patient drinks a quantity of warm water; then the *excutia* being dipped in ſome proper liquor, is paſſed down into the ſtomach, where it is moved about, the better to waſh the ſtomach.

EXECHEBRONCHOS. An epithet for a perſon who hath a prominent throat. See BRONCHOCELE.

EXECHEGLUTOS. One who hath prominent buttocks.

EXELCOSIS, from ἑλκος, *an ulcer*. See EXULCERATIO.

EXERAMA. The matter ejected by vomiting.

EXERCITATIO. EXERCISE. The *exerciſe* of the body for the benefit of health is called gymnaſtic. See GYMNASTICA. The military *exerciſes*, gardening, huſbandry, or other employ in the open air, very much conduce to health. To *exerciſe* moderately in the open air an hour or two before breakfaſt, improves the appetite, and conduces much to cheer the ſpirits: and, as to glandular obſtructions, they are both beſt prevented and cured by moderate *exerciſe*.

On the other hand, when *exerciſe* is too freely uſed, it occaſions loſs of appetite, loathing of food, heat in the bowels, coſtiveneſs, rigors, and fainting. In this caſe, a moderate uſe of wine, warm bathing, quiet ſleep, and a moiſt nouriſhing diet, afford the moſt proper relief. See Fordyce's Elements, part i. Mackenzie on Health.

EXERRHEUSIS, EXERRHOSIS, EXERRHYSIS. See ECROE.

EXFOLIATIO. DESQUAMATIO. EXFOLIATION. The proceſs by which the dead part of the bone ſeparates from the ſound. One principal cauſe of an *exfoliation* of a bone, is an interruption of the continuity of the veſſels which nouriſh it. The coldneſs of the air, by contracting and drying up the extremities of the ſmall veſſels of the bone, alſo puts a ſtop to the circulation of the nouriſhing matter through them. Mr. John Hunter obſerves, that "one part of a bone is never ſeparated from another by the rotting of the dead part, for that which comes away is as ſound as it ever was. *Exfoliation* takes place ſooneſt in bones wherein are the feweſt cells, and whoſe texture is the cloſeſt. Before any part of a bone can be thrown off by *exfoliation*, it muſt be dead. But even then, till the proceſs of *exfoliation* begins, the bone adheres as ſtrongly as ever, and would remain for years before it could be ſeparated by putrefaction alone. Bones are compoſed of two ſubſtances, viz. a true animal matter, and an earthy one, which are only intermixed with each other. A dead bone acts on the ſyſtem in the ſame manner as any other extraneous body. It ſtimulates the adjacent living parts; in conſequence of which, ſuch a proceſs is begun that muſt terminate in its being thrown off. The effects of this ſtimulus are, FIRST, that the living adjacent bone becomes more vaſcular; a circumſtance which always takes place when a part hath more to do than is juſt ſufficient for the ſupport of life. SECONDLY, that the earth of the living part, where it is in contact with the dead bone, is abſorbed; hence the bone becomes ſofter, and adheres by its animal matter only. THIRDLY, that the living animal part is at laſt abſorbed along the ſurfaces of contact: this part of the proceſs commences long before the laſt is finiſhed. Both of them begin firſt at the ſurface, though in their courſe they do not every where take place in an equal degree at the ſame time. FOURTHLY, in proportion to the waſte made by the laſt part of the proceſs, a fungus ariſes from the living ſurface, and fills up the intermediate ſpace,

ſpace, ſo that there may be no vacuum. Theſe different ſtages taken together, conſtitute ulceration. When any part of a bone is once looſe, it will be puſhed to the ſurface in the ſame manner as moſt other inanimate bodies would be, and this ſtage is partly mechanical, partly a continuation of ulceration. A proof of the third ſtage above mentioned may be derived from thoſe caſes where people die while *exfoliation* is going on. A ſmall groove or worm-eaten canal can then be diſcovered, which becomes gradually deeper, and follows the irregularities of the living and dead ſurfaces. After the application of the trepan, a circular piece of bone is frequently thrown off, which is always leſs than the ſpace from whence it came. This, however, would never be the caſe, were there not a loſs of ſubſtance."

When a bone is laid bare by any accident, and an exfoliation is feared, if ſeveral perforations are made in the bone, the *exfoliation* will be prevented; in ſuch caſes, the wound ſhould be kept clean, and defended from unctuous and watery medicaments: pledgets of lint are as proper applications as any; or they may be dipped in a mixture of the ol. tereb. and tinct. myrrh. As to cauſtics, Mr. Hunter ſays, that "cauſtics, or the actual cautery, do neither of them haſten *exfoliation:* they produce death only in part of the bone, which is the firſt ſtep towards *exfoliation*. If cauſtics ever haſten *exfoliation*, where the bone is already dead, it muſt be by producing inflammation in the adjacent living bone; this brings about a change in it, and makes it exert a power which it was incapable of before." See CARIES.

EXFOLIATIVUM. See DESQUAMATORIUM.

EXIPOTICOS, from ἐξιπόομαι, *to preſs out* or *filtre*. An epithet for digeſting, or deterging medicines. Galen ſays, they are the ſame as drawers.

EXITURA. A SUPPURATED ABSCESS. But Paracelſus applies it to all ſorts of putrid excrements.

EXITUS ANI. See PROCEDENTIA ANI.

EXOCHAS, or EXOCHE, from ἐξω, *without*, ἐχω, *to have*. A tubercle on the outſide of the anus.

EXOCYSTE, } A prolapſus of the inner membrane
EXOCYSTIS. } of the bladder.

EXOMPHALOS, from ἐξ, *out*, and ομφαλος, *a navel*. Any protuberance of the navel. See HERNIA UMBILICALIS; alſo HYDROPS UMBILICALIS.

EXONCHOMA, from ἐξ, *out*, and ογκος, *a tumor*. Any large prominent tumor.

EXONEIROSIS, from ἐξ, *out*, and ονειρος, *ſleep*. NOCTURNAL POLLUTION. It is when in ſleep the ſemen is ejected. This, if rare, may be from redundant vigour; if frequent, it proceeds from weakneſs of the ſeminal veſſels. This latter cauſe is the moſt frequent.

EXOPHTHALMIA, from ἐξ, *out*, and οφθαλμος, *the eye*; called alſo *buphthalmus*, *ecpieſmos*, *melon*, a diſlocation of the eye; its natural ſize increaſed, or not ſenſibly changed; therefore the globe, more or leſs diſtended, riſes from its orbit, either ſwelling or puſhed out, and falling downwards, its bulk ſcarce altered; nor can it be covered by the palpebræ, which ſhould cloſe over the eye, healthful in other reſpects. See WALLIS's Noſologia Meth. Oculorum.

EXORESCENTIA. See EXACERBATIO.

EXOS. A fiſh from which iſinglaſs is obtained. See alſo HIRUDO.

EXOSTOSES. See GUMMA.

EXOSTOSIS, from ἐξ, *of*, or *out*, and οστεον, *a bone*, called alſo *hyperoſtoſis*. It is a preternatural excreſcence of a bone, or a tumor on a bone. Mr. Pott calls it an enlargement of the bone. Its hardneſs equals, or rather exceeds that of the bone from which it proceeds. Monſ. Petit calls the *ſpina ventoſa* by the name of *exoſtoſis*, but the two diſorders are very different.

Dr. Cullen places this genus of diſeaſe in the CLASS LOCALES, and ORD. TUMORES; which he defines, a hard tumor forming in the bone.

The *exoſtoſis* ſeems to be cauſed by the diſcharge of a ſuperfluous quantity of oſſific matter upon the part where it is ſeated, or from a ſeparation of the bony lamellæ. The cauſe of the firſt is not known, but the other may be the effect of irritation, which will occaſion a ſwelling of the bone, and this irritation may be diſeaſed or not; if diſeaſed, the part muſt be amputated; if not, which is not unfrequently the caſe, the patient may live to an old age, without any conſiderable inconvenience.

This diſorder ſhould be diſtinguiſhed from venereal nodes, from the rickets, from tophs, and from the ſpina ventoſa.

The diſeaſed irritation may be known by its violent and frequent pain.

IN ORDER TO CURE, as ſoon as the nature of the cauſe is underſtood, and encouragement to hope for ſucceſs is manifeſt, make an inciſion, and lay the bone bare; then with a chiſſel take the diſeaſed part away. This will ſucceed if the habit is not much vitiated; but if the conſtitution is alſo faulty, and the *exoſtoſis* proceeds from the exuberance of bony matter, amputation is the only method of relief, though generally, in this caſe, the whole is beſt left to nature.

Sometimes a preternatural hardneſs of the ligament is called an *exoſtoſis*; this ſpurious ſort, as well as the venereal nodes, are relieved by mercurials.

Exoſtoſes happening in the middle of hard bones are generally hard in all their parts, but thoſe near the ends of them, or about the joints, have often only an hard external lamina. When this diſorder happens on the bones within the ſkull, the conſequence may be an apoplexy, epilepſy, or a palſy. See Petit's Diſeaſes of the Bones, part ii. ch. xvi. Bell's Surgery, vol. v. p. 541.

EXOTICUS. EXOTIC, from ἐξω, *without*. Any thing brought from foreign countries.

EXPECTORANTIA. EXPECTORANTS, called alſo *hechita*. Medicines ſuited to promote the excretion or rejection of pus or mucus, from the lungs, or from the aſpera arteria. Some *expectorants* operate by rendering the matter fit for a diſcharge;—others ſtimulate to an excretion;—and ſome open the emunctories in order to the ſame end. Hence, when thin ſharp humours are to be excreted, and the ducts through which they are to paſs are to be conſtringed, give ſuch medicines as obtund and incraſſate; of this kind are the ſucc. glych. ſp. ceti althæa, ſyr. e mecon. pil. ſtyrac.—If thick viſcid matter is to be diſcharged, and a ſtimulus is required to aſſiſt its evacuation, give infuſions of hyſſop, orris root, or of elecampane; the ſal diureticus, gum. ammon. gum. benz. gum. myrrh, or flos ſulphuris, will be proper.—When a ſtronger ſtimulus is required, the ox. ſcillæ, or ſmall doſes of antimonial preparations, will be neceſſary. See Hoffmann's Med. Rat. Syſt. See ANACATHARTICA.

In ſome inſtances when *expectorants* are required, their efficacy is checked by the uſe of the bark, iron, &c. but if theſe medicines are mixed with the expectorating ones, thoſe inconveniencies are not obſerved. However, Dr. CULLEN thinks, that the common theory of expectoration ſeems to be unſatisfying; and that the caſe moſt frequently where expectorants are required, is, when the mucus which naturally exudes, or is poured out from the follicles of the bronchia, flows in unuſually larger quantity, and often in a more viſcid ſtate, than can be eaſily detached from the cells of the bronchia. In this caſe, *it is ſuppoſed*, by the uſe of (*what are called*) expectorants, the mucus may be brought up more largely, and with more facility. In what manner this is done, he finds it difficult to explain. They may, perhaps, produce the effect, by merely exciting coughing; but he knows of no internal medicine capable of doing this, nor any other means of exciting cough with expectoration, except by employing vomiting.

EXPECTORATIO, EXPECTORATION, from *ex*, and *pectus*, or from *expectoro*, *to throw out of the veſſels*. See EXPECTORANTIA and ANACATHARTICA.

EXPIRATIO, called alſo *Ecpneumatoſis*, *Ecpnœa*. That part of reſpiration, wherein the air is expelled out of the lungs. See RESPIRATIO.

EXPLORATIO. EXPLORATION. IN SURGERY it is the probing a wound or ulcer.

EXPLORATRIX. See CUPELLA.

EXPLOSIO. EXPLOSION. IN CHEMISTRY it is called detonation, or fulmination.

EXPRESSIO. EXPRESSION. It is a mechanical operation, by which the juices of many plants are obtained, and ſweet oils, which are not volatile, may be extracted from many ſubſtances, in which they reſide ſuperabundantly, and uncombined. Such are all emulſive ſeeds, and ſome fruits, as oranges, lemons, olives, &c.

This operation is effected by firſt bruiſing the ſubſtance, and then forcibly ſqueezing it in a preſs. The more ſucculent bodies may be bruiſed and wrapped in a linen cloth, before they are committed to the preſs; but more viſcous ſubjects require that a little water be added to them before they undergo this operation.

When ſeeds, from which an oil is to be obtained, are ſubjected to this management, the cheeks of the preſs ſhould be heated, in order to a more copious diſcharge of

the oil: the product will by this means be increased; but when oils are to be taken internally, *expression* with cold plates is the most proper, as those which are heated dispose the oil to become soon rancid and offensive.

EXSICCATIO. DRYING. This pharmaceutic operation is effected by exhaling the moisture from the body to be dried, over a gentle fire, or by absorbing it, as when such subjects are laid on chalk-stones for this end.

When heat is employed, the operation is by *coction*, *insolation*, or *by torrefaction*; the *first* relates to fluids, the *second* to fluids and solids, and the *third* to solids only. Decantation and filtration subserve the process of *exsiccation*.

EXSUCCATIO. See ECCHYMOMA.

EXSTASIS. See ECSTASIS.

EXTENSOR. An EXTENDER. This name is given to several muscles.

—— CARPI RADIALIS. This muscle takes its origin from the rising line of the os humeri, that runs towards the outer condyle, and from the same condyle it runs close to the radius, and passing through a groove, where it is bound down, it divides into two tendons, where the muscle is called by some *bicornis*. One of these tendons is inserted into the basis of the first, and the other into the second metacarpal bone. Some call this muscle by the name of *radiæus externus*; others by that of *extensor* carpi *exterior*, & *geminus*. Winslow calls it ULNARIS EXTERNUS.

—— CARPI ULNARIS. Some call it extensor carpi interior. It rises from the outer condyle of the os humeri, and then receives an origin from the edge of the ulna; its tendon passes in a groove behind the styloid process of the ulna; it passes and is inserted into the inside of the basis of the metacarpal bone of the little finger.

The extenders, whether belonging to the fingers or carpus, arise from the outward extuberance of the os humeri: and their antagonists, the flexors, from the internal protuberance of the same bone, as also from the upper and external part of the ulna next to the anconæus.

—— DIGITORUM COMMUNIS. It is also called *digitorum tensor*. It partly rises from the outer condyle of the os humeri, and partly from the outer edge of the ulna; it passes behind the lower extremity of the radius, where there is a groove for its lodgement, and forms four tendons; that for the little finger passes different from the others: the three last communicate, and are inserted into the second bone, and partly into the last of the respective fingers, that is, the third, middle, and fore-fingers.

—— DIGITORUM BREVIS. It is also called *pedicus*. It rises from the anterior part of the os calcis, runs across the instep, and divides commonly into four tendons, but sometimes only into three, which are inserted into the three toes next to the greater one, or into all the four.

—— DIGITORUM LONGUS; called also *cnemodactylæus*. Dr. Hunter calls this extensor longus digitorum pedis. It rises from the upper part of the tibia and fibula, and the interosseous ligament; its tendon passes under the annular ligament, and then divides into five, four of which are inserted into the second and third phalanges of the toes, and the fifth goes to the basis of the metatarsal bone. This last Winslow reckons a distinct muscle, and calls it *peronæus brevis*.

—— INDICIS. It is also called *indicator*, and extensor indicis proprius. It rises with the extensor digitorum communis, lies between the ulna and radius, runs close to the interosseous ligament, passes over the back of the hand, and is inserted into the posterior part of the index.

—— LONGUS. It rises from the inferior costa of the scapula; and the

—— BREVIS rises from the outer spine of the humerus, then they make one tendon with the brachiæus internus.

—— MINIMI DIGITI. It is also called *auricularis*. It rises partly tendinous at the extremity of the external apophysis of the os humeri, and partly fleshy from the superior part of the ulna, and becomes tendinous as it passes under the annular ligament at the carpus: it is there divided into two, and sometimes into three tendons, which are united into one at its insertion into the superior part of the third bone of the little finger.

—— PRIMI INTERNODII POLLICIS. It rises high up from the radius, ulna, and interosseous ligament; it wheels round the radius, runs across the carpus, and is inserted into the trapezium, and the first bone of the thumb.

EXTENSOR SECUNDI INTERNODII POLLICIS. It rises from the radius, and the interosseous ligament, describes the same course as the preceding, and is inserted into the second bone of the thumb.

—— TERTII INTERNODII POLLICIS. It rises from the back part of the ulna, near the middle, and from the interosseous ligament; then goes obliquely across the carpus to the third bone of the thumb. When it acts, it not only extends, but also brings the thumb backward, so that some people can bring the end of the thumb to the wrist.

—— POLLICIS LONGUS. It rises from the middle and fore-part of the fibula, and the interosseous ligament, and passes over the instep to be inserted into the last bone of the great toe.

—— POLLICIS BREVIS. It is only a slip from the extensors of the toes, and is inserted into the first bone.

EXTENUATIO. LEANNESS. This may arise in two ways, one from the sensible or insensible evacuation of the useful and nutritious particles of the habit; the other from cacochymia, or a collection of such as are vitiated, or useless. PROSPER ALPINUS observes, in his Presages of Life and Death, that if, after being extenuated by a disease, the disease is removed, but the body continues *lean*, the nutriment being duly received, it denotes a relapse. —Again, *leanness* from a spitting of blood, attended with a slow fever, portends death. And, lastly, that it is a bad sign in an ardent fever for the body not to become speedily *lean*; or to waste immoderately; the *first* prognosticates a tedious disease; the *latter*, death.

—— TYMPANI AURIS. See LAXATOR EXTERNUS.

EXTINCTIO. See COMMINUTIO.

EXTIRPATIO. AMPUTATION.

EXTRACTIO. EXTRACTION. The liquors which dissolve bodies in their pure state, extract them from impurities, or other extraneous bodies with which they are mixed, and take up all their virtues. *Extraction* is performed by macerating the subject in its appropriated menstruum in the cold; or digesting or circulating it in a moderate warmth; or infusing it in boiling liquor, and suffering them to stand until they are cold; or by actually boiling them for some time. Heat greatly expedites *extraction*; but it is injurious to some substances, by occasioning the menstruum to take up their grosser and more ungrateful parts; yet others again impart but little to a heat that is not equal to that of boiling water. As heat promotes, so cold prevents *extraction*. Tinctures made by heat deposit much of their contents in cold weather.

Vegetable juices obtained by expression, or watery, or spirituous decoctions or infusions, when exposed to a continued heat, the fluid gradually exhales, carries off the more volatile parts, and leaves the more fixed in one mass; which, if from a vegetable juice obtained by expression, is called an *inspissated juice*; if from a watery decoction or infusion, it is called an *extract*; if from a spirituous tincture, it is called a *resin* or *essential extract*: the term *extract* is frequently used as a general appellation of all three kinds.

Inspissated juices, when evaporated no farther than to the consistence of honey or oil, are called *rob* or *sapa*. Spirituous tinctures reduced to a like consistence are called *balsam*. See the New Dispensatory, and the Dict. of Chemistry.

———. EXTRACTION, IN SURGERY, is the drawing from, or out of the body, any thing that is offensive.

EXTRACTUM. An EXTRACT, called also *ecchylsma*. IN PHARMACY it is a solution of the purer parts of a mixt body inspissated by evaporation nearly to the consistence of stiff honey. (See EXTRACTIO); each of which commonly take their name from the substance used from whence this *extract* is formed, as EXTRACTUM CHAMÆMELI, CORTICIS PERUVIANI, &c. which see.

EXTRACTUM PURGANS. See HEDERA ARBOREA.

EXTRAVASATIO. EXTRAVASATION, from *extra* and *vasa*, *out of the vessels*. This is applied to any of the fluids in the body which are out of their proper vessels; thus an ecchymosis, sugillation, or aneurism, may be called *extravasations*.

Fallopius, Chalmet, Albucasis, and some others, think that though some *extravasated* blood should putrefy in the belly, it cannot do the intestines or other viscera any hurt, but will subside to the groin, and there form an abscess; or that more likely it will be absorbed and discharged by stool, before it putrefies at all.

An *extravaſation* on the brain produces one or more of the following ſymptoms, viz. a palſy of one leg or arm, or both; dizzineſs; ſleepineſs; impaired ſight; ravings; bleeding at the noſe or ears; vomiting; loſs of ſenſe; ſtupor, &c. See CEREBRI COMPRESSIO.

An *extravaſation* on the brain ſhould be diſtinguiſhed from a concuſſion thereof; in the firſt, the ſymptoms are often better and worſe; in the latter they are continually the ſame.

Wounds on the head with *extravaſations* are very fallacious, becauſe the *extravaſation* may be between the ſkull and the dura mater, or under it, both at the ſame time; or under the pia mater, or in ſeveral other parts of the brain; but when theſe happen, bad ſymptoms are directly produced.

Whenever the dura mater, either by depreſſion, fiſſure, or fracture, loſes its adheſion, there will be, from its blood-veſſels that are broken, an *extravaſation* between the bone and it. An *extravaſation* is leſs conſiderable when a fracture of the ſkull happens than when there is a fiſſure. An *extravaſation* is alſo more or leſs dangerous, according to what part of the brain the accident happens. *Extravaſations* from a blow are moſt commonly found under the ſkull, that is, between it and the dura mater; in this caſe a lethargy or other ſymptom will continue, until the *extravaſation* is removed.

Mr. Bromfield recommends the uſe of opiates in fractures and concuſſions of the brain (ſee CONCUSSIO); the ſame practice may be alſo uſeful in ſome degrees of *extravaſation*; but beſides this, he obſerves, that when violent accidents have happened to the head, an iſſue in the opening formed by the ſeparation of the additamentum of the temporal bone is of ſingular advantage. See his Chirurgical Obſervations, vol. i.

EXTRAVERSIO. EXTRAVERSION. IN CHEMISTRY, it is the rendering manifeſt any thing ſaline, alcaline, or acid, concealed in mixed bodies, and is juſt the reverſe to one ſpecies of concentration.

EXTRINSECI. The external parts, particularly the limbs. Alſo painful diſorders of the external parts.

EXTUBERANTIA. Tumors that are ſeated under the ſkin, but do not elevate it.

EXUBERES. Children which are weaned are thus called.

EXULCERATIO. The ſame as *ulcus*, called alſo *exulceſis*; but generally uſed to expreſs thoſe beginning eroſions, which wear away the ſubſtance, and form an ulcer; or when an excoriation begins to ſuppurate.

—— OSSIS. See CARIES.

EXULCERATUS. See APERTUS.

EXUMBILICATIO. A protuberance of the navel.

EXUNGULATIO. EXUNGULATION. The cutting off the ungues, or white part of the petals of roſes.

EXUVIÆ. See ANGUIUM SENECTÆ.

EXYDATOO, ἐξυδάτω, *in aquam reſolvo*. When, inſtead of blood, a watery humour is generated and collected; whence water readily appears within the ſkin.

EZQUAHDUITL. The DRAGON-BLOOD-TREE.

EZULA. See ESULA.

F.

F A C

FABA. The BEAN, called alſo *cyamus*, *phaſeolus*. This plant hath a long unicapſular pod, full of kidney-ſhaped ſeeds; the ſtalks are firm; the leaves grow in pairs, and are as it were conjugated to a rib which ends in a point.

Faba was called by the Faliſci, a people of Hetruria, *haba*; whence probably comes the word *faba*. Martinus derives the word from φαω, *to feed*, as if it were *paba*. The word *bean* ſeems to be from the Italian word *baiana*.

—— BENGALENSIS, —— CAMBAIA, —— MALABAR. } See MYROBALANI.

—— CRASSA. See CRASSULA.

—— ÆGYPTIACA, called alſo *cyamos Ægyptiacus*, *nymphæa Indica*,—*glandifera*—*Madaraſpatana*, *bem tamara*, *nelumbo*, *lien Sinarum*, *colocaſia*. The PONTIC BEAN, or ÆGYPTIAN BEAN. It grows on marſhy grounds in Egypt, and ſome of its neighbouring countries. Some call it *ciborium* and *cibotium*, from the manner of planting it, which is firſt to lodge it on a moiſt clod, which is afterwards immerſed in water. When the flower falls, a ſmall pod appears, in which the *bean* is lodged. It is eaten either raw or boiled, and is of an aſtringent quality; it alſo ſtrengthens the ſtomach. See Dale.

—— FEBRIFUGA. See NUX VOMICA.

—— GRÆCA LATIFOLIA. See GUAJACANA.

—— INDICA. See NUX VOMICA SERAPIONIS.

—— INVERSA. See CRASSULA.

—— MAJOR, —— CYAMUS LEGUMINOSA. } Called alſo *phaſeolus major*, TURKEY BEANS, and GARDEN BEANS.

They are a ſtrong flatulent kind of food, nutritious, but not eaſily digeſted, eſpecially when old. The flowers afford an agreeable fragrance, which they impart to water by diſtillation. The freſh leaves beat up into a poultice with cream are cooling and repellent. The ancients call the flour of *beans*, *faba freſa*, and *lomentum fabæ*, becauſe it is prepared without the ſkin, in which lies the aſtringency, falſely, though generally attributed to the flour. Raii Hiſt.

—— MINOR, alſo called *equina freſa*, HORSE-BEANS. Theſe differ no other way from the garden ſpecies than in being leſs.

—— PURGATRIX. See CATAPUTIA MINOR.

—— SANTI IGNATII. See NUX VOMICA SERAPIONIS.

—— SUILLA. See HYOSCYAMUS NIGER.

FABAGINEA, FABAGO. } Alſo called *leguminoſa*, *capparis portulacæ*, *peplios Lutetianorum*, *telephium*, and *capparis fabago*. It is a bitter plant, which the Syrians uſe for killing worms.

FABARIA. See CRASSULA.

FABRILIS NIGRICA. See PLUMBUM NIGRUM.

FABRORUM AQUA. Water in which hot iron is quenched.

FACIES. The FACE. It comprehends the forehead, eye-brows, eye-lids, eyes, noſe, mouth, chin, cheeks, and ears. Its bones are thoſe of the upper and lower jaws.

—— HIPPOCRATICA. The HIPPOCRATIC FACE. It is when the noſe is ſharp, the eyes hollow, the temples ſunk, the ears cold and contracted, and their lobes inverted; the ſkin about the forehead hard, tenſe and dry; the countenance pale, greeniſh, or blackiſh. Some call this the CADAVEROUS FACE. If it appears within three days after the onſet of an acute diſeaſe, it indicates death.

FACIES RUBRA. See GUTTA ROSACEA.

FACULTAS. A FACULTY. It is the power of performing any action. The animal *faculty* is an action whereby a man exerciſes ſenſe, motion, and the principal functions of the mind, which are three; imagination, reaſoning, and memory. See ACTIO.

FÆCES. See FÆX.

FÆCULA. It is a medicine which conſiſts of the fæces of vegetable juices.

—— BRYONIÆ. The FÆCULA of BRYONY. Take of the roots of white *bryony*, any quantity; ſcrape them and ſqueeze out their juice; which, after ſtanding a while, depoſits a ſediment, from which the thinner part may be ſeparated by decantation, and the reſt dried for uſe.

FÆX. Alſo, *Cheriſa*; *Fæces*; and *Fæcula*. It is properly the ſediment or lees or grounds of any fermented liquor; but in medicine it is generally underſtood of wine. The alvine excretions are thus called.

FAGARA MAJOR, alſo called *cayutana Luzonis*, *cubebis*.

It is a plant which is found in the Philippine iſlands. The berries are uſed: according to AVICENNA, they are heating and drying, and good for a cold weak ſtomach to help digeſtion, and are aſtringent to the bowels: the outer rind was not uſed: it is aromatic.

—— OCTANDRA. See TACAMAHACA.

FAGOPYRUM, FAGOTRITICUM. } Called alſo *fegopyron*, *frumentum Saracenicum*, *eryſimum Theophraſti*, *tragopyron*, BRANK, BUCK WHEAT. It is ſaid to be originally from Africa. It thrives every where; delights in a wet ſoil; is ſown in fields, flowers in July, leſs nutritive than barley or rye, but more ſo than millet or panic. Raii Hiſt.

FAGUS, called alſo *oxya* or *oxyas*; *balanda*; *valanida*. The BEECH-TREE. Its leaves reſemble thoſe of the horn-beam: the fruit is produced at a remote diſtance from the flower, but on the ſame tree, and is a callous ſubſtance, acuminated, and incloſing two triangular ſeeds or nuts. It grows in woods and in hedges. The maſt (i. e. fruit) is in uſe; it agrees in its properties with thoſe of the cheſnut. The oil expreſſed from *beech* nuts is extolled as a deſtroyer of worms: a child may take two drams of it every night and morning; an adult may take an ounce. The poor people in Sileſia uſe this oil inſtead of butter. Raii Hiſt.

FAIRBURN WATER. *Fairburn* is in the county of Roſs, in Scotland, about two miles from the Caſtle-Leod well. It is a ſtrong ſulphureous *water* ſomething of the ſame nature, but not ſo powerful; a gallon, on evaporation, yielded, of abſorbent, dark-coloured, light earth, two grains; of white calcareous earth, fifteen; of Glauber's ſalt, mixed with yellow matter, &c. twenty-four grains; but no ſelenites. It is uſed for the ſame purpoſes as *Caſtle-Leod waters*, but not ſo much frequented. Monro's Medical and Pharmaceutical Chemiſtry, vol. ii.

FALCIFORMIS PROCESSUS. See DURA MATER.

FALDELLA. Contorted lint uſed for compreſſes.

FALX. See DURA MATER.

FAMES. HUNGER. That peculiar ſenſation of the ſtomach by which we are ſolicited to a deſire for food; which, according to WILLIS, ariſes from acid effluvia, and

and vapours affecting the animal ſpirits in the left orifice of the ſtomach, and its nerves, and by conſent of continuity, the internal coat of the ſtomach itſelf and throat, which impreſſion is communicated to the brain, in which the animal ſpirits of the brain are in like manner affected. Thus, when the ſtomach is empty, or when we faſt longer than ordinary, it is common to ſay that the ſtomach pinches us. But as the liver is not at that time ſuſtained by the ſtomach and inteſtines, it deſcends by its own weight; and principally by means of its middle ligament, pulls the diaphragm along with it: it is in that place, therefore, that we have this uneaſy ſenſation, and not at the ſuperior orifice of the ſtomach as is generally thought. See Haller's Phyſiology.

When animals die for want of food, their death is not directly the conſequence of *hunger*, but a putrid fever, which is excited by the blood's loſing its bland gelatinous conſiſtence, for want of the uſual neceſſary ſupplies.

FAMES CANINA. See BOULIMUS.

FAMIGERATISSIMUM EMPL. A plaſter uſed in intermittent fevers, made of aromatic irritating ſubſtances, and applied to the wriſts.

FAR. Aetius ſays that it is any kind of frumentaceous grain, decorticated, cleanſed from the huſks, and afterwards bruiſed and dried.

FARCIMINALIS. See ALLANTOIS.

FARCTURA. In PHARMACY it is the ſtuffing of any exenterated animal, or excavated fruit with medicinal ingredients.

FARCTUS, from *farcio*, to *ſtuff*, or *cram*; ſtuffed, crammed, or full; thus in botany, FOLIUM FARCTUM is a ſtuffed leaf full of pith or pulp; in oppoſition to *tubuloſum* and *fiſtuloſum*, tubular, or hollow, like a pipe. It is applied alſo to the ſtem and pericarp.

FARFARA, FARFARELLA. } See TUSSILAGO.

FARFARUS. See POPULUS ALBA.

FARINA. MEAL or FLOUR.

—— FŒCUNDANS. IMPREGNATING DUST. It is placed on the apices of flowers, and falls from thence upon the head of the piſtil or female part of the flower, and is thence conveyed to the matrix, in order to impregnate the ſeed.

FARINACEA. Under this title, are included thoſe ſubſtances employed as aliment, called *cerealia*, *legumina*, and *nuces oleoſæ*, and are diſtinguiſhed as they contain more or leſs ſaccharine and oily matter. In the *cerealia*, the ſugar is large in proportion to the oily matter; in the *legumina*, the oil ſomewhat larger in proportion to the ſugar; in the *nuces oleoſæ*, the oil ſomewhat ſtill in greater proportion. Under the title cerealia, are commonly put the ſeeds of ſeveral gramineous, and culmiferous plants that are employed as food for men, viz. *barley*, *rye*, *millet*, *rice*, *oats*, *maiz*, *wheat*, *buckwheat*, *ſalep*, *cheſnut*, and *potatoe*. The legumina, or pulſes, are the *pea*, *bean*, and *kidney bean*; which laſt are in this country only employed in their young, green ſtate. The nuces oleoſæ are the *nut*, *almonds*, *walnut*, *piſtachio nut*, and ſome products of others, as chocolate. CULLEN's Mat. Med.

FARINACEUS PANIS. See PANIS.

FARINARIUM. See ALICA.

FARINHA, FRESCA. —— RELADA. } See CASSADA.

FARNESIANUS FLOS. See BATTATAS CANADENSIS.

FARRAGO. See ALCYONUM.

FARREA NUBES. See FURFUROSI.

FASCIA, called alſo *ligatio*, *ligatura*, *alligatura*. A BANDAGE, FILLET, ROLLER, or LIGATURE. Of BANDAGES, Æſculapius is ſaid to be the firſt inventor. For the application of them, and ſeveral ſpecies, ſee DELIGATIO. The chief uſes of *bandages* are to maintain the due ſituation of dreſſings, or to make a proper compreſs on a particular part. Ideas of *bandages* are difficultly conveyed otherwiſe than by the actual application of them. Much hath been ſaid by various authors on this ſubject: but a moderate ſhare of practice, and of ſagacity, will beſt ſupply proper hints, as each caſe requiring them occurs to the practitioner. However, under the reſpective name of each ſort of *bandage*, a deſcription of it is attempted in the courſe of this work. On this ſubject, Heiſter's Surgery, James's Med. Dict. Verduc, and Le Clerk, may be conſulted.

1. THE SLING.

The French call it *echarpe*. This name is given to ſeveral ſorts of *bandages*.

2. THE SLING *with four Heads*.

Its length ſhould be four feet (more or leſs according to the ſize of the head) its breadth that of ſix or eight fingers. Its uſe is to retain the dreſſing on a wounded head. It muſt be ſlit in the middle, from each end, ſo as to leave about two hands' breadth undivided in the middle, and the four ends muſt be rolled up to where the diviſion ends. Apply the middle of the undivided part upon the dreſſings, then tying the two poſterior heads forward, and having ſecured their ends, the two anterior ends muſt be carried backward, and ſecured behind the head.

3. THE SLING *with ſix Heads*, called *Periſcepaſtrum*.

Its length is about three feet, its breadth about twelve or fourteen inches. Divide it from each end, up to within a hand's breadth of the middle, into three parts. Apply the middle undivided part to the vertex, then tie the two anterior tails behind the head, the two middle under the chin, and the two poſterior upon the forehead.

4. THE SLING *for the Noſe*.

It hath four heads, and is eight feet long, and two or three inches broad; in the middle it is left entire, but from thence, each way, it is ſlit to the ends. In the middle, where it is entire, an opening is made for the apex of the *noſe*, that the *bandage* may be firm. The middle is applied upon the noſe, the two upper heads to the neck, and then to the forehead; the lower ones behind the neck, but a little higher than the firſt, and then up to the forehead too.

5. THE SLING *for the Breaſts*.

It is four feet long, and ſix inches broad, and ſlit like the ſling with four heads, about a foot in the middle being left entire. The middle is to be applied upon the dreſſings on the affected breaſt, then carry the two upper heads over the oppoſite ſhoulder, and the two lower under the arm of the affected ſide, towards the ſcapula of the other ſide; faſten them there to the upper ends which are over the ſhoulder.

6. THE SINGLE BRIDLE, called *Capiſtry*.

It is a ſingle-headed roller, fourteen or ſixteen feet long, and two or three fingers broad, for ſecuring the jaw when fractured or luxated. It is applied under the chin, and over the head; and called by Galen *genicas*.

7. THE DOUBLE BRIDLE.

It is the ſame as the ſingle, only rolled up with two heads; but the ſingle may always be uſed inſtead of it. See CHEVASTRE.

8. BANDAGES *for the Lips*.

Theſe are of a proper length and breadth, and formed as the ſling with four heads.

9. BANDAGE *for the Eyes, or Eyelids*. ſee MONOCULUS.

10. THE DIVIDER *for the Neck*.

This *bandage* for the neck is twenty-four feet long, two or three fingers' breadth broad, and is rolled into two heads. Its middle is placed on the forehead, and thence paſſes round the head two or three times; then being pinned to ſecure it, the rollers are carried under each arm-pit, and brought back over the ſhoulders, and croſs the neck in the form of an X, then paſs on to the forehead, &c. until the whole is taken up.

11. THE UNITING *or* INCARNATING BANDAGE.

It is about eight feet long, and two inches broad; in the middle is a ſlit about the length of three or four fingers. It is rolled up from each end to the ſlit in the middle. It is uſed for keeping together the lips of large wounds on the head or face, or where elſe it can conveniently be applied. A narrow compreſs being laid on each ſide of the dreſſings which are on the wound, the ſlit part of this *bandage* is applied near the wound, ſo that one of the heads of the *bandage* being carried round the head, (or where it is applied) may be paſſed through this ſlit: the *bandage* then being drawn ſo tight as to confine the lips of the wound in an eaſy contact, bring back the head which was paſſed through the ſlit, and then continue the application of both heads according to the direction they lie in, or as beſt ſuits the intention. Except

cept extraordinary ſymptoms require, this *bandage* muſt not be removed during ſix or eight days.

12. THE RETENTIVE BANDAGE *for the Neck.*

Two diſtinct ones are uſually directed, but one circular roller anſwers every uſeful purpoſe.

13. THE BANDAGE *of* Heliodorus, *or the* T BANDAGE.

The letter T, whence the name of this *bandage*, deſcribes its ſhape. The tail is ſometimes ſlit up to ſuch a length as is required. It is generally uſed when a *bandage* is required to retain the dreſſing on the groins, pubes, or lower part of the belly. One part of it is faſtened about the waiſt, the other part, which hangs down, is brought betwixt the thighs up to the belly, and is faſtened to the part which is already ſecured.

14. THE NAPKIN *and* SCAPULARY.

It is uſed when a *bandage* is required on the breaſt, or belly, or back. It conſiſts of a napkin pinned round the body, higher or lower, as is the ſituation of the diſorder which requires it; then, to prevent its falling, the ſcapulary is applied, which is a piece of linen, four or ſix inches broad, with a ſlit in the middle for the head to paſs through; its length ſufficient, when the head is paſſed through, and it reſts on the ſhoulders, for one end to be pinned to the napkin behind, and the other end to the napkin before. Some faſten the ſcapulary behind, and then ſlitting the other end far enough to bring each part over the ſhoulders to be faſtened before.

FASCIA. See APONEUROSIS.

—— LATA. It is a large, membranous, tendinous, or ligamentary covering. Winſlow deſcribes it as a muſcular ligament, which is fixed about the edge of the criſta of the os ilium, from the large tuberoſity, to the anterior ſuperior ſpine, to the ligamentum Fallopii, and to the aponeuroſis of the oblique external muſcle of the belly. It is alſo fixed on the lateral inferior part of the os ſacrum, and to the neighbouring part of the ligaments by which that bone is connected to the bones of the ilium and iſchium. From thence it advances over the glutæi and thigh, between the membrana adipoſa and muſcles, all the way to the interior and outer part of the knee. It is very thin on the patella, but is eaſily ſeparated from it. It is alſo continued over the external anterior part of the tibia, covering the muſcles which lie there, and is ſtrongly inſerted into the head of the tibia and of the fibula. It is ſtrongly inſerted into the linea aſpera femoris between the vaſtus externus and biceps, forming a ſort of ſeptum between theſe muſcles. See APONEUROSIS.

FASCIÆ LATÆ MUSCULUS. It riſes from the outſide of the ilium, runs downwards and outwards, and, below the trochanter major, joins with the tendon of the glutæus maximus, and runs down laterally to the leg. This muſcle ſtretches the faſcia lata above deſcribed, wherefore Albinus calls it *tenſor faſciæ femoris.*

—— LUMBORUM. It is a ſtrong tendon fixed to the lateral part of the os ſacrum, from the ſpines of the ſacrum, from the ſpine of the ileum, and the ſpines of the lumbar vertebræ.

FASCIALIS. See SARTORIUS.

FASCICULUS. See MANIPULUS.

FASTIDIUM CIBORUM. LOATHING OF FOOD. Some barbarous writers, for this term, uſe *abominatio.*

FATUITAS. From *fatuus, fooliſh, inſipid.* Aliments that were inſipid, the Latins called *fatui*, whence the term is applied both to fooliſhneſs and unſavourineſs. In Cullen's Noſology, it is ſynonymous with *amentia.* See alſo MOROSIS.

FAUCES, called alſo *iſthmion*; *amphibranchia.* The top of the throat; the ſpace about the openings into the larynx and pharynx, which can be ſeen when the mouth is open and the tongue depreſſed. Upon looking into a perſon's mouth when wide opened, we ſee a ſoft curtain hanging from the palate bones, named *velum pendulum palati*; in the middle of which we likewiſe obſerve a papilla projecting from the velum, named uvula, or pap of the throat. From each ſide of the uvula, at its root, two arches or columns are ſent down, the anterior to the root of the tongue, the poſterior to the pharynx. Between theſe arches, on each ſide, the cellular glands, called *amygdalæ*, or almonds of the ears, are ſituated. The common opening behind the anterior arch may be named *fauces*, from which there are ſix paſſages, viz. *two upwards*, being one to each noſtril; *two at the ſides*, or *one to each ear*, called the Euſtachian tubes; *two downwards*: the anterior is the paſſage through the glottis and larynx into the trachea, which terminates in the lungs; the poſterior is the largeſt, named pharynx, or the top of the œſophagus, which leads to the ſtomach. Inues on the Muſcles.

FAUFEL. See ARECA; alſo TERRA JAPONICA.

FAVAGO AUSTRALIS. A ſpecies of BASTARD SPONGE. See ALCYONUM FARRAGO.

FAVUS. See CERION and ACHOR.

FEBRIFUGA. FEVERFEW, from *febrem fugare, to drive away a fever.* See MATRICARIA. Alſo ſuch medicines as mitigate or remove fevers. The *contaurium minus* is thus called by ſome.

FEBRIFUGUS PULVIS CRÆNII. See ANTIMONIUM, N°. 13.

—— OLEUM. FEBRIFUGE OIL. When the flowers of antimony are made with ſal ammon. and antimony ſublimed together, if they are expoſed to the air, they run into a liquid thus called.

FEBRIFUGUS PULVIS. The Germans give this name to the ſtypt. pulv. Helv. In England a mixture of ocul. cancr. 5ſs. and tart. emet. gr. ii. hath obtained the ſame appellation; in fevers it is given in doſes of gr. iii. to vi. with ſuch other things as preſent circumſtances require.

—— SAL, i. e. SAL MARIN. REGENERAT. See MARINUM SAL.

—— SPIRITUS DOMINI CLUTTON. Mr. CLUTTON'S FEBRIFUGE SPIRIT.

Take the oil of ſulphur, by the bell, and rightly prepared, rectified oil of vitriol, and ſpirit of ſalt, of each equal parts; and of rectified ſpirit of wine, triple the quantity of the whole. Digeſt them together for a month, then diſtil to dryneſs.

As much of this ſpirit as renders pure water agreeably acid is given in every draught of common drink in ardent and inflammatory fevers; and in the nervous and putrid kinds it is adminiſtered in ſuch cordial and antiſeptic liquors as are proper in the reſpective caſes. See the Certain Method of curing all Continued Fevers, by Jo. Clutton.

FEBRIS, πυρέτος, from πῦρ, *ignis, fire.* A FEVER. Dr. Cullen makes febrile affections, under the word PYREXIÆ, his firſt claſs of diſeaſes, and defines their character in general,—after chilline's, a frequent pulſe, increaſed heat, ſeveral of the functions of the body injured, the ſtrength of the limbs particularly diminiſhed. The firſt order of which is FEBRIS, which is deſcribed, a languor, laſſitude, and other ſigns of debility preceding, a pyrexia comes on, without any primary local diſeaſe.

It hath generally been ſaid that a *fever* is an effort of nature to remove or expel ſome morbific matter from the blood, and ſo to reſtore health; and this is attempted to be proved by eruptive *fevers* abating when eruptions appear on the ſkin; but this ſeems not to be the caſe, for the *fever* is no other than a ſymptom, which increaſes and protracts the diſeaſe; and an immediate extinction of the *fever*, at or near its onſet, if poſſible, is the ſureſt and moſt rational method of removing the diſorder by which it was cauſed.

Various are the diviſions and ſubdiviſions of *fevers*, which different writers have enumerated; but ſome have included them in thoſe of the INFLAMMATORY, NERVOUS, and PUTRID kind: at leaſt every acute *fever* is beſt managed by the methods required in one or other of the juſt named three kinds.

In *inflammatory fevers*, the red blood is redundant, and the heat of the body increaſed beyond the medium of health. In *the nervous kind*, the lymph is diſordered; and in the *putrid ſort*, there is ſuch a defect of the natural heat as admits of a putrid quality taking place, and increaſing in the blood.

An acute *fever* is when the pathognomonic ſymptoms proceed with rapidity, and danger to the patient. When theſe ſymptoms proceed more ſlowly, and with leſs danger, the *fever* is ſaid to be chronical.

All fevers are ſymptomatical. And perhaps it is but the truth to aſſert, that all *fevers* are but every *fever* differently circumſtanced; or, that *fever* is one and the ſame diſorder, but appearing differently, according to the various circumſtances that it meets with in different conſtitutions.

A ſtimulus is the only immediate cauſe of fevers. Dr. Kirkland obſerves, in his Treatiſe on Child-bed *Fevers*, p. 53, "that all *fevers* are owing to inflammatory irritability, or nervous irritation." An acute inflammatory

fever

fever takes its rife from the fmall veffels being inflamed and diftended, fo preffing on the medullary part of the nerves, which are every where diffufed. A *fever* from acrimony, is from the matter irritating the nerves, or their medullary part.

As to the diagnoftics of *fevers*, they vary, for the moft part of them, in different patients, and in the fame patient at different times; and a *fever* may manifeftly exift, though many of the ufual attendants be not prefent. However, it is fufficient to know that the pathognomonic figns of a *fever*, that is, thofe figns that are prefent in every *fever*, and without which a *fever* cannot fubfift, are *heat* and *a difordered pulfe*; thefe attend every *fever*, every degree and every ftage of it; and from thefe marks alone do we judge of the prefence or abfence of this diforder.

As a preternatural heat excited is a principal conftituent of a *fever*, fo to this circumftance may be attributed many of the fymptoms which attend in its different ftages. But it fhould be adverted to, that the fame degree of heat is not in the fame degree immoderate in different perfons, for the natural temperament varies greatly in one from what it is in another; therefore that degree of heat is moderate, or its contrary, which is neareft or fartheft from the natural ftate of the individual in that refpect.

The only indication of cure is, to abate the heat. To anfwer this one indication, will require fome circumftantial differences in different cafes; but the pulfe and urine will always direct the judicious practitioner in thofe particulars.

Every *fever* is a fymptom of fome difeafe, either manifeft or latent; and as the fecretions are difturbed more as this fymptom increafes, the immediate fuppreffion of it will at once appear to be the neceffary aim. Both the fecretions and excretions are beft performed in a regular ftate of health; when then the *fever* is fubdued, medicines adapted to the diforder which produced it, are more at liberty to act, and nature is alfo better able to difcharge what is morbid.

Contraries are the cure of contraries; and cold, the natural oppofite to heat, is its certain antidote. Hippocrates, Galen, Celfus, Avicenna, and all the ancients, ufed the prefent cold method of relieving from *fevers*. They expofe their patients to cold air; they give them cold water to drink, and that not only to fatiety, but alfo often to make them vomit.

Proper evacuations being made, if poffible, let the patient walk in the cool air; if he is incapable of this, let him be expofed to it in his room; the windows may be opened, and the chamber fprinkled frequently with water: if this fuffice not, let him drink cold fmall liquors in proportion to his thirft, and put his hands and feet into veffels of cold water, there to remain, at leaft until the fenfations it produces are no longer quite agreeable. When by thefe means, a tendency to fweat appears, affift it by fuch diluting liquors as the cafe requires: as the patient's heat abates, and his thirft is leffened, let his drink be given warm.

This method of fuppreffing *fevers* by means of cold is not to be rejected, even when cordials are required to fupport the patient's ftrength. See FEBRIFUGUS SPIRITUS DI. CLUTTON.

Whilft thefe cooling methods are purfued to fuppreffs the morbid heat, fuch other medicines fhould be prefcribed as the other fymptoms may require.

Under this management, befides that the cure is fhort, the ufual horrible fymptoms are kept off. If the patient recovers, he is not reduced to the low eftate to which, by other management, he would have been; and if he dies, he at leaft retains his fenfes to the laft.

As in the fmall-pox, fo in every kind of *fever*, the great defign of medicine is to reduce the patient's heat to that degree which conftitutes his healthy ftate. Sydenham hath obferved, that, "*the fitteft degree of heat to promote the expulfion of the variolous matter, is the natural one, and fuch as is fuited to the temper of the fleffy parts; and whatever exceeds or falls fhort of it, is dangerous on either hand.*" From this it appears, that a *fever* will increafe the difeafe, and that its affiftance is not needful for the expultion of the morbid matter. No greater proof can be given or defired in favour of the above propofed procedure than its conftant fuccefs in the prefent practice of inoculators for the fmall-pox.

BLEEDING fhould begin the cure in all ardent *fevers*; the difcharge, as to its quantity, will be determined by the pulfe. If there is a fanguine plethora (fee PLETHORA), bleed from a large orifice in the arm; and if the patient faints, the heat will more effectually be reduced. Sometimes the heat is much increafed, when the veffels are diftended only by the rarefaction of the blood. In cafes of this kind, the cooling perfpiratives will reduce both the heat and rarefaction, alfo fupercede the neceffity of bleeding. Give Clutton's febrifuge fpirit freely in the patient's common drink; or in want of it, let nitre be adminiftered, but let it always be fwallowed the inftant that it is diffolved, for thus its efficacy is beft infured.

VOMITING is alfo among the needful aids on the *fever's* firft attack; and among the reft, the antimonial ones are to be preferred. Antimonial medicines, given on the firft onfet of a *fever*, curb the circulation, and promote all the difcharges. They cool for the prefent by promoting excretions, which, with the fecretions, they influence beyond all other medicines now in ufe: befides thefe, their influence on the nervous fyftem is fuch, that the ftrength is rarely fo much reduced, when they are duly adverted to, as it is when they are omitted.

PURGES. Sydenham well obferves, that "*nothing cools the body fo fpeedily and fo laftingly, as bleeding, when immediately fucceeded by a purge. Bleeding is the fpeedieft; but a purge immediately fucceeding, increafes its effect, both as to its degree and continuance.*" Proper medicines of this kind are the natron vitriolatum, kali vitriolatum; natron tartarifatum; tamarind. rhab. manna, &c. and if to thefe, two or three grains of the antimonium tartarifatum is added, the operation will be both ways; and thus the emetic feparately adminiftered, will not be needful.

CLYSTERS. A copious injection of warm water into the inteftines fhould never be omitted in ardent *fevers*; the patient is more relieved by them than by a much greater quantity of any fluid that may be taken by the mouth. *In putrid fevers*, antiputrefcent medicaments conveyed clyfterwife into the body, are equally advantageous; amongft thefe fixed air is juftly ranked with the moft falutary.

COOLING MEDICINES. Thefe are nitre, fal ammoniac, aqua ammoniæ acetatæ, Clutton's febrifuge fpirit, antimonial wine, cold air, cold water, and the faline mixture. The antimonium tartarifatum, joined in fmall dofes as a diaphoretic to the faline draughts, is one of the moft volatile remedies in the early ftages of moft acute diforders; or, inftead of the vin. ant. the tinct. ipecacuanha may be added in fuch quantities as the ftomach can eafily retain. It is ufual to prefcribe the faline mixture in dofes, to be repeated at the diftance of four, fix, or eight hours; but in ardent *fevers*, they fhould be repeated every hour, day and night, until the fymptoms abate, or at leaft as often as may be without purging.

COLD WATER. Hippocrates fays, "If the patient is very thirfty whilft labouring under an acute *fever*, cold water is of great ufe, if given till it makes him vomit." Celfus advifes the ufe of cold water, and directs the patient to drink it even beyond fatiety. Galen fays, that "cold water is a perpetual remedy againft the *fever* itfelf." He directs its ufe both in ardent and putrid *fevers*, and even to immerfe the patient in the cold bath, if a copious drinking of it does not fuffice. Paulus fays, that "the heat may be extinguifhed by cold water, by which we have wholly cured burning *fevers*:" and elfewhere, he fays, that "the cold bath alone is of ufe to thofe who labour under an ardent *fever*, without an inflammation, a tumor, or an eryfipelas." To the fame purpofe many others of the ancients fpeak, and the practice continued about 1500 years. Indeed, among the moderns, there are, and have been thofe, who purfue the fame practice; they proportion the degree of cold to the degree of heat, and continue its ufe until the abatement of inward heat, and the pulfe, foretel that this diforder is entirely fubdued. The patient's fenfation will, with very little attention, determine the neceffary degrees of cold and heat in the management of them under *fevers*; *that degree which feels the moft agreeable, is the proper one.* To render the ufe of cold water more effectual, fmall quantities of tamarinds, cryftals of tartar, or kali tartarifatum may be diffolved in it; apples, or other fruits, of mucilaginous matters, fuch as lint-feed, or marfhmallows, may be previoufly boiled in it.

This practice of the ancients refpecting cold water in ardent *fevers*, or expofure to fevere degrees of cold, is at prefent a hazardous practice; and however proper it may appear to be, it fhould be adviſed with great caution; and nothing but a certainty of fuccefs fhould induce at leaft

leaſt young practitioners to direct it, in the manner as above recommended: the world would readily condemn it for its apparent raſhneſs, and one accident tend to deſtroy a reputation, perhaps meritoriouſly obtained.

Cool air. Beſides rendering the air in the room as cool as may be, farther advantages will ariſe in ardent *fevers*, by actually expoſing the patient to the cold air itſelf; always remembering, that the degree of heat or cold is always to be determined by the patient's feelings; that which is agreeable is alſo profitable. Sometimes the inſpiration of cold air is beneficial, when, becauſe of other ſymptoms, it would be injurious to expoſe the body to any degree of cold; however, in every febrile caſe, a pure cool air is the beſt to breathe in. As the redundant heat is the only ſymptom to which the cold is expoſed, its uſe is equally called for in putrid, as in ardent *fevers*; but the application of cold is not to be conſidered as a cure. Of other ſymptoms, or of the cauſes of the reſpective kinds of *fevers*, therefore, antiphlogiſtic cordials, or antiputreſcents, muſt be alſo preſcribed as required, and that through the whole progreſs of the complaint.

Diaphoretics. A burning uneaſy heat attends the patient who labours under any kind of *fever*, until by perſpiration, a general moiſture is diffuſed over all the ſkin. Betwixt 83 and 98, by Farenh. therm. are the ſtandards of heat in healthy men; and the body cannot ſweat if heated or cooled many degrees above or below its natural ſtate. If the heat ariſes farther than ſix degrees above, or ſinks in the ſame proportion below the medium of health in ſome; or in others, above ten degrees, or below them; no ſweat can be excited, until by cooling medicines, or by cordials, the morbid degrees of heat are removed. Beſides the uſe of cooling or of cordial medicines, whether the *fever* is of the ardent or the putrid kind, flannels wrung out of hot water may be wrapped round the patient's legs and thighs, to aſſiſt in exciting perſpiration. When a ſweat is excited in the ardent *fever*, keep it up with due ſupplies of whey or water-gruel, gently heated; if in the low or putrid kind, red-wine negus, or beef-tea, will be moſt proper. See Sudorifics.

Cordials. Their good effects in *fevers* are not from their increaſing the degrees of heat, but from their ſtimuli, by which the too languid powers are rouſed, and the circulation puſhed to the extremities of the veſſels.

Blisters. In ardent *fevers*, bliſters are beſt applied after the abatement of the heat, and when the pulſe begins to flag, except in caſe of local inflammation being an attendant, and then a bliſter applied over the part affected affords conſiderable relief; but in thoſe *fevers* where the pulſe is languid, as it is in the low and putrid kinds, the early uſe of bliſters is of the greateſt advantage.

Confinement in bed. Though continual confinement in bed is inconvenient in inflammatory *fevers*, yet ſitting up too long ſubjects the patient to flying rheumatic pains, or to a jaundice when the *fever* goes off. At the decline of the *fever*, the patient lies conſtantly in bed, with leſs prejudice, or rather with advantage.

Irritability. As a preternatural irritability, or an unuſual irritation, are the cauſes of *fevers*, camphor hath been uſed to abate them, and that with conſiderable advantage; it powerfully leſſens ſpaſmodic irritability, and is no leſs efficacious in relieving internal local inflammations. Small doſes of laudanum have been preſcribed on the ſame principle; but both theſe medicines are to be given in conjunction with antiphlogiſtics, or antiſeptics, according to the nature of the attending *fever*. At the decline of ardent *fevers*, and throughout the whole courſe of putrid ones, the bark is not to be omitted, for it proves in theſe caſes both an antiſpaſmodic and antiputreſcent.

Acids. In general they all cool powerfully, but the dulcified mineral acid ſpirits are to be preferred, ſuch as the ſpt. ætheris nitroſi, ſp. ſeb. Di. Clutton, &c.

Neutral salts. They all lower the pulſe, cool, and prove ſedative; but the dulcified mineral acids are ſtill to be preferred.

Absorbent powders. They are commonly preſcribed in *fevers*: and may be uſeful in as much as they unite with the acid upon the ſtomach, and form neutral ſalts; otherwiſe they are of no ſervice, and are much better omitted.

Longings. When this ſymptom happens in *fevers*, it ſhould be moderately gratified; what is longed for, the ſtomach will eaſily digeſt; and theſe gratifications often tend to promote the cure.

Hemorrhage at the nose. Never attempt to ſtop it when happening in a *fever*, whilſt the pulſe is full, the extremities warm, and the lips red.

Purging. When this ſymptom occurs in *fevers*, an emetic is generally the propereſt remedy, but in general it may be left to nature, until it manifeſtly reduces the patient's ſtrength; and when medicines are required, cordials, perſpiratives, bliſters, and nutritive diet, are preferable to aſtringents.

Delirium. When this ſymptom happens, *if the pulſe is full and quick*, bleed, and apply ſtimulating cataplaſms to the feet. *If the pulſe is weak and irregular*, let a bliſter be laid betwixt the ſhoulders, and give warm nervous medicines.

Hiccough. This ſymptom is generally dangerous; the camphorated mixture, large doſes of muſk, and gentle cordial opiates, are the neceſſary aids when it comes on.

Night sweats. Theſe happen frequently at the decline of a *fever*, or after it is quite abated, and are beſt relieved by a light but nouriſhing diet, moderate exerciſe in the air, the diluted vitriolic acid, and an infuſion of the bark.

Nausea, sickness, or vomiting. Theſe may happen at any time of the diſeaſe; if in the beginning, after an emetic, give two or three large ſpoonfuls of an infuſion of columbo-root, and repeat as the frequency of the vomiting may require.

A cough and spitting often follow, as the conſequence of a *fever*, but may be relieved for the moſt part by bitters, bark, light chalybeates, and exerciſe in the air.

When patients recover from *fevers*, they are generally feeble for ſome time, and apt to take cold. Trifles at this time endanger a relapſe: chearful company is uſeful; exerciſe ſhould be gradually engaged in; the diet ſhould be light, nouriſhing, frequently taken in ſmall quantities, and full meals ſhould be carefully avoided.

See Wallis's Sydenham in the article of *Fevers*; Grant's Obſervation on the Nature and Cure of *Fevers*; Lyſon's Eſſay on the effect of Camphor and Calomel in continual *Fevers*; Kirkland's Eſſays towards an Improvement in the Cure of thoſe Diſeaſes which are the Cauſes of *Fevers*; Fordyce's Elements, part ii. Notwithſtanding the vaſt variety which there appears in *fevers*, we cannot avoid ſuggeſting, that they may all, in a *practical point of view*, be compriſed in a much narrower compaſs; and that all *fevers* of whatever denomination may be reduced to five in number; SIMPLE CONTINUED, INFLAMMATORY, NERVOUS, PUTRID, and MIXED; or to a leſs, if the type is only regarded, viz. CONTINUED, REMITTENT, INTERMITTENT; but as theſe laſt denominations lead us not to the method in which they ought to be treated, the former diviſion appears the moſt unexceptionable; as it points out to us, in a great degree, the mode which ought to be purſued for their alleviation, and cure; and practically involves the latter; for *fevers* may be conſidered as owing to one common cauſe, *ſtimulus*; and their variations, according to parts of the conſtitution, of which it is formed, generally diffuſed through the habit, which are attacked, and the nature of fluids; whatever other deviations occur, muſt be viewed as accidental contingencies, dependant on peculiarities of certain parts locally affected, or ſome fortuitous circumſtances happening from neglect, miſmanagement, indiſcretion, or conſtitutional idioſyncracy. See Wallis on Health and Disease, *Recapitulation after the article* MIXED FEVERS.

FEMORALIS ARTERIA. The FEMORAL ARTERY. Beſides oſſification and wounds, this *artery* may be the ſeat of an aneuriſm. This laſt named accident is diſtinguiſhed in its earlier ſtage by its being circumſcribed, and ſmall, but it gradually increaſes; for a time the pulſation in it is ſufficiently remarkable; but as the tumor enlarges, the pulſations in it are more obſcure, and at laſt not to be perceived: when the aneuriſm is arrived to this ſtate, the lower part of the leg becomes œdematous from the preſſure above: and the limb in general is more and more unfit for uſe. Arrived at this ſtate, if relief is not afforded, a mortification will be the iſſue. It rarely happens that the operation for the aneuriſm will ſuffice in this caſe; for in general, the *artery* is not only dilated and burſt, but it is alſo diſtempered to ſome diſtance above the dilatation. Beſides, the want of collateral branches to carry on a due circulation is another impediment to a ligature being applied. Amputation, in ſhort, in this inſtance, as well as when this veſſel is wounded high up, near the belly, or low, near the ham, is the only relief. In caſe of an aneuriſm, if, on performing the operation, and tying the *artery*, pain follows, with fever, tenſion, &c. the iſſue will be fatal, if amputation does not befriend. If the tumor is about the middle of the thigh, when from an aneuriſm, and is yet but ſmall, it may be laid bare, and the *artery* tied above and below. But if the tumor is much enlarged, the *artery* will be found diſeaſed to a conſiderable diſtance above, and then the ligature will fail. If the tumor is near the groin, amputation itſelf is very uncertain as to ſaving the patient's life; if it is low, near the ham, or in it, amputation will be indiſpenſable, being the only means of reſcuing from a fatal mortification. See Mr. Pott's Works, and his Remarks on the Neceſſity, &c. of Amputation in certain Caſes.

FEMORIS, Os. THIGH BONE, called alſo *anchæ os*. In the thigh is only one; it is the largeſt and ſtrongeſt of any of the cylindrical bones. On its outſide, near the neck, is a large tuberoſity called the *trochanter major*, *rotator major*, *rotator natis*; and there is a leſſer one, on the inſide, named the *trochanter minor*, *rotator minor*. The poſterior concave ſurface of this bone hath a ridge riſing in its middle, called the linea aſpera, whoſe inferior extremity divides into two. The inferior extremity of this bone is formed into two condyles, between which a conſiderable cavity is found, eſpecially at the poſterior part. The two condyles are contiguous forwards, but at a diſtance backwards. The os *femoris* is articulated to the acetabulum by enarthroſis; to the tibia and the patella, by ginglymus. Winſlow obſerves, that all the proceſſes from this bone are cartilaginous in new-born children.

FEMUR. The THIGH. It is alſo called *femen*, *coxa*, *agis*, *ancha*, *crus*, *meron*.

FENESTRA OVALIS & ROTUNDA, from *feneſtra*, *a window*, and φαινω, *to ſhine*. See AUDITUS.

FERENTIS. See ARBUTUS.

FERINA, alſo *maniodes*. That delirium in which the patient rages violently, and is furious.

FERINUS. Savage, or brutal; but in a medical ſenſe it ſignifies noxious or malignant; hence it is applied to coughs, &c.

FERMENTATIO. FERMENTATION, alſo called *Ebrioſmus*, *Brioſmos*, is an inteſtine motion excited ſpontaneouſly, with the aſſiſtance of proper heat, and fluidity, betwixt the integrant and conſtituent parts of certain very compound bodies, from which reſult new combinations of the principles of theſe bodies. The heat required is betwixt ſixty and ſeventy degrees of Farenheit's thermometer. When the various juices of vegetables are diffuſed in water, and the action of the fluid is favoured by the action of air and heat, a decompoſition of theſe juices enſues. As the firſt agent of *fermentation*, the oxygenous gas is conſidered; which is afforded either by the atmoſphere or by the water which is decompoſed. The conditions then neceſſary for the eſtabliſhment of *fermentation* are, 1. The contact of pure air. 2. A certain degree of heat, (ſee above.) 3. a quantity of water more or leſs conſiderable, which produces a difference in the effects.—The phenomena which neceſſarily accompany *fermentation* are, 1. the production of heat; 2. the abſorption of oxygenous gas. *Fermentation* may be aſſiſted; 1. By increaſing the maſs of fermentable matter. 2. By uſing a proper leaven.

1. By increaſing the fermentable maſs, the principles upon which the air muſt act, are multiplied; conſequently, the action of this element is facilitated; more heat is therefore produced by the fixation of a greater quantity of air; and, conſequently, the *fermentation* is promoted by the two cauſes which moſt eminently maintain it; heat, and air.

2. Two kinds of leavens may be diſtinguiſhed. 1. Bodies eminently putreſcible, the addition of which haſtens the *fermentation*. 2. Thoſe which already abound with oxygene, and which conſequently afford a greater quantity of this principle of *fermentation*. This effect is produced by the inhabitants of the banks of the Rhine, by throwing freſh meat into the vintage to haſten the ſpirituous *fermentation*. The Chineſe throw an excrement into a kind of beer made of a decoction of barley and oats. The products of *fermentation* have cauſed different ſpecies to be diſtinguiſhed; but their variety of effects depends on the variety of principles in the vegetables themſelves. When the ſaccharine principle predominates, the reſult of the *fermentation* is a ſpirituous liquor: when the mucilage is moſt abundant, the product is acid; if the gluten be one of the principles of the vegetable, there will be a production of the ammoniac in the *fermentation* ſo that the ſame fermentable maſs may undergo different alterations which always depend upon the nature and reſpective properties of the conſtituent principles, the ſuſceptibility of change, &c. Thus a ſaccharine liquid, after having undergone the ſpirituous *fermentation*, may be ſubject to the acid *fermentation*, by the decompoſition of the mucilage, which had reſiſted the firſt *fermentation*. But in all caſes the concourſe of air, water, and heat, is neceſſary to develope *fermentation*. See CHAPTAL's Elements of Chemiſtry.

But this term is often made uſe of by medical writers, to expreſs that proceſs which is ſuppoſed to be carried on in the fluids of the human machine, when the found humours are converted into the nature of ſome morbid miaſmata which have been abſorbed into, or generated in the body, as in caſes of eruptive and ſome other fevers, the formation of pus, the lues venerea, &c.

FERMENTUM, FERMENT, BARM, YEST, LEAVEN, called alſo *cerocrum*.

Pliny, in his Nat. Hiſt. lib. xviii. c. vii. ſpeaks of the *barm* from malt liquor being uſed in Spain and Gaul, whence their bread was lighter than that of other nations. There are many other ſubſtances which excite *fermentation*, but this from malt liquor is always preferred to the others, whether for the purpoſes of pharmacy, or other inſtances wherein it is employed.

FERRAMENTA CANDENTIA. See ESCHAROTICA.

FERRAMENTUM. Inſtruments made of iron.

FERRAR. HESP. The abbreviation for Ferrarii Heſperides.

FERRAR. FLOR. The abbreviation for Ferrarius de Florum Cultura.

FERRATÆ, AQUÆ. See AQUÆ CHALYBEATÆ.

FERRI RUBIGO. See FERRUM, N° 2.

—— TINCTURA MURIATI. See FERRUM, N° 5.

FERRUGO. See FERRUM, N° 2.

FERRUM. IRON. It is alſo called *chalybs*, *Mars*, *edic*, *edich*, *edir*, *aquarius*, *biladen*, *hadid*. Its chemical character is ♂, by which is meant, that *iron* is gold at the bottom, the circle being the character of that perfect metal.

Iron is a greyiſh metal, very hard, the next in ſpecific gravity to copper, between ſeven and eight times ſpecifically heavier than water, diſtinguiſhable from all other

bodies, in its metallic ſtate, by its attracting, or being attracted by the loadſtone, but loſing this peculiarity on being reduced by fire to a calx. It is the hardeſt and moſt elaſtic of all metals, not fuſible without an intenſe white heat; it melts the floweſt of any metal, and calcining by the continuance of a weaker heat: it calcines more eaſily, though it melts with more difficulty, than any other metal. If *iron* is long kept in fuſion, it loſes its ſulphur, becomes more brittle, and at length is converted into a bluiſh glaſs, which if expoſed to the heat of a large burning-glaſs, after placing it on a piece of charcoal, it takes up the ſulphur it had loſt, and is true *iron* again. *Iron* is corroſible by a moiſt air, into a reddiſh yellow ruſt, and is ſoluble in all acids, on mixing with which it emits a garlic odour. Acids precipitate from *iron* all the common metallic bodies except zinc, forming with the marine acid, a yellow, with the nitrous, a dark red, and with the vitriolic, a pale green ſolution. All ſalts, except the alkaline, diſſolve *iron*.

In medicine, the diſtinction betwixt *iron* and ſteel is not neceſſary, though the ſteel is ſuppoſed to be harder than *iron*, yet it is not ſo, but by an additional proceſs; and, as a medicine, as well as in chemical proceſſes, the ſofteſt *iron* is preferred.

Iron combined with acids becomes an aſtringent ſubſtance; and upon its aſtringent and tonic powers its medicinal virtues entirely depend; for by increaſing the tone of the veſſels, it increaſes their vigour and activity. Melampus cured a man of impotency by the ruſt of *iron*; which is the firſt record of its uſe as a medicine. Boerhaave ſays, that *iron* is nearer allied to the human body than any of the other metals, ſo as to be almoſt wholly ſoluble therein.

The medical uſes of *iron* are moſt confined to, and manifeſted in chronical diſorders; *in which its efficacy is ſuperior to that of all animal and vegetable ſubſtances put together*. Weak, lax, pale, and leucophlegmatic habits, and all diſorders in which is a defect of vital heat, are relieved by this metal. It ſtrengthens the ſtomach, and chylopoetic organs in particular; and by its continued uſe, the whole ſyſtem is invigorated, the pulſe is raiſed, and every evidence of health reſtored.

By the ſame corroborating power, whereby it promotes deficient, and reſtrains redundant diſcharges, where the ſuppreſſion, or exceſſive flux ariſes from debility and relaxation, it contrariwiſe increaſes fluxes, and confirms obſtructions, when they proceed from tenſion, rigidity, or ſpaſmodic ſtrictures of the veſſels.

An aperient and aſtringent virtue hath been attributed to different preparations of *iron*; but they are all aperient or aſtringent, according to the ſtate of the conſtitution of the patient who takes them, and not as they have any ſuch property in themſelves. Chalybeate waters are ſaid to have ſimilar effects on the conſtitution, as *iron*. See AQUÆ CHALYBEATÆ.

IN THE CHLOROSIS, *iron* with aromatics, bitters, and aloetic purges, is almoſt a ſpecific. In this as in moſt other caſes, the crude *iron* filings, when very ſmall, excel all the other preparations; and in this caſe, the filings are peculiarly proper; for the ſtomach of chlorotic patients abounds with acids, which are abſorbed by the filings of *iron*. It may be that on the gas which is excited by the ferment of the *iron* with the acid in the ſtomach, the principal efficacy of the *iron* is dependent. The aloetics to be joined with *iron* in this diſorder, are the pil. ex aloe cum myrrha, or vinum aloes: theſe may be taken not as purgatives, but as alteratives, and to evacuate the inteſtinal contents only. If, in this diſorder, the breathing is rendered difficult by the uſe of *iron*, join it with myrrh, or gum ammoniacum.

SUPPRESSED MENSES, and alſo the IMMODERATE DISCHARGE of THEM, are reſtored to their natural order by this ſalutary metal. See MENSES. In HYPOCHONDRIAC and HYSTERIC COMPLAINTS, no medicine is to be preferred to this, though others have a uſeful influence herein, and are not to be omitted. IN THE RICKETS, *iron* is the ſpecific; and though in fevers, or where the heat of the body is exalted above the par of health, *iron*, as it increaſeth the heat, is generally prohibited, yet in ſome low fevers, it hath been adminiſtered in conjunction with nitre, and thus was productive of the moſt deſirable effects; when the fibres were lax, a mixture of ſal martis and ſal nitri, in equal parts, was given in doſes of ten or twenty grains; thus the velocity of the pulſe and feveriſhneſs were abated, though the habit in general was thus improved.

In ſome inſtances, where *iron* is a neceſſary medicine, it, notwithſtanding, is apt to occaſion ſickneſs and perturbation; in this caſe, give a mild opiate, or direct the medicine to be taken in bed, half an hour before the patient riſes in the morning, and when he goes to reſt at night; or he may be directed to walk after each doſe.

The beſt forms for adminiſtering *iron* will be determined by the intentions of preſcribing it. If to correct the depraved ferment in the ſtomach be the primary intention, the filings may be given in the form of a powder, or an electary; but if to exalt the blood, open obſtructions, and improve the general habit, a ferrugineous wine is by ſome preferred.

Small doſes, and duly repeated, are better than large ones; ten grains of the pure filings, and two or three grains of ſolutions in acid vehicles, are ſufficient.

The preparations in general uſe, are as follow:

1. *Limaturæ* Ferri. *Filings of* IRON, called alſo *Ducnez*.

Of all the preparations, this alone poſſeſſes all the virtues of *iron*. The ruſt is the next uſeful one, but it is not ſo powerful an abſorbent of acids in the primæ viæ, nor does it poſſeſs ſo large a ſhare of the gas, which is ſeparated by the action of acids on pure *iron*. If pure *iron* is reduced into fine filings, it is the leaſt offenſive to the taſte, and the moſt extenſively uſeful in its effects.

2. FERRI RUBIGO, called formerly, *Ferrugo, Chalybis rubigo. The Ruſt of* IRON *prepared.*

Moiſten clean filings of *iron* with water, and ſprinkle them over with a little powdered ſal ammoniac; and when the whole is dried, powder and paſs it through a fine ſearſe. The doſe is the ſame as that of pure filings. The College of Phyſicians of London order one pound of *iron* filings to be expoſed to the air, often moiſtened with water until they are corroded into ruſt; then pounded in an iron mortar, and the very fine powder to be waſhed off with diſtilled water. The remainder, which will not by moderate rubbing be reduced into a powder, eaſily waſhes off, and muſt undergo the ſame proceſs; the waſhed powder muſt be dried for uſe. Pharm. Lond. 1788. In hypochondriac, and epileptic complaints, it has been given; and, alſo, been ſucceſsful in worm caſes, in weak relaxed habits in which it has proved emmenagogue. The following electary is not an inelegant form of adminiſtration. ℞ conſerv. abſinthii maritimi, ℥ j. rubiginis ferri, ℥ ſs. conſ. ari ʒ ij. corticis aurant. q. ſ. ut fiat electarium: exhibeatur ℧. N. M. nocte maneque. During the continuance of taking this, the body ſhould be kept open by ſome gently aperient medicine.

3. *Flores Martiales. Martial Flowers*; alſo *Ens Veneris*, now called *Ferrum Ammoniacale.*

Take of *iron* filings, one pound: of ſal ammoniac, two pounds. Mix, and ſublime; what remains at the bottom of the veſſel, mix, by rubbing together with the ſublimed matter, and again ſublime. Pharm. Londin. 1788.

The ſucceſs of this proceſs depends chiefly upon the fire's being haſtily raiſed, that the ſal ammoniac may not ſublime before the heat is become ſtrong enough to enable it to carry up a portion of the *iron*; hence earthen or *iron* veſſels will be the propereſt for carrying on this work. The moſt convenient veſſel is an *iron* pot, to which may be luted an inverted earthen jar, with a ſmall hole in its bottom to paſs off the elaſtic vapours which ariſe during the operation.

When theſe flowers are ſophiſticated, they are of a dull and pale yellow colour; but if theſe ſophiſticated flowers are placed over the fire in a proper veſſel, the flowers will fly off, and leave the mixture behind.

The doſe of theſe flowers is from gr. vi to ϑ i. They are beſt taken in a bolus, or in the form of tincture; and are conſidered deobſtruent and corroborant.

They may be ſubſtituted for all the other preparations of *iron*; they are eſteemed as a ſpecific in the rickets, but, in reality, poſſeſs no advantages above the filings even in this particular inſtance. They have been called ens Veneris, and flor. ſal. ammon. martiales.

From theſe flowers, diſſolved in warm water and precipitated with the aq. kali, is produced that powder, which is called *Mars diaphoreticus*, and, by Zwelfer, ſulphur vitrioli anodynum martiale.

Theſe flowers diſſolved in ſp. vini r. form the ſedativum Archæi.

4. *Vinum.*

4. *Vinum Chalybeatum. Chalybeate Wine*, now called *Vinum Ferri. Wine of* IRON.

Take four ounces of the filings of *iron*; of cinnamon and mace, of each half an ounce; and of Rhenish wine, four pints. Macerate without heat for a month; then strain off the wine for use. But the College of London order four ounces of the filings of iron to be digested for a month in four pints of Spanish white wine, often shaking the vessel, and then strained. Phar. Lond. 1788.

Solutions of *iron* in vegetable acids are much more mild, and less ungrateful, both to the palate and stomach, than such as are made with the mineral acids.

The dose is from a tea-spoonful to a table-spoonful, two or three times a day, in any convenient vehicle. In chlorotic cases, and in debilitated phlegmatic habits, it is an excellent remedy, but in habits of a contrary nature it should be cautiously administered.

5. *Tinct. Martis in Sp. Salis. Tincture of* IRON *in Spirit of Salt*; now called Tinctura Ferri muriati. *Tincture of muriated* IRON.

Take of the rust of *iron*, half a pound; muriatic acid, by weight, three pounds; pour the muriatic acid upon the *iron*, in a glass vessel, and shake the mixture now and then, during three days; set it by, that the fæces may subside, evaporate the liquor poured off to one pound, and add thereto three pints of the rectified spirit of wine. Pharm. Lond. 1788.

This was formerly called tinct. martis Mynsichti. The virtues of this are the same as other preparations of *iron*; but it is generally more speedy and certain in its effects; its dose, from ten to sixty drops, two or three times a day. It has sometimes been given for gleets; also, in dysuria, occurring in consequence of stricture, ten drops every ten minutes; it relaxes the spasm by producing nausea, and thus relieves. It is very efficacious in destroying venereal warts, either used alone, or diluted with a small proportion of water.

6. *Tinct. Flor. Mart. Tincture of the Flowers of* IRON.

Take of the martial flowers four ounces; and of proof spirit one pint. Digest and strain.

All the tinctures of steel are no other than real solutions of *iron* made in acids, and combined with vinous spirits; but the first of these two is the strongest. The dose of the first may be from ten to twenty drops three times a day; and, of the latter, three times the quantity may be allowed.

7. LIXIVIUM MARTIS.

Let the matter which remains after subliming the flowers, be set by in a moist place, and it will run into a liquor which is the lixivium.

Some call it *oleum martis per deliquium*, and *essentia martis*. The dose is from one to three or four drops, as an astringent, and a very powerful one. In SURGERY, it is used as a styptic, in cases of hæmorrhage, applied to the bleeding vessels on lint.

8. *Mars Saccharatus. Candied* STEEL.

Put any quantity of clean filings of *iron* into a brass kettle, suspended over a gentle fire; add to them, by little and little, twice their weight of white sugar boiled to the consistence of candy, with which powdered starch hath been previously mixed, in the proportion of one dram to a pound, agitating the kettle continually, that the filings may be crusted over with the sugar, and taking great care to prevent their running into lumps. The dose is 3 ss. two or three times a day.

9. MARS SOLUBILIS, called also *Chalybs Tartarizatus*; now *Ferrum Tartarizatum. Tartarised* IRON.

Take of *iron* filings, one pound; powdered crystals of tartar, two pounds; mix them with distilled water into a thick paste, which expose to the air, in an open earthen vessel, for eight days; then rub the matters, dried in a bath of sand, to the finest powder. Pharm. Lond. 1788. This is said to have taken effect after all other preparations of *iron* have failed; for it is *supposed* to be more soluble in the animal fluids. The dose, from ten gr. to thirty twice a day.

10. SAL MARTIS. *Salt of* STEEL. *Chalybis Sal*, now called *Ferrum Vitriolatum. Vitriolated* IRON.

Take filings of *iron*, vitriolic acid, by weight, of each eight ounces; distilled water, three pints; mix them in a glass vessel, and when the effervescence has ceased, place the mixture for some time on hot sand; then pour off the liquor; filter it through paper, and after proper evaporation set it by to crystallize. Pharm. Lond. 1788. It is given from three or four grains for a dose, to twenty. It is deobstruent, quickens the circulation, gives tone and vigor to the system, and destroys worms: ten grains may be dissolved in a pint of water, and given in repeated draughts, with proper exercise, after the mode of taking chalybeate waters.

11. EXTRACTUM MARTIS.

Iron filings are to be dissolved in some vegetable acid, and then evaporated to a due consistence.

As to the *crocus martis aperiens*, and *crocus martis astringens*, the College of London substitutes the colcoth. vitriol for them. They are all three but a calx of *iron*; and of all the preparations of this metal, the calces are supposed to be the least useful, as they are the least soluble in acids. Though Mr. Beaumé observes, that these calces recover their original metalline state by digesting in olive-oil during an hour or two; whence probably a revival of them. See Dict. of Chem. 4to. from the French; Lewis's Mat Med. Neumann's Chem. Works.

FERRUM AMMONIACALE. See FERRUM, N° 3.

—— EQUINUM. HORSE-SHOE VETCH. Boerhaave mentions three species, and Dale says they are astringent.

—— TARTARIZATUM. } See FERRUM, N° 9—10.
—— VITRIOLATUM. }

FERSÆ. See MORBILLI.

FERULA. FENNEL GIANT. It hath a large, succulent, milky root; the stalk is fungous, and full of a pithy matter. Boerhaave enumerates thirteen species.

—— AFRICANA GALBANIFERA, FRUTICOSA, SEMPERVIRENS. See GALBANUM.

FERULA ASAFŒTIDA. See ASAFŒTIDA.

—— FOLIO BREVIORI. See MEUM LATIFOLIUM ADULTERINUM.

—— GLAUCO FOLIO, &c. also called *thapsia ferulacea*, *libanotis fœniculi folio*, *panax asclepium*, and CANDY ALL-HEAL. This species grows in Candy; its roots and seeds are diuretic and emmenagogue.

—— MAJOR SEU FŒMINA;——tenuiore folio,—— fœniculi folio. FENNEL GIANT. It is cultivated in gardens, and flowers in July. The gum which is obtained from this plant is the SAGAPENUM, which see.

—— MINOR, called also *panax asclepium*, *libanotis ferulæ folio & semine*. ALL-HEAL of Esculapius.

FESTUCA AVENACEA. The GREAT WILD OAT-GRASS. See ÆGYLOPS.

FIBER. See CASTOR.

FIBRA. A FIBRE. Among the fluids in ovo, there is a terrestrial matter, the particles of which, soon after conception, begin to cohere (by the power of nature) and form themselves into threads called *fibres*. These terrestrial particles are united by a gluten. The most simple *fibre* consists of the most minute parts applied to each other longitudinally, so that the smallest *fibre* is that which consists of two elements longitudinally applied to each other; since one such element belongs only to the fluids.

Haller says, that the least discoverable *fibres* are of two kinds. The first are lineal; the second are conjoined with a breadth frequently larger than their length: and these latter, he informs us, are those of which the cellular membrane is made up.

On the different proportions of the terrestrial matter, and the gelatinous which forms the simple *fibre*, depend the different degrees of hardness and softness in the different parts of the body; and from the firm cohesion of these parts, or the defect therein, Boerhaave deduces the general source of diseases. See Boerh. Aph. and Haller's Physiology, in the article of ANIMAL FIBRE.

The strength or weakness of a *fibre* can only be defined in a relative sense. Soon after conception, the cohesion is so small as to be destroyed by a very gentle shock; but as time advances, different degrees of cohesion are observed, till the degree is attained which gives perfection to the being. The perfection of cohesion is when a *fibre*, or vessel, &c. will bear, in some degree, more force to be exercised against it, than what they are particularly designed for by their state and office. Many, but equally unsatisfactory, are the rules laid down to distinguish betwixt the rigid and lax *fibre* in particular constitutions; but with a view to practice in the recovery and preservation

tion of health, as a rigid *fibre* is a concomitant of exceſſive heat, and the lax *fibre* of a deficience thereof; an attention to the heat of a patient's body will be a more eaſy and ſatisfactory principle on which to proceed. See CALIDUM INNATUM.

The ſtate of the body in which there is a lax *fibre*, Dr. Geo. Fordyce calls the general weakneſs. He obſerves that weakneſs may be divided into two kinds: *the firſt*, in which the irritation and ſenſation are conſiderably increaſed: *the ſecond*, in which theſe ſenſations are greatly diminiſhed; as in the apoplexy and palſy. The firſt is called *ſingle weakneſs*, which may be ſubdivided into two varieties; 1. When by any means it is produced on a ſudden, in which caſe it is eaſily reſtored. 2. When it comes on ſlowly, then it is reſtored with difficulty. Theſe two, then, differ eſſentially; from their cauſes, ſymptoms, effects upon the ſyſtem, and their manner of cure. The ſecond is called *paralytic weakneſs*. Various are the cauſes of weakneſs: e. g. bleeding, by exhauſting the living power; all evacuations, when too copious, and too long continued; antiphlogiſtic medicines, all which leſſen the living power: a particular part may be weakened by exciting a ſecretion from the mucous gland of that part, or from a part which lies near, though not connected with it. The ſyſtem may be ſtrengthened by various means, as follow: 1. *By nouriſhing, ſtrengthening diet.*—If the veſſels have been ſuddenly emptied, give freely of nouriſhing food, as much as the powers of the conſtitution will eaſily digeſt: the veſſels will receive it, and the ſtrength will ſoon return. If the weakneſs approached ſlowly, good nouriſhment will not reſtore ſo ſpeedily; for the organs of digeſtion being conſiderably weakened, and that gradually, renders the digeſtion of food difficult; therefore, in theſe caſes, give moderate quantities of proper food, and repeat it often.—In hectic fevers, ſometimes the arteries are acting ſtrong; thence it is neceſſary ſometimes to take off that great degree of contraction, by diminiſhing the ſyſtem, by bleeding; then the patient may be capable of receiving nouriſhing diet.—When the ſtomach is weak, the patient ſhould avoid thoſe vegetables that produce acidity in the primæ viæ: hence cabbage, beans, peas, &c. are not proper. Farinaceous ſeeds, prepared and given with animal food, are the beſt. 2. *The body may be ſtrengthened by exerciſe.*—When exerciſe is uſed, it ſhould not be carried on to ſuch a degree as to weaken the patient by it; it ſhould be equal and univerſal through the whole body, not in any one part more than another: for this reaſon, riding in a carriage, &c. where the body is equally moved, is much preferable to any other; but if we want to uſe a more violent degree of exerciſe, riding on horſeback would be of great ſervice. The patient ſhould go out when the air is free and pure; thus the circulation is increaſed and paſſes through the lungs without being obſtructed; but if he goes out in a moiſt air, the lungs become ſomewhat obſtructed; then anxiety, &c. are produced. The exerciſe ſhould be agreeable to the patient, in order that the mind may be agreeably affected. 3. *The ſtrength may be reſtored by means of cold.*—Cold contracts the external veſſels, by which the internal, about the præcordia, are kept filled, which always tends to keep up the ſtrength of the patient; farther, it takes off the irritability of the ſyſtem, and prevents people, when expoſed to cold, from readily ſuffering by it. If the cold be ſuddenly applied, it contracts the external veſſels too much, by which the interior veſſels are over-loaded, and diſeaſes, ſuch as fevers, &c. are produced; therefore, expoſure to cold ſhould be gradual, that is, it ſhould be by living in a cold atmoſphere; and farther, it ſhould not be too conſiderable, though applied ſlowly, for it will produce weakneſs, and by its ſedative power, often numbneſs of the limbs, anxiety, &c. This however muſt be according to what degree the man hath been habituated to.—The tranſition from heat to cold, or cold to heat, ſhould not be ſudden.—The cold bath has been employed to ſtrengthen the ſyſtem; it ſeems to be a very uncertain remedy; for a ſudden expoſure to cold contracts the veſſels too much, and the interior veſſels are filled, ſo that after the patient comes out, the heart acts with greater force, and propels it again upon the ſkin; hence a ſweat is produced; by this a kind of paroxyſm is brought on. Sometimes it is of great ſervice; but in diſeaſes that are attended with weakneſs, where there are conſiderable ſecretions, as in a gonorrhœa benigna, &c. the diſcharges are ſometimes re-produced, inſtead of being taken off. A temperate bath, in which is diſſolved a quantity of aſtringent ſubſtances, as the ſea-water, acts as an aſtringent on the ſkin after the patient comes out, and often ſtrengthens the ſyſtem.—Cold climates have a greater tendency to ſtrengthen the habit than the warm, as the atmoſphere is more denſe, and reſpiration more free. 4. *The ſyſtem may be ſtrengthened by the patient being ſituated ſo as to breathe properly.*—It is eſſentially neceſſary to have a quantity of reſpirable air to breathe in. There are two effects that reſpiration produces on the blood; *in the firſt place* by propelling it backwards and forwards through the lungs, that it may not be accumulated in the right ſide of the heart; *in the ſecond*, by what it conveys to and returns from the blood, its colour changes from a dark to a florid red. From a want of pure air, anxiety, &c. is produced, and a weakneſs ſoon follows. Thoſe who dwell in large towns are more ſubject to diſeaſes from weakneſs; thoſe who live in villages are generally more robuſt, and ſubject to inflammatory complaints. But although a cool air conduces in general to increaſe the ſtrength, when the patient is greatly exhauſted by profuſe evacuations, or from long-continued weakneſs; by ſending him into the country, the purer air there may cauſe too free and great a circulation; as the large veſſels then contain but a ſmall quantity of blood, ſuch a weakneſs will thereby be produced as to cut the patient off. 5. *Medicines are the next means of reſtoring loſt ſtrength.* Theſe are ſuch as invigorate the ſolids, chiefly by increaſing the living power; of this ſort are camomile, gentian, wormwood, the bark, and ſome other bitter vegetables.—Among the metals, iron is peculiarly adapted to uſefulneſs on this principle. All theſe leſſen irritability, whilſt they give tone to the relaxed *fibres*. In caſes where the habit hath been ſuddenly weakened, but the organs of digeſtion and the appetite are not impaired, there is not often occaſion to employ theſe remedies, but only to uſe a nouriſhing diet. If, for example, a patient is weakened by a fever, and a little of the inflammatory ſymptoms remain, it is better to omit theſe medicines; but, if a degree of fever be left, and there is a want of appetite, colliquative purges, &c. and the ſtrength does not return, we may uſe them with advantage.—If weakneſs be brought on ſuddenly, and is attended with partial evacuations, it is neceſſary to employ them.—When ſtrength is ſuddenly loſt, it is obſervable, that amongſt all the juſt-named medicines, the bark is the beſt.—When the weakneſs is ſlowly produced, theſe medicines may be employed with great advantage, if ſuitable precautions are not neglected. 1. In people of melancholy temperaments, where there is evidently a contraction of the veſſels, as well as a weakneſs, which is indicated by a hard pulſe, we ſhould endeavour to take off this diſpoſition to contraction before we employ them, which may be done by evacuation. Indeed in melancholic habits, it often happens that we cannot by any means employ them.—2. They are apt to deſtroy the irritability with regard to themſelves; for if you give them, at the firſt, for about a week, their effects are produced; the patient ſeems much relieved: but after a continuance through a ſecond or third week, their effects are in a manner loſt. *For this purpoſe, it is better to vary the medicines; giving the bark and ſteel alternately, and leaving them off for a time, ſo that they do not become habitual to the patient, and then after ſome time the patient repeating them again, his ſtrength is reſtored.*—When weakneſs is gradually brought on, and in conſequence of lingering diſeaſes, it is generally better relieved by bitters and other ſtrengtheners, than by the bark.—If there be relaxation of the moving powers in general, preparations of iron are often preferable to either the bark or bitters; but when the ſyſtem is diſpoſed to be ſtimulated, they cannot be employed with advantage. Iron having a ſtimulus, it ſhould be given in a ſtate of ſolution, which will leſſen its ſtimulating power. But it ſhould be remembered, that ferrugineous preparations are not proper in melancholic habits, becauſe their ſtimulus produces coſtiveneſs. *In lax habits only, they are to be employed.*—When ſtrengthening medicines are given, they ſhould not be directed in too large doſes. If the bark (for inſtance) is given, two, or at the moſt, four drams will ſuffice in twenty-four hours. Too large doſes create weakneſs.—When the ſtomach and the inteſtines are weak, the whole ſyſtem is generally affected; and on the contrary, vice verſâ. If the weakneſs of the primæ viæ is very great, it ſometimes produces a palſy in theſe parts.—In anxiety and loſs of appetite, give acids, particularly ſuch as do not ferment in the ſtomach; and give them an hour or two before dinner.—If flatulencies attend, wine and ſpices may be ſerviceable.—If the ſtomach

is

is loaded with mucus, give an antimonial vomit; and direct the patient to live on animal food, and farinaceous feeds, properly prepared.—If neither the piles nor the menſes forbid, aloetic purgatives will be the beſt for guarding againſt coſtiveneſs: in caſe of either of theſe forbidding the uſe of aloes, it may be adviſeable to give rhubarb with the magneſia alba. See Edinb. Med. Com. vol. iv. p. 399, 413.

FIBULA. It is the name of a contrivance of the ancients for bringing the lips of wounds together. Alſo a BUCKLE. Hippocrates ſometimes uſes the word for the part only of the bone that forms the outer ankle, perhaps, becauſe they uſed to buckle their ſhoe in the place. A CLASP or BUTTON. The ancients called the ſmall bone of the leg thus, from its joining the tibia and muſcles together: this bone is alſo called *perone*, *ſocile minus*, *arundo minor*, *canna minor cruris*, *foſſilus*, *ſura*, and *radius*. On the outſide of the leg and behind the tibia, the *fibula* is placed: its upper extremity is flattened where it is connected to the tibia; its lower extremity hath an oblong head, which is received by the external cavity of the tibia; below this, the head of the *fibula* is extended in a coronoid proceſs, contiguous to the outſide of the aſtragalus, which proceſs is called the *malleolus externus*.

FIBULEUS. See PERONÆUS MUSCULUS LONGUS.

FICARIA. See SCROPHULARIA MAJOR, and CHELIDONIUM MINUS.

FICATIO. See FICUS.

FICOIDES. It is a ſucculent plant, which reſembles houſe-leek. Boerhaave enumerates fifty-three ſpecies. They are ſaid to be emollient. *Ficoides* is alſo a name of the *banana*.

FICUS, vel *ficatio*. The name of a tubercle about the anus or the pudenda. See CONDYLOMA.

—— INDICA. See BANANA and MUSA.

—— INDICÆ GRANA. See COCINILLA.

—— INFERNALIS. See CATAPUTIA.

—— SATIVA,—ARIDA—COMMUNIS, called alſo *caprificus*, *erineos*. THE FIG-TREE. The FICUS CARICA, *foliis palmatis*. CL. POLYGAMIA. ORD. TRICŒCIA. LINN. Gen. Pl. 1168. The unripe fig is called *groſſus*; the dried, *caricæ*. The grain or ſeed of which is called *cenchramis*. This tree is of a middling ſize, with large leaves cut into five ſegments. It is remarkable for producing no flowers previous to the fruit. It grows ſpontaneouſly in the warmer climes, and is cultivated in our gardens.

The beſt *figs* are brought from Turkey; many are brought alſo from the ſouth of France, where they dry them, firſt by dipping them in ſcalding hot ley, made of the aſhes of the *fig*-tree, and then expoſing them to the ſun. The recent fruit, completely ripe, is ſoft, ſucculent, and eaſily digeſted, unleſs eaten in immoderate quantities, when it is apt to occaſion flatulency, pain of the ſtomach, and diarrhœa.

This fruit is glutinous and ſalt; for firſt they ſtick to the hands, and then ſcour them after the manner of lixivial ſalts, whence it is that they excite to ſtool without griping. They are conſiderably nutrimental, perhaps more ſo, becauſe their ſugar is united with a large portion of mucilaginous matter, which is generally ſuppoſed to be of an oily nature, and therefore contributing to a nutritious quality; grateful to the ſtomach, and eaſier to digeſt than any other of the ſweet fruits. But their principal medicinal uſe is as a lubricating emollient ſweet; they are an ingredient in pectoral decoctions and ſuppurating cataplaſms. In this laſt intention, they are ſometimes uſed by themſelves, as warm as they can eaſily be borne, to phlegmons of the gums, and other parts, where poultices cannot be conveniently applied. See Lewis's and Cullen's Mat. Med.

FIDICINALES. See LUMBRICALES MUSCULI.

FILACEÆ RADICES. FILACEOUS ROOTS. They are ſuch as are furniſhed with many filaments.

FILAGO. See GNAPHALIUM.

—— ALPINA. The herb LION'S FOOT. See LEONTOPODIUM.

FILAMENTUM. A FILAMENT, (from *filum, a thread*). A body appearing in the form of a ſlender thread. In botany, it is that thread-like part of the ſtamen which ſupports the anthera, and connects it with the *receptaculum*. By ſome Engliſh botaniſts, it is called *filament*; by others, *thread*.

FILELLUM. See PENIS.

FILETUM. See LINGUA.

FILICES, (from *filum, a thread*; quaſi filatim inciſa,) FERNS; one of the ſeven tribes or families of the vegetable kingdom, according to LINNÆUS, by whom it is thus characteriſed; having the fructification on the back ſide of the frondes. They conſtitute the firſt Order in the Claſs Cryptogamia, and conſiſt of ſixteen genera, which are divided into fructificationes ſpicatæ, frondoſæ, and radicales. This order comprehends the entire ſixteenth claſs of Tournefort, in whoſe ſyſtem, the *filices* make only a ſingle genus, in the firſt ſection of the abovementioned claſs.

FILICES, an order of plants in the Fragmenta Methodi naturalis of Linnæus. MARTYN ſays, the *filices* are the fourth family, and the ſixth tribe or nation in Linnæus's general diſtribution of vegetables; the firſt order of the claſs cryptogamia, in his artificial ſyſtem; the ſixty-fourth order in his fragments of a natural method; and the fifty-fifth of his natural orders at the end. Gen. Plant.

FILICULA. See ADIANTHUM NIGRUM.

FILIPENDULA. DROPWORT, alſo called *ſaxifraga rubra* and *œnanthe*.

It grows wild in fields and chalky grounds: it is rough and bitter, and is ſlightly pungent. The ſpecies uſed in medicine, is the *ſpiræa filipendula*. Linn.

—— CICUTÆ FACIE. See ŒNANTHE CHÆROPHYLLI FOLIIS.

FILIUS ANTE PATREM, becauſe its flowers appear before the leaves. See TUSSILAGO. This name is alſo given to other plants whoſe flowers appear before their leaves.

FILIX, alſo PTERIS. FERN. For which ORIBASIUS uſes the term *blancnon*. Boerhaave mentions nine ſpecies.

Fern is divided into the male and female kinds; the male hath no branches, but only one main rib; the female is branched.

—— ACULEATA. See LONCHITIS.

—— FLORIDA, RAMOSA, *oſmunda vulgaris*, and *paluſtris*. FLOWERING FERN, and OSMUND ROYAL. It is the *oſmunda regalis*, Linn. It is the largeſt of the true Engliſh *ferns*; it bears no flowers, but its fruit in cluſters. Towards their tops, are round, ſlender, ſeed-bearing, curled heads of a browniſh colour, covered with ſeeds; they appear in June and ripen in July. The root conſiſts of many ſmall, long, round parts matted together, blackiſh on the outſide, and green within, covered with ſmall fibres. It is found in marſhy and boggy places. The roots are eſteemed as uſeful in all the caſes that the roots of the other ſpecies are recommended againſt; but a conſerve of the tender buds or heads is the beſt.

—— FŒMINEA, RAMOSA MAJOR. FEMALE FERN, BRAKES, or BRACKEN. It is the *polypodium filix fœminea*, Linn.

FILIX FOLIIS POLYPODII. See POLYPODIUM ANGUSTIFOLIUM.

—— MAS. MALE FERN, called alſo *lonchitis*; *polypodium filix mas*; or POLYPODIUM *frondibus bipinnatis, pinnis obtuſis crenulatis, ſtipite paleaceo*. CLASS, CRYPTOGAMIA. ORD. FILICES. LINN. Gen. Pl. 1179. The *ferns* are well enough known to render their deſcription needleſs; but it may be obſerved, that on the leaves of this ſpecies, are tubercles which contain the ſeed; and about the end of the ſummer, they may be found. The root of the male *fern* reſembles that of the oſmund royal, and is often ſold for it. The roots of moſt of the ſpecies, when chewed, are of a ſweetiſh taſte, and are glutinous, but ſoon become bitteriſh, ſubaſtringent, and nauſeous: they are uſed by ſome for deſtroying the worms called tænia, and given in the following manner: the patient is firſt prepared by an emollient clyſter, and a ſupper of panada, with butter and ſalt; in a morning, two or three drams of the powder of the male *fern*-root are given, waſhed down with a draught of water; and, two hours afterwards, a ſtrong cathartic, compoſed of calomel and ſcammony, proportioned to the ſtrength of the patient: ſhould not this operate in due time, a doſe of purging ſalts is to ſucceed; and, if the worm is not expelled in a few hours, this proceſs, at proper intervals, muſt be repeated. It ſeems, though, doubtful to Dr. Cullen, whether the *ferns* have any ſpecific power in killing worms, either of one kind or another; for the ſtomach bears conſiderable quantities of it without uneaſineſs; and when given by itſelf, it has no ſenſible effects: it is generally given with ſome draſtic purge, therefore its apparent good may, in ſome caſes, be de-

rived from that fource. It appears, however, from fome experiments made in Germany, that in feveral inftances, the tænia has been expelled by the repeated exhibition of the root, without the aid of any purgative; others ufe them as deobftruents, and extol them againft the rickets. The male *fern*, and thofe that bear flowers, are moft antifeptic and fubaftringent; the female *fern* is more vifcid, faponaceous, and diuretic. Cullen's Mat. Med. Woodville's Medical Botany.

FILIX QUERNA REPENS. See POLYPODIUM TENERUM MINUS.

FILTRATIO. See DEPURATIO. Generally a paper is folded into the fhape of a funnel, and then placed in one; into which fome of the liquor is to be poured, which is to pafs through the paper thus placed.

FILTRUM. See FILTRATIO. It is alfo a ftone which is found in the bay of Mexico, which is ufed for filtering liquors through.

FILUM ARSENICALE. See MERC. CORR. ALB.

FIMBRIA. FRINGE. Thofe leaves are faid to be fimbriated that are jagged about the edges. In SURGERY, this word means the fame as CATABLEMA, which fee.

FIMUS. DUNG. The *dung* of many animals hath been in ufe; but the prefent practice excludes them all from the materia medica.

FISSILIS LAPIS HIBER. See HIBERNICUS LAPIS.

FISSURA. A FISSURE or CRACK, from *findo, to cleave*. Thefe are either natural or morbid: thus the mouth, or other natural apertures into the body, are called *fiffures*. Morbid *fiffures* are cracks in the fkull, &c. or when a bone is fractured in any part lengthways.

A morbid *fiffure* differs from a fracture, becaufe the firft hath fome degree of cohefion; but in the latter, there is a total folution of continuity. A fracture is tranverfe or oblique, and a *fiffure* is longitudinal.

Fiffures moft frequently happen in the fkull; and of thefe there is, FIRST, the CONTRA-*fiffura*, or *counter-fiffure*, when the blow is received on one fide of the head, and the fkull is cracked on the other; or, where the internal table is broken, the external remaining found; or, where the ftroke is received on one bone, and the *fiffure* is in that adjoining. Many authors doubt the exiftence of a *counter-fiffure*, and it is difficult to account for it; but the facts are too well atteſted to deny them. Hippocrates, Galen, Celfus, Berengarius, Fallopius, and feveral others, affert their having met with inftances of them. SECONDLY, that kind which is moft frequent, is that which, when large, is foon difcovered by laying the bone bare, and cleaning the part with fponge. But fometimes they are fo fmall, that fome art is neceffary to difcover them; in which cafe, rub a black liquor, made of burnt bone, or cork, mixed with water, and immediately wafh it off again; this black liquor, finking into the crack, difcovers where its fituation is; or, if the head is clean fhaved, and the patient is bled freely, an œdematous puffinefs will appear in a day or two over the part affected.

Fiffures are often productive of worfe confequences than fractures; for there is often, at the fame time, a concuffion of the brain; whence it is the more neceffary to be well aſſured of the attendance of this accident, or the contrary. Inftances of the ill effects of *fiffures* have happened ten months or more after the accident. It is not fimply the *fiffure* that is dangerous, but the violence that occafioned it, which alfo occafions the teguments and the bone to fuffer: all the bad fymptoms depend principally upon the rupture of a great number of veffels, and a detention of extravafated liquids, whence the bone is corrupted; and when this happens, a fudden and unexpected death is often the conſequence. The cranium cannot be *fiffured* without being alfo contufed, by which many veffels in the fubftance of the bone, and in the diploe, are broken.

Trepanning feems to be the propereft method of relief, though the method recommended by Mr. Bromfield, in concuffions of the brain, hath alone effected a cure.

FISSURA CEREBRI MAGNA SYLVII. The anterior and middle lobes of the cerebrum on each fide are parted by a deep narrow fulcus, which afcends obliquely backwards from the temporal ala of the os fphenoides to near the middle of the os parietale, and this fulcus is thus called.

FISSURÆ ORBITARES INFERIORES. See SPHENO-MAXILLARES FISSURÆ.

FISTULA. So the Latins called a *catheter*. See CATHETERUS; and alfo a *clyfterpipe*. See ENEMA.

FISTULA. In SURGERY, it is a kind of ulcer, called alfo *Eligii morbus*. It differs from a finus thus: a *fiftula* is narrower, generally continues longer, and hath its internal furface and its orifice for the moft part callous. Paulus Ægineta fays, "a *fiftula*, which derives its name from its refemblance to a reed or pipe, is a callous finus, generally the conſequence of abſceſſes." And Celfus defines a *fiftula* to be "a deep, narrow, and callous ulcer." The ſeat of a *fiftula* is in the cellular membrane.—*It is known to be preſent when there is an aperture on the ſurface of the body from which a ſanious, or other matter, either flows, or may be preſſed out*: its depth and direction is difcovered by a probe; or, if the directions are various, warm water may be injected therein; and if the courſe is near the fkin, it will be obſerved by the elevation made by the water; or, if otherwife, the quantity of water retained will determine the fize of the cavity. The probe indeed difcovers whether the *fiftula* runs upon an adjacent bone, or whether or not the bone is carious, which the water does not. The various parts in which theſe ulcers are ſeated, and the different circumſtances attending them, conſtitute the chief differences betwixt one *fiftula* and another. As to the prognoſtics, the thicker the cellular membrane, or the more ſtrata of muſcles upon each other, the more miſchievous a *fiftula* uſually proves: whilſt it is ſimple, and extends no farther than it can be wholly come at with a knife, it may be generally cured; when ſo ſituated as to open into the neck of the bladder, or when it is attended with a caries in the adjacent bone, particularly the os ſacrum or the coccyx, the cure is very difficult, and often impoſſible.

Mr. Bell, in his Treatiſe on Ulcers, includes the *fiftula* in his ſpecies of ſinuous ulcer. By ſinuous ulcer, he means that kind of ſore which hath one or more openings running into it from chinks of the ſame, or of different directions, and generally ſeated in the cellular membrane. A *ſinus*, as thus deſcribed, he ſays, *is the moſt ſimple ſtate of the diſorder, and is, by long continuance, or by the uſe of drying aſtringent applications, liable to become hard and callous in its internal ſurface, and in ſuch a ſtate*, from its ſuppoſed reſemblance to a pipe, *is termed a fiſtula*. The moſt frequent cauſe of ſinuſes forming in ulcers and abſceſſes, is the want of vent to the diſcharge, which eaſily inſinuates itſelf into the ſoft yielding ſubſtance of the cellular membrane, and proceeds on gradually till it ſomewhere or other finds an opening either externally, or into ſome of the neighbouring cavities. An improper application of bandages on ulcers is ſometimes a cauſe.

When *fiſtulas*, as yet not become callous, are complicated with ulcers, the moſt expeditious relief is from an inciſion to the very bottom, if it can be done without danger, after which they are to be deterged and conſolidated. Another ſtep is, to preſs their bottoms towards their orifices; for which purpoſe a narrow compreſs, or a ſlip of plaſter wrapped up in that form, is, after the ulcer is cleaned, and proper medicines put into the *fiſtula*, to be applied externally over the bottom, and ſecured, as in other ulcers, with plaſter, and bandages, to make it tighteſt there, that the peccant matter may be propelled from the bottom to the mouth of the *fiſtula*, in conſequence of which the bottom will be ſooneſt healed; this happens moſt frequently when the *fiſtula* is in the arms or legs, or when its mouth is lower than its bottom. Belloſte, and ſome others, abſolutely diſcard all tents and injections; but as to the latter, when *fiſtulas* lie too deep for having their moſt remote parts cleanſed, detergent injections muſt be uſed, ſuch as a decoction of birthwort, mixed with honey of roſes, or with the tincture of myrrh and aloes: this or ſome other ſuch like muſt be injected warm at every dreſſing, and retained for a ſhort time, at the ſame time gently compreſſing the bottom and mouth of the *fiſtula*, that the peccant matter may more effectually be waſhed off, and this method muſt be continued until the bottom of the *fiſtula* begins to be conglutinated; then dreſs with ſome ſoft digeſtive, in which is the balſ. Peruv. or balſ. capivi. This method failing, the manual operation muſt be attempted, but indeed, it is not to be depended on, except when the opening can be made to the bottom of the ulcer. The inciſion is made with moſt eaſe to the patient with a knife; but whatever inſtrument is uſed, as much ſkin and fleſh is to be cut, as is thought ſafe and ſufficient to anſwer the end; for when the bottoms of *fiſtulas* are laid open, the corrupted matter is not only diſcharged, but medicines are alſo more commodiouſly applied. If upon making the inciſion a large quantity of blood is diſcharged, fill the wound with dry lint and

and proceed afterwards as is uſual in recent wounds. Mr. Bell, in his Treatiſe on Ulcers, adviſes almoſt univerſally to ſhun the practice of laying the different ſinuſes open from one end to the other, then cutting out all the hardened parts, ſo to convert the whole into one common ulcer. This method he owns will frequently effect a cure; but independent of the great pain, and very large unſeemly cicatrix which it occaſions, it cannot, in every caſe, with ſafety be put in practice. For inſtance, when ſinuſes run far up the rectum, it cannot ever be conveniently done; they penetrate deep, and run below either large blood-veſſels, tendons, or nerves; it would never ſurely in theſe caſes be adviſeable to have recourſe to ſuch treatment. The intention of cure, in every caſe of ſinus, is to produce a coaleſcence of its ſides, ſo as to deſtroy any vacuity that may have occurred: the moſt effectual means of accompliſhing which, is, 1ſt. *to make a depending orifice for a free exit to the matter*; 2dly, *by a gentle irritation to induce, on the internal ſurface of the ſinus, a ſlight degree of inflammation*, which, by experience is known to be that ſtate moſt favourable to the production of adheſion between any two parts; ſo that a firm union of the ſides of the ſinus to one another, may, in due time, be obtained. To anſwer both theſe intentions, Mr. Bell ſays, that the introduction of a ſeton is ſufficient. The ſeton muſt paſs from the orifice in the ulcer along the courſe of the ſinus to its other extremity, where an opening, large enough for the diſcharge, ſhould be made, as is done in caſes of abſceſs. The cord of cotton, or of ſilk, ſhould at firſt be pretty large, more or leſs ſo, according to the capacity of the ſinus; it ſhould be diminiſhed gradually as the cure advances, by taking away a thread or two from its thickneſs every ſecond or third day; and at laſt, when the diſcharge is greatly leſſened, by the vacuity occaſioned by the ſinus being moſtly filled up, the ſeton ſhould be totally withdrawn, and a bandage ſomewhat tight being applied over the part, and continued for ſome time longer, a complete cure will, in general, be in due time effected. The firſt ſtep then to be taken, is to diſcover the direction of the ſinus, or ſinuſes, which may commonly be done, either by introducing a probe, or by obſerving where the matter points, or being allowed to collect for ſome time, and from whence it comes on the parts being preſſed; then into every ſinus that opens into the ulcer, a ſeton ſhould be introduced. This method of curing ſinuſes, by the uſe of a ſeton, is free from all danger, and is admiſſable in all caſes of this kind. A ſeton, by means of a director, may always be uſed with ſafety. The ſinuſes, being removed by the ſetons, the ulcers they were connected with are then to be cured as is uſual with that ſpecies to which it happens to belong. This practice rarely fails in any caſe of ſimple ſinus; in general it anſwers in real *fiſtulæ*; when a *fiſtula* happens in the perinæum, this practice is peculiarly advantageous, not producing that troubleſome cicatrix which happens when the knife is uſed. The only objection to the uſe of the ſeton in caſes of *fiſtula in ano*, is the irritation it would occaſion in the gut. But as Mr. Pott hath ſo ſimplified the management of the *fiſtula in ano*, to his method in that inſtance reference may be had. See Celſus, lib. vi. c. iv. Boerh. Aph. the Engliſh tranſlation, p. 102, 103. Pott's Treatiſe on Fiſtulas. Bell's Treatiſe on Ulcers, edit. 3. p. 244, &c.

Fistula in Ano.

No part of the body is more ſubject to abſceſſes than the part immediately ſurrounding the lower part of the rectum; it is much expoſed to preſſure and other external injuries, which impede the free motion of the blood there, which turns into pus, and as the ſkin here is pretty thick, the pus will inſinuate itſelf up amongſt the ſoft neighbouring parts, and form ſinuſes, which degenerate into *fiſtulas*.

This kind of *fiſtula* is called complete when there is an opening into the gut, and another externally; it is called incomplete when there is no external aperture.

The ſymptoms of the incomplete kind are analogous to thoſe of the piles, hence are they difficultly diſtinguiſhed. The complete kind hath generally callous lips, which, with the diſcharge therefrom, more readily points out the nature of the caſe.

Abſceſſes in this part ſhould be opened as ſoon as we find a fluctuation of matter, and that by a large aperture, which is the moſt effectual method to prevent a return. In examining one of theſe *fiſtulas*, if the probe does not readily paſs, inject warm milk into it, and obſerve if any returns by the rectum; if it does, it is clear that the gut is perforated. When the probe is uſed for examining with, let the patient ſtand on the ground, with his feet pretty far aſunder, and lean on his belly over a table, then an aſſiſtant can hold the buttocks aſunder, that the operator may more readily introduce his finger into the anus before he examines the *fiſtula* with a probe. If the *fiſtula* runs ſo deep that the finger introduced into the anus cannot eaſily reach the orifice, *then the cure is not practicable*; on account of the hæmorrhage from the veſſels, which admit not either of compreſſion or ligature. If a *fiſtula* hath been of long ſtanding, in a bad habit, and the diſcharge is ſuch as to weaken the patient, *the operation ſhould not be attempted*, at leaſt till the conſtitution is repaired; but if the patient is of a good habit, if the *fiſtula* returns, the operation may be repeated.

The method of operating is as follows, according to Monro's inſtruction: "Wherever the opening of the *fiſtula* is, if it hath any turnings where it reaches the gut, divide them, and make them ſtrait, avoiding the ſphincter. After this I attempt to promote incarnation, which might leſſen the cavity and by degrees fill it up, by injecting balſamic ſoftening medicines; though ſometimes a patient of a good habit may be cured by applying a poultice of bread and milk, and a digeſtive. If this fail, I endeavour to render the parts entirely callous and inſenſible, by injecting a mixture of lime-water and brandy, with a little honey of roſes, increaſing the brandy and diminiſhing the reſt, as the parts loſe their ſenſibility, until at length I inject pure alcohol, which renders them quite inſenſible." See Heiſter's Surgery; Le Dran's Operations. Sharp's Operations. Celſus ſpeaks well on this ſubject. Pott's Treatiſe on *Fiſtula's*. Bell's Surgery, vol. ii. p. 282. Kirkland's Med. Surgery, vol. ii. p. 201, 235. London Med. Journal, vol. v. p. 392. White's Surgery, p. 386.

Fistula *in the* Epididymis

In the Lond. Med. Obſ. and Inq. vol. ii. p. 273. is an inſtance of a *fiſtula* in this part being cured. The ſubſtance of the relation is as follows: a man of thirty-five years of age hurt his teſticles by a fall; a ſuppuration followed, and the matter was diſcharged externally. After this, the ſwelling being reduced by means of an emollient cataplaſm, a *fiſtula* was diſcovered in each *epididymis*; a probe director was then introduced into the left ſinus, which was cut open its whole length; after which all the indurated parts were diſſected, and all the diſeaſed ſkin; the ſame was done on both ſides, and a part of the *epididymis* on the right ſide was cut away. After this the dreſſings as in common wounds finiſhed a cure. And what deſerves ſome notice in this caſe is, that the functions of the teſtes were afterwards fully executed.

Fistula Lachrymalis. See Ægylops.

It is generally underſtood to be ſuch a diſorder of the canals leading from the eye to the noſe as obſtructs the natural paſſage of the tears, and makes them trickle down the cheeks. In the firſt and mildeſt ſtage of this diſeaſe an inflammation on this part is alone obſerved: in the next ſtage there is matter diſcharged from the puncta *lachrymalia*, which flows along with the tears; or it may be that the matter proceeds from an orifice broken through the ſkin, between the noſe and the angle of the eye. The laſt and worſt degree is, when the matter of the abſceſs has not only corroded the neighbouring ſoft parts, but alſo the ſubjacent bone, by which it becomes carious.

For a diſtinct idea of the ſeat of this diſeaſe, ſee a figure of the *lachrymal* ducts in a plate annexed to the chapter on this ſubject, in Sharp's Operations of Surgery.

If the ſkin which ſeparates betwixt the angle of the eye and the noſe is not corroded through, it is called *imperfect*; if it is corroded through, it is a *perfect*; and if the ſubjacent bones are affected, it is a *compound fiſtula lachrymalis*.

Other diſorders about the ſeat of the *fiſtula lachrymalis* are confounded with it; but properly this kind of *fiſtula* is a corroſion of the ducts of the *lachrymal* ſac; in conſequence of which, pus flows out of them into the great angle of the eye: when the clear *lachrymal* fluid flows out without a mixture of pus, the diſorder is an Epiphora, which ſee. The matter of a proper *fiſtula* flows through the upper puncta for the moſt part, but ſometimes through the lower only, or in a few inſtances through both.

The ſymptoms are, frequent droppings of tears, and of a purulent

a purulent matter, eſpecially in a morning, and this without any manifeſt external inflammation; by preſſure with the finger upon the *lachrymal* ſac, a diſcharge of pus follows, which is emitted through the puncta *lachrymalia*; if this pus is ill ſcented, the adjacent bones are generally carious; the ſame is indicated by a green or blackiſh colour of the diſcharged matter, although the ſmell be not offenſive: when the matter is of a bad ſmell or colour, the probe will readily determine the ſtate of the bone; for ſometimes it is not injured. notwithſtanding the attendance of the uſual ſigns; as, *on the contrary*, there is ſometimes a caries when the pus is diſcharged with every laudable appearance; though, if there is a daily and conſiderable diſcharge of faulty matter, a caries will for the moſt part be formed in the *lachrymal* bone, the os planum, or in the jaw-bone. If the naſal duct is obſtructed, it is known by injecting ſome fluid into it, when, inſtead of the fluid paſſing through the noſe, it returns by the puncta lachrymalia: if there is an encyſted tumor, the exterior parts ſwell with a hardneſs, and will not yield to the preſſure of the fingers, but there is no inflammation; *on the contrary*, if the tumor yields upon preſſure, there is a *lachrymal* hernia. Inſtances have occurred of a *fiſtula lachrymalis* not diſcharging pus with the tears, but the pus was diſcharged alone when the patient was aſleep, and this hath happened when a caries attended.

If the diſeaſe is recent, the habit of body not remarkably faulty, the external ſkin not corroded, the naſal duct unobſtructed, the matter of a good colour and conſiſtence, forbear inciſion, and alſo the cautery; for compreſſion and mild aſtringent collyriums will frequently ſucceed in this mild ſtage of the diſorder; the matter ſhould be now and then gently preſſed out with the finger, by which its acquiring an acrimony will be prevented. But if the duct into the noſe is ſtopped, nothing will ſucceed but the operation: in performing which, puſh the looſe ſkin of the under eye-lid upon the globe of the eye as much as you can, then cut a paſſage into the *lachrymal* groove, which is known by the crackling of the os unguis under the preſſure of the knife; then, if need be, introduce a probe, and perforate into the noſe: be well aware of getting your knife upon the upper part of the maxillary bone, which you will know by the reſiſtance; in this caſe go a little farther back with your inſtrument: further obſerve in perforating the os unguis not to preſs upon it too forwards, for then you will be obſtructed by a part of the maxilla ſuperior, which makes part of the canal wherein the ſac is lodged; if you preſs inwards there will be danger of injuring the os naſi, or the ſeptum naſi, or the os ethmoides: but if the inſtrument is paſſed backwards and downwards towards the uvula, no obſtruction will be met with.

For compreſſing inſtruments with which to cure the ſlighter caſes, ſee Sharp's Operations, and Gooch's Caſes. On the *Fiſtula Lachrymalis*, ſee Sharp's Operations, Le Dran's Operations, Edinb. Med. Eſſays, vols. ii. and iii. Pott's Treatiſe on the *Fiſtula Lachrymalis*, St. Yves on Diſorders of the Eyes, Heiſter's Surgery, Bell's Surgery, vol. iii. p. 469. Kirkland's Med. Surgery, vol. ii. p. 134, London Med. Journal, vol. i. p. 62. vol. ii. p. 77, 245. Wallis's Sauvages's Noſology of the Eyes, p. 77, 83. White's Surgery, p. 256.

Fistula in Perinæo.

This kind of *fiſtula* is when an opening in the ſkin correſponds with one in the urethra. It ſometimes happens that one opening out of the ſide of the urethra is attended with ſeveral through the ſkin, but it rarely happens that there are more than one opening through which the urine is diſcharged from the ſide of the urethra.

After lithotomy, a puncture of the perinæum, an abſceſs in the ſame part near the urethra, a ſcirrhus in the glandula proſtata, &c. a *fiſtula* is ſometimes formed, through which the urine makes its way in part, whilſt the reſt is paſſed through the natural paſſage.

A *fiſtula* proceeding from the urethra runs in various directions before it reaches to the external opening of the ſkin, ſo that when the external opening is near the anus, it may be taken for a *fiſtula* in that part; *but the diſcharge of urine through the fiſtula at once diſtinguiſhes its ſeat.*

Beſides the calloſities on the external orifice of theſe *fiſtulas*, there are ſometimes calculous concretions lodged in their cavities; indeed, ſo various are the circumſtances attending different caſes of this kind, that only general rules can be laid down for proceeding to the cure.

In general, in order to the cure, the outward opening muſt be enlarged by cutting away the callous lips, or deſtroying them by cauſtic; but it ſometimes happens that this end may be anſwered by introducing a bougie into the urethra, in order to diſtend its capacity. Le Dran obſerves, that though there are ſeveral *fiſtulous* orifices, and ſeveral calloſities in the perinæum, when the water paſſes off in a ſmall ſtream through the natural paſſage, the chief remedy will be the introduction of bougies; for as this canal is enlarged, the external orifices are diminiſhed and healed, and the calloſities are ſoftened. Mr. Bell prefers the cure of this *fiſtula* by the introduction of a ſeton. See Fistula, above. See Le Dran's Operations, where this article is well treated on. Bell's Surgery, vol. ii. p. 226. London Med. Journal, vol. i. p. 379. White's Surgery, p. 395.

On *fiſtulas* in general, ſee Celſus, Cæſar Magatus, Boerhaave's Aphoriſms, the Engliſh tranſlation, and Pott's Treatiſe on *Fiſtulas*.

FISTULARIS. Fistular. In botany, thoſe flowers are thus called which are compounded of many long hollow ſmall florets, like pipes. And thoſe plants are called *fiſtulous* whoſe ſtalks are hollow like a pipe.

FISTULOSUM FOLIUM. See Farctus.

FIXATIO. Fixation. In chemistry it is the rendering any volatile ſubſtance fixed, ſo as not to fly off upon being expoſed to an intenſe heat.

FL. LAP. The abbreviation of Car. Linnæi Flora Lapponica,

Fl. Norib. The abbreviation of Johannis Georgii Volckameri Flora Noribergenſis.

FLAMMULA. So the ſkein of ſilk uſed to be called with which ſetons were made. It is a name of ſeveral ſpecies of *ranunculus*. See Ranunculus longifolius, &c. of the *artragene* and *clematis*.

Flammula Jovis,—*ſurrecta alba*. The upright lady's bower. It is the clematis recta, or clematis *foliis pinnatis: foliolis ovato-lanceolatis integerrimis, caule erecto, floribus alvis pentapetalis tetrapetaliſque*. Class, Polyandria; Ord. Polygynia. Linn. Gen. Plant. 696. Upright traveller's joy. This, like ſome other ſpecies, is extremely acrid, hence the name flammula. The recent leaves on being chewed, excite a burning heat of the tongue and fauces; and if retained long in the mouth, ulcerate and bliſter; though, by drying, this acrimony is conſiderably diminiſhed; the flowers poſſeſs the ſame acrimony, though in a leſs degree. The herb with the flower is cauſtic; the root, ſeed, and bark, if rubbed with the fingers, then held to the noſtrils, ſtrike them very quickly with a ſtrong ſmell. This plant yields a water as ſtrong as ſpirit of wine, but it does not ſeem ſafe to adminiſter it internally. Though Stoerck publiſhed ſeveral caſes of its ſucceſsful exhibition, particularly in inveterate ſyphilitic diſeaſes, producing headachs, pains in the bones, nodes, ulcers, cutaneous affections, &c. He chiefly recommends an infuſion of two or three drams of the leaves in a pint of boiling water, four ounces to be taken three times a day, whilſt the powdered leaves were employed as an eſcharotic. See Stoerck de Flammula Jovis. However in this country it has not acquired any reputation; the phyſicians do not receive with any degree of confidence the medical facts of Vienna.

FLATUARII See Chemici.

FLATULENTUS, } See Ambulo.
FLATUS FURIOSUS. }

FLATUS. Flatulence. Vapours rarified by the heat of the part where they are contained; whence diſtenſions, uneaſy ſenſations, and often a conſiderable degree of pain. It is for the moſt part an inſtance of dyſpepſia.

FLAVII CLEMENTIS MEDICAMEMTUM. The name of a medicine for the gout; it is deſcribed by Actuarius.

FLAVUS CORTEX. Yellow bark. This bark, very lately introduced into practice, is ſuppoſed to be a ſpecies of cinchona, growing in the interior parts of America in a mountainous country, the ſame as that deſcribed by Murray, under the title of Cortex Chinæ, vel Chinchinæ Regius, ſeu Cortex chinæ flavus; who gives the following deſcription of it. This bark conſiſts of flattiſh pieces of about the length of a finger, the breadth of the thumb, and a line in thickneſs. Its colour is yellowiſh, inclining to that of the ruſt of iron. It partakes more of the ferrugineous colour on its external, than on its internal ſurface, owing to the cloſe adheſion of the epidermis to the bark. Both in its fracture, and on its ſurface, it appears fibrillous,

† breaking

breaking ſo eaſily between the fingers, that it may be rubbed into a yellow powder. In taſte it is intenſely bitter, with a ſlight degree of aſtringency. Its efficacy, by certain of the Frankfort phyſicians, is conſidered as far ſuperior in intermittent fevers to the bark commonly employed. Dr. RELPH ſays, this bark (the yellow) is only to be underſtood as approaching nearer to that colour than any other ſpecies of Peruvian bark imported into this country, eſpecially when reduced to powder. It conſiſts of flattiſh irregular pieces, of a cinnamon colour, inclining to red, and having, in certain directions of the light, a peculiar ſparkling appearance on the ſurface. The pieces are very generally diveſted of the cuticle, of a fibrous texture, dry, and rigid to the feel, and eaſily rubbed to powder between the finger and the thumb; neither remarkably weighty, nor the contrary. They have little odour, but to the taſte manifeſt intenſe bitterneſs, with a moderate ſhare of aſtringency, together with a certain flavour correſponding unequivocally to thoſe of the cinchona officinalis. The external ſurface of this bark is ſomewhat of a deeper colour than the internal, and in ſome ſpecimens it is as deep as that of the red bark. The pieces vary much in ſize; ſome are about two inches and a half in length, an inch in breadth, and the ſixth of an inch in thickneſs; while others are ſtill ſmaller; and ſome are to be found from twelve to eighteen inches in length, with the breadth and thickneſs in proportion. Pieces ſometimes through the whole cheſt are nearly cylindrical, and completely covered with outer coat, as the moſt perfect ſpecimen of common bark. The epidermis of the large pieces of the yellow bark is of a reddiſh brown colour, rough, and of a ſomewhat ſpongy texture; but that of the ſmaller pieces is of a grey colour, harder and much more compact.

Like the cortex Peruvianus, it gives out its virtues to water by infuſion or decoction, to proof or rectified ſpirits, and extracts may be formed of it in the ſame modes. It is conſidered to poſſeſs the ſame virtues but in a greater degree than either the common, or red bark, conſequently to be more efficacious, and requires to be given in ſmaller doſes. For the complaints to which it is adapted, we muſt refer our readers to Cortex Peruvianus. The doſe of the powder is from ℈ ſs. to ℈ ij. — of the extract half the quantity will ſuffice. See alſo RELPH, on the Yellow Bark.

FLEMEN. A tumor about the ankles. Sometimes it imports callous furrows in the hands or feet.

FLERESIN. See ARTHRITIS.

FLETUS. WEEPING.

FLEXOR A name applied to ſeveral muſcles, from their office, which is to bend the parts to which they belong.

—— BREVIS MINIMI DIGITI MANUS. It riſes from the unciform proceſs of the carpus, toward the annular ligament, and is inſerted into the baſis of the little finger.

—— CAPITIS. See RECTUS INTERNUS MAJOR.

—— CARPI RADIALIS. Some call it *flexor carpi exterior*, and *bicornis*. It riſes from the anterior part of the inner condyle of the os humeri, paſſes toward the outſide, and runs through the annular ligament, being partly inſerted into the trapezium, and partly into the firſt metacarpal bone.

—— CARPI ULNARIS. It is alſo called *flexor carpi interior*. It riſes from the inner condyle of the os humeri, and almoſt from the whole ſurface of the ulna, forming a tendon, which is inſerted into the os piſiforme.

—— DIGITI PARVI MINIMI. See ABDUCTOR MINIMI DIGITI MANUS, No. 2.

—— DIGITORUM ACCESSORIUS. See FLEXOR LONGUS PEDIS. Dr. Hunter calls it *acceſſorius*.

—— DIGITORUM PEDIS. See FLEXOR SUBLIMIS.

—— SECUNDI INTERNODII DIGITORUM PEDIS. See FLEXOR SUBLIMIS.

—— INTERNODII PRIMI DIGITORUM. See LUMBRICALES. Dr. Hunter deſcribes the lumbricales as productions of the flexors, and diſtinctly that called

—— INTERNODII PRIMI POLLICIS MANUS. It riſes from the annular ligament of the carpus, and is inſerted into the firſt bone of the thumb.

—— INTERNODII PRIMI & SECUNDI POLLICIS. Theſe muſcles riſe ſharp and fleſhy about the middle of the back part of the fibula; then running into a tendon in paſſing over the joint, and through a channel in the inner part of the os calcis, are inſerted into the upper end of the ſecond bone of the great toe.

FLEXOR INTERNODII SECUNDI DIGITORUM MANUS, alſo called *flexor ſublimis*, or *perforatus*. It riſes from the inner condyle of the os humeri, and from the forepart of the head of the ulna and radius; it paſſes through the annular ligament, and ſpreads out into four tendons, which are inſerted into the baſis of the ſecond phalanx: theſe are bound down by what is called an annular ligament, which is really a general ſheath of the fingers, thicker at the joints than elſewhere. Brown calls this muſcle flexor ſecundus.

—— INTERNODII SECUNDI POLLICIS MANUS. It is made up of two portions, the anterior of which is inſerted into one ſeſamoid bone, the poſterior into the other.

—— INTERNODII TERTII DIGITORUM MANUS. Dr. Hunter calls it *perforans manus*; *profundus manus*. It riſes from the inner condyle of the os humeri, from the external part of the ulna about its middle, and from the interoſſeous ligament it runs between the perforatus, and forms four tendons, which paſs through as many ſlits in the perforatus, to be inſerted into the baſis of the laſt phalanx.

—— INTERNODII TERTII POLLICIS, vel *longiſſimus pollicis manus*. It often hath a two-fold beginning, one from the internal ſubſtance of the os humeri, between the perforatus and perforans; this head is ſometimes wanting, and ſometimes ſprings from the upper and fore part of the ulna; the ſecond head riſes on the radius; it paſſes over the articulation of the carpus, and is implanted in the upper part of the third bone of the thumb.

—— LONGUS, or *perforans pedis*, called alſo *acceſſorius*. It riſes from the poſterior part of the tibia juſt below the poplitæus, and from the interoſſeous ligament; then goes on the inſide of the aſtragalus and os calcis (from whoſe internal part a ſhort head riſes, which is called acceſſorius), and paſſing through the ſlit of the perforatus, its four tendons are inſerted into the baſis of the laſt bones of the toes. This muſcle receives ſome fibres from the flexor pollicis longus.

—— PERFORANS MANUS. See FLEXOR INTERNODII TERTII DIGITORUM MANUS.

—— POLLICIS BREVIS. It is ſhort, thick, and fleſhy, ſeemingly divided into two muſcles, by the tendon of the flexor *pollicis* longus paſſing over it. It riſes from the upper part of the os cuneiforme medium, and running over the termination of the muſculus peronæus primus, is implanted into the oſſa ſeſamoidea of the great toe, which are likewiſe tied to the ſuperior part of the ſecond bone of that toe.

—— POLLICIS LONGUS MANUS. It riſes from the fore part of the radius, and commonly receives one ſlip from the coronoid proceſs of the ulna; it forms a tendon which paſſes deep under the annular ligament, runs between the two ſeſamoid bones, over the firſt and ſecond bone, to be inſerted into the baſis of the third.

—— POLLICIS LONGUS PEDIS. It riſes from the poſterior part of the fibula; paſſes in a groove between the aſtragalus and os calcis, is covered by the abductor *pollicis*, and goes between the ſeſamoid bones, betwixt which is an annular ligament, to be inſerted into the laſt bone of the great toe. It gives ſome fibres to the perforans *pedis*.

—— POLLICIS OSSIS PRIMI & SECUNDI. It is a large diſgregated muſcle, ariſing from the ligamentum tranſverſale carpi, the bones of the carpus at the baſis of the mons lunæ, and the os metacarpi of the middle finger, whence it paſſes to its inſertion into the firſt and ſecond bones of the thumb. In its tendon, near the inſertion into the firſt bone of the thumb, are placed two ſeſamoid bones. Its actions are various, as are the directions of the muſcles.

—— SUBLIMIS, or *perforatus pedis*. Winſlow calls it *flexor digitorum brevis*, and Brown calls it *flexor ſecundi internodii digitorum*. It riſes from the lower and inner part of the os calcis: it is divided into four tendons under the ſole of the foot, which are inſerted into the bones of the ſecond phalanx.

FLORES. FLOWERS. IN CHEMISTRY, they are the moſt ſubtil parts of bodies, ſeparated from the more groſs, by ſublimation in a dry form, and found under the reſpective name of the material uſed, as *flores benzoini—antimonii*, &c. Mace is ſometimes called the *flowers* of nutmeg. IN BOTANY, *flowers* are conſidered as under the article FLOS, which ſee. IN PHARMACY, they are directed to be gathered when moderately expanded, on a clear dry day before noon. Red roſes are taken before they open, and the white heels are clipped off and thrown

away. Thoſe *flowers* that are gathered for keeping ſhould be dried in the ſhade, but as quickly as poſſible; in ſome inſtances, the place may be warmed by a fire, though the ſun is not ſo conveniently permitted to ſhine upon them. When the *flowers* are dried, they muſt be kept cloſe and dry; if they become damp, expoſe them to a warm ſun until they are dry, and then they do not ſoon attract moiſture from the air. With their ſcent and colour their virtues go. Conſidered as an article in the materia medica, it may be obſerved, that the virtues of different *flowers* reſide in different parts of them; e. g. *ſaffron* is a production which riſes from the ſtyle of the *flower*; it contains all the medicinal qualities of the plant, at leaſt all thoſe for which ſaffron is eſteemed; the active part of *camomile flowers* is in the yellow diſk; *in roſes, lilies*, and ſeveral others, the virtues are in the petala; and the flavour admired in *roſemary flower* is chiefly in the cups.

FLORES ANTIMONII. See ANTIMONIUM, No. 9.

FLOS. A FLOWER, which PARACELSUS calls *cheizi*, when he ſpeaks of vegetables. IN BOTANY, it is that part of a plant in which are the parts of generation, and that of both the ſexes. In ſome *flowers* are the parts proper to one ſex only; in others, both ſexes are included in the ſame *flower*. A flower, when complete, conſiſts of a *calyx*, *corolla*, *ſtamen*, and *piſtil*; but the eſſential parts are the *anther* and *ſtigma*, which are ſufficient to conſtitute a flower, either together in hermaphrodite flowers, or ſeparate in male and female flowers. See PLATE 3d *of the Botanical Plates*.

—— ABORTIENS. Abortive flower producing no fruit.

—— APETALUS, called APETALI. Theſe are without corolla; called, by ſeveral writers, ſtamineous, incomplete, imperfect. They have no other covering on the parts of generation but the calyx.

—— CAMPANIFORMIS, or *cumpaniformis*. Theſe *flowers* are ſhaped like a bell. Thoſe whoſe edges ſpread wide are termed open bell-ſhaped *flowers*; but thoſe which are much leſs ſpread, are called tubulous bell-ſhaped *flowers*.

—— CARYOPHYLLEUS. It is ſuch a *flower* as reſembles a ſingle pink, or carnation, having five regular petals, ending at the bottom in a long narrow claw.

—— COMPOSITUS. It is a ſpecies of aggregate flower, containing ſeveral florets, incloſed in a common perianth, and on a common receptacle, with the anthers connected in a cylinder.

—— CRUCIFORMIS. It is compoſed of four equal petals, placed in the form of a croſs. Of this ſort are the cabbage, the wall-*flower*, and muſtard.

—— CULI. See CARDAMINES.

—— FŒMINEUS. FEMALE FLOWER, which has piſtils, or ſtigmas, without ſtamens or at leaſt antheræ.

—— FLOSCULOSUS. A FLOSCULOUS FLOWER. By LINNÆUS called TUBULOSUS, *a tubulous compound flower*, compoſed wholly of tubulous florets, exemplified in tanſy, and other naked diſcous flowers.

—— INFUNDIBULIFORMIS. A funnel-ſhaped *flower*. Of this kind is the primroſe, &c.

—— LABIATUS. LIP-SHAPED FLOWER. A monopetalous corolla, with a narrow tubular baſis, expanding at the top in one entire, or in two lips; Linnæus uſes the term ringens, including under it both labiated, and perſonate flowers. This creates confuſion, which MARTIN ſays would be cleared up, if we might be allowed to put labiate for an irregular monopetalous corolla with two lips; and to appropriate the term ringens to ſuch as have the lips gaping and open, perſonate to ſuch as have them cloſed. Sometimes the upper lip is wanting, and then the ſtyle and chives ſupply its place, as in the ground-pine, bugulæ, &c. Some call this an unilabiated *flower*. In ſome ſpecies, the upper lip is turned upwards, as in the ground-ivy; but moſt commonly the upper lip is convex above, or turns the hollow part down to the under lip, and ſo repreſents an helmet, whence they are called galeate, *cucullate*, and galericulate.

—— LILIACEUS. A LILY-SHAPED FLOWER. It is generally compoſed of ſix petals, which reſemble thoſe of the lily. Of this ſort are the tulip and the aſphodel.

—— MONOPETALUS. A *flower* compoſed of one leaf. All thoſe *flowers* whoſe leaves are joined at the bottom, ſo that they fall off entire, are termed *monopetalous flowers*.

—— MASCULUS. MALE FLOWER. Bearing ſtamens only without piſtils; or at leaſt wanting the ſtigma.

FLOS MONOPETALUS ANOMALUS. An irregular *flower* conſiſting of one leaf.

—— PAPILIONACEUS, from *papilio*, a butterfly, a PAPILIONACEOUS, or BUTTER-FLY SHAPED flower. This is irregular, and uſually four-petalled. The lower petal is ſhaped like a boat, and is called *carina* or keel; the upper petal, which ſpreads and riſes upwards is called *vexillum*, ſtandard or banner; the two ſide ones ſtand ſingly, being ſeparated by the keel and are called *alæ*, the wings: the keel is ſometimes ſplit, and then this corolla is properly five-petalled. Theſe flowers are called pea-bloſſomed, becauſe the pea is the moſt obvious of theſe.

—— PERSONATUS. A maſked *flower*. It is an irregular monopetalous *flower*, in which the piſtil becomes a capſule entirely diſtinct from the calyx; it has ſomething of the ſame appearance as the labiate flower; but does not ill repreſent a maſk, the ſnout of ſome animals, or the beaks of fowls.

—— PETALODES. A PETALOUS FLOWER. It is a *flower* whoſe organs of generation are ſurrounded with petals.

—— POLYPETALUS. A *polypetalous flower* is one compoſed of ſeveral petals. When theſe agree in figure and poſition, it is called a regular *polypetalous flower*; but when the petals do not agree in figure and poſition, it is called an irregular *polypetalous flower*.

—— PYRAMIDALIS *Farneſianus*. See BATTATAS CANADENSIS.

—— RADIATUS. A RADIATED FLOWER. It conſiſts of two parts, viz. the diſk and the rays, which are ſeveral ſemiflorets ſet round the diſk in the form of a ſtar: theſe are called radiated diſcous *flowers*; but thoſe which have no ſuch rays are called naked diſcous *flowers*.

—— ROSACEUS. ROSE-SHAPED FLOWERS. They conſiſt of four or more regular petals inſerted into the receptacle by a ſhort broad claw, as in the wild roſe.

—— ROTATUS. It is a *flower* in the form of a wheel; wheel-ſhaped corolla; monopetalous; ſpreading flat, without any tube; ſuch as thoſe of borrage.

—— SANGUINEUS MONARDI. See NASTURTIUM INDICUM.

—— SCORPIOIDES. Thoſe *flowers* are ranged on one ſide of the pedicle, which twiſts at top, in the form of a ſcorpion's tail. Of this ſort is the heliotropium.

—— SEMIFLOSCULOSUS. A SEMIFLOSCULOUS FLOWER. It is compoſed of ſeveral ſemi-florets, included in one common calyx.

—— SOLIS PYRAMIDALIS. See BATTATAS HISPANICA.

—— SPICATUS. A SPIKED-FLOWER. It is one whoſe *flowers* are ſet thick on the pedicle, ſo as to form an acute cone.

—— STAMINEUS. A STAMINEOUS FLOWER. It is one which is compoſed of many chives included in a calyx, having no petals. Of this ſort is the biſtort, &c.

—— STERILIS. BARREN FLOWERS. Theſe have no embryo adhering to them, ſo are called male *flowers*.

—— TERRÆ. See CŒLI FLOS.

—— TUBULOSUS. See FLOS FLOSCULOSUS.

—— VENTRICULATUS. WHORLE-SHAPED FLOWER. Theſe grow cloſely united, ſurrounding the ſtalk at the joints.

—— UMBELLATUS. AN UMBELLATED FLOWER. It is when the extremity of the ſtalk or branch is divided into ſeveral pedicles, or rays, beginning from the ſame point, and opening in ſuch a manner as to form a kind of inverted cone like an umbrella. When the pedicles, into which the ſtalk is divided, are ſubdivided into others of the ſame form upon which the *flowers* are diſpoſed, the firſt order is called *rays*, the ſecond *pedicles*. That umbel which conſiſts of pedicles only is called a *ſingle umbel*; that which is compoſed both of rays and pedicles is called a *compound umbel*.

—— URCEOLATUS. PITCHER-SHAPED FLOWER, bellying out like a pitcher; applied to the calyx, corolla, and nectary. Of this ſort are the arbutus and whortleberry.

FLUOR, alſo *fius*. This word, when uſed adjectively, is applied to ſignify the habitual fluidity of any ſubſtance; or that property by which a ſubſtance cannot be rendered ſolid; and it is employed as an epithet to diſtinguiſh ſuch ſubſtances from others of the ſame kind, but which are habitually ſolid, or which may be rendered ſo: e. g. a volatile alkali treated with quicklime is always liquid, and cannot be made to concrete or cryſtallize, ſo is called *fluor* volatile alkali, to diſtinguiſh it from the concrete and cryſtallizable volatile alkali.

When the word *fluor* is uſed *ſubſtantively*, it ſignifies a certain kind of ſtone which is fuſible, or which facilitates fuſion. Of this kind are moſt ſpars, which are called *fluors*. Mineralogiſts differ much in deſcribing *fluors*; but by the word *fluor*, that kind of ſtone which we call SPAR is generally underſtood. SPAR appears like cryſtal; it is colourleſs and pellucid, but not ſo bright as cryſtal; it commonly riſes in triangular points, and when burnt, it is converted into lime, whereas cryſtal runs into glaſs. Spar is the baſis of moſt ſtones; it is the petrifying matter of all the tribe of animal petrifactions. Springs that are impregnated with ſpar are diuretic. See Dict. of Chem. Neumann's Chem. Works. AS AN OBJECT OF FOSSILOGY, the *fluor*, or the *fluſſes*, are an order in the claſſes of ſtones: their characters are, that they are foſſile bodies, which ſtrike not fire with ſteel; effervеſce not with acids; very readily are brought into fuſion, either by themſelves, or when mixed with certain other earths and ſtones, eſpecially the calcareous; and more eaſily brought into fuſion, under ſimilar circumſtances, than the foſſil bodies with which they can be confounded. See Edward's Elements of Foſſilogy.

FLUOR ALBUS. THE WHITE FLUX, commonly called the WHITES, alſo *cachexia uterina*, *leucorrhœa*, *leucorrhois*. It is a *flux* of matter from the vagina, which is of different colours and conſiſtencies, but generally of a pale or whitiſh colour, called *eluvies*. Aſtruc diſtinguiſhes this diſorder into the *lymphatic*, *ſemilacteous*, and *lacteous*. Dr. Shebbeare ſays, that the *fluor albus*, *the hectic fever*, and *the diabetes*, are of the ſame general kind, and that they are cauſed by a defective vital heat in different circumſtances. In Dr. Cullen's Noſology it is the MENORRHAGIA ALBA. It is the fifth variety of Dr. CULLEN'S MENORRHAGIA. He defines it "a ſerous menorrhagy without any local injury in women not pregnant," and aſſigns the following reaſon for placing it under this head; becauſe the leucorrhœa is almoſt always joined either with the menorrhagy, or ſoon follows it; and from the periods in which the leucorrhœa appears, it is very probable that the ſerum poured forth under this circumſtance flows from the ſame veſſels from whence the menſes iſſue, and that the leucorrhœa often ariſes from the ſame cauſes as the ſanguinary menorrhagia.

The ſeat of this diſorder ſeems moſt probably to be in that part of the uterus next to the os internum, though principally in the vagina. Aſtruc ſays, that the ſeat is in the glands, ſituated on the third or internal tunic of the uterus, and that they are veſicular bodies about the fundus uteri; theſe glands he calls *colatoria lactea*, and ſays, that when they diſcharge more than is required by the deſign of nature intheir proper uſe, this diſeaſe is formed. Hoffman ſays, "that in a natural ſtate the uterine exhaling veſſels become blood-veſſels at the menſtrual period, and when their plenitude is regularly diſcharged, they contract to their former dimenſion and tone; but when by immoderate evacuations, or other cauſes, their elaſtic power is much weakened, they never fully contract, but ſeparate the ſerous part of the blood, which by its ſtagnating, or from the particular ſtate of the body, acquires various degrees of acrimony and conſiſtence." But as pregnant women are liable to this complaint, it does not appear that this matter in them proceeds from the uterus, except as above obſerved, from about the os internum; for the ſpongy chorion firmly adheres to its inner ſurface in almoſt every part. Some women, it is true, have the menſes returning in every month of pregnancy, which, though deficient both in quantity and quality, yet rather confirms Hoffman's opinion on this ſubject, as well as that the vagina may be a principal ſeat of the diſcharge.

Women who abound with ſerum, thoſe with lax fibres, women at the flower of their age, and girls at the approach of the menſes, are the moſt ſubject to this diſorder; though girls of three years old, &c. up to old age, have been its ſubjects. Hoffman obſerves, that women who are ſubject to a mucous defluxion at the noſe, are, upon a ſuppreſſion of the menſes, affected with a *fluor albus*.

That the immediate cauſe of a *fluor albus* is debility of the veſſels from which the menſtrual diſcharges are made, or a retarded circulation of the blood through them, appears from ſome women having always a *fluor albus* whenever their menſes are detained. In ſome languid habits, the *fluor albus* returns periodically inſtead of the proper menſtrual evacuation, until the patient's conſtitution is duly invigorated; and in many inſtances, the *fluor albus* is manifeſt only during the abſence of the menſes, as alſo from ſeveral circumſtances obſervable in the manner of its appearance in different perſons.

The more remote cauſes are, whatever can weaken the veſſels from whence this morbid flux makes its exit; and theſe are cold moiſt air, a ſedentary life, poor diet, exceſſive menſtrual diſcharges, abortions, violent extraction of the placenta, &c.

From Hippocrates's deſcription of this diſeaſe it appears to have a great affinity to a cachexy. He ſays, "that the matter diſcharged reſembles the white urine of an aſs; white ſwellings appear in the patient's face, the part below the eyes ſwells, the eyes are diſordered, and appear as if the patient was dropſical; the colour of the ſkin is whitiſh, and the lower part of the belly tumid; in the legs appear tumors ſo lax and ſo ſoft, as to retain the impreſſions of the finger; a biting pain is perceived in the ſtomach, and a ſenſation of an acid water lodged in it, either when the patient is faſting or happens to vomit; when ſhe goes up a ſteep place ſhe is ſeized with ſhort breathing; her legs are cold, her knees feeble, her uterus is preternally opened, and fallen down with a ſenſe of weight to its mouth. In ſome, this diſcharge is daily, and in others, it appears two or three times in a month, and continues each time only a few days; the humour is ſerous and limpid in ſome, and in others more viſcid; ſometimes it is acrid, and occaſions an itching, pricking, or even an excoriation; in its greater degrees of virulence, it appears of different ſhades, from the ſlighteſt yellow to a green or even a blackiſh green colour, and it is then more or leſs fetid. When the caſe is of a milder kind, the ſymptoms are often not regarded; but when it is more violent, a cachexy is ſoon the conſequence; then there is a pain and ſenſe of weight in the loins, turbid urine, longings and loathings, indigeſtion, ſwelling of the face in the night, and of the feet in the day, palpitation of the heart, fainting; all which ending in dropſy, or a conſumption, proves fatal.

This diſorder ſhould be diſtinguiſhed from a cachexy, a gonorrhœa, pale and ill-coloured menſes, and from ulcerations and abſceſſes in the parts of generation.

If this diſorder is moderate, it is ſupported a long time without much inconvenience, but in increaſed degrees it ſoon ſpoils the beauty of a fine face, weakens the digeſtive powers, and produces a general bad habit; it occaſions ſterility in ſome women, and, in more, a diſpoſition to miſcarry. If the flux is unſeaſonably checked, the belly ſwells, a hectic fever comes on, and a train of the moſt diſagreeable ſymptoms follow.

THE INDICATIONS OF CURE are, *to promote digeſtion*, *increaſe the vital heat*, and *reſtrain the preternatural diſcharge*; in order to which, the diet ſhould be light, cordial, and nouriſhing; iſinglaſs diſſolved in milk is peculiarly uſeful, and ſo are frequent moderate quantities of red Port. The exerciſe ſhould be moderate, carefully avoiding fatigue. The ſtate of the ſtomach muſt be attended to, and digeſtion promoted by warm ſtomachics. The blood will be beſt improved by warm aromatics, chalybeates, and the bark; antimonials may be occaſionally uſed, when ſlight febrile heats are troubleſome.

An emetic of ipecacuanha, or of the antimonial kind, may begin the cure, if any ſymptom attends which requires it, ſuch as load and oppreſſion of the ſtomach, eſpecially after eating; conſtant naufea, coldneſs in the extremities, and other ſymptoms, which beſpeak an increaſed degree of languor in the circulatory ſyſtem. But from the nature of the diſeaſe, a ſpeedy cure is not to be expected, if the degree of diſorder is conſiderable; the patient ſhould, therefore, be guarded againſt impatience at the firſt onſet towards relief; this adverted to, Dr. Cheyne recommends mild mercurials to alter, then chalybeates to invigorate, and at laſt the bark and cold bathing, to finiſh the cure. See his Cure of the Diſeaſes of the Body and Mind.

In the beginning, *warm baths*, made by ſuſpending aromatic herbs in ſoft water, are very uſeful.

Mild purges, ſuch as rhubarb, or, which is yet to be preferred, the ol. ricini; one or other of theſe ſhould be now and then repeated in groſs plethoric habits.

As a mercurial alterative, the following may be uſed: it neither injures the ſtomach, nor diſturbs the bowels. ℞ hydrargyri purificati, ʒ ii. tereb. Venet. ʒ ii. ad hydrarg. fixand. cui adde rhabarb. ʒ i. ſs. elix. prop. q. ſ. f. maſſa pilular. Of this ſuch doſes may be repeated night and morning as the patient can take, without increaſing the ſenſible diſcharges.

Aſtringents are univerſally prohibited by Hoffman; his cautions in this reſpect deſerve a peculiar regard.

Injections

Injections of water, mixed with small quantities of vinegar are useful at the latter end of the cure. This mixture may be injected up the vagina two or three times a day.

Diuretics are peculiarly proper for lessening the serous plethora.

When the *fluor* is much discoloured and fetid, and is also attended with heat, pain, and ulcers, it is probable that a scirrhus is seated in the uterus, or that a cancer may be formed there; in this situation, *palliatives only can be proposed*, such as bleeding once in a month, or at longer periods, as may seem most needful; purging now and then with manna, a milk diet, and narcotics repeated night and morning.

Dr. Leake observes that, the *fluor albus* is, first, from simple weakness, and relaxation of the solids, which may either be *general*, where the whole system is enervated and unstrung; or *partial*, where the *womb* only is thus affected, in consequence of hard labour, frequent miscarriages, suppression, or immoderate quantity of the menses, or sprains of the back.

Weakly women with lax solids, who have had many children, and long laboured under ill health, are, of all others, the most subject to this disease, from which they suffer more than others.

He also observes that, the discharge proceeds from the *vessels subservient to menstruation*; because in tender habits, where those vessels are weak, and so remain too long uncontracted, the *fluor albus* sometimes immediately follows the menses, and goes off by degrees as they gradually close. This discharge also proceeds from the *mucous glands* of the womb, as is evident in very young females of eight or ten years old, in whom, though rarely, it is observed, and where it must then necessarily have escaped from these parts; the uterine vessels not being sufficiently enlarged for its passage at so early a period. Sometimes, as in pregnant women, it proceeds from the *vagina*, and not from the womb itself. The application of *pessaries*, from the pain of irritation they occasion, are also apt to bring on this discharge: hence it is plain, that this disease may happen, when the blood is in a pure state, and where the fault is in the vessels or strainers, by which the fluids are vitiated and changed from their natural qualities.

The *fluor albus* is, first, from simple weakness of the solids in general: or, secondly, of the womb in particular. He therefore proposes as follows.

First, Nourishing simple food, such as veal broth, jelly, fresh eggs, milk diet, &c. ℞ rad. sarsaparil. ℥i. fs. coq. in aq. font. ad ℔i. cola & adde infus. cort. Peruv. lb. i. extract. cort. Peruv. moll. ℥ss. elix. vitriol. acid. gut. 160. m. cap. cochl. vi. bis in die. The same method is proper when the whites follow the menses. Smiths'-forge-water may be injected into the womb twice a day; the cold bath may be used every other day in obstinate cases; and lime-water with a little milk for common drink.

Secondly, Where the discharge is sharp, and of long standing, it is improper to suppress it suddenly, until the blood is freed from its impurities, and hath recovered its soft and balmy quality of which it hath been deprived. ℞ Infus. senn. limoniat. ℥ ii. mann. ʒ iii. spt. lavend. c. ʒi. m. bis septimana repetendus. diebus. a purg. liberis ℞ pil. merc. Ph. Ed. extr. cicut. ää ʒi. m. f. pil. xx. cap. i. mane nocteque. After this course for a few weeks, begin with the following strengthening bitter: ℞ pulv. cort. Peruv. ℥i. centaur. min. et cort. aurant. rec. ää ʒ fs. aq. font. bull. ℔i. m. f. infus. cui adde tinct. gentianæ comp. ʒii. cap. cochl. vi. bis vel ter in die. The same food and regimen should be persisted in, as in the first case. The patient should abstain from malt liquors, drink rice-water, in each pint of which dissolve gum arabic ℥ fs. If weak and of a cold bloated habit, infus. of sassafras wood, or infus. of juniper berries with a little French brandy in it, may be the common drink. When she begins with the bitter infusion, at the same time use chalybeate water for common drink: if it occasions costiveness or head-ach, desist, and let the drink be imperial water, made of a solution of cream of tartar, in which is infused a quantity of lemon peel, sufficient to give it an agreeable flavour: this sweetened with sugar; instead of which, in this case use manna, until the head-ach and costiveness are removed.

See Cullen's First Lines, vol. iii. p. 24. 31. Hamilton's Midwifery, edit. 2. p. 119. 137. 140. Hoffman's Dissertation on the *Fluor Alb.* This last deserves an attentive perusal. Leake's Medical Instructions, edit. 5. Wallis's Sydenham. As to forms for stomachic, and chalybeate medicines, a sufficient variety occurs in the works of medical writers on this subject, and every Practice of Physic, particularly that of London.

FLUS. See Fluor.

FLUXIO. See Catarrhus.

FLUXUS. A flux. Sometimes it signifies a defluxion, and in this sense, it is the same as *catarrhus*. Sometimes it bears a restrained sense, as *fluxus ventris*, which is a continued evacuation of humid fæces, without either a tenesmus or lientery; or a *fluxus hepaticus*, which is when, from a weakness in the liver, the excrements are like water in which flesh hath been washed. Hippocrates uses the word ῥοὴ, *fluxus*, in his work de Nat. Mulieb. of which there are the *fluor albus*, and *fluor ruber*, i. e. menses. *Fluxus*, ῥοὴ, is spoken of a falling off of the hair. See Trallian, lib. i. cap. 2. In Cullen's Nosology, it is synonymous with Apocenoses.

FOCARIUS. Bread broiled on the hearth or gridiron.

FOCILE MAJUS & MINUS. *Focile*, an Arabic term but a barbarous one. Names formerly given to the *ulna* and *radius* in the arm, and to the *tibia* and *fibula* in the leg.

FOCUS. *Focus morbi*. The *focus* of a disease is the part where it is supposed to keep its principal residence, and whence it communicates its noxious influence. Some ancient anatomists gave this name to the first lobe of the liver. See Auriga.

FODINA. See Labyrinthus.

FŒDULA. A species of fungus.

FŒNICULI, vel Fœniculatum Lignum. See Sassafras.

FŒNICULUM. Fennel. *Fœniculum* seems to be a diminutive of *fœnum*, *hay*, because when withered and dried, it is like hay reposited against winter. Boerhaave mentions eight species; when wine is impregnated with this, it is then called *marathrites*.

—— vulgare, called also *fœniculum* Germanicum, *marathrum*, common fingle, or common fennel. The anethum fœniculum, or anethum fructibus ovatis. Class. Pentandria. Ord. Digynia. Linn. Gen. Plant. 364.

This plant is so common on our tables, that its description is here needless. Its seeds are small and dark-coloured, being of a blackish brown. The plant is perennial, native in the southern parts of Europe, but thrives in our gardens.

This was supposed to be the *marathron* of the Greeks, highly esteemed among them for promoting the secretion of milk; which opinion the experience of Bergius, and some others seems to confirm.

The seeds are warm and pungent, more so than those of the sweet kind, but they are not so palatable; the same difference is observed in the waters and oils obtained from these seeds by distillation, and also in the extracts which are made from them. These seeds are stomachic and carminative, and are commended against nauseas and loathing; and if eaten in the morning fasting, they are said to help the sight; though dill, anise, and caraway, are allowed to be superior, in their stimulant, and aromatic qualities, upon which all their effects seem to depend.

The leaves have the same flavour with the seeds, and smell stronger; but to the taste are weaker and less agreeable. They impregnate water sufficiently strong with their virtues, by distillation; and by the same process they afford a considerable quantity of essential oil. Rectified spirit of wine extracts an agreeable aromatic from them, which retains the whole strength, after evaporation, to a proper consistence.

The roots, taken up in spring, have a pleasant sweet taste, are slightly aromatic, and are ranked amongst the aperient roots.

Fœnic. dulc. Sweet fennel. This species of plant is annual, a native of warm climes, and cultivated in gardens. A variety of the *fœniculum* vulgare. The seeds are larger, paler, and sweeter than those of the common sort; they contain a gross oil, which is easily obtained by pressure, and have been esteemed pectoral and diuretic: but when freed from the essential oil, are perfectly insipid. The London College directs to distil a simple water from the seeds; a pound of these bruised, to draw off a gallon. This is said to be diuretic and carminative. See Lewis's Mat. Med. Neuman's Chem. Works.

—— Alpinum. See Meum.

FŒNICULUM ANNUUM. See AMMI VERUM.

—— ERRATICUM. See SAXIFRAGA ANGLICA.

—— MARINUM MAJUS & MINUS. See CHRITHMUM.

—— ORIENTALE. See CUMINUM.

—— PORCINUM. See PEUCEDANUM.

—— SINENSE. See ANISUM IND.

—— SYLVESTRE. See MEUM LATIFOLIUM ADULTERINUM.

—— TORTUOSUM. See SESELI MASSILIENSE.

FŒNUM.

—— CAMELORUM. See JUNCUS ODORATUS.

—— GRÆCUM. FENUGREEK. It is called alſo *bouceras carpos*, *buceras*, becauſe the fruit is corniculated, and *ægoceras*, becauſe the pods were ſuppoſed to reſemble the horns of a goat, and is a plant with ſerrated, roundiſh leaves; whitiſh papilionaceous flowers, followed by long, ſlender, crooked, flattiſh pods, containing yellowiſh rhomboidal ſeeds furrowed from angle to angle; or, as Neumann obſerves, oblong, flattiſh, quadrangular, and roundiſh at one end. Theſe ſeeds are ſown annually in the ſouth of Europe, from whence they are brought to us. The ſpecies is the TRIGONELLA FŒNUM GRÆCUM,—or TRIGONELLA MONSPELIENSIS, *foliolis obovatis, leguminibus ſeſſilibus, ſtrictis, erectiuſculis, ſubfalcatis, acuminatis, caule erecto.* CLASS, DIADELPHIA. ORD. DECANDRIA. Linn. Gen. Plant. 898.

The ſeeds only are in uſe, and their prevailing principle is a mucilaginous matter. An ounce of theſe ſeeds renders a pint of water very ſlimy; their chief uſe is in emollient cataplaſms and fomentations, and in emollient and carminative clyſters. The ſeeds are brought to us from the ſouthern parts of France and Germany, where they are annually ſown for the purpoſe of exportation. See Lewis's Mat. Med. and Neumann's Chem. Works.

FŒNUM GRÆCUM SYLVESTRE. See GLAUX VULG. LEGUMINOSA.

FŒTABULUM. So M. A. Severinus calls an abſceſs with a cyſt.

FŒTIDA TINCTURA. See ASA FŒTIDA.

FŒTUS. *Fœtus* a fovendo, vel a φοιτάω, commeo, or rather *fetus*, from *feo*, (ſee VOSS. ETYMOL.) called alſo *epicyema*, and *epigonion*. The young of all viviparous animals whilſt in the womb, and of oviparous animals before being hatched. See CONCEPTIO. The name is transferred by botaniſts to the embryos of vegetables.

In the human *fœtus* are ſeveral peculiarities not to be found in the adult; ſome of them are as follow: 1. The *ductus*, or *canalis, arteriosus*. See ARTERIOSUS DUCTUS. 2. The *arteries of the navel-ſtring*, which are continuations of the hypogaſtrics, after the birth are ſhrivelled up, and form the *ligamenta umbilicalia inferiora*. 3. *The veins of the navel-ſtring*, which are formed by the union of all the venal branches in the placenta, and paſſing into the abdomen, *become the falciform ligament of the liver*. 4. *The ductus venoſus*, which ſee. 5. *The lungs*, which, before being inflated with air, are compact and heavy; but after one inſpiration they become light, and, as it were, ſpongy: and it may be noted here, that the notion of the lungs ſinking in water before the child breathes, and of their ſwimming after the reception of air, are no certain proofs that the child had or had not breathed, much leſs that it was murdered; for the uninflated lungs become ſpecifically lighter than water as ſoon as any degree of putrefaction takes place in them; and this quickly happens after the death of the child: beſides, where the utmoſt care hath been taken to preſerve the child, it hath breathed once or twice, and then died. 6. *The thymus gland* is very large in the *fœtus*, but dwindles away in proportion as years advance. 7. *The foramen ovale* in the heart of a *fœtus* is generally cloſed in an adult. 8. *The circulation of the blood*. See CIRCULATIO.

On the nutrition of the *fœtus*, ſee the Edinb. Med. Eſſays, vol. ii. They ſeem to be nouriſhed by a ſpecies of abſorption.

The EXTRA-UTERINE FŒTUSES are generally lodged in the Fallopian tubes; though ſometimes they are in the cavity of the abdomen. One inſtance has occurred where the *fœtus* was found in the cavity of the abdomen, the uterus, Fallopian tubes, and ovaria, being at the ſame time in an unaltered ſtate, ſimilar to what happens, where impregnation has not taken place. May not this circumſtance throw ſome light on the nature of conception? Would it be abſurd to conjecture, that this proceſs of nature was performed by what might be termed *aura vivificans*, impregnating the ovum, whilſt in the ovarium, or within the fimbriæ of the Fallopian tube, called *morſus diaboli?* From ſuch an idea, it appears, that we can only account for the phenomenon here adverted to. See Medical Memoirs, London, vol. iii. However, in general, when they are formed, they point to the anus, or, as now and then happens, to the navel; and by occaſioning an irritation and inflammation, an abſceſs is formed; on the opening of which, a paſſage is made for the child, which generally comes away by piece-meal. See inſtances recorded in the Lond. Med. Obſ. & Inq. vol. ii. and iii.

As to MARKS, &c. impreſſed on the *fœtus* by the force of the mother's imagination, &c. much is ſaid with greater plauſibility than ſatisfaction on both ſides: ſome things of the kind which are gravely related, are doubtleſs abſurd; but that the whole ſhould be rejected, ſeems to be very unreaſonable. See NÆVUS.

FOLIACEUM ORNAMENTUM. See TUBÆ FALLOPIANÆ.

FOLIATA TERRA. See SULPHUR.

FOLIATIO. It is the diſpoſition of the naſcent leaves within the bud, having different terms, according to the diſpoſition of the leaves. See MARTIN's Botanical Dictionary.

FOLIUM. A LEAF. It is a part of a plant, extended in length and breadth, ſo as to have one ſide diſtinguiſhed from the other. In Latin it is called *folium*, to diſtinguiſh it from the *leaf* of a flower, which is called *petalum*. See PETALA. As the pencil of the artiſt will give a more perfect idea of different terms, by which botaniſts diſtinguiſh the ſhapes and peculiar diſtinctions of leaves, than the pen of an author, the reader is referred to the two tables of leaves, Pl. 1 and 2, where he will find the following catalogue delineated, each leaf being referred to by the number under which it is placed, and here alphabetically digeſted.

FOLIA LEAVES.

FOLIUM ABRUPTUM PINNATUM, abruptly pinnate, when they have neither leaflet, nor tendril, nor claſper at the end.

ACINACIFORME, ſabre-ſhaped.	51
ACUMINATUM, awl-winted, or INTEGERRIMUM, entire.	38
ACUTUM, Acute.	37
BIFIDUM, bifid.	16
BINATUM, two-lobed.	58
CANALICULATUM, channelled.	54
CARTILAGINEUM, cartilaginous.	30
CILIATUM, ciliated.	45
CIRRHOUS, winged leaf.	63
CONJUGATUM, conjugated.	66
CORDATO-HASTATUM, heart arrow pointed.	14
CORDATUM, heart-ſhaped.	10
CRENATUM, crenated.	34
CRENATUM ACUTUM, acute crenated	31
—— DUPLEX, double crenated.	29
—— OBTUSUM, obtuſe crenated.	32
CRISPUM, curled.	35
CUNEIFORME, wedge-ſhaped.	40
DECOMPOSITUM, decompoſite.	72, 73

DECURRENS, running winged. 64
DELTOIDES, deltoid. 53
DIGITATUM, fingered, or handed. 56
DOLABRIFORME, hatchet-ſhaped. 52
DUPLICATO-PINNATUM, vel PINNATO-PINNATUM. double winged. 68
DUPLICATO-SERRATUM, double-ſerrated. 28
EROSUM, gnawed. 20
HASTATUM, pike, or javelin ſhaped. 15
HISPIDUM, ſtinging. 44
INTEGERRIMUM, entire. 38
INTERRUPT WINGED. 62
LACERUM, lacerated, or torn, or LANCINIATUM jagged. 23
LANCEOLATUM, ſpear-ſhaped. 6
LINEARE, linear; narrow. 7
LINGUIFORME, tongue-ſhaped. 50
LUNATUM, moon-ſhaped. 11
LYRATUM, lyre-ſhaped. 67
NERVOSUM, nervous 48
OBLONG. 5
OBTUSUM, obtuſe. 36
OBTUSUM CUM ACUMINE. blunt-pointed. 39
ORBICULUM, round. 1
OVATUM, oval. 3
OVAL, or ELLIPTIC. 4
PALMATUM, palmated. 21
PAPILLOSUM, warted. 49
PILOSUM, velvet. 42
PINNATIFIDUM, wing-pointed. 32
PINNATO-PINNATUM, double-winged. 68
PINNATUM ABRUPTUM, abrupt-winged. 61
——IMPARI, unequal winged. 60
PLICATUM, plaited. 33
PRÆMORSUM, bitten. 18
QUINQUE-ANGULARE, five-cornered. 19
QUINQUE-PARTITA, quinque-partite 26
RACEMOSUM, branching. 59
RENIFORME, kidney-ſhaped. 9
REPANDIDUM, repandid. 41
RUGOSUM, wrinkled. 46
SAGITTATUM, arrow-pointed. 13
SERRATUM, ſawed. 27
SINUATO-DENTATUM, indented, ſinuated. 25
SINUATUM, ſinuated. 24
SUBROTUNDUM, roundiſh. 2
SUBULATUM, awl-ſhaped. 8
SUPRA-DECOMPOSITE. 70, 71
TERES, taper. 55
TERNATUM, trifoliate. 57
TOMENTOSUM, downy. 43
TRIANGULARE, triangular. 12
TRILOBUM, trilobated. 17
TRIPLICATO-TERNATUM. 69
WINGED LEAF, with membranous foot-ſtalks. 65

FOLIUM. It is a name of the philoſopher's ſtone: alſo of that triangular membranaceous ſinus, where there is a concourſe of the ſagittal and coronal futures in infants: it ſignifies a relaxed uvula in Arnaldus. See alſo DEXAMENE.

FOLIUM, called alſo *fol. Indum, malabathrum, malabatrum, tamalapatrum*; *cardegi Indi*; *catsu-karua, pſeudo-caſſia*. INDIA LEAF.—This, called by way of diſtinction, FOLIUM, is of a firm texture, of an oblong oval ſhape, pointed at both ends, ſmooth and gloſſy on the upper ſide, and leſs ſo on the under; of a yelloviſh green colour on the upper, and of a pale brownith one on the under ſide, furniſhed with three ribs running its whole length, very protuberant on the lower ſide, and two ſmaller ones which bound the edges. Both the *leaves* and their pedicles are very mucilaginous: chewed, they render the ſaliva ſlimy or glutinous; infuſed in water, they give out a large quantity of ſtrong tenacious mucilage; but of the aroma, which is ſtrong in the bark, they poſſeſs but little. Ray ſays, that theſe *leaves* are diuretic. See Lewis's Mat. Med.

FOLLICULUS. } A FOLLICLE, a little bag, called
FOLLIS. } alſo *crypta*. It is likewiſe the name of a large leathern bag, filled with wind, and uſed as an exerciſe by the ancient Romans. In SURGERY, it is a bag which contains the matter of ſome abſceſſes and tumors, and the melliceris, &c. In BOTANY, it is the thin involucrum, or membranaceous cover which incloſes the ſeeds of plants. IN ANATOMY, it is a ſimple gland.

FOLLICULUS FELLIS. See VESICULA FELLIS.

FOLLIS. See FOLLICULUS.

FOMENTATIO. See FOTUS.

FOMES. FEWEL. From *fovendo*. When ſpoken of diſeaſes, it is the internal or antecedent cauſe, which foments and continues the diſeaſe.

—— VENTRICULI. See SPLEN.

FOMITES. Cloaths, &c. receive contagious matter from human bodies, and retain it in an active ſtate for a long time. The ſubſtances thus imbibed are called *fomites*; and many think, that contagion received from them, is more powerful than that ariſing from human bodies. See CONTAGIO.

FONS CHYMIÆ. The FOUNTAIN of CHEMISTRY. A name for QUICKSILVER.

—— PHILOSOPHORUM. The philoſophers' fountain. A name for the balneum Mariæ.

—— PULLANS, vel PULSATILIS. See FONTANELLA.

FONTALE ACETOSUM. See ACIDULÆ.

FONTANELLA, IN ANATOMY, it is the membranous part which is found in new-born infants at the coronal and ſagittal commiſſures, and which, in length of time, hardens into a bone. It is called *fons pullans*.

FONTANELLA, a diminutive of *fons*, alſo *fonticulus*. A LITTLE FOUNTAIN. IN SURGERY, it is metaphorically uſed to ſignify the ſmall aperture called an ISSUE. *Iſſues* were made in Hippocrates's time, and have more or leſs maintained their credit down to the preſent age. By *iſſues*, ſerum is diſcharged from the body. Hippocrates obſerved, that ulcers and *iſſues* dry up in the beginning of fevers, and experience hath ever confirmed the ſame: others obſerve, that when *iſſues* dry up, and become livid or black, ſome diſorder is approaching. The parts where *iſſues* are generally made, are, 1. On the coronal future, juſt where it joins the ſagittal; but a perpetual bliſter on this part is to be preferred. ally. The

neck. 3dly. The arms, near the loweſt part of the deltoide muſcle, in the interſtice between it and the biceps muſcle. 4thly. Above the knee, on the inſide of the thigh, where there is a ſinus, which may eaſily be perceived by the finger. 5thly. Below the knee, on the inſide of the leg, where generally a ſinus may be perceived. 6thly. On the back; but on all occaſions, when the two laſt are neceſſary, they would be more uſeful and leſs troubleſome, if placed above the knee.

The method of making an *iſſue* is, firſt to mark the part with ink, then the operator and an aſſiſtant having raiſed the ſkin with their fore-fingers and thumbs, the operator puſhes a lancet through the ſkin, ſo as that an opening may be made into it, ſpacious enough to receive a ſmall pea, or a larger ſubſtance if neceſſary, which being introduced, is to be ſecured by a ſticking-plaſter and bandage; after which, every twenty-four hours it muſt be renewed, and the old one thrown away.

Some apply a cauſtic, and let it continue ſix or eight hours, then cut the eſchar and inſert a pea.

Inſtead of common peas, ſome uſe wooden or ſilver balls to promote the diſcharge; others take the dried oranges, called orange peas, or cut pieces of gentian or oris-roots to a proper ſize: and

When *iſſues*, or perpetual bliſters are diſagreeable, a plaſter of Burgundy pitch may be worn for ſome time with advantage; when it fails to adhere, a freſh one may be put in its place.

Iſſues are formed with great advantage, when we would heal ulcers of long ſtanding. In many caſes, after the ulcers are healed, the *iſſues* may be gradually diminiſhed, as the conſtitution improves; but even then, to dry up the *iſſue*, would not be judicious, as many diſagreeable, and ſometimes fatal effects have been the conſequence; beſides there is ſo little neceſſity for running any riſque, as we can with advantage chuſe the ſituation, and thus render its continuance leſs exceptionable. See Bell on Ulcers, ed. 4. p. 140. his Surgery, vol. 4. p. 376, 384. White's Surgery. Lera on the Theory of *Iſſues*; and Hoffman on the ſame, in the 6th vol. of the fol. edit. of his works.

FONTICULUS. See FONTANELLA.

FORAMEN. An HOLE, from *forando, to perforate.* See Os and CAPUT.

—— CÆCUM. The name of a *hole* in the middle of the tongue. See LINGUA.

—— LACERUM. See CAPUT.

—— OVALE. See COR.

FORAMINULENTUM Os. See ETHMÖIDES OS.

FORCEPS, PINCERS; from *formus*, an obſolete word, ſignifying *hot*, and *capere*, to take hold. A little forceps, is called *volſella*.—A ſurgeon's inſtrument uſed for taking hold of dead, or corrupt parts, and cutting or pulling them off. There are alſo a variety of inſtruments thus called, adapted to different purpoſes, both in ſurgery and midwifery. See Cyclopædia, Surgery, Pl. 1, Fig. 14. Tab. 3, 31, 32, 33, 43. Heiſter's Surgery. Tables of midwifery in this work. Mulder on the Forceps and Lever. See alſo EMBRYULCIA.

FORMA. The FORM. Among the chemiſts, it not only ſignifies the outward *form* of things, but alſo it is uſed to expreſs the *quinta eſſentia*.

FORMICA. The name of a ſort of black wart with a broad baſe, and cleft ſuperficies: alſo the name of a varicoſe tumor on the anus and glans penis.

—— MILIARIS. See *Herpes, under* 3 and 4.

—— MINOR. The ANT, or PISMIRE. This inſect contains an acid juice, which it emits on being irritated: this acid is what moſt likely occaſions the uneaſineſs on our ſkins when they are ſaid to have ſtung us. A groſs oil is obtained by expreſſion from ants, after diſtilling them in water; and an eſſential oil ariſes with the acid liquor in diſtillation. The medical qualities of this inſect are not known. See Lewis's Mat. Med. Neumann's Chem. Works.

FORMICANS. FORMICATING. An epithet beſtowed by Galen on a low unequal pulſe.

FORMIX. See HERPES EXEDENS.

FORMULA. A technical term, ſpoken of the conſtitution of medicines, whether ſimple or compound, both with reſpect to their conſiſtence and deſcription. Morellus and Gaubius have writ treatiſes profeſſedly on the forms of medicines.

FORNAX, alſo *Furnus*. A FURNACE. Furnaces are chemical inſtruments for containing combuſtible matters, by the burning of which, heat requiſite for operations is procured, and alſo for containing the ſubſtances themſelves, to which the heat ought to be applied. In all furnaces, four principal things ought to be attended to; 1ſt. To confine the heat as much as poſſible to the matter, to be operated upon; 2d. To prevent its being diſſipated; 3d. To produce as much heat with as little fuel as poſſible; 4th. To have it in our power to regulate the degree of heat, according to our pleaſure. The beſt conſtruction for furnaces has not been well aſcertained from experience. There are facts, which ſhew, that a fire, made on a grate near the bottom of a chimney of equal width throughout, and open both above and below, will produce a more intenſe heat than any other furnace. What may be the limits for the height of the chimney is not aſcertained from any preciſe trials; but thirty times its diameter would not probably be too high. It ſeems to be a diſadvantage to contract the diameter of the chimney, ſo as to make it ſmaller than that of the fire-place, when no other air is to go up the chimney, than that which has paſſed through the fire; and there is no proſpect of advantage to be derived by widening it.

Of *furnaces*, there are a great variety invented by chemiſts, for the performance of their operations, which may be ſeen, with their conſtructions and uſes, particularly in the Encyclopædia Britannica, under the Article, Chemiſtry; Lavoiſier's Elements of Chemiſtry; and the Table of Chemical Veſſels inſerted at the latter end of this Work. See alſo ATHANOR, BALNEUM MARIÆ; the Dict. of Chem. and Dr. Lewis's Commercium Philoſophico-technicum, part the firſt.

FORNICATUS, from *fornix, an arch* or *vault*. Fornicated petals are ſuch flower-leaves as are arched, like the roof of the mouth, after the manner of the creſt of clary or ſage.

FORNIX. See ACHICOLUM.

FORNIX. It is part of the *corpus calloſum* in the brain; and is ſo called, becauſe of a diſtant reſemblance that it hath to the arches of ancient vaults, when viewed in a particular manner. See CEREBRUM and LYRA.

FORTIS, AQUA. It is a name which artiſts have given to the nitrous acid, becauſe of its diſſolving power. See NITRUM, N° 5, 7, 8, 9, 10. It is alſo called *Elephas*.

FOSSA. In anatomy it is the ſame as *foſſa navicularis*. It is properly a ditch.

—— AMYNTÆ. It is a DOUBLE-HEADED ROLLER, about four yards long, and an inch and a half broad. Begin the application at the tip of the noſe; and croſſing at the neck again, croſs on the noſe, and finiſh with circulars.

—— NAVICULARIS. See AURICULA.

—— MAGNA. The interior cavity, and rima vel foſſa magna of the pudendum muliebre, which appears on a ſeparation of the labia.

—— PITUITARIA. See SELLA TURCICA.

FOSSILIS SAL. See GEMMÆ SAL.

FOSSILUS. A name of the *tibia*, alſo of the *fibula*.

FOTUS, or FOMENTATIO, from *foveo, to cheriſh* or *nouriſh*, called alſo *embroche*. To foment, is to cheriſh with heat, to bathe with warm liquors. Indeed, dry powders, or other things, in bags; liquids in a bladder, or ſponge, or flannel, applied warm to the diſeaſed parts, come under this deſcription, and are named dry fomentations. Thoſe called liquid are fluids externally applied, uſually as warm as the patient can bear them, and in the following manner: two flannel cloths are dipped into the heated liquor, one of which is wrung as dry as the neceſſary ſpeed will admit, then immediately applied to the part affected; it lies on until the heat begins to go off, and the other is in readineſs to apply at the inſtant in which the firſt is removed; thus, theſe flannels are alternately applied, ſo as to keep the affected part conſtantly ſupplied with them warm. This is continued fifteen or twenty minutes, and repeated two or three times a day.

Every intention of relaxation and ſoothing by *fomentations*, may be anſwered as well by warm water alone, as when the whole tribe of emollients are boiled in it; but when diſcutients or antiſeptics are required, ſuch ingredients muſt be called in as are adapted to that end.

FOTUS COMMUNIS. COMMON FOMENTATION.

℞ Florum chamæmeli ℥ ij. aquæ ferventis ℔ iv. aquæ adjiciantur flores & parumper coquantur, deinde coletur liquor. This, by many practitioners, is preferred to that of the London College DECOCTUM pro FOMENTO, which is thus made. ℞ Abrotoni exſic-

cati,

cati; abſinthii maritimi exſiccati; chamæmeli exſiccati, ſingulorum, p. ʒ j, foliorum lauri exſiccatorum, p. ʒ ij. aquæ diſtillatæ m. ℔ 6. pauliſper coque, & cola. The preference is ſaid to be given to the former, on account of its being leſs complicated, becauſe little or no good can be done by any of the medicinal ingredients. This ſhould be (though) rather adopted as a chirurgical pretion than a medical fact.

The degree of heat ſhould never exceed that of producing a pleaſing ſenſation; great heat produces effects very oppoſite to that intended by the uſe of *fomentations*. For theſe applications, Hippocrates, according to Fæſius, makes uſe of the word *thermaſma*. They are alſo named *chiliaſma*.

FOTUS ANODYNUS. See ANODYNUM.

FOVEA. In anatomy, it is the ſinus of the pudendum muliebre. In the bath rooms it is a ſudatory for receiving one or both the legs, in order to ſweating.

FOVILLA, a fine ſubſtance imperceptible to the naked eye, exploded by the pollen in the anthers of flowers.

FRACASTORII SPECIES, i. e. pulv. e bolo. See BOLUS.——CONFECTIO. See DIASCORDIUM.

FRACTURA, from *frango, to break*. Alſo called by the Greeks *catagma*; *claſis*; *claſma*; *agme*. A FRACTURE. Paulus Ægineta ſays, that "a *fracture* is ſuch a ſeparation of a bone as is made by external force." Lib. vi. cap. 89. and thus a *fracture* is diſtinguiſhed from a caries. Dr. Cullen places this genus of diſeaſe in the CLASS LOCALES, and ORDER DIALYSES, and defines it part of a bone having its coheſion deſtroyed by violence, and ſeparated into large fragments.

Fractures are differently denominated, according to their different direction; as a *tranſverſe, oblique, longitudinal*, &c. *fracture*. The French diſtinguiſh *fractures* thus: 1ſt, when one bone is broken in one place only, and no remarkable injury is perceived in the adjacent parts, it is called a SIMPLE FRACTURE; 2dly, when a bone is broken in more parts than one, or when two bones that are joined together, as the radius and ulna, are both broken, it is called a COMPOUND FRACTURE; but, 3dly, if with a *fracture*, there is a diſlocation or a wound, it is then a COMPLICATED FRACTURE.

In *fractures*, the power of nature is great in producing new bone. The reunion of the ſeparate parts of the bone is by a renewal of the organical bony ſtructure, and not by a gluey matter, which hardens into what is called callus.

Fractures are diſcovered by the eye, the ear, and touch.

It is never prudent to promiſe a ſpeedy cure, becauſe certain accidents may occur, which may for a time prevent the re-union of the fractured bones: when this accident happens to pregnant women, a cure is ſometimes not effected until after delivery. See an inſtance in the Lond. Med. Obſ. & In. vol. iv. Hildanus mentions three caſes of this kind. Heiſter ſays, that a *fracture* will not heal in a pregnant woman; but this is not always true. A bad habit of body, as when there is a ſcorbutic or a venereal taint, may prevent the bone from healing; or a caries may retard the union: if a waſting of the limb, or a palſy comes on upon a fractured bone, the cure will be ſlow, if it is ever effected. If a *fracture* happens under where an ulcer hath been a long time, it is very difficultly united. A *fracture* in the cranium, vertebræ, ribs, ſternum, os ilium, or os pubis, are dangerous, on account of the near vicinity of the brain, ſpinal marrow, or other of the viſcera.

IN ORDER TO A CURE, if called after the tumor or a violent inflammation is come on, the extenſion muſt be deferred until they are removed; but if theſe ſymptoms are ſlight, proceed to extenſion, to prevent their increaſe. If there is a wound, all foreign matters ſhould be removed at the firſt dreſſing, if poſſible; all ſtrictures, &c. made eaſy; if the wound is too ſmall, it ſhould be dilated; and, if poſſible, this ſhould be done before inflammation comes on, for then the parts become more ſenſible. If poſſible, contrive that the matter may have a depending diſcharge from the wound, that all danger from abſorption may be avoided; but do this without altering the relaxed ſtate of the limb, which is of ſuch importance, that hardly any thing ſhould interfere with this particular. If a bone protrudes, it is better to ſaw off a part than to permit the matter to lodge ſo as to be abſorbed: this operation is but very little trouble to the patient, but the lodging of the matter is extremely ſo. If a luxation accompanies a *fracture*, reduce the luxation firſt, and afterwards proceed with the *fracture*; though, if the *fracture* is very near the head of the luxated bone, reduce the *fracture*, and wait its healing before you make any attempt on the luxation.

When a ſimple *fracture* happens, reduce it, and lay the limb eaſy; when reduced, the reduction was called by the Greeks, *cathidruſis*; then apply a cataplaſm of oatmeal, oil, and vinegar, or, as a ſubſtitute, a plaſter of cerat. alb. The bandage with eighteen tails is the beſt, both in ſimple and compound *fractures*; it is more commodious than the roller, as it allows of viewing the limb without diſturbing it. At the concluſion, if the leg is œdematous, the laced ſtocking is the beſt; and rubbing it daily with a flannel, or a fleſh-bruſh, will reſtore the plumpneſs of the calf.

Compound *fractures* are often attended with mortification; but this ſhould not always haſten to amputation. As ſoon as any tendency to this ſymptom appears, make uſe of an antiſeptic fomentation, in which ſal ammon. is diſſolved, dreſs the wound twice a day, and wrap the part up with the catap. cumini; then apply bladders of warm water, one third or half full, to keep up a proper warmth from dreſſing to dreſſing; beſides theſe, give the bark joined with rhubarb; in ſome caſes the bark ſhould be given with nitre, and in others with camphor, volatiles, and ſnake-root. Inſtances where it ſeems proper to deviate from this advice are as follow:

When amputation ſeems neceſſary, conſider, whether, if amputation is omitted, life will not be endangered. It is impoſſible in ſome inſtances to know immediately whether a limb can be ſaved or not. However, when a bone or bones are broken into many pieces, and that to a conſiderable extent, as often happens from cannon-ſhot, broad wheels of carriages, &c. paſſing over or falling on a limb, the ſoft parts being ſo torn and bruiſed, as to render a mortification of the part the moſt probable, and the moſt immediate conſequence, amputation will be the moſt proper aid, and that without loſs of time. If the ends of a bone, or two bones, by which a joint is formed, be cruſhed, and the ligaments which make a part of the joint, are conſiderably injured, another inſtance occurs, in which amputation cannot with propriety be deferred. —Some inſtances of compound *fractures* require ſpeedy amputation: all who die from this cauſe, die of an inflammation ſeizing the limb, tending to a gangrene; this gangrene makes a rapid progreſs along the cellular membrane to the vital parts, and deſtroys before nature can accompliſh a ſeparation, or art ſtop its career; therefore, inſtead of waiting for a ſeparation of the mortified from the ſound part, or inſtead of waiting two or three days to try what art can do, proceed immediately to the ſeparation. To wait in this caſe, is to loſe all opportunity of ſaving life, except perhaps in an inſtance of one in fifty, a diſproportion too great to admit of any heſitation. A very ſhort time makes all the difference between probable ſafety and fatality. If in a compound *fracture* this juſt named inflammation hath taken place, and hath continued ſome hours, amputation would ſurely deſtroy; the only chance then is to uſe ſuch antiphlogiſtic regimen, &c. as appears to be indicated; and when theſe have no farther uſe, then ſupport the patients with cordials, the bark, &c.—Again, inflammation may not run high; yet frequently, there are lodgments of matter, and after ſeveral openings, freſh collections are formed; the patient, inſtead of being recruited, waſtes by the diſcharge; he hath night-ſweats, loſs of appetite, &c. In theſe caſes, the bone continues diſunited, and amputation at laſt is neceſſary. Mr. Pott obſerves, that in compound *fractures*, there are three points of time in which amputation may become neceſſary. 1. Immediately, or as ſoon as may be after the receiving of the injury. 2. When the bones continue a conſiderable length of time without any manifeſt diſpoſition to unite, and the diſcharge from the wound is ſuch, that the patient's ſtrength fails, and general ſymptoms of diſſolution approach. 3. When a mortification ſhall have taken ſuch complete poſſeſſion of the inferior part of the limb, quite down to the bone, that, upon ſeparation of their parts, the bone or bones ſhall be left bare in the interſpace. The firſt and ſecond of theſe are matters of ſerious conſideration; the third hardly requires any. The neceſſity of early amputation in the above caſes, where it is thus urged, ariſes from the dread of the ill effects of a greatly obſtructed circulation, owing to a large deſtruction of veſſels; theſe added to thoſe ariſing from pain, irritation, and the admiſſion of air, often produce a great degree of fever and inflammation, which hurries on quickly to a gangrene and death; and,

and, if a joint is injured, the danger is increaſed. If poſſible then, determine for the operation before inflammation approaches; for, if this ſymptom, with irritation and tenſion, have taken place, the operation will be too late. In the ſecond inſtance, with reſpect to the point of time for amputation, the patient or his friends muſt determine it; for, with the ſurgeon, it is not a matter of choice, but of abſolute neceſſity. In the third inſtance, with reſpect to the point of time, it requires no conſideration; for if the ſoft parts are deſtroyed down to the bone or bones, either the ſurgeon muſt ſaw them, or they muſt be left to ſeparate. In either caſe, the patient loſes his limb. Theſe are ſome of the principal inſtances which determine in favour of amputation; experience, and the ſeveral authors who have writ well on this ſubject, will ſuggeſt more, and amongſt theſe may be conſulted Pott's Works, quarto edition; alſo, by the ſame author, a pamphlet entitled, Remarks on the Neceſſity, &c. of Amputation in certain Caſes, &c. See Gooch's Works. Obſ. or Mr. Pott's General Remarks on *Fractures*, by Thomas Kirkland, Surgeon, and the Syſtems of Surgery, &c. by Bell, Deaſe, Kirkland, &c.

1. Carpi Fractura. Fracture *of the* Carpus.

Theſe bones are ſmall, and rarely broken; and when they are, they cannot be properly replaced, nor will they conſolidate. Beſides, the ligament and tendons are ſo much bruiſed, that in conſequence thereof, the joint of the hand becomes rigid; and abſceſſes, fiſtulas, and caries, generally enſue, and relief is ſeldom obtained but by amputation of the hand. However, an attempt may be made by two aſſiſtants extending, while the ſurgeon endeavours to replace the fractured bone or bones. White's Surgery, p. 145.

2. Claviculæ Fractura. Fracture *of the* Clavicle.

Whatever part of the clavicle is broken, the part which joins the ſcapula deſcends below that part which is fixed to the ſternum, on account of the weight of the arm. When this bone is fractured, the patient cannot lift up his arm; it hangs inclined towards his breaſt, and in a ſlight motion of the humerus, the *fracture* in the clavicle will be evident to the touch, ſight, or ear, or them all. To reduce this *fracture* is eaſy, but to retain the bones in their proper ſituation is more difficult. An aſſiſtant ſhould place his knee between the ſcapulæ of the patient, then with his two hands draw the ſhoulders back; thus the clavicles will be extended; the ſurgeon ſtanding before the patient, muſt then reduce the ends of the bone, by raiſing the arm to its proper ſituation, inſtead of loading the other end next the ſternum, with compreſſes to bring down the riſing end of the bone, as they call it, which is only ſo from the other being carried below it by the weight of the arm: this done, apply above and below the clavicles, a narrow, but thick bolſter to fill up the cavities; upon theſe, lay two narrow bolſters, in the form of the letter X; over theſe places, a piecee of thick paper moiſtened with vinegar; then put a wad of tow, or a ball made of ſoft rags, under the arm-pit, next to where the *fracture* is, for the ſupport of the ſhoulder; after this, apply the bandage, ſo as to keep the fractured ends from moving; and, laſtly, ſuſpend the arm in a ſling fixed about the neck. See Bell's Surgery, vol. vi. p. 59. White's Surgery, p. 138.

3. Coccygis Fractura. See N° 18.

4. Colli Fractura, *a* fractured Neck.

What is called a broken neck is as follows: the proceſſus dentatus of the ſecond vertebra is tied to the ſkull by a ligament, and kept cloſe to the fore part of the firſt vertebra by another in that vertebra, that it may not bruiſe the ſpinal marrow; and when either this ligament or proceſs is broken, it makes that ſort of broken neck whoſe conſequence is ſudden death.

5. Costarum Fractura. Fracture *of the* Ribs.

When the ribs are broken, and their ends recede from each other, when they project outward, no conſiderable damages enſue; but if they preſs inward, they produce an uneaſy pricking, inflammation, cough, fever, an abſceſs, or ſpitting of blood, &c. In order to the cure, it is generally completed by applying an exact uniform circular compreſſive bandage, if neither inflammation nor ſwelling forbid; if theſe ſymptoms attend, reduce them by bleeding, &c. then the bandage and a cooling diet will ſucceed. See Bell's Surgery, vol. vi. p. 63. White's Surgery, p. 140.

6. Cranii Fractura. Fracture *of the* Skull.

When, from an injury done to the head by external violence, there follows a loſs of ſpeech, and of ſenſe, a lethargy, convulſions, &c. as theſe ſigns may be the effect of an extravaſation of matter on the brain, of a concuſſion thereof, as well as of a *fracture*, no certain concluſions can be made therefrom: for certainty, you muſt proceed to inciſion upon the part where the injury was received: if, upon making an inciſion, you find the pericranium looſe, you may certainly conclude there is a *fracture*. In examining for a *fracture*, care is required to diſtinguiſh it from a ſuture, particularly the uncommon ones, as thoſe about the oſſa triquetræ; however, if, upon ſcalping, we find the pericranium firmly adhering to any part that reſembles a *fracture*, we may be aſſured that there is a ſuture; but if the pericranium eaſily ſeparates, the caſe is a *fracture*. If, when the head is ſhaved, you can feel the pericranium under your finger to be looſe, a *fracture* is clearly the caſe.

When a *fracture* happens on the ſkull, the trepan is immediately uſed by ſome ſurgeons, with a view to obviate or prevent the effects of ſuch a degree of violence, as hath fractured the ſkull; but others of the firſt rank in eminence forbid its uſe, except when a part of the ſkull is depreſſed. Celſus adviſes not to proceed to an operation before the approach of unfavourable ſymptoms, and Ruyſch ſays, that "when the ſymptoms are not augmented, we are not to proceed to inciſion and perforation, but, after bleeding, we are to attempt the cure by often repeated application of warm cephalic fomentations." Agreeable to theſe is the advice and practice of Mr. Bromfield, when a concuſſion of the brain happens. See Concussio. The ſame proceeding is equally proper in caſe of a *fracture*. See White's Surgery, p. 211.

7. Cruris Fractura, *a* fractured *Leg*.

In the leg, there are two bones, viz. the tibia and the fibula. The tibia is generally fractured near its lower extremity, where it is weakeſt; and often, when the tibia is broken, the fibula ſuffers the ſame at its upper extremity. When there is a diſlocation of the maleolus internus, the fibula is commonly fractured, and has occaſioned it.

A fractured fibula ſeldom gives any uneaſineſs, or hinders from walking; however, it may be diſcovered by taking hold of the leg under the ſura with one hand, and with the other moving the foot; for thus, the hand which holds the leg will diſtinguiſh the *fracture*. Mr. Pott ſays that, in this caſe, a tight bandage upon the fractured part is not to be admitted: but that, if it is applied to the two extremities, the broken end will be brought into contact, and thus a cure will be effected.

When the tibia is fractured, lay the patient on the injured ſide, on a flat ſurface, and raiſe the knee on the fractured limb towards the abdomen, at the ſame time bending the joint of the knee; thus, the extenſor muſcles of the foot are relaxed, and the extenſion required for the reduction will be performed with eaſe. Having replaced the fractured bone, apply a long ſplint padded with tow to the fibula, and another on the inſide of the leg, and over part of the tibia, and ſecure them with ſtraps. The patient may lay on the injured ſide during the cure, and thus a cradle or fracture-box will be needleſs; the knee may alſo continue in the ſame poſture as that in which the *fracture* was reduced.

There is an important difference attends a *fracture* from a gun-ſhot, and the like accident from any other cauſe. For example, in caſe the tibia is fractured at its lower end by a gun-ſhot, although the part of the tibia above is apparently unhurt; yet, if the amputation is not performed above the next joint, the patient will loſe his life; the limb, in this caſe, muſt be taken off above the knee. Though, if any other cauſe had produced the like *fracture*, the operation would have been performed below the knee. Bell's Surgery, vol vi. p. 121. White's Surgery, p. 149.

8. Cubiti Fractura. Fracture *of the* Cubit.

The cubit hath two bones, viz. the radius and ulna. *Fractures* here are diſcovered by the ſight, touch, and ear: by the touch and ſight, by moving the hand of the affected cubit inward and outward; though a fractured

ulna, from its inability to ſupport the joint, will ſhew itſelf ſooner than that of the radius: the ear diſcovers a grating noiſe, if the elbow is held ſteady, and the hand is moved inward and outward.

If the RADIUS is to be reduced, and the fragments have receded towards the ulna, an aſſiſtant ſhould ſtretch the arm, and the ſurgeon ſhould preſs down the patient's hand towards the ulna, until the depreſſed part is elevated; after this, compreſs the arm on each ſide with the palms of the hand, ſo as to reſtore the compreſſed muſcle; between the ulna and radius, and the fragments of the radius to their natural poſition; then lay a compreſs and ſtrong paſteboard upon the fore-part of the arm, over the quadratus muſcle, to prevent it drawing the fractured bone toward the ſound one; after which, apply the circular bandage, and ſuſpend the arm in a ſling, with the hand in a prone ſituation.

If the ULNA is fractured, proceed as when the accident happens to the radius; only remember to turn the hand towards the radius, until the depreſſed part of the ulna has recovered its former poſition.

IF BOTH THESE BONES are broken, proceed, as with either of them ſingly. Mr. Pott obſerves in this caſe, it is neceſſary to put the longitudinal compreſſes as near as may be betwixt the bones, in order to prevent the callus uniting them, which would hinder the rotatory motion of the arm.

It often happens in *fractures* of this part, that, notwithſtanding all poſſible care, a ſtiff joint follows; therefore, though (in this particular inſtance, and in the patella) keeping the whole limb ſtrait relaxes the particular muſcles of the bones; yet, if a ſtiff joint is to be feared, as ſoon as ever the benefits from relaxation are over, gently bend the limb. A ſtiff bent cubit being much more uſeful than a ſtrait one. See Lond. Med. Jour. vol. i. p. 356. Edin. Med. Com. vol. ix. p. 382. White's Surgery, b. iv. Bell's Surgery, vol. vi. p. 84.

9. DIGITI FRACTURA, *a* FRACTURED Finger.

When the contuſion of the hand or fingers is very conſiderable, amputation is moſt adviſeable; but if you can ſave the part, proceed as follows: having placed the fractured bone properly, and reduced the fragments, roll it up with a narrow fillet to the next finger. Begin the bandage about the wriſt, carry it over the back of the hand to the finger; and, if more fingers than one are fractured, carry it round each ſeparately, and then round them all; then put a ball into the hand, and bind it tight to the fingers; after which continue the roller back to the wriſt, and finiſh by placing the hand in a ſling. Bell's Surgery, vol. vi. p. 93. White's Surgery, p. 145.

10. FEMORIS FRACTURA, *a* FRACTURE *of the* Thigh.

Hippocrates juſtly obſerves, that when either the bone of the humerus, or of the thigh, breaks inwardly, a worſe train of ſymptoms follow than when the ſame happens outwardly, becauſe of the veſſels and nerves that are lodged in their inner parts.

When the thigh is fractured in its middle or lower part, its reſtitution may be effected by the hand, but when the accident happens on the upper part, a greater force is generally required. Wherever the ſeat of the *fracture* is, the poſition of the patient, and of the limb to be reduced, ſhould be ordered as in the caſe of a fractured leg; then a due extenſion being made, and the ends of the fractured bone replaced, ſplints, properly padded with tow, muſt be ſecured; and if Gooch's machine for *fractures* of the thigh-bone is made uſe of, little more than patience will be required in order to the cure; but in want of this machine, the poſition propoſed, when the leg is fractured, may be truſted to, and that particularly when the neck of the thigh is the ſeat of the diſorder.

When a *fracture* of the thigh is complicated with a wound, it is dangerous, and ſometimes incurable. Happening near the joints, it is uſually fatal, as the large blood-veſſels are then too frequently lacerated. The danger is not much leſs if the wound is on the back part of the thigh, becauſe of the difficulty of dreſſing it. If the hæmorrhage can be reſtrained by uſing the tourniquet, and taking up the wounded veſſel, the *fracture* may then be reduced; but if the bone is much injured, and the hæmorrhage violent, amputation is uſually the moſt eligible method.

A *fracture* of the neck of the thigh-bone is ſometimes miſtaken for a luxation, but it is more eaſy to break than to luxate this bone, and *fractures* in its neck are more frequent than in its other parts. A *fracture* in the neck of this bone is both more difficult to be reduced and retained than in the body of it, and a lameneſs uſually follows the re-union. The oblique direction of the neck, with the quantity and ſtrength of the muſcles, are the cauſes of theſe difficulties.

The ſigns of this kind of *fracture* are, according to Gooch, "The thigh and knee turning outwards, the limb is much ſhortened, and conſiderably ſhrunk, pain in the courſe of the ſartorious muſcle, which, from its origin and inſertion, muſt frequently be put upon the ſtretch, often cauſing pain on the inſide juſt below the knee, and a crepitus is obſerved when the patient moves his limb." When theſe ſymptoms appear, the limb being gently but ſteadily extended until the fractured limb appears as long as the ſound one, let the patient be laid in the poſture recommended, when the leg is the part thus affected, and let bleeding, &c. be employed to prevent or to remove inflammation. If Gooch's extending machine could be obtained, its uſe would be the moſt eligible method for preventing future inconveniences. Bell's Surgery, vol. vi. p. 95. White's Surgery, p. 146.

11. HUMERI FRACTURA, *a* FRACTURED Humerus.

If this bone is fractured in the middle, no great difficulty attends; but if near the ſuperior and anterior head, both pain and danger are ſometimes preſent. To reduce this *fracture*, place the patient in a chair; his elbow being bent, let an aſſiſtant ſteadily graſp the fractured bone at its lower end, and another aſſiſtant do the ſame a little below the ſhoulder; then the arm being extended gently, the operator takes the fractured part in his hand; and as ſoon as the extenſion is ſufficient, the bone being thereby replaced, he applies the bandage, and confines it by hanging the fore arm in a ſling.

It ſometimes happens, that when the caſe is an oblique *fracture*, the ſharp end of the bone is ſo intangled in the adjacent muſcles as to prevent a re-union; but an inciſion being made upon them, and the point ſawed off, makes way for an eaſy replacing them, and a ſpeedy cure. See Med Muſ. vol. ii. p. 404, &c. Bell's Surgery, vol. vi. p. 79. White's Surgery, p. 143.

12. INNOMINATI OSSIS FRACTURA, *a* FRACTURED Os Innominatum.

When this accident happens, there is great danger, eſpecially if the patient vomits a brown or bloody matter. In reducing this kind of *fracture*, the patient muſt lie on the ſound ſide; the fractured parts muſt be reſtored by the ſurgeon's hands alone; then compreſſes dipped in rectified ſpirit of wine muſt be ſecured by means of the ſpica bandage. See White's Surgery, p. 143.

13. MAXILLÆ FRACTURA. FRACTURED Jaw.

When *fractures* of the UPPER JAW ſtretch towards the eyes, the conſequent inflammation is often dangerous; and when they penetrate the antrum, they are generally tedious, and occaſion much deformity. Replace the fractured bones with the fingers, when there is no wound; or with forceps, or a narrow ſcapula, when the parts are laid open; and a piece of adheſive plaſter is the beſt for reſtraining the dreſſings. Bleeding, and an antiphlogiſtic regimen, muſt be adviſed to obviate inflammation of the eye, and contiguous parts. The reunion of fractured parts muſt be left to nature.

When the LOWER JAW is fractured, and its ſituation is aſcertained, replace the bones carefully; which may be done by placing the patient in a proper light, with his head well ſecured, and the fingers of one hand preſſing upon the inſide of the jaw, while the other hand is employed externally in guarding againſt any perceptible inequality of the bone. If a tooth is ſeated in the courſe of the fracture, extract it immediately; but if a tooth, not ſeated in the courſe of the *fracture*, is forced out of its ſocket, replace it if you can, and fix it by tying it to the contiguous firm teeth. This done, endeavour to retain the fractured bones in a proper ſituation till they are firmly reunited. For this end, the beſt means are a compreſs and bandage of ſoft old linen or cotton. The parts being kept firm by an aſſiſtant, a thick compreſs ſhould be laid over the chin, and made to extend from ear to ear along each jaw; and over the whole, a four-headed roller ſhould be applied. Liquid diet is beſt until the cure is performed. See Bell's Surgery, vol. vi. p. 52. 58. White's Surgery, p. 137.

14. METACARPI

14. METACARPI FRACTURA, *a* FRACTURED Metacarpus.

An aſſiſtant may extend the fractured hand upon a ſmooth table, while the ſurgeon, with his fingers, endeavours to replace the fragments. White's Surgery, p. 145.

15. NASI FRACTURA, *a* FRACTURE *of the* Noſe.

Both the bones and the cartilages are liable to be broken. If the bones are broken, the noſe appears flat where the *fracture* is; and if the cartilage is the ſuffering part, the noſe leans to one ſide. If the injury is conſiderable, the cure is incomplete; and from the nearneſs of this part to the brain, the danger is conſiderable; an ozæna, a caries, or a polypus, may be the conſequence. IN ORDER TO A CURE, place the patient in a reclining poſture, and elevate the depreſſed parts of the noſe with a quill, replacing them in their proper order with the fore-finger and thumb of your other hand: to prevent their collapſing, fill the noſtril with lint, or introduce a canula there: if there is no wound, a plaſter may ſuffice to ſecure the whole; and if there is a wound, treat it as if on any other part. If a ſplinter is ſo ſituated as not to be re-united but with difficulty, remove it. When the bones are reduced, they do not eaſily ſeparate again. Mr. Bell ſays, any portion of bone that is quite looſe, and nearly ſeparated from the reſt, ſhould be removed immediately, whether it be raiſed up, or forced into the noſtril; but whatever adheres to the remaining portion of bone, with much firmneſs, ſhould be replaced. See Bell's Surgery, vol. vi. p. 49. See White's Surgery, p. 137.

16. PATELLÆ FRACTURA, *a* FRACTURED Knee-Pan.

When a ſmall fragment of the patella is attracted upwards, if the patient is fat, it is not very eaſy to diſcover this caſe. In ſearching to know whether or no the patella is broken, do not bend the knee, becauſe you ſeparate the fragments thereby farther from each other, and occaſion unneceſſary pain. This bone is generally broken tranſverſely, the lower part remains fixed to the knee, but the upper is drawn by the muſcles on the fore part of the thigh. When the caſe is diſcovered, lay the patient on his back, extend his leg, and gently preſs the muſcles above the fractured part downwards, until the fragments of the bones approach within an inch of each other; in this ſituation, retain them by a compreſs and bandage. The fractured parts ſhould never be brought cloſe together, for thus a ſtiff joint ſhould be occaſioned.

Sometimes the ligament which ſecures the knee-pan to the tibia is broken, and this caſe is miſtaken for a *fracture* of the knee-pan; however, the miſtake is not of much conſequence, as the prognoſtics and method of cure are the ſame. See Warner's Caſes of Surgery; Med. Muſ. vol. iii. p. 349, &c. Bell's Surgery, vol. vi. p. 111. White's Surgery, p. 147.

17. PEDIS FRACTURA. FRACTURE *in the* Foot.

Fractures in the *tarſus*, *metatarſus*, and *toes*, are generally accompanied with wounds from the contuſion of the nerves, tendons, ligaments, and membranes. They are cured much in the ſame manner as thoſe of the carpus, metacarpus, and fingers. *Fractures* in this part, as well as in the hand and leg near the ankle, eſpecially when the malleolus recedes from the principal bone, ſeldom admit of ſo complete a cure as to leave the limb free from ſome inconvenience. Bell's Surgery, vol. vi. p. 130.

18. SACRI & COCCYGIS OSSIUM FRACTURA, *a* FRACTURE *of the* Os Sacrum *and* Os Coccyx.

It is diſcovered by the pain perceived in the part, and by the touch. Endeavour to reduce the fragment with your fingers; but if it be depreſſed inwardly, pare the nail of your fore-finger pretty cloſe, then greaſe and introduce the finger into the inteſtinum rectum, and thus the depreſſed part may eaſily be replaced; this done, the T bandage may be applied over a proper compreſs; the patient muſt be directed to keep his bed for two or three weeks; and when he turns from one ſide to the other, let him turn over his belly; when he riſes, the propereſt ſeat will be a bottomleſs chair. See Bell's Surgery, vol. vi. p. 74. White's Surgery, p. 143.

19. SCAPULÆ FRACTURA, *a* FRACTURE *of the* Scapula.

If the acromion is broken, it is eaſily reduced with the fingers, if the os humeri is raiſed upwards a little; but it is ſo difficultly retained, that thoſe patients ſeldom can lift up their arms afterwards freely: after the reduction, put a compreſs on it, and a ball under the arm-pit; apply the bandage, and put the arm in a ſling.

If the neck of the ſcapula, which is below the acromion, or the acetabulum, be broken, the accident is not eaſily diſcovered; but a ſtiffneſs of the joint, an inflammation, an abſceſs, or other bad ſymptoms, follow.

All other *fractures* of this bone are leſs hazardous; and to reduce them, an aſſiſtant ſhould extend the arm forward, whilſt the ſurgeon, in the beſt manner he can, is employed in reſtoring the fragments with his hands, laying thereon compreſſes, and paſte-board ſplints, and ſecuring all with the faſcia ſtellata, or quadriga. See Bell's Surgery, vol. vi. p. 76. White's Surgery, p. 140.

20. STERNI FRACTURA, *a* FRACTURED Sternum.

After a depreſſion or a *fracture*, the part is in pain: this accident is alſo known by the bone grating, if moved by the fingers, and by its moving in conſequence of a little preſſure againſt it; though the proper indication is a manifeſt ſinus or inequality in the part.

The latent veſſels in the ſternum are broken, from whence proceed pains in the breaſt, difficulty of breathing, violent cough, ſpitting of blood, extravaſations of blood on the precordia, or within the mediaſtinum, with other dangerous ſymptoms.

To reduce this kind of *fracture*, lay the patient on his back over ſome hard pillows, that his ſhoulders may be depreſſed, and the breaſt elevated; the operator muſt then preſs forcibly, and with ſome violence ſhake each ſide of the breaſt; for thus the ribs are extended, and the ſternum puſhed forward. If this fails, make a crucial inciſion into the ſkin, and elevate the depreſſed part of the ſternum with a terebra gently ſcrewed into the part.

After the reduction, the napkin and ſcapulary may be applied to keep the thorax firm.

Mr. Bell ſays, in the ſixth vol. of his Surgery, page 67, &c. that, "In ſome caſes, it is fractured without being diſplaced; in others, it is not only broken, but at the ſame time beat in upon the pleura. When it therefore happens that the pain, cough, oppreſſed breathing, and other ſymptoms, do not yield to blood-letting and other parts of an antiphlogiſtic courſe, ſome other method of cure ſhould be attempted. An inciſion ſhould be made upon the injured part, of a ſufficient length to admit of a free examination of the bone; when the depreſſed piece may be raiſed either with a common ſcalpel, or a levator, if there be an opening that will admit an inſtrument; or when this is not practicable, an opening may be made for this purpoſe with the trepan. If the operation be performed with caution, the bone may be raiſed with ſafety; and this being done, the ſore muſt be treated in the uſual way. See White's Surgery, p. 139.

21. VERTEBRARUM FRACTURÆ. FRACTURES *of the* Vertebræ.

When any of the vertebræ are fractured without affecting the ſpinal marrow, then there are only the poſterior apophyſes, or acute tubercles, injured, and they are not dangerous. When theſe parts only are fractured, replace them with your fingers, and apply on each ſide the ſpina dorſi, narrow compreſſes moiſtened with ſpirit of wine, and ſecure them with paſteboard ſplints, and the napkin and ſcapulary.

Fractures in theſe parts are eaſily known by the pain there; as alſo on ſlightly touching them.

If the tranſverſe apophyſes which tend towards the cavity of the thorax are broken, then the heads of the ribs which are inſerted into them will likewiſe be broken, and much danger attends this caſe.

When the body of a vertebra is broken, the ſpinal marrow is injured; then the parts of the arms, viſcera, or legs which are below them, become immediately motionleſs, and death is ſooner or later the conſequence. In this caſe, not to ſeem either negligent or ignorant, lay the injured part bare, elevate the fragments which preſs the medulla, and if looſe, extract them; then clean the wound, and dreſs with balſamics as long as life continues. See Boerhaave's Aphoriſms, the Engliſh tranſlation, p. 84. 88. Petit. on the Diſeaſes of the Bones; Aitkin's Treatiſe on *Fractures*; Pott's general Remarks on *Fractures*, and Kirkland's Obſervations on the ſame: and for machines to be uſed after the reduction of *fractures*, ſee Gooch's Caſes and Remarks. Bell's Surgery, vol. vi. p. 71. White's Surgery, p. 142.

FRÆNUM.

FRÆNUM. See LIGAMENTUM ANNULARE, LINGUA & PENIS.

FRAGA. The STRAWBERRY. See ARBUTUS. Boerhaave mentions ſix ſpecies. The common wood *ſtrawberry* is the moſt agreeable, flowers in May, and the fruit ripens in June. *Strawberries* are apt to putrify in the ſtomach; hence the cuſtom of eating them with ſugar and wine. A decoction of the whole plant is uſed againſt the jaundice.

FRAGARIA. See ARBUTUS.

FRAGAROIDES. BARREN STRAWBERRIES. See ARBUTUS.

FRAGILITAS OSSIUM, alſo called *friabilitas oſſium*. It conſiſts in a too great redundance of the earthy principle in the ſound habit. In the diſeaſed, the ſcurvy, lues venerea, and ſcrophulous diſorders, may be the cauſe. Mr. Sharp ſays that the cauſe is a defect of the oil.

FRAMBŒSIA. See YAWS.

FRANCOLIN. See ATTAGEN.

FRANGULA. See ALNUS NIGRA.

FRAXINELLA. See DICTAMNUS ALBUS.

FRAXINUS, called alſo *bumelia*. The ASH-TREE. It is the *fraxinus excelſior*. Linn. It is a tall tree common in woods and hedges. Its bark is whitiſh; the ſeeds are oblong, reddiſh, or browniſh-coloured, ſhaped ſomewhat like a bird's tongue, whence their name *lingua avis*, *ornithogloſſum*, &c.

The freſh bark is bitteriſh and aſtringent, but loſes much in drying. In doſes of a dram it is diuretic, and the watery extract hath the ſame effect. The middle bark hath been uſeful in intermitting fevers, when aſſiſted by alkaline ſalts.

The ſeeds called *lingua avis*, from their being ſhaped like a bird's tongue, are diuretic, healing, and drying. Their doſe is a dram or more. Raii Hiſt. Lewis's Mat. Med. That called

—— ORNUS, the FLOWERING ASH, is the ſpecies on the ſurface of which manna exudes and concretes. This ſpecies is alſo called *ornus*; *manniſera arbor*. See MANNA.

FRENA. See ALVEOLUS.

FRIABILITAS OSSIUM. See FRAGILITAS.

FRICTA. See COLOPHONIA.

FRICTIO. RUBBING. *Friction* of the body upon its whole ſurface, if duly repeated, will do more in the recovery of health, and towards the ſupport of it, than is generally apprehended; it promotes perſpiration, quickens the circulation, and opens the finer veſſels through which thoſe diſcharges are made, on which health and vigour much depend. *Friction* contributes not only to the conveyance of medicines into the body, but alſo to their action and uſefulneſs there, when introduced. This means of health is beſt uſed when the primæ viæ are moſt empty, when the chylopoetic organs are too languid. *Friction* with rough cloths over the whole belly, when the patient is faſting, produces advantageous effects. Gentle *friction* with pinguious ſubſtances relax; but ſtrong *friction* with rough dry cloths ſtrengthen. It has been conſidered particularly uſeful in caſes of aſcites, and many other where the action of the abſorbent ſyſtem is neceſſary to be promoted.

FRIESEL. See MILIARIS FEBRIS.

FRIGIDARIUM. A veſſel in the baths for holding cold water. Alſo the cold bath itſelf.

FRIGERARIA. See PUTRIDA FEBRIS.

FRIGUS. COLD. In Vogel's Noſology, it ſignifies the coldneſs of the feet and hands. *Cold* is ſaid, *by ſome*, to be a privation of heat; but heat and *cold* are the names of certain ſenſations in living animal bodies; and the ſenſe of *coldneſs* is produced by bodies which exiſt, and that are the ſubjects of the ſenſes in the ſame degree as are thoſe which produce the ſenſation called heat. Many ſubſtances excite the ſenſe of *coldneſs*, and extinguiſh fire itſelf; and a greater degree of artificial *cold*-making matter is produced by a mixture of the ſpirit of nitre with powdered ice, than nature manifeſts in any inſtance. See the proceſs by which profeſſor Braun produced an artificial *cold*, and by which quickſilver was ſo frozen as to become malleable, in the Med. Muſ. vol. i. p. 123, &c.

The effect of *cold* on our bodies. See CONGELATUS.

FRITTA. FRITT, called alſo *ammonitrum*. It is a maſs of ſalt and aſhes concreted to the ſand, by the cold, in making of glaſs.

FROND. A twig of a tree with its leaves; LINNÆUS applies this term, to the peculiar leafing of palms and ferns; he defines it to be a kind of trunk or ſtem, which the branch united with the leaf, and frequently with the fructification. MARTYN ſays, it was anciently written *frons*, from *ſpuo*, *pollulo*, *to germinate* or *bud*.

FRONDIPORA. See ESCHARA.

FRONS. The FOREHEAD. It is that part which is above the eyes, deſtitute of hair, and reaches from one temple to the other.

FRONTALE. A name for any topical medicine which is applied to the forehead, called alſo *anacollema*; ſee CATAPLASMA: but particularly it means a linen bag, in which cephalic ingredients are tied, in order to be applied to the forehead. See EPITHEMA.

FRONTALIS, MUSCULUS VERUS. See CORRUGATOR COITERII.

FRONTALIS NERVUS. The fifth pair of nerves from the brain, ſends off its firſt branch called *orbitarius*, *& ramus ſuperior*, which is ſubdivided into three, the firſt of which ſubdiviſions is the *frontal*; it ſpreads on the upper part of the orbit of the eye, to the fat which ſurrounds the globe of the eye, the muſculus elevator palpebræ &c.

—— SINUS. The FRONTAL SINUS. There are two of theſe formed of the ſeparated laminæ of the os frontis; placed above the orbits at the bottom of the os frontis on each ſide the top of the noſe; they are lined with the ſame membrane which lines the noſtrils, and they open into them. Sometimes they are wanting.

—— VENA. It is a branch from the external jugular, forming a vein in the forehead, called by the ancients, *præparata vena*.

FRONTIS, Os. The BONE of the FOREHEAD; called alſo *coronale os*, *inverecundum*, *metopon*, *metopium*. The external ſurface of this bone is ſmooth at its upper convex part, but below, ſeveral cavities and proceſſes are obſerved. At each angle of the orbit the bone juts out to form two internal and two external proceſſes. The ridge which makes the ſupercilium, is called the ſuperciliary proceſs. The lower part of the forehead where the hair of the eye-brows grows, is called *ophrys*. The *proceſſus naſalis*, naſal proceſs, is ſituated between the two internal angular proceſſes. The two orbiter proceſſes are continuations of the ſuperciliary. There is a notch between theſe for the reception of the ethmoid bone. At the internal angular proceſs there is a cavity, where the *caruncula lachrymalis* is lodged; at the external angular proceſs there is another cavity for the pulley of the muſculus obliquus major. The foramina are three on each ſide; one in each ſuperciliary ridge, through which a nerve, vein, and artery, paſs to the teguments, &c. of the forehead. Near the middle of the internal ſide of the orbit, in the tranſverſe ſuture, or near it, is a ſmall hole called *orbiter internus*: the orbiter internus poſterior is ſmaller, and lies about an inch deeper in the orbit. On the inſide of the *os frontis* there is a ridge, which, on the upper part, is imperceptible, and grows more prominent at the bottom, where there is a foramen cæcum; to this ridge the falx is attached. The *frontal* ſinus is placed over the orbits, and is divided by the ſeptum juſt deſcribed.

FRUCTIFICATIO FRUCTIFICATION, or FRUITING, is a temporary part of vegetables, appropriated to generation, terminating the old, and beginning the new vegetable. The eſſence of it conſiſts in the flower and fruit, and there is no fructification without anther, ſtigma, and ſeed. When perfect, it conſiſts of ſeven parts.—1. Calyx—2. Corolla—3. Stamen—4. Piſtil—5. Pericarp—6. Seed—7. Receptacle.—Of theſe the four firſt belong to the flower; the two next to the fruit; and the laſt is common to both.

FRUCTUS. FRUIT; called alſo *carpos*. Properly it is the part of a plant wherein the ſeed is contained, but in general it is any ſeed or grain covered or uncovered, but with the coverings when there are any. The chemiſts call metals the fruits of the earth.

FRUCTUS UMBILICATUS. Umbilicated fruit. It is that which had the other parts of the flower growing on its top when it was an ovary. They uſually form a cavity, when it is known by the name of the umbilicus, or navel, as in the medlar, roſe, &c.

FRUMENTACEUS. A term applied to all ſuch plants as have a conformity with wheat, with reſpect either to their fruit, leaves, ears, or the like.

FRUMENTUM. CORN. It is ſpontaneous in no climate, but induſtry raiſes it in all. They are a ſpecies of graſs in their primitive ſtate, whoſe ſeed are improved by culture. A name given alſo to wheat. See TRITICUM.

FRUMENTUM CORRUPTUM. See BRASIUM.

—— INDICUM. } See MAYS.
—— TURCICUM. }

—— SARACENICUM. See FAGOPYRUM.

FRUTEX. A SHRUB. It is a plant with many woody perennial trunks, ſuch as roſes, ſyringos, &c. which divide into ſeveral ſtems near the ground. LINNÆUS makes the diſtinction of a ſhrub from a tree, to conſiſt in its having no buds; though trees have not buds in hot climates. He acknowledges, however, that nature has placed no limits between them. The word is generally uſed by gardeners for all woody plants of low growth.

—— BACCIFER BRASILIENSIS. See CAAGHIYUYO.

—— INDICUS BACCIFER. See BELILIA.

—— INDICUS SPINOSUS. See CARA-SCHULLI.

—— ODORATUS SEPTENTRIONALIUM. See MYRTUS BRABANTICA.

—— PAVONINUS. See POINCIANA.

—— TERRIBILIS. See ALYPIA.

FRUTICOSUS. FRUTICOSE. Plants which are of a hard woody ſubſtance.

FUCOIDES. A ſpecies of plant which grows in water. It is of a middle nature betwixt conferva and corallina, and fucus. It is often finely divided, and of a more tender ſubſtance than the fucus, and not diſtinguiſhed by nodes and joints like the conferva and corallina.

FUCUS. It is a ſpecies of plant growing in water, whoſe leaves and ſtalks are of various figures. It is generally of a viſcid and coriaceous ſubſtance, and is furniſhed with veſicles on both ſides, which admit of the air being formed to aſſiſt its floating. Its extremities are often ſet with tubercles, which ſeem to contain ſomething of a ſeminal nature.

Botaniſts enumerate many ſpecies: but, except two of them, they are not noted in medicine; and theſe are,

1. Alga marina latifolia vulg. See QUERCUS MARINA.

2. Lactuca marina; which is of the ſame uſe as the alga.

—— MARITIMUS. } See KALI.
—— VESICULOSUS. }

—— MARINUS. See ALGA.

FUGA DÆMONUM. See HYPERICUM.

FUGILE. EAR-WAX. See CERUMEN AURIS. In Paracelſus, it means an appearance in the urine like wax. Some expreſs by it a *bubo*, and others the tumor called *parotides*.

FULIGO. SOOT, alſo called *araxos*, *aſoper*, ASUOLI. It is the ſhining black concrete, formed by the ſmoak from wood, that is uſed in medicine, and to be here underſtood by *ſoot*. It hath a diſagreeable ſmell, and a pungent bitter nauſeous taſte; the more reſinous the wood, the more bitter will be the *ſoot*. By a chemical analyſis it affords a volatile alkaline ſalt, an empyreumatic oil, a fixed alkali, and an inſipid earth.

The *ſoot* gives out its virtues to water, or to proof ſpirit, each of which diſſolves about one-fourth part of good ſoot; and is conſidered as an antiſpaſmodic.

FULMINATIO. FULMINATION, from *fulmino*, *to lighten* or *thunder*. IN CHEMISTRY it hath two ſignifications: 1ſt, An explоſion, and is the ſame as *detonatio*. 2dly, In the depuration of the more perfect metals, it is when upon infuſing them with lead, a bright colour ſucceeds a kind of ſulphureous cloud before appearing in the metal during the fuſion.

FUMARIA. FUMITORY. Alſo call *fumus terræ*, *capnos*, and *herba melancholifuga*. It is the FUMARIA OFFICINALIS, or FUMARIA pericarpiis monoſpermis racemoſis, caule diffuſo, flore purpureo. CL. DIADELPHIA; ORD. HEXANDRIA. LINN. Gen. Plant. 849. COMMON PURPLE FUMITORY. It is a plant with bluiſh green, finely-divided leaves, producing, towards the tops of the ſtalks, ſpikes of irregular purpliſh flowers, followed each by a ſingle ſeed. It is annual, flowers in May and June, and delights in ſhady places. The leaves have a bitter ſaline taſte; an extract obtained by inſpiſſating the expreſſed juice, of a decoction of the leaves in water, is very bitter. The juice of theſe leaves, if dropped into the eyes, is ſuppoſed to cure dimneſs of ſight; whence the name *fumaria*, becauſe it provokes tears, and clears the ſight after the manner of ſmoke. It has been ſuppoſed by phyſicians of the firſt authority, both ancient and modern, to be very efficacious in opening obſtructions, and infarctions of the viſcera, particularly thoſe of the hepatic ſyſtem. It is alſo highly commended in ſcorbutic and acrimonious ſtates of the fluids; and therefore employed in various cutaneous diſeaſes, taken in pretty large doſes, eſpecially the juice mixed with whey; and uſed as common drink, it proves diuretic, and laxative. Dr. CULLEN has found it uſeful in many caſes, wherein bitters are preſcribed; but its remarkable virtues are thoſe of clearing the ſkin of many diſorders; and has experienced its good effects in many inſtances of cutaneous affections, which he would call lepra. The doſe, two ounces of the expreſſed juice twice a day; or, the dried root may be given in infuſion, or decoction, or the extract; for theſe all retain the virtues of the freſh herb.

FUMARIA ALBA, alſo called *cyſticapnos Africana ſcandens*. AFRICAN CLIMBING BLADDER FUMITORY.

It is a *climbing* plant, chiefly reſembles the fumitory above deſcribed, only that the fruit is an oval bladder, in which are the ſeeds.

FUMIGATIO, from *fumus*, *ſmoak*. FUMIGATION. By the ſubtil *fumes* that are inſpired as well as inhaled into our bodies, much benefit or prejudice is produced, according to the nature of the matter, and the conſtitution in which it is received. It is evident from the palſies produced among workers in lead mines, &c. and the benefits received in many caſes when the air is impregnated with ſalutary materials; catarrhs and catarrhous coughs are relieved by *fumes* received with the breath; and by the ſame method, expectoration is aſſiſted in humoral aſthmas; and even ulcers in the lungs are ſaid to have been healed by this method. The advantage of mercurial *fumigations* in the cure of venereal ulcers is known to every practitioner.

FUMUS ALBUS. See ETHEL.

—— TERRÆ. See FUMARIA.

FUNCTIO. See ACTIO.

FUNGUS. TOADSTOOL, called alſo *beſacher*. It is the loweſt, and a very imperfect genus of plants, having neither viſible ſeed nor flowers, as in other vegetables, and remarkably differing from other plants, becauſe it hath not an herbaceous colour nor leaf, properly ſpeaking, nor any thing elſe analogous in its contexture. Moſt of them ſpring up, and are ſoon diſſolved into the mucous matter whence they aroſe. The ſpecies are very numerous. See Ray's Synopſis. For the eſculent kind, ſee AMANITA.

FUNGUS. IN SURGERY, it is a ſpongy excreſcence which ariſes in wounds and ulcers, commonly known by the name of *proud fleſh*, though often improperly ſo called. In general, dry lint is the beſt application. But a ſpongy lax fleſh riſing up in ulcers, differs much from the *fungus* in healing wounds; it often requires the knife, or ſome cauſtic application; this ſpongy fleſh is in one maſs, but the *fungus* in healing wounds is in many little protuberances. When this ill-conditioned ſpongy fleſh ariſes, it is of very little uſe to attempt its deſtruction before the general habit of body is improved, and when this is effected, dry lint, or other gentle means, will generally ſuffice. The *fungus* over a carious bone cannot be removed before the caries is put a ſtop to, and the exfoliation completed; but after theſe the *fungus* diſappears ſpontaneouſly.

If *fungous* excreſcences ariſe from the brain, after trepanning, they may be cut away with a knife, and ſuppreſſed with lint dipped in rectified ſpirit of wine, and gentle preſſure.

Fungus is alſo the name of a tubercle about the anus; the cauſe and cure of which are the ſame as the condyloma.

White ſwellings are called *fungi* by ſome authors. In Vogel's Noſology, it ſignifies a ſoft œdematous tumor of the joints. Dr. GOTTLIEB RICHTER recites a caſe of the FUNGUS ARTICULI, wherein he ſays, "In conſequence of external bruiſes, ſometimes after catching cold, and frequently alſo ſpontaneouſly, there ariſes about the patella a ſwelling, which is round, pretty regularly circumſcribed, not painful, and in which an evident fluctuation is felt. It ſometimes occupies both ſides of the patella, and ſometimes is chiefly confined to the place of the ligament of the patella; it frequently ſurrounds the whole knee-pan, like a ſauſage. The patient feels no complaint, except ſome degree of ſtiffneſs in the motion of the knee-joint." This tumor muſt not be opened on any account. The following plaiſter applied, taking alſo tartar emetic in ſmall doſes, and rubbing the knee with the volatile liniment, has been ſucceſsful in theſe

eaſes. R. Gum. ammon. ʒ. i. ſolv. in aceti ſcillitici. q. ſ. ad conſiſtentiam unguenti tenuioris. This muſt be ſpread thick upon leather, applied over the whole knee. Similar tumors on the joints of the elbow have been obſerved.

FUNGUS ALBUS ACRIS. } See AGARICUS PIPERA-
—— PIPERATUS ALBUS. } TUS.
—— ARTICULI. See SPINA VENTOSA.
—— IGNIARIUS. } See AGARICUM & AGARICUS
—— LARICIS. } QUERCUS.

—— SAMBUCI. }
—— PETRÆUS MARINUS. See ANDROSACE.

FUNIS BRACHII. See MEDIANA VENA.

FUNIS vel FUNICULUS UMBILICALIS. The NAVEL-STRING. It is commonly about half a yard long, though this is uncertain, it being ſometimes not above half this, and at others it is a yard or more. It is uſually fixed near the middle of the placenta, but ſometimes it is near the edge thereof; it is compoſed of two arteries and two veins, though ſometimes there are two arteries and one vein, and at others two veins and but one artery. Theſe veſſels are convoluted, and are ſurrounded by a fine net-work of fibres of a gelatinous texture. The arteries are continuations of the internal iliacs or hypogaſtrics; the veins are formed by the union of all the branches in the placenta; they are continued into the abdomen at the navel, and ſo on to the vena portæ in the liver. After the birth, the remaining parts of the arteries in the abdomen form the ligamenta umbilicalia inferiora, and the veins the falciform or ſuſpenſory ligament.

There is always a point where the *funis* begins, and where the integuments ſeparate from it; whence it is indifferent whether you cut it nearer or further from the belly, ſo that a ligature can be made upon the portion that is left with the child, as it always drops off at the ſame place.

If the *funis* is torn off from the child, ſo that a ligature cannot be made on it, La Motte aſſures us, he ſucceeded in preventing an hæmorrhage by applying pledgits of lint, and confining them with proper compreſſes and bandage; but ſome recommend the needle and ligature.

If the child deſcends to the os externum, but ſeems to be drawn up and down as though it was ſuſpended by a rope, it may be ſuſpected that the *funis* is very ſhort, or that it is entangled; in which caſe ſome practitioners have cut it at about five or ſix inches from the child's belly. But a neceſſity for this can hardly occur, for with a little patience it will ſtretch ſufficiently.

FURCULÆ. See CLAVICULÆ.

FURCELLA. } See ENSIFORMIS.
FURCULA INFERIOR. }

FURFUR. BRAN. Called by CÆLIUS AURELIANUS, *cantabrum*; alſo *leptopityron*. It is commended as excellent for removing offenſive ſordes from the head; and for relieving head achs, by rubbing the head with it after well heating it.

FURFURATIO. See FURFUROSI.

FURFURES. So urine is called which poſſeſſes a ſediment reſembling bran, alſo *petyroides*. It is a name for *furfuroſi*.

FURFUROSI. Thoſe patients are ſo called who are afflicted with a ſort of ſcurf or ſcalineſs on the head, which upon combing diſcharges a ſcaly ſubſtance like bran, whence the diſeaſe is called *furfures*, and *furfuratio*; though ſome call it *porrigo*, and *farrea nubes*.

FURNUS. See FORNAX.

FURIOSUS. See AMBULO.

FUROR UTERINUS; called by the Arabians, *acrai*, *brachuna*, ŒSTROMANIA; *araſcon*, *arſatum*. Dr. Cullen calls it *nymphomania*; and places this diſeaſe in the CL. LOCALES, and ORD. DYSOREXIÆ; and defines it an unreſtrained deſire for venereal enjoyment, of which there is only one ſpecies, varying in its degrees of violence. It is a ſpecies of madneſs, or an high degree of hyſterics. Its immediate cauſe is a preternatural irritability of the uterus and pudenda of women, or an unuſual acrimony of the fluids in theſe parts.

Its preſence is known by the wanton behaviour of the patient; ſhe ſpeaks and acts with unreſtrained obſcenity, and as the diſorder increaſes, ſhe ſcolds, cries, and laughs, by turns. While reaſon is retained, ſhe is ſilent, and ſeems melancholy, but her eyes diſcover an unuſual wantonneſs. The ſymptoms are better and worſe, until the greateſt degree of the diſorder approaches, and then by every word and action her condition is too manifeſt.

In the beginning a cure may be hoped for, but if it continues, it degenerates into a mania; long intervals and a recovery of fleſh alſo give hopes.

In order to the cure, bleed in proportion to the patient's ſtrength. Camphor, in doſes of 15 to 20 grains, with nitre, and ſmall doſes of the tinct. opii ſhould be repeated at proper intervals. Some venture to give the ceruſſ. acetata in doſes of three to five grains. Beſides bleeding, cooling purges ſhould alſo be repeated in proportion to the violence of ſymptoms, &c. What is uſeful in maniac and hypochondriac diſorders, is alſo uſeful here, regard being had to ſanguine or phlegmatic habits, &c. When the delirium is at the height, give opiates to compoſe, and uſe the ſame method as in a phrenitis, or a mania. Injections of barley-water, with a ſmall quantity of hemlock-juice, may be frequently thrown up into the uterus; this is called ſpecific; but matrimony, if poſſible, ſhould be preferred. See Riverius's Practice of Phyſic.

FURUNCULUS, from *furo, to rage*; called alſo *dothien*; and by Paracelſus, *chiadus*, *chioli*; a BOIL or BILE. It is a phlegmonous tumor which commonly terminates in a ſuppuration of a peculiar kind. It is a variety of the phlogoſis phlegmone. (See Culleni Syn. Nos. Meth. vol. 2.) So diſtinguiſhed, on account of the form in which it appears. A BOIL is a ſmall circumſcribed inflammation, ariſing in the exterior parts, and terminating in an acute tubercle, about the ſize of a pigeon's egg, ſeldom larger, attended with redneſs and pain, and ſometimes with a violent burning heat. It is wrong to attempt to repel theſe inflammations; they cannot be diſcuſſed, nor ought they; they for the moſt part ſuppurate ſpontaneouſly, and break open at firſt on their top, or the moſt pointed part, when ſome drops of pus, like that from an abſceſs, come out; after which the GERM, or what is commonly called the CORE, is ſeen; this core is a purulent ſubſtance, but ſo thick and tenacious, that it appears like a ſolid body, which may be drawn out in the ſhape of a cylinder, like the pith of an elder, ſometimes to the length of an inch. The emiſſion of this core is uſually followed by the diſcharge of a certain quantity of liquid matter, ſpread through the bottom of it. As ſoon as this diſcharge is made, the pain entirely ceaſes, and in a few days the ſwelling diſappears, and the opening heals of its own accord: if it ſhould not, it may be effected by a ſmall quantity of Peruvian balſam.

Suppuration is the beſt method of removing this kind of tumor; for if repelled, it almoſt as certainly returns on ſome other part; but indeed the ſurgeon is ſeldom applied to on account of it, the common method of applying a poultice of flour and honey anſwering every purpoſe. Theſe complaints are ſeldom attended with any danger; they are more frequently ſigns of a ſtrong conſtitution, capable of throwing ſome morbid matter out of the habit. They have been conſidered ſometimes habitual: then by the uſe of alterative medicines, they ſhould be prevented. For which purpoſe roſemary has been recommended; and alſo the burdoc root, by ſome, has been conſidered ſo efficacious, as to be thought a ſpecific. See Lond. Med. Journal, vol. i. p. 332. Pearſon's Principles of Surgery, vol. i. p. 66, &c. White's Surgery, p. 17.

FUSANUS, or FUSARIA. See EUONYMUS.

FUSIO. FUSION, alſo *diachyſis*. It is the reduction of ſolid bodies into a ſtate of fluidity by fire. *Fuſio* and *ſolutio per ignem* mean the ſame thing; but in the common mode of ſpeech, by *fuſion*, we underſtand a ſolution, or liquation of metals or minerals; by *liquefaction*, a ſolution of pinguious and concreted ſubſtances

GAGEL. See MYRTUS BRABANTICA.

GAL. The abbreviation for Galen.

GALACIA. See GALAXA.

GALACTIA. } An exceſs or overflowing of
GALACTIRRHŒA. } milk.

GALACTINA. See LACTICINIA.

GALACTODES. In Hippocrates it ſignifies both milk-warm, and a milky colour.

GALACTOPHORA MEDICAMENTA. Medicines which increaſe the milk.

GALACTOPHORI DUCTUS. See LACTEA VASA.

GALACTOPOETICA, from γαλα, *milk*, and ποιεω, *to make*. MILK-MAKING. An epithet applied to the faculty of generating milk.

GALACTOPOSIA. The method of curing by a milk diet.

GALÆNA INANIS. BISMUTH. See BISMUTHUM.

GALANGA. GALANGAL. It is the MARANTA GALANGA Linn. It is a graſſy-leafed plant, which grows in China and in the Eaſt Indies. The dried roots are brought into Europe in pieces of about an inch long, and half an inch thick; it is branched, full of knots and joints, with ſeveral circular rings; it is of a reddiſh brown colour on the outſide, and of a pale red within.

This root hath an aromatic ſmell and bitteriſh hot biting taſte; but the heat and pungency prevail more than the bitter. Dr. Lewis obſerves, that the pungent matter appears to be of the ſame nature with that of pepper; that it reſides not in the volatile oil, but in a more fixed matter. Neumann ſays, it reſembles ginger in its ſmell, taſte, and chemical compoſition, but that ginger is to be preferred, as it is more agreeable.

There is a *galanga* major, called *acori radix*, but as it is weaker and much more diſagreeable, it is not uſed. See Lewis's Mat. Med. Neumann's Chem. Works.

GALAXA, alſo *galacia*, is a term of Paracelſus. It is ſaid to be a meteor, but it commonly denotes that white line in the heavens which CICERO calls the *circulum lacteum*; the Greeks, γαλαξιας κυκλος; we, the MILKY WAY, from the Latin *via lactea*; and is nothing more than a congeries of fixed or nebulous ſtars. Paracelſus ſays its principle is a moſt ſubtile ſulphur, the cauſe of winter, and producing clouds. Some ſpeaking analogically, apply the word *galaxa* to the poroſities in the cranium; and CHARLTON diſtinguiſhes the paſſages and diſtribution of the chyle by the name of galaxia.

GALBANUM, GUM, called *albetad*, *chalbane*, *geſor*. It is the concrete, gummy, reſinous juice of an evergreen plant, with leaves like thoſe of aniſe, growing in Syria, the Eaſt Indies, and Ethiopia. This plant is named *ferula Africana*, *oreoſelinum Africanum*, *aniſum fruticoſum galbaniferum*, and *aniſum Africanum fruticeſcens*, &c. *ayborzat*. The plant is the BUBON GALBANUM or the BUBON FOLIOLIS RHOMBEIS *dentatis glabris ſtriatis*, *umbellis paucis*, CL. PENTANDRIA, ORD. DIGYNIA. LINN. Gen. Plant. 350. LOVAGE-LEAVED BUBON. The gum is brought to us in pale-coloured, ſemitranſparent, ſoft, tenacious maſſes, of different ſhades, from white to brown; the better ſorts of which, on being opened, appear compoſed of clear whitiſh tears, often intermixed with little ſtalks or ſeeds of the plant. It partakes more of the reſinous than of the gummy quality, though it is nearly all ſoluble in water. It hath a ſtrong unpleaſant ſmell, and bitteriſh warm taſte, is unctuous to the touch, and ſoftens in the fingers.

In medical virtue and ſenſible qualities it reſembles the gum ammoniacum, but is leſs efficacious than it in aſthmas, though more efficacious than it in hyſteric diſorders. When aſſafœtida is too ſtrong, *galbanum* may be tried; and if it diſagrees, give ammoniacum. It may be ſaid to hold a middle place between the two, though it is leſs antiſpaſmodic than aſſafetida, and not ſo powerful an expectorant as the ammoniacum. Dr. Cullen ſays, by itſelf it has little power, but ſerves to afford a variety; ſo requiſite in the uſe of antiſpaſmodics.

A mixture of ſpirit of wine two parts, with one part water, diſſolves all but the impurities, which are commonly in conſiderable quantities.

Great part of the virtue of *galbanum* conſiſts in its eſſential oil, and is carried up in diſtillation, either with water or with ſpirit, whence great care is required in purifying it. For making of plaſters, and ſuch like inferior purpoſes, the beſt method is to expoſe it in winter to a ſharp froſt, and whilſt it is brittle to powder it: thus the impurities may in ſome meaſure be ſeparated in the ſearce; for internal uſes, it is beſt managed by including it in a bladder, and keeping it in hot water, until it is ſoft enough to be ſtrained by preſſure through an hempen cloth.

Beſides the eſſential oil yielded by diſtillation with water, an empyreumatic oil is obtained, by diſtilling in a retort without mixture. This empyreumatic oil is of a fine blue colour, but changes in the air to a purple.

It is common to ſpread *galbanum* on leather, and to apply it to the belly in hyſteric diſorders, and when ſpaſms diſorder the belly of a woman ſoon after delivery; but the following is to be preferred. ℞ Gum. aſſ. fœtid. ʒvi. camph. ʒ ſs. f. empl. See Neumann's Chem. Works; Lewis's Mat. Med. Cullen's Mat. Med.

The College of Phyſicians order the following tincture to be made.

Take of *galbanum* cut into ſmall pieces, two ounces; proof ſpirit of wine, two pints; digeſt with a gentle heat, for eight days, and ſtrain. They conſider it as a warm antiſpaſmodic, promiſing to be of ſervice in flatulency, hyſteria, and the aſthmatic complaints of old people. Pharm. Lond. 1788. Externally, *galbanum* has been applied to expedite the ſuppuration of inflammatory and indolent tumors; and medically, as a warm ſtimulating plaiſter. For the firſt purpoſes, the following is often ſucceſsfully applied:

CATAPLASMA GALBANI COMPOSITUM. ℞. Rad. lilii albi ʒ iv. caricarum ʒ i. rad. cepæ vulgaris contuſæ, ʒ iſs. gummi galbani, ʒ ſs. radix lilii, & caricæ coquantur, & ſimul contundantur, poſtea radix cepæ adjiciatur, & denuo galbanum vitello ovi ſolutum.

Galbanum is alſo an ingredient in the *pilulæ e gummi*, *emplaſtrum Lithargyri cum gummi*, and the *emplaſtrum ad clavos*. PHARM. EDINENSIS.

GAALBEI, or GALBEUM. A ſort of ornamental and medical bracelets worn by the Romans.

GALA. See GALEA.

GALBULÆ. } See CUPRESSUS.
GALBULI. }

GALBULUS. When the ſkin of the body is naturally yellow.

GALE. See MYRTUS BRABANTICA.

GALEA. A HELMET. See PILEUS. In ANATOMY it is the name for the *amnion*. In SURGERY, a bandage for the head is thus called. In BOTANY, the upper lip of a ringent corolla or labiated flower, is called its *gala* or creſt. Among diſeaſes, it is by analogy a name for a ſpecies of head-ach, which ſurrounds the head like an helmet.

GALEANTHROPIA. It appears to come from γαλεη, *a cat*, and ανθρωπος, *a man*, as it is a ſpecies of madneſs in which a patient imagines himſelf to be a cat, and then he imitates its manners.

GALEGA, called alſo *ruta capraria*, and GOAT'S RUE. It is the *galega* officinalis, Linn. The root is perennial; on the ſtalks are pods with oblong kidney-ſhaped ſeeds. It is a native of Spain and Italy, where it is eaten as food, but it is not noted in medicine.

—— NEMOROSA VERNA, a ſpecies of orobus.

GALEGÆ. A ſpecies of ſenna.

GALENA, from γαλην, *a calm*. It was a name of the theriaca before the addition of vipers to it. It is the name of a lead ore, in which is a little ſilver. According to ſome it is the ſame as *plumbago*, or *molybdæna*. Some ſay that no metal can be extracted from it, and others ſay it is an ore of zinc, but mixt with various other ſubſtances. This laſt is the moſt proper aſſertion.

GALENION. The name of a malagma, in P. Ægineta.

GALEOBDULON. } See LAMIUM LUTEUM. Alſo called *lamium rubrum, urtica iners magna fœtidiſſima, ſtachys fœtida*, and HEDGE-NETTLE. Boerhaave enumerates fourteen ſpecies. This ſpecies, he ſays, is a good antihyſteric, and an infuſion of the leaves and flowers is uſeful in a nephritic colic. He attributes ſome degree of virtue to the ſpecies called CLOWN'S ALL-HEAL, ſee PANAX COLONI; to the YELLOW ARCHANGEL, and SPOTTED ARCHANGEL, ſee LAMIUM; but to the reſt nothing medicinal is known to belong to them.
GALEOPSIS, vel GALIOPSIS. }

—— LUTEA. See LAMIUM MACULATUM.

GALERITA. See PETASITES.

GALI. See INDICUM.

GALIA, from *gallæ*, GALLS. There are two compoſitions; one called pure, the other aromatic, and *galls* were a part of the compoſition. *Galia* moſchata, or muſcata: in this was NUTMEG. *Galia* zibettina; in this was CIVET.

GALIANCON. See ANCI. When one arm is ſhorter than the other, this is the term uſed; and people thus affected are called *galianconei*.

GALIUM APARINE. See APARINE.

—— VERUM. See GALLIUM.

GALLÆ, called *nuces gallæ*, *gallæ* maximæ orbiculatæ, *gallæ* ſpinoſæ, GALLS. Theſe are the productions of the QUERCUS ROBUR, foliis oblongis glabris ſinuatis; lobis rotundifoliis glandibus oblongis AITON, Hort. Kew. CL. MONŒCIA ORD. POLYANDRIA. LINN. Gen Plant. 1070. A gall is called *ceſis* or *ciſis*.

They are hard round excreſcences, *nidi cynipidis*; found in the warmer countries on the oak-tree. They are produced from the puncture of an inſect, and affording a lodgment for its young, until they are capable of eating a paſſage through; the tear which iſſues from the wound, gradually increaſed by acceſſions of freſh matter, forms a covering to the eggs and ſucceeding inſects. Thoſe *galls* which have no hole, are found to have the dead inſects remaining in them. Two ſorts are diſtinguiſhed in the ſhops, one ſaid to be brought from Aleppo, called Oriental, or Aleppo nut, or *galla* ſpinoſa; the other from the ſouthern parts of Europe, called European *galls*. The former are generally of a bluiſh colour, or greyiſh or blackiſh, and verging to a blue; unequal in their ſurface, hard to break, and of a cloſe texture: the others are of a pale browniſh or whitiſh colour, ſmooth, round, eaſily broke, leſs compact, and of a much larger ſize. The two ſorts differ in ſtrength, but in other reſpects are of the ſame quality.

Chuſe the ſmall, protuberant, bluiſh, and heavy ones.

Galls are a ſtrong aſtringent, ſuppoſed to be one of the ſtrongeſt in the vegetable kingdom. They have no peculiar ſmell or taſte; their medical character is ſimple aſtringency. Both water and ſpirit take up nearly all their virtue. The ſpirituous extract is the ſtrongeſt preparation, but the ſimple powder is as good as any other mode of adminiſtering them. The doſe of the powder is from a few grains to a dram.

They are not much uſed in medicine, though they have been ſaid to be beneficial in intermittents, and one of the moſt powerful of the vegetable aſtringents. Dr. Cullen has cured intermittents, by giving half a dram of the powder of *galls* every two or three hours, during the intermiſſion; and both by itſelf, and joined with camomile flowers, has prevented the return of the paroxyſms. The following fomentation has been uſeful for the piles, &c. Take of bruiſed galls ʒ ſs. boiling water, ℔ ii. macerate them for an hour, and then ſtrain off the liquor. This is alſo ſerviceable in the prolapſus ani, and the fluor albus, applied cold. An injection merely aſtringent is made, by adding two ounces of diſtilled water to the ſame quantity of the fomentation above, and uſed in gleets, and leucorrhœa. Againſt the piles alſo, the ointment called camphorated ointment of galls has been found ſerviceable after the uſe of leeches, and is thus made. Incorporate half a dram of camphor with one ounce of hog's lard, and then add two drams of galls in very fine powder. They are much employed for making black writing-ink, and the colouring matter for dying black with. A decoction of *galls* ſeems more rough and aſtringent to the taſte; but an infuſion of them in cold water ſtrikes a deeper black with green vitriol. See Lewis's Mat. Med. Neumann's Chem. Works. Cullen's Mat. Med.

GALLATURA. See ALBUMEN OVI.

GALLENA TESSULATA. See PLUMBUM.

GALLI GALLINACEI CAPUT. See GALLINAGINIS CAPUT.

GALLIA MOSCHATA. A compoſition of troches, in which are only aloes, amber, and muſk, made up with ſome mucilage.

GALLICUS MORBUS. The FRENCH DISEASE. See LUES VENEREA.

GALLINAGINIS, CAPUT, alſo *galli gallinacei caput*. When the proſtata is cut open, we diſcover the eminence called *caput gallinaginis*. It is thick behind and ſlender before; on each ſide of this eminence appear the orifices of the veſiculæ ſeminales.

GALLION. See GALLIUM.

GALLITRICHIS. WILD CLARY.

GALLITRICHUM. See HORMINUM.

GALLIUM, called *gallion*, CHEESE-RENNET, LADY'S BED-STRAW. It is the GALLIUM VERUM, Linn. It is a plant with ſquare ſtalks, long narrow leaves, which commonly ſtand eight at a joint in the form of a ſtar. On the tops appear thick cluſters of ſmall yellow monopetalous flowers, which are followed each by two ſeeds. It is perennial, found in dry waſte grounds, and flowers in June and July.

The flowers have a ſtrong, not diſagreeable ſmell; the leaves little or none: but they both poſſeſs a degree of acidity, on which account they are uſed in ſome places for turning milk or ſeparating its curd from the whey, whence its name *cheeſe-rennet*. The whole plant is ſaid to be cooling and reſtringent, but it is not much uſed in medicine. Boerhaave mentions five ſpecies. It is alſo a name for MADDER. See RUBIA SYLVATICA LÆVIS

—— LATIFOLIUM FLORE LUTEO. See CRUCIATA VULGARIS.

GALREDA. A kind of jelly made by boiling the cartilaginous parts of animals. In Paracelſus, it ſignifies an excrementitious mouldineſs.

GAMANDRA. See GAMBOGIA.

GAMBOGIA. The largeſt quantities are produced in the province *Cambogia*, or Cambodia, from whence it is called *Cambodia, Cambogium, Gambogia, Carcapuli*, &c. From the virtues aſcribed to it againſt the gout, it is called *gummi ad podagram, gummi gutta*, &c. By a corruption of the above names it is called, *getta, ghitta, gutta gamba, gamon, germandra, catagemu, jemsu, gamma, gamboida, gemandra, geheathu*, &c. From its gold colour it hath been called *chryſopus*, and from its purgative quality it is named *ſuccus laxativus, ſuccus Indicus purgans*, and *ſcammonium orientale*. With us it is uſually called GAMBOGE.

It is a gummy reſinous concrete, brought from the Eaſt Indies, ſaid to be the produce of certain trees called coddam-pulli; but ſome ſay it is obtained from a ſhrub of the eſſula, or tithymalus kind. The tree is the *Cambogia*

bogia gutta, or *Cambogia* of Linn. Indian *Cambogia*. It is brought to us in large cakes and rolls; it is ſolid, brittle, of a ſmooth ſurface, perfectly opake, free from any viſible impurities, of a deep reddiſh-yellow colour, equal and uniform throughout its whole ſubſtance. It ſtains the moiſt hands of a yellow colour: when chewed, it hath little or no taſte; but ſoon after it impreſſes a pungent acrimony and heat, and occaſions a dryneſs in the mouth. It eaſily melts over the fire; it takes flame from a candle, it burns with a white flame, and leaves a grey aſh.

In medicine it is chiefly uſed as a draſtic purge, but it weakens the ſtomach. It produces copious diſcharges by ſtool, and its operation is uſually very quick. On the firſt uſe of it, it generally vomits, and then purges; in dropſies it hath been much recommended; but in a hot, dry habit, it ſhould never be ventured on. The doſe is from gr. iii. to xx. When given with calomel, or other purgatives, it is not ſo apt to be diſcharged upwards. If given in a liquid form, and duly diluted, it needs no corrector; boiling in water leſſens its activity; ſolutions of it in alkalized water act only by ſtool and urine; the latter it promotes very freely.

It is beſt given in doſes of three or four grains rubbed down with a little ſugar, and repeated every three or four hours: it then operates without vomiting or griping, and after the third or fourth exhibition, evacuates water freely, both by ſtool and urine. See SPIRITUS COCHLEARIÆ AUREUS.

The GAMBOGIÆ TINCTURA AMMONIATA, *Ammoniated Tincture of Gamboge*, has been ſaid to be of conſiderable ſervice in ſome cutaneous co nplaints, given to the quantity of a tea ſpoonful, or two, every night and morning, and is made by diſſolving eighteen grains of gamboge in two ounces of the ſpirits of ammonia.

Rectified ſpirit of wine diſſolves five parts out of ſix, and acquires a deep gold-colour from it; water, aſſiſted by heat, takes up nearly as much, but on cooling it depoſits much of the reſin; but if the water is firſt impregnated with an alkaline ſalt, it depoſits none. See Tournefort's Mat. Med. Lewis's Mat. Med. Cullen's Mat. Med.

GAMBOIDA. } GAMBOGIA.
GAMMA. }

GAMMATA, FERRAMENTA. An inſtrument mentioned by P. Ægineta, made like the Greek letter Γ; it was uſed for cauterizing an hernia aquoſa.

GAMMARUS. See CANCER FLUVIATILIS.

GAMON. See GAMBOGIA.

GAMPHELE. The CHEEK. The jaw, from γαμφω, *crooked*. See BUCCÆ.

GANGAMON. A name of the *omentum*, from its ſuppoſed likeneſs to a fiſhing-net, which the Greeks call *gangamon*. Some call that contexture of nerves about the navel thus.

GANGILA. See SESAMUM VERUM.

GANGLION. A primitive in the Greek. IN ANATOMY, it imports a knot frequently found in the courſe of the nerve, and which is not morbid; from wherever any nerve ſends out a branch, or receives one from another, or where two nerves join together, there is generally a *ganglion* or *plexus*, as may be ſeen at the beginning of all the nerves of the medulla ſpinalis, and in many other places of the body. See PLEXUS.

IN SURGERY, it is a moveable tumor formed any where about the tendons of muſcles, and the ligaments; the moſt frequent ſituation is about the carpus; but whatever part of the body it is in, it is near the ſkin, and is not attended with any conſiderable uneaſineſs to the patient. *Ganglions* are formed of lymph, which is ſecreted within the vaginæ of tendons; they are different in their form, conſiſtence, and other appearances, but they never ſuppurate. Mr. Sharp reckons theſe tumors among thoſe encyſted ones called meliceris. For the moſt part the matter of a *ganglion* reſembles the white of an egg. Dr. Cullen ranks it as a genus of diſeaſes in the claſs locales, and order tumores, and defines it a hard moveable extuberation, fixed upon a tendon.

As to the cure, Mr. Sharp aſſures us that he hath frequently ſucceeded, by making an inciſion through its whole length, and at the ſame time dividing the ligament of the wriſt, and afterwards dreſſing as in wounds in general. Mr. Warner gives two inſtances of his ſucceſsfully extirpating them: he obſerves, that the objection from danger of wounding the ſubjacent tendon or ligament, is of no weight, ſince the accident can be generally avoided, and ſhould it happen, the diſaſter may be eaſily healed, as occurs daily in wounds of this ſort; he recommends the cutting away part of the cyſt, and then digeſting the reſt away. See Sharp's Operations in Surgery, in the chapter on encyſted tumors. Warner's Caſes in Surgery, Heiſter's Surgery, Bell's Surgery, vol. v. p. 476.

GANGRÆNA. See MORTIFICATIO.

—— ORIS. See CANCRUM ORIS.

—— OSSIS. See SPINA VENTOSA.

GANGRENE SCORBUTIQUE DES GENCIVES. See CANCRUM ORIS.

GANGRINOS, SAL. Fuchſius ſays it is the *foſſilis ſal.*

GANNANA, and GANNANAPERIDE. See CORT. PERUV.

GARAB. See ÆGILOPS.

GARB. A Mooriſh name for an Arabian ſpecies of willow.

GARENT OUGUAN. See GENSING.

GARGALE, GARGALOS, GARGALISMOS. TITILLATION, *Irritation*, alſo *itching*.

GARGAREON. See UVULA.

GARGARISMA, or GARGARISMUS, from γαργαρεω, and that from γαργαρων, *the throat*, called alſo *anagargaliſton*, *anagargariſton*, *diaclyſma*, and *colluterium oris*, *to waſh the mouth*. A GARGLE. Its uſe is, for waſhing the mouth and throat with, when inflammations, ulcerations, &c. are there. A ſmall quantity may be taken into the mouth, and moved briſkly about, and then ſpit out; or if the patient cannot do this to any advantage, the liquor may be injected with a ſyringe. When *gargles* are required, their uſe ſhould be more frequently repeated than is done in common practice. See more particular obſervations on this ſubject in the article ANGINA.

—— ALUMINIS. See HYPOSTAPHILE.

GARGATHUM. A bed on which lunatics, &c. were formerly confined.

GARID. HIST. The abbreviation of Petri Garidel, M. D. HIST. PLANT.

GARON, or GARUM. A kind of pickle prepared of fiſh; at firſt it was made from a fiſh which the Greeks called *gares*; but the beſt was made from mackerels. Among the moderns, *garum* ſignifies the liquor in which fiſh is pickled. A compoſition of this and vinegar is called *oxygarum*.

GAROSMUM. See ATRIPLEX FŒTIDA.

GARROTILLO. So the Spaniards have named the cynanche maligna, or ulcerated ſore throat. See ANGINA GANGRÆNA.

GARYOPHYLLA. See CARYOPHYLLATA.

GARYOPHYLLON PLINII. See CASSIA CARYOPHYLLATA.

GARYOPHYLLUS. See CARYOPHYLLI AROMATICI.

GARZ. The abbreviation of *Garzia ab horto aromat. ſimpl.* &c.

GAS. From *geiſt*, which in the German language is *ſpirit*. The word *gas* is an invention of Helmont's; in general it is a *ſpirit* incapable of coagulation, ſuch as riſes from fermenting liquors, &c. MACQUIER ſays, that this name is given by the chemiſts, to the volatile inviſible parts, which eſcape from certain bodies, and which cannot be retained, and collected, at leaſt, without great difficulty, and mixture with other ſubſtances. LAVOISIER ſays that the term GAS expreſſes the fulleſt degree of ſaturation in any body, with caloric; being, in fact, a term expreſſive of a mode of exiſtence. Thus, in diſtinguiſhing each ſpecies of gas, a ſecond term is employed from the name of the baſe, which, ſaturated with caloric, forms each particular gas. Water, combined to ſaturation with caloric, ſo as to form an elaſtic fluid, is called aqueous gas. *Æther*, in this manner combined, *ætherial gas*; the combination of alkohol with caloric, *alkoholic gas*; and following the ſame principles, we have *muriatic acid gas*; *ammoniacal gas*; and ſo on of every ſubſtance, ſuſceptible of being combined with caloric, in ſuch a manner, as to aſſume the gaſſeous, or elaſtic aëriform ſtate.

Fixed air is by ſome called gas. See AER; PRIESTLEY on Air, Introduction, p. 3. Chemical Dictionary. LAVOISIER's Elements of Chemiſtry.

—— FRUCTUUM. Elementary water which exhales from fruits.

—— PINGUE SULPHUREUM. The lethiferous exhalations from caves, &c.

—— SALIUM. See GAS FRUCTUUM.

GAS SICCUM, SUBLIMATUM. See MERC. CORROS. ALBUS.

—— SULPHURIS. The ſpirit of ſulphur called *ſulphurata aqua*.

—— SYLVESTRE. The ſubtile ſpirit which riſes from fermenting liquors.

—— VENTOSUM, &c. The AIR. See AER.

—— VITALE. The ſpirit of our life.

GASCOIGNI PULVIS. See BEZOAR ORIENTALIS.

GASELLA, or GASSILA. The AFRICAN WILD GOAT, from which a ſpecies of bezoar is taken.

GASTER. In Hippocrates it generally ſignifies the ſame as *abdomen*; but ſometimes it means only *uterus*; at others, *ſtomachus*.

GASTERANAX. See BITHNIMALCA.

GASTRICA. See GASTRODYNIA.

—— ARTERIA DEXTRA, vel GASTRICA MAJOR. It proceeds from the hepatica arteria; paſſes behind the pylorus, and beyond it ſends out the *duodenalis* or *inteſtinalis*; then runs along the right ſide of the great curvature of the ſtomach, to the neighbouring parts of which, on both ſides, it diſtributes branches, and at laſt ends in the *gaſtrica ſiniſtra*.

—— ARTERIA SINISTRA vel GASTRICA MINOR. It is a branch of the ſplenica; it runs from the left to the right, along the left portion of the great curvature of the ſtomach. It ſupplies the omentum with branches called gaſtro-epiploicæ ſiniſtræ, and then it communicates with the *gaſtrica* arteria dextra; and from this union, the gaſtro-epiploicæ mediæ are produced.

—— VENA, EPIPLOICA SINISTRA. See GASTRICA VENA SINISTRA.

—— VENA RECTA; called alſo *gaſtro-epiploica dextra*. It is ſometimes a branch from the vena portæ ventralis, or from its principal branches. It goes to the pylorus, to the great curvature of the ſtomach, and communicates with the *gaſtrica* ſiniſtra, &c.

—— VENA SINISTRA. It goes out from the ſplenica, at the left extremity of the pancreas, from whence it runs to the great extremity of the ſtomach, and along the great arch, until it meets the *gaſtrica* dextra. In its paſſage it ſends branches to the ſides of the ſtomach, and communicates with the coronaria ventriculi.

GASTRICUS SUCCUS. The GASTRIC JUICE. It is ſo called from *gaſter*, *the ſtomach*. It is a thin, pellucid juice, which diſtils from certain glands in the ſtomach for the digeſtion, &c. of the food.

GASTRINUM. See CLAVELLATI CINERES.

GASTRITIS. See INFLAMMATIO VENTRICULI.

GASTROCELE, from γαστηρ, *the ſtomach*, and κηλη, *tumor*, A RUPTURE OF THE STOMACH. The tumor is in the upper part of the linea alba. When this accident happens, there is continual vomiting; every thing taken is immediately rejected; ſo an atrophy ſucceeds. All herniæ of the linea alba require the ſame management; but this of the ſtomach deſerves particular attention. They are eaſily reduced, and ſhould be kept up by a truſs. See ABDOMEN.

GASTROCNEMII, from γαστηρ, *a belly*, and κνημη, *the leg*, or *ſhin bone*. Albinus calls theſe muſcles by the name *gemellus*. At the origin of each of theſe muſcles, it is a biceps riſing from each condyle of the femur; the heads ſoon join and leave a notch, through which the large veſſels and nerves paſs, and is inſerted into the upper poſterior part of the os calcis. The tendon of the ſoleus, with the tendon of this muſcle, forms the *tendo Achillis*. Theſe muſcles form the greateſt part of the calves of the legs. Brown calls them *gaſtrocnemii externi*, and ſays that ſome call them *ſuræ*.

GASTROCNEMIUS INTERNUS. See SOLEUS.

GASTRO-COLICA VENA. It is a branch from the meſeraica minor, and is ſoon divided into two *branches*, one of which runs to the head of the pancreas, and forms the *gaſtrica recta vena*, and the *colica recta vena*.

GASTRODYNIA. *Gaſtrica*; *periadyſmia*; when it ariſes from wind, it is called *pneumatoſis*, PAIN in the STOMACH. It is an inſtance of DYSPEPSIA.

GASTRO-EPIPLOICA, from γαστηρ, the *ſtomach*, and επιπλοον, the *omentum*. An epithet for the arteries and veins that go to the ſtomach and omentum.

GASTRO-EPIPLOICA VENA. A branch of the *gaſtrica ſiniſtra* is thus named.

—— DEXTRA. See GASTRICA RECTA VENA.

—— SINISTRA ARTERIA. See SPLENICA ARTERIA.

GASTRORAPHIA. GASTRORAPHY, from γαστηρ, *a belly*, and ραφη, *a ſuture*. In ſtrictneſs of etymology this word ſignifies the ſewing up of any wound of the belly; yet in common acceptation it implies that an inteſtine is wounded as well as the belly. This operation is uſeleſs in ſmall wounds, but neceſſary in large ones. The beſt method is to paſs double ligatures in one needle, in order to include the rolls at one end, and be tied upon them with bow-knots on the oppoſite ſide, which gives an opportunity of ſtraitening and looſening the knots at pleaſure. After paſſing in as many ligatures as ſeem neceſſary, bring the lips of the wound gradually together, and keep them ſo until the knots are tied.

As to the operation of ſtitching the bowels, it can only take place where they fall out of the abdomen ſo as to ſee where the wound in the inteſtine is, or how many wounds there are. See Sharp's and Le Dran's Operations.

GASTROTOMIA. GASTROTOMY. From γαστηρ, *belly*, and τεμνω, *to cut*. Opening the belly and uterus, as in the Cæſarean operation.

GATRINUM. See CLAVELLATI CINERES.

GATTARIA. See MENTHA CATARIA.

GAUDIUM. JOY. If ſudden and immoderate, it ſo wears away the ſtrength, that madneſs or ſudden death ſometimes enſues.

GAZAR. See LAURUS ALEXANDRINA.

GAZELLA. The GOAT which affords the oriental bezoar. *Gazella Africana* is the ANTELOPE. See ANTELOPUS.

GECHYTON. The external parts of the earth which are ſoft.

GEDWAR, GEID, or GEIDWAR. See ZEDOARIA.

GEISON. See VALLUM.

GELASINOS, from γελως, *laughter*. An epithet for the four middle fore-teeth, becauſe they are ſhewn in laughter.

GELASMUS. See SARDONICUS RISUS.

GELATINA. JELLY. *Jellies*, gums, and mucilages are ſomewhat ſimilar. *Jellies* are the productions of art, and are either vegetable or animal; mucilages are alſo either animal or vegetable; *jellies* are made of the juice of ripe fruit boiled up with ſugar to a proper conſiſtence; or of ſtrong decoctions of horns, ſoft bones, &c. The *jellies* of fruits are aceſcent; thoſe of animal ſubſtances are alcaleſcent.

GELATIO. FREEZING. Sometimes it expreſſes the rigidity of the body which happens in a catoche or catalepſis.

GEMANDRA. See GAMBOGIA.

GEMELLÆ CYSTICÆ. See CYSTICÆ VENÆ.

GEMELLI. See GEMINI MUSC.

GEMELLUS. See GASTROCNEMII and GEMINUS.

GEMELLUS. See BRACHIÆUS EXTERNUS.

GEMINI. Thus Albinus calls the two muſcles which Winſlow calls *gemelli*. By ſome they are named *marſupiales*, becauſe they reſemble marſupium, a purſe. They are two flat, narrow, ſmall muſcles, ſituated almoſt tranſverſely one above the other, between the tuberoſity of the iſchium and the great trochanter, immediately below the pyriformis, and parted by the tendon of the obturator internus. See alſo QUADRIGEMINI.

GEMINUS. A TWIN. It is alſo called *gemellus* and *didymus*. According to the preſent theory of conception, twins are formed by two ova ſwimming in the uterus, and are impregnated by the animalcula in the male ſeed. It is a name alſo for the *extenſor carpi radialis*.

GEMMÆ, } SAL, alſo called *foſſilis ſal*, *adrum*, *lu-*
GEMMEUS } *cidum ſal*, *maltheorum*, *almene*; *amene*, *cibarius ſal*; *ſal rupeus*; ROCK SALT, FOSSIL SALT, COMMON SALT, and *ſal gem*. *Sal gemma*, or *ſal gem*. It is ſo called by reaſon of its tranſparency. It is found in many high mountains of Europe, &c. as in Poland, Catalonia, Perſia, Eaſt Indies, &c. It is probable the rocks of this ſalt are in the ſea, whence the ſaltneſs of the water is preſerved; for as ſalt ſoon loſes its ſavourineſs and antiputreſcent property, freſh ſalt is neceſſary for the purpoſes which it effects in the waters it impregnates. The ſalt in the ſea-water all comes from the earth. It is the ſame as the *ſal marinus*; but when found in rocks in the earth, it receives the name of *ſal gem*, and *ſal foſſilis*. It is purified by ſolution in water, and when the pure ſolution is evaporated to dryneſs, the ſalt is uſed as the common or alimentary ſalt. In the mines of Wilizca is a ſort that is hard enough for making into toys, vaſes, &c. but the ſofter they uſed in the kitchen. There

are

are ſpecies of different colours, but the pellucid is that which is uſed in medicine; it is eſteemed more penetrating than the other ſalts which are formed by evaporation.

GEMS. See CAPRA ALPINA.

GEMURSA. The name of an excreſcence betwixt the toes.

GENA. The upper part of the face between the noſe and ears.

GENEIAS. The downy hairs which firſt cover the cheek; alſo the name of a bandage mentioned by Galen. It comes under the chin. See FASCIA, No 6.

GENEION. See ANTHEREON.

GENERATIO. GENERATION. The parts of *generation* proper to men are thoſe which prepare the ſeed and ſeparate it from the body; theſe are the teſtes, the veſiculæ ſeminales, and proſtatæ; and thoſe which convey the ſeed into the womb, which office is performed by the penis. The parts of *generation* proper to women are the vulva, mons Veneris, labia pudendorum, nymphæ, clitoris, hymen, vagina, uterus, and ovaria.

Much is ſaid that is both curious and entertaining with reſpect to the manner how *generation* is effected; but, except that the ſemen is ejected through the penis into the uterus, where it renders the female ovum prolific, the whole is hypotheſis. However, the curious may ſee what is ſaid by Ariſtotle and Galen among the ancients, and by Harvey, Steno, de Graaf, Swammerdam, Van Horne, and Lewenhoeck, among the moderns. It may be noted that Lewenhoeck's doctrine of animalcula ſeems to fall to nothing, when it is conſidered that they cannot be diſcovered before the ſemen begins to corrupt. See Haller's Phyſiology, lecture 33; alſo the article CONCEPTIO in this work.

GENIALIS ARTERIA. See MAXILLARIÆ ARTERIÆ.

GENICULATUS. See GENICULUM.

GENICULUM, or GENICULUS, (from *genu*, a knee, knot or joint.) Properly a joint where there is a bending like that at the knee: but frequently put for a joint in general, and then ſynonymous with nodus; hence all roots and pods of plants divided into joints are ſaid to be geniculated.

GENIO-GLOSSI, from γενιον, *the chin*, and γλωσσα, *the tongue*, alſo called *meſogloſſi*. Theſe muſcles ariſe from the chin, above the genio-hyoides, and enter the middle of the tongue to move it forwards. Winſlow ſays that they can puſh the tongue out, retract, or expand it.

—— HYOIDÆUS, from γενιον, *the chin*, and *hyoides*, *the bone of the tongue*. A ſmall muſcle ariſing from a tubercle above the beginning of the mylo-hyoides, and is inſerted into the upper part of the baſe of the os hyoides. It is alſo called *rectus attollens*.

—— PHARYNGÆI, called alſo *mylopharyngæi*, by Dr. DOUGLAS. Theſe are muſcular fibres joined to the ſide of the genio-gloſſi, and inſerted into the ſides of the pharynx, and continue their conjunction with the genio-gloſſi all the way to the chin.

GENISTA, called alſo *cytiſo-geniſta*, *cytiſus ſcoparius vulgaris*. COMMON BROOM. It is the SPARTIUM SCOPARIUM, or SPARTIUM *fol. ternatis ſolitariiſque, ramis inermibus angulatis, flore luteo*. CLASS, DIADELPHIA. ORD. DECANDRIA. LINN. Gen. Plant. 858. It is a ſhrubby plant, with numerous angular twigs; the leaves are ſmall, and ſomewhat oval, ſet three on a pedicle; the flowers are papilionaceous, and of a deep yellow colour; after the flowers there follow broad pods, with flat, hard, and browniſh ſeeds. It is common on heaths, and uncultivated ſandy grounds; it flowers in May and June.

The leaves and tops have a nauſeous bitter taſte, which they give out by infuſion in both water and ſpirit, and which, on inſpiſſating the liquors, remains concentrated in the extracts. They are commended for their purgative and diuretic powers, and have been ſucceſsfully employed in dropſical caſes, as related by Mead and others. A decoction of the tops of green *broom*, made of half an ounce of the freſh tops boiled in a pound of water to half a pound, and two ſpoonfuls given every hour till it operates by ſtool, or the whole is taken, repeating it every day, or every other day, cures ſome dropſies. See Lewis's Mat. Med. and Cullen's. The aſhes of broom have been much uſed in dropſies, particularly by the recommendation of SYDENHAM; the utility of which has been confirmed by the experience of other writers; but their whole power is ſuppoſed, and that perhaps very juſtly, to depend upon the alkaline ſalt contained in the aſhes, and not in the leaſt on the vegetable from whence it is obtained.—An extract, called EXTRACTUM CACUMINIS GENISTÆ, is ordered to be made by the College of Phyſicians, London. Ph. 1788, in the ſame manner that of chamomile, ſee CHAMÆMELUM, which is given as an aperient and diuretic, in doſes from 3 ſs. to 3 j. repeatedly, in hydropic caſes.

GENISTA CANARIENSIS. See ASPALATHUS.

—— HISPANICA, } called alſo *ſpartium arboreſcens*,
—— JUNCEA, } *ſpartium Hiſpanicum frutex*, and SPANISH BROOM. It is common in gardens, flowers in June and July. It is of the ſame nature as the common *broom*, but more efficacious.

—— SPARTIUM SPINOSUM. See ALHAGI.

—— SPARTIUM, alſo called *nepa Theophraſti*, *geniſta ſpinoſa minor*, and the LESSER FURZE. It is ſo generally known as not to need a deſcription. Its virtues are the ſame as thoſe of the common *broom*.

—— SPINOSA INDICA, &c. See BAHEL-SCHULLI.

—— SPINOSA MAJOR, alſo called *ſpartium majus*, *ſcorpius*, *geniſtellæ ſpinoſæ affinis*, *bahel-ſchulli*, *nepa*, FURZE, or GORS. Its medical virtues are the ſame as thoſe of common broom.

—— TINCTORIA, alſo called *chamæſpartium geniſtella*, *tinctorius flos*, GREEN-WEED, and DYER'S WEED. It is found in paſture ground; it flowers in June and July, and ſeems to be of a ſimilar nature, as a medicine, with the common *broom*.

Botaniſts enumerate twelve or more ſpecies of *broom*. See Raii Hiſt. Plant.

GENITALIUM. Diſeaſes of the genital paſſages.

GENITURA. The *ſemen maſculinum*; alſo the *pudendum virile*.

GENOU. See *diarthroſis*, and *enarthroſis*, but does not agree ſo well with other ſpecies, though uſed for them all.

GENSING, called alſo *ginſen*, *ginſeng*, *aralia humilis*, *minzin*, *nindſin*, *niſi*, *ſiſarum montanum Coræenſe*, *zingin*, *aureliana Canadenſis Iroquæis*, *garent-ouguan*, *Indiæ orientalis radix genuina*, *plantula Marilandica*, &c. It is the PANAX QUINQUEFOLIUM; or, PANAX *foliis ternis quinatis*. CLASS, POLYGAMIA. ORD. DIŒCIA. LINN. Gen. Pl. 1166.

Genſing is the root of a ſmall plant growing in China, Turkey, and in ſome parts of North America, particularly in Canada and Pennſylvania. It is two or three inches long, taper, about the thickneſs of the little finger, often forked at the bottom, which gives it a diſtant reſemblance of a man, whence it is called *ginſeng*; it is elegantly ſtriated with circular wrinkles; it is of a browniſh yellow colour on the outſide, and whitiſh, or of a pale yellow within; on the top are commonly one or more little knots, which are the remains of the ſtalks of the preceding years, and from the number of which the age of the root is judged of. Thoſe roots which are brought from China are ſomewhat paler than thoſe from America, but in no other reſpect is any difference found.

Ninzin has been ſuppoſed to be a ſynonymous name with *genſing*; but *ninzin* is a root of a different ſpecies; its virtues are weaker, but of the ſame kind as thoſe of *genſing*: the ninzin root is larger, lighter, and leſs firm than the *genſing*; it is whitiſh on the ſurface, yellow within, hath a ſlight aromatic ſmell, an acrid bitteriſh taſte, and is a ſpecies of ſium.

The Chineſe eſteem this root as a general reſtorative and powerful aphrodiſiac; but theſe qualities are ſo weak that it is ſcarce worſe retention. See Cullen's Mat. Med. Indeed, though the Chineſe give ſuch extravagant accounts of the many virtues it poſſeſſes, we know of no proofs of its efficacy in Europe; and from its ſenſible qualities, we conclude it has very little power as a medicine. To the taſte it is mucilaginous, and ſweet like liquorice, yet accompanied with a degree of bitterneſs and a ſlight aromatic warmth, with little or no ſmell: the ſweet matter of theſe roots is preſerved in the watery as well as in the ſpirituous extract, and ſo is their aroma; the ſpiritous extract is a pleaſant warm bitteriſh ſweet.

A dram of the *genſing* root may be ſliced and boiled in a quarter of a pint of water to about two ounces; then a little ſugar being added, it may be drank as ſoon as it is cool enough; the doſe muſt be repeated morning and evening, but the ſecond doſe may be prepared from the ſame portion of root which was uſed at firſt, for it may always be twice boiled. M. Reneaum ſays that the he-

 patica

patica nobilis Tragi is endued with the principal virtues of the *genſing*. See Raii Hiſt. Plant. Kempf. Amæn. James's Med. Dict. Lewis's Mat. Med. Lond. Med. Tranſ. vol. iii. p. 34.

GENTIANA. GENTIAN, GREATER YELLOW GENTIAN, or FELWORT. Some have called it the *European kinkina*. It is the GENTIANA LUTEA, or GENTIANA MAJOR LUTEA, *corollis quinquefidis*. CL. PENTANDRIA. ORD. DIGYNIA. LINN. Gen. Pl. 322. In ſome editions it is writ corollis ſubquinquefidis.

This plant is ſaid to be called *gentiana*, becauſe Gentius, a king of Illyria, firſt took notice of it. Boerhaave enumerates ſeven ſpecies; but the above, whoſe root only is uſed, is the principal one of note in medicine. The ſtalk is unbranched and jointed; the leaves are oblong, acuminated, ribbed, and ſet in pairs at the joints; the flowers are in cluſters at the top of the ſtalk; they are of a pale yellow colour, ſomewhat bell-ſhaped, and deeply cut into five ſegments; the ſeeds are contained in oblong capſules; the root is moderately long, ſlender, branched, browniſh on the outſide, and of a deep gold colour within: its pith is woody, though more ſpongy than the reſt of the root. It is perennial, a native of the mountainous parts of Germany, Switzerland, France, and their neighbouring countries, from whence the dried roots are brought to us; but the plant is ſometimes found wild in England.

Sometimes another root is ſold for that of *gentian*, but ſhould be carefully diſtinguiſhed, as it is poiſonous; it is thought to be the *thora valdenſis* of RAY, or *aconitum primum pardalianches* of GESNER. It is known from the true *gentian* by being of a paler colour externally, having longitudinal wrinkles: when cut into, its texture is cloſer than that of *gentian*; it is whitiſh within, and it is not bitter, but when chewed is only perceived to be mucilaginous.

The beſt roots of *gentian* are of a middling ſize, of a lively yellow colour, tough, and moſt free from fibres. The older and larger the roots, the more porous, and the younger and ſlenderer are more compact.

Neumann obtained from ʒ xvi. of this root, by means of ſpt. vin. r. to the quantity of ʒ vii. ſs. of reſinous extract; and by means of water, ʒ ix. of a gummy one. The London College directs a watery extract; ſee CHAMÆMELI EXTRACTUM: but the ſpirituous is to be preferred; their doſes may be from gr. x. to ℈ ii. or ʒ i. In diſtillation, ſpirit carried nothing over, and water too little to deſerve notice.

It is a ſtrong flavourleſs bitter, and by any agreeable addition is rendered very grateful to the ſtomach. Of all the preparations, an infuſion in cold water is the moſt acceptable to the palate, and it poſſeſſes more of the virtue of this root than a decoction does; but indeed, when a warm vehicle is required, the tinct. *gentianæ* is to be preferred.

The febrifuge virtues of the *gentian* root, by ſome writers, have been made equal to thoſe of the Peruvian bark, but in many caſes have failed; ſtill, though joined with gall and tormentil roots in equal parts, and given in ſufficient quantity, *gentian* has cured intermittents in Scotland. See Cullen's Mat. Med. It is however one of the principal bitters employed now by phyſicians, and as intenſe bitters are generally admitted to be not only tonic and ſtomachic, but alſo *anthelmintic*, *antiſeptic*, *emmenagogue*, *antarthritic*, and *febrifuge*, this root s ſaid to have a better claim to the poſſeſſion of theſe powers, than moſt of this kind. Bitters by ſome are allowed to relieve more effectually dyſpeptic complaints, though ariſing from debility of the ſtomach, than Peruvian bark, and hence infer their ſuperior tonic power on that organ. When applied as a tent in wounds, it does not make callous lips, whence it is often uſed for imbibing the moiſture in iſſues, which it alſo dilates. See Lewis's Mat. Med. Raii Hiſt. Neumann's Chem. Works.

The officinal preparations of this medicine are with the extract above noticed.

Tinctura GENTIANÆ compoſita. P. L. 1788. *Compound Tincture of* GENTIAN.

℞ *Gentianæ* inciſæ & contuſæ p. ʒ ij. corticis exterioris *aurant*. Hiſpalenſium exſiccati ʒ i. ſeminum cardamomi minoris contuſorum demptis capſulis ʒ ſs. ſpt. vinoſi nuioris lb. ij. Digeſt for eight days, and ſtrain.

This is an elegant compoſition, a warm ſtomachic, and well calculated for keeping. This was formerly the tinctura amara. Pharm. Lond.

Infuſum GENTIANÆ Compoſitum. P. L. 1788. *Compound Infuſion of* GENTIAN.

℞. Radicis *gentianæ* p. ʒ i. ſs. cort. limon. exterioris recentis p. ʒ ſs. *cort.* aurant. Hiſpalen. ſicci ʒ i. ſs. aquæ ferventis ℥ xij. macerate for an hour.

This was the infuſum amarum of the former Pharmacopœia; though in this it has ſuffered ſome change, by the omiſſion of two drams and an half of the *gentian* root.

This is a light pleaſant bitter, ſtrengthens the ſtomach, and reſtores the appetite: two ounces ſhould be taken twice a day, and in caſe of flatulence, ſome cordial carminative tincture ſhould be added to it.

VINUM AMARUM, *Ph. Edin.* BITTER WINE.

Take of gentian root ʒ ſs. Peruvian bark ʒ j. Seville orange peel dried ʒ ij. canella alb. ʒ j. proof ſpirit ʒ iv. Spaniſh white wine lb. ii. ſs. Firſt pour on the ſpirit, and after twenty-four hours add the wine; then macerate for three days, and ſtrain. This is conſidered a very uſeful and elegant ſtomachic medicine.

GENTIANA MINOR, called alſo *gent.* cruciata, and CROSS-WORT GENTIAN. It grows in Hungary on hills and in dry meadows, but is rarely brought to us.

—— ALBA. See LASERPITIUM.

—— CENTAURIUM. See CENTAURIUM MINUS.

—— NIGRA. See OREOSELINUM APII FOLIO, &c.

GENU. The knee; alſo the patella, KNEE-PAN. The *knee* is the articulation of the thigh and leg bone; the joint of the *knee* being a ginglymus joint, admits, conſequently, of only flexion and extenſion, except when it is bent, when it will allow of a ſmall rotation by the ligaments being relaxed. This joint is made up of the femur, patella, and tibia; the fibula does not reach the joint, and therefore hath no part in its compoſition. The patella in extenſion is drawn up, in flexion it is pulled down. Under the ligament of the patella is a facculus mucoſus; this mucus is very like the ſynovia. The ſtrength of this, as of all joints of the ginglymus kind, is on the ſide. The capſular ligament is large, and admits of the collection of a fluid within the joint; in which caſe the ſwelling appears above and on each ſide the patella, but chiefly above, on account of the ligaments being thinner there; what is called the ſynovial gland, Dr. Hunter concludes is not one: becauſe in general, he thinks that there are no ſuch glands; and that this, like all the reſt called ſynovial, is mere fat; and that what is called ſynovia, is ſecreted here and in all the other joints, by the veſſels of that vaſcular membrane covering the cartilages, and this fatty ſubſtance under the internal lamen of the capſular ligament of each joint. Beſides the capſular ligament, there are *two others* covering the poſterior parts of the condyles of the femur, and fixed into the head of the tibia, between its two cavities; theſe ligaments are ſtretched when the leg is extended, and relaxed when the leg is bent, at which time they allow the little lateral motion of the joint by their being relaxed. Between the tibia and the femur are two ſemilunar cartilages; they are thick on their external edges, and thin in their centre. They are tied to the tubercle by their horns; they alter their figure according to the ſituation of the bones, to make the ſhape of one correſpond to that of the other.

It ſometimes happens, that pieces of cartilage, or bone covered by cartilage, are found looſe in the cavity of the joint of the *knee*. Theſe are of different ſizes. Some of them are as large as common garden beans. They are generally flat, oblong, having their edges rounded. It is ſeldom that there are more than one of theſe looſe cartilages in a joint; but ſometimes there are two. Mr. Cruikſhank ſays, that he formerly conſidered them as belonging to the patella; and that, like the oſſa triquetra in the ſkull, they owed their origin to diſtinct points of oſſification. But having ſince found one entirely cartilaginous, and another, which, though bone covered by cartilage, was formed on the lower end of the femur, and this convinced him of his miſtake. In the laſt mentioned caſe Mr. Cruikſhank ſays, that there was a cavity in the lower end of the femur, correſponding to the looſe bone, ſhewing that they had been connected with one another; though, as both ſurfaces were nearly ſmooth, the manner of their connection was not evident. He ſuppoſes that, during their growing, theſe cartilages and bones are connected to the neighbouring parts by veſſels; and that, when either their determined growth is finiſhed, or their ſize is too large for the eaſy motion of the joint, they become

become looſe. When they become looſe, the ſynovia, from the irritation they induce, is ſecreted in greater quantity; the capſular ligament becomes diſtended, the *knee* appears ſwelled, a degree of ſtiffneſs takes place in the motion of the joint, with more or leſs of external inflammation. There is alſo the diſtinct feel of the fluid underneath; and the looſe bit of cartilage gets frequently above the condyles of the femur, on the out or inſide of the *knee*, and may be laid hold of with the thumb and finger through the integuments. When the patient hath walked much, the ſynovia is ſenſibly increaſed, and on remaining more quiet, for two or three days, is as ſenſibly diminiſhed. The ſymptoms are ſometimes ſo mild as not to need an operation, but at other times it is the only expedient for relief. Mr. Cruikſhank here obſerves, that much ſeems to depend on the ſurgeon, whether this operation ſhall be a dangerous one or not. Mr. John Hunter recommends the moving them by inciſion; but thinks the particular ſpot where the operation is to be performed, as well as the manner of operating, deſerve the greateſt attention. There is a part within the cavity of the joint of the *knee*, which receives the baſis of the patella, during the extenſion of the leg. It partakes more of the nature of cellular membrane than capſular ligament, and lies under the lower extremities of the vaſti and crureus muſcles, before they are inſerted into the patella. Mr. Hunter propoſes to lay hold of the cartilage or bone, and cut down upon them at this place; the inciſion, he thinks, ſhould be no larger than juſt to allow of their being eaſily thruſt out. A ſtitch or two is then to be paſſed through the divided integuments, and the lips of the wound, by theſe means, are to be brought together. Theſe ſtitches, however, muſt not paſs into the cavity of the joint; inſtead of uniting the parts in this caſe, they would act as ſetons, and produce inflammation in place of preventing it. To be convinced of this laſt aſſertion, he refers to the introduction of a ſeton into the tunica vaginalis teſtis, for the radical cure of the hydrocele. The aim of the ſurgeon then is, if poſſible, to heal the wound by the firſt intention. A piece of ſticking plaſter, with proper bandage, and poſition of the joint, may even make ſtitches in the integuments unneceſſary. Mr. Hunter recollects ſix or ſeven caſes in which theſe cartilages were removed by exciſion, though not juſt in the manner recommended: all of theſe, except one, did well. The operation in this one was attended with great inflammation, and followed by an anchyloſis of the joint. Other inſtances of failure I have heard of; but, it muſt be obſerved, that there are conſtitutions where any wound, much more a penetrating wound into the cavity of the joint of the *knee*, will be attended with danger. The circumſtances which the operator has moſt to avoid, Mr. Hunter aſſerts, are the expoſing the cavity of the joint too much; lacerating or bruiſing of the capſular ligament; not properly cloſing the orifice in the integuments; or employing a blunt or dirty inſtrument in the dividing them. All, or any of theſe circumſtances, he thinks, will produce inflammation in the joint, and render the operation exceedingly dangerous. But in tolerably ſound conſtitutions, the operation now recommended, performed with the neceſſary precautions, he is convinced, is as ſafe a one as moſt operations in ſurgery. When the cavity of the joint has inflamed, the danger, he owns, is very great. Ligament and cartilage, the ſubſtances compoſing joints, have fewer veſſels than any other parts perhaps of an animal body; they inflame, ſuppurate, or go through the uſual proceſſes of parts under irritation, with greater difficulty; and, when they have gone through them, the conſequences are generally deſtructive of the ordinary intentions of theſe proceſſes; the joint anchyloſes, and is deſtroyed inſtead of being recovered. The irritation, meanwhile, attending ſuch fruitleſs proceſſes, generally proves fatal. See Mr. Cruikſhank's Letter to Dr. Duncan, in the Edinb. Med. Commentaries, vol. iv. p. 342, &c.

GENUFLEXIO. KNEELING. In *kneeling*, the oſſa pubis are lower than when we ſtand; and this not only increaſes the hollow of the loins, and throws the belly and its viſcera more outward and forward, but alſo, in ſome meaſure, ſtrains the abdominal muſcles; which is ſo uneaſy to ſome perſons as to cauſe them to faint away. This depreſſion of the os pubis in *kneeling* depends partly on the tenſion of the two muſculi recti anteriores, the lower tendons of which are, in this ſituation, drawn with violence under the condyloid pulley of the os femoris. Winſlow.

GENUGRA. A name in Paracelſus for the gout in the knee. See ARTHRITIS.

GENUINI DENTES. See DENS and SAPIENTIÆ DENTES.

GENUS. In BOTANY, is the third ſubdiviſion in a ſyſtematical arrangement of vegetables, containing plants of the ſame claſs and order, which agree in their parts of fructification. In NOSOLOGY, it is alſo the third ſubdiviſion of diſeaſes, which agree in ſome characters that diſtinguiſh them from all others.

GEODES LAPIS, λιθος γεωδης, *a ſtone*, ſo called from γη, *earth*, which it contains. It is rather aſtringent and drying, ſomewhat detergent when applied to the eyes, and mitigates inflammations in the breaſt, &c. if mixed with water, and rubbed thereon. Dioſ. lib. v. cap. 169.

GEOF. M. M. The abbreviation of Step. Franc. Geoffroy Tractatus de Materia Medica.

GEOFFRÆA INERMIS; called alſo *Geoffroya inermis*; *Geoffræa Jamaicenſis inermis*; SMOOTH GEOFFROYA, or BASTARD CABBAGE-TREE. It is the GEOFFROYA INERMIS, *foliolis lanceolatis*, SWARTZ. CLASS, DIADELPHIA. ORD. DECANDRIA. LINN. Gen. Plant. 876. For a botanical account of which, ſee Philoſ. Tranſ. vol. 67, p. 507, tab. 10. This tree is a native of Jamaica, diſtinguiſhed by the name of CABBAGE BARK TREE, or WORM BARK TREE. The bark, which *externally* is ſmooth, and of a grey colour *internally*, black, and furrowed, and has a mucilaginous, and ſweetiſh taſte, with a diſagreeable ſmell, is the beſt appropriated to medical purpoſes, and is conſidered as poſſeſſed of ſtrong anthelmintic powers. Dr. Wright, who reſided a long time in Jamaica, has ſupplied the ſafeſt and moſt efficacious modes of exhibition, from his own experience. It may be given either in DECOCTION, SYRUP, POWDER, or EXTRACT. The DECOCTION is made by boiling one ounce of freſh-dried, or well-preſerved cabbage bark, in a quart of water, over a ſlow fire, till the water is like, in appearance, deep coloured Madeira. This muſt be ſtrained off, ſweetened with ſugar, and *uſed* very early, as it does not keep many days. The SYRUP is formed by diſſolving double the quantity of ſugar in any portion of the decoction. *This will retain its virtues for years.* By evaporating the ſtrong decoction of this bark, in balneo Mariæ, to a proper conſiſtence, the EXTRACT is acquired; though it muſt be continually ſtirred to prevent the reſinous part from riſing to the top, on which probably its efficacy may depend. The POWDER, to make, requires not any directions; it looks like jalap, though it is not ſo heavy.

Doſes to be begun with, according to the age and ſtrength, are:

	Decoction.	Syrup.	Extract.	Powder.
For a ſtrong healthy grown perſon,	Cochl. 2	Cochl. 2	Gr. 3	Gr. 30
For a youth,	—— i. ſs	—— i. ſs	— 2	— 20
For a perſon ten years old,	—— 1	—— 1	— i. ſs	— 15
For children, two or three years old,	—— 1	—— 1	— 1	— 10
For children, one year old,	—— ſs	—— ſs	— ſs	— 5

Theſe doſes may be gradually encreaſed till a nauſea is excited, which will be a full doſe. Thus, from frequent uſe, the common doſes can be determined: it is ſafeſt to begin with ſmall ones, and gradually encreaſe them. The decoction is moſtly given in Jamaica, and ſeldom fails to deſtroy worms in the inteſtines, and bring them away in large quantities. By frequent uſe, however, theſe animals become familiarized; and we find it neceſſary to intermit it, or have recourſe to others of inferior merit. Cold water ſhould not be drank during the operation of this medicine, as it is apt to occaſion ſickneſs, vomiting, fever and delirium. When theſe occur, or when an over large doſe has been given, the ſtomach muſt be waſhed with warm water: the patient muſt ſpeedily be purged with caſtor oil, and uſe plenty of lime-juice beverage for common drink; vegetable acid being a powerful antidote in this caſe, as well as in an over doſe of opium.

For Mr. Anderſon's account of this bark, and the mode of giving it, ſee PALMA NOBILIS.

GEOPILYSIA. Rulandus ſays that it means a ſeparation by ſolution.

GER. The abbreviation of Gerarde: by it is often to be underſtood the Herbal gathered by John Gerarde, and which was improved by Tho. Johnſon.

GER. EMAC. The abbreviation for Gerarde's Herbal enlarged, &c.

GERANIS. A bandage uſed by the ancients in caſe of a fractured clavicle, or a diſlocated ſhoulder.

GERANIUM. A bandage which, from the days of Hippocrates, was thus named, but is now called *ſpica ſimplex*. In BOTANY, it is the name for BATRACHIUM, CROW'S FOOT, or CRANE'S BILL. Of this kind of plant, Boerhaave enumerates ſixty-eight ſpecies. It hath its name from the remarkable long beak of its ſeed-veſſel, which reſembles that of a crane: it conſiſts of five capſules opening inwards, and containing each a ſingle ſeed; the flowers are pentapetalous.

—— ROBERTIANUM, Linnæus; alſo called *gratia Dei*, and HERB ROBERT. It hath reddiſh or purpliſh flowers on one pedicle; the leaves are divided quite to the foot-ſtalk into three ſegments, and theſe again are deeply cut. It is the only ſort uſed in medicine.

—— BATRACHIOIDES, alſo called *gratia Dei Germanorum*, and CROW'S FOOT CRANE'S BILL. It is the GERANIUM PRATENSE, Linn. It hath two blue (but ſometimes white) flowers on one pedicle; the leaves are large, wrinkled, and divided into five or ſeven ſegments, which again are deeply cut on their edges.

—— COLUMBINUM, called alſo *pes columbinus*, DOVE'S FOOT and DOVE'S FOOT CRANE'S BILL. It hath purple flowers, ſtanding two on a pedicle; the leaves are ſhaped like thoſe of mallows, and have long foot-ſtalks.

—— MOSCHATUM, called alſo *acus moſchata*, MUSCOVY, and MUSKED CRANE'S BILL. It hath a number of red flowers on one pedicle; the leaves are indented, oval-ſhaped, ſet in pairs along a middle rib, which is terminated by an odd one.

—— SANGUINARIUM, called alſo *hæmatodes*, and BLOODY CRANE'S BILL. It hath ſolitary flowers which on their firſt appearance are red, but ſoon change to a bluiſh colour; the leaves are roundiſh, but divided almoſt to the pedicle into five ſegments, which are often ſubdivided at the extremities into three.

All theſe plants are found wild in different parts of this kingdom; they flower in May, June and July. They have an aſtringent taſte; the firſt ſpecies hath an unpleaſant ſmell; the ſecond, third, and fifth have no ſmell; the fourth hath a muſky ſcent, but it is ſoon loſt by bruiſing the plant. Their ſtyptic matter is extracted both by water and rectified ſpirit, and on evaporating the filtered liquor, remains in the extract. See Raii Hiſt. Lewis's Mat. Med.

GERARAT. A name in Avicenna for ſome poiſonous animals.

GERMANDRA. See GAMBOGIA.

GERMANIS OLEUM. See CARPATHICUM. MELISSA.

GERMEN. See BLASTEMA.

GEROCOMIA, from γερων, *an aged perſon*, and κομεω, *to be concerned about*. It is that part of medicine which preſcribes to old age.

GERONSTERRE WATER. See SPAÆ AQUÆ.

GERONTOXON. See BOTHRION.

GERSA. See PLUMBUM, N° 1.

GERULA. In Paracelſus it is a monſtrous plant.

GERYON. QUICKSILVER. See ARGENT. VIVUM.

GESN. The abbreviation of Conradi Geſneri Hiſt. Plant.

GESOR. See GALBANUM.

GESTATIO. See ÆORA.

GESTATIO. GESTATION or PREGNANCY, alſo called *cyſpheria*. It is the progreſs of the fœtus from the time of conception to that of parturition.

When the ovum falls into the uterus, it is ſaid to be about the ſize of a poppy head; that, in ten days, it weighs half a grain; in thirty days, twenty-one grains; in three months, about three ounces; and, at the end of nine months, children are of different ſizes, from four to nine pounds in weight: ten or eleven pounds are very rare.

Women, with the firſt child, frequently have great pain in the parietes of the belly from the uterus dilating the muſcles; in this caſe, ſome relief is obtained by rubbing the parts in pain with warm oil.

The time of a woman's *pregnancy* is nine ſolar months, each of which is reckoned to be *about thirty days, ten hours and a half*; but it often happens that the child is born at ſeven months, and ſometimes at ten.

After the conception, the face ſoon points out that an alteration in the conſtitution hath taken place. It is from increaſed irritability that the chief of the ſymptoms attending *pregnancy* ariſe; they proceed from the uterus as the principal ſituation of the firſt cauſe. The uterus becoming more habituated to diſtenſion, &c. ſome of the ſymptoms abate, but there ſtill remains a ſufficient number to prove, that *pregnant* women are attended with an increaſed ſpaſmodic irritability, and which ſeems to be neceſſary for promoting the delivering of the fœtus at the proper period; for it is increaſed during labour, but after that it diſappears.

Women, who conceive whilſt they give ſuck, frequently have not the menſes to reckon from: therefore, the beſt way is to ſet down four months, when the firſt motions of the child are perceived: thoſe who have the menſes ſhould count from the middle of each period, and they will ſeldom differ more than four or five days.

Though, in ſome few inſtances, women are met with who know their ſtate from the moment of conception; yet, in general, it is not eaſy to aſſure a patient of her *pregnancy*, or the contrary, until the end of the fourth month, and then the only proof is by the touch, which in this caſe may be thus performed: place the woman on her feet, with her buttocks againſt a chair that is rather higher than common, let her lean forward with her breaſts, and then introduce two fingers into the vagina; then, if ſhe is *pregnant*, the os internum will be found entirely cloſed, the neck of the uterus will be felt, but it is yet very little or not at all altered: as the *pregnancy* is more advanced, the nearer it is to parturition, the thinner or flatter is the neck of the uterus, and the larger the uterus itſelf. If the touch is attempted before the fourth month, when you endeavour to preſs againſt the uterus, it being light, evades the touch, and riſes above the finger. If, on thus examining, you feel the flat, ſmall, and hard body of the uterus, ſhe is not *pregnant*; but if ſhe is, the uterus will be in ſome degree enlarged. La Motte, before he makes his eſſay by the touch, lays the woman on her back, with her knees elevated, and the heels near the buttocks; and, if he finds the belly more hard and diſtended in the hypogaſtrium than in the epigaſtrium, he judges the woman to be *pregnant*.

As to all the other uſual ſigns of *pregnancy*, they are uncertain, as they may be produced by obſtructed menſes, a nervous fever, tympany, aſcites, dropſy of the uterus, hydatids forming themſelves on remaining pieces of the placenta, a ſcirrhous womb, dropſy of the ovaries, a polypus in the uterus, &c. from all which a *pregnancy* ſhould be diſtinguiſhed.

Many intereſting obſervations on this ſubject may be ſeen in the practical treatiſes on midwifery, and on the management of pregnant and puerperal women.

GESTICULATIO. GESTICULATION. Two ſpecies of gymnaſtics, conſiſting of a ſpontaneous agitation of the parts, and throwing the body into different poſtures, much like actors on the ſtage. Oribaſius ſays, it is a middle kind of exerciſe betwixt dancing and mock-fighting.

GEUM URBANUM. See CARYOPHYLLATA.

GHITTA. See GAMBOGIA.

GHODHAKADURA. See NUX VOMICA.

GHORAKA. See CARCAPULI FRUCTU MALO, &c.

GIALAPPA, or GIALAPIUM. See JALAPA.

GIBBER, } GIBBOSITY, CROOKEDNESS. The
GIBBOSITAS. } cheſt and ſpine are both diſtorted by a faulty arrangement of the vertebræ. See CYRTOIDES and CYRTOMA.

GIFFÆ. Tumors behind the ears.

GIGARUS. See DRACONTIUM.

GILARUM. See SERPYLLUM.

GILIADENSE BALSAMUM. See BALSAMUM.

GILLA VITRIOLI. See VITRIOLUM ALBUM.

GINGIBERIS AMARITUDO. See CANELLA ALBA.

GINGIBRACHIUM. See SCORBUTUS.

GINGIDIUM. See CHÆROPHYLLUM.

—— HISPANICUM. See VISNAGA.

GINGIHIL. See ZINGIBER.

GINGIPEDIUM. See SCORBUTUS.

GINGIVÆ. The GUMS. They are called *ula*, the plural of *ulon*. POLLUX ſays, the fleſh on the outſide of the teeth is named *ulon*, and on the inſide *enulon*, or that part which is betwixt the teeth; *ula* alſo ſometimes means a tumor on the gums. They are that reddiſh, compact, fleſhy ſubſtance which covers the two ſides of the whole alveolary border of both jaws, inſinuates itſelf betwixt the teeth, then called *harmos*, and adheres to them. Arteries from the carotids run in the gums and nerves from the fifth pair.

The

The gums are apt to become ſpongy, and to ſeparate from the teeth; but the cauſe is frequently a ſtony kind of cruſt; which forms itſelf therein, which, when ſeparated, the *gums* ſoon return to their former ſtate, eſpecially if rubbed with a mixture of the infuſion of roſes four parts, and the tincture of myrrh one part. In caſes alſo of ulcerations in the gums, mouth, throat, fauces, &c. the following gargles are very uſeful.

GARGARISMA ALUMINIS. ALUM GARGLE.

℞ Aluminis, ʒ ij. decoct. hordei, lb 2. mellis roſæ ℥iij. m. This is alſo uſeful in relaxations of the uvula, and other caſes where aſtringents are requiſite.

GARGARISMA MYRRHÆ. MYRRH GARGLE.

℞ Tinct. myrrhæ, ʒ ſs. mellis roſæ, ʒ i. ſs. aq. calcis, ℥ iij. m. In ſcrophulous ulcers, where greaſy applications are inadmiſſible, this is very uſeful.

The ſcurvy is another diſorder which affects the *gums*. This diſorder, when not manifeſt in any other part, ſometimes appears in this: indeed, when a ſcorbutic diſorder invades the whole habit, its firſt ſymptom is a putrid ſtate of the *gums*. Sometimes a ſcorbutic complaint attacks the *gums*, and occaſions heat, pain, and itching there; and preſently after, if they are ſlightly touched, they bleed; then white ſpots appear here and there, which are red and inflamed about their circumference. If this caſe is neglected, eſpecially in young perſons, it ſpreads, and a copious flux of thin fetid ſaliva is diſcharged, which corrodes all around it. In Holland, it is called the WATER CANCER. Beſides proper internal antiſcorbutics, the beſt external application is the acidum muriaticum, diluted with water.

GINGLYMUS. See DIARTHROSIS.

GINSEN, GINSENG. } See GENSING.

GIR. See CALX.

GIRMER. See TARTARUM.

GISISIM. See GUMMI.

GITH, or GIT. See NIGELLA ROMANA.

GITHAGO. See NIGELLASTRUM.

GLABELLA. The ſpace betwixt the eye-brows.

GLABULÆ. See CUPRESSUS.

GLADIOLUS. FRENCH CORN-FLAG; alſo called *xiphium*, *anacterion*. Its root is tuberous and double; the leaves are like thoſe of the iris; the flower is like that of the lily, funnel-ſhaped below, but expanded above, and divided into ſix ſegments. It is cultivated in gardens, and flowers in June. The root is diſcutient externally; internally it is alexipharmac. See Raii Hiſt.

—— FŒTIDUS. See IRIS FŒTIDUS.

—— LUTEUS. See IRIS PALUSTRIS.

GLAMA, or GLAME. The ſordes of the eye in a lippitude; alſo ſordid and tumid eyes.

GLANDES UNGUENTARIÆ. See MYROBALANI.

GLANDIUM. See THYMUS.

GLANDULA. ADEN. A GLAND. A *gland* may be defined a circumſcribed apparatus of the ſoft parts, whoſe office is to ſecern a certain juice, and throw it out of the immediate circulation.

The *glands* are roundiſh bodies, ſeated in the cellular membrane, generally near the large veſſels; their ſubſtance is firm, and of various colours. Sylvius was the firſt who divided the *glands* into conglobate, now called lymphatic, and conglomerate. See CONGLOBATA and CONGLOMERATA GLANDULA. Malpighi added what he called the folliculus or ſimple *gland*; inſtances of which are the ſmall *glands* behind the ears, but the moſt remarkable are thoſe in the fauces.

Dr. Nicholls divides the *glands* into SINUOUS, TUBULAR, and EQUAL. What he means by *ſinuous gland* is when each little *gland* hath its own excretory duct, through which it tranſmits its liquor to a common baſon, as the kidnies; his *tubular* is the ſame as the conglobate *gland* of Sylvius, of which the teſtes are an inſtance. By an *equal gland* he means where the veſſels are branched, as in the liver.

Ruyſch proves by ſubtle injections, that the ſubſtance of the *glands* is vaſcular, conſiſting of a ramifying artery, partly terminating in a vein, and partly in an excretory duct.

Mr. Hewſon ſays, that the little corpora globoſa, which moſt modern anatomiſts call cryptæ and folliculæ, are nothing but convoluted arteries.

The *glands* are often diſordered by becoming large and indurated; when they are ſwelled and hard, they are ſaid to be *indurated*; if they grow harder, they are ſaid to be *ſcirrhous*; if, when hard, they become painful, they are *incipient* or *occult cancers*; if their hardneſs and pain continue long, they are called *carcinomata*, or *inveterate occult cancers*; and, if the ſkin breaks, they are called *ulcerated cancers*.

Indurated *glands*, in children's necks, are generally from voracity, or a bad diet; the cure therefore will conſiſt in moderating the quantity, and amending the quality of their aliment. Theſe tumors, even though they tend to ſuppuration, may generally be removed by the uſe of ſmall doſes of calomel. Sea-water is alſo uſed before ſuppuration begins, and the extract. cicutæ powerfully reſolves them. See SCROFULA, SCHIRRUS, CANCER, LUPIA, NÆVUS. See alſo Kirkland's Medical Surgery, vol. ii. p. 475.

On the *glands*, as a ſubject of anatomy, ſee Sylvius, Malpighi, Ruyſch, Cowper, Havers, de Bordeu, &c.

GLANDULA LACHRYMALIS. LACHRYMAL GLAND, is a hard conglomerate gland, ſituated in a cavity of the os frontis, within the orbit, above the external canthus. There deſcend from the lachrymal gland, on the inſide of the tunica adnata of the eye-lid, ſix or more excretory ducts perforating the tunica adnata by ſo many orifices, at the diſtance of a few lines from the tarſus, and evacuating a ſaline aqueous fluid, called the tears, between the eye-lid, and the bulb of the eye. Beſides, the extremities of very ſmall arteries exhale a moiſture from the whole ſurface of the tunica conjunctiva, which, mixed with the liquor of the lachrymal gland, and the ſmegma of the Meibomian glands, moiſtens and lubricates the eye, and the inſide of the eye-lids.

GLANDULA LACHRYMALIS, —— INNOMINATA. } See CARUNCULA LACHRYMALIS.

GLANDULÆ CERUMINIS. See AUDITORIUS MEATUS.

—— MYRTIFORMES. When the hymen is torn, its fibres contract in three or four places, and form what is thus named.

—— ODORIFERÆ. They are ſituated on the inſide of the glans penis; and ſecrete a fluid, whoſe thin part flies off, and the thicker remaining, acquires a particular odour, whence the name. Theſe glands are often the ſeat of a clap in thoſe who have a long prepuce; and when affected, they emit a pus exactly ſimilar to that which flows from the urethra.

—— SUPRA-RENALES, and *renales*. See CAPSULÆ ATRABILARIÆ.

—— VASCULARES. See COWPERI GLANDULÆ.

GLANDULOSOCARNEUS. An epithet given by Ruyſch to ſome excreſcences which he obſerved in the bladder.

GLANS. See PENIS. It is alſo a ſtrumous ſwelling; and a name for a peſſary, or a ſuppoſitory.

GLANS JOVIS THEOPHRASTI. See CASTANA.

—— PENIS, called alſo *balanus*, *cuſpis*, and NUT. It is formed by the corpus ſpongioſum urethræ, which is turned over the corpora cavernoſa penis. Its external ſurface is a continuation of the integuments; and when the cuticle is taken off, every little villa ſeems a veſſel. In the fifth volume of the Edinb. Med. Eſſays, is an account of a *glans penis* being regenerated after amputation.

GLANS UNGUENTARIA. See BEN.

GLASTEA BILIS. A ſort of bile.

GLASTUM. WOAD. It is alſo called *iſatis ſativa* vel *latifolia*. It is the ISATIS TINCTORIA, Linn. It is cultivated only for the uſe of dyers, who obtain from it their beſt blue; an inferior ſort is called by the French *vouede*; and indigo is reckoned the produce of the worſt ſpecies. This plant is not uſed in medicine, though it is ſaid to be aſtringent. From the iſatum ſylveſtre, a volatile ſalt hath been obtained by fermenting the herb only, and without the aſſiſtance of fire. See Lewis's Mat. Med. Neumann's Chem. Works.

GLASTUM INDICUM. See INDICUM.

GLAUBERI SAL. GLAUBER'S SALT, *ſal mirabilis*, *admirabilis*, *ſal catharticum Glauberi*, now called NATRON VITRIOLATUM, VITRIOLATED NATRON. The *Dauphiny ſal* is a natural production of this kind, obtained from an earth in the province of Dauphiny in France; but that in general uſe, and which receives the name of *Glauber* its author, is artificial. It conſiſts of a vitriolic acid in union with the mineral alkaline ſalt, and ſo is a neutral ſalt.

The

The London College directs to take of the salt which remains after the distillation of the muriatic acid, two pounds: burn out the superfluous acid with a strong fire, in an open vessel; then boil it a little in two pints and an half of distilled water, strain the solution, and set it by to crystallize. Ph. Lond. 1788. In cold weather it will shoot in forty-eight hours, and in warmer weather in about twice the time.

The fineness and largeness of the crystals depend, in a good measure, on the quantity of acid. The Edinburgh College directs one part of the oil of vitriol to two parts of sea-salt for obtaining the spirit of salt, and the residuum is as nearly of a due degree of acidity as can be ascertained by a general rule.

Mr. Fergus, in Piccadilly, London, says, that from kelp ℔ ii. ß and something less than two ounces of the oil of vitriol, he obtained half a pound or more of *Glauber's salt*. This is cheaper than when the soda is used. He prepares it as follows: take calcined kelp, ℔ i. powder and dissolve it in a glazed earthen pan with boiling water, ℔ ii. then filter or decant the clear liquor into another glazed earthen dish, which being placed over a gentle fire, as soon as it is hot, gradually pour into it as much oil of vitriol, diluted in the proportion of one part oil with one and a half of water, as is necessary to saturate it; when no effervescence is observed on adding the diluted oil of vitriol, then filter the mixture through paper, or let it stand to depurate: then decant and evaporate to a pellicle, and set it by to crystallize.

The *sal. cath. amar.* is nearly of the same quality with the *natron vitriolatum*, and is often substituted for it, after being shot into crystals resembling the natron vitriolatum, but though both these salts have the vitriolic acid, their bases are not the same. The *Glauber salt* hath the mineral fixed alcaline salt for its basis; but the sal cath. amar. hath the alcaline earth called *magnesia alba* for its basis. When one is imposed for the other, the deception may be detected as follows; dissolve a little of the suspected salt in water; then add to it a small quantity of a solution of any fixed alkaline salt; let both these solutions be clear; if no change happens on the mixture, the suspected salt is the genuine *Glauber salt*; but if a milky turbidness succeeds, which after a while falls in the form of a powder, it is the sal cath. amarum.

The true natron vitriolatum is apt to lose so much of its water as to become opake, and at length, if kept in a dry place, it falls into a white powder. It is applied externally in the following form.

CATAPLASMA NATRI VITRIOLATI. *Cataplasm of vitriolated Natron.*

℞ Natri vitriolati ℥ i. aq. ferventis lb ss. micæ panis q. s. misce. This is said to be particularly useful in those inflammations of the eye, where the secretions are deficient. The form is attributed to Dr. KIRKLAND.

In small doses plentifully diluted with water, it is aperitive, and diuretic; in larger ones, it is diuretic and cathartic; as a purge it is given from ℥ ss. to ℥ ii. and if it is diluted in water, from one pint to two should be made use of; it answers every purpose of the Epsom and other such purging waters. It is cooling, and checks the vis vitæ so much, that Dr. Alston observes it to be a specific in hæmorrhages from a rarefaction of the blood. Some surgeons wash gangrenes with a solution of it in vinegar. But on the other hand, a too free use of it hath often produced palsies and dropsies, which no means could remove, so that prudence is required in the administration of it. See Lewis's Mat Med. and Dict. of Chem. For many curious properties discovered in this salt, see Glauber, Boyle, Becher, and Stahl.

GLAUCIUM. See PAPAVER SPINOSUM.

GLAUCOMA, GLAUCOSIS, or GLAUCEDO, from γλαυκος, *a sky-blue colour*, or from γλαυξ, *an owl*, whose eyes are of that colour. Mr. Sharp, in his Operations of Surgery, p. 158—163, says, that the *glaucoma* of the ancient Greeks is the *suffusio* of the Latins, and the cataract of the present times. See CATARACTA. Mr. St. Yves says, it is a cataract accompanied with a gutta serena; called *cataracta glaucoma*, according to which nothing need be added, except that, in such a case, the operation and all other means are useless, unless to ease pain, and to mend the figure of the eye. See Wallis's Sauvages, on the Eyes, p. 221.

GLAUCOMA VOGELII. See CALIGO HUMORUM.

—— WOOLHOUSII, MAITRE JEAN, S. IVES. See CALIGO LENTIS.

GLAUCOSIS. See CATARACTA.

GLAURA. See SUCCINUM.

GLAUX VULG. LEGUMINOSA; also called *astragalus*; *glycyrrhiza sylvestris flore luteo*; *fœnum Græcum sylvestre*; *hedysarum glycyrrhizatum*. LIQUORICE VETCH. It grows in thickets and about buthes, and under hedges; it flowers in July: the herb and seed are commended for increasing the milk in women's breasts; the root is sweetish, astringent, and diuretic, but it is very rarely used. This plant is often sold for the galega. Raii Hist.

GLECOMA HEDERACEA. See HEDERA TERREST.

GLECHON. See PULEGIUM VULG.

GLECHONITES. Wine impregnated with penny-royal.

GLENE, γλην, *the socket of the eye*. Properly, it is the cavity of the eye, and the pupil; but it is used to express any slight depression, or cavity of a bone, which receives another bone in articulation. *Cotyle* is such a cavity, but deeper. See OS.

GLENOIDES. The same as *glene*; but, particularly it is an epithet for two cavities, or small depressions in the inferior part of the first vertebra of the neck.

GLEUCINUM OLEUM. GLEUCINE OIL. It was formerly made by infusing several aromatic vegetables in wine and olive oil.

GLEUCOS. MUST; and sometimes it signifies sweet wines. See MUSTUM.

GLEUXIS. Wine in which is much sapa, or defrutum.

GLISCHROCHOLOS. An epithet for bilious viscid excrements.

GLISOMARGO. See CRETA ALBA.

GLOBULARIA FRUTICOSA. See ALYPIA.

GLOBUS HYSTERICUS. In hysteric disorders a globe seems to ascend from the stomach, or from the breast, into the throat, and almost suffocates the patient; this seeming ball is a spasmodic affection, produced by the spasm of the upper orifice of the stomach when relaxed, and the air rushing up into the œsophagus, where it is confined in consequence of a spasm in the muscles of this part. In violent attacks for immediate relief, put the feet in warm water, and give an opiate.

GLOSSA. See LINGUA.

GLOSSAGRA. A rheumatic pain in the tongue.

GLOSSOCATOCOS, from γλωσσα, *tongue*, and κατεχω, *to repress*. An instrument in P. Ægineta for depressing the tongue.

GLOSSOCELE. An EXTRUSION of the TONGUE.

GLOSSOCOMA. A RETRACTION of the TONGUE.

GLOSSOCOMON. Properly a case for the reeds of an hautboy, from γλωσσα, *a tongue*, and κομεω, *to guard*: or GLOSSOCOMION. An instrument or case for containing a fractured limb.

GLOSSO-PHARYNGÆI. These muscles are fibres which come from the tongue, running along its lateral edges, from which they are parted backward, and run down on the sides of the pharynx, under the stylo-pharyngæi. See PHARYNX. Also a name of the *cephalo-pharyngæi*.

GLOSSO-STAPHYLINI. These two muscles are fixed in the lower and lateral part of the basis of the tongue, whence they run up obliquely backward, along the anterior half arches of the septum palati, and terminate insensibly on each side near the uvula. The thickness of the two anterior arches of the palatum molle is occasioned by these.

GLOTTA. See LINGUA.

GLOTTIS, from γλωττα, *the tongue*. It is the narrow slit at the upper part of the aspera arteria, and covered by the epiglottis when we hold our breath, and when we swallow. The *glottis*, by its dilatation and contraction, modulates the voice.

GLUMA, (from γλυφω, *to scrape*, or *bark*.) HUSK, CHAFF; a species of calyx peculiar to corn, or grass, infolding the arista; it may be uniflora; multiflora; univalvis; bivalvis; multivalvis; colorata; glabra; hispida. BERKENHOUT's Botanical Lexicon.

GLUS. See DYSENTERIA MUCOSA.

GLUTÆA ARTERIA. It is a branch of the HYPOGASTRIC ARTERY, and generally the largest; near its beginning, it sometimes sends out the iliaca minor, and sometimes the small branch that goes from that artery to the os sacrum, and other parts fixed to that bone; afterwards, this artery passes out of the pelvis, in company with the sciatic nerve, through the upper part of the great sinus of the os innominatum, below the musculus pyriformis,

pyriformis, and is distributed in a radiated manner to the three glutæi muscles. In its passage it gives branches to the os sacrum, os coccygis, the musculus pyriformis, the muscles of the anus, and to the neighbouring parts of the rectum, forming a particular hæmorrhoidalis interna. It sends twigs to the bladder, and parts near it; and detaches a pretty long branch, which runs down along with the sciatic nerve.

GLUTÆUS MAXIMUS. Brown calls it *glutæus major*. This muscle rises from the posterior lateral part of the os coccygis, from a ligament which is extended between the os sacrum and os coccygis, from the flat surface of the ileum, where it is connected to the os sacrum, and from the spine of the ileum. Its anterior portion grows tendinous, where it runs over the trochanter major, and makes part of the fascia of the thigh. Its posterior portion is inserted into the hind part of the femur, serving to extend it. This muscle, with the glutæus medius and glutæus minimus, make up the fleshy part of the buttocks; whence their name.

—— MEDIUS. It rises as high as the spine of the os ilium, and is inserted into the very uppermost part of the trochanter major, serving to bring the thigh backward and outward.

—— MINIMUS. It rises rather lower than the preceding, and forms a middle tendon, which is inserted into the trochanter major, blended with the medius. It is an abductor of the thigh.

GLUTIA. See CEREBELLUM.

GLUTOS. A BUTTOCK, from γλουτος, *buttock*.

GLUTTUPATENS. An epithet for the stomach, because the saliva, or any liquids drank, are swallowed, *crebris glutis*, by frequent gulps.

GLYCYMERIDES MAGNA. See CHAMA.

GLYCYPICROS. WOODY NIGHT-SHADE.

GLYCYRRHIZA, called also *liquiritia*; *dulcis radix*; and *adipson*; LIQUORICE. It is the GLYCYRRHIZA GLABRA, or GLYCYRRHIZA *foliolis ovatis, impari petiolato, stipulis nullis, floribus pallide cæruleis, leguminibus glabris*. CLASS, DIADELPHIA. ORD. DECANDRIA. LINN. Gen. Plant. 882. SMOOTH LEGUMENED, or COMMON LIQUORICE. It is a plant with oval leaves, set in pairs along a middle rib; the flowers are small, bluish, and papilionaceous, standing in spikes or naked pedicles; the flower is followed by a smooth pod, containing flat kidney-shaped seeds; the root is long, slender, flexible, of a brownish colour on the outside, and yellow within. This plant is perennial, a native of the southern parts of Europe, and plentifully cultivated in England. The roots may be taken up the third year after the slips or off-sets have been planted.

The English *liquorice* is as good as any of the foreign: the root, when carefully dried and powdered, is of a richer and more agreeable taste than when fresh, and of a dull yellow colour, with a cast of brown; but what is commonly sold is adulterated by a mixture of flour. The dry root is as good as the fresh; the fresh may be kept from drying, if buried in dry sand; wet sand rots it.

Liquorice is almost the only sweet that quenches thirst; and for this quality the Greeks call it *adipson*. But this is supposed more to arise from long chewing the root, which brings out the acid and bitterish taste from the root, stimulates the mouth and fauces, and thus acts by producing a flux of saliva. If it is mixed with other unpalatable medicines, it covers their offensive tastes; it is the least disposed to ferment, of any of the sweets: it has been esteemed attenuant, detergent, diuretic, expectorant, and also demulcent; though by some it is only allowed to have properties similar to sugar, and considered as a pectoral and emollient, in catarrhal defluxions on the breast, tickling coughs, hoarsenesses, &c. It gives out all its virtue to water; but as spirit dissolves less of the mucilage, the spirituous tincture and extract are the sweetest.

Extractum, vel succus GLYCYRRHIZÆ. *Extract or juice of* LIQUORICE.

This *extract* would be best made, by pressing the fresh roots betwixt iron rollers, and then the juice might soon be inspissated without the loss of any of its virtue.

This *extract* is adulterated by mixing the pulp of prunes with it. See Lewis's Mat. Med. Cullen's Mat. Med. Neumann's Chem. Works.

The College of Physicians of London order this extract to be made in the same manner as that of camomile. See CHAMÆMELUM.

GLYCYRRHIZA SYLVESTRIS FLORE LUTEO. See GLAUX VULG. LEGUMINOSA.

GLYCYRRHIZÆ TROCHISCI. See BECHICA.

GNAPHALIUM. CUDWEED, called also *albinum*. Boerhaave enumerates seven species under the name of *filago*. Blanchard says, it is the *centunculus*.

—— ALPINUM. See LEONTOPODIUM.

—— LUTEUM. See ELYCHRYSUM.

—— MARITIMUM, called also *gnaphalium* marinum, *gnaphalium* cotonaria; COTTON-WEED, or SEA-CUDWEED.

All the species of *cudweed* are drying, and esteemed for stopping fluxes and hæmorrhages.

—— MONTANUM; also called *pes cati*; *hispidula*; *elichrysum montanum flore rotundiore*; *helychrysum montanum*; *pilosella minor*; MOUNTAIN CUDWEED, or CAT'S-FOOT. It is very common in France, &c. A syrup made of it hath been noted there, under the name of *syr. de hispidula* seu *æluropo*.

—— VETERUM. A species of BASTARD DITTANY See PSEUDO-DICTAMNUS.

GNATHOS. Sometimes it signifies the entire cheek, sometimes only the lower part, between the angles of the mouth and ear, which the Latins call *bucca*; it sometimes is used to express the jaws and the jaw-bones.

GNIDIA GRANA. See CNIDIA GRANA.

GOACONEZ. The name of a large tree in America; it affords the balsamum purius, vel album, vel Americanum. See Raii Hist.

GOAN. The name of a tree in Persia, of whose ashes a sort of putty is made.

GOBIUS. The fish called the GUDGEON. See AMYGDALOIDES.

GOHCATHU. See GAMBOGIA.

GOMPHIASIS. See AGOMPHIASIS.

GOMPHIOI. See MOLARES.

GOMPHOMA, from γομφος, *a nail*, GOMPHOSIS, or ENGOMPHOSIS, from γομφος, a Greek term, for that species of synarthrosis which resembles a nail driven into a piece of wood, of which the teeth in their sockets are an instance, called also *clavatio*.

GONAGRA, from γονυ, *a knee*, and αγρα, *a pain*, also called *gonyalgia*. The GOUT in the KNEE.

GONE. The SEED. But in Hippocrates it is the *uterus*.

GONGRONA, from γογγος, *a round tubercle in the trunk of a tree*. Any hard round tumor of the nervous parts, but particularly a *bronchocele*, or other hard tumor of the neck.

GONGYLION. See PILULA.

GONOIDES, from γονη, *seed*, and ειδος, *form*. Resembling seed. Hippocrates often uses it as an epithet for the excrements of the belly, and for the contents of the urine, when there is something in them which resembles the seminal matter.

GONORRHŒA, from γονη, *seed*, and ῥεω, *to flow*, is an involuntary efflux of seminal juice. Dr. Swediar observes, that this name is improperly applied to the disease known by it. He proposes, if a Greek word is necessary, to name it *blennorrhagia*, from βλεννος, *mucus*, and ῥεω, *to flow*, i. e. *mucifluxus activus*; and thus he distinguishes it from the real *gonorrhœas*, and from gleets, to which latter he gives the name *blennorrhœa*, *mucifluxus passivus*, i. e. *without phlogistic symptoms*.

Some reckon three species of this disorder. 1st. A simple *gonorrhœa*, also called a benign *gonorrhœa*, and a gleet. 2dly. A virulent or venereal *gonorrhœa*; improperly so called from its resemblance to the preceding. 3dly. An involuntary efflux of a whitish fluid from the urethra, in consequence of a venereal *gonorrhœa*. Dr. Cullen places this genus of disease in the CLASS LOCALES, and ORDER APOCENOSES; which he defines a preternatural flux of fluid from the urethra in males, without any libidinous desires. He distinguishes four species. 1. *Gonorrhœa* pura, called also *benigna*, when, without venereal engagements, a purulent discharge is observed from the urethra, without dysuria, or lascivious inclination. 2. *Gonorrhœa impura*, called also *maligna*, *syphilitica*, when, after impure coition, there is a purulent discharge from the urethra, with heat of urine, &c. to which oftentimes succeeds a discharge of mucus, with little or no dysury, from the urethra, called a GLEET. 3. *Gonorrhœa laxorum*, also called *libidinosa*, when there is a pellucid discharge from the urethra, without erections of the penis, but with venereal thoughts while

awake. 4. *Gonorrhœa dormientium*, called alſo *oneirogmos*, when during ſleep, but, in dreaming of venereal engagements, there are erections of the penis, and conſequent ſeminal diſcharges.

The benign *gonorrhœa* is defined by Dr. Fordyce, in his Elements of the Practice of Phyſic, part the ſecond, to be "an increaſed ſecretion from the mucous glands of the urethra, without infection." The matter diſcharged is whitiſh and mild, producing no excoriation or other diſorder on the parts through which it paſſes, or on which it falls.

The principal cauſe is a weakneſs in the parts, which are the ſeat of the diſorder; occaſional cauſes are acrimony in a cacochymic, ſcorbutic, or arthritic habit, violent or too frequent purging, violent exerciſe, too frequent coition, cold, exceſs of ſpirituous liquors, &c.

Dr. Swediar well obſerves, that the virulent *gonorrhœa* is a local inflammation, attended with the diſcharge of a puriform matter from the urethra in men, and from the vagina in women; accompanied with a frequent deſire of making water, which occaſions a ſcalding, or pricking and burning pain, during the time of its paſſage; and ariſing from any ſtimulus applied to theſe parts, provided it be ſufficiently ſtrong. Sometimes, by the violence of the irritation, the ſecretion of mucus ſeems to be totally ſuſpended, or at leaſt conſiderably diminiſhed, ſo that no diſcharge, or only a very ſmall one, takes place, though the other ſymptoms rage with the utmoſt violence. In this caſe the diſeaſe hath obtained the very improper name of *gonorrhœa* ſicca. He adds, though the matter (i. e. of the diſcharge) hath a purulent appearance, it is not a real pus; it is only the mucus of the urethra or vagina ſecreted in a larger quantity than uſual, and changed in its colour and conſiſtence by the ſtimulus applied to the parts; like the mucous diſcharge from the noſe or lungs, on taking cold, where the mucus aſſumes nearly the ſame appearance. That the diſcharge from the urethra, &c. is only an increaſed diſcharge of the mucus of the parts, hath been ſome time ſuppoſed, but is firſt rendered undoubted by Dr. Stoll, of Vienna, with which evidence Dr. Swediar hath favoured us, by a note in his valuable publication on this ſubject. It is as follows: Dr. Stoll had, about the year 1782, the inſtructive opportunity of diſſecting a man who died while labouring under a virulent *gonorrhœa*. On opening the urethra carefully, he found its internal ſurface preternaturally red; two of the lymphatics preternaturally white and enlarged; and the puriform matter oozing out from the internal membrane, eſpecially at the lacuna, where the ſeat of the diſorder was, without the leaſt appearance of an ulceration or excoriation."

When this complaint is the conſequence of a venereal taint, the matter of the diſcharge is commonly adheſive and whitiſh, and capable of communicating infection, though the inflammatory ſymptoms are entirely carried off; though ſome ſay it is incapable of communicating infection, even when the inflammatory ſymptoms are not entirely removed. See LUES VENEREA. When it takes place from any other cauſe, it begins with a running nearly ſimilar to that in a venereal *gonorrhœa*, but generally leſs in quantity, and is not attended with ſo much inflammation, and is never infectious. In both caſes, the inflammatory ſymptoms may, by expoſure to any of the cauſes, be increaſed to as great a degree as when there is infection; but they go off of themſelves in a few days, and ſometimes the running with them. The running ſometimes ceaſes of itſelf in a week or two; ſometimes it continues for years without any detriment to the patient; and now and then a caſe occurs, in which the patient is much weakened by it; for when it occaſions involuntary emiſſions of ſemen, it may be fatal.

It is the moſt obſtinate after a venereal taint, in phlegmatic habits, and in thoſe who, when young, were ſubject to catarrhous defluxions; for the fibres of ſuch perſons are very lax. When it is attended with a chordee, it is named GONORRHŒA CHORDATA. Sometimes it reſiſts all means, and at laſt departs ſpontaneouſly.

The indications of cure are, 1. To deſtroy the venereal virus. 2. To defend the parts from its acrimony. 3. To abate the irritation which it occaſions.

To anſwer theſe ends, oleous and mucilaginous injections are well adapted, particularly if they have opium, and the mildeſt mercurial preparations, combined with them.

A mild regimen, in all reſpects, is the moſt proper; mucilaginous drinks, as the almond emulſion and ſuch like, ſhould be plentifully taken; and if required, an anodyne may be given at bed-time. Much and ſtrong exerciſe, and external cold, are to be avoided. Thoſe of a leſs robuſt frame may be leſs ſparing in their diet, and be not ſo abſtemious with reſpect to cordial liquors.

If the venereal taint gave riſe to it, and mercury hath been either not uſed at all, or in an undue quantity; or if there is ſuſpicion of any remaining infection, the ſafeſt method is to begin the cure by a mercurial courſe.

If ſymptoms of an inflammatory fever appear, bleeding may ſometimes be uſeful; but, in general, more ſervice will be derived from topical evacuations of blood, and from emollient and ſedative fomentations and poultices. Dr. Swediar obſerves, that on the other hand, when the patient is of a weak and irritable habit of body, the diſcharge very thin and copious, attended with violent pains and quick pulſe, the cort. Peruv. given internally, according to circumſtances, with or without opium, is the moſt uſeful adminiſtration; and that opium given in emollient clyſters is ſometimes particularly uſeful in theſe caſes: it allays or prevents the frequent painful erections, the return of which ſhould be prevented as much as poſſible.

To prevent the more violent ſymptoms, the patient ſhould, from the beginning of the diſeaſe, wear a bag-truſs, or other means to keep the ſcrotum ſupported and warm.

Neutral ſalt, and other purgatives than thoſe which keep the bowels lax, are injurious.

When the ſymptoms are more exaſperated, as when the heat of urine is great, a tenſion is perceived in the length of the urethra, the urine is only paſſed by a few drops at a time, erections are frequent, pains ſhooting through the urethra, ſtreaks of blood paſſing with the urine, or other ſigns of ulceration; in this ſituation, beſides what is already recommended, mercurial frictions will be neceſſary along the perinæum, and the inſide of the thighs.

The ſame treatment will be proper when the diſcharge, during the inflammatory ſtage, is ſuppreſſed, and a hernia humoralis is threatened or hath taken place.

If a ſcorbutic or other acrimony is the cauſe, allay it at leaſt before ſtrengtheners are begun with.

When no circumſtance, beſides a weak habit, requires our notice, an infuſion of the bark in red wine may be given to two ounces three times in the day; and other means of ſtrengthening the general habit may be uſed.

Sometimes it happens that the cold bath increaſes the running; but when there is neither plethora, nor a bad habit of body, nor any other contraindication, the patient may go into the bath every morning and evening; and after each immerſion he may go into bed; and, whilſt there, he may drink two cups of ſome warm infuſion, by which the humours will be derived to the ſkin.

Reſinous aſtringents, ſuch as the balſ. capivi, &c. may be given three or four times a day; but in inflammatory habits much caution is required, to avoid the exciting any new degree of inflammation.

The following injection may be uſed at proper intervals during two or three weeks. ℞ Aq. pur. vel aq. calcis ſi. ℥ vj. pulv. e ceruſ. c. ʒ i. zinci vitriolati purificati, gr. x. ad ʒ ſs. m. See ÆRIS, vel VENERIS TINCT. alſo the article INJECTIO, under which are given many formulæ.

GOSSUM. See BRONCHOCELE.
GOTTA. See GAMBOGIA.
GOUI. See BAOBAB.
GOUTIER. See BRONCHOCELE.

GRACILIS. The name of ſome muſcles; ſo called from their thinneſs and flatneſs.

—— INTERNUS. See RECTUS INTERNUS.

—— ANTERIOR. See RECTUS CRURIS.

GRADATIO. GRADATION. It is an exaltation of the qualities of metals in degree, by which their weight, colour, and conſiſtence are chiefly brought to a degree of perfection, for it has not the power of changing the ſubſtance by itſelf, but only produces their qualities, or quantities, and makes them from a hidden ſtate more manifeſt, their former ſpecies nothing changed; but if nature gives white gold, *gradation* makes it red; if volatile, fixes it; if impure, purifies it. Rulandus, Johnſon. See EXALTATIO.

GRAMEN. GRASS. Tournefort enumerates eighty-ſix ſpecies; and others add many more. See SCEUCHZER'S AGROSTOGRAPHIA.

Graſſes are one of the ſeven natural families, into which all vegetables are diſtributed by Linnæus. They are defined to be plants which have very ſimple leaves, a jointed ſtem, a huſky calyx, termed *gluma*, and a ſingle ſeed. In Tournefort, they conſtitute a part of the fifteenth claſs, termed *apetali*; and in the ſexual ſyſtem of Linnæus, they are moſtly contained in the ſecond order of the third claſs, termed *triandria digynia*. Wheat, oats, barley, and rye, are *graſſes* improved by culture. It is alſo a name for ſeveral ſorts of *triticum*. MARTYN ſays, graſſes are the fifth family, and the ſecond nation, tribe, or caſt in Linnæus's general diviſion of the vegetable kingdom: the fourteenth order, in the fragments of a natural method in *Philoſoph. Botan.*—and the fourth of the natural orders at the end of *Gen. Plant.* In the artificial ſyſtem, moſt of the graſſes are contained in the ſecond order of the fifth claſs.

—— AVENACEUM. See ÆGYLOPS.

—— CANINUM; alſo called *gramen* Dioſcoridis; *gramen* repens; *gram.* loliaceum radice repente; QUICK GRASS; COUCH-GRASS; and DOG'S GRASS. The French call it *chien-dent*. It is the TRITICUM REPENS Linn. It is a creeping *graſs*, of a whitiſh green colour, with knotty ſtalks, bearing a ſpike of imperfect flowers ſomewhat reſembling a wheat-ear; the roots are whitiſh, or a pale yellow, long, ſlender, jointed at diſtances, variouſly bent and interwoven. It is perennial. Scheuchzer deſcribes ſixteen ſorts of this *graſs*.

The roots are ſweetiſh, mildly aperient in obſtructions of the viſcera, diluent, deobſtruent, diuretic, of uſe in ulcers of the bladder, difficulty of urine, and the ſtone in the gall-bladder. But in order to any good advantage, Boerhaave's direction to take ſome pints of the expreſſed juice of freſh roots every day, muſt be attended to; he obſerves, that ſheep and cattle, when afflicted with the ſtone, indurations of the liver, &c. in winter, are relieved in ſpring by the freſh *graſs*, which produces a diarrhœa at the firſt, and then a reſolution of obſtructions, &c.

—— CRUCIS,
—— CYPERIOIDIS,
—— ÆGYPTIACUM.

} Alſo NEIEM-EL-SALIB. Are roots in medicine named *cyperi*; the long and round; and the plants which produce them both, grow in watery places, and have leaves and flowers, in ſome meaſure reſembling the water-*graſſes*, hence called cyperus-*graſſes*. ÆGYPTIAN COCK'S-FOOT GRASS, or GRASS of the CROSS. The roots and plants are poſſeſſed of the ſame virtues as attenuants, deobſtruents, diuretics, emmenagogues, and ſtomachics, and are ſerviceable in the earlier ſtages of dropſy; they cure ill-ſcented breaths, are good in nephritic diſorders, in colics, and uterine complaints. They are taken in powder and decoction, though the preſent practice diſregards them.

—— DACTYLON; alſo called *dactylon radice repente*; *gramen dactyloides*; *gramen canarium iſchæmi paniculis*; *gramen legitimum*; COCK'S FOOT GRASS.

It grows in fields and vineyards, in ſandy places: its virtues are the ſame as thoſe of *dog's graſs*. See GRAMEN CANINUM.

—— DACTYLON AROMATICUM. See JUNCUS ODORATUS.

—— LOLIACEUM. See LOLIUM.

—— MANNÆ; alſo called *gram.* dactylon eſculentum; *iſchæmon ſativum*: RUSSIA SEED, and MANNA-GRASS. It grows in Germany and Poland; its ſeeds are uſed; they are ſmall, oblong, pellucid, white, of a faint taſte, and, when decorticated, they reſemble, and are found to poſſeſs the ſame qualities as rice.

GRAMEN PARNASSI. See PARNASSIA.

—— SPICATUM. See PHALARIS.

GRAMIA. The ſordes of the eyes.

GRAMINULÆ. TADPOLES.

GRAMMA. See SCRUPULUS.

GRAMME. See IRIS.

GRANA INFECTORIA. KERMES. See CHERMES.

GRANADILLA PERUVIANA. See CATAPUTIA MAJOR.

GRANAL. An evergreen tree in America, of a poiſonous quality.

GRANA PONDUS. A grain weight. It is the weight of a wheat-corn.

—— RAGIUM. See CATAPUTIA MAJOR.

—— TIGLIA. See CATAPUTIA MINOR.

GRANATA MALA. GRANATUM. Alſo called *mala punica*; *malus punica*; *punica*; *malum granatum*; *malicorium*; POMEGRANATE. It is the PUNICA GRANATUM, or PUNICA SYLVESTRIS ITALICA, *foliis lanceolatis, caule arboreo*. CL. ICOSANDRIA. ORD. MONOGYNIA. LINN. Gen. Plant. 618. It is a prickly tree, or ſhrub, with long narrow leaves, deep red flowers, ſet in bell-ſhaped cups of the ſame colour; the fruit is about the ſize of an orange; it conſiſts of a thick, tough rind, externally browniſh, and internally yellow, with a juicy pulp, and numerous ſeeds, called *coccones*, in cells like a honey-comb. It is a native of the ſouth parts of Europe.

The flowers are a mild aſtringent, ſimilar to thoſe of the wild *pomegranate*; which laſt are preferred only on account of their being larger. The pulp of the ripe fruit is a grateful ſubacid ſweet, and of the ſame general qualities as the ſummer fruits. The rind is moderately aſtringent, and is called *cortex granati*; *malicorium*; *pſida*; *pſidium*, and *ſidium*: its gives its virtue out moſt abundantly to water, but the flower yields it moſt freely to ſpirit. Dr. Cullen aſſerts, that the ſtrong ſtyptic taſte of this bark, and the black colour it ſtrikes with green vitriol, ſhew ſufficiently its aſtringent power; and it is commonly ſuppoſed to be among the ſtrongeſt of this kind. He has frequently found it uſeful in gargles; in diarrhœas; and in external applications; nor does he think it, internally uſed, more dangerous than others: from its powerful aſtringency, and with regard to ſuppreſſing the catamenia, that ſeems to him to be very doubtful. Its doſe, in powder, is from 3 ſs. to 3 j. in infuſion, or decoction, to half an ounce. See RAII Hiſt. LEWIS'S, and CULLEN'S Mat. Med.

GRANATRISTUM. See CARBUNCULUS.

GRANATUS SYLVESTRIS. See BALAUSTIUM.

GRANDEBALÆ. The hairs under the arm-pits.

GRAND-GOR. See LUES VENEREA.

GRANDINES. Tumors on the eye-lids reſembling hail-ſtones. See CHALAZA.

GRANDINOSUM, (from its reſemblance to an hail-ſtone.) OS. See CUBOIDES OS.

GRANDO. See CHALAZA. CRITHE.

GRANULATIO. It is a reduction of metals into ſmall grains, ſee COMMINUTIO; and the raiſing of the fleſhy parts in ulcers in a healing ſtate.

GRANUM MOSCHI. See ABELMOSCHUS.

GRAPHIOIDES, from γραφις, *a pencil*, and ειδος, *a form*. See STYLIFORMIS PROCESSUS. It is alſo a name for a proceſs of the ulna towards the wriſt.

GRAPHISCUS. An inſtrument for extracting darts with. Diocles invented it, and Celſus deſcribes it.

GRAPHOIDES, or STYLIFORMIS, from γραφις, *ſtylus*, becauſe of its ſuppoſed origination from the proceſs of the temple bone, ſo called. See BIVENTER MUSCULUS.

GRAPHOY. BROAD-LEAVED LEOPARD'S BANE. See DORONICUM GERMANICUM.

GRATIA DEI. A name of the HERB-ROBERT, of the HEDGE-HYSSOP, and of ſeveral other vegetables. See GERANIUM ROBERTIANUM. GRATIOLA.

—— DEI GERMANORUM. See GERANIUM BATRACHIOIDES.

GRATIOLA; alſo called *digitalis minima*; *gratia Dei*; *centaurioides*; WATER-HYSSOP, and HEDGE-HYSSOP. GRATIOLA OFFICINALIS, or GRATIOLA *flori-*

bus

bus pedunculatis, foliis lanceolatis ferratis. CLASS, DIANDRIA. ORD. MONOGYNIA. LINN. Gen. Pl. 29. It is a low plant, with finely ferrated leaves, ſet in pairs on the ſtalks without pedicles; the flowers are whitiſh, jointed, and ſurrounded with fibres. It is perennial; a native of the ſouth of Europe; but it is raiſed in our gardens.

The leaves have a nauſeous, bitter taſte, but no remarkable ſmell; they purge briſkly, and vomit alſo; 3 i. of the dry herb, infuſed in wine and water, is a full doſe; 3 ſs. in powder: a ſlight decoction of it in milk operates the moſt mildly; an extract made with wine is given to two ſcruples, or 3 i. and is ſaid to be more efficacious than the plant itſelf. Kramer ſays, that this root is ſimilar to ipecacuanha, and equally uſeful in *diarrhœas* and *dyſenteries*; he ſays it cures *intermittents*, and is preferable to the decoction of the woods in the *lues venerea*. See Raii Hiſt. Lewis's Mat. Med. It has been ſaid to be a powerful *promoter of urine* and *ſweat*, *purging* and *vomiting alſo at the ſame time*; and has been beneficial in *mania*, *gonorrhœa*, *ozena*, ulcers in the fauces, &c. Edin. Med. Com. vol. v. p. 6.

GRATIOLA CŒRULEA. See CASSIDA.

GRATTERONA. See APARINE.

GRAVATIO. See CAROS.

GRAVATIVUS. An epithet for a ſort of pain attended with a ſenſe of weight.

GRAVEDO. A COLD. *Gravedo* imports a pain in the head with a ſenſe of heavineſs, or ſuch a running from the noſe as is experienced when we take *cold*; it is the ſame with catarrhus and coryza. Celſus tranſlates κόρυζα, by the word *gravedo*; and Cœlius Aurelianus tranſlates it by the words *catarrhus ad nares*. PLINY applies this term to that diſeaſe, called *caros*. But it is, moſt properly, that weight or liſtleſſneſs which accompanies a leſſened tranſpiration, or taking of *cold*, as it is commonly called; and, as Dr. Cullen obſerves, is generally a ſymptom of catarrh.

By a *cold*, is generally underſtood a ſudden check of perſpiration, from an improper expoſure to cold; the conſequences of which, whilſt confined to the general notion, are the ſame as attend the leſſer degrees of a catarrh: in its further advances, it is productive of fevers, conſumption, and other diſorders, both troubleſome and dangerous.

Perſons who eaſily take cold ſhould uſe frequently moderate exerciſe, and take ſuch medicines as increaſe the vigour of the circulation, and ſtrengthen the general ſyſtem: the too great irritability of their conſtitutions may be diminiſhed by opium, bark, reſiding in dry *cold* places, &c. The diſpoſition to take *cold* may be in a good degree leſſened, by gradually acquiring the habit of being expoſed to ſudden changes of *heat* and cold.

Beginning diſorders of this kind are much and ſpeedily relieved by immerſing the feet in warm water, juſt before going to ſleep. See Catarrhus; alſo, on the ſubject of taking *cold*, Dr. Fordyce's Elements, in the article CATARRH; Heberden's Obſerv. in the Lond. Med. Tranſ. vol. ii. p. 521, &c. and Dr. Stern's Advice to the Conſumptive, &c. edit. 7. p. 9, &c.

GRAVIDITAS. PREGNANCY. Alſo an extraordinary diſtenſion of the abdomen during *pregnancy*.

GRENETTE. See SANTONICUM.

GRESSURA. See PERINÆUM.

GRIELUM. See HIPPOSELINUM.

GRINDERS' ROT. *Scythe-grinders* are ſubject to a diſeaſe of the lungs, from the particles of ſand mixed with iron duſt; and this diſorder is among themſelves called by this name.

GRIPHOMENOS. Pains which go from the loins to the hypochondres.

GROSSULARIA, alſo called *uva criſpa*, and GOOSEBERRY BUSH. It flowers in April, and its fruit ripens in July. The unripe fruit is ſaid to abate the longings of pregnant women.

GROSSULARIA *non ſpinoſa*. See RIBES.

GROSSUS. See FICUS SATIVA.

GRUMUS. A concentrated clod of blood, milk, &c.

GRUTUM. A ſort of groſs oatmeal.

GRYPA. An ointment deſcribed by N. Myrepſus.

GRYPHIUS PES. An inſtrument mentioned by Parey for extracting a mole from the uterus.

GRYPHUS. See ADAMAS.

GRYPOSIS. An incurvation of the nails.

GUABAM. A ſweet cooling fruit which grows in the Weſt Indies. See Raii Hiſt.

GUACATANA, alſo called *ſcrophularia Indica*. It is a plant which grows in New Spain. A cataplaſm of it eaſes the piles. See Raii Hiſt.

GUACU. See CERIPIRA BRASILIENSIBUS.

GUAIABARA. A tree that grows in Hiſpaniola; the Spaniards call it *uvero*; the leaves are large, and uſed as paper.

GUAIACUM. GUYAC. Alſo called *guaiacon*, *hagioxylon*, *lignum benedictum*, *vitæ lignum*, *palus ſanctus*, *palma ſancta*, *euonymo affinis occidentalis*, *ibirace*, &c. The blacker ſort the Americans call *hiacan*, or *huiacan*; that which is mixed with yellow they call *hoaxecan*. The ſpecies uſed in medicine is the GUAIACUM OFFICINALE, or GUAICUM JAMAICENSE, *foliolis bijugis obtuſis, flore cæruleo, fructu ſubrotundo*, CL. DECANDRIA. ORD. MONOGYNIA. LINN. Gen. Plant. 518. COMMON GUAIACUM, or POCKWOOD.

ULRIC HUTTEN ſays this wood was introduced into Europe in 1517; but BRASSAVOLUS ſays, not until 1525. It is brought from Jamaica, Mexico, and other parts of the Weſt Indies, particularly from the Antilles. It is brought over in large pieces, each weighing from four to five hundred weight; it is hard, compact, and ſo heavy as to ſink in water; the outer part is often of a pale yellowiſh colour, but the heart is blacker, or of a deep brown. Sometimes it is marbled with different colours. It hath little or no ſmell, except when heated, and then a ſlight aromatic one is perceived. When chewed, it impreſſes a mild acrimony, biting the palate and fauces. Its pungency reſides in its reſinous matter, which it gives out in ſome degree to water by boiling, but ſpirits extract it wholly.

Of the bark of *guyac* there are two kinds, one ſmooth, the other unequal on the ſurface; they are both of them weaker than the wood.

In the choice of the wood, that which is the freſheſt, moſt ponderous, and of the darkeſt colour, is the beſt; the largeſt pieces are to be preferred; and the beſt method is to raſp them as wanted; for the finer parts are apt to exhale when the raſpings or the chips are kept a while.

The *guyac* wood was firſt introduced in Europe as a remedy for the venereal diſeaſe; it is a good aſſiſtant to mercury, as it warms and ſtimulates, and ſo promotes perſpiration and urine; it alſo proves a gentle purgative in a ſomewhat increaſed doſe: and theſe ſeem to be its primary virtues. When the excretory glands are obſtructed, the veſſels lax and flaccid, the habit replete with ſerous humours, in many cutaneous and catarrhous diſorders, ſome female weakneſſes, in gouty complaints, and rheumatic diſorders, it produces good effects. The hectic fever which ſometimes follows a ſalivation gives way to a decoction of the woods. *Guaiacum* is very valuable as a diaphoretic, for it ſeems to ſtimulate the exhalant veſſels more than it does the heart and great arteries; hence, ſafer than thoſe which act more powerfully on the latter parts of the ſyſtem; hence, from its action, it is juſtly eſteemed more effectual than other ſudorifics in the lues venerea; and has, on this account, been found uſeful in all caſes of rheumatiſm, and, perhaps, in the gout.

A long uſe of this medicine hath been obſerved to produce a yellowneſs of the ſkin. In thin emaciated habits, and an acrimonious ſtate of the fluids, it often does harm. It is alſo improper in hot bilious habits, and where the fibres are very tenſe.

Three ounces of the wood, or four ounces of the bark, may be boiled in lb iv. of water to lb ii. and if a little liquorice is added at the latter end of the boiling, or when the decoction is taken from the fire, it will abate the diſagreeable pungency of this medicine, which affects the throat very much in ſwallowing it. Of this decoction, at leaſt half a pint ſhould be taken in a day.

If the thin ſhavings of *guyac* are diſtilled in a retort, at firſt there ariſes a liquor which is almoſt purely water; then on increaſing the fire, an acid, reddiſh, empyreumatic liquor paſſes over with a little fluid reddiſh oil; beſides theſe, much air is ſeparated from this wood; the reſiduum is a perfect coal. A pound of *guaiacum* wood, diſtilled over an open fire, gave ʒ iii. ſs. of acid, which is called ſpirit, and ʒ i. ſs. of empyreumatic oil.

1. Extractum Ligni GUAIACI, molle & durum. *Extract of* LIGNUM VITÆ, *ſoft and hard.*

Boil lb i. of *guaiacum* ſhavings in a gallon of water until half of the liquor is waſted, repeating the operation by adding the ſame quantity of freſh water to the ſame ſhavings

ſhavings four or five times. The ſeveral decoctions paſt through a ſtrainer, are to be mixed and inſpiſſated together: when the aqueous parts are almoſt exhaled, a little ſp. vini rect. may be added, that the whole may be reduced into an uniform tenacious maſs. This extract is called ſoft when of the conſiſtence of a maſs for pills, and hard when it can be powdered. The ſpirit is added at the concluſion of the boiling, that the reſinous part may be perfectly mixed with the gummy.

Beſides the virtues attributed to *guyac* in general, the harder extract is an excellent errhine.

2. Reſina GUAIACI. *Reſin of* GUAIACUM.

It is prepared in the ſame manner as the reſin of JALAP, which ſee.

The reſin is the only active part of this wood; it is obtained pure by means of rectified ſpirit of wine both from the wood and the gum. Beſides, this gum, or rather gummy reſin, is obtained by wounding the bark in different parts of the body of the tree, from whence it exudes copiouſly; and when accumulated upon the ſeveral wounded trees, and hardened by expoſure to the ſun, it is collected, and packed in ſmall kegs for exportation. This natural reſin is never pure; and about ℥ xii. of pure reſin is obtained from ℥ xvi. of gum.

The gum, or rather reſin, is of a brown colour, partly reddiſh, and often greeniſh, brittle, having a gloſſy ſurface when broke, of a pungent taſte, affecting the tongue and palate in the ſame manner as is ſaid of the wood. The chief of what is brought to us is in irregular maſſes, of a duſky green colour. There is a ſort in drops; it is the beſt, but is very rarely met with.

In chuſing the gum, prefer thoſe pieces which have ſlips of the bark adhering to them, and that eaſily ſeparate therefrom by a few quick blows.

Neumann aſſures us, that a compoſition of colophony and balſam of ſulphur is impoſed on the unwary for true *gum guaiacum*; but the cheat is eaſily detected by expoſing it to a due degree of heat, by which the odour of the falſe is perceived to be quite different from that of the true.

It is only the wood and reſin which are in general medical uſe in Europe, and as the efficacy of the former is ſuppoſed to be derived merely from the quantity of reſinous matter which it contains, they may be conſidered indiſcriminately as the ſame medicine. Of the *gum*, or extracts, the doſe may be from gr. v. to ʒ i. which laſt purges pretty much. Theſe ſhould be diſſolved by the mediation of egg, or the mucilage of gum arabic, for otherwiſe they do not eaſily mix with the juices in the ſtomach.

3. Balſ. GUAIAC. *Balſam of* GUAIACUM.

℞ *Gum. guaiac.* lb. i. balſam. Peruv. ʒ iii. ſp. vini rect. lb. i. ſs. m. This was formerly called *polychreſtum*. DOSE from one to three drams every night and morning, in milk or any other convenient vehicle.

Tinct. GUAIACI. *Tincture of* GUM GUAIACUM.

Take of *gum guaiacum*, four ounces; compound ſpirit of ammonia, a pint and an half, digeſted for three days, and ſtrain. Pharm. Lond. 1788.

The doſe is from a ſmall tea-ſpoonful to a large table-ſpoonful two or three times a day. Dr. Dawſon frequently directs the larger of theſe doſes with great advantage in rheumatic and arthritic complaints, in which caſes, and againſt palſies from lead, he extols this tincture as almoſt a ſpecific.

See Raii Hiſt. Plant. Miller's Dict. Lewis's Mat. Med. Neumann's Chem. Works. Dict. of Chem. Cullen's Mat. Med.

GUAIANA. CORT. See SIMAROUBA

GUAJABO. } See GUAJAVA.
GUAJABO POMIFERA INDICA. }

GUAJACANA, called alſo *dioſpyros*, *faba Græca latifolia*, *pſeudo lotus*. The name of a plant, three ſpecies of which are mentioned by Boerhaave. They are not much known, but the leaves and fruit are ſomewhat aſtringent.

GUAJACUM PATAVIUM ANGUSTIFOLIUM. i. e. Guajacana.

GUAJAVA. The *guava*, *guajabo*; *guajabo pomifera Indica*. The name of a tree in the Weſt Indies, whoſe fruit is cooling and moderately aſtringent; the root is alſo aſtringent. Boerhaave mentions three ſpecies. See Raii Hiſt.

GUAO. A Weſt India tree called *thetlatian*; its juice is ſo acrid as to be injurious to thoſe who ſleep under it.

GUAPARAIBA. The MANGROVE-TREE. It grows in the Weſt Indies. It is alſo called *mangle*, and *parcuvier*. If the root is ſlit and toaſted, then applied to the punctures made by the poiſonous fiſh called *niqui*, it performs a cure. See Raii Hiſt.

GUARERVA-OBA. See CUCUMIS AGRESTIS.

GUARIRIGUIMYMIA. A ſhrub in Braſil like a myrtle. Lemery ſays its ſeed deſtroys worms.

GUASSEM. Certain black ſcorbutic ſpots mentioned by Avicenna.

GUATIMALA. See INDICUM.

GUAVA. See GUAJAVA.

GUIDONIS. BALS. See ANODYNUM BALS.

GUILAND. The abbreviation for Melchior Guilandinus de Papyro.

GUILANDINA MORINGA. See NEPHRITICUM LIGNUM.

GUITY-COROGA. See GUITY-IBA.

GUITY-IBA. A tree growing in Braſil, and bearing the fruit called *guity-coroga*, which contains a ſtone as large as a gooſe's egg, the kernel of which is aſtringent.

GULA. See ŒSOPHAGUS.

GUMA. See ARGENT. VIVUM.

GUMMA. Plur. *Gummata*, a ſort of tumor, ſo called from the reſemblance of their contents to gums. It is a tumor ariſing out of the ſubſtance of a bone; it is ſo ſoft as to yield to the finger. When theſe tumors are harder they are called *tophi*, tophs; when harder ſtill, they receive the name of *nodi*, nodes: but the hardeſt tumors in bones are *exoſtoſes*. In venereal patients ſuch tumors often happen on the head, and even in the middle of the moſt ſolid bones. They ſeem to be produced by the veſſels running between the bony laminæ being either obſtructed or inflamed, being dilated, and ſo raiſing the incumbent laminæ. Perhaps the bone degenerates too into a morbid ſoftneſs. A ſoftneſs of the bones ſometimes ſucceeds abſceſſes of the adjacent parts, and ſometimes the origin of the diſorder is lodged in the ſubſtance of the bone, eſpecially in the lues venerea; *gummata* have, however, been diſcovered, when no ſuch adequate cauſe could be obſerved. Perhaps there is an acid cacochymy, or a partial degree of what cauſes the mollities. See Petit on Diſeaſes of the Bones. LUES VENEREA. Bell's Surgery, vol. v. p. 541.

GUMMI. GUM, called alſo GISISIM. It is a concrete vegetable juice of no particular ſmell or taſte, becoming viſcous and tenacious when moiſtened with water; totally diſſolving in water into a liquid more or leſs glutinous, in proportion to the quantity of the *gum*; not diſſolving in vinous ſpirits or in oils; burning in the fire to a black coal without melting or catching flame; ſuffering no diſſipation in the heat of boiling water.

The true *gums* are, *gum arabic*, *gum tragacanth*, *gum ſenega*, the *gum* of cherry and plum-trees, and ſuch like. All elſe have more or leſs of reſin in them.

The virtues of *gums* are ſimilar to all mucilaginous ſubſtances in general, vegetable and animal; the more tenacious, glutinous vegetable productions, are called *gums*; thoſe that are leſs ſo are mucilages. The firſt diſtil naturally from trees, the ſecond are the produce of art. See Neumann's Chem. Works. When the ancients uſed the word GUMMI, or COMMI, without any other word to reſtrain their ſignification, they meant gum arabic. The Κομμι λευκον, mentioned by Hippocrates in his De Morbis Mulierum, is gum arabic.

GUMMI ARABICUM, called alſo *acanthinum gum. lamac*, *gum. Thebaicum*; *gum. Serapionis*, *comiſdi*. GUM ARABIC, and the true GUM ACACIA. It exudes from the Egyptian acacia, or thorn-tree, whoſe fruit affords the inſpiſſated juice of that name. See ACACIA. This gum is brought from Turkey in ſmall irregular maſſes, of a clear whitiſh, or very pale yellow colour.

It does not diſſolve in ſpirit, nor in oil; yet when it is ſoftened with water into a mucilage, it is eaſily miſcible with both, alſo with reſins, and renders them miſcible with water. Dr. Grew was uſed to mix eſſential oil with water by means of *gum* arabic; and in the Lond. Med. Obſ. and Inq. vol. i. a variety of experiments are inſerted, by which it appears that oils, both expreſſed and diſtilled, reſins, balſams, &c. may by the ſame means be mixed uniformly with water or with ſpirit. Alcaline ſalts both fixed and volatile, though they render pure oil miſcible with water, prevent the mixture of *gum* with oil. Acids do not in the leaſt prevent the effect of the *gum* in this particular.

Animal glues have the general qualities of the vegetable *gums*, with this difference, that the former are more nutrimental, and apt to run into a putrid ſtate. Conſidered as the ſubject of chemiſtry, their difference is very great; *thoſe of the animal kind* are changed by fire into a volatile alkaline ſalt, and a fetid oil; *the vegetable* into an acid liquor, and a very minute portion of oily matter, conſiderably leſs fetid than the former.

The medical character of *gum* arabic is its glutinous quality, in conſequence of which it ſerves to incraſſate and obtund thin acrid humours, ſo proves uſeful *in tickling coughs, alvine fluxes, hoarſeneſſes, in fluxes of the belly with gripes*, and where the *mucus is abraded from the bowels*, or *from the urethra*. *In a dyſuria* the true *gum* arabic is more cooling than the other ſimple *gums*, ſo ſhould be preferred. It is by ſome, and with apparent probability, only ſuppoſed to act as an internal demulcent in the alimentary canal, notwithſtanding the univerſally prevailing doctrine of the much greater extent of its demulcent power and action. Cullen's Mat. Med.

One ounce of *gum* arabic renders a pint of water conſiderably glutinous; four ounces gives it a quick ſyrupy conſiſtence; but for mucilage one part *gum* to two parts water, is required, and for ſome purpoſes an equal proportion will be neceſſary. See Lewis's Mat. Med. Neumann's Chem. Works.

GUMMI FUNERUM. See BITUMEN.

—— GUTTA. } See GAMBOGIA.
—— AD PODAGRAM. }

—— RUBRUM ASTRINGENS GAMBIENSE. The RED ASTRINGENT GUM from Gambia, named alſo *Kino*. Some call it *ſang. draconis offic.* or the fineſt and true DRAGON'S BLOOD. Dr. Oldfield calls it true *gum Senegal*. In the inland parts of Africa it is called *pau de ſangue*; *pau* is ſaid to be a corruption of the Portugueſe word *palo*, which ſignifies *wood*.

It is ſuppoſed to exude from inciſions made in the trunks of certain trees called pau de ſangue, which grow in the inland parts of Africa. It is very friable, eaſily breaking between the fingers; it is of an opake, dark, reddiſh colour, appearing almoſt black in the maſs, and, when powdered, it is of a deep brick red. In chewing, it firſt crumbles, then ſticks together a little, and in a ſhort time ſeems wholly to diſſolve, impreſſing a very conſiderable aſtringency, accompanied with a ſlight ſweetiſhneſs. It hath no ſmell.

It differs from the red lumps of the common *gum* Senegal in being much more brittle; and from the dragon's blood, in diſſolving in water; and from both, in having ſo remarkable a ſtypticity when taſted. It diſſolves both in ſpirit and in water; they each take up about two-thirds of it.

This *gum* ſeems calculated for uſefulneſs in many diſorders from laxity and acrimony; as in chronic diarrhœa, and leucorrhœa from theſe cauſes. It is the moſt gummy of all the aſtringent drugs, and is a powerful aſtringent, proving ſuch in ſeveral inſtances of diarrhœa; it is alſo ſerviceable in uterine hæmorrhages, and joined with alum, (as in the pulvis ſtypticus,) Ph. Edin. is conſidered by ſome as one of the moſt powerful aſtringents which they have ever employed. It is thus formed: kino, one part; alum, three parts: DOSE, from five to fifteen grains every four hours. There is alſo an aſtringent tincture, made of one dram of kino, forty grains of gum arabic, ſyrup of white poppy, q. ſ. DOSE, a tea ſpoonful occaſionally. Cullen's Mat. Med. See the Lond. Med. Obſ. and Inq. vol. i. p. 358, &c.

—— SENEGALENSE, called alſo *gum Senega*, *gum Senica*, *gum Orientale*, and *gum Senegal*. It is brought from the iſland Senegal, on the coaſt of Africa. It is ſaid to be the produce of a tree of the ſame genus with that which affords the *gum* arabic, acacia ſiliquis compreſſis, Ph. Pariſ.

Greateſt part of this *gum* is in larger and darker pieces than the *gum* arabic; it is rough on the outſide, but *gum* arabic is ſmooth: and in theſe two circumſtances conſiſts the chief known difference, except that the *gum* arabic is dry and brittle, whereas this is clammy and teſtacious.

The cleareſt pieces of *gum* Senegal are ſold for *gum* arabic; in general their qualities are the ſame; but the *gum* arabic is thought to be more cooling, and the *gum* Senegal is certainly more adheſive.

—— TRAGACANTHA, from τραγος, *a goat*, and ακανθα, *a thorn*, becauſe its pods reſemble a goat's beard; alſo called *dragacantha*; *adraganth*; *dragantum*; GUM DRAGANT, and TRAGACANTH. This *gum* exudes from a prickly buſh of the ſame name which grows in Crete, Greece, and Aſia, (*tragacantha*; or *ſpina hirci*, or *aſtragalus aculeatus*; GOAT'S-THORN.) It is the ASTRAGALUS TRAGACANTHA, or TRAGACANTHA MASSILIENSIS, *caudice arboreſcente, petiolis ſpineſcentibus*. CLASS, DIADELPHIA. ORD. DECANDRIA. LINN. Gen. Plant. 892. GOAT'S THORN, or MILK VETCH. The gum, the produce of this buſh, is chiefly brought to us from Turkey, in irregular lumps, or in long vermicular pieces. In Candy, it begins to exude about June, and is more or leſs pure and white, according to the weather after its exudation, and its accidental mixture with duſt.

Chuſe that which is white, light, ſmooth, and tranſparent in vermicular ſtriæ, of a ſweetiſh taſte, and without ſmell. A yelloviſh or browniſh colour is no mark of imperfection or impurity.

It differs from all other *gums* in giving a thick conſiſtence to a much larger quantity of water, and in being much more difficultly diſſolved in water. Put into water, it ſlowly imbibes a great quantity of fluid, ſwells into a large ſize, and forms a ſoft but not liquid mucilage: if more water is added, a fluid ſolution may be obtained by agitation; but the liquor looks turbid, or wheyiſh; and, on ſtanding, the mucilage ſubſides, the limpid water on the ſurface retaining little of the gum. It is the ſtrongeſt of the ſimple *gums*, and more powerful as a mucilage, but not as a demulcent. In common with other *gums*, it ſoftens and thickens acrid humours.

The pulvis e *tragacantha* compoſitus of the London College, is thus made:

℞ *Tragacanthæ* in pulverem tritæ, *gum.* arabici, amyli, ſingulorum ℥ i. ſs. ſacchari purificati, ℥ ij. ſimul in pulverem tere. Ph. Lond. 1788.

It is mild, emollient, and uſeful in tickling coughs, and for obtunding thin acrid humours. See Lewis's Mat. Med. Neumann's Chem. Works. Cullen's Mat. Med.

GUMMI, E, PILULÆ, } See ASAFŒTIDA.
GUMMOSÆ. —— }

GUMMOSUM ELECTARIUM. See DYSURIA.

GURGEATIO. See SUDOR ANGLICUS.

GURGULIO. See UVULA; alſo the inſect called a WEAVIL.

GUSTATORII. See HYPOGLOSSI EXTERNI.

GUSTATORIUS. A name of the third maxillary branch of the fifth pair of nerves.

GUSTERANAX. See BITHINIMALCA.

GUSTUS. The TASTE. Upon the tongue, towards the apex and ſides under the ſkin, are obtuſe papillæ of various figures. Theſe papillæ are prominent in the tongue of a living perſon, when put out and applied to any body to be *taſted*. In dead perſons, they abſolutely diſappear, but are very prominent in living hungry ones. They riſe from the nervous body which covers the muſcular fleſh of the tongue, whence they paſs through the perforations of the corpus reticulare in the ſame manner as in the ſkin, and are covered with ſmall vaginæ, formed by the exterior membrane of the tongue. Theſe vaginæ are porous, that what is *taſted* by preſſure may have the greater influence on them. Laurentius Bellini has ſhewn, that theſe papillæ only are the medium of *taſte*; and, that the other parts of the mouth, tongue, and palate, contribute nothing to it, except perhaps thoſe parts of the inner ſide of the cheek which lie near the meeting of the dentes molares.

It hath been generally ſaid, that the parts of ſubſtances which contain an oil and a ſalt, are the true objects of *taſte*; whence ſalt, ſpirit, ſoap, and oil, muſt alike be the ſame. It hath been alſo aſſerted, that the diverſity of *taſtes* are owing to the different figures which are natural to ſalts; but as to this, profeſſor Haller replies to the contrary; and ſays, that the mechanical reaſon of the diverſity of flavours, ſeem to reſide in the intrinſic fabric, or appoſition of their elements, which do not fall under the ſcrutiny of the ſenſes. He ſays, that in general, whatever contains leſs ſalt than the ſaliva, is inſipid; but that the nature or diſpoſition of the covering with which the papillæ are clothed, together with that of the juices, and of the aliments lodged in the ſtomach, have a conſiderable ſhare in determining the ſenſe of *taſte*; inſomuch, that the ſame flavour does not equally pleaſe or affect the organ in all ages alike, nor in perſons of all temperatures, nor even in the ſame perſon at different times.

In general the *taſte* determines what aliment is ſalutary; for the moſt part, whatever offends the *taſte* is injurious in the ſtomach. See Haller's Phyſiology, in his Lectures of the *Taſte*.

GUTTA. A DROP; alſo *aluaſel*. *Drops* are an uncertain

uncertain form of adminiſtering medicines; and where great exactneſs is neceſſary, they ſhould not be preſcribed. The ſhape of the bottle from whence the *drops* fall, occaſions a conſiderable difference in the quantity ſo adminiſtered; the conſiſtence of the fluid is often a ſtill greater cauſe of difference.

GUTTA is alſo a name of the apoplexy, from a ſuppoſition that its cauſe was a *drop* of blood falling from the brain upon the heart.

—— GAMBA. See GAMBOGIA.

—— OPACA. See CATARACTA.

—— ROSACEA. Dr. Cullen thinks this ſynonymous with *varus*, and *bacchia*; and places theſe as a variety of the *phlogoſis phlegmone*; alſo called ſimply *roſacea*, from the little red *drops*, or fiery tubercles diſperſed about the face and noſe; ſome call it *rubedo maculoſa*, or *rubereum maculis, Ionthos*; *butiga, gutta rubea*; *rubia, roſea*, and *bacchia*, by LINNÆUS. CULLEN places it under phlogoſis phlegmone, in his firſt variety. Nicholaus Florentinus diſtinguiſhes three degrees of it, viz. 1. *Rubedo ſimplex*, ſeu *facies rubra* 2. *Rubedo paſtuloſa*. 3. —— *ulceroſa*. He alſo ſays, that the cauſe is a hot viſcous blood, generated from an intemperies in the liver, which being brought to the face, ſtops there, and cauſes redneſs; and when it does not ſoon obtain a paſſage through the ſkin, it riſes into pimples, and at laſt ulcerates, having vitiated the frame of the cutaneous glands by its long ſtagnation.

That the cauſe is in the liver, ſeems to be ſupported by obſerving that often, on the diſappearance of fiery pimples in the face, an indurated liver is a conſequence, and thence a dropſy; and, *on the contrary*, diſorders of the liver are ſometimes relieved by eruptions in the face, whence great care ſhould be uſed in applying topics.

Though tipplers are moſt ſubject to this complaint, the moſt abſtemious are ſometimes affected with it, by ſuddenly drinking a draught of cold water when they are hot.

The prognoſtic is doubtful as to the cure. If the caſe is recent and mild, and the habit of body good, there is hope; if of a long ſtanding, inveterate, or malignant, a cure is a deſideratum.

In general, a temperate regimen is proper; but if the patient is accuſtomed to a generous diet, a ſudden alteration is not adviſeable; all violence ſhould be avoided as to exerciſe; the mind ſhould be kept as calm as poſſible; Scarborough water is generally eſteemed very uſeful: ſpirituous and ſpicy food ſhould be omitted; ſo ſhould pork, cheeſe, and all that does not eaſily digeſt.

As to topicals, practical writers abound with variety of them: but great caution is required in their uſe; nay, they are often dangerous. Heiſter ſays, that the pimples or puſtules in the face, are ſmall biles, and as ſuch are cured with whey and mineral waters.

Internally, the ſpring juices, mercurial deobſtruents, with antimonials, ſaponaceous, and, after theſe, ferruginous preparations, are to be preferred. Antimonials, as they have the beſt effect in the emunctories of the ſkin, are moſt to be relied on; and, as purges, the mercurial kind are not to be omitted. The bowels ſhould be kept conſtantly lax. And during the ſeaſon, the ſpring juices may be conſtantly taken. Bitters, particularly an infuſion of the Seville orange peel, is an excellent auxiliary. See Heiſter's Surgery. Turner's Diſeaſes of the Skin. Brooke's, and London Practice of Phyſic. Med. Obſ. and Inq. vol. i. p. 189.

—— SERENA. See AMAUROSIS. To which it may be uſeful to add the following account:

GOTTLIEB RICHTER ſays, "I have lately reſtored to ſight ſeveral perſons who laboured under *gutta ſerena*. In all theſe caſes, the cauſe ſeemed to be ſeated in the abdominal viſcera; for I cured them all by means of medicines which diſſolve obſtructions in the viſcera, and evacuate. Two patients were cured by theſe ſame medicines, where there was much reaſon to ſuſpect another cauſe, and to chuſe other medicines. Experience, therefore, confirms me more and more in the opinion, that the cauſe of *gutta ſerena* is moſt frequently to be found in the abdominal viſcera; and daily juſtifies me more in recommending the uſe of deobſtruent viſceral medicines, even in caſes where there is no determined indication to any medicine whatever. I can affirm, that I have not unfrequently performed a complete cure, in caſes where I hardly expected it; and in ſome, where the diſeaſe had actually continued ſeveral years." The pills he made uſe of, were the following:—℞ Gum ammon. aſſafetidæ, ſapon. venet. valerianæ, ſummitat. arnic. ää ʒ ij. tartar. emetici, gr. xviij. ft. pil. pond. gr. ij. quarum ſum. ter quotidie xv. The doſes of theſe pills were gradually encreaſed, and vomiting occaſionally produced by emetic tartar. See the caſes in his Medical and Surgical Obſervations, page 254, &c. —— Mr. WARE recommends, as a remedy, in *gutta ſerena*, one-fourth of the following powder to be ſnuffed up the noſtrils, once, or twice a day. ℞ Hydrargyri vitriol. g. i. pulv. glycyrrhizæ gr. viij. miſce.

GUTTÆ VITÆ. BALS. TRAUMATICUM. See BENZOINUM.

GUTTALIS. See ARYTENOIDES.

GUTTETA. Caſtellus informs us that the word *goutte* in French ſignifies *convulſion*; hence the name of a preparation called *pulvis ad guttetam*: it conſiſted of dittany, human ſkull, contrayerva, &c. but many mix only equal parts of peony and valerian roots. It was originally an invention of Riverius, and by ſome is called EPILEPTIC POWDER.

GUTTUR. The throat; called alſo *brochthus*; likewiſe ſome diſeaſe. See BRONCHOCELE.

GUTTURALIS ARTERIA. The firſt conſiderable branch of the external carotid is the ſuperior *guttural*, which ariſes juſt where it parts from the internal, and runs to the thyroid gland, and to the muſcles and other parts of the larynx or pharynx, hence called *laryngea*.

The inferior *guttural artery* is the TRACHEALIS ARTERIA; which ſee.

GUTTURALIS VENA, called alſo *trachealis*. The right goes from the under-part of the biſurcation above the mammaria of the ſame ſide, and ſometimes from the ſubclavia. The left from the left ſubclavian near its origin.

GUTTURIFORMIS CARTILAGO. See ARYTÆNOIDES.

GYCYPICROS. See SOLANUM LIGNOSUM.

GYMNASTICA. GYMNASTICS. Theſe are the exerciſes of the body which were propoſed for the reſtoration and preſervation of health, and for the cure of diſeaſes. Theſe exerciſes were of Greek origin; they are ſo called from the word γυμνος, *naked*; for theſe exerciſes were performed by naked men in the public games. Theſe exercites were wreſtling, running, leaping, and other acts of agility and force.

Herodicus, the father of Hippocrates, was the firſt who introduced theſe exerciſes into medicine.

The Egyptians conſidered *gymnaſtics* not neceſſary; they thought that by them a genuine health was not generated, but in its ſtead a ſhort-lived ſtrength, highly dangerous to young people. See Hieronymus Mercurialis de Arte *Gymnaſtica*. Fuller's Medicina *Gymnaſtica*.

GYMNOSPERMIA, from γυμνος, *naked*, and σπερμα, *ſeed*. The name of the firſt order in the claſs DIDYNAMIA, in Linnæus's ſyſtem, comprehending thoſe plants which have four ſtamens; of which the two middle ones are ſhorter than the two outer ones, with a ringent flower, ſucceeded by four naked ſeeds.

GYNÆCIA, from γυνη, *woman*. See LOCHIA and MENSES.

GYNÆCIUM, from γυνη, *a woman*. A SERAGLIO; alſo a name for antimony.

GYNÆCOMASTON. An enormous increaſe of the breaſt of women.

GYNÆCOMASTOS, from γυνη, *a woman*, and μαστος, *breaſt*. A man whoſe breaſts are large like a woman's.

GYNÆCOMYSTAX, from γυνη, *a woman*, and μυσαξ, *a beard*. The hairs on the female pudenda.

GYNANDRIA, from γυνη, *a woman*, and ανηρ, *a man*. The name of the twentieth claſs, in the Linnæan artificial ſyſtem, containing all plants, with hermaphrodite flowers, which have the ſtamen growing upon the ſtyle; or elſe having an elongate receptacle, bearing both ſtamens and ſtyles. This claſs has been conſiderable reduced by ſome modern reformers, and the plants referred to other claſſes.

GYNANTHROPOS. That ſpecies of hermaphrodite which partakes more of the female than of the male: that ſpecies which partakes moſt of the male is called *androgynus*. Theſe diſtinctions are groundleſs, for all hermaphrodites, ſo called, are properly women.

GYNECANTHE. See BRIONIA NIGRA.

GYPSOPHYTON. See PIMPINELLA ALBA GERMANORUM.

H.

HABA. See FABA.

HABASCUM. The name of a Virginian root which reſembles a parſnip, and is a ſalutary food.

HABENA. The name of a bandage, contrived to keep the lips of wounds together.

HABILLA DE CARTHAGENA. See BEJUIO.

HABITUS, HABIT. See CONSUETUDO.

HABITUS PLANTÆ. The *habit of a plant* is the outward appearance of plants, or what is called their port.

HACUB. A ſpecies of CARDUUS, the young ſhoots of which are eat by the Indians, but the roots are emetic.

HADID. See FERRUM.

HÆCCEITAS. See QUINTA ESSENTIA.

HÆMA. See SANGUIS.

HÆMAGOGOS, from αιμα, *blood*, and αγω, *to bring away*. The name of an antidote in Nicolaus Myrepſus, which was uſed for promoting the menſtrual and hæmorrhoidal fluxes.

HÆMALOPIA. A variety of the *pſeudoblepſis imaginaria*. In which all things ſeem to be of a red colour.

HÆMOLOPS, from αιμα, *blood*, and ωψ, *the countenance*. The livid marks of ſugillations in the face and eyes.

HÆMATAPORIA. A waſting, from a poverty of blood.

HÆMATEMESIS. See VOMITUS.

HÆMATIA. } An epithet for a ſort of *garon*, or
HÆMATION. } *garum*, made of the inteſtines of fiſh macerated in ſalt.

HÆMATITES, from αιμα, *blood*. The Greeks call the ore of iron thus, from its ſuppoſed virtue of ſtopping blood. It is called alſo BLOOD-STONE, *azedegrin*, *aſdenigi*; *aſedenigi*. When it was in flattiſh cakes, with knobs on the ſurface, then the ancients called it *hæmatites*; but when it was in long ſtriated pieces, they called it *ſchiſtus*, but they poſſeſs no diſtinguiſhing qualities different from each other. The *terra ſinopica* is alſo called *blood-ſtone*.

From twenty-four parts of good *hæmatites*, nine parts of iron hath been extracted, but it often affords half its weight. Plenty of it is met with in Germany, France, and Spain, but we have as good as any, in England. It is very hard, of a dark red colour; but on powdering it, the redneſs becomes brighter. As a medicine, nothing can be expected from it that is not afforded with more advantage by iron; and as it is very difficultly powdered, the crocus martis may be ſubſtituted in its room, on the rubigo ferri. See Lewis's Mat. Med.

HÆMATITINOS. An epithet of a collyrium in Galen, in which is the hæmatites.

HÆMATOCELE, from αιμα, *blood*, and κηλη, *a tumor*. It is a ſpecies of falſe hernia in the ſcrotum; it conſiſts of a collection of blood in the tunica vaginalis; its appearance is the ſame as when an hydrocele is the diſorder, and ſo is the method of its cure. See Celſus. P. Ægineta. Bell's Surgery, vol. i. p. 482. Pott's Works, 4to. 1775. White's Surgery, p. 342.

HÆMATOCELE ARTERIOSUM. See ANEURISMA.

HÆMATOCHYSIS, from αιμα, *blood*, and χεω, *to pour out*. See HÆMORRHAGIA.

HÆMATODES. See GERANIUM SANGUINARIUM.

HÆMATOMPHALOCELE, from αιμα, *blood*, ομφαλος, *navel*, and κηλη, *a tumor*. A tumor in the navel, turgid with blood.

HÆMATOPEDESIS. BLOODY SWEAT.

HÆMATOPHLŒBŒSTASIS, from αιμα, *blood*, φλεψ, *a vein*, and ſταſις, *a ſtation*. It is a ſuppreſſion of the impetuous current and intumeſcence of the blood in the veins. But Galen ſays, that ſome underſtand by it the veins full and tumeſcent with blood.

HÆMATOXYLON CAMPECHIANUM. See CAMPECHENSE LIGNUM.

HÆMATURIA. See URINA.

HÆMITRITÆUS. See SEMITERTIANA FEBRIS.

HÆMOCERCHNUS. Blood brought up from the fauces, with a noiſe, or rattling, or bloody excretions diſcharged in a dry form.

HÆMODIA. A painful ſtupor of the teeth, cauſed by acid and auſtere ſubſtances touching them.

HÆMOPTOE. See HÆMOPTYSIS.

HÆMOPTYICUS, alſo *hæmotericus*. A perſon who diſcharges blood from the mouth is thus called.

HÆMOPTYSIS, } from αιμα, *blood*, and πτυω, *to ſpit*.
HÆMOPTYS, } A SPITTING OF BLOOD; alſo called HÆMOPTOE. If blood is diſcharged from the noſe or mouth, it is generally called a ſpitting of blood; but it ſeems more proper when blood flows from the noſe, to call it a bleeding at the noſe; when from the ſtomach, a vomiting of blood; and when from the lungs, a ſpitting or *coughing up* of blood. When it happens from the veins of the lungs, it is called *perirrhexis*.

Dr. Cullen places this genus of diſeaſe in the claſs pyrexiæ, and order hæmorrhagiæ, and defines it, a fluſhing of the cheeks; an uneaſy ſenſation, or pain, and ſometimes heat in the breaſt; a tickling of the fauces, a cough, by which blood of a florid colour, often frothy, is ejected by the mouth. He obſerves five ſpecies. 1. *Hæmoptyſis plethorica*, when no external force has been applied, nor any cough, or ſuppreſſion of any uſual evacuation has preceded. 2. *Hæmoptyſis violenta*, where ſome external violence hath been the cauſe. 3. *Hæmoptyſis phthiſica*, where there is a waſting and continued debility takes place after a cough. 4. *Hæmoptyſis calculoſa*, when with the diſcharges by coughing there are calcareous concretion ſthrown up. 5. *Hæmoptyſis vicaria*, when the ſuppreſſion of ſome accuſtomed evacuations is the cauſe.

Paſſionate people, weakly ſlender people with long necks, and flat breaſts, and thoſe who while young were ſubject to bleed at the noſe, are moſt ſubject to an *hæmoptyſis*.

An HÆMOPTYS may happen three ways: 1. By an accidental rupture of the veſſels; in which caſe, if the veſſels are ſmall, and the patient is quiet, there is no danger; but if large, the danger is conſiderable. 2. From an ulcer in the lungs, whence in coughing it will be forced up, and mix with phlegm or pus, in which caſe the danger is great, as ſome large veſſel may be eroded. 3. By anaſtomoſis; this is without danger, and often relieves women whoſe menſes are ſuppreſſed.

Sometimes the bronchial artery is ruptured. If the orifice is ſmall, the diſcharge is ſoon at an end, for the blood ſtagnating in the cellular ſubſtance of the lungs, the artery is compreſſed, and the rupture cloſed: in ſome inſtances this blood is abſorbed, in others it corrupts and excites an inflammation, which terminates in ſuppuration,

tion, then making its way into the bronchia, is by degrees ſpit up, but often a conſumption follows.

Sometimes the rupture happens in the pulmonary artery, and then the diſcharge of blood is ſudden, more copious and florid than when from the bronchial artery; it is alſo without pain, and unmixed with phlegm.

When this diſorder is from a rupture of the pulmonary artery, as juſt obſerved, for the moſt part the preceding ſymptoms are *anxiety about the præcordia, difficulty of breathing, an oppreſſive undulatory pain about the diaphragm, flatulencies in the belly, a coldneſs of the extremities, hoarſeneſs, a dry tickling cough*, &c. As theſe ſhew a general ſtricture on the veſſels, and a tendency of the blood to inflammation, ſo they are commonly the fore-runners of a copious diſcharge of blood *from the fauces*, by which means it may always be diſtinguiſhed from an hæmoptoe. Though the diſcharge be from the bronchial artery, if it hath not lain any time in the breaſt, it may appear thin and florid; but in this caſe its ejection is not ſudden, and its appearance is blackiſh, and ſomewhat thick; though *a frothy cough attends, there is a pain and heat in the breaſt, with a ſenſe of weakneſs there, during the diſeaſe, ſometimes a feveriſhneſs appears, but it abates with each diſcharge of blood, which returns at intervals until the cure is effected.* Sometimes matter is mixed with, or follows after the diſcharges.

Spitting of blood is generally uſeful *in pleuriſies*, and *peripneumonies*;—*in a dropſy, the ſcurvy, and conſumption*, it denotes an ulcer in the lungs; *in the robuſt*, a ſpitting of blood is not very dangerous, but *in the tender and feeble* the cure is very difficult, and often impoſſible; if blood proceeds from an ulcer it is fatal.

The patient ſhould be kept cool and quiet both in body and mind; his diet ſhould be ſoft, cooling, and ſlender, but yet ſufficiently nouriſhing; ſpirituous liquors and fermented ones ſhould be at leaſt ſo ſparingly uſed, that the blood may never be rarefied thereby; the voice ſhould not be exerted in any extraordinary degree.

Medicines need not be given before the patient ſeems weakened by his complaint; and then in proportion to the ſtrength of the patient, bleeding in the arm may be repeated. When the conſtitution will admit of this operation, the diſcharges by it ſhould be copious, *for one free bleeding is far more uſeful than many ſparing ones.*

NITRE, if taken early in this diſorder, is much to be depended on. The following method is the moſt convenient and uſeful; ℞ Sal. nitri ʒ ſs. conf. roſar. ʒ iv. m. cap. q. n. m. major. 6ta vel 3tia quaq. hora pro re nata.

Purges of the natron vitriolatum are ſingularly uſeful in checking internal hæmorrhages, and may be ſo repeated as to keep the bowels always lax.

De Haen recommends the drinking of cold water.

Styptics are not to be depended on.

If the cough is troubleſome, an electary with nitre and ſperma ceti will be uſeful; and as an opiate the pil. e ſtyrace may be given in ſuch doſes as juſt to allay this troubleſome ſymptom. See Wallis's Sydenham. Lond. Med. Obſ. and Inq. vol. iv. p. 206, and Med. Muſeum, vol. ii. p. 257–259. Brooke's Pract. of Phyſ. Cullen's Firſt Lines, vol. ii. p. 336, edit. 4.

—— PERIODICA, } RIA.

HÆMORRHAGIA, from αἷμα, *blood*, and ῥηγνυμι, *to break forth*, or ῥαγνυμι, *to break forth*, called by Willis *Hæmatochyſis*; alſo *Sanguiſluxus*. There are but few *hæmorrhages* (not owing to external violence) which would prove fatal, if no means were uſed to ſtop them; hence many medicines have, at different times, had the repute of being ſpecifics. Periodical and critical *hæmorrhages* have generally their cauſe in the primæ viæ, and their propereſt remedies are ſuch as thoſe that purge, and render the bile temperate, of which kind are the natron vitriolatum; but ſtill is to be preferred the ol. ricini ver. The ſeat of ſpontaneous *hæmorrhages* is generally where the veſſels are tender, and not braced up by neighbouring membranes, &c. as in the noſtrils, bronchia of the lungs, the gums, ſtomach, inteſtinum ileum, the extremity of the inteſtinum rectum, the uterus, and vagina; though rare inſtances are recorded of *hæmorrhages* from veſſels which lie deeper, and are more defended.

Thoſe who abound with thick fibrous blood rarely are affected with this diſorder; a diſpoſition to it is generally hereditary, and is increaſed by action, cloſe thinking, hot acrid aliments, &c. Thoſe who have too much ſerum in their veſſels, who have a ſoft texture of body, are ſedentary, or have a defective perſpiration, and who eat more than they can eaſily diſcharge, are moſt ſubject to *hæmorrhages*.

The cauſes are not directly a redundancy of blood, its acrimony, or thinneſs; but rather from an irregular unequal circulation, which happens when the parts remote from the heart are by a ſtricture ſo braced up that the blood cannot eaſily return through the veins: hence the ſmall arteries, and particularly thoſe that are the leaſt defended, are ruptured. But the cauſes of thoſe *hæmorrhages* that are of the ſymptomatic kind are to be ſought for in infarctions and obſtructions, or indurations of the veſſels and the viſcera, which put a ſtop to the free circulation of the fluids, and occaſion a glut on particular parts. From what is juſt ſaid, acrimony and rarefaction are not excluded from the occaſional cauſes, as is evident in ſcorbutic habits, &c.

In acute diſeaſes, when there are ſmall diſcharges of blood, which ſuddenly ceaſe, they indicate at leaſt a tedious diſeaſe. *Hæmorrhages* are ſalutary when no inconvenience is obſerved from them, for then the habit is one way or other relieved. When this accident happens from diſordered viſcera, eſpecially if the liver, ſpleen, or lungs, are the parts affected, the conſequence is generally fatal, by producing a dropſy, a hectic, &c. which uſhers in death.

As to the cure, the beſt remedies, where topical applications cannot be admitted, are, a cool air, reſt, a ſparing mild diet, given in ſmall quantities at a time, acidulated drinks, nitre and natron vitriolatum, as directed in the hæmoptyſis, and opiates in ſmall doſes. Hoffman adds to theſe, frictions of the feet, and bathing them in warm water. If the diſorder is ſymptomatic, the cure depends chiefly on the removal of the original diſeaſe. Perſons rarely die of *hæmorrhages*, unleſs the large arteries are divided; but thoſe who ſuffer a great loſs of blood fall into a deliquium, and then the *hæmorrhage* ſtops: if the patient is thus left dead, as it were, in a moderately warm room, give only a ſmall quantity of fleſh broth frequently, and thus drooping life may be ſupported, until the divided veſſels contract themſelves and conſolidate. Thoſe who endeavour to recover perſons from the deliquiums which *hæmorrhages* occaſion, by giving cordial liquors, do not reſtore the loſt quantity of fluids, but increaſe the action of the veſſels on their remaining contents, by which more blood is ſtill diſcharged: again, if a large artery is not wounded, or ſuch a one as being affixed to a bone cannot retract itſelf and cloſe, the orifice, by the elaſticity of the veſſel, is contracted and concealed within the lips of the wound. Dr. Hunter recommends to leave all internal *hæmorrhages* to nature; and ſays, *that life is ſafe if the patient be permitted to faint.*

As to external *hæmorrhages*, which admit of topical aſſiſtance, it may be obſerved, that almoſt all the blood diſcharged from wounds, is diſcharged from the arteries; for pretty large veins, when divided, diſcharge but little blood. Sometimes the bleeding veſſel admits of a compreſs on the ruptured or wounded part; but when this cannot be effectually applied, the needle and ligature are the propereſt means of relief. *Hæmorrhages* in the mouth ſometimes require the actual cautery; but in other caſes eſcharotics are not adviſeable. See WOUNDS *of the* ARTERIES.

HÆMORRHAGIA NASI, or *Hæmorrhages* from the noſe, named in Dr. CULLEN's Noſology, EPISTAXIS, and diſtinguiſhed as a genus of diſeaſes, placed in the Claſs PYREXIÆ, and Order HÆMORRHAGIÆ; which he defines, pain, or load of the head, flushing of the face, a flux of blood from the noſe, of which he names one idiopathic ſpecies, *Hæmorrhagia plethorica*, and ſix ſymptomatic, four from internal and two from external cauſes. HIPPOCRATES expreſſes by it repeated diſtillations of blood from the noſe. *In perſons of a ſpungy habit* they are copious and frequent, eſpecially if the veſſels are ſmall and numerous. *In lean perſons*, whoſe veſſels are large, they do not ſo frequently happen; but when they do, they are profuſe. Fernelius obſerves, that "perſons whoſe viſcera and liver are weak and ſcirrhous, are ſubject to

frequent *hæmorrhages* of the noſe, as well as dropſical patients."

The cauſes in general are the ſame as in other morbid *hæmorrhages*.

Bleeding at the noſe is often preceded by ſome degree of quickneſs in the pulſe, a flushing in the face, pulſation in the temporal arteries, heavineſs in the head, dimneſs of ſight, heat in the noſtrils, an itching there, &c. All *hæmorrhages*, but eſpecially from the noſtrils, are generally accompanied or preceded by a ſtricture of the ſkin and external parts, a detumeſcence of the veſſels, a refrigeration, laſſitude in the limbs, coſtiveneſs, and pains in the belly.

In many inſtances the loſs of blood by the noſe is ſalutary, as the vertigo, head-ach, epilepſy, dimneſs of ſight, &c. Thoſe who in childhood often bleed at the noſe, when older become ſubject to diſorders in the breaſt, the rheumatiſm, piles, nephritic, or colic pains.

In attempting a cure, it ſhould be remembered, *that periodical bleeding at the noſe ſhould not be ſtopped, at leaſt before the patient is much weakened by it, leſt an apoplexy or a lethargy ſhould be the conſequence.* What is related above, concerning *hæmorrhages* in general, ſhould be remembered in this particular caſe. *Gently purging with the natron vitriolatum, is in this inſtance almoſt a ſpecific*; putting the hands and feet in warm water aſſiſts in removing the ſpaſm of the veſſels in the extremities.

When, notwithſtanding internal medicines, and doſſils of lint put up the noſtrils, the blood continues to flow from the noſe, the following method, communicated (if I remember right) by a ſurgeon in Birmingham, is effectual. The hint of this method of ſtopping up the noſtrils and paſſage into the throat, is mentioned alſo in Le Dran's Operations, Caſe vi. in the Remarks, and eaſily puts an end to the complaint. "Take a piece of ſtrong ſewing ſilk, wax it well, and to one end of it faſten a doſſil of lint; then take a piece of catgut (about the ſize of a ſecond ſtring of a violin) and introduce it up the bleeding noſtril; when you perceive it in the mouth, take hold of its end with a forceps, and draw it out from thence, make a knot upon it, and faſten the end of the waxed ſilk to it; then withdraw the catgut back again by the noſtril, take hold of the ſilk, and pull the doſſil of lint into the poſterior noſtril: after which, ſtuff the anterior noſtril full of lint, and thus you certainly ſtop the bleeding. After a few days the lint may be taken away." See Hoffman; and Van Swieten's Comm. on Boerh. Aph. Cullen's Firſt Lines, edit. 4. vol. ii. p. 256. Bell's Surgery, vol. iv. p. 70. London Med. Tranſactions, vol. iii. p. 217. White's Surgery, p. 263.

HÆMORRHAGIA UTERINA. See MENORRHAGIA.

HÆMORRHOIDALE, or HÆMORRHOIDALIS HERBA. See CHELIDONIUM MINUS.

HÆMORRHOIDALES ARTERIÆ. HÆMORRHOIDAL ARTERIES. They are the external and internal.

HÆMORRHOIDALIS. HÆMORRHOIDAL FEVER. This is a fever of ſhort duration, mentioned by Vogel, and conſidered as ſymptomatic, which he defines an ephemera, attended with pain of the ſpine, piles, or at leaſt painful varices breaking out about the fourth day, which terminate the febrile affections.

—— INTERNA ARTERIA. See MESENTERICÆ ARTERIÆ. It ſoon divides into branches, one of which runs down behind the inteſtinum rectum, to which it is diſtributed by ſeveral ramifications, and it communicates with the arteriæ hypogaſtricæ.

—— EXTERNA ARTERIA. See PUDICA ARTERIA.

—— EXTERNÆ VENÆ. The EXTERNAL HÆMORRHOIDAL VEINS. They ſpread about the inteſtinum rectum and anus; and proceed from the hypogaſtricæ venæ: they communicate with the *hæmorrhoidales* internæ.

—— INTERNA VENA, called alſo *meſaraica minor vena*. The INTERNAL HÆMORRHOIDAL VEIN; alſo called the leſſer meſaraic vein. It is called *hæmorrhoidal*, from the tumors often found at its extremity next the anus, which are called hæmorrhoides. It is one of the three great branches of the vena portæ ventralis; though ſometimes in ſprings from the ſplenica: it ſends a branch to the duodenum from near its beginning: then it is divided into two branches, one of which aſcends, the other deſcends; the deſcending branch runs down on the left portion of the colon on its lower incurvations, and on the inteſtinum rectum to the anus. The *hæmorrhoidal* veins have no valves.

HÆMORRHOIDES, from αἷμα *blood*, and ῥέω, *to flow*. The HÆMORRHOIDS, or PILES. A diſcharge of blood from the hæmorrhoidal veins is thus named, and is alſo called the OPEN, or BLEEDING PILES: when inſtead of this hæmorrhage there are large tumors, which are generally painful at the lower part of the rectum, they are called the BLIND PILES. Dr. Cullen places this genus of diſeaſe in the claſs PYREXIÆ, and order HÆMORRHAGIA; which he defines, a heavineſs, or pain of the head, giddineſs, pain of the loins, alſo of the anus; livid painful tubercles about the anus, from whence, for the moſt part, blood iſſues, which ſometimes alſo flows without any tumors appearing. He diſtinguiſhes four ſpecies: 1. *Hæmorrhois tumens*, when there are external ſwellings on the edge of the anus; called alſo mariſca. Theſe he diſtinguiſhes by the terms bloody and mucous. 2. *Hæmorrhois procidens*, when the *piles* are external, and cauſed by a bearing down of the anus. 3. *Hæmorrhois fluens*, when the *piles* are internal without external tumor, or bearing down of the anus. 4. *Hæmorrhois cæca*, when there are pains and tumor about the anus, and no diſcharge of blood. There are ſome caſes alſo, where there is a diſcharge only of mucus: the caſe is then called *leucorrhois*. Dr. CULLEN ſays, that the *hæmorrhois* is often a diſeaſe of the whole machine, or depending upon a certain ſtate of the whole body; but it is often a mere local complaint. He would not therefore refer a complaint of this ſort to local diſeaſes; becauſe ſome piles, though in the beginning they may be merely local, if they ſhould return often, as they are wont to do, at length, like any other hæmorrhage often returning, neceſſarily become a diſeaſe of the habit in general. Therefore, on this account, he has not made any diſtinction between the two, but thinks that every ſpecies of the piles ſhould be arranged amongſt general diſeaſes.

From diſſections, this diſeaſe ſeems to be an ecchymoſis in the cellular membrane of the lower part of the rectum, from the extremities of the neighbouring veſſels: if this be true, it accounts for the great loſs of blood this way, without loſs of ſtrength, for it is gradually emptied into the ecchymoſis, and it is from thence that it pours out ſo ſeemingly plentifully.

There is ſeldom much diſcharge from the external hæmorrhoidal veſſels, but they readily admit of varices being formed in them, which are painful. But the internal hæmorrhoidal veſſels not only diſcharge a large quantity, but, when ſuppreſſed, thoſe diſorders are generated which ariſe from diſorders of the liver, ſpleen, pancreas, meſentery, and inteſtines.

Near the extremity of the inteſtinum rectum, internally, are little jagged proceſſes, ſomewhat like the carunculæ myrtiformes in the vagina, which are the ſeat of the internal, as well as of the external *piles*.

Thoſe who are of a lax, ſpongy habit, and diſpoſed to ſweat; who eat heartily, and drink freely; who indulge in eaſe; who are habitually coſtive, &c. are the moſt ſubject to this diſorder.

The *piles* often affect pregnant women, from the preſſure of the uterus on the hæmorrhoidal veins. *In all other caſes, the immediate cauſe is a difficult circulation of the blood through the hæmorrhoidal veins, in conſequence of their perpendicular ſituation, and want of valves.* The diſcharge happens when the extremities of the veſſels in the inteſtinum rectum are ſo diſtended by the accumulated blood, as to be returned. Whatever generates a redundance of blood, retards its paſſage through the ramifications of the vena portæ, or invites it in too large quantities to the hæmorrhoidal veins, diſpoſes to this complaint. Aloes, garlic, jalap, and even rhubarb, in ſome conſtitutions, bring on the *piles*, by deriving an afflux of humours to their ſeat: aromatic food, ſweet and ſtrong wines, anger, grief, or any violent commotion of body or mind do the ſame.

The *blind piles* appear in the form of tubercles of different ſizes, from that of a pea, up to a pullet's egg. They are diſtinguiſhed from other tubercles about the anus, *by their colour and reſiſtance to the touch, for they appear livid or black, and, when preſſed by the finger, they feel like a bladder filled with water*; which circumſtances are not obſerved in other tubercles in the anus, or about it: ſome of theſe are ſoft and not painful, others are hard, painful, and inflamed. This kind of *piles* generally appear in coſtive habits that are plethoric, and in women

women that are pregnant, or after difficult labour, or ſuppreſſed menſes. If theſe *blind piles* burſt, they form the *open*, or *bleeding piles*. The *blind piles* ſometimes cauſe ſuch a ſpaſm in the anus, as renders ſitting difficult, and the adminiſtration of a clyſter impoſſible; and ſometimes give riſe to a fiſtula.

The eruption of the hæmorrhage in the *open piles* is often preceded by ſpaſmodic ſtrictures, flatulencies, pain about the os ſacrum, and various other ſymptoms, which diſorder the whole frame. In the beginning of exceſſive diſcharges, the blood is black and grumous; after this, it appears of a redder colour, and after this the diſcharge is ſerous and mucous, reſembling the white of egg: at length the ſtrength is impaired, the pulſe is languid and trembling, and a cachexy, an hectic fever, or a dropſy, comes on, and the caſe becomes deſperate.

The *piles* are not always readily diſtinguiſhed; and attention is ſometimes required, leſt they be confounded with the colic, or a dyſentery, or with tumors about the anus.

When the cauſe is a tumor in the liver or ſpleen, a fatal atrophy, or hectic is the conſequence. Exceſſive hæmorrhoidal diſcharges often terminate in dropſies; but if they ſucceed a dropſy from an indurated liver, death is at hand. *On the contrary*, moderate diſcharges from the hæmorrhoidal veins give great relief to the conſtitution that is oppreſſed by the gout, aſthma, iſchiadic pains, diſeaſes of the kidnies or bladder, hypochondriac, hyſteric, or maniac diſorders, &c. Only thoſe diſcharges of blood from the anus are to be deemed morbid, by which the patient is enfeebled, and the digeſtion, &c. are hurt.

The general indications are, 1. To take off the increaſed impetus to the ſeat of the diſeaſe, by bleeding, and ſmall doſes of ipecacuanha. 2. To induce an aſtriction on the relaxed veſſels; this ſhould be done ſlowly; and to this end, alum is a proper application, or the bark may be uſed, but other vegetable aſtringents are too powerful. 3. To avoid all irritation, by regulating the ſtools.

An incautious uſe of improper diet will render the beſt medicines ineffectual in this diſeaſe; carefully, therefore, avoid that, and every accident that can increaſe the malady.

Bleeding at proper intervals, where there is a ſanguine plethora, will in ſome meaſure prevent the returns, or at leaſt moderate the violence of them; a light diet, that is cooling and laxative, ſhould be kept to; broths and gruels are uſeful, but inflaming liquors ſhould be cautiouſly drank.

When the *piles* do not bleed, they are attended with conſiderable pain; in which caſe, doſſils of lint, dipped in warm olive oil, may be applied, or other emollient liniments may be ſpread on ſoft rags, and kept on with proper bandages: if the piles are troubleſome by their bulk, dreſs them with a mixture of ſimple lime-water, in which is a ſmall quantity of camphorated ſpirit of wine and a little ceruſſa acetata. See alſo GALLÆ.

The bowels muſt be kept lax; and for this end, the elect. e caſſia is far preferable to the elect. e ſenna comp. Sulphur, and the ol. ricini, are alſo proper laxatives.

If the want of tone in the rectum be a cauſe, chalybeate tinctures, with bitters, and caſcarilla, may be taken for ſome time.

If other diſorders attend, which conduce to the production or continuance of the piles, ſuch remedies as are adapted to their removal, muſt not be omitted.

Forms of medicines, both internal and external, are abundantly preſcribed in practical authors; therefore the reader is deſired to ſelect, as circumſtances may ſeem to require.

If the caſe requires the aſſiſtance of a ſurgeon to check he hæmorrhage, a cooling purge may be adminiſtered, and five or ſix hours before any operation, inject a clyſter: then laying the patient with his belly acroſs a bed or able, let an aſſiſtant ſeparate the nates, then the operator may tie up the bleeding veins with a needle and thread; but if there are tubercles, take hold of them with the forceps, and cut them off, tying them up alſo; but be careful not to leave the ſmalleſt vein open.—If the profuſion ceaſes not thus, apply lint, with proper compreſſes, and the T bandage.—If the veins are high in the rectum, diſtend it with a convenient inſtrument until the veins can be come at.—If the *blind piles* encompaſs the anus, ſo as to prevent the diſcharges by ſtool, and to prove otherwiſe troubleſome, remove the largeſt of them by a ligature, which may be tightened daily until the tumor drops off: but before this attempt, let warm ſpirit of wine be uſed, in order to diſperſe it.—If the diſtended vein is high and inflamed, open it with a lancet.

See Hoffmann. Heiſter's Inſtitutes. Lobb on Painful Diſtempers; Le Dran's Operations. Brooke's and London Practice of Phyſic. Cullen's Firſt Lines, vol. ii. p. 424. Edit. 4. Bell's Surgery, vol. i. p. 249. White's Surgery, p. 383.

HEMORRHOIDES EXCEDENTES;—*immodicæ*; *polyposæ*;—theſe are to be conſidered as belonging to the *Hæmorrhois tumens*; ſo alſo do the—*decoloratæ*—*albæ mucidæ*; but then the diſcharge is mucous, not bloody. See HÆMORRHOIDES.

HÆMORRHOIS AB EXANIA. See HÆMORRHOIS PROCIDENS.

HÆMORRHOIS. So Dr. Cullen names the hæmorrhoides.

HÆMORRHOUS. The name of a poiſonous ſerpent, ſee P. Ægineta, lib. v. cap. 15. Hippocrates calls thoſe large veins thus, which, when opened, diſcharge the blood copiouſly.

HÆMOSTASIA. A general ſtagnation of blood from a plethora.

HÆMOSTATICA, from ἁιμα, *blood*, and ἱστημι, *to ſtop*. Medicines which ſtop hæmorrhages.

HÆMOTOICUS. See HÆMOPTYICUS.

HÆRMIA. A ſort of Indian fruit like pepper. See Lemery des Drogues.

HAGIOSPERMON. See SANTONICUM.

HAGIOXYLON. See GUAIACUM LIGNUM.

HALCHEMIA. The art of fuſing ſalts.

HALCYON. See ALCEDO.

HALCYONIUM. The ſpume or froth of the ſea. It is oily, or bituminous.

HALEC, alſo called *harengus*, the HERRING. Pickled *herrings* are applied to the ſoles of the feet as ſynapiſms are. Freſh ones produce the alkaline putrefaction in the ſtomach, ſo are uſeful when an acid prevails there.

HALICACABUM. See ALKEKENGI.

HALICES. Pandiculations after ſleep, or upon awaking.

HALIMUS; called alſo *portulaca maritima*; *atriplex maritima anguſtiſſimo folio*; COMMON SEA-PURSLANE, and TREE SEA-PURSLANE. It is found in ſalt marſhes; flowers in July and Auguſt. Dioſcorides tells us, that the leaves are eaten as food; and Aetius ſays, the buds are uſed as pickles. The plant is hot, and, pickled in vinegar, helps the appetite.

HALINITRON. NITRE.

HALLUCINATIONES. See DYSÆSTHESIÆ.

HALMYRAX. A ſort of nitre produced in the valleys of Media.

HALMYRODES. SALSUGINOUS. Hippocrates uſes this word as an epithet for ſome fevers, in which, according to Galen, the external parts, when touched, communicate ſuch an itching ſenſation as is perceived from handling ſalt ſubſtances. When applied to the ſkin, it ſignifies a ſort of roughneſs as if it was ſalted. It is alſo an epithet for many excretions that are ſalt and acrimonious.

HALO. See AREOLA.

HAMBARA, HAMBRUS. } See SUCCINUM.

HAMMONIACI LACRYMA. See AMMONIACUM, GUM.

HAMPSTEAD WATERS. See AQUÆ CHALYBEATÆ.

HAMULUS, HAMUS. } An hooked inſtrument for extracting a dead child from the uterus.

HANDALA. See COLOCYNTHIS.

HAOUVAY. See AHOVAI THEVETE CLUSII.

HAPSIS. The ſenſe of FEELING. It alſo ſignifies connection with reſpect to bandages. And ἀφρος φρενων in Hippocrates, ſignifies madneſs, delirium. or loſs of reaſon.

HAPSICORIA. A ſort of LOATHING; when people altogether ſatiated immediately abſtain.

HARDESIA HIBERNICA. See HIBERNICUS LAPIS.

HARENGUS. See HALEC.

HARMALA, HARMEL. } Called alſo *ruta ſylveſtris*; ASSYRIAN WILD RUE. Its leaves are longer and narrower than the common rue; it hath but little ſcent: it grows in Spain, and ſome of the Eaſtern countries;

tries: it is rarely uſed, but is much like the common rue in its qualities. Raii Hiſt. See RUTA.

HARMONIA. IN ANATOMY, it is a ſpecies of articulation, and is when two thin bones meet, and lie over each other a little way.

HARMOS. See GINGIVÆ.

HARONKAHA. See ZEDOARIA.

HARPAGA. See SUCCINUM.

HARPASTRUM. A ſpecies of exerciſe with a ball.

HARPAX. See SUCCINUM. Alſo a mixture of quicklime and ſulphur.

HARROWGATE WATER. This is a ſalt, purging, ſulphureous water. It had long been doubted whether theſe waters contained any ſulphur; but it is now put out of diſpute, by the experiments of Dr. Kilvington and the right reverend biſhop of Landaff. The former of which being at the wells, which had been cleared for the approaching ſummer, obſerved a circle of yellowiſh concretion around the margin of the baſon, as high as the water roſe, a ſmall portion of which he ſcraped off, and dried; and on putting a little of it on a red-hot iron, it produced a blue flame, and ſmelt ſtrong of ſulphur. The biſhop examined the ſcum which the waters had thrown up, the mud or ſediment which they dropped, and the ſubſtance ſcraped off the inſide of the baſon, and by every trial, found that they contained ſulphur. Theſe waters are drank from half a pint to three quarts, or more. In ſmall quantities, they prove diuretic; in large, ſtrongly purgative. They are extremely uſeful in cutaneous and ſcrofulous diſorders; alſo as anthelmintics, deſtroying and evacuating worms, and their nidus; where the digeſtive powers are weak, and the inteſtines loaded with viſcid ſaburra, they have been beneficial, and indeed ſerviceable in many chronic complaints. They have been employed externally in form of waſhes, fomentations, and baths, particularly in cutaneous diſeaſes. See Dr. Monro, on Mineral Waters, and AQUÆ SULPHUREÆ. Beſides there are three other wells which contain different waters.

1ſt. The SWEET SPA. This ſtrikes a light purple with galls, and from a gallon, on evaporation, were acquired a ſcruple of ſolid matter at one time, and only eight grains at another; of theſe ſediments, above one half was earth, the reſt a calcareous nitre, vitriolated magneſia.

2d. TUWHET. A gallon of this yielded at one time thirteen grains, at another nineteen, of a reſiduum, of which three fifth parts were calcareous earth mixed with ochre; the other two fifths vitriolated magneſia.

3d. ALUM WELL. From the roughneſs of this water, it was ſuppoſed to contain alum; a gallon of which yielded, on evaporation, eight grains of a dark coloured brown ſediment, which had a rough vitriolic taſte, and curdled milk. It is probable, Dr. Monro thinks, on further examination, that this water may be found to be a weak vitriolic water. Dr. Short conſiders theſe as chalybeate ſprings.

HARTFELL WATER. This iſſues from the *Hartfell* mountain in the county of Annandale, Scotland. It is quite pure and pellucid; has an irony, and ſo ſtrong a ſtyptic taſte, that it is ſuſpected to contain alum. By being expoſed to the open air, it becomes weaker, and is obſerved to be ſtronger in wet, than in dry weather. On evaporation, a gallon afforded, of ſolid matter, forty-two grains; thirty-ſix were ſal martis, and ſix earth. It is ſuppoſed that the ſalt contains more than the common ſal martis. As this water, on being expoſed to the air, drops an ochreous ſediment, and becomes weaker; it is probable, that part of the impregnated matter is diſſolved and ſuſpended by aërial acid, though great part is kept in its ſtate of ſolution, by means of the acid of vitriol.

This water is recommended in cures, where chalybeates are uſeful; in menorrhagia, fluor albus, gleets, old dyſenteries, in diſeaſes ariſing from relaxation, and many other complaints. See Monro, on Mineral Waters, and AQUÆ CHALYBEATÆ.

HASACIUM. See AMMONIACUS SAL.

HASTA REGIA. See ASPHODELUS LUTEUS.

HASTELLÆ. Splints uſed in fractures.

HAUD. Wood. So the Arabs call the agallochum, by way of eminence; it is called *haud alcumeri*, *haud hend*, and *haud heud*.

HAUR, } See SUCCINUM.
HAURUS. }

HAUSTUS. A DRAUGHT. *Draughts* differ not from any liquid form, only in their being in ſingle doſes; vomits, purges, opiates, and ſuch others as require great nicety in determining the doſe.

HAVELIA. See HURA.

HAVERI GLANDULÆ. HAVER'S GLANDS. They are the ſinovial glands, and are thus called becauſe *Haver* firſt diſcovered them.

HEBDOMADARIA. It is one of the febres erraticæ.

HEBE. The hairs which grow upon the pubes; the part on which they grow, or the age when they appear.

HEBISCOS. See ALTHÆA.

HECTICA vel ETHICA. From ἕξις, *habit*. An epithet for a ſpecies of fever. It is alſo named by different writers, the SYMPTOMATIC FEVER; IRREGULAR INTERMITTENT FEVER; FEVER of SUPPURATIONS, and LENTA FEBRIS, SLOW FEVER. Hippocrates deſcribes this fever under the name of phthiſis; Celſus is the firſt who ſpeaks of it under the name of an *hectic* fever, and he directs the cure: what were afterwards called ſlow *hectic* fevers, were, among the firſt phyſicians, called tabid, or long continued fevers, or maraſmi. At preſent, by ſlow and *hectic* fevers are meant thoſe which are chronical, and continually, by a preternatural, though by a mild and unremitting heat, conſume the juices, induce a conſumption, and impair the ſtrength. There is a confirmed ſteady health when it is ſaid there is a good habit of body: and when it is ſaid there is a *hectic* cough or fever, it is underſtood that the diſorder is not caſual, but permanent, or that it makes a part (as it were) of the conſtitution. Dr. Cullen does not rank this kind of fever as a genus, but conſiders it always as ſymptomatic. He deſcribes it, a fever returning every day; with meridian and evening acceſſions; a remiſſion in the morning, but ſeldom a total freedom from fever; for the moſt part attended with night ſweats, the urine depoſiting a furfuraceous, lateritious ſediment.—To which he adds, that as all noſologiſts have admitted the *hectic* amongſt the number of fevers, he has given its character; but that he never had obſerved a fever of this ſort, except as a ſymptomatic one, therefore he could not admit it to be enumerated amongſt idiopathic fevers. In many examples given by SAUVAGES, it is manifeſt, that the ſpecies of this fever are in fact ſymptomatic. It may be called *febris remittens chronica non critica*, as it has no criſis, and is of long continuance.

On diſſecting patients whoſe death was the conſequence of an *hectic* fever, there were found abſceſſes in one or other of the viſcera, or ſcirrhous tumors, or thoſe of the ſteatomatous kind; whence it is evidently a ſymptomatic fever.

Lying-in women, and thoſe in whom the menſes ceaſe, are liable to this diſorder; intemperate drinkers, by the injury they do the ſtomach and liver, are very ſubject to it; as are all in whom are diſordered glands, or abſceſſes, or ulcers in the internal parts.

The principal cauſe is the matter of internal ulcers, which is abſorbed into the blood: this matter, according to its quality and quantity, excites a fever more or leſs frequent and violent. The matter, producing this kind of fever, may be formed in any part of the body indifferently, though perhaps the glands of the meſentery may be its moſt frequent ſource. A ſcirrhous gland in any part, almoſt conſtantly excites this fever; hard drinking, by injuring the ſtomach and liver, produces the ſame effect. A ſalivation is ſometimes the cauſe. Dr. Reid, in his Eſſay on the Nature and Cure of the Phthiſis, denies that the abſorption of pus is the cauſe of the fever which attends the pulmonary conſumption. He attributes it to the following cauſe, viz. "In a ſtate of health, a very large quantity of perſpirable matter is diſcharged from the ſurface of the lungs: but when the lungs, from inflammation, or the formation of tubercles and vomicæ, are rendered in part impervious to the air in inſpiration, the uſual quantity of fluid cannot be carried off by the action of reſpiration; the quantity ſo retained will remain in the habit, till excreted by ſome other emunctory. That quantity of fluid ſo retained in the habit, he conceives to be the great and principal cauſe of the *hectic* fever, which invariably abates as ſoon as it is diſcharged by the pores of the ſkin: and as the impediment to its exit by the lungs continues, ſo the fever is daily renewed, that the conſtitution may be relieved from its accumulated burden. He adds, as the lungs, by the increaſe of the diſeaſes, become more and more incapable of exhaling the uſual quantity of lymph, we find the morning ſweats proportionably increaſed, and the exacerbations of the fever more violent, till towards the cloſe of the diſeaſe,

when the patient's ſtrength is ſo exhauſted, and the muſcular force and action of the veſſels ſo much weakened, as probably to be unable to produce ſuch a degree of fever as is neceſſary to force the fluid through the pores of the ſkin; it falls upon the inteſtines, and produces a diarrhœa. From being uſually coſtive, the patient hath frequent motions in a day; till in a ſhort time the purging becomes confirmed: we then find the fever and ſweating conſiderably diminiſhed, and the expectoration of purulent matter in leſs quantity. The quickneſs of the pulſe betwixt the paroxyſms of the fever, he ſuppoſes to have ariſen from the form of the progreſſive inflammation of one ſet of tubercles after another.

Its appearance is like that of an intermittent of an irregular kind, the pulſe rarely ſettles to a natural ſtate; but remains quick, though weak; the chillneſs of the hectic fever is not regularly ſucceeded either by a dry heat or ſweat, though one or other of them generally follows it; and the hot fit ſometimes approaches without any ſenſible degree of chillneſs preceding. The ſweat coming on does not ſeem to relieve the patient much; when the ſweat is over, the fever will ſometimes continue; and in the middle of the fever the chillneſs will return, which Dr. Wm. Heberden denotes *as a certain ſign of the preſence of this fever and its pathognomonic ſymptom.* This fever is very irregular in its returns. In the fit, the urine is ſo various, that nothing can be aſcertained from its appearances. When the cauſe is an ulcer on the ſurface of the body, there are often pains which reſemble the rheumatiſm; but theſe pains are generally ſituated very remote from the ulcer which is their original cauſe. A ſudden puffing up of ſome part of the body is ſometimes obſerved in this diſorder, which ſoon ſubſides ſpontaneouſly. For the moſt part its approach is gradual, but its iſſue is not the leſs to be dreaded on that account. The ſkin is dry, the tongue hard and parched, the cheeks flushed, the ſleep is not refreſhing. Hippocrates obſerves, in his treatiſe De Internis Affectionibus, that, on the approach of the fit, the whole breaſt is pained as far as the back; that a cough is often an attendant, and a quantity of thin ſaline ſaliva is diſcharged: that in the progreſs of the diſeaſe the whole body is emaciated, except that the legs becoming rather tumid, ſeem not much affected: the breathing reſembles a whiſtling through a reed.

Galen ſays, that the pathognomonic ſign is, *the fever being increaſed after eating and drinking.*

The *hectic fever* ſhould be diſtinguiſhed from the intermittent, the common inflammation, and the ſlow or nervous fevers. Dr. Reid diſtinguiſhes the *hectic* from a pulmonary conſumption, as differing from the *hectic* from abſceſſes or ulcers in other parts: the *hectic* fever occaſioned by abſceſſes in the liver, under the pſoas muſcle, and other parts of the body, he ſays, have not the remiſſions and morning ſweats like the pulmonary *hectic:* on the contrary, it is continued leſs violent; and the ſkin uſually dry.

If the pulſe runs on to above 90, or, as ſometimes happens, to 120 in a minute, much danger attends; though ſometimes the pulſe will be unaffected under a variety of other fatal ſymptoms. In lying-in women it is generally fatal; though it muſt be confeſſed that ſome have recovered, when attended with every ſign of a fatal caſe. The fatal ſigns are, *a continually weak, quick pulſe, an entire loſs of appetite and ſtrength, an Hippocratic countenance, a little red or oily urine made with an hiſſing noiſe, the hair falling off, a diarrhœa, immoderate ſweats, and ſwelling of the feet.*

As a variety of circumſtances give riſe to fevers of this kind, a diverſity muſt be expected in the cure.

As far as this diſeaſe is conſidered of the putrid kind, the bark will be that on which relief will principally depend; but if there is no manifeſt ulcer, it does not promiſe much; if it affects the breathing, add to each pint of the infuſion, two or three drams of balſam of Peru. In ſome inſtances, the cort. elutheriæ is preferable to the bark, and vice verſa.

In moſt caſes the ſole intention is to relieve the ſymptoms, ſuch as moderating the heat, preventing coſtiveneſs and its oppoſite, checking the night ſweats, and at the ſame time putting the body into as good a general health as may be, by exerciſe, air, and a proper diet.

When ſalivation is the cauſe, a milk diet, with the decoctions of guaiacum, is generally ſucceſsful.

Bleeding in ſmall quantities give a temporary relief.

When it follows other diſeaſes, and is attended with a bad digeſtion, internal heat, ſweating in the hands and feet, give an emetic, and repeat it every two or three days: then let the kali acetatum with as much rhubarb be given as ſuffices to keep the bowels moderately lax for a few days; and after theſe the bark, joined with bitters, and a nouriſhing diet. The columbo-root is here to be preferred.

In cacochymic and ſcorbutic habits, in caſes from a defect of the menſes or *hæmorrhoids,* or *the abuſes of ſpirituous liquors,* the Bath waters may be uſed with ſome advantage.

In general, a milk diet is to be preferred. Aſſes milk is the moſt cooling; but in want of it, mix barley-water with equal quantities of cow's milk, and let two or three pints be taken in a day. Seltzer water may be uſed with the milk inſtead of barley-water.

Riding is to be regarded, as noticed in the article Phthisis. See Hippocrates de Intern. Affect. Aretæus de Cur. Acut. lib. ii. Fernelius, Hoffmann, Shebbear's Theory and Practice of Phyſic; Dr. Wm. Heberden's Obſ. in the Lond. Med. Tranſ. vol. ii. p. 1—17. Dr. Fordyce's Enquiry into the Cauſes, &c. of putrid Fevers. Cullen's Firſt Lines, vol. ii. 221, &c.

HEDERA. Ivy.

—— arborea. Common, or tree-ivy, called alſo *corymbus,* or *corymbe.* It is the HEDERA HELIX, Linn. It is an ever-green plant, climbing and ſpreading on old walls and trees; the leaves are angular; the flowers appear in autumn, and are followed in winter by cluſters of blackberries.

The leaves are nauſeous to the taſte, not uſed with us, but are commended by the Germans, as being uſeful in the atrophy of children; the doſe is from ℈ i. to ʒ i. Quercetanus uſed to make an extract from the berries, which he called *extractum purgans.* From the ſtalks of the plant, a reſinous juice exudes in warm countries, which is called *gummi hederæum*; it is of a reddiſh brown colour outwardly, and of a bright brown yellow inwardly, of a vitreous gloſſineſs, but not pellucid; when rubbed, it emits a light agreeable ſmell, and is of a reſinous ſubaſtringent taſte: it is chiefly uſed as other reſins in plaſters.

—— terrestris. Ground-ivy. Called alſo *chamæciſſus*; *chamælema*; *calamintha humilior*; *corona terræ*; *bacchica chamæclema,* ale-hoof; sun-hoof; jack in the hedge; gill go-by-the ground; Glecoma hederacea, or glecoma *foliis reniformibus crenatis, floribus ex cæruleo purpureis.* Cl. Didynamia. Ord. Gymnospermia. Linn. Gen. Pl. p. 714. It is a low, hairy, creeping plant, with ſquare ſtalks; roundiſh, or kidney-ſhaped leaves ſet in pairs at the joints; the flowers are bluiſh and labiated; the upper lip is cloven, and turned backwards; it is common in hedges and ſhady places; it flowers in April, and moſt of the warm months after, and is generally found greeniſh all the winter. There are four ſpecies.

This herb had a quick, bitteriſh, warm taſte, an aromatic, but not very agreeable ſmell, which is in a great meaſure diſſipated by drying. It is ſuppoſed to be uſeful in diſorders of the breaſt, and is an attenuant. In obſtinate coughs, it is a favourite medicine with the poor, given in the form of tea, and ſweetened with honey, who from the long perſeverance in its uſe, muſt probably experience ſome good effects. Dr. Pitcairn ſpeaks highly of it in conſumption. Ray alſo gives it a high character, though Dr. Cullen thinks it of no conſequence, and ſays, that in many caſes in which he employed it, he had had no evidence of either its diuretic, or pectoral effects, and thinks it very improbable that it ſhould be powerful in curing ulcers of the lungs, and various caſes of phthiſis. Mat. Med. Ale, in which *ground-ivy* is infuſed, is rendered very fine by it, and is called gill-ale. It gives out its virtue moſt perfectly to water by infuſion, on inſpiſſating the filtered liquor, only the unpleaſant ſmell is diſſipated. See Lewis's Mat. Med.

HEDERÆUM GUMMI. See Hedera arborea.

HEDERULA AQUATICA. See Lenticula aquatica trisulca.

HEDRA. See *anus*; alſo the excrements thence voided; it ſometimes ſignifies the baſis of an abſceſs, or that part which is ſubjected to that which is converted into matter. Hippocrates ſometimes uſes this word to ſignify a ſpecies of fracture.

HEDRICOS. An epithet for remedies appropriated to the anus.

HEDYCHROI. A name for certain troches. Their compoſition is in ſome of our later diſpenſatories.

HEDYOSMOS. See MENTHA.

HEDYPNOIS. See DENS LEONIS.

HEDYSARUM GLYCYRRHIZATUM. See GLAUX, vulg. leguminoſa.

HEDYSMATA. See STYMMATA.

HELCYDRION. A ſmall ulcerous puſtule.

HELCYSTER, from ἕλκω, *to draw*. An hook for extracting the fœtus.

HELENIUM. See ENULA.

—— INDICUM. See BATTATAS CANAD.

HELEOSELINUM. See APIUM.

HELIANTHEMUM. See CHAMÆCISTUS, BATTATAS CANAD.

HELICALIS MAJOR. } See AURICULA.
—— MINOR. }

HELICHRYSUM, from ἥλιος, *the ſun*, and χρυσὸς, *gold*. GOLDYLOCKS. See ELICHRYSUM, alſo GNAPHALIUM MONTANUM.

HELIDÆI, PULV. See EUPHRASIA.

HELIOCHRYSON. See ELYCHRYSUM.

HELIOSCOPIOS. See TITHYMALUS.

HELIOTROPIUM. TURNSOLE, or HELIOTROPE. Botaniſts enumerate ten or eleven ſpecies; but they are not much uſed medicinally. The flowers of this kind of plants are funnel ſhaped; their brims are cut into ten unequal ſegments; they are collected into a long reflexed ſpike, reſembling a ſcorpion's tail; each flower is followed by four naked gibboſe ſeeds.

HELIOTROPIUM MAJUS. The GREAT TURNSOLE. Its leaves are bitter; they give a deep red colour to blue paper. The juice of this plant deſtroys warts; a decoction of it is ſaid to purge off pituitous humours.

—— TRICOCCUM; called alſo *ricinoides*; FRENCH, or COLOURING TURNSOLE. This ſpecies grows plentifully in France; the leaves are of pale green, almoſt of an aſh colour: the flowers are yellow: when the berries are expreſſed, linen rags are dipped in the juice, and then expoſed to the vapour of urine, which gives them a red colour. The colour of turnſole is extremely ſuſceptible of alteration in acids, which, according to their ſtrength, give different degrees of redneſs to it. Alcaline ſalts do not affect it. See Raii Hiſt. Plant.

—— INDICUM. See BATTATAS CANADENSIS.

HELITIS. See ÆRIS SQUAMÆ.

HELIX, from ἕλιξ, *to turn*. A SPIRAL LINE. See AURICULA.

HELLEBORASTER, HELLEBORASTRUM. BEAR'S-FOOT. See HELLEBORUS FŒTIDUS.

HELEBORIZE. Hippocrates and others after him uſed prepared *hellebore*, which they introduced into the rectum, both for vomiting and purging, which they made ſtronger or weaker as they required; and the vomiting, purging, or both, produced thus, they called *helleborizing*.

HELLEBOROIDES, called alſo *aconitum hyemale*; *aconitum luteum minus*; *aconitum unifolium luteum bulboſum*. The leaves are like thoſe of the aconitum; but in general it agrees both in appearance and virtues with black hellebore.

HELLEBORO-RANUNCULUS. The leaves are ſingle and roundly turned like thoſe of the ranunculus. They are of the ſame colour with the flower. The flower is roſaceous. It is ſaid to be cauſtic.

HELLEBORUS, or *Elleborus*, from ἕλλειν βορὰ, *to kill by eating*; called alſo *nicon*. This name is applied to ſeveral roſaceous flowered plants, and is a name of female ſanicle. See IMPERATORIA NIGRA.

—— FŒTIDUS; called alſo *helleboraſter*; *helleboraſtrum*; *helleborus niger fœtidus*; *conſiligo*, *enneaphyllum*; *elleborine*; *helleboraſter maximus*; *veratrum nigrum*; GREAT BASTARD BLACK HELLEBORE; FETID BLACK HELLEBORE; SETTLE, or SETTERWORT; BEAR'S FOOT. It is the HELLEBORUS FŒTIDUS caule multifloro folioſo, foliis pedatis. CLASS, POLYANDRIA. ORD. POLYGYNIA. LINN. Gen. Plant. 702. This root is ſmall, but beſet with a prodigious number of dark-coloured fibres, or ſtrings, involved, and wrapped one within another very intricately: the ſtem riſes to a foot and a half in height, or more; towards the bottom, it is ſtrong, round, firm, naked, and marked with alternate cicatrices, the veſtiges of the former leaves; at the top, it divides and ſubdivides into branches, producing many flowers; and is garniſhed with ſcaly leaves, which are numerous, and ſtand upon long foot-ſtalks, ſurrounding the middle of the ſtem. They are divided, like the black hellebore, into ſimple leaves, commonly eight or nine, long, narrow, ſerrated, lanceolated, and of a dark green colour; the ſcaly leaves, placed at the ramifications of the flower ſtem, are ſmooth, trifid, alternate, and often purpliſh; but thoſe near the flowers are oval and pointed; the flowers are numerous, terminal, pendent, of a roundiſh ſhape, and ſtand upon peduncles, forming a ſort of umbel; the petals are five, oval, concave, perſiſtent, of a pale green colour, and their margins are uſually tinged with purple; the ſtamina are the length of the petals; the antheræ are white; the germina three, hairy, and ſhaped ſimilar to thoſe of the black hellebore. The plant grows wild in many parts of England, and flowers about February. WOODVILLE'S Medical Botany. The ſmell of the recent plant is extremely fœtid; the taſte bitter, and remarkably acrid: it operates as a cathartic, ſometimes as an emetic; and, in large doſes, it is highly deleterious. It is uſed chiefly as a vermifuge; the dried leaves, in powder, is given from ſix to fifteen grains; or, the decoction, of about a dram of the green leaves, to children betwixt four and ſeven years old. It is uſually repeated for two, and ſometimes three ſucceſſive mornings; the ſecond has commonly a greater effect than the firſt, and never fails to expel round worms by ſtools, ſhould there be any lodged in the alimentary canal. It ought, however, at firſt, to be given very cautiouſly, and in ſmall doſes. The beſt form for children, is ſyrup, thus made. The bruiſed leaves are firſt moiſtened with a little vinegar, as a corrector of this medicine, then the juice is expreſſed from the leaves, and made into a ſyrup with coarſe ſugar. A tea ſpoonful is given at bed time, and one or two, in the morning, for two or three ſucceſſive days, increaſing or diminiſhing the doſe according to the ſtrength of the patient. Dr. Biſſet ſays, this is the only remedy he had uſed for three years paſt againſt round worms; and ſpeaks of the plant as uſeful in ſome aſthmatic, and hypochondriacal diſorders. See *his Eſſay on the Medical Conſtitution of Great Britain*. Another beneficial and ſafe inſtance of their uſefulneſs, is to ſprinkle the powder of them in iſſues, to increaſe their diſcharge. They grow wild in ſhady places. See Tournefort's Mat. Med. Raii Hiſt. Plant.

HELLEBORUS ALBUS; alſo called *veratrum*; COMMON WHITE HELLEBORE. VERATRUM ALBUM, racemo ſupra de compoſito, corollis exalbidis erectis, CL. POLYGAMIA. ORD. MONŒCIA. LINN. Gen. Pl. p. 1144. This plant hath large, oval, ribbed leaves, placed alternately on a round ſtalk, which they embrace by a tubulous baſis; in their boſoms towards the top, appear cluſters of hexapetalous, greeniſh white flowers, followed each by three flat pods, containing whitiſh triangular ſeeds; the root is ſhort, commonly near an inch thick, with numerous fibres hanging from it: externally, it is of a browniſh colour, but internally much more white. It is common on mountainous places in Germany, Switzerland, &c. It is not certain that our hellebore is the ſame as the ancients, though generally this ſpecies is thought to be ſo.

When the root of *white hellebore* is freſh, it hath a diſagreeable ſmell, which is loſt in drying; to the taſte it is nauſeous, bitteriſh, acrid, penetrating, and durable. When powdered, it is uſed externally againſt ſome cuticular eruptions, and for deſtroying cutaneous inſects; but if applied to any ſore, it excites vomiting, and other diſagreeable ſymptoms: ſnuffed up the noſe, it proves a violent ſternutatory. If the powder is taken from gr. x. to xv. it operates powerfully both upward and downward; but except in maniac caſes, it is rarely uſed. If, on taking this root, it does not work off freely, give an emetic to bring it upwards, or it will probably produce convulſions. Hoffman obſerves, that it affects the fauces, producing ſtrangulation and danger of ſuffocation, with great anxiety; and he recommends the juice of quinces as the cure.

Tinctura Veratri. Tincture of WHITE HELLEBORE.

Take of powdered white hellebore roots, eight ounces; of proof ſpirit, two pints. Digeſt, and filter through paper.

This is the beſt internal preparation. It is given to actuate cathartics, &c. in apoplectic, lethargic, and maniac caſes. In chronical diſorders it might be uſed to great advantage, if ſmall doſes were begun with, and gradually increaſed. The powder, in doſes, to the quantity of a grain and an half to a dram of ſneezing powder, quickens the operation. It is alſo uſed in decoction.

DECOCTUM

DECOCTUM HELLEBORI ALBI. DECOCTION OF WHITE HELLEBORE. One ounce of this root is to be boiled in two pints of diſtilled water till they are reduced to one; when cold, two ounces of rectified ſpirit of wine are to be added. This is uſed in cutaneous diſeaſes, but chiefly the itch, which it frequently cures; and is more cleanly than any ointments.

Geſner, in his treatiſe on this plant, ſays, that an oxymel, with the root, is a powerful expectorant, and opens all natural ſecretions. This is moſt indiſputably a very powerful medicine, and ſhould be given, at firſt, in very ſmall doſes, and gradually increaſed.

HELLEBORUS NIGER; called alſo *melampodium*; by PARACELSUS, *daura eſtomon*; CHRISTMAS FLOWER, BLACK HELLEBORE.

It is the HELLEBORUS NIGER, OF HELLEBORUS *ſcapo ſubbiflore, ſubnudo, foliis pedatis.* CLASS, POLYANDRIA. ORD. POLYGYNIA. LINN. Gen. Plant. p. 702. The CHRISTMAS ROSE.

It is called MELAMPODIUM, from Melampus, who was the firſt that uſed it in medicine. He obſerved its purging quality in the goats which fed on it, and thence introduced it into the Materia Medica. It is a low plant, without any other *ſtalk than the pedicles* of the leaves and flowers; the *leaf* is divided quite to the pedicle, into ſix, ſeven, or more ſmooth, firm ſegments, reſembling bay-leaves, indented from about the middle to the extremity; *the flower* is large, naked, pentapetalous, of a pale roſe-colour, with numerous ſtamina in the middle, which are followed by five or ſix pods full of ſhining black ſeeds, the petala continuing and changing greeniſh; *the root* conſiſts of numerous fibres, hanging generally from a knotty head, externally of a blackiſh colour, internally white. It is perennial, grows wild in the mountainous parts of Germany, Switzerland, &c. It flowers in our gardens in January.

The *hellebore* of the ancients is generally believed to have been a more active kind than ours.

The root to the taſte is bitter and pungent; if chewed for a few minutes, it benumbs the tongue. Dr. Grew obſerves, that it is firſt felt on the tip of the tongue, and then on its middle. The fibres are ſtronger, and more active than the tuberous head, and the cortical part of this than the internal. It frequently loſes its virtue by long keeping; and when it hath loſt its ſmell, it is good for nothing.

The roots of the poiſonous aconites reſemble thoſe of black *hellebore*, but are diſtinguiſhed by their colour; the aconitum being lighter coloured than the paleſt black hellebore roots; therefore, for ſafety, chuſe the darkeſt.

Long coction deſtroys the active parts; water extracts, by boiling, and ſpirit, by digeſtion, nearly all the virtue of the root. Rectified ſpirit takes up chiefly the irritating reſinous part. After due coction in water, it gives out little to ſpirit; but after repeated digeſtion in pure ſpirit, it yields to water a large portion of mucilaginous diuretic matter.

In the preſent practice, the black *hellebore* root is only uſed in ſmall doſes as an attenuant and deobſtruent. Its peculiar and principal uſe is in obſtructions of the menſes, when the habit is plethoric, and the conſtitution ſanguine, in which caſe, ferruginous preparations would be improper. The emmenagogue virtues of this medicine may be conſidered as very doubtful, for Dr. Cullen ſays, he never found any in many trials, nor has he met with any practitioners of this country (Scotland) though often trying it, who had better ſucceſs in this reſpect; and particularly, neither in his own practice, nor that of others, has he met with one inſtance of the power of *hellebore* in producing hæmorrhagy. Mat. Med. It promotes urine and perſpiration; in *hypochondriac diſorders*, it may be joined with chalybeates, ; and, if the pulſe is low, add the fetid gums, with a julep of volatile ſalt: in *dropſies* it is uſeful, if joined with lixivial ſalts. In all nervous caſes which do not admit of chalybeates, its advantages are conſiderable. It is one of the principal ingredients in Bacher's famous tonic pills. See ASCITES.

The London College directs a watery extract. See EXTRACT. GLYCYRRHIZÆ, and a tincture with proof ſpirit, which is made in the following manner:

℞. Rad. helleb. nigri in pulverem craſſum tritæ ℥ iv. coccinellarum in pulv. tritarum ℈ ij. ſpt. vinoſi tenuioris, m. ℔ ii. digere leni calore per dies octo, & cola. Pharm. Lond. 1788. The extract is a good and ſafe preparation when deſigned for a cathartic; it contains alſo the diuretic part; the irritating power is in a good degree deſtroyed by boiling. The doſe is from gr. x. to ʒ ſs. and ſo is it of the powder, which purges, though the extract is thought milder; but as an alterative, the tincture is far preferable; for it poſſeſſes the whole virtue of the roots; of which a tea-ſpoonful twice a day may be conſidered a common doſe. See Neumann's Chem. Works. Tournefort's Materia Medica. Lewis's Materia Medica.

HELOCAPOLLIN. A ſort of cherry. See CAPOLIN, MEXIC. HERNAN.

HELODES, from ἕλος, *a fen.* An epithet for certain fevers, attended in the beginning with profuſe but uſeleſs ſweats. The *ſudor Anglicus* is of this kind. It is the ſame as the TYPHODES.

HELOSIS. A diſorder of the eye, conſiſting in an everſion or turning up of the eye-lids.

HELOTIS. See PLICA POLONICA.

HELW. LITHOGR. The abbreviation of M. G. A. Helwing, Lithographia.

HELXINE. See PARIETARIA;

HEMALOPIA. Sight divided into two. A ſpecies of pſeudoblepſis.

HEMERALOPS, from ἡμέρα, *a day*, and ὤψ, *the eye*; called alſo by RHAZES, *dorca.* A defect in the ſight, which conſiſts in being able to ſee in the day time only, but not in the evening; hence the defect, named *hemeralopia.* See NYCTALOPS.

HEMEROCALLIS. See LILIUM RUBRUM.

HEMEROLOPIA. Blindneſs in the night. A ſort of pſeudoblepſis.

HEMICERAUNIOS. The name of a bandage, in Galen, for the back and breaſt.

HEMICRANIA, from ἥμισυ, or ἡμι, *half*, and κρανιον, *the ſkull.* See CEPHALALGIA.

HEMICRANIA LUNATICA. A kind of febris erratica.

HEMIOBOLION, or HEMIOBOLON. Half an obolus, or the twelfth part of a dram; for a dram has ſix oboli, therefore it will be five grains.

HEMIOLION. It is, according to Galen, twelve drams, and in another ſenſe it is the ſame as *ſeſqui altera*, the whole of a thing and half as much more, as ſeſquiuncia, ſeſcuncia, *an ounce and an half.*

HEMIONITIS. MULE'S FERN. It grows in Italy. It reſembles the hart's tongue in appearance and virtues; ſee LINGUA CERVINA.

HEMIONIUM. See ASPLENIUM.

HEMIPAGIA. See CEPHALALGIA.

HEMIPLEGIA, } from ἥμισυ, *half*, and πλήσσω, *to*
HEMIPLEXIA, } *ſtrike.* Dr. Cullen arranges it as the ſecond ſpecies of paralyſis, in which one ſide or the other of the body is affected; of which he forms two varieties. 1. When it occurs in plethoric, 2. when in leucophlegmatic habits. It uſually begins with, or follows a paroxyſm of apoplexy; and when the *hemiplegia*, after ſubſiſting for ſome time, becomes fatal, it is commonly by paſſing again into the ſtate of apoplexy. The relation, therefore, or affinity between the two diſeaſes, is ſufficiently evident, and is further ſtrongly confirmed by this, that the *hemiplegia* comes upon perſons of the ſame conſtitution, and is preceded by the ſame ſymptoms that are obſerved in caſes of apoplexy. See PARALYSIS. Lond. Med. Journal, vol. i. p. 323. vol. ii. p. 198.

HEMIRHOMBION, } A ſort of bandage mentioned
HEMITOMON. } by Hippocrates, called alſo *ſemirhombus*, from its figure.

HEMITRITÆUS, from ἥμισυ, *half*, and τρίτος, *third*, or *tertian*: ſee SEMITERTIANA FEBRIS.

HEPAR. HEPER. Martinius and Gorræus derive it from ἕπω, *to work*, and ἑαρ, *blood*; upon a ſuppoſition it was to prepare the blood. The LIVER. See JECUR.

—— SULPHURIS. See KALI.

—— UTERINUM. See PLACENTA.

HEPATALGIA, from *epar*, jecur, *the liver*, and *algos*, dolor, *pain.* When pain affects the liver, as well as ſpleen, it is very often impoſſible to diſtinguiſh them from ſome of the ſpecies of colic, during the life of the patient; nay, indeed, ſome practitioners think it unneceſſary, ſince they require the ſame mode of cure as the colic from a bilious cauſe.

But as theſe ariſe from different cauſes, it may not be uſeleſs to deſcribe ſome of them; viz. thoſe which ariſe from *ſcirrhoſity, or hard tumefaction of the liver, —obſtructions of the gall ducts*, from very viſcid bile —the gall bladder being alſo full of bile—and *gall ſtones*, ſo called.

When pain of the liver owes its origin to SCIRRHOSITY, it is attended with the following ſymptoms:

DESCRIPTION.

DESCRIPTION. There is a tumor and hardneſs on the right ſide below the ſhort ribs—a ſenſe of weight, with a dull and tenſive pain, which is conſtant—the patient breathes with difficulty, and has a dry cough—and, after eating moderately, there comes on a loathing, and ſenſe of preſſure on the ſtomach, with an increaſe of the difficulty of breathing—beſides, he cannot lie with eaſe on his left ſide—the countenance is yellowiſh, pale, and ſallow—the urine often of an orange colour, and depoſits a thick mucous ſediment—theſe are generally the firſt appearances, which, if the complaint continues, as is too frequently the caſe, the feet are ſeized with a ſoft paſty ſwelling—the ſuperior parts fall away—and the concluſion is, a dropſy of the belly, with a remittent fever.

When the cauſe is OBSTRUCTION OF THE GALL DUCTS, from biliary or viſcid obſtructions, the ſymptoms of a ſcirrhous liver, which come on in the beginning, attend, but in a much ſlighter degree—beſides, there is a flushing heat of the face, with redneſs and heat coming on now and then in the palms of the hands—an irregular thirſt—dryneſs, and bitter taſte in the mouth—a dry cough—viſcid ſaliva—loſs of appetite—heart-burn—wearineſs and heavineſs of the limbs—increaſe of pain on touching and preſſing the left ſide—and the habit moſt commonly coſtive.—In this caſe the hardneſs on the right ſide is not ſo firm as in the former, nor are there any paſty ſwellings, or hectic ſymptoms.

When it ariſes from GALL-STONES, there is a deep-ſeated and excruciating pain on the right ſide of the ſtomach, extending to the back, about the place where the ductus communis choledochus, or duct of the gall-bladder, is inſerted into the duodenum, which remits and increaſes; the patient complains of ſickneſs, and vomits much—the right ſide is diſtended with flatulence—the belly coſtive—the excrements pale coloured, ſometimes white—the pulſe is weaker, but ſcarce at all quickened, unleſs the pains are very violent, and continue long—indeed, *the violence of the pain being unattended with fever, and quickneſs of the pulſe*, is conſidered as the certain ſymptom of this diſeaſe—the patient, either in an erect poſture, or lying on the left ſide, feels much uneaſineſs—hence becomes reſtleſs—there attend alſo difficulty of breathing—heart-burn, and ſometimes convulſions—at firſt the urine is pale, afterwards yellow—and the ſkin and white of the eyes have a jaundice-like appearance—the pain at laſt vaniſhes ſuddenly, which is ſometimes ſucceeded by a looſeneſs, by which the gall-ſtones are thrown out of the habit—and the yellowneſs wears gradually away.

CURE. Pain in the liver from ſcirrhoſity, is apt to attack gluttons—hard drinkers—thoſe who lead indolent ſluggiſh lives—and alſo ariſes from ſuppreſſion of ſome hæmorrhages—bruiſes upon the right ſide—and very often in thoſe afflicted with long-continued intermittent fevers—and generally proves fatal, when once completely formed—though, if attacked in the beginning, it may be ſometimes prevented.

Decoctions of vegetable aperients, with the more powerful attenuating gums, joined with mercurials and cathartics, are ſerviceable; alſo graſs-roots, dandelion, endive, ammoniacum, myrrh, rhubarb, aloes, calomel, ſmall doſes, not to ſalivate; hemlock, in all curable caſes, is very uſeful.

In CONSTITUTIONS, *conſidered as dry and bilious* decoctions of the mild opening roots, goats' whey, and tartarized iron.

In *the cold and phlegmatic*, the mode here recommended will be proper when the complaint ariſes from obſtructions of the biliary pores; but, in delicate and irritable habits, ſpaſmodic affections will ſometimes be the cauſe; ſedatives and antiſpaſmodics may then be joined with the aperients, aſſafœtida, camphor, or with opium—and when, by theſe means, the bile has paſſed into the bowels, a courſe of bitters and ſteel may be neceſſary to complete the cure,—taking care always to keep the body open with ſuch medicines as are beſt adapted to move the bile.

Bath water, and chalybeate ſprings in general, are beneficial and proper to prevent a relapſe.

When it ariſes from GALL-STONES, we muſt endeavour to promote the expulſion by long perſeverance in the uſe of emollients, and gentle cathartics,—warm baths afterwards, occaſionally repeated, in which a cathartic may be given—this mode has proved ſucceſsful—vomits, and ſtrong expiration, with glyſters of freſh urine, and ſage infuſion, have fortunately ſucceeded—opiates ſhould be adminiſtered to alleviate the pain, joined with aperients; becauſe they promote at the ſame time a relaxation of the duct—æthereal ſpirit of turpentine, has been recommended as a ſolvent.

In habits full of blood, in any of theſe complaints, bleeding may be had recourſe to, leſt inflammation ſhould be the conſequence of the violence or long continuance of the pain.

Old people and women are moſt ſubject to this complaint—thoſe who lead ſedentary lives, drink much of ſtrong ardent ſpirits, feed on viſcid, coarſe, and dry aliment, or are ſubject to the ſtone and gout.

In order to prevent a return of theſe complaints, gentle exerciſe, particularly riding on horſeback, ſhould be perſevered in; light eaſily digeſtible food taken, avoiding all that is viſcid. WALLIS on Health and Diſeaſe.

HEPATARIUS. HEPATIC.

HEPATEROS, from ἧπαρ, *the liver*. It is an epithet for a ſort of dyſentery, in which an aqueous blood is excreted.

HEPATICA, a name of the *hepatica nobilis*. Alſo a pain in the region of the liver.

—— VULGARIS, *fontana, terreſtris, ſtellata*. STONE, or STAR LIVER-WORT; called alſo *jecoraria*; *lichen petræus latifolius*. It is a ſpecies of moſs; it grows in moiſt ſtony places; it is perennial, and runs up to ſeed in March and April. It is ſaid to be aperient and reſolvent, but it is very little known in practice.

—— NOBILIS, called alſo *trifolium aureum, hepatica trifolia, herba trinitatis, trifolium hepaticum, ranunculus tridentatus vernus*. HERB TRINITY, and NOBLE LIVER-WORT. It is the ANEMONE HEPATICA, Linn. It is a low plant, without any other ſtalk than the pedicles of the leaves and flowers; the flower is commonly blue, ſometimes reddiſh or white, and are followed by white ſeeds. It is perennial, grows in gravelly ſhady grounds in Germany, and other parts of Europe. It flowers in our gardens in March, or ſooner.

This plant is eſteemed a mild reſtringent and corroborant, and infuſions of it are ſometimes drank as tea. Its aſtringent matter is equally diſſolved in water or ſpirit, and wholly remains in the extract made by inſpiſſating the infuſion or tincture over a gentle fire. See Lewis's Mat. Med. Raii Hiſt.

—— ALBA. See PARNASSIA.

—— ARTERIA. The HEPATIC ARTERY. As ſoon as this artery leaves the cœliaca, it runs to the upper and inner part of the pylorus. Sending off two branches, a ſmall one called *pylorica*, and a larger one called *gaſtrica dextra*, or *gaſtrica major*. Having ſent out theſe two, it advances behind the ductus *hepaticus*, towards the veſica fellis, to which it gives two branches, called *arteriæ cyſticæ*, and another called *hilaria*, which are loſt in the great lobe of the liver. Afterwards this artery enters the fiſſure of the liver, and joins the vena portæ, with which it runs in the capſula Gliſſonii, and accompanies it through the whole ſubſtance of the liver by numerous ramifications, which may be termed arteriæ *hepaticæ* proprie.

—— BRACHII VENA. See BASILICA VENA.

—— MINOR VENA. A branch from the vena portæ ventralis; or, ſometimes it is a branch of the cyſticæ venæ.

—— STELLARIS. } See ASPERULA.
—— STELLATA. }

HEPATICÆ VENÆ. They ſpring directly from the vena cava inferior, as it paſſes down through the poſterior part of the great fiſſure of the liver. Sometimes theſe branches riſe from the vena cava by one main branch, and then divide. Theſe correſpond with the venæ portæ. The vena cava alſo ſends others, which correſpond with the *hepatic* artery.

HEPATICO-CYSTICI DUCTUS. That ſide of the body of the gall-bladder which lies next the liver, is connected to that bowel by a vaſt number of filaments which run a great way into the ſubſtance of the liver; and among theſe filaments there are ſome ducts which form a communication between the pori biliarii and gall-bladder. Theſe ducts are the moſt numerous about the neck of the bladder.

HEPATICUS. HEPATIC, from ἧπαρ, *liver*. It is an epithet for any thing belonging to the *liver*. The ancients confined the word to an inflammation of the *liver*; but the moderns uſe it to ſignify thoſe perſons whoſe *livers* are diſordered from any cauſe.

HEPATICUS DUCTUS. See PORTÆ VENA.

HEPATIRRHŒA. A ſpecies of diarrhœa, which ſee. All other *hepatirrhœas* are ſymptomatical.

HEPATIRRHŒA INTESTINALIS, i. e. Diarrhœa hepatirrhœa. See DIARRHŒA.

HEPATITIS. *Inflammatio Hepatis.* An INFLAMATION of the LIVER.

An inflammation may be in different parts of the liver, as in the membranes only, or in its ſubſtance; in the concave or the convex ſide thereof, &c. Inflammation in the hepatic arteries is ſaid to cauſe ſome ſymptoms not unlike thoſe of the hydrophobia. See Hippocrates Coac. lib. cxxxix. Aretæus de Cur. Acut. lib. i. and Trallianus, lib. i. c. xv.

Dr. Cullen places this genus of diſeaſe in the CLASS PYREXIÆ, and ORD. PHLEGMASIÆ, and defines it, febrile affections, attended with tenſion and pain of the right hypochondrium, often pungent, like that of a pleuriſy, but more frequently dull, or obtuſe; a pain at the clavicle, and at the top of the ſhoulder of the right ſide; much uneaſineſs in lying down on the left ſide; difficulty of breathing; a dry cough; vomiting; hiccough. SAUVAGES, and SAYER, he ſays, amongſt the ſymptoms, have placed a yellow colour of the face; and alſo, here adds, yellow coloured, bilious urine, the ſerum of the blood drawn, and ſcabby eruption, alſo of a yellow colour; but theſe ſymptoms of a regurgitation, and reſorption of the bile, has been, he thinks, very properly omitted by LINNÆUS and VOGEL; becauſe ſymptoms of this ſort are not always attendant, but occur very rarely. Of this diſeaſe, he makes two varieties, the ACUTE, the CHRONIC. The pathognomonic ſymptoms of the firſt are above recited: The CHRONIC often affords no ſigns by which it can be diſtinguiſhed; ſtill, ſometimes, it may be ſuſpected to be preſent, from ſome cauſes of the hepatitis having preceded; from a certain ſenſe of fullneſs and weight in the right hypochondrium; from pains, more or leſs pungent, perceptible now and then in the ſame part; from pain, on preſſing the hypochondre on the right ſide, or on being perceived from lying down on the left ſide; and laſtly, from a ſlight fever accompanying now and then the above ſymptoms.

Winſlow ſays, that the ſeat of inflammation in the liver is in the ramifications of the vena portæ, or the hepatic artery; but Dr. Heberden gives it as his opinion, that the inflammation is firſt in ſome of thoſe parts to which the liver is contiguous, and ſo is communicated to it from them. Dr. Cullen aſſerts, that the inflammation is only in the extremities of the hepatic arteries.

THE ACUTE HEPATITIS may be ſeated either on the convex or on the concave ſide of the liver. *In the former caſe*, a more pungent pain and hiccough may be produced, and the reſpiration is more conſiderably affected. *In the latter*, there occurs leſs pain, and a vomiting is produced, commonly by ſome inflammation communicated to the ſtomach. The inflammation of the concave ſurface of the liver, may be readily communicated to the gall-bladder and bilious ducts; and this perhaps is the only caſe of idiopathic *hepatitis*, attended with jaundice.

This diſorder is moſt frequent in warm climes; it is produced by the common cauſes of internal inflammation, and by obſtruction of the hepatic ducts, or of the ductus communis choledochus. It ſometimes ariſes at the beginning of a fever, as other internal inflammations. Dr. Cullen obſerves, that the remote cauſes of *hepatitis* are not always to be diſcerned.

When the ſeat of the diſorder is in the membranes, the pain is more acute, and reſembles a pleuriſy more than when the ſubſtance of the liver is the part affected. In this acute kind, the pain is pungent, the fever very conſiderable, the pulſe is frequent, ſtrong, and hard, and the urine is high coloured.

In general when the ſubſtance of the liver is inflamed, a pain is perceived there, which is not often very acute, at the firſt, but gradually increaſing, it ſhoots up to the top of the left ſhoulder, and ſometimes into the throat and about the clavicle. Some reckon the pain darting into the throat to be the pathognomonic ſymptom. The pulſe is not ſo much altered in the beginning if there is not much fever, which ſometimes is the caſe during the firſt days, and indeed during the whole of the time of inflamation is only known to have happened, by the conſequent abſceſs in the liver. In this chronical kind, it ſometimes happens that very little diſeaſe is obſerved until the ſuppuration takes place. When the ſwelling is large, or when the convex part of the liver is affected, a tumor is viſible externally, and occaſions a cough, a difficulty of breathing; the pulſe is then quickened, and the patient cannot well lay on his left-ſide. When the inflammation chiefly affects the concave, in proportion as it is near the ſtomach, it brings on ſickneſs, thirſt, hiccough, and vomiting; or if near the hepatic ducts, or the ductus communis choledochus, it prevents the paſſage of the bile into the duodenum, and the ſymptoms of a jaundice appear; but in all caſes of inflammation in this viſcus, the quantity of the bile thrown into the duodenum is increaſed, and the evacuations become bilious.

Dr. Cullen ſays, that the acute *hepatitis* may be known by a pain more or leſs in the right hypochondrium, increaſed by preſſing upon the part. The pain is very often in ſuch a part of the ſide as to make it appear like that of a pleuriſy, and frequently, like that, is increaſed on inſpiration. The diſeaſe is ſometimes alſo attended with a cough, which is commonly dry, but ſometimes humid. When the pain thus reſembles that of pleuriſy, the patient cannot lie eaſily, except upon the ſide affected. In every kind of acute *hepatitis*, the pain is often extended to the clavicle, and to the top of the ſhoulders. The diſeaſe is attended ſometimes with hiccough, and ſometimes with vomiting. The jaundice is often mentioned as a conſtant ſymptom of the *hepatitis*; but experience ſhews that the diſeaſe may often occur without that ſymptom.

The importance of this ſubject, particularly to thoſe who may be ſituated where their actual attention to it is required, will, it is hoped, apologize for ſeeming repetition, when improvement in the deſcription and cure of this diſeaſe, are the attending advantages. Mr. Mathews, in his excellent obſervations on *hepatic* diſeaſes, ſays that the diagnoſtics of this diſeaſe vary conſiderably in different conſtitutions. It is not only in the firſt attack of the diſorder, that we are to form our opinion reſpecting the certainty of the complaint, but in the ſecond alſo; for men who are in the zenith of health are more frequently affected with the diagnoſtics of the ſecond ſtate, than with the ſymptoms of the firſt; and although in the healthy, the modes of the diſorder are the ſame, yet, according to the ſtrength of the afflicted perſon, we find the ſymptoms more or leſs violent. Thus a robuſt, athletic man, will have the ſymptoms in every ſtage of the diſeaſe much more violent on him, than a thin perſon, whoſe frame is more irritable. Thoſe who are of a coſtive habit of body generally ſuffer very much by this complaint, and frequently after the cure, are ſubject to ſanguinary drainings from the hæmorrhoidal veſſels. Men who are reduced by diſeaſes, or by medicines for imaginary evils, are always attacked by this diſorder in a regular manner, and are generally relieved before the ſecond or ſmall effects take place; therefore, to be well acquainted with the various approaches and progreſs of the complaint, *it is neceſſary to diſtinguiſh the ſymptoms as they occur in an enervated habit, which may be divided into two claſſes*; THE FIRST OF WHICH, *attended with inflammation and pain, is removed by evacuations and mercury*; THE SECOND, *that originates in obſtructions of this viſcus with all its alarming ſymptoms, is cured by mercury only*: then we will remark the diagnoſtics peculiar to the healthy and vigorous, which may be alſo claſſed in the former, with this difference, that the ſecond ſtage of the afflicted becomes the firſt in the healthy, and is cured by the like means: the ſecond, or final period in the healthy patient, is ſuppuration or ſcirrhus: the method of cure the ſame. THE SYMPTOMS of the firſt ſtate of the diſeaſe, in the reduced habit, conſequent on medicine, or the effects of a bilious remitting fever, *are a great flatulency in the ſtomach, with ſour and fetid eructations; putrid and hot borborygmi; acute pains in the muſcles of the thighs and legs, drowſineſs, particularly after taking any nouriſhment, with univerſal laſſitude and inactivity; in the morning, an inclination to vomit, and ſometimes a little frothy bilious fluid is brought off; a ſevere periodical pain in the right lumbar region, ſtretched along the ſpermatic chord, frequent deſire of making water, which is always crude and pale.* In thoſe who have a ſmall abdomen and large thorax, the pain of the loins does not follow, but a dull fixed pain under the enſiform cartilage, with tenſion of the recti muſcles; frequent ſneezings, and a plenitude about the epigaſtric region; the pulſe generally tenſe, ſmall, and rather full, ſometimes riſing to the natural ſtate; the ſkin hot and dry, and the circle of the hepatic region remarkably heated. This is the deſcription of the early part of the diſeaſe, which, if properly attended to, may generally be prevented from running into the ſecond ſtage. But if from ſome cauſe, the diſorder gets worſe,

the next effects will follow, and must be treated accordingly. This, though tedious and alarming, seldom proves fatal, and is thus distinguished; *a rotundity of the hepatic region, with great pain under the false ribs, and the liver very sensible to the touch; a slight, dry, hectic cough; oppressive sighing, and great difficulty to read, or repeat long sentences; frequent periodical purgings, attended with griping in the umbilical region; depraved appetite, vagrant pains on the right side of the thorax, with laborious respiration, particularly when by accident a larger quantity of air than usual is received into the lungs; total inability of blowing the nose, followed by acute pains in the diaphragm and inferior parts of the scapula; inflammation of the eyes, with small, quick, tense pulse; an universal parched dry skin, with insatiable thirst; a contraction of the right pectoral muscle, and an aptness to incline the body forward; tremor of the hands, and a remarkable pale whiteness of the nails; the urine voided in small quantities, and seldom; though always exceedingly high-coloured and hot.* These are the most material indications of a fixed *hepatitis* in the female habit, which, according to the age or strength of the patient, will be more moderated or increased. We now come to that mode of the *hepatitis* which acts on the body of a healthy, vigorous man, reducing him in a few days to the most feeble state. It hath been before noticed, that the second stage of the valetudinarian is the first of the healthy; but we are also to remark, that the diagnostics of this period in this case are amazingly more acute and rapid than in the former; for in one day all this train of evils will be complained of, but in the other, the complicated symptoms move slowly. We next describe the final stage of the disease, by describing it as operating on the body of an healthy person. The diagnostics of this disorder are very violent and severe; *grievous pains in the forehead; staring wildness of the eyes; exceeding acute fixed pain under the ribs, extended to the right pap; hard laborious cough, and by reclining the body forward, in the action of stooping, an immediate inclination to vomiting follows, with a stupid dizziness, and a reflection of green rays; but the patient on resuming an erect posture, in a few minutes recovers his sight; the urine is rendered in small quantities turbid, and of a saffron colour, the breathing short and oppressively heavy, with frequent singultus, and an universal parched heat over the body; total loss of appetite and perspiration; costiveness and insatiable thirst; startings and twitchings of the muscular system; the countenance remarkably pale, with a black mass surrounding the mouth and the eyes, tinged with an inflammatory yellowness; the right side of the abdomen considerably enlarged, very dense and hard, and, if forcibly pressed, occasioning a pain in the scapula, and an instantaneous sickness, with coughing and sneezing; the pulse small, hard, and quick, frequently fluttering, and very often the vibrations are not to be distinctly felt; then instantly falling and rising to almost the natural state, and again returning and sinking as before; amazing periodical tremor of the hands,* and IN SOME PLETHORIC THIN HABITS, *the ankles are puffed and swelled; those who do not cough much, have always a great discharge of acrimonious fluid from the nose, with continual spitting, sometimes accompanied with large ulcerous blotches in the mouth and tonsils.* In this mature state of the disorder, the patient can rest on either side, but not on his back, without being immediately affected with incubus; but in the less advanced state of it, or after plentiful evacuations, this is a common symptom, occasioned by the size and weight of the liver, which when lying on the left side, falls down from the diaphragm, and rends the adhesion, or stretches the accreted part, either of which will occasion the symptom; but in the former case, the liver is so much increased in size, that there is not sufficient room in the abdomen for this accident to occur, which reasoning will hold good also before the adhesions have taken place, or before the bulk of the liver is considerable. The severity of the disease does not always depend upon the immediate size of the liver, but frequently on that of the gall-bladder, or ducts, or the adhesions formed to the diaphragm, which is always the case when the upper or gibbous portion of the liver is the seat of the disease. When the *symptoms are severe, without any apparent enlargement on the right side of the abdomen, with little tension and hardness, yet, on pressing the liver, a sickness, cough, &c. are brought on, it is a certain and manifest testimony that the disease is situated about the region of the gall-bladder,* and *that the bladder with the bilious ducts are principally affected*; but when the liver is in the large state before related, it is the actual bulky substance of that viscus which is diseased. Sometimes the belly is universally swelled, with pain in the umbilical region; this originates from the entire mass of liver being affected; and occupying a great portion of the left abdominal sphere; when the suppuration is matured, and breaks out with severe coughing and most copious spitting, the mercurial course will be improper. The great object now is, to support with nutritious food and emollient ptisans. This is the first state of the *hepatitis* that does not admit of a cure by mercury; and it is worth notice, that medical assistance in the first appearance of the disorder will sometimes entirely prevent the fatality of it. The second state of the *hepatitis*, which does not require mercury, is, where the matter points outwards; when the suppuration is in the superior part of the liver, it appears in a conical form, but when the collection is lower down, and tends externally, the tumor is of a round, flat shape; both may be distinguished by the great fluctuations in them, and their yielding so readily to gentle pressure, without creating pain.

Inflammation in the liver may terminate by resolution, &c. but most frequently it ends in a suppuration, and so proves fatal by bringing on an incurable hectic fever, though when the matter can be discharged externally a cure may be expected. If properly treated in the beginning, it is rarely mortal.

The resolution of the *hepatitis* is often the consequence of, or is attended with evacuations of different kinds. An hæmorrhage, sometimes from the eyes, sometimes from the hæmorrhoidal vessels, gives a solution of the disease. Sometimes a bilious diarrhœa contributes to the same event; and the resolution of the *hepatitis*, as of the other inflammations, is attended with sweatings, and with an evacuation of urine, depositing a copious sediment.

This kind of inflammation should be distinguished from inflammation of the pleura, of the diaphragm, of the stomach, and of the muscles of the belly, also from spasmodic pains. See PLEURITIS, &c. and compare the distinguishing symptoms.

The symptoms in the beginning do not much alarm the patient; whence early assistance is not always had recourse to. However, if called in before the fifth day, bleed, and repeat the operation; if the symptoms do not soon subside, the strength of the patient, and other attendant circumstances, will determine the quantity of blood to be taken away, and the frequency of repeating the operation. After a free bleeding, a large blister may be laid over the part affected. This done, if there is a free passage for the bile into the duodenum, keep the bowels lax with proper doses of antimonium tartarisatum cum pulv. rhab. vel infus. tamarind. with vitriolated natron, &c. In other cases, the pulv. antimon.—haust. salin.—and such other antiphlogistics as are generally useful against internal inflammations; but in all cases, blistering, as just named, is necessary.

If these means fail, or if it is too late for their proper use, and the symptoms of a beginning suppuration are manifest, begin with the bark; give ʒ ss. of the powder four or five times a day, and increase the quantity, until ʒ ss. is taken every twenty-four hours.

If the abscess points externally, encourage it by maturating cataplasms, and open it as soon as possible, particularly if, from its immobility, the liver seems to adhere to the peritoneum, and then the bark may be given to two ounces in twenty-four hours, if the stomach will retain it, and thus proceed until a good suppuration appears. If from purulent or ichorous stools, it is evident that the abscess is burst into the duodenum; or from other symptoms, that it hath made its way into the cavity of the belly, the same methods may be used, though the same effects cannot be so fully expected.

In the East Indies, it is usual after bleeding to excite a salivation, and support it according to the strength of the patient; but the bark seems to be a preferable method. A looseness coming on answers as well as a spitting.

See Dr. Pringle on the Diseases of the Army. Dr. Fordyce's Elements, part the second; Dr. Brooke's, and the London Practice of Physic; Mathews on *Hepatic* Diseases; Cullen's First Lines, vol. i. p. 376. edit. 4. Bell's Surgery, b. v. p. 387. Lond. Med. Trans. b. ii. p. 147.

HEPATIZON.

HEPATIZON. See MORPHEA.

HEPATOCELE. RUPTURE of the LIVER. This complaint happens from the liver paſſing through the relaxed parietes of the abdomen, ſeparated in the vicinity of the umbilicus, or through the umbilicus itſelf. This diſeaſe may be diſtinguiſhed from the place which the protuberance occupies; from the liver being traced, which is perceived to protuberate and extend from the region of the right hypochondrium; from the parenchymatic firmneſs of the protuberance, which is livid, as natural; from the abſence of thoſe ſymptoms which point out the enterocele, epiplocele, gaſtrocele, and particularly the hyſterocele. From the place it occupies there are formed two ſpecies; *Hepatocele ventralis—Umbilicalis*. The mode of cure is much the ſame as in other ruptures, particularly the GASTROCELE; which ſee.

HEPATORIUM. See EUPATORIUM.

HEPATORIUM AQUATILE. See BIDENS.

HEPSEMA. See MUSTUM.

HEPTANDRIA, ἑπτὰ, ſeven, ἀνὴρ, a huſband. Of Linnæus's Syſtem this is the ſeventh claſs, including thoſe plants which have ſeven ſtamens to the flowers.

HEPTAPHARMACUM, from ἑπτὰ, *ſeven*, and φαρμακον, *a medicine*, or *remedy*, a plaſter or ointment, in which were ſeven ingredients, was thus called. It was compounded of litharge, wax, colophony, fat, &c.

HEPTAPHYLLUM. See TORMENTILLA.

HEPTAPLEURON, from ἑπτὰ, *ſeven*, πλευρα, *a rib*. So the *plantago latifolia* is called, becauſe it is furniſhed with ſeven ribs

HERACANTHA. See CARLINA.

HERACLEA. See MARRUBIUM AQUATICUM.

HERACLEIOS, or HERACLEIUS, from Ἡρακλης, *Hercules*. HERCULEAN. A name given to epilepſy; mania, and loadſtone.

HERACLEOTICUM. See ORIGANUM.

HERACLIUM OL. It is thought to be the oil of boxwood.

HERACLIUS, LAP. See MAGNES.

HERBA. An HERB. All ſuch plants whoſe ſtalks die to the ground every year. Thoſe whoſe roots continue only one year, are called *annual*; if they continue two years, they are called *biennial*; and, if they continue many years, they are *perennial*. In common language an herb is uſed in oppoſition to a tree. By LINNÆUS the herb is put for that part of a vegetable which ariſes from the root, is terminated by the fructification, and comprehends the ſtem, leaves, fulcres, and hybernacle.

Herbs are to be gathered when the leaves are at their full growth, before the flowers unfold, except it be thoſe whoſe flowery tops are preferred. They are beſt when quickly dried, and that in a room that is heated by a fire to a degree equal to the hotteſt ſummer's day with us. Aromatic plants ſhould be gathered from warm dry ſoils; fetid ones from moiſt and rich ſoils. All *herbs* and leaves ſhould be gathered in clear dry days, as ſoon as the morning dew is diſſipated. When *herbs* are well dried, they are good as long as their colour remains, both for decoctions, and for diſtilling; thoſe that are good when dry, are better than when they are green.

HERBA PARIS, alſo called *uva lupina, aconitum pardalianches, ſolanum quadrifolium, bacciferum*, HERB PARIS, HERB TRUE-LOVE, or ONE-BERRY. It is the PARIS QUADRIFOLIA, LINN. It is a low plant, grows wild in ſhady woods; it flowers in April and May; the berry is ripe in July. Geſner ſays its juice is narcotic, but it is not much in uſe. See Raii Hiſt. For that called ALBA, ſee ABSINTHIUM VALESIACUM.

—— PARIS BRASILIANA POLYCOCOS. See IPECACUANHA.

—— PETRI. See PRIMULA VERIS, under PARALYSIS.

—— REGIA. See BASILICUM, and ARTEMESIA.

—— SANCTÆ BARBARÆ. See BARBAREA.

—— SANCTI PETRI. See CRITHMUM.

—— STELLA. See CORONOPUS.

—— TRINITATIS. See HEPTICA NOBILIS.

—— VETERIBUS IGNOTA. See CARDIMINES.

—— VIVA. See CAACO.

†

HERBATUN CANADENSIUM, called alſo *panaces moſchatum*, SWEET SCENTED ALL-HEAL of AMERICA. This plant is found in Canada; and is more alimentary than medicinal.

H. BEAUM. The abbreviation of Herberti à Beaumont, Horti Beaumontiani Exoticarum Plantarum Catalogus.

HERCULES. The name of ſeveral potent medicines.

HERCULIS BOVII. The name of a once famous emetic and cathartic preparation.

HERMANNIA. The name of an herb in Africa, of which Boerhaave enumerates ſeven ſpecies; their virtues are ſimilar to thoſe of marſhmallows.

HERMAPHRODITUS, from Ἑρμης, *Mercury*, and Ἀφροδιτη, *Venus*. An HERMAPHRODITE. Named alſo *andria*. One who is ſuppoſed to be of both ſexes; but the truth is, the clitoris of a woman being of an extraordinary ſize, is all the peculiarity in this ſuppoſed ſpecies of the human kind. See Cheſelden's Anatomy.

HERMODACTYLUS. HERMODACTYL. It is the COLCHICUM ILLYRICUM, LINN. called alſo *alſurengium*, by the Arabians, *ſurengiam, aſaba, Hermes, dactyletus, ephemeron*. It is the root of a plant, brought from the Turkiſh dominions. It is of the ſhape of a heart, of different ſizes and colours; ſome are reddiſh, others yellowiſh, browniſh, or white; the white and hardeſt are the beſt. Each root is flatted on one ſide, and hath a furrow on the other. Some reckon it a ſpecies of colchicum.

It hath a viſcous farinaceous ſweetneſs to the taſte, but no ſmell. The ancients ſay it is cathartic, but the dried ones which we receive, are quite inert. Proſper Alpinus informs us, that the Egyptian women eat them as a means of becoming fat. They are not of any known uſe in medicine. See Lewis's Mat. Med. Neumann's Chem. Works.

HERMODACTYLUS FOLIO QUADRANGULO, called alſo *iris tuberoſa*; *iris bulboſa*, and SNAKE'S-HEAD IRIS.

The roots of this plant hath a tubercle, which is both emetic and cathartic.

HERN. The abbreviation of Franciſci Hernandez Nova Plantarum, Animalium, & Mineralium Mexicanorum Hiſtoria.

HERNIA, a TUMOR, called alſo *terexis, ramex*. A RUPTURE. In conſequence of ſome ſudden effort, part of the abdominal contents are forced through the interſtices left between the tendinous expanſions of the abdominal muſcles, for the paſſage of nerves and blood-veſſels, or ſome other part, and a tumor is formed. Dr. Cullen places this genus of diſeaſe in the CLASS LOCALES, and ORDER ECTOPIÆ, and defines it an ectopia, or diſplacing of a ſoft part, though ſtill covered with the ſkin and other integuments.

According to the ſituation of theſe tumors, or from their contents, or both, they obtain their reſpective denominations; though ſome take their name from attending circumſtances. 1. Thoſe from the ſituation, are the umbilical, ſcrotal, ventral, &c. 2. Thoſe from the contents are the enterocele, epiplocele, entero-epliplocele, pneumatocele, &c. 3. Thoſe from attending circumſtances, are the incarcerated *hernia*, &c. Diſtinction hath been made indeed betwixt the true and falſe *herniæ*; they are all tumors of the ſcrotum, but the true are from the abdominal viſcera deſcending into it, and exiſt either in the groin or ſcrotum; whereas the falſe are from other cauſes: they begin below and aſcend upwards; they are the *hernia* humoralis, hydrocele, hæmatocele, ſarcocele, &c. they are not diſplacements of parts, but a morbid ſtate of, or diſeaſes in the part where the tumor appears; from the Greek term κηλη. *Hernia* means alſo *tumor* as well as *rupture*.

This accident being unattended with rupture, or diviſion of the containing parts, the whole of the diſeaſe muſt at firſt be conſidered as a change of ſituation of the contained parts; and as ſuch, were they immediately returned, and kept in their place, the diſorder would entirely ceaſe; but continuing in that preternatural ſituation, they are preſſed upon by the tendons through which they paſs, and the circulation of blood being obſtructed, inflammation and mortification ſpeedily ſupervene; which, however, is not owing to any change of ſtate in the tendons, but merely to their natural elaſticity, acting upon an increaſed and yielding ſubjacent bulk. The obſtacle to the reduction of the prolapſed contents is, therefore, the increaſed bulk which they have acquired from ſtricture,

by

by which they become incapable of returning through the ſame paſſage at which they eſcaped.

If aſſiſtance is called to the patient in time, the return of the protruded parts muſt be attempted by ſuch means as cauſe the veſſels to contract, thereby diminiſhing the bulk of the ſolids, and repelling the fluids, ſuch as cold. aſtringent, and ſtimulating applications. *Emollients are abſolutely to be avoided*, for they cannot relax the tendons; but they may, and often do enlarge the bulk of the *hernia*, and render its reduction more difficult, if not impoſſible. Cold aſtringents ſhould be immediately applied, ſuch as Goulard's ſaturnine water; at the ſame time theſe may be aſſiſted by gentle but continued compreſſion on the part with the fingers, or with ſmall bolſters of ſoft linen cloth; by continuing theſe efforts for ſome time, the veſſels become viſibly leſs diſtended, the ſwelling grows flaccid, at length the ſtricture gives way, and the diſorder is removed.

When all proper attempts fail to reduce the contents of an *hernia*, the ſooner the operation, called *celotomia*, is performed, the better; but when there are evident ſigns of the inteſtine being in a mortifying ſtate, ſuch as the tumor having loſt its renitence, &c. Mr. Gooch recommends it as a very reaſonable practice to make an inciſion into the tumor, ample enough to evacuate the feces freely, which may effectually remove the ſtrangulation of the inteſtine at the abdominal ring, and then to treat the wound as a mortification, not being over buſy with the knife in cutting away what appears to have loſt its vitality, but allowing nature to throw off the mortified ſlough. If it is a doubtful point what condition the parts contained in the tumor are in, proceed with caution in the operation, until you come to the inteſtine, and if that is mortified, open it too, and if the evacuation of the feces do not effectually make way for the return of the parts, the abdominal ring muſt be opened by inciſion.

But, after replacing the *hernial* contents, to retain them requires very often the aſſiſtance of a bandage, or a proper compreſs. Mr. Pott obſerves, "*all that can be done by ſurgery towards the cure of the hernia, is to replace the prolapſed body or bodies in the cavity of the belly, and to prevent them from ſlipping out again. When whatever formed the tumor is replaced, the ſurgeon hath done his part; the reſt is nature's; whether the tendinous aperture will ſo contract as to prohibit a future deſcent or not, is matter of uncertainty, and not to be known but from the event.*"

When a rupture happens, and is unattended with any ſigns of ſtricture, or other violent ſymptoms, a bandage or a truſs will be the moſt eligible means of relief. As to the modes of operation, when the knife is neceſſary, ſee the reſpective ſpecies of this diſorder, and the authors referred to below, and at the concluſion of this article.

HERNIA AQUOSA. See HYDROCELE.

—— BRONCHIALIS. See BRONCHOCELE.

—— CARNOSA. See SARCOCELE.

—— CEREBRI. A RUPTURE OF THE BRAIN. This is a protruſion of the cerebrum, cerebellum, or either, through an opening of the bones of the cranium not perfectly oſſified; which is diſcoverable by a protuberance, differing with reſpect to magnitude, figure, and place of the cranium which it occupies, covered with the common integuments, preſerving their natural colour, unleſs there ſhould be a gangrene; it is only obſervable in the head of infants; the protuberance is ſoft, indolent, (by inflammation reſiſting the touch, and becoming painful); for the moſt part fluctuating, ſurrounded at the circumference of its baſis by a bony circle, which may be traced by the fingers, and diſcovering a defect of oſſification; it is attended, at leaſt in the beginning, by no violent ſymptoms: if the tumor is ſmall, and ſhould be ſituated in the vertex, or ſides of the head, but the ſymptoms are very violent, ſuch as paralyſis, ſopor, convulſions, ſtupor, &c. if it ſhould poſſeſs the occiput, or ſhould be large, though differently ſituated, we ſhould be careful to diſtinguiſh it from a ſpurious aneuriſm, which often in infants ariſes from a blow, or violent pulling of the hairy ſcalp. TREW, and LE DRAN, cured this complaint by placing thick compreſſes, moiſtened with ſpirit of wine, or aqua vitæ, upon the part affected, for ſeveral days, nay months, renewing them every twenty-four hours, and confining them only by the common covering of the body. See SAUVAGES' NOSOLOGIA, vol. i. p. 217. WARNER'S Obſ. Chir. xi. 59.

HERNIA CONGENITA. It is a *rupture* where the inteſtine and teſticle are found in contact. The teſtes are originally ſituated in the abdomen, juſt beneath the kidneys, and gradually deſcend near the time of birth through the ſheath of the ſpermatic chord into the ſcrotum, each carrying along with it a peritoneal coat, which makes the tunicæ vaginales. This diſcovery was made by Dr. Hunter, in the year 1755, aſſiſted by his brother Mr. John Hunter; it was demonſtrated by the doctor in his public lectures that year.

Soon after the birth of the child, the communication between the tunicæ vaginales, and the abdomen, is obliterated by the ſtricture of the parts; but if the inteſtine falls very ſoon, it prevents this ſtricture from taking place, and thus this kind of *hernia* is formed.

In the treatment of *ruptures* of this kind, little difference occurs from the management of the bubonocele, in its more ordinary form. See Bell's Surgery, v. i. p. 340.

Dr. Wriſberg obſerves, that in his diſſections, he ſeveral times found a part of the omentum or inteſtines adhering to the teſticle in the abdomen of the fœtus, and when this happens, an *hernia congenita* will be likely to take place. The ſame thing, he adds, will occur, when the peritonæum in its courſe over the ſeminal veſſels to the meſentery, ſends off a minute proceſs to the ileum or cœcum, and by means of it draws down the inteſtines on the right ſide, which is the common ſeat of the *hernia congenita*. See the London Med. Journal, v. i. p. 376. White's Surgery, p. 332.

—— CRURALIS. See HERNIA FEMORALIS.

—— CYSTICA. See HERNIA VESICALIS.

—— FEMORALIS, called alſo CRURALIS FEMOROCELE. This ſpecies of *rupture* is the ſame in both ſexes, and formed by the falling of the omentum, or inteſtine, or both of them, into the inſide of the thigh, through the arch made by the os pubis and ligamentum Fallopii, where the iliac veſſels and tendons of the pſoas and iliacus internus muſcles paſs from the abdomen. See BUBONOCELE. Treat it firſt by the ſame methods as are propoſed for *ruptures* in general; if the operation is neceſſary, proceed as for the bubonocele, with the difference of dilating the ligament inſtead of the rings of the muſcles; the dilation muſt be made obliquely outwards, inſtead of perpendicularly upwards, to avoid dividing the veſſels. White's Surgery, p. 324.

—— FLATULENTA. See PNEUMATOCELE.

—— FORAMINIS MAGNI ISCHII. It is when the inteſtines or omentum fall through the great hole of the iſchium into the internal part of the thigh, between and under the two anterior heads of the triceps muſcle. In ſuch a caſe there muſt be great laxity of the ligament, and the inteſtine muſt lie behind the pectineus muſcle, wherefore no preſſure can be uſed to keep it up, and the operation cannot be attended with ſucceſs; becauſe as the inteſtine is ſtrangulated, the orifice cannot be dilated, by reaſon of the vicinity of the veſſels.

—— GUTTURIS. See BRONCHOCELE.

—— HUMORALIS; called alſo *inflammatio teſtium*; though this is often a diſeaſe of the tunica vaginalis of the teſticle: it conſiſts of an inflammation and ſwelling there; but any of the integuments of the teſticles, or the teſticles themſelves, may be the ſeat. Dr. Swediar, ſays, that the teſticle itſelf is never ſwelled, or in the leaſt affected, in the beginning of this complaint, and that the only affected and ſwelled part is the epididymis. He adds, if the teſticle becomes ſwelled, it is not till after the other part is affected, and that from bad treatment. It is moſt frequently a venereal ſymptom, but may alſo happen from irritation, from bruiſes, and other external injuries. It may terminate any of the ways that are common to inflammation in other parts.

It is often cauſed by a ſtoppage of the venereal gonorrhœa, or rather from a tranſpoſition of the venereal poiſon, or, in other words, the irritation of the poiſon tranſpoſed to a different place in the urethra; viz. the caput gallinaginis, or the mouth of the excretory ducts of the ſeminal veſicles; in which caſe, briſk purgatives, if they produce a return of the running, are uſeful. Vomits, when the conſtitution can bear them, powerfully aſſiſt in removing this diſorder whilſt in its inflammatory ſtate, but they ſhould not be given until the inflammation begins to give way, and then the pulv. ipecac. is as uſeful as the hydrargyrus vitriolatus.

Whatever be the cauſe, endeavour to remove the in-

ſtammation and tumor, by bleeding according to the ſtrength of the patient; let the bleeding be immediately ſucceeded by a briſk purge, and let the topical application be of the common aſtringent and ſtimulating kind, ſuch as Goulard's ſaturnine water; let them be applied cold by means of rags folded ſeveral times, and repeat them as often as they grow warm and begin to dry. In want of this water, a mixture of vinegar and brandy may be uſed, or ſome other diſcutient lotion; ſee LOTIO. Thus, if the part is ſuſpended properly, and if the patient can conform to lay much on his back, this tumor will be removed in a ſhort time, without the uſual violent pain or the hardneſs remaining afterwards, which is almoſt the conſtant effect of emollients. As ſoon as the inflammatory ſymptoms abate, mercury may be preſcribed internally, and the ungt. hydrargyri fort. may be rubbed on the ſcrotum every night, either to prevent or remove any degree of induration. If, notwithſtanding every endeavour to the contrary, a ſuppuration cannot be prevented, an emollient cataplaſm muſt be applied warm, and continue until a due diſcharge of the matter is effected. The knife is uſually preferred for opening this kind of abſceſs with, but care is required leſt the teſticle ſhould be wounded: the dreſſings may be the ſame as directed for abſceſſes in general. On abſceſs in the teſticles, ſee Kirkland's Med. Surgery, vol. ii. p. 256. Dr. Swediar propoſes, in caſes of virulent gonorrhœa, in order to prevent the hernia humoralis, that the patient avoids expoſing himſelf to cold, violent exerciſe, venery, ſtrong purges, and that he keeps the ſcrotum duly ſuſpended. If the hernia humoralis takes place, he propoſes, firſt, to allay the irritation, and then to recall the poiſon to its former original ſeat: to this end, if the pulſe is quick, full, and ſtrong, bleed immediately, but with due regard to the conſtitution. If coſtive, a glyſter ſhould next be adminiſtered, to empty the preſent contents of the inteſtines; after this, if it can be conformed to, the patient may ſit half an hour in a warm bath, or on a perforated chair over the ſteam of hot water, for the ſame length of time, previouſly ſuſpending his teſticles. From thence he muſt go to bed, and a warm dry bag-truſs ſhould be immediately applied. After this, a warm bread poultice may be applied to the penis, to reproduce the running, or determine the retropulſed poiſon to its original ſeat again. And what is peculiarly beneficial is, to give a full doſe of opium by the mouth; or in its ſtead, a glyſter of ol. lin. and decoctum hord. aa p. æq. cum tinct. opii gt. xl. lx. The diet muſt be low. When the running returns, relief is proportionably obtained. If required, repeat the opiate every twenty-four hours; and the parts muſt be expoſed two or three times a day to the ſteam of hot water. Dr. Sweidar's Obſ. on Venereal Complaints. Aikins's Obſ. on Prep. of Lead. London Med. Obſ. and Inq. v. iii. p. 152, &c.

HERNIA INCARCERATA. An incarcerated, impriſoned, or confined *hernia*. It is either when the protruded inteſtine ſo adheres that it cannot be returned; or when it cannot be returned, becauſe of the flatus or other matter which is deſcended into it, not being capable of a return. Its ſymptoms are, a ſwelling in the groin and upper part of the ſcrotum, larger or ſmaller, according to the quantity of contents, very painful to the touch, and reſiſting the impreſs of the fingers; the pain is increaſed by coughing, ſneezing, or ſtanding upright, and there is a frequent vomiting, with a ſuppreſſion of all diſcharge by the anus, and a fever preſently comes on.

If ſpeedy relief is not obtained, the conſequence is fatal.

Very copious or repeated bleeding, and a proper poſture, are the principal helps; the patient ſhould be laid with his hips much higher than his ſhoulders, and thus by gently raiſing the ſcrotum, and a light preſſure on the tumor, the inteſtine may return. The tobacco glyſter is uſed in St. Bartholomew's hoſpital in caſes of ſtrangulated rupture, to effect a reduction, and is thus made. Infuſe two drams of dried tobacco, in one pint of boiling water, for the ſpace of ten minutes. This is ſaid to act by producing nauſea, and depreſſing the living power in the ſyſtem, which it ſometimes does to an alarming degree; and alſo to be equally efficacious, and leſs indeterminate with regard to the doſe, than adminiſtering this herb by means of ſmoke; ſmall doſes of opium may be given at due intervals: but if there is an adheſion, the operation is neceſſary, and if a gangrene is obſerved in the detained inteſtine, keep the ſound part of it ſo united with the aperture in the groin as to be the future anus. London Med. Journal, vi. p. 118, 259. Edinb. Med. Comment. v. 270.

HERNIA INGUINALIS. See BUBONOCELE.

—— INTESTINALIS. See HERNIA SCROTALIS.

—— LACHRYMALIS. When the tears paſs through the puncta lachrymalia, but are ſtopped in the naſal duct, they ſtagnate in the ſaeculus lachrymalis, and generally diſtend it; whence this name. Anel calls it *hydrops ſaculi lachrymalis*, a dropſy of the lachrymal ſac.

If the inner angle of the eye is preſſed, and an aqueous humour flows out, it is the fiſtula lachrymalis, which ſee: alſo Kirkland's Med. Surgery, v. ii. p. 135.

—— OMENTALIS. See EPIPLOCELE.

—— SCROTALIS,
—— OSCHEALIS,
—— ENTEROSCHOCELE.

Called alſo *Inteſtinalis*, *eptoma*, *enterocele*. PARACELSUS calls it *crepatio*, or *crepatura*. It is when the omentum, the inteſtine, or both, protrude and deſcend into the ſcrotum; when the omentum only, it is called *epiploſcheocele*. It is called a perfect rupture, in contradiſtinction to a bubonocele, which is the ſame diſorder, only that the deſcent is not ſo low. The *hernia ſcrotalis* is diſtinguiſhed into the true and falſe; the true is when the omentum, or inteſtine, or both, fall down into the ſcrotum; the falſe is when an humour or an inflammation cauſes a tumor in this part; ſuch as in the caſe of an hydrocele, hernia humoralis, &c. Sometimes there will be a collection of ſuety matter in the ſcrotum: the hernia, thus formed, is called *ſteatocele*.

—— UMBILICALIS; called alſo *Epiplomphalon*, *omphalocele*; *exomphalos*, *omphalos*. When this rupture ariſes from flatulence, it takes the name *pneumatomphalos*. It is when the omentum, or inteſtine, or both, protrude at the navel. It rarely admits of other relief than the palliative. White's Surgery, p. 323.

—— UTERI; HYSTEROCELE. Inſtances have occurred of the uterus being thruſt through the rings of the muſcles, but this is hardly to be diſcovered, if there is no child in it, whoſe ſtrugglings would lead us to the proper diſtinction of it from the rupture of any other part. It is called by HIPPOCRATES, ECREXIS.

—— VAGINALIS. There is naturally a deep ſort of cavity between the rectum and the back part of the uterus, made by the peritoneum deſcending pretty low, and forming a kind of pouch, in which a portion of the ſmall inteſtines, when the uterus is not pregnant, is commonly lodged; and ſometimes the inteſtines themſelves, by preſſing hard againſt the peritoneum at this moſt depending part of the abdomen, gradually ſtretch this membrane ſo as to deepen this cavity much, and thereby diſſect as it were the back part of the vagina from the fore part of the rectum, and thus form the tumor in the vagina, which is called an hernia vaginalis.

—— IN VAGINA. See COLPOCELE.

—— VARICOSA. See CIRSOCELE.

—— VENTOSA. See PNEUMATOCELE.

—— VENTRALIS, called *Hypogaſtrocele*. This may happen in almoſt any point of the fore part of the belly, but is moſt frequently found between the recti muſcles, either above or below the navel. It is generally large, and is only to be relieved by returning the protruded parts, and preventing their return by a proper bandage. The tumor which requires this operation is ſeldom bigger than a walnut; ſo when theſe are the ſymptoms of a *hernia*, and yet no appearance of one in the groin, the belly ſhould be examined. The manner of relieving the ſtricture will be by dilating the part, as in other caſes. But after the operation a bandage muſt always be worn, as the cicatrix cannot be truſted to. White's Surgery, p. 324.

—— VESICALIS, ſeu CYSTICA. In this ſpecies, the urinary bladder is the part protruded, either in the groin or ſcrotum, through the opening in the external oblique muſcle of the abdomen; in the fore part of the thigh, under Poupart's ligament, or in the perinæum, through ſome of the muſcular interſtices of that part, indeed the bladder has been puſhed into the vagina, and formed hernial tumors of no inconſiderable degrees of magnitude. The common attendant ſymptoms are; a tumor with fluctuation, either in the groin, fore part of the thigh, or perinæum; which tumor, on being preſſed, ſubſides, by the liquor it contains being puſhed into the body, and occaſions either a deſire to make water, or the liquor runs immediately out at the common urinary paſſages. When the ſwelling is large before water can be made with freedom, it is commonly neceſſary to have recourſe to preſ-

fure, at the ſame time that the tumor, when in the groin or thigh, is as much elevated as poſſible; but when the ſwelling is ſmall, and eſpecially when no ſtricture is as yet produced, water is generally made with great eaſe. When this complaint is ſimple, it commonly proceeds from a ſuppreſſion of urine. Hence every cauſe of ſuppreſſion ought to be guarded againſt as far as poſſible; and when no adheſions take place, and if the protruded portion of the bladder can be reduced, a truſs properly fitted to the part ſhould be worn for a conſiderable length of time. When the parts cannot be reduced, as long as no ſymptoms occur to render the operation neceſſary, a ſuſpenſory bag, ſo fitted as effectually to ſupp rt the prolapſed parts, while at the ſame time it does not produce ſevere preſſure, is the only probable means of relief. When a portion of the bladder happens to protrude into the vagina, after reducing the parts, deſcents may be prevented by the uſe of a peſſary; and the ſame means will be ſucceſsful in preventing a falling down of part of the inteſtinal canal into the vagina; a ſpecies of *rupture* which now and then occurs. But ſhould the protruded parts be attacked with pain and inflammation, in conſequence of ſtricture, ſo as to render the operation neceſſary, we muſt proceed as in other ſimilar caſes of dividing the parts occaſioning the ſtricture; but if the bladder adheres to the rupture of an inteſtine, great caution is required (if the operation becomes neceſſary) to avoid opening the bladder. See Le Dran's Operations; Mem. de l'Acad. Royale Chirurg. Sharp's Operations; Sharp's Critical Enquiry; Monſ. Arnaud on Ruptures; Pott on Ruptures; Gooch's Treatiſe on Wounds, p. 427, &c. Aikins's Obſ. on Prep. of Lead, p. 91, &c. Bell's Surgery, v. i. p. 360, to 377.

HERNIARIA. RUPTURE-WORT; alſo called *polygonum minus*, and *millegrana major*. It is the HERNIARIA GLABRA, Linn. It is a ſmall ſpreading plant, found in ſandy ground; it flowers in June and July; is ſaid to be diuretic and aſtringent; but is not of much note.

Boerhaave mentions other ſpecies alſo.

HERPES, vel ERPES, from ἕρπω, *to ſpread or creep*. TETTER. Theſe diſorders are apt to creep on and ſpread about in the ſkin. Dr. Cullen places this genus of diſeaſe, in the CLASS LOCALES, and ORDER DIALYSES; and defines it, phlyctenæ, or a great number of ſmall ulcers crowding together, creeping, and difficult to heal; it belongs alſo to the *impetigines*.

Theſe ulcers in the ſkin are divided by ſome into five ſpecies.

1. The *ſimple*. Theſe conſiſt of ſingle puſtules of a yellowiſh white colour, and ſharp pointed; they are inflamed about their baſes, and are naturally dry; theſe burn, itch, and ſmart a day or two, and then diſappear.

2. The TETTER, RING-WORM, or *ſerpigo*; *dartos*. Theſe are the ſame in appearance as the firſt, only that they run in heaps; they more difficultly paſs away; for they contain more corroſive matter; their ſmarting and itching is more violent; they eat ſometimes through the ſkin, and ſpread conſiderably; they neither form matter nor come to digeſtion. The cure is ſometimes difficult; in ſome perſons they return at certain ſeaſons. If the habit of body is faulty, reſtore it, purge gently with mercurials, and then apply the following to the parts affected: ℞ Hydrarg. muriati, gr. xvi.a q. calc. fi. ℔ i. m. f. lotio. Vel, ℞ Calcis hydrarg. albæ, ℥ ii. ungt. ſimplicis, ℥ i. m. When a ſerpigo is a ſymptom of the ſcurvy, the great water-dock root is an excellent remedy, as indeed it is in all reſpects of herpes.

3 and 4. SHINGLES, or *zona aurea*, &c. Dr. Cullen makes this, i. e. *Herpes zoſter*, ſynonymous with his eryſipelas phlyctænodes. It is ſometimes accompanied with inflammation and fever. This kind appears in large cluſters, on the neck, breaſt, loins, hips, or thighs; the heads are white and watery, and are ſucceeded by a ſmall round ſcab reſembling millet ſeed, whence the name herpes miliaris; and now the diſorder is ſtill more grievous. In theſe caſes the ill habit of body being firſt attended to, it muſt be remembered that the external applications muſt be more mild than thoſe above preſcribed. Internally the treatment may be as in the eryſipelas: the chief indication is to take off the irritability of the ſyſtem; which is beſt done by a proper uſe of the cort. peruv. The prognoſtic of death from its ſurrounding the body is falſe; the malignity of the tumor alone being the only ground of fear.

Theſe two kinds were called by the ancients by the names *vermis repens*; *vermis mordicans*; *formica miliaris*; Wiſeman calls them *ambulativa*.

5. *Herpes depaſcens exedens*, alſo called *nome*, *noma*, *noli me tangere*, *ulcus depaſcens*, *eſthiomenos*, *formix*; and Celſus calls it *ignis ſacer*, becauſe it corrodes like the ulcerous eryſipelas, as deep as the fleſh, raiſing the ſkin chiefly on the ſcalp into ſcales of different thickneſſes, and leaving a hard ſwelling on the part. According to Dr. Cullen, it is of the ſpecies of inflammation which he calls erythematous. It reſembles an ulcerous eryſipelas; its humour is the moſt corroſive of any of the ſpecies; it corrodes down the fleſhy parts, and ſeparates it into ſcales: when it diſappears it leaves hard tumors behind it, on the parts that were ulcerated. In order to the cure, the hydrargyr. muriatus may be given, as directed in the lues venerea, with a decoction of the woods or ſarſa. The ſores may be waſhed with a ſolution of hydrarg. muriat. in aq. calcis.

Some have ſucceeded with a doſe of jalap every fourth day, and an electuary of bark, two parts to one of ſaſſafras.

Mr. Bell, in his Treatiſe on Ulcers, places the tinea and the *herpes*, as varieties in his ſpecies of ulcer, which he denominates cutaneous. He further obſerves that the cutaneous ulcer may in all its varieties be included in the four following; viz. 1. The *herpes* farinoſus; which includes what ſome call the dry tetter. 2. *Herpes* puſtuloſus; which includes the *cruſta lactea*, and the *tinea capitis*, ſee ACHOR. 3. *Herpes miliaris*; called alſo *formica miliaris*, *cenchrius*; of this variety is the ulcerous eruption called the ring-worm. 4. *Herpes exedens*; this includes the ulcers called depaſcent, and phagedenic.

The *herpes farinoſus* is the moſt ſimple kind. It appears on any part of the body, moſt frequently on the face, neck, arms, or wriſts; it comes out in broadiſh ſpots, which conſiſt of very ſmall red pimples, which are attended with a troubleſome itching; they ſoon fall off in the form of a white powder which reſembles fine bran; they leave the ſkin perfectly ſound, but are apt to return in the form of a red efflorescence, fall off, and renew as before.

The *herpes puſtuloſus* occurs moſt frequently in children, generally attacks the face, and behind the ears; often on other parts of the head alſo, but rarely elſewhere. It appears in the form of puſtules, which are originally ſeparated and diſtinct, but afterwards run together in cluſters. At firſt they ſeem to contain nothing but a thin watery ſcum, which afterwards turns yellow, and exuding over the whole ſurface of the part affected, at laſt dries into a thick cruſt or ſcab: when this falls off, the ſkin below frequently appears entire with only a ſlight degree of redneſs on its ſurface; but on ſome occaſions when the matter hath probably been more acrid upon the ſcab falling off, the ſkin is found ſlightly excoriated. See ACHORES.

The *herpes miliaris* generally appears in cluſters, though ſometimes in diſtinct circles of very minute pimples. Theſe are at firſt perfectly ſeparate, and contain only a clear lymph, which, in the courſe of the diſeaſe, is excreted upon the ſurface, and there forms into ſmall diſtinct ſcales; theſe at laſt fall off, and leave a conſiderable degree of inflammation below, that ſtill continues to exude freſh matter, which likewiſe forms into cakes, and ſo falls off. The itching in this ſort of ulcer, is always very troubleſome, and the matter diſcharged from the pimples is ſo tough and viſcid, that every thing applied to the part adheres ſo as to occaſion much trouble and uneaſineſs to the patient on its being removed. The whole body is ſubject to this diſorder, but it moſt frequently appears on the breaſt, perinæum, ſcrotum, and the loins.

The *herpes exedens* diſcovers itſelf on any part of the body, but moſtly about the loins, where it ſometimes ſpreads to ſuch a degree as to extend quite round the waiſt. At firſt it uſually appears in the form of ſeveral ſmall ulcerations, collected into larger ſpots of different ſizes and various figures, with always more or leſs of an eryſipelatous like inflammation. Theſe ulcerations diſcharge large quantities of a thin, ſharp, ſerous matter, which ſometimes forms into ſmall cruſts that in a ſhort time fall off; but moſt frequently the diſcharge is ſo thin and acrid, as to ſpread along the neighbouring parts, and there to produce the ſame kind of ſores. Though theſe excoriations or ulcers, do not in general proceed further than the true ſkin, yet ſometimes the diſcharge is ſo very penetrating and corroſive as to deſtroy the ſkin, the cellular membrane, and, on ſome occaſions, the muſcles themſelves.

Dr. George Fordyce ſpeaks of an inſtance of this diſ-

caſe,

eaſe, under the name of *herpes rapiens*; and ſays, it ariſes upon the head in ſmall ulcers, covered with a brown moiſt cruſt, and ſhining, but ſimilar to venereal ulcers. He adds, its cure is the ſame as for the venereal ulcers, which ſee.

In the cure of theſe various cuticular diſeaſes, it hath been generally believed to be unſafe, and even dangerous, to proceed in any other way, than by correcting the original diſorder of the fluids, which was ſuppoſed to produce them. It may occaſionally happen, that ſome diſorder in the general habit is attendant on any of theſe ulcerous complaints, and that a regard thereto may be required; but in the greateſt number of inſtances, they are more certainly and more ſpeedily removed by the uſe of local remedies merely. In many diſeaſes of the ſkin, antimonials are frequently given with advantage, but their efficacy ſeems principally to depend upon their producing a determination to the ſkin, and keeping up a free diſcharge of the matter of perſpiration; which from various cauſes is long retained on the ſurface of the body, and there becomes acrid, and doubtleſs is a frequent cauſe of diſordered affections in this part. Accordingly, all ſuch remedies are more or leſs effectual, as they are more or leſs powerful in keeping up a free perſpiration. This is further evident by obſerving, that a due uſe of the warm bath is as efficacious, in theſe caſes, as the uſe of antimonials and other medicines ſuppoſed to carry off morbid particles through the ſkin. In the treatment of every herpetic diſorder, the firſt and principal circumſtance to be attended to, is that not only the parts affected, but even the whole ſurface of the body, be kept as clean and perſpirable as poſſible; to this end the frequent uſe of warm bathing, and of frequent gentle frictions, with clean linen cloths (in the dry ſorts of theſe complaints) are ſingularly ſerviceable. In the milder inſtances, the following externals generally ſuffice. 1. The aq. calcis ſimpl. uſually is all that is required in *herpes farinoſus*. 2. The ſolutions of lead in vegetable acid, are alſo very effectual; the following is a uſeful general form. ℞ Ceruſſæ acetatæ, ʒ ſs. Acet. acerrim. ʒ iv. aq. diſt. ℔ ij. m. This may be applied in the form of cataplaſm, mixed with bread, or by means of ſoft rags dipped into it, and laid directly on the parts. *In ſome particular and more inveterate caſes*, the following is ſometimes to be preferred; viz. ℞ Hydrargyri muriati gr. x. aq. diſt. ℔ i. m. This is very efficacious as an embrocation in any of theſe diſorders. *In the moſt obſtinate inſtances of this complaint*, the greateſt care is required that perſpiration is duly ſupported, viz. warm diluent drinks frequently taken, as well as the uſe of the warm bath. The ant. crud. ppt. to ʒ ii. in the day, if mixt with a little gum guaiac. is an admirable aſſiſtant to the diſcharge through the ſkin, and contributes further aid by its efficacy in unloading the bowels. *In the more vigorous and plethoric habits*, cooling laxatives are peculiarly beneficial. Iſſues are ſometimes neceſſary in the *more inveterate ſorts of herpes*. *In the herpes exedens*, a degree of inflammation is often a concomitant, this requires attention; here the ſaturnine applications, above all others, check its progreſs, and at length totally remove it. *But if*, as it ſometimes happens, *the herpetic ulcer hath made its way into the muſcles*, the following ointment is preferable to either the ſaturnine ſolution, or that of hydrarg. muriati. ℞ Zinci pulv. ſubtiliſſ. ʒ ij. Axung. porc. ʒ vj. m. The ungt. ſaturnin. of the different diſpenſatories, is alſo an uſeful application in this laſt mentioned inſtance. But care muſt be taken that this ointment is not become rancid. *If by the uſe of the above, the diſorder is unconquerable*, it may be ſuſpected that a venereal taint at the ſame time ſubſiſts in ſuch a patient. A ſlight herpetic diſorder becomes obſtinate by being accompanied with the itch; in ſuch caſes, attention muſt be had to ſuch diſeaſes reſpectively, before thoſe of the herpetic kinds can be removed. *In ſome inſtances of the herpes exedens*, the following bolus has been uſed with conſiderable advantage; ℞ Hydrargyri calcin. gr. iſs. Confect. opiatæ ϑ i. m. omn. noct. ſumend.

See Tulpius, lib. iii. Marc. Aurel. Severinus, lib. iv. de Abſceſſ. cap. 9. Turner's Diſeaſes of the Skin. Bell on Ulcers, article Cutaneous Ulcer, Edit. iii. p. 345. White's Surgery, p. 26.

HERPES. See PURPURA SCORBUTICA.

—— FACIEI. There is, ſays Mr. Bell, a ſpecies of *herpes*, to which, in ſome conſtitutions, eſpecially in females, the face is particularly liable, and no variety of the diſorder proves more diſtreſſing, or more perplexing to practioners; but the following compoſition has been found to ſucceed, where all others commonly uſed, both of the ſulphureous and mercurial, have failed. ℞ Sulphuris præcipitati, ʒ ij. Ceruſſæ acetatæ, ʒ i. Aq. Roſarum, ℥ viiij. m. nocte maneq. utendum, phiala prius agitata. See Bell on Ulcers, p. 373.

HERPES FERUS. See ERYSIPELAS.

HERPETON. In Hippocrates it is a creeping puſtule or ulcer.

HERVA DE ANIL LUSITANIS. See INDICUM.

HESP. An abbreviation of Heſperides.

HESPERIS. Boerhaave mentions twenty-four ſpecies of this plant: it is ſaid to be diaphoretic and antiſeptic; but is not of much note in practice.

HESPERIS ALLIUM. See ALLIARIA.

HETEROGENEUS, HETEROGENEOUS, from ἕτερος, *alterum*, and γένος, *kind*. See ANOMŒOMERES.

HETERORRYTHMUS. See ARYTHMUS.

HETICH INDIS, AMERICANUM, vel ÆTHIOPICUM. A ſpecies of turnip in America, with leaves like thoſe of bryony: the root is as thick as two fiſts, and a foot and a half long. It is agreeable food, and aperitive.

HEUD, HEUD HEN, or HEUDEEN. See AGALLOCHUM.

HEXANDRIA (ἕξ ſex, and ἀνὴρ, Vir.) The name of the Sixth Claſs of Linnæus's ſyſtem, comprehending thoſe plants which have hermaphrodite flowers, with ſix equal ſtamens. It contains five orders: MONOGYNIA, DIGYNIA, TRIGYNIA, TETRAGYNIA, POLYGYNIA.

HEXIS. An HABIT. From ἔχω, *to have*. It is a permanent habit, in oppoſition to diatheſis, or a tranſient diſpoſition, which may more eaſily be removed. Habit from cuſtom or uſe. See CONSUETUDO.

HIACAN. See GUAIACUM.

HIBERNICUS LAPIS. IRISH SLATE, called alſo *tegula Gallis*, *ardeſia* vel *hardeſia Hibernica*; *lapis*, *fiſſilis Hiber*. It is a kind of ſlate or ſoft ſtone, found in Ireland and other countries, of a bluiſh black colour; it ſtains the hands. When powdered it is whitiſh at firſt, but ſoon grows blacker. In the fire it yields ſulphureous fumes, acquires a pale red colour, and becomes harder. It is an argillaceous earth, impregnated with alum and iron in a very ſmall portion, and ſeems to be much of the ſame nature as the boles. To its aluminous contents it owes its aſtringent property. It is inwardly taken againſt bruiſes, but on account of the variability of its contents, it is not much to be commended. See Lewis's Mat. Med. Neumann's Chem. Works.

HIBISCUS. See ALTHÆA and KETMIA.

HIBISCUS ABELMOSCHUS. See ABELMOSCHUS.

HIDROA, from ἱδρώς, *ſweat*. A kind of puſtules which ſpring up on ſome conſtitutions, from ſweating in hot weather. It is the ſymptomatic kind of miliary fever called ROA, which ſee; alſo DESUDATIO.

HIDROCRITICA, from ἱδρώς, *ſweat*, and κρίνω, *to judge*. Signs taken from ſweat.

HIDRONOSOS, or HIDROPYRETOS. See SUDOR ANGLICUS.

HIDROTES CENCHROIDES. See CENCHROS.

HIDROTICA. } See SUDORIFICA.
HIDROTOPSEA. }

HIDRUS. See ÆRIS FLOS.

HIERA DIACOLOCYNTHIDOS. An electary was formerly prepared under this name, but it hath long been neglected.

HIERANOSOS. See CONVULSIO. Some expreſs by it a continued kind of convulſion without pain or loſs of ſenſibility.

HIERA PICRA, ἱερὰ πικρὰ. HOLY BITTER; now called *pulvis aloeticus*. It was formerly called hiera logadii, and was made in the form of an electary, with honey, but now the ſpecies is kept in dry powder.

The London College directs the powder to be prepared as follows: take the gum of ſocotorine aloes, one pound; of white canella, three ounces. Rub them into a fine powder ſeparately, then mix.

HIERABOTANE, from ἱερὸς, *holy*, and βοτάνη, *an herb*. HOLY HERB. In Dioſcorides, it is a ſpecies of verbena. See VERBENA.

HIERACIUM, from *hierax*, a *hawk*. *Accipitrina*, *hieraculum*, HAWKWEED. Boerhaave mentions forty ſpecies, but only four have any medical virtues attributed to them.

—— LONGIUS RACIDATUM. LONG-ROOTED HAWKWEED. The ſtalks of all the kinds are full of branches,

branches, ſlender, and elegant; the leaves are diſpoſed alternately; the calyx is thick, firm, and expanded; the ſeeds are ſmooth and angulous, or ſtriated.

The root of this ſpecies ſtrikes deep into the ground; is long, thick, and but little branched; the leaves lie flat on the ground, are rough and hairy; the flowers are like thoſe of the dandelion, but leſs of a yellow colour, and turn into down; the ſeeds are long and ſlender. It grows in fields and meadows, and flowers in May, and ſo on to Auguſt or September. It is cooling, aperitive, and diuretic.

HIERACIUM ALPINUM, alſo called *Pannonica, coſta herba, coſta pulmonaria, piloſella major, dens leonis, pulmonaria lutea.* BROAD-LEAVED HUNGARIAN HAWKWEED. It grows on chalky hills, flowers in June, and is extolled in pulmonary diſorders.

—— MINUS, called alſo hieracium leporinum. LESSER HAWKWEED. It grows in paſture ground, flowers in June and July, and its virtues the ſame as the hieracium majus, but bitterer, and otherwiſe preferable.

—— MAJUS, alſo called *ſonchus repens.* GREATER HAWKWEED. It is found in fields; it flowers in July; the leaves cool, and are moderately aſtringent. See Raii Hiſt.

—— MONTANUM, & PULCHRUM. See CHONDRILLA. Sp. 7.

HIERACULUM. See HIERACIUM.

HIERATICUM. The name of a malagma, formerly appropriated to diſorders of the liver, ſtomach, and other of the abdominal viſcera.

HIEROPYR. The ſame as the erythematous ſpecies of inflammation.

HIGHMOIRANUM ANTRUM. See ANTRUM GENÆ.

HIGUERO. The CALABASH-TREE. It is a large tree, common in all the American iſlands, and on that continent. The flowers are ſhaped like thoſe of a lily, of a white and greeniſh colour, but a diſagreeable ſmell. The fruit is of various ſizes and figures; it is green at the firſt, but when ripe it is black and hard, containing ſeeds like a gourd, and a yellow kernel. The unripe fruit contains a white juicy pulp, that ſmells like naſturtium, but of a ſweetiſh taſte. The unripe fruit is preſerved with ſugar, and is uſed in fevers. The ripe affords a ſhell for cups, &c. See Raii Hiſt.

HIMANTOSIS. Relaxation or lengthening, and ſmallneſs of the uvula.

HIMAS. Properly a leather thong or ſtrap. But in medicine it is a laxneſs of the uvula, when it becomes long and ſlender, called alſo *cion.* It differs from the *elonis*, which is when the uvula is thickened.

HIN,
HINDISCH,
HING. The Indian and Perſian name.
HINGISCH.
} See ASAFÆTIDA.

HIN-AWARU. See INDICUM.

HINKA. See CARYOPHILLUS AROMATICUS.

HIPPACE. The rennet of a colt. Alſo cheeſe made of mare's milk.

HIPPECACUANNA. See IPECACUANHA.

HIPPOCASTANUM, or HIPPOCANTANUM. The HORSE CHESNUT TREE, called alſo *caſtanea equina, pavina.* The ſort recommended by the Edinburgh College, is the ÆSCULUS HIPPOCASTANUM, or ÆSCULUS, *foliolis ſeptenis.* CLASS, HEPTANDRIA. ORD. MONOGYNIA. LINN. Gen. Plant. 462. This tree frequently grows to a great height, and from the upper part of the trunk uſually ſends off numerous ſpreading branches, covered with a rough brown bark; the wood is white, ſoft, ſoon decays, and therefore is of little value. The fruit in appearance reſemble the Spaniſh cheſnut, and is eaten by ſheep, goats, deer, oxen, and horſes; the latter of which are ſaid to eat of this fruit greedily, and by it have been cured of coughs, and pulmonary diſorders; hence the name HORSE-CHESNUTS; ſtarch alſo, and that very good has been made of it, alſo ſoap for waſhing, and was it deprived of its bitterneſs and acrimony by any proper proceſs, from the quantity of farinaceous matter it contains, it has been ſuppoſed, that it would make a kind of bread. It has been recommended as a ſternutatory employed in powder; nay this effect may even be produced by a decoction or infuſion, drawing the ſteams up the noſtrils. It has therefore been recommended to produce a diſcharge from the noſe, which, in ſome caſes of ophthalmy, headach, &c. may produce good effects. On the Continent, the bark is held in great eſtimation as a febrifuge, and is conſidered to be a medicine by many authors of great efficacy. Jo. Jac. Zannichelli affirms, that after many trials, he has found the bark of theſe trees to have the ſame effect as the Peruvian bark. By ſome it has been ſubſtituted for the Peruvian bark, and is ſaid, in every caſe where the bark is indicated, to be attended with equal, if not ſuperior advantage. The bark for medical purpoſes is to be taken, from thoſe branches which are neither very old, nor very young, and exhibited under ſimilar forms and doſes as the Peruvian bark. It rarely diſagrees with the ſtomach, but its aſtringent effects generally require the adminiſtration of aperient medicines. See RAII Hiſtoria Plant. WOODVILLE's Medical Botany.

In England we have the white, yellow, and ſcarlet flowering cheſnut trees. They are cultivated in gardens, and walks, and flower in May and June.

HIPPOCRAS. See CLARETUM.

HIPPOGLOSSUM. DOUBLE-TONGUE. See LAURUS ALEXANDRINA.

HIPPOLAPATHUM. See LAPATHUM HORTENSE.

HIPPOLAPATHUM, ROTUNDIFOLIUM. See LAPATHUM ALPINUM.

HIPPOLITHUS, from ἵππος, *a horſe*, and λίθος, *a ſtone.* A ſtone found in the ſtomach or inteſtines of a horſe.

HIPPOMANES, from ἵππος, *a horſe*, and μαίνομαι, *to be mad.* It is a name for the *cynocrambe*, or *apocynum*, called alſo *cynomoron*, becauſe it makes horſes mad if they eat of it. It is alſo a name of the juice of *tithymalus.* Some take it to ſignify the fecundines of a mare. Laſtly, the fleſhy ſubſtance which ſometimes adheres to the forehead of a new foaled colt is thus named: alſo the *hippophæs.*

HIPPOMARATHRUM, from ἵππος, *an horſe*, and μάραθρον, *fennel*, HORSE-FENNEL; alſo ENGLISH SAXIFRAGE. See Raii Hiſt. Plant. SAXIFRAGA ANGLICA.

HIPPONE. The name of a malagma which Aetius deſcribes.

HIPPOPHÆS, } Dioſcorides deſcribes it in
HIPPOPHÆSTUM. } lib. iv. cap. 162, but it is not certainly known what it is. The ſynonyme, according to Dale, is the *cnaphos rhamnus, lappago, hippomanes.* The PURGING THORN. It grows in the Morea. The juice purges powerfully. Though the *rhamnus catharticus*, and the *tithymalus maritimus* vel *ſpinoſus*, have alſo been conſidered as ſynonymes, ſtill they ſeem to have different properties, which are ſpecified under their ſeparate titles.

HIPPOSELINUM, ALEXANDERS, alſo called *oluſatrum, Smyrnium, macerona, herba Alexandrina, grielum agrioſelinum.* It is the SMYRNIUM OLUSATRUM, Linn. An umbelliferous plant, with leaves like ſmallage, but larger. It is a large kind of parſley, and was formerly blanched in gardens for culinary uſe. The ſeeds, according to FUCHSIUS, called *macedonenſium ſemen*, are bitteriſh, aromatic, and carminative; they give out all their virtue to rectified ſpirit of wine, but not fully to water. The roots are bitter, and are recommended as reſolvent, diuretic, and emmenagogue. On inciſion they yield a whitiſh juice, which when inſpiſſated, reſembles myrrh; whence the plant hath been called, from one of the names of that gummy reſin, *Smyrnium.* Boerhaave mentions three ſpecies. See Raii Hiſt. Plant.

HIPPUS, from ἵππος, *equus, a horſe.* It is an affection of the eyes, under which they are continually trembling and twinkling, as is uſual with thoſe who ride on horſeback. The author of the Definitiones Medicæ, ſays, that it is an affection contracted from the birth, and is owing to a defect in the muſcle which ſuſtains the eye.

HIRA. This word is variouſly underſtood: however, ſome expreſs by it the inteſtinum jejunum; others extend it to all the inteſtines, and others mean by it all the contents of the abdomen.

HIRAPITANGA. BRASILIENSIBUS. See BRASIL. LIGNUM.

HIRCUS BEZOARTICUS. The goat which affords the oriental bezoar. See BEZOAR ORIENTALIS.

HIRQUUS. The great angle of the eye.

HIRSUTIES. Unnatural hairneſs of the body.

HIRUDO. The LEECH, alſo called *ſanguiſuga, hirudo medica, exos.* Themiſon is the firſt who takes notice of

of *leeches*. Thoſe ſhould be choſen whoſe backs are ſtriped, and bellies ſpotted, and which are taken from running waters that are clear, and have a ſandy bed.

They are only uſed for drawing of blood, where and when the lancet cannot be conveniently uſed; and for this end, many prefer thoſe which have been kept in a veſſel of clean water for ſome time, to thoſe which are but newly taken from the running waters where they originally reſided.

Some think that *leeches* have a poiſonous quality, becauſe the wound they make ſometimes heals with difficulty; but this happens when the lancet is uſed, and depends on the bad habit of the body. Perhaps from the manner of their biting it is, that the eryſipelatous kind of inflammation ariſes: but be that as it may, it almoſt always goes off in a day or two.

To make *leeches* faſten ſoon, keep them hungry, and rub the part to which they are to be applied with warm milk or blood; if they ſtick longer than is thought convenient, they muſt not be pulled off; but if their heads are touched with common ſalt, they ſoon drop off of themſelves: if they are thought not to have drawn a ſufficient quantity of blood, apply cloths wrung out of warm water upon the orifice, or, if convenient, put the part into warm water, and thus the bleeding may be prolonged.

Keep the *leeches* in bottles not quite filled with water, and renew it every three or four days at the lateſt: a little ſugar may be added to the water in which they are kept.

Leeches are ſometimes applied to the anus, when the hæmorrhoids are ſuppreſſed; but bleeding in the ankle or foot ſeems more likely to be uſeful, for the *leeches* can only be applied to the external hæmorrhoidal veins. When local inflammation, &c. is to be removed, in many inſtances, topical bleeding is preferable to general. By applying *leeches* we moſt probably open the ſmall veins only, and as no preſſure is made as is done when the lancet is uſed, the veſſels of the part are certainly more evacuated than the reſt of the ſyſtem. Though one *leech* may be allowed only to draw one ounce of blood, yet as it makes a kind of lacerated wound, the diſcharge may be continued until double the quantity is evacuated. In ophthalmies, *leeches* have been uſeful when general bleeding hath failed; ten or twelve *leeches* applied about the temples have relieved a violent cephalalgia almoſt immediately, &c.

The curious may conſult the following writers on *leeches*, viz. Aldrovandus, Geſner, Botallus, Sebizius, Heurnius, Cranſius, Schroder, and Stahl.

HIRUNDINARIA. SWALLOW-WORT. See ASCLEPIAS.

HISMAT. See LITHARGYRUM.

HISPANICUM VIRIDE. See ÆRUGO ÆRIS.

HISPIDITAS. Hairineſs in general; but in a particular ſenſe, it is uſed to ſignify either the diſeaſe called phalangoſis, or that called diſtichiaſis.

HISPIDULA. } See GNAPHALIUM MON-
HISPIDULÆ SYR. } TANUM.

HISTORIA. *An hiſtory.* In medicine, it is the ſame as a medical caſe or obſervation.

HOAXACAN. See GUAIACUM.

HOCIAMSANUM. See AGRIMONIA.

HOITZILOXITL. See BALSAMUM PERUVIANUM.

HOLCIMOS, from ἕλκω, *to draw.* An epithet applied to what may be drawn out, and ſtill preſerve its continuity. It is alſo ſpoken of the liver affected with a tumor. See Galen de Loc. Affect.

HOLCUS. See MILIUM INDICUM.

HOLERA. See CHOLERA.

HOLIPPÆ. Thin cakes made with flour and ſugar, poured upon a hot iron, figured, and then ſet to the fire. The name is now appropriated to ſweet-meats; though in ſome diſpenſatories, to ſuch as are purging, and other *holippæ*.

HOLLI. The Indian name for what the Spaniards call *alli*; which is a reſinous liquor, that diſtils from the tree called *chilli*. It is uſed in dyſenteries. See Raii Hiſt.

HOLOCYRON. See CHAMÆPITYS.

HOLOPHLYCTIDES. See PHLYCTÆNÆ.

HOLOSCHŒNOS. See JUNCUS ODORATUS.

HOLOSTES, } See MYOSUROS.
HOLOSTEUM. }

HOLOSTEUS. See OSTEOCOLLA.

HOLOTHURION. Whether plant or animal is not known; but, according to Bontius, it is poiſonous.

HOLOTONICOS, from ὅλος, *whole*, and τείνω, *to ſtretch.* It is ſpoken of univerſal convulſion, or rigor of the whole body. It is the ſame as *tetanus*.

HOLQUAHUILT. See CORT. PERUV.

HOMA. A kind of anaſarcous ſwelling.

HOMOGENEUS, from ὅμοιος, *like*, and γένος, *kind*, an uniform body, or mixture.

HOMOLINON. CRUDE FLAX, or coarſe flaxen cloth, of which towels were made in the public baths.

HOMONOPAGIA. See CEPHALALGIA.

HOMOPLATA. See SCAPULA.

HOMORUSIA. A medicine mentioned by Avicenna.

HOMOTONOS. Equable. It is an epithet for a continual putrid fever, which preſerves the ſame tenor through all ſtages.

HOMUNCULUS PARACELSI. See ADOLESCENS.

HOPLOCHRISMA. The WEAPON SALVE, Χρίσμα τὸ ὅπλου.

HORÆOS, ὡραῖος. According to HIPPOCRATES and AURELIANUS, it is applicable to any thing that occurs opportunely, or in proper time; τὰ ὡραῖα, ſignifies the catamenia obſerving a regular period. Properly it is fruit that is ripe about autumn: but modern authors expreſs by it any fruits which are ripe.

HORDEACEUM VINUM. See ALLA.

HORDEOLUM. STIAN. It is a tubercle on the eye-lids, reſembling a barley-corn in ſhape; it is alſo called *crythe*, and *crithe*, which ſee. It is ſmall, red, hard, and immoveable: it is ſeated above the eye-laſhes. It is an encyſted tumor which contains a thick matter. It is painful; ſometimes hurts the ſight. Its ſeat is either on the inſide or outſide of the eye-lid. It is a ſpecies of wen, according to Dr. Aitken's ſyſtem: but Dr. Cullen places it as a variety of phlogoſis phlegmone. See Wallis's Sauvages. Bell's Surgery, vol. iii. p. 264.

HORDEOLUM HYDATIDOSUM. See AQUULA.

HORDEUM. BARLEY. In the ſhops there are two kinds of *barley*; or at leaſt the ſame kind of *barley* in two forms.

HORDEUM DISTICHON; alſo called *hordeum* Gallicum vel mundatum; COMMON, and SCOTCH BARLEY. It is the HORDEUM VULGARE, Linn.

Barley is leſs nutrimental, leſs glutinous, and more cooling, than either wheat, oats, or rice. It was the principal aliment and medicine amongſt the ancients in acute diſeaſes: and from the common uſe of the ſhelled barley, in the form of decoctions, ptiſana, and other preparations of the ſame general nature have been diſtinguiſhed by that name. The common *barley* is freed from the ſhells in mills, and in this ſtate is called French or Scotch *barley*. A ſort of ſhelled *barley* is formed into ſmall round grains in Holland and Germany, which, from their pearly whiteneſs, are called *pearl-barley*. There are three preparations of this ingredient, made in the following manner.

DECOCTUM HORDEI, olim AQUA HORDEATA: *Decoction of barley*, formerly *barley-water*.

℞ Hordei omni cortice nudati, p. ℥ ii. aquæ diſtillatæ m. ℔ iv. The barley is firſt to be waſhed, and cleared from all adhering ſubſtances, in cold water—then about half a pint of water is to be poured upon it, and boiled for a ſmall ſpace of time.—This liquor is to be decanted, and to the barley the diſtilled water is to be added, boiled to two pints, and ſtrained for uſe.

DECOCTUM HORDEI COMPOSITUM, olim DECOCTUM PECTORALE. *Compound decoction of barley*, or *pectoral decoction*.

℞ Decoct. hordei m. lb. ii. uvarum paſſarum acinis exemptis: caricarum inciſarum, ſingulorum, P. ℥ ii. Glycyrrhizæ inciſæ & contuſæ, P. ℥ ſs. Aquæ diſtillatæ, m. lb. i. Decoque ad libras duas, & cola.

DECOCTUM HORDEI cum gummi. *Decoction of barley with gum.*

In two pints of the decoctum hordei, whilſt warm, one ounce of gum arabic is to be diſſolved.

The decoction of barley with gum is an uſeful diluent and demulcent in ſtrangury, dyſury, &c. for the gum *is ſuppoſed* to find its way into the bladder in an unaltered ſtate, mix with the urine, and prevent the action of its ſaline particles on the urinary canal.

Decoctions of theſe in water contain their lighter and more agreeable parts, and are important aſſiſtants in acute and inflammatory diſorders: but decoctions of barley are moſt uſeful, when accompanied with ſaline ſaponaceous medicines; for otherwiſe they run off by urine, without mixing with the blood. Beſides being applied in the modes above directed, or by way of nutriment, barley, in its malted ſtate, proves remarkably antiſeptic. See BRASIUM.

HORDEUM CAUSTICUM. See CEVEDILLA.

HORMINUM. CLARY; called alſo *gallitrichum*; *ſclarea*, *orvala*; GARDEN-CLARY. It is the SALVIA HORMINUM, Linn. It is a whitiſh, green, ſlightly hairy plant, with ſquare ſtalks, on the tops of which are long ſpikes of bluiſh flowers. It is perennial, a native of warmer climes, cultivated with us in gardens, and flowers in July and Auguſt.

The leaves are bitteriſh, have an aromatic kind of ſmell, but diſagreeable to many people; they are recommended as antiſpaſmodic; their active part reſides in an unctuous, reſinous matter, which is wholly taken up by ſpirit of wine; and, on inſpiſſating, the tincture remains in the extract. Water takes up the greateſt part of their virtue by infuſion; and in diſtillation, carries the whole of it over. The ſeeds poſſeſs the ſame qualities as the leaves.

HORMINUM SYLVESTRE. WILD-CLARY; called alſo *ſclarea Hiſpanica*, and *oculus Chriſti*. This ſpecies reſembles the other in appearance and qualities; but as to the latter, it is much inferior. See Raii Hiſt.

Boerhaave enumerates twenty-nine ſpecies of *garden-clary*, and fourteen of the *wild* ſort.

HORROR, from *horreo*, *to ſhake with cold*. A *tremor* is only a vibration of one limb. A *refrigeration* is becoming very cold. A *perfrication* is when great coldneſs is accompanied with a gentle unequal motion of the ſkin, or ſhivering, called *phricaſmus*. An *horror* is, when the coldneſs ſpoken of in a perfrication is conſiderable, and attacks by fits, without attacking the whole body; ſo that an *horror* is ſuch an affection of the ſkin alone, as a rigor is of the whole body. A *rigor* is an irregular agitation of all the body. See RHIGOS.

HORTUS. See PUDENDUM MULIEBRE.

HORTUS LÆTITIÆ. See CROCUS.

HOUI POUN. See TINCAL.

HUAXACENSIS, } alſo called *Ricinus Novæ Hiſ-*
HUCIPOCHOTL, } *paniæ*. Hernandez deſcribes it as a ſhrub which creeps like a vine, with a fruit like a hazel-nut, the kernels of which operate upwards and downwards, but not violently.

HUICAN. See GUIACUM.

HUILE DE GRANDE BAYE. See CETUS.

HUMERALIS ARTERIA. The HUMERAL ARTERY. It riſes from the lower and fore-ſide of the axillaris, and runs backward between the head of the os humeri and teres major, ſurrounding the articulation, till it reaches the poſterior part of the deltoides, to which it is diſtributed. In its courſe it gives off ſeveral branches to the neighbouring parts. From a puncture of this artery, near the ſhoulder, though the hæmorrhage may be reſtrained by ligature, yet ſuch a mortification will probably enſue, as, without amputation, will generally occaſion the loſs of the perſon's life.

HUMERALIS MUSCULUS. See DELTOIDES.

—— NERVUS. See CERVICALES.

HUMERI OS. The BONE of the ARM; called alſo *adjutorium*. It is articulated by its head, to the ſcapula: in children, this head is an epiphyſis; immediately below the head is the part called the neck of the humerus. This bone grows broader at its lower extremity; and at the end, it is formed into two condyles, on the external of which the head of the radius moves; and, in the cavities, betwixt theſe condyles, the ulna chiefly hath its motions.

HUMERUS; called alſo *omos*, *adjutorium*; the SHOULDER, or joint which connects the arm to the body; the head of which is called *olecranon*. In HIPPOCRATES it is called *brachium*; which ſee.

HUMILIS, RECTUS MUSC. See DEPRESSOR OCULI.

HUMIRUBUS. DEWBERRY. See RUBUS IDÆUS.

HUMOR. HUMOUR. A general name for any fluid. The ancients ſeem to have called the nutritious juices, the radical *humours*.

HUMORALIA. In Linnæus's Noſology, it is an order of diſeaſes in the claſs vitia; and ſignifies diſorders attended with vitiated or extravaſated fluids.

HUMORARIA. A kind of continued fever, which ſeems to be inflammatory. It is noticed by Sagar.

HUMULUS. See LUPULUS.

HUMUS NIGRA PICTORIA. See CRETA NIGRA.

HUNGARICA AQUA, vel *Hungaricus ſpiritus*. See ROSMARINUS.

HURA The SAND-BOX TREE; alſo called hura Americana; JAMAICA WALNUTS; *avarnelia* and *havelia*. It is a native of the Spaniſh Weſt Indies; the leaves are full of a milky juice; the ſeeds purge upwards and downwards. The ſhell is uſed for holding ſand, after the ſeeds are taken out; whence the name. Miller's Dictionary.

HUSO. See ICHTHYOCOLLA.

HUTZOCHITL. See PERUVIAN BALS.

HYACINTHUS. HARE-BELLS. HYACINTHUS *oblongo flore cæruleus major*; called alſo HYACINTHUS Anglicus ſive Belgicus, vel Hiſpanicus. The roots are bulbous: the flowers of this ſpecies are agreeably ſcented, and of a purple or blue colour. It is found in woods, hedges, and thickſets: it flowers in May. Galen ſays, that the roots are antihiſteric; and others ſay, that they reſtrain all kinds of fluxes. See Miller's Bot. Off. For that called STELLARIS, ſee LILIO-HYACINTHUS.

—— RACEMOSUS MOSCHATUS. See BULBUS VOMITORIUS.

HYALODES, from ὑαλος, *glaſs*, or *glaſſy*. An epithet applied to urine which depoſits much vitreous, white, viſcid ſediment.

HYALOIDES, from ὑαλος, *glaſs*, and εἰδος *likeneſs*. An epithet of the vitreous humour of the eye. See OCULUS.

HYANCHE, from ὑς, *a ſwine* and ἀγχω, *to ſtrangle*. A quinſey, accompanied with an external tumor on each ſide the throat, is thus called, becauſe the necks of *ſwine* are ſubject to ſwellings.

HYBOUCOUHU AMERICANUS. The name of an American fruit, of the ſize of a date, but not eatable; an oil is expreſſed from it, which the natives keep in the ſhell of a fruit called *caramcou*, whence the oil itſelf is ſometimes ſo called. This oil is chiefly uſed againſt an American diſorder called TOM, which ſeems to be the ſame with *chigres*, or a collection of very ſmall worms in the fleſhy parts, which cauſe a tumor.

HYDARTHROS, from ὑδωρ, *water*, and ἀρθρον, *a joint*. A ſort of clear water which iſſues from wounded joints. It is alſo a name of the *ſynovia*.

HYDARTHRUS. A WHITE SWELLING. Dr. Cullen places this genus of diſeaſe in the claſs locales, and order tumores, which he defines, a tumor of the joints, chiefly of the knee; at firſt, the ſwelling is ſlight, of the ſame colour of the ſkin, very painful, diminiſhing the mobility of the part affected. Here we ſhall notice two diſorders, perhaps agreeing only in the difficulty to relieve them.

Mr. Bell, in his Treatiſe on Ulcers, ſpeaks of this diſeaſe under the name of *white ſwellings* of the joints. He ſpeaks of it as of two ſpecies, viz. the *rheumatic*, and the *more inveterate or ſcrophulous ſpecies*. Theſe ſwellings are more frequent in the large, than in the ſmaller joints. The FIRST SPECIES begins with an acute pain in the joint, and frequently the tendinous aponeurotic expanſions of ſuch muſcles as are connected with it. There is, from the beginning, an uniform ſwelling of the whole ſurrounding teguments; and conſiderable tenſion generally prevails; but there is ſeldom, in this period of the diſorder, any external diſcolouration. The patient, from the beginning, ſuffers much pain from the motion of the joint; and always finds it eaſieſt in a relaxed poſture, ſo keeps it bent; which, eſpecially in the knee, produces a kind of rigidity in all the flexor tendons of the limb. In conſequence of the want of motion happening from this circumſtance, ſuch joints ſoon become ſtiff. The ſwelling gradually increaſes to twice, or perhaps thrice the natural ſize of the part. The cuticular veins become turgid and varicoſe; the limb below the ſwelling decays in its fleſhy ſubſtance; at the ſame time that it frequently acquires an equality in point of thickneſs, by becoming œdematous; the pain increaſes, eſpecially if the patient is warm in bed; and abſceſſes form in different parts of the ſwelling. In all theſe abſceſſes, a fluctuation of a fluid is evident on preſſure, and all ſuch ſwellings afford a peculiar elaſtic feel: they riſe as ſoon as the preſſure is removed. Theſe different collections, on breaking, or being laid open, diſcharge much matter, which at firſt is of a good conſiſtence, but ſoon degenerates into a thin fetid ſanies; the ſwelling, notwithſtanding the diſcharge, retains nearly its former dimenſions. If the orifices are not kept open by art, they ſoon heal, and new collections, forming in different parts, again break out and heal as before: in length of time, the whole ſurrounding teguments are covered with cicatrices. But long before this time, the patient's health hath ſuffered conſiderably, firſt from the pain, which deſtroys both ſleep and appetite; and ſecondly, from the abſorption of matter into the ſyſtem, a quick pulſe, night-ſweats, and diarrhœa occur,

cur, and carry off the patient, if either an amputation of the limb, or a cure of the diſorder does not befriend him. All this happens without any affection of the bones of the joint; when, however, by a long continuance of the complaint, theſe ligaments are corroded, the cartilages, and even the bones, are ſoon brought to ſuffer. *The cauſes of this ſpecies* are ſtrains affecting the ligaments of the joints, ſo as to produce inflammation, bruiſes, luxations, or rheumatic diſpoſition. This ſpecies of *white ſwelling* occurs moſt frequently in young plethoric people: the pain, in this ſpecies, is diffuſed over the whole joint, and ſometimes extends along the muſcles that are attached to it: the ſwelling is confined to the ſoft parts, and is from the beginning exceedingly evident. And we may add, when ſuch ſwellings occur in young, ſtrong, plethoric people, and eſpecially thoſe who have been ſubject to rheumatiſm, they will moſt probably prove to be of the rheumatic ſpecies. In the rheumatic *white ſwelling*, as it is *always at firſt* of an inflammatory nature, bleeding will be adviſable, and is beſt taken from the part affected. Cupping and ſcarifying are here principal remedies; the inſtrument ſhould be applied to each ſide of the diſeaſed joint; at leaſt eight or ten ounces of blood ſhould be diſcharged, and repeated at proper intervals, according to the violence of the ſymptoms and ſtrength of the patient. Cupping is in general preferable to leeches; but when the ſwelling of the joints is conſiderable, it is impoſſible to procure a ſufficient quantity of blood this way; in which caſe leeches muſt be applied. On the anterior part of the joint, where the cupping-glaſſes, or leeches, have not been placed, a bliſter ſhould be directly applied; and the part ſhould be kept open with iſſue-ointment, till the wounds from whence the blood was diſcharged are ſo far healed, that a bliſter may be laid on one ſide of the joint; and, as ſoon as this is nearly healed, the other ſide ſhould be alſo bliſtered. By thus alternately applying them, firſt to one ſide, and then to the other, almoſt a conſtant ſtimulus is kept up; and thus the advantage is more frequently to our wiſh. Cooling laxatives are neceſſary at proper intervals; as is alſo a ſtrict antiphlogiſtic courſe of diet, &c. It is in the firſt ſtages only that this or any other courſe can be of much ſervice; and in theſe, cures are ſometimes effected. The original inflammatory affection being removed, drains ſhould no longer be uſed; and while there are yet no appearances of the formation of matter, mercury is ſometimes uſeful, if continued a few weeks to keep the mouth merely ſore; for this purpoſe, an ointment of quickſilver and hog's-lard may be prepared, but with ſo ſmall a proportion of the former, that two drachms of the ointment may be uſed three times a day. In order to rub this medicine in with every advantage, an hour ſhould be ſpent each time in rubbing. Falls of warm water on ſwellings of this kind are much recommended by Le Dran, &c. By a proper uſe of the ſeveral topical remedies in the firſt or inflammatory ſtate of the diſeaſe, and afterwards, but ſtill before the formation of matter, of mercurials, friction, &c. many have been cured. In many inſtances, by the bent poſition in which the limb has long been kept, the uſe of the joint is loſt; and this, from the contracted ſtate of the flexor tendons, when it happens in the knees: in this caſe, all other ſymptoms being removed, pure olive-oil may be applied warm; as much of it as can be eaſily conſumed by an hour's gentle friction ſhould be rubbed in, three times a day; the friction ſhould be extended over the whole muſcles about the part. Gentle action of the parts, as ſoon as it can be borne, as recommended by Mr. Pugh, on the Utility of Muſcular Motion, promiſes to be highly beneficial. But, ſhould ſuppuration come on, by opening the different abſceſſes ſoon after their formation, the matter may probably be prevented from injuring the capſular ligaments of the joints; the deſtruction of which renders amputation neceſſary.

The SECOND SPECIES hath the pain more acute, for the moſt part, but it is more confined moſt commonly to a particular ſpot, and that generally the middle of the joint. The ſwelling is at the firſt for the moſt part very inconſiderable; and little difference is ſeen in point of ſize between it and the oppoſite ſound one. The leaſt motion gives great pain; ſo that the joint being conſtantly in a bent poſition, ſtiffneſs and rigidity is ſoon produced. As the diſorder advances, the pain is more violent, the ſwelling increaſes, and the ends of the bones that compoſe the joint grow larger. In proceſs of time there is perceived a very peculiar elaſtic feel; varicoſe veins appear over its ſurface, and collections of matter occur in different parts of it: theſe, upon burſting, or being laid open, diſcharge conſiderable quantities of purulent matter, or more frequently a thin fetid ſanies; and, if a probe can be paſſed to the bottom of the ſores, the bones are found carious, and pieces of them are often diſcharged at the openings. As the diſorder continues, the conſtitution ſuffers, a diarrhœa, with night-ſweats, commencing, the patient is reduced to extreme weakneſs. From every ſymptom, and appearance on diſſection, this ſpecies ſeems evidently to be an affection of the bones; the ſurrounding ſoft parts only ſuffer from their connection. This ſpecies ſeldom occurs as the conſequence of any external accident. It generally begins, without the patient's being in the leaſt able to account for it. From the effects uſually produced on the bones which it attacks, *it would appear to be a ſpecies of the real ſpina ventoſa; and which again is very probably a diſeaſe of the ſame nature in the bones that ſcrophula is of the ſoft parts.* It is further obſerved, that this ſpecies of *white ſwelling* is generally either attended with other evident ſymptoms of ſcrophula ſubſiſting at the time; or that the patient in an earlier period of life has been ſubject to that diſorder; or what is nearly the ſame, he is deſcended from ſcrophulous parents. In this ſpecies of the diſeaſe, the pain is at the firſt, and alſo when the complaint has been of conſiderable ſtanding, confined to a very ſmall ſpace; there is ſeldom for ſome time any perceptible ſwelling; and when it does more ſenſibly appear, the bones are found evidently to be the parts chiefly affected, the ſurrounding teguments coming only to ſuffer on the further progreſs of the diſeaſe. When ſwellings of this nature appear in ſuch patients as are evidently of ſcrophulous diſpoſitions, where, together with a fine ſkin and delicate complexion, there are either hardened glands in the neck, arm-pits, or the groin: when any, or all theſe occur, if the diſorder has begun without any evident external cauſe, we need not doubt its being of a ſcrophulous nature. We may here add, in the ſmall joints, when the diſeaſed parts of the bone begin to caſt off, a cure may be ſometimes promoted by aſſiſting the efforts of nature; but in all the large joints, particularly in the knee, and ankle, it is not probable that any other reſource than amputation will afford relief. And even the effects of this operation can ſeldom be depended on as laſting. In this caſe opiates in large doſes will be found the beſt remedy.

As to amputation, in caſes of *white ſwelling*, it ought never to be adviſed till the complaint is pretty far advanced: I have conſtantly obſerved in this diſorder, that amputation has more frequently ſucceeded, when the patient was previouſly much reduced by diarrhœas, &c. So that in no caſe whatever is it proper to have recourſe to amputation, until every probable means for ſaving the limb has been tried in vain.

On diſſection, after the appearance called a WHITE SWELLING, there is always found a great thickening of the ligaments, which ſo confounds the ſeveral parts, that they can ſcarce be diſtinguiſhed, together with crude matter, forming ſinuſes, through this undiſtinguiſhed maſs; and generally an eroſion of the cartilages at the end of the bones.

Edinb. Medical Eſſays, vol. iv. p. 242 and 246. Reimaurus de Fungo Articulorum. Leyd. 1757. Bell on Ulcers, ed. 3. p. 435, &c. Lond. Med. Tranſ. vol. i. p. 104. White's Surgery, p. 66.

HYDATINON. The name of an ancient collyrium.

HYDATIS. See AQUULA.

HYDATIS. HYDATIDS. See PHLYCTÆNÆ. They are tranſparent bags filled with water. Sometimes they are ſingle; at others, in cluſters; generally on the liver, but are alſo on many other parts. Hydropic patients, for the moſt part, have them on their livers. In the Lond. Med. Tranſ. p. 486, is an inſtance of *hydatids* coughed up from the lungs.

Dr. Cullen places this genus of diſeaſe in the CLASS LOCALES, and ORDER TUMORES; and defines it a cuticular veſicle, full of aqueous humour.

There are two ſpecies of *hydatids* in human bodies.

The FIRST SORT is organized, and is connected with veſſels by peduncles. It conſiſts of a bag, or bags of different ſizes, filled with ſerum; as theſe bags increaſe, they thicken. Sometimes their contents are bloody, and flakes of coagulable lymph are floating in them. This kind of *hydatids* only diſturb by their ſize. The *hydatids* of the ovaria are of this ſort, ſo are thoſe in the kidnies, uterus, &c.

THE

THE SECOND are ſuppoſed to be confined to the liver, and conſiſt of a ſtrong bag formed in the ſubſtance of that viſcus; this bag is vaſcular, and lined with a ſoft, pulpy, opake coat, reſembling the retina of the eye. It contains a liquor of a whey colour, in which a number of detached veſicles are found ſwimming, or there is a ſeries of them, one within another. This ſpecies is productive of worſe effects than the former. This bag ſometimes burſts, and its contents falling into the cavity of the belly, a kind of aſcites is the conſequence; its external cyſt is ſubject to inflammation, and adheſion to the adjacent parts, whence, if ſuppuration takes place, various ill conſequences may follow. See Med. Communications, vol. i. p. 101. Lond. Med. Journal, vol. i. p. 125. vol. vi. p. 139.

HYDATODES, } from ὑδατος, the genitive caſe of
HYDATOIDES, } ὑδωρ, *water*, and εἶδος, *a ſhape*. WATERY. It is an epithet for wine much diluted with water; for limpid urine; for the aqueous humour of the eye; and for one in an anaſarca.

HYDEROS. See HYDROPS and ANASARCA.

HYDRAGOGOS, from ὑδωρ, *water*, and ἀγω, *to bring away*. *Hydroticus*; *aquiducus*. HYDRAGOGUE. Remedies that evacuate much water are thus named. In Hippocrates, Epidem. lib. vi. it imports a perſon grown dropſical from drinking water.

HYDRARGYRUM, } from ὑδωρ, *water*, and ἀργυρος,
HYDRARGYRUS, } *ſilver*. Thus the ancients named QUICKSILVER. This term, the College of Phyſicians of London have adopted for the argentum vivum, in their Pharmacopœia of 1788, and uſe it for the word *mercurius*, in all the preparations, wherein this is the material part of the compoſition. See ARGENTUM VIVUM.

HYDRARGYRI MURIATI LIQUOR. Hydrargyri muriati drachmæ uni, gradatim ad ſolutionem perfectam, adjiciatur acidum muriaticum, q. ſ. ope mortarii marmorei. Two drops of this liquor is nearly equivalent to one grain of muriated quickſilver: in a dilute ſtate, it therefore may be given in the ſmalleſt quantity poſſible.

HYDRARGYRUS ACETATUS. ACETATED QUICKSILVER. Pharm. Lond. 1788.

Take of *quickſilver* purified, one pound; nitrous acid diluted, two pounds; water of kali, a ſufficient quantity; mix the *quickſilver* with the acid in a glaſs veſſel, and diſſolve it in a ſand-bath, then gradually drop in the water of kali, that the calx may be depoſited. Waſh this well with diſtilled water, and dry it by a gentle heat. Then take of this calx, one pound; acetous acid, a ſufficient quantity to diſſolve the calx; mix in a glaſs veſſel, and the calx being diſſolved, filter the liquor through paper; afterwards let it be evaporated, until a pellicle appears, and ſet it by to cryſtallize, which let be kept in a veſſel well corked; one grain to five every night is a doſe. This compoſition is ſaid to be the baſis of KEYSER'S PILLS. See KEYSERI PILULÆ.

HYDRARGYRUS MURIATUS MITIS. MILD MURIATED QUICKSILVER. Pharm. Lond. 1788.

Take of purified quickſilver, nitrous acid diluted, of each half a pound; mix them in a glaſs veſſel, and let them ſtand till the quickſilver is diſſolved; let them boil to produce the ſolution, pour the boiling liquid into a glaſs veſſel, in which muſt be firſt put another boiling liquor conſiſting of muriatic ſalt four ounces, diſtilled water eight pints; after the white powder is depoſited at the bottom of the veſſel, let the limpid liquor ſwimming above be poured off; and the remaining powder be often waſhed with warm water until it becomes inſipid to the taſte; then let it be laid on filtering paper and dried by a gentle heat.

HYDRARGYRI PILULÆ. See LUES VENEREA.

HYDRARGYRUS CALCINATUS. See MERCURIUS CALCINATUS.

—— CUM CRETA. See MERCURIUS ALKALIZATUS.

—— MURIATUS. See MERCURIUS CORROSIVUS ALBUS.

—— MURIATUS MITIS of SCHEELE. See MERCURIUS DULCIS SUBLIMATUS.

—— NITRATUS RUBER. See MERCURIUS PRÆCIPITATUS RUBER.

—— PURIFICATUS. See ARGENTI VIVI PURIFICATIO.

—— CUM SULPHURE. See ÆTHIOPS MINERALIS.

HYDRARGYRUS SULPHURATUS RUBER. See CINNABARIS FACTITIA.

—— VITRIOLATUS. See MERCURIUS EMETICUS FLAVUS.

HYDRARGYRUS PRÆCIPITATUS CINEREUS. *Grey Precipitate of Quickſilver.*

℞. Hydrargyri purificati. Acidi nitroſi diluti, ſing. partes æquales: ſolvatur primo hydrargyrus in acido nitroſo, & aqua diluatur, poſtea adjiciatur portio propria aquæ ammoniæ, ut acidum perfecte ſaturetur; deinde præcipitatum optime lavetur, & ſiccetur. Doſis gr. ij. ad v. ſingulis noctibus. When fumigation is neceſſary in the lues Venerea, this preparation is more eligible than the red ſulphurated quickſilver, becauſe it does not yield any vapour offenſive to the patient.

HYDRARGYRUS MURIATUS FORTIOR. STRONGER MURIATED QUICKSILVER.

℞. Calcis hydrargyri albæ ℥ ſs. Acidi muriatici q. ſ. Pour as much of the acid upon the calx, put into a flux, and placed in a moderately warm ſand-heat, as it will require to diſſolve it; then continue the heat, ſufficient to evaporate the fluid, till proper for cryſtallization; and ſet it in a cool place. Theſe cryſtals are the ſtrongeſt preparation of mercury yet known; one grain forming ſixteen doſes. This is ſuppoſed to enter into certain quack medicines, ſaid to be VEGETABLE; and, on the account of the extreme ſmall quantity introduced, it eſcapes detection by chemical analyſis. Beſides theſe, there are a variety of extemporaneous preſcriptions to be met with in almoſt every author, in the form of *pills*, *powder*, *ſolution*, *ſyrup*, *ointment*, *collyrium*, *gargle*, *lotion*, *injection*, &c. particularly in the Pharmacopœia Chirurgica, London, 1794. See PLENCK and SWEDIAAR, on the Venereal diſeaſe.

HYDRELÆUM. A mixture of oil and water. Oribaſius and P. Ægineta.

HYDRENTEROCELE, from ὑδωρ, *water*, ἐντερον, *an inteſtine*, and κηλη, *a tumor*. A dropſy of the ſcrotum. Vogel deſcribes this diſorder as compounded of a dropſy and a hernia.

HYDROA. See BOA; alſo a ſort of puſtule called *Alhaſef*, and *aſef*.

HYDROCARDIA, from ὑδωρ, *water*, and καρδια, *the heart*. Hildanus coined this word to ſignify a ſerous, ſanious, or purulent tumor of the pericardium.

HYDRO-ENTERO-CELE, } from ὑδωρ, *water*, and
HYDROCELE. } κηλη, *a tumor*. It is when water is in the contents of ruptures, but particularly is applied to a DROPSY in the SCROTUM, called *hydrops ſcroti*, alſo *hydrops teſtis*, *hernia aquoſa*, *oſcheocele*, and *oſcheophyma*. By *oſcheocele*, VOGEL means a rupture which deſcends into the ſcrotum; Dr. Cullen places this genus of diſeaſe in the CLASS CACHEXIÆ, and ORD. INTUMESCENTIÆ, which he defines a ſoft, fluctuating, pellucid tumor of the ſcrotum, not painful.

There are two kinds: THE FIRST is when the water is lodged in the cells of the membrana cellularis ſcroti, but this is generally a ſymptom of an anaſarca. THE SECOND, and only proper ſpecies, is formed by water lodged within the tunica vaginalis of the teſticle. *The firſt* is known by pits remaining for a time where it is impreſſed by the finger; *the ſecond* is not ſubject to this accident.

The cauſe, when not anaſarcous, is a preternatural diſcharge of that water, which is continually ſeparating on the internal ſurface of the tunica vaginalis, for the moiſtening, or lubricating the teſticle.

From the time of its firſt appearance, it is ſeldom known to diſappear, or diminiſh, but generally continues to increaſe, though in ſome much faſter than in others. *In one* it grows to a painful degree of diſtenſion in a few months; *in another*, it continues many years, with little diſturbance. As it enlarges it becomes more tenſe, and is ſometimes tranſparent, ſo that if a candle is held on the oppoſite ſide, a degree of light is perceived through the whole bulk of the tumor; but the only poſitive way of knowing that a fluid is the contents, is to feel for the fluctuation thereof, or to diſcover that the diſtenſion of the tunica vaginalis is the cauſe of the tumor, and not an hernia of the omentum or inteſtines, or ſome other diſorder of the part.

The *hydrocele* muſt be diſtinguiſhed from an hernia of the abdominal contents, an hernia humoralis, and a ſarcocele.

In order to the cure, if the water is lodged only in the cellular membrane, fcarifications may be made in the legs, as in an anafarca; for in this cafe an anafarca is attendant, and the caufe of the diftenfion of the fcrotum.

If the cafe is a proper *hydrocele*, if any other diforder is fufpected to give rife to it, the original diforder muft firft be removed. If no fuch diforder attends as a palliative cure, the trochar may be puflhed into the feat of the water, in order to its difcharge; and as the teflicle lies always on the pofterior part of the tumor, the perforation muft be made into the anterior and lower part of it.

Mr. Bell, in the firft volume of his Surgery, propofes for the palliative cure of this complaint, the ufe of a flat trochar in preference to a lancet. The moft proper part for introducing the inftrument is the moft anterior point of the under part of the tumor. The patient being feated, the operator with his left hand fhould grafp the tumor on its back part, fo as to pufh the contained fluid into the anterior and under part of the fwelling. Make an opening through the fkin and cellular membrane, about half an inch long, with a lancet; then take the trochar and introduce it through the tunica vaginalis, withdraw the ftillete, and the water will be difcharged. After which the canula may be alfo withdrawn, and a piece of adhefive plafter fhould be applied to the orifice, likewife a compref of foft linen may be laid over the fcrotum, and the whole may be firmly fupported by a T bandage.

Mr. Pott propofes a radical one, by exciting an artificial inflammation in the tunica albuginea, and the tunica vaginalis, by means of a feton, fo as to produce an obliteration of the cavity, which is the feat of the difeafe. Mr. Elfe prefers the application of a cauftic (fee Causticum opiatum) to the fore and lower part of the fcrotum. And Mr. Bell recommends an incifion to be made into the upper and fore part of the fcrotum, and for it to be directed downwards. It is propofed here to give a general account of thefe three methods, and recommend their authors' works on the fubject for further particulars.

Mr. Pott's Method, by a *Seton*.

The point to be aimed at, is *to excite fuch a degree of inflammation both in the tunica vaginalis and tunica albuginea, as fhall cauſe a general and perfect cohefion between them*; and this, if poffible, without the production of flough or abfcefs; without the hazard of a gangrene, and without that degree of fymptomatic fever which now and then attends both the cauftic and the incifion; and which, when they do happen, are fo alarming both to the patient and to the furgeon. Thefe ends I have frequently obtained by the ufe of the feton. It requires confinement to bed only for a few days, after which the patient may lie upon a couch to the end of the attendance, which is generally finifhed in about three weeks or a month at fartheft, and during all the time, no other procefs or regimen is neceffary, than what an inflammation of the fame part from any other caufe would require. *The manner of performing it is as follows.* Chufe a time when the vaginal coat is moderately diftended, and having pierced it with a trochar of a tolerable fize, draw off the water; when that is done, introduce into the canula, a probe armed with a feton, confifting of ten or twelve ftrings or threads of filk; pafs the probe as high to the upper part of the vaginal coat as you can, and on the end of that probe make an incifion of fuch a fize as to enable you to pull it out eafily, together with a part of its annexed feton; then cut off the probe, and tie the filk very loofely, covering the orifices with pledgits. By the next day, the feton will be found to have contracted fuch an adhefion to the tunica albuginea, as would cauſe a great deal of pain to detach; but this it is perfectly unneceffary to do, and it fhould be fuffered to remain without moleftation. In about forty-eight hours the fcrotum and teflicle begin to fwell and inflame; the patient fhould then lofe a little blood, and have a ftool or two, and the whole tumefied part fhould be wrapped in a foft poultice and fufpended in a bag-truſs. The difeafe from this time bears the appearance of a large hernia humoralis, and muft be treated in the fame manner, by fomentations, cataplafms, &c. The adhefion of the feton to the albuginea generally continues firm, and I never meddle with or move it, till it becomes perfectly loofe, which it feldom does for the firft fortnight, or until the inflammation is going and the humours fubfiding. By the time the feton become loofe, the coalition of parts is univerfally and firmly accomplifhed. I then withdraw it, and heal the orifices with a fuperficial pledgit, &c.

Mr. Else's Method, by a *Cauſtic*.

My method is this:—to lay a fmall cauftic upon the anterior, inferior part of the fcrotum, taking care to avoid the teflicle: a large cauftic is quite unneceffary, and every advantage may be derived from one whofe efchar will be no bigger than a fhilling. The loofe and pendulous fituation of the fcrotum renders the application of a bandage fo very inconvenient, that we cannot eafily prevent the cauftic from fpreading fomewhat; for this reafon, I cover no more than the fize of a fixpence, on a prefumption that it may make an efchar as broad as a fhilling, though it commonly makes one of the fize of a half-crown. The intention is, that it fhall affect, and if poffible, penetrate through the tunica vaginalis; fo that the time it is fuffered to lie on, is proportioned to the fuppofed thickneſs of the cyft. The cauftic fhould never remain on lefs than five hours; but if it be fuffered twenty-four hours, it can do no mifchief when properly guarded. On the removal of the cauftic, digeftives may be applied to the efchar, or the common cataplafm of white bread and milk. The fcrotum muft be fufpended in a bag-truſs; and the patient had beft be confined to his bed; though even this circumftance is fometimes omitted without detriment. Sometimes, immediately after removing the cauftic, fometimes within twelve or twenty-four hours, or even at the diftance of two or three days, the patient begins to complain of pain in the fcrotum and loins, has now and then fome colic pains, and the pulfe a little quickened, and the tongue whitifh. At different periods of time, from the removal of the cauftic, but generally within forty-eight hours, an alteration is perceptible in the fcrotum; the tumour upon grafping feels more tenfe and hard than it was before; and this hardneſs anfwers to the figure of the tunica vaginalis in its whole extent; and a little attention will convince an obferver, that it is this membrane alone which gives the fenfation of tenfion and hardneſs, and no other part. The colic pains and febricula feldom continue more than twenty-four or forty-eight hours; and very frequently are fo inconfiderable, as to require neither evacuation, nor any internal medicines. If, however, the pulfe is quickened a little, the pain of the back and the colic diftreffing to the patient, they will be fpeedily removed by one or two bleedings, and injecting one or two glyfters. As foon as the pain of the back, (except what arifes from the weight of the fcrotum), the febrile heat, and other fymptoms are removed, for they commonly go off altogether, the patient need no longer be confined to his bed, but may be fuffered to get up and walk about the room, provided the fcrotum be fufpended. In a few days the efchar of the fcrotum will loofen and come away, expofing to view the tunica vaginalis, which bears evident marks of its having been affected by the cauftic and prepared to flough off; and when preffed with the finger, the undulation of the water may be felt within it. As the cure proceeds, the floughy tunica vaginalis will project more and more through the orifice in the fcrotum; and when it appears ready to burft, it may be punctured with a lancet, and for this reafon only, that it will relieve the patient from the weight of the tumor; for no other advantage can be derived from it. If the water is difcharged by a puncture, the fcrotum by degree collapfes, and the orifice in it is filled up with flough, which prevents the acceſs of external air to the teflicle. Thefe floughs continue to come away with the dreffings daily for about four, five, or fix weeks, and in proportion to their difcharge, the hard tumor of the fcrotum leffens. Upon caſting off the laft flough, the hardneſs is entirely gone, the wound immediatelycicatrizes; and the cicatrix being about the fize of a finger's end, adheres ſtrongly to the body of the teſtis, which has never come in ſight, nor has had any application brought in contact with it during the whole procefs.

Mr. Bell's Method, by *Incifion*.

The patient being placed upon a table of a convenient height, and being properly fecured by two aſſiſtants, with the fcrotum lying nearly upon the edge of the table, the operator with one hand ſhould graſp the tumor ſo as to hold it firm, and make it ſomewhat tenſe on its anterior part; and with a common round-edge ſcalpel in the other, he is now to divide the external teguments by one continued inciſion from the ſuperior extremity of the tumor, all along its anterior ſurface down to the moſt depending point of the ſwelling. By this means, as the

divided ſcrotum retracts a little, the tunica vaginalis is laid perfectly bare, for the breadth of half an inch or ſo, from one extremity to the other. An opening is now to be made with a lancet into the vaginal coat, juſt at its upper extremity where the firſt inciſion commenced. This opening ſhould be of ſuch a ſize as to receive the operator's finger, which being inſerted, the probe-pointed biſtory is to be conducted upon it, and by means of it the ſac is to be divided to the very bottom, all along the courſe of the firſt inciſion. By making the firſt opening into the ſac at the upper end of the tumor, much trouble and inconvenience is prevented, which making the firſt orifice below, is ſure to occaſion: for as we have before remarked, when the tumor is firſt opened below, the water is inſtantly evacuated; and as that produces an immediate collapſe of the tunica vaginalis, the paſſage through its cavity is not afterward eaſily diſcovered; whereas, by making the firſt opening above, as the water is thereby evacuated gradually as the inciſion is extended downwards, the vaginal coat continues diſtended to the bottom till the inciſion is completely finiſhed. The inciſion being completed in the manner directed, the teſticle covered with its tunica albuginea comes into full view. Sometimes the teſtis protrudes from the wound altogether; in which caſe it muſt be replaced with great caution, and it ought by all means to be covered as quickly as poſſible from the external air; and provided none of the tunica vaginalis is to be removed, this may be always done immediately, by finiſhing the dreſſing directly on the ſac being opened. When the ſac is not much thickened, there is no neceſſity for removing any part of it; but when it is diſcovered to be otherwiſe, to be thick and very hard, the removal of a portion of it on each ſide of the inciſion, makes the cure of the remaining ſore more eaſy and expeditious. As in this hardened ſtate, the ſac generally ſeparates with great eaſe from the ſurrounding teguments, any quantity of it may be eaſily taken away with the ſcalpel without the leaſt hazard of wounding the ſcrotum. Add to what has been ſaid, that as ſoon as the inciſion has been made, Mr. Bell inſerts between the tunica vaginalis, and the body of the teſtis, ſlips of ſoft linen, ſmeared with ſome ſimple ointment, which cauſes much leſs irritation than dry lint, and is much more eaſily removed afterwards.

Mr. EARLE's Method, by *injection*.

Profeſſor Alexander Monro, of Edinburgh, having ſupplied the hint of curing the hydrocele by inflammation, Dr. Monro, ſurgeon to lord Hume's regiment, attempted to make a radical cure in the following manner: having let out the water of a large hydrocele, that had been often tapped, he injected a little ſpirit of wine into the ſcrotum, which raiſed ſo violent an inflammation, as to bring the patient into great danger; but by bleeding pretty freely he was at length relieved. He recovered, and had never any return of the hydrocele. This violent inflammation, which the ardent ſpirits produced, in the caſe which offered, induced him to try a milder remedy. Having let out the water, he injected ſome claret into the ſcrotum, by which means only a ſlight degree of inflammation was raiſed; ſtill it ſucceeded to his wiſh, by completing a cure; ſince which time, he has made ſeveral radical cures by this remedy alone. See MONRO on the DROPSY, p. 165, note (w), London, 1756.

Mr. Earle's method is ſo extremely ſimilar to this, that it can ſcarce be doubted, but he took his ideas of the cure, by injection, from what has been juſt recited; for he directs, that if the tumor be very large, it ſhould be emptied, and the water afterwards be ſuffered to accumulate till about ſix ounces are collected. The cyſt is then to be tapped in the uſual mode, and as much of the following injection, (℞. vini rubri ℥ xij. aquæ puræ ℥ iv. m.) made blood warm, is to be thrown in through the canula of the trochar as will diſtend the tumor to its original ſize It is to be allowed to remain there for four or five minutes, and then to be preſſed out: and ſhould the ſubſequent inflammation prove conſiderable, a common bread poultice muſt be applied.

Perhaps neither Dr. Monro nor Mr. Earle *evidently* can have a claim to the diſcovery, for the ſame method has been recommended by M. Lambert above a century ago, in his Œuvres Chirurgicales, publiſhed at Marſeilles. A ſtrong ſolution of corroſive ſublimate in lime-water was the compoſition of which he made uſe; and he gives a variety of caſes in which ſucceſs was the conſequence.

See Monro, on the Tumors of the Scrotum, in the Edinb. Med. Eſſays, vol. v. Pott's Account of the Method of obtaining a Radical Cure of the *Hydrocele*. Elſe, on the *Hydrocele* of the Tunica Vaginalis Teſtis. Bell's Surgery, vol. i. p. 403, &c. Lond. Med. Journal, vol. xi. White's Surgery, p. 328.

HYDROCELE PERITONÆI. See ASCITES.

—— SPINALIS. See SPINA BIFIDA.

HYDROCELODES ISCHURIA. A ſuppreſſion of urine from a rupture of the urethra opening into the ſcrotum. See ISCHURIA.

HYDROCEPHALUM, } from ὑδωρ, *water*, and κε-
HYDROCEPHALUS, } φαλη, *the head*. DROPSY of the HEAD. This has been divided into two ſpecies: 1. EXTERNAL; 2. INTERNAL. *In the firſt*, water occupies the outward part of the head, and is confined between the ſkull and the integuments. *In the ſecond*, the fluid is within the cranium, between it and the brain; between the membranes; or, taking riſe from the ventricles, the ſerum is infiltrated through the whole ſubſtance of the brain. Dr. CULLEN places the HYDROCEPHALUS as a genus in the CLASS CACHEXIÆ, and ORD. INTUMESCENTIÆ, which he defines a ſoft, inelaſtic, intumeſcence of the head, with the ſutures of the cranium gaping. This complaint is ſo obvious, that it requires not any deſcription for its diſcovery, nor much trouble in its cure, *if it ſhould not be united with the ſecond ſpecies*. Diſcutient fomentations, with the uſe of cathartics and diuretics, will generally be all that is requiſite in common caſes; in thoſe that are more obſtinate, bliſters, ſcarifications, and ſetons may be alſo neceſſary. Lond. Med. Obſ. vol. v. p. 13. Med. Tranſ. vol. ii. p. 18. Edinb. Med. Eſſ. v. iii. p. 22.

The hydrocephalus internus, the doctor places as a ſpecies of *apoplexia hydrocephalica*; for the following reaſons. In a noſological work, he ſays, it is difficult to arrange accurately diſeaſes, which put on through their courſe different appearances; conſequently, extremely difficult to aſſign a proper place for the hydrocephalic apoplexy. But he had rather place this diſeaſe under the title Apoplexy than Hydrocephalus; in the firſt place, becauſe the hydrocephalus here ſpoken of, is by no means evident to the ſenſes; and alſo, that it greatly differs in its ſymptoms from the hydrocephalus, which is clearly perceptible; and, laſtly, becauſe, in the proximate cauſe, at length ſymptoms, it is very nearly allied to apoplexy. Dr. Fothergill names the internal *hydrocephalus*, the dropſy of the ventricles of the brain, for the ventricles are the proper ſeat of the diſeaſe. Dr. Macbride names it the *febris hydrocephalica*. It is alſo called *cataphora hydrocephalica*.

The INTERNAL HYDROCEPHALUS ariſes gradually, affecting infants, and thoſe not arrived at puberty in common, with laſſitude at firſt, ſlight fever, and pain of the head; afterwards, the pulſe becomes ſlower, the pupil of the eyes dilated, and a ſomnolency takes place. Indeed, this diſorder, whether external or internal, though it is ſaid moſt frequently to happen to children, ſtill inſtances have occurred of adults being the ſubjects of it. Notwithſtanding the ſymptoms, in the beginning, may ſomewhat vary in different ſubjects; in general, it proceeds in the following manner. A pain ſeizes in general the nape of the neck, or the ſhoulders, or ſometimes the lower limbs; very rarely, though it now and then happens, that the arms are complained of; when theſe parts are not the ſeat of complaint, the head and ſtomach are more or leſs uneaſy, a ſickneſs comes on, and various other ſymptoms, which ſo reſemble diſorders from worms, that ſome difficulty attends the judging the diſorder to have any other cauſe; after a few days, ſymptoms are more alarming; a violent pain is deep ſeated in the head, extending from temple to temple, and acroſs the forehead; ſickneſs is at times conſiderable; now and then the patient doſes, the breathing becomes irregular, and the patient frequently ſighs; the pulſe becomes ſlow and irregular; at the beginning, and a little before death's approach, feveriſhneſs attends, eſpecially towards evening; at laſt the pulſe quickens, the breathing is very laborious and difficult, the heat exceſſive; almoſt every ſymptom, from irritation in the brain, by turns, attend; the patient is averſe to the light, takes things greedily, and cannot bear any poſture but to lie horizontally; the excrements are inſenſibly voided; the hands are commonly kept about the head; the eyelids become paralytic, and the iris immoveable; a great heat and ſweat ſpreads all over the body; the pulſe trembles, and ſtrength ſoon fails, if a ſudden convulſion does not end the cataſtrophe.

Many of theſe ſymptoms are common to worm caſes,

teething, and other irritating cauſes, that it is difficult to fix upon any which particularly characteriſes the diſeaſe. The moſt peculiar ſeem to be *the pains in the limbs, with ſickneſs and head-ach, which laſt are inceſſant, and which, though frequent in other diſeaſes of children, are neither ſo uniformly nor ſo conſtantly attendant as in this.* Another circumſtance obſerved to be familiar, if not peculiar to this diſtemper, is, *that the patients are not only coſtive, but it is with the greateſt difficulty that ſtools can be procured: theſe are generally of a very dark greeniſh colour, with an oilineſs or glaſſy bile, rather than the ſlime which accompanies worms; and they are for the moſt part extremely offenſive.* In complaints ariſing from worms, from dentition, and other irritating cauſes, ſpaſms are more frequent than in this diſorder.

No cauſe is diſcovered of theſe violent ſymptoms, *except a quantity of pure ſerum in the ventricles of the brain*; in a natural ſtate there is not more than half an ounce in all the four cavities, whence four ounces may be eaſily ſuppoſed to be the adequate cauſe of this diſorder, as well as that a ſmall degree of depreſſion of the ſkull is the cauſe of its uſual effects.

In infancy, before the bones of the cranium are fully formed, a much larger quantity of water is contained under them, without the attendance of any of theſe violent ſymptoms. When the diſorder is begun thus early, the head is ſometimes greatly enlarged, the bones then grow ſoft, the features are greatly changed, and the eyes goggle.

There is a ſpurious kind of *hydrocephalus*, much of the ſame nature as the ſpina bifida. It appears on the lower part of the occiput like a bladder of water, underneath which is a deficiency of bone. Opening it would be as fatal as the opening the ſpina bifida.

Many authors have wrote on this ſubject; Dr. WHYTT's Hiſtory of the *Hydrocephalus*; the Obſervations on it, by Dr. FOTHERGILL, and Dr. WATSON, in the London Med. Obſ. and Inq. vol. iv. and vi. Dr. QUIN, of Dublin, has alſo treated of this complaint, and under the idea and term of *apoplexia hydrocephalica*; and WITHERING, of Birmingham, in his Eſſay on the *Digitalis Purpurea*, has mentioned this complaint, page 197; and thinks, that it is at firſt dependent upon inflammation or congeſtion; and, that the water in the ventricles is a conſequence, and not a cauſe of the diſeaſe. See his reference to different caſes, in the work before quoted. With reſpect to the cure, nothing certain has ever been ſaid on that ſubject; but it hath been advanced, that as the ſymptoms from worms are ſo ſimilar to the beginning ſymptoms of the *hydrocephalus*, which happens to thoſe whoſe ſkull is perfectly oſſified, anthelmintics are to be tried; for, ſhould worms be the cauſe, relief is thus obtained; and, when the *hydrocephalus* produces them, ſuch remedies are not in any degree injurious.

Much has been aſſerted in favour of exciting a ſalivation by means of mercury, at leaſt of uſing it ſo as to reſtore the neceſſary abſorption of the fluid in the ventricles of the brain; but it is objected, that when mercury hath been uſeful, the diſeaſe hath been miſtaken, and that it was not the internal *hydrocephalus*. See the Lond. Med. Tranſ. vol. ii. Edinb. Med. Com. vol. v. vii. and viii.

Dr. Monro, in his Obſervations on the Structure, &c. of the Nerves, proves, that the four ventricles of the brain communicate with each other. He obſerves, that in the bodies of every one of fifteen children, who died from internal *hydrocephalus*, that all the ventricles were diſtended, and their paſſages from one to the other were much enlarged: in none of theſe caſes was there any water between the dura mater and ſurface of the brain; but on cutting into one of the lateral ventricles, all the ventricles were emptied. He further adds, that in the chronic ſpecies of internal *hydrocephalus*, where the head is enlarged by water within the ventricles, ſome ſurgeons have ventured to diſcharge the water by a puncture with the trochar. But in two or three caſes, where children had died from a great collection of water within the ventricles, he hath obſerved that, when the brain collapſed after cutting into one of the ventricles, ſome part of the ſeptum lucidum was lacerated by the weight of the brain, or of the water in the oppoſite ventricle, which did not readily enough eſcape by the natural communication. So that, upon the whole, if we properly conſider the various dangers which muſt ariſe from the puncture of the brain, and the laceration of the ſeptum between the ventricles, from the unequal bending and preſſure of the parts when the brain collapſes; from the admiſſion of the air to the ſurface of the brain, which cannot well, or at all, be prevented, becauſe the bones cannot, by the application of a bandage, be brought to yield inwards, ſo as to be adapted exactly to the ſhape of the brain, ſuch propoſals will appear improper in the higheſt degree. If, indeed, the water is ſituated between the dura mater and ſurface of the brain, and of courſe between the ſpinal marrow and its ſheath from the dura mater, a caſe which, perhaps, more rarely happens than is generally ſuppoſed; or if, from a very evident fluctuation, chiefly about the bregma, we ſtrongly ſuſpect this to be the caſe, it will, probably, be adviſeable to give the patient the only, though ſmall, chance of cure by the operation. In one caſe of a boy of three years of age, whom I viſited in 1764, with the late Dr. Whytt, &c. the head was greatly enlarged, with all the ordinary ſymptoms of *hydrocephalus*. Dr. Whytt, who had ſeen ſeveral patients killed by a few ounces of water within the ventricles, and had never ſeen the head ſenſibly enlarged by water lodged in the ventricles, inſiſted, that the water muſt be ſituated on the outſide of the brain; and, as I could not prove what I ſuppoſed, that it was within the brain, it was agreed that a ſurgeon ſhould be called, and a puncture made. Mr. James Rae was aſked to attend, and I propoſed that the puncture ſhould be cautiouſly made with a lancet, at the outer ſide of the bregma, as far as poſſible from the ſuperior longitudinal ſinus. The ſkin being accordingly firſt cut, and then the dura mater, and a probe introduced without diſcharging water, we deſiſted from making any farther attempt. The puncture ſoon cloſed, and the child ſurvived three months. After death, I opened the head: we drew from the ventricles above two pounds of water. See Med. Communications, vol. i. p. 404. Lond. Med. Journal, vol. i. p. 357. Memoirs of the Medical Society of London, vol. i. p. 165, 169. From my own experience, I am fully perſuaded, that in very many of theſe caſes, if not in all, congeſtion, and ſlight inflammation, are præcurſors to the aqueous accumulation. In the beginning, therefore, of complaints of this kind, bleeding and purgatives ſhould be depended upon: which, if adviſed in proper time, might, I am led to believe, ſnatch many unfortunate objects from the jaws of death. In the latter ſtages, I fear we can never promiſe ſucceſs; for the diſtenſion of the ventricles of the brain rapidly encreaſes the accumulation of the aqueous fluid, and prevents the action of the abſorbents, from whence alone muſt relief be expected. However, raiſing a ſalivation, as quickly as poſſible, by mercury internally given, and externally applied, bliſtering the head, vapour baths, and the uſe of the digitalis purpurea, adminiſtered in ſmall doſes, as one of our moſt certain diuretics, bid the faireſt for relief: if any, under theſe deplorable circumſtances, are to be had, though I am greatly doubtful with reſpect to a radical cure, ſtill as the moſt rational means they ought to be purſued. WALLIS on Health and Diſeaſe.

HYDROCISTIS. ENCYSTED DROPSY, or DROPSY of a PARTICULAR PART.

HYDROCERATOPHYLLON. See CERATOPHYLLUM.

HYDROGARON. Garum diluted with water.

HYDROLAPATHUM. See LAPATHUM AQUATICUM.

HYDROMELI, HYDROMEL. It is water impregnated with honey. It is alſo called *mulſum, aqua mulſa, melicratum, braggat.* After it is fermented, it is called vinous *hydromel*, or mead.

HYDROMELON. It is made of one part honey, impregnated with quinces, and two parts of boiled water, ſet in the ſun during the dog-days.

HYDROMETRA, from ὑδωρ, *aqua*, and μήτρα, *matrix*. DROPSY of the WOMB. See HYDROPS UTERI.

HYDROMPHALUS, from ὑδωρ, *water*, and ὀμφαλος, *a navel*. A tumor of the navel, containing water. See HYDROPS UMBILICALIS.

HYDRONOSOS, from ὑδωρ, *water*, and νοσος, *a diſeaſe*. See SUDOR ANGLICUS.

HYDROPEGE. SPRING-WATER.

HYDROPEDESIS. See EPHIDROSIS.

HYDROPHOBIA, from ὑδωρ, *water*, and φοβεω, *to fear*, vel HYGROPHOBIA, a DREAD of WATER; called alſo *aquæ pavor*. It is a ſymptom of that ſpecies of madneſs cauſed by the bite of a mad animal, whence the diſtemper is called ſo itſelf; but this ſymptom is not peculiar

culiar to this diſeaſe, nor always attendant on it. See DYSCATAPOTIA. This diſorder is called *canina rabies*, when, from the bite of a mad dog, the patient has a deſire of biting; alſo *cynanthropia*, *cynoleſia*. Dr. James obſerves, that this kind of madneſs properly belongs to the canine genus, conſiſting of three ſpecies, viz. *dogs*, *foxes*, and *wolves*, to whom only it ſeems inherent and natural, ſcarcely ever appearing in other animals except it be inflicted by thoſe of the dog-kind. Dr. Heyſham defines it to be an averſion and horror at liquids, as exciting a painful convulſion of the pharynx, occurring at an indetermined period, after the canine virus has been received into the ſyſtem.

The *hydrophobia* is a nervous diſorder, though followed by inflammatory ſymptoms. Dr. Cullen places this genus of diſeaſe in the CLASS NEUROSES, and ORD. SPASMI, which he defines, a loathing and great dread of drinking any liquids, becauſe of creating a painful convulſion of the Pharynx, occaſioned moſt commonly from the bite of a mad animal. He diſtinguiſhes two ſpecies. 1. *Hydrophobia* rabioſa, when there is a deſire of biting, from being bitten by a mad animal. 2. *Hydrophobia* ſimplex, without rabies, or a deſire of biting.

The general diviſion of this diſorder is into the dumb, and the raving madneſs; but inſtances are related in which it hath appeared periodically.

The principal and original ſeat ſeems to be about the ſtomach, and parts contiguous to it. Dr. Seleg thinks that it is in the par vagum and intercoſtal nerves; for moſt of the ſymptoms happen where theſe nerves are interſperſed.

The ſmalleſt quantity of the ſaliva of a mad-dog, and that either freſh or dry, produces this diſeaſe. The infection may lay dormant for many months, but in general it appears in three or four weeks; and, if in ſix weeks no ſign of diſorder manifeſts itſelf, the patient is uſually concluded to be ſafe. Some have obſerved, that the nearer the place bitten is to the ſalivary glands, the ſooner the ſymptoms appear. In order to communicate the infection, a wound ſeems to be no more neceſſary than it is in the ſmall-pox; *to man it is communicated by the ſaliva only*; but dogs have received it by being in the kennel where mad-dogs have been before. It is above obſerved, that the dog kind only have this diſorder naturally; but other animals having received the infection, may communicate it to other ſpecies. The dread of water is a ſymptom in ſome fevers, and in ſome particular inflammations, &c. See Edinb. Med. Commentaries, vol. xi. p. 331.

The MATERIAL or PROXIMATE CAUSE ſeems to be in the irritation of the nerves that are the more immediate ſeat of this complaint.

According to Boerhaave, the ſigns of madneſs in a dog are as follow: he becomes dull, ſolitary, and endeavours to hide himſelf; he ſeldom barks, but makes a kind of murmuring noiſe; at the ſame time he refuſes all kinds of meat and drink; he is enraged at and flies upon ſtrangers; but in this ſtage he remembers and reſpects his maſter; his ears and head hang down; he walks nodding, as if overpowered with ſleep: this is the firſt ſtage; and a bite now, though dangerous, is not ſo bad as afterwards. After theſe ſymptoms, the dog begins to pant; he breathes quick and heavy; hangs out his tongue to emit a great deal of froth from his mouth, which he keeps perpetually open; ſometimes he walks ſlowly, as if half aſleep, and then ſuddenly runs, but not always directly forward as is pretended: at length he forgets his maſter; his eyes look diſpirited, dull, full of tears, and red; his tongue is of a lead colour; he is ſuddenly extenuated; he grows faint and weak, oft falls down, then riſes up, and attempts to fly at every thing, and now grows mad and furious: this ſecond ſtage ſeldom continues thirty hours, death by that time putting an end to the diſeaſe, and a bite received now is incurable.

To theſe ſymptoms, the following may be added, which are conſidered as certain ſigns of a dog's being mad. 1. All other dogs, upon ſmelling the dog that is going mad, will avoid him, and run away with horror. 2. The tone of the dog's voice, when he barks, ſeems hollow and hoarſe. In the dumb madneſs, if the dog is confined, he barks inceſſantly for a day or two.

When the human ſpecies are the ſubjects of this diſorder, though in particular inſtances ſome variation may be obſerved, the ſymptoms are in general a ſlight pain in the wound, ſometimes attended with itching, but always reſembling a rheumatic pain; it extends alſo into the neighbouring parts, and, at length, from the extremities it paſſes into the viſcera; the cicatrix (if there hath been a wound) begins to ſwell, inflames, and at length diſcharges an ichor; *this pain is conſidered as the primary invariable mark of a beginning hydrophobia.* There are other more general pains reſembling rheumatic ones; they are of a quick, flying, convulſive kind; they affect the patient in the neck, joints, and other parts; often a dull pain ſeizes the head, neck, breaſt, belly, and even runs along the back-bone; towards the concluſion of the diſorder, the patient complains of this kind of pain ſhooting from the arms towards the breaſt and region of the heart; beſides theſe ſymptoms, a laſſitude, a dull pain in the head, and a vertigo come on; the patient is gloomy, murmurs much, is forgetful, drowſy; at times his mind ſeems diſordered, by turns he is wrathful, his ſlumbers become diſturbed, and, awaking from them, convulſive agitations immediately follow; a deafneſs is ſometimes complained of, the eyes are watery, the aſpect ſorrowful, the face becomes pale and contracted, ſweat alſo breaks out about the temples, an unuſual flow of ſaliva at length comes on, with a dryneſs of the fauces, a foulneſs of the tongue; and in ſome the breath becomes fetid. Beſides theſe, from the beginning, there is a peculiar ſtricture and heavineſs on the breaſt, a ſtruggling as it were for breath, a ſighing, a naufea, and vomiting. *This oppreſſion of the præcordia is one of the primary and conſtant ſymptoms of this diſorder*; it begins, increaſes, and ends only with it: this is THE FIRST STAGE, under which different patients vary as to their continuance. As the above ſymptoms increaſe, THE SECOND STAGE advances; a fever comes on, which at firſt is mild, and attended with momentary horrors, but in ſome there is no fever; wakefulneſs becomes continual, the mind is more and more diſturbed, a delirium approaches, and an averſion to fluids and poliſhed bodies. At firſt, a conſtriction of the gullet is perceived, and difficulty of ſwallowing; but as yet liquids are freely taken; afterwards, however, they are refuſed; this ſymptom augments ſo viſibly, that when any liquid comes before their ſight, immediately an horror ſeizes them; and if they ſtrive to drink, ſpaſms are produced, on which anxiety and loſs of ſenſes follow; as ſoon as the ſurface of the liquid is touched, a ſtrangulation in the throat is felt, the ſtomach is inflated, the larynx outwardly is ſwelled, and that quite ſuddenly, and as ſuddenly falls; though liquids are thus obſtructed, ſolids are nevertheleſs ſwallowed with tolerable eaſe; yet this ſymptom may become ſo violent as totally to prevent the ſolids from paſſing as well as liquids. In ſome an exquiſite ſenſibility is induced, ſo that the air offends if it touches the ſkin, the light becomes painful, and the leaſt ſound is intolerable. The patient now murmurs and mourns grievouſly; at times he loſes all knowledge of his intimate acquaintance, he then becomes deſirous of biting; reaſon returns at intervals, and he laments his own calamity; the thirſt excites a deſire of drink, but in vain they ſtrive, and ſoon ſink into the moſt affecting deſpondency; conſcious of the approaching inclination to bite, he warns his friends of their danger, and adviſes them to keep at a diſtance: a priapiſm, and involuntary emiſſions of ſemen, ſometimes attend this ſtage, at the approaching concluſion of which the fever and thirſt encreaſe: the urine is lixivious, and but in ſmall quantities, the tongue hangs out, the mouth foams, the pulſe is throbbing and convulſive, ſtrength fails, cold ſweats come on, the tightneſs in the breaſt increaſes, by which the patient ſoon expires in ſpaſms.

The ſymptoms appear, in ſome, two or three days after the bite, more frequently not until after as many weeks; and inſtances are well atteſted, in which a year hath paſſed before the infection hath taken place; when the diſorder is once manifeſt, the ſymptoms are ſometimes ſo rapid, that a quarter, or half an hour, makes a conſiderable change.

The infection may be communicated, as that of the ſmall-pox is, by inoculation; and it is obſervable, that when the ſmall-pox is inoculated, if no inflammation appears about the puncture, or till after the inflammation appears, there is no ſmall-pox ever comes forth; ſo the ſame is obſervable in the bite of a mad dog: though the wound readily heals ſometimes, yet it conſtantly breaks out afreſh, and inflames before any of the terrible ſymptoms appear.

That this diſorder is primarily and principally nervous, appears

appears from the conſtant and chief ſymptoms that attend, viz. the flying pains, the tightneſs of the precordia, the difficulty of ſwallowing, the horror on the approach of water, the quick ſenſibility manifeſt by the uneaſineſs felt on the air's approach, &c. Diſſection diſcovers nothing with reſpect to this diſorder.

Agreeable to the nature of the immediate cauſe, the cure is effected only by ſuch means as deſtroy nervous or ſpaſmodic irritation, or, as by ſome it is ſaid, by a ſpecific property deſtroying the peculiar acrimony which cauſes the diſorder. Of the firſt, opium is the only one to be depended on; and of the ſecond, mercury in ſuch portions as to excite a ptyaliſm, is the approved means.

Solid opium, to the quantity of gr. i. vel gr. i. ſs. may be given every three hours, or as often as the effect of the preceding doſe ſeems to have ceaſed. Muſk, in large doſes, every ſix or eight hours; ſponges dipt in vinegar may be applied to the mouth and noſtrils; and a piece of flannel, moiſtened in the following, three or four times a day: ℞ Tinct. opii ℥ ii. camp. ʒ i. m. The warm bath is alſo uſeful.

In ſome inſtances, mercury, given by the mouth, or applied by unction, until a ſpitting came on, has proved effectual. The ſalivation ſhould be kept up by the ſame means as at firſt it was excited, and continued during two or three weeks. The unguentum hydrargyri fort. ſhould be well rubbed into the wound two or three times a day.

A late foreign writer ſays, that if vinegar is given to a pint a day, divided into three doſes, one in the morning, another at noon, the third at night, it effects a cure. On the contrary, ſome others ſuppoſe the poiſon communicated by a mad-dog, is of an acid nature, and propoſe abſorbent alkaline earth, as chalk, bole, &c. for the cure. Dr. Vaughan propoſes the actual cautery to be applied to the part after the bite as ſoon as poſſible; or rather a dilatation of the wound, if ſmall, and filling it with gun-powder, then ſetting fire to it; this, he ſuppoſes, would produce a laceration of the part, would ſecure a free and continued diſcharge for ſome time, and he thinks that the action of the ignited gun-powder upon the poiſon may have its uſe.

Perhaps the following may be purſued as the moſt probable means of relief that the preſent art directs. Avoid ſea and cold bathing; keep the wound open by a pea, and ſprinkle cantharides into it every ſecond or third day; rub in the ung. hydrargyri fort. ſo as to raiſe a gentle ptyaliſm, and particularly rub the throat with it; if ſpaſmodic ſymptoms appear, give opiates with antimonials to excite perſpiration. ℞ Opii, gr. xij. f. pil. ix. cujus cap. i. tertia quaque hora. And ℞ antimonii tartarizati gr. ½; micæ panis q. ſ. f. pil. ſexta quaq. hora ſpatiis intermediis ſumend. Opiate glyſters ſhould be frequently thrown into the rectum, indeed it ſhould be applied to every place, and by every means as expeditiouſly as poſſible, in hopes of allaying the violence of that highly increaſed degree of nervous incitability and muſcular ſenſation. The warm bath, if the patient does not object to it, generally palliates.

See Aetius, Cœlius Aurelianus, Lommius, Layard, Deſault, Choiſel; Dr. James's Treatiſe on Canine Madneſs; Dr. Mead on the Bite of a Mad-dog; Dr. Seleg's Diſſertation on the *Hydrophobia*; Dr. Nugent's Eſſay on the *Hydrophobia*; Med. Muſ. vol. ii. p. 97, &c. Lond. Med. Tranſ. vol. ii. and Lond. Med. Obſ. and Inq. vol. iii. Edinb. Med. Comment. vol. v. p. 42. Dr. Vaughan's Two Caſes of the *Hydrophobia*. Cullen's Firſt Lines, vol. iv. White's Surgery, p. 102. Memoirs of the Medical Society of Lond. vol. i. p. 243.

Perhaps the beſt mode for preventing the miſchief from taking place, would be to let the part, immediately on the bite being given, be ſucked well for ſome little time, then let a portion of the fleſh be cut out, larger and deeper than the wound given by the dog, that filled with mercurial ointment, and the whole ſurrounded with bliſtering ointment, then proceed to give mercury internally, with antiſpaſmodics, as mentioned above, and let a ptyaliſm be raiſed by means of inunction with mercurial ointment, and this continued for ſome time. Theſe means appear the moſt effectual, and would, if obſerved, moſt likely be conſtantly ſucceſsful. Oil has lately been recommended in this complaint, thrown into the habit, by means of external frictions all over the body, into the inteſtines by way of glyſters, and given by the mouth when patients can be prevailed upon to conform to the mode. And this is ſaid to have been ſucceſsful in a caſe of *hydrophobia*. Notwithſtanding this, ſome practitioners ſeem greatly to doubt its efficacy: however, as the application is ſimple, and may be uſed in co-operation with any other modes which have been recommended for this malady, it ought by all means to be had recourſe to. The SECOND SPECIES ariſes without any contagion being communicated, in ſome fevers, from ſome preceding diſeaſe; from the acceſſion of an epilepſy; from the bite of an epileptic patient; by the bite from people in violent fits of rage, &c. according to the accounts of different authors; indeed, an inferior degree of it will be obſervable in ſome hyſteric caſes, when from the difficulty of ſwallowing, patients are extremely fearful of taking liquids, nay, they ſometimes cannot be prevailed upon to make the attempt. In all which caſes, muſk and opium appear to be productive of the greateſt efficacy.

HYDROPHTHALMIA. See PROPTOSIS.

HYDROPHTHALMION. It is the part under the eye, which ſwells in cachectic and hydropic caſes.

HYDROPHYSOCELE, from ὑδωρ, *water*, φυσα, *a flatus*, and κηλη, *an hernia*. An HERNIA proceeding from a mixture of water and flatulencies.

HYDROPIPER. See PERSICARIA URENS.

HYDROPNEUMOSARCA, from ὑδωρ, *water*, πνευμα, *ſpirit* or *wind*, and σαρξ, *fleſh*. It is a tumor, or abſceſs, from a mixture of flatulent, aqueous, and carneous ſubſtances.

HYDROPOIDES, from ὑδρωψ, *a dropſy*, and ειδος, *a reſemblance*. It is applied to aqueous excretions, ſuch as are common in dropſies.

HYDROPS, from ὑδωρ, *water*, called alſo *hyderos*. A DROPSY. In reality there are but two kinds, viz. the anaſarca, and the aſcites, though many other diſorders have this name annexed to them, as hydrocephalus, hydrocele, &c. under which terms the reader will find particular ſpecifications belonging to each recited; in this place is taken only a general view of dropſy, with the modes of relieving ſome ſymptoms, which may attend every ſpecies of this diſorder.

All *dropſies* are chronical diſeaſes from lax fibres; this laxity of the fibres may be general or particular: its general if not univerſal concomitant, is a redundant ſerum. In the anaſarca, the water is clear and limpid, but in the aſcites it is more thick and gelatinous, or even ſometimes mixed with fleſhy concretions.

All ages, and both ſexes, are liable to this diſorder; but generally it happens to men advanced in years, and to women after child-bearing; thoſe who live in low wet ſituations, whoſe employ requires much ſitting, and thoſe who make too free with ſpirituous liquors.

The general or immediate cauſe of all *dropſies*, is the exhaling veſſels throwing off more fluid than the abſorbent veſſels can take up again. Dr. Hunter thinks that the water in anaſarcas tranſudes through the ſides of the veſſels; but however this may be, if the water is not taken up by the abſorbent veſſels, a *dropſy* is the conſequence. The mediate cauſe is a defect of vital heat. The remote cauſes are numerous: ſuch as immoderate evacuations, diſeaſes of long ſtanding, immoderate uſe of ſpirituous liquors, water-drinking too ſuddenly after being accuſtomed to more generous liquor, a ſcorbutic acrimony, a ſcirrhous liver, which generally begets an aſcites, becauſe of the rupture of one or more of the lymphatics which ſpread on its ſurface, a defect in the kidnies, an aſthma, &c.

One of the firſt ſigns of a *dropſy* is the pitting of the ankles; this indicates the anaſarcous ſpecies: but this is not ſo certain a ſign in women as in men, becauſe women are ſubject to it from pregnancy, a ſuppreſſion of the menſes, &c. Nor, indeed, is it always a ſign in men, for in old men, with groſs habits, who have been aſthmatic during ſome years, and are ſuddenly freed from it, a ſwelling will affect their legs, without any farther harm; yet when a difficulty of breathing attends this ſtate in men, a dropſy is certainly their diſorder.

Dropſies are not readily fatal, except they have polypous concretions in the heart, or pulmonary veſſels; a ſcirrhous liver: tumefied meſenteric glands; or, if women have a ſcirrhous, or otherwiſe diſordered uterus. Purging prevents the efficacy of medicines, and ſo is a dangerous circumſtance. Bleeding of the noſe, ulcers breaking out, or a gangrene appearing in any part, are fatal. Great thirſt, the upper parts greatly extenuated, febrile horror with external heat, are very dangerous.

An eryſipelas on the legs, livid ſtreaks or ſpots on the ſkin, or a dropſy coming on in the breaſt, are alſo among the fatal ſymptoms.

The general indications of cure are, to promote the natural ſecretions, and to increaſe the animal heat; but if the viſcera are unſound, this latter cannot be effected.

The diet ſhould be nouriſhing, light, and cordial; ſpices, muſtard, horſe-radiſh, &c. are to be freely uſed, and vinous liquors ſhould be freely drank.

Proper evacuations for carrying off the redundant humours, and ſuitable alteratives for reſtoring the natural vigour of the conſtitution. See ANASARCA and ASCITES.

Whether the cure be of the radical or palliative kind, much relief is afforded to the patient by moderating certain ſymptoms, ſuch as,

THIRST. This is cauſed by the acrimony of the lymph, and a defective ſecretion of the ſaliva; in this caſe let the patient drink in proportion to his inclination, and his palate may direct the choice of liquor. Acid liquors, ſuch as cyder, or in want of it, give vinegar mixed with the ſpirit of juniper and water, or Rheniſh wine and water, or ſuch others as convenience will admit of. Nitre may be held in the mouth.

DIFFICULTY OF BREATHING. If the *dropſy* was cauſed by a ſanguineous aſthma, ſome recommend the loſs of a few ounces of blood; but though a momentary relief is thus obtained, the injury from it is more to be feared than the advantage will reaſonably admit of hazarding. The ſafeſt method is, if poſſible, to obtain relief with a mixture of the gum. ammon. gr. vi. or viii. and acet. ſcillæ ʒ i. ſs. in any proper vehicle; this may be repeated as the occaſion requires. The infuſion of garlic is alſo efficacious.

HYSTERIC OR NERVOUS AFFECTIONS. Theſe are often occaſioned by an acid in the primæ viæ: give the mixture preſcribed againſt a diarrhœa; and if the globus hyſtericus diſturbs the patient, the following liniment may be rubbed on the belly every night: ℞ Balſ. anod. Bat. ʒ i. ol. palmæ ʒ ſs. ol. menth. ʒ ii. m.

A PURGING. In this caſe all other medicines than what remove it, are uſeleſs. ℞ Kali ʒ i. ſs. fac. alb. ʒ ſs. aq. menth. ſativ. ʒ x. m. cap. cochl. ii. quatuor in die. This mixture neutralizes the acidity in the primæ viæ, directs the offending matter to the kidnies, and not by the anus, and thus this ſymptom is often removed.

VOMITING. This is often occaſioned by acidity in the ſtomach, and a gentle doſe of ipecacuanha as often relieves it.

SICKNESS. This is frequently relieved by the julep. perlat. or a little of the ſp. ammon. comp. in aq. menth. pip. though, as the cauſes vary, they ſhould be attended to, and the remedies reſpectively adapted.

GRIPES. ℞ Calom. gr. iv. vel vi. pulv. rhab. gr. xxv. ol. menth. gut. ii. Kali, gr. v. fyr. q. ſ. f. bol. h. ſ. ſum.

PAIN IN THE SCROBICULUS CORDIS. This is generally relieved by two or three grains of ipecacuanha.

Cantharides has ſucceeded after all other means have failed. Four grains diluted with a large quantity of barley-water, has acted as a very powerful diuretic; and a fourth part of that quantity was given at three different times. The bark, ſalt of wormwood, and rhubarb, were alſo preſcribed; and a cure was ſoon obtained.

See Hoffmann, Boerhaave, Liſter, and Lyſſon on this diſeaſe; Wallis's Sydenham, Shebbeare's Theory and Practice of Phyſic, Le Dran's Operations, Lond. Med. Tranſ. vol. ii. Brooke's and London Practice of Phyſic, Cullen's Firſt Lines, vol. iv.

HYDROPS AD MATULAM. See DIABETES.

—— ARTICULI. A ſpecies of ſpina ventoſa.

—— CYSTICUS. The ENCYSTED DROPSY. It is a collection of water enclоſed in a cyſtis, that is, in an hydatid, and is moſt frequently in the abdomen. Generally it is ſeated on the liver; but on whatever part it is fixed, a ſcirrhus is previouſly there; ſo that a radical cure is not to be expected. Whilſt the ſize is moderate, there is no uneaſineſs, but pain increaſes with its bulk. If there is a ſingle cyſtis, and it is large, its water is diſcovered as in an aſcites, by applying one hand to the ſide of the belly, and tapping with the other on the oppoſite ſide; but if the cyſts are many, the fluctuation is not eaſily perceived. When the cyſt is ſingle, tapping may be uſed as a palliative remedy; but when the cyſts are more, leſs advantage is to be obtained from them. See Le Dran's Operations, edit. 2. p. 129.

—— GENU. A DROPSY in the KNEE. When water is collected under the capſular ligament of the knee, this diſorder is formed. Dr. Hunter obſerves, that if the ſynovia is ſeparated in too large a quantity, and the abſorbent veſſels do not their duty properly, an hydrops articuli ſucceeds, which cauſes a relaxation of the ligament. Mr. Sharp recommends, in order to the cure, a tight bandage, leaving the ſuperfluity to be abſorbed by the bibulous veins. To this might be added ſome attenuating and diſcutient embrocation, ſuch as the aq. amm. acetatæ; or a ſolution of ſal ammon. crud. in acet. acerrim. their proportion may be ʒ ſs. to ℔ i. See Gooch's Caſes and Remarks, vol. ii. p. 259—266. Edin. Med. Commentaries, vol. vi. p. 132.

HYDROPS MEDUL. SPINALIS. See SPINA BIFIDA.

—— OVARII. A DROPSY of the OVARIUM. This ſpecies of *dropſy* moſt frequently happens to barren and ſuperannuated women. It is one of the encyſted kind, and ſometimes happens to pregnant woman. It uſually begins without any pain, the women at the ſame time continuing in good health. It is not perceived until it is much enlarged, and commonly affects but one ſide. It is known by its being moveable, when the patient is laid on her back, to relax the muſcles; then the lumps may be moved from ſide to ſide; by paſſing the finger up the vagina, the orifice of the uterus is found to move with the tumor, which diſtinguiſhes it from the aſcites, &c. though when the fluid is contained in one bag, and is very thin, if the bag alſo extends to the ſcrobiculus cordis, it is very difficult to ſay whether the diſorder is the aſcites or the *dropſical ovary*; but when there are ſeveral cyſts, there are manifeſt inequalities. Generally this diſorder terminates in an univerſal leucophlegmacy. Internal medicines are of no efficacy towards a cure, and it rarely happens otherwiſe than that other methods of relief increaſe the complaints and haſten death. Dr. Percival gives an inſtance of a cure being effected by a ſpontaneous vomiting; ſee his Eſſays Med. and. Exp. But the general health of the patient is the whole that can reaſonably be attempted.

—— PECTORIS, alſo HYDROTHORAX. A DROPSY in the BREAST. Dr. Cullen places this in the CLASS CACHEXIÆ, and ORDER INTUMESCENTIÆ, which he defines a difficulty of breathing, pallid countenance œdematous ſwelling of the feet; difficulty in lying down; a ſudden and ſpontaneous ſtarting out of ſleep with palpitation, and water fluctuating in the cheſt. When water is extravaſated in the cavity of the breaſt, this diſorder is formed; the water may be on only one, or both ſides of the mediaſtinum. But ſometimes this fluid is contained in hydatids, whoſe ſituation may be on the diaphragm, the pleura, on the external ſurface of the lungs, or in the ſubſtance thereof, alſo on the ſurface of the heart, or in the pericardium.

When the water is contained in the hydatids, the knowledge of the caſe and cure are alike hid from us.

Any of theſe cauſes of a *dropſy* may produce this ſpecies; it ſometimes happens from a diſorder of the lungs, and generally the rupture of a lymphatic is the cauſe.

The ſymptoms, particularly when the water is extravaſated on the diaphragm, are, an oppreſſion of the præcordia, and an extraordinary ſhortneſs of breath, which is better when the patient is in a ſupine poſture than when erect; by which it is diſtinguiſhed from the aſthma, in the fits of which the patient cannot lie down. In the *dropſy of the breaſt, œdematous ſwellings* are not only obſerved in the feet, but alſo *in the hands*, which Baglivi ſays is a *pathognomonic ſign*. Inſpiration is more eaſy than expiration; if there is much water in one ſide, that ſide appears ſomewhat larger than the other, and the face, arm, and leg on that ſide are puffy.

Inſtances have occurred in which the water hath been abſorbed; but, for the moſt part, the patient falls a victim to the diſeaſe. As a palliative, however, when the water is perceived to fluctuate, it may be drawn off by a canula and trochar, introduced betwixt the fourth and fifth of the falſe ribs, and about four fingers breadth from the ſpine. See Le Dran's Operations, edit. 2. p. 117, 118. Cullen's Firſt Lines, vol. iv. Bell's Surgery, vol. ii. p. 356, &c.

—— PERICARDII. DROPSY of the PERICARDIUM. This is a ſuperabundance of watery fluid collected within the pericardium. There are no ſymptoms by which the diſeaſe can be diſcovered in the living body certainly; caſes can only be referred to, in ſome of which the cauſe has only been ſuſpected, in others made obvious by diſſection. See SAUVAGES's Hydrothorax Pericardii, Morgagni

gagni de Cauſis Sedibuſque Morborum, xvi. 34, 36. Senac de Cœur, tom. ii. p. 349. Dr. Bouillet, Diſſert. 1758. Edinb. Med. Eſſ. vol. v. 56, 58, 59.

HYDROPS PULMONUM. The DROPSY of the LUNGS. Its ſeat is in the cellular membrane of the lungs. Sometimes it approaches ſuddenly, and then it happens moſt probably from an hydatid burſting, and ſo filling the cellular membrane in this viſcus.

The diagnoſtics are very obſcure; however, though the following is ſometimes equivocal, it will generally point out this diſorder, particularly when the attack is ſudden. The difficulty in breathing is conſtant, and increaſed by the leaſt motion, though not much varied by different attitudes of the body; the patient complains of great anxiety about the præcordia, and when he attempts to take a deep inſpiration, he finds it impoſſible to dilate his cheſt, and his breath ſeems to be ſuddenly ſtopped; the pulſe is ſmall, languid and oppreſſed: the face pale and bloated; the legs uſually ſwelled, and the whole habit is for the moſt part leucophlegmatic.

In order to relief, a briſk mercurial cathartic ſhould immediately be given; after this give the ſeneca root in liberal doſes, for it contributes to relieve in every intention, operating powerfully by expectoration, urine, and perſpiration. Beſides theſe, the uſual diuretics, ſudorifics, &c. may be adminiſtered, as ſometimes one medicine ſucceeds when others fail. If the caſe is deſperate, an opening may be tried, as in the operation for the empyema, and then a puncture may be made into the lungs to diſcharge its morbid contents. See Edinb. Med. Eſſays, vol. vi. p. 126. Percival's Eſſays, Medical and Ex. p. 172. Bell's Surgery, vol. ii. p. 356. &c.

—— SACCULI LACHRYMALIS. See Hernia lachrymalis.

—— SCROTI, } See HYDROCELE.
—— TESTIS. }

—— UMBILICALIS; UMBILICAL dropſy. It is the EXOMPHALUS aqueus Platneri; the HYDROMPHALUS of Ægineta, Heiſter, Dionis.

It occurs in gravid women, from ſevere labours; in aſcitical infants, and more commonly in thoſe who labour under an hernia umbilicalis. Indeed, according to Platner, it ſcarce can happen without an umbilical rupture and aſcites; the tumour is ſoft, fluctuating, permanent, and pellucid, on examining it by the light of a candle. It is to be cured in the ſame manner as a hydrocele.

—— UTERI. DROPSY of the WOMB. Its ſeat is in the cavity of the womb. Boerhaave obſerves, that when the internal cavity of the womb is cloſed up, there is ſometimes ſo great a collection of water there, that the belly appears as if affected with an aſcites.

For, in this caſe, the hypogaſtric region in women is gradually increaſed, and the ſwelling reſembles the ſhape of the womb; on preſſure, a fluctuation is perceived; it may take place during pregnancy, but is not uſually an attendant. It is formed by ſerosity accumulated in the cavity of the womb. Dr. Cullen places this genus of diſeaſe in the CLASS CACHEXIÆ, and ORD. INTUMESCENTIÆ, which he defines, a tumor of the hypogaſtric region, ſlowly and gradually increaſing, reſembling the figure of the uterus, yielding to, or fluctuating on preſſure; without iſchury, or being pregnant. Of which, from SAUVAGES, he enumerates ſeven ſpecies, which, though, cannot be diſtinguiſhed by external ſigns. Theſe HYDROMETRA *aſcitica*;—*gravidarum*;—*hydatica*;—*ſanguinea*;—*puriformis*;—*aſcites uterinus*;—*ſanguineo-uterinus*.

The diagnoſtics are not diſtinct, for many fallacious ſigns of pregnancy accompany this diſorder. It is diſtinguiſhed from the aſcites by its being confined to the region of the uterus; and by the thinneſs of the os tincæ. If the tumor is from a ſcirrhus, it is never in the middle, nor is it round as is the *dropſy*.

The cure is difficult; for this kind of *dropſy* is ſoon followed by an anaſarca, a ſlow fever, and a maraſmus.

If a canula can be introduced into the uterus, it is the beſt and ſpeedieſt remedy; but ſometimes a ſcirrhus, a cicatrix, or tubercles prevent it. If the canula cannot be introduced, uſe hard riding, violent ſhocks with emetics, ſternutatories, and briſk cathartics. As a deobſtruent, borax may be given from ten to twenty-five grains, twice a day. A peſſary may alſo be tried.

HYDROPYRETOS, from ὑδωρ, *water*, and πυρετος, *a fever*. Blanchard ſays it is the ſame with the *ſudor Anglicus*.

HYDRORACHITIS. See SPINA BIFIDA.

HYDRORHODINON. It is water mixed with the oil of roſes. This Galen was uſed to give as an emetic in caſes of poiſon.

HYDROSACCHARUM. It is a compoſition of ſugar and water, which anſwers to the hydromeli by changing honey for ſugar.

HYDROSARCA, from ὑδωρ, *water*, and σαρξ, *fleſh*. A tumor or abſceſs produced of water and fleſh. See M. A. Severinus.

HYDROSARCOCELE, from ὑδωρ, *water*, σαρξ, *fleſh*, and κηλη, *an hernia*. See SARCOCELE.

HYDROSELINUM. See APIUM.

HYDROTHORAX. See HYDROPS PECTORIS.

HYDROTICUS. See HYDRAGOGUS.

HYGIDION. A collyrium deſcribed by Ægineta, lib. vii. c. 16; called *ammonii collyrium*.

—— HYGEIA, } from ὑγιης, *ſound*. HEALTH or
—— HYGIEIA, } SOUNDNESS. *Health* admits of latitude, and is not one and the ſame in every perſon. In general it is when the functions of the body are uninterrupted, and the occaſions of life are performed with eaſe It is alſo the name of a plaſter, which is called *panacea*, and the PLASTER of the THREE BROTHERS. It is deſcribed in Aetius.

HYGIEINE. See MEDICINA.

HYGIENISTES. *Hygieniſts*. Phyſicians who only attended people in health, and that in order to preſerve the ſame, and to prevent diſeaſes. The temperaments of the conſtitution, the air lived in, the food lived on, the houſes dwelt in, the changes in the functions of the body, thoſe changes to which different ages, ſeaſons, climes, &c. expoſe people, were the objects of their attention.

HYGRA. LIQUID PLASTERS. See alſo COLOPHONIA.

HYGROBLEPHARICUS, from ὑγρος, *humid*, and βλεφαρον, an *eye-lid*, alſo *Hygrophthalmicus*. An epithet given to ſome ducts of emunctories diſcovered in the extreme edge or inner part of the eye-lids.

HYGROCIRSOCELE, from ὑγρος, *humid*, κιρσος, *a varix*, and κηλη, *a tumor*. A ſpecies of hernia: it is when the ſpermatic veins are varicous, and the ſcrotum is filled with water.

HYGROCOLLYRIUM, from ὑγρος, *humid*, and κολλυριον, *a collyrium*. A liquid collyrium, or when a collyrium conſiſts chiefly of liquids.

HYGROLOGIA. HYGROLOGY. It treats of the various humours of the body.

HYGROMETRUM. The HYGROMETER, from ὑγρος, *humid*, and μετρον, *a meaſure*. It is an inſtrument by which is ſhewn the different degrees of moiſture in the atmoſphere. Wedelius gives this name to thoſe infirm parts whoſe ſuſceptibility of impreſſions ſhew different ſtates of the air, with reſpect to its moiſture, more exactly than the inſtruments contrived for ſhewing the ſame; for ſuch patients may be truly called hygrometers.

HYGROMYRON. The name of a liquid ointment deſcribed by Aetius.

HYGROPHOBIA. See HYDROPHOBIA.

HYGROPHTHALMICUS. See HYGROBLEPHARICUS.

HYMENEA. COURBARIL. See ANIME.

HYMEN, ὑμην. A membrane *in general*; but by it is uſually underſtood the membrane which appears in the form of a creſcent, and is ſituated at the entrance of the vagina, called alſo *Clauſtrum Virginitatis, Eugeos, Buffon*. When this membrane is ruptured, it is ſhrivelled up, and forms the *caruncuiæ myrtiformes*. See CARUNCULA. It naturally ſhrinks with years, and often diſappears before the age of twenty, ſo can be no proof of virginity.

In ſome infants this membrane ſo cloſes up the urethra, that the urine cannot be voided; in others the urine paſſes, but when the menſes flow, they cannot be diſcharged, becauſe of the imperforated hymen.

When the mark of perforation cannot be ſeen, the cure is thought to be impracticable; but when the puncture of a lancet could not produce the deſired effect, a trochar and canula hath ſucceeded, though a paſſage of four inches was perforated before the end was obtained. See Heiſter's Surgery, and the Edinb. Med. Commentaries.

HYOGLOSSUS. The name of a muſcle of the tongue. It riſes from the baſis, but chiefly from the cornu of the os hyoides, running laterally and forwards,

to

to ſhorten the the tongue. Some divide this muſcle into three, and call them *baſio-gloſſus*, *hypſiloglossus*, or *ypſiogloſſus*, or *hypſiloides* the *chondro-gloſſus*, and the *ceratogloſſus*. Douglas divides it as follows. He ſays, it ariſes fleſhy from three different places; its firſt origin is broad and carnous from the cornu of the bone hyois; this is properly the *ceratagloſſus*: its ſecond head comes from part of the baſis of this bone, and its name *baſiogloſſus*: the third beginning is derived from the cartilaginous appendage of the hyoides, which ſome call *chondrogloſſus*: theſe three unite, and their fibres running in the ſame direction, they are inſerted broad and thin near the root of the tongue laterally. The uſe of each is to draw the tongue obliquely to one ſide; but if both act at once, the tongue is pulled directly backwards into the mouth. Douglas adds, that in ſome ſubjects he hath obſerved that a great part of the muſcles did ariſe from the baſis of the bone, and in ſome others he found few or none of their fidres to ſpring from thence.

HYOIDES Os, from ὑ and εἶδος, becauſe formed like the Greek letter υ upſilon, hence called *yoides*; *hypſiloides*; and *upſiloides*. It is likewiſe named *bicorne*, *lambdoides*, and ſituated in an horizontal poſition between the root of the tongue and the larynx; it is convex on its anterior part, and hollow on the poſterior; the cornua become ſmaller as they run back, and rather diverge; at the end of the cornua there is a graniform appendicle, from whence a ligament runs to the ſtyloid proceſs of the os temporis, and another ligament connects the bone to the larynx. It is the baſis and ſupport of the tongue.

HYOPHARYNGÆUS. The *hyopharyngæi* muſcles, in general, are thoſe on each ſide which are inſerted in the os hyoides; and they may be reckoned three pairs, viz. the *baſio-pharyngæi*, *cerato-pharyngæus major & minor*. They come from the baſis and the horns of the os hyoides. Innes calls it *conſtrictor pharyngis medius*. It ariſes from the appendix of the os hyoides, from the cornu of that bone, and from the ligament which connects it to the thyroid cartilage, the fibres of the ſuperior part running obliquely upwards, and covering a conſiderable part of the ſuperior conſtrictor (i. e. *cephalo-pharyngæus*) terminate in a point. It is inſerted in the middle of the cuneiform proceſs of the os occipitis, before the foramen magnum, and joined to its fellow at a white line in the middle back part of the pharynx. The fibres at the middle part run more tranſverſely than thoſe above or below. Its uſe is to compreſs that part of the pharynx which it covers, and to draw it and the os hyoides upwards. See PHARYNX.

HYOPHTHALMOS, from ὗς, *a ſwine*, and ὀφθαλμος, *an eye*. HOGS EYE. See ERYNGIUM.

HYOSCIAMUS, from ὗς, *a ſwine*, and κυαμος, *a bean*, HOG'S BEAN; but the plants to which this name is given are called HEN-BANES; it is alſo called *dens caballinus*. Theſe plants have hairy, oblong, deep-indented leaves, and bell-ſhaped flowers, which are followed by irregular cup-like capſules, which contain the ſeeds. Boerhaave enumerates eight ſpecies. It is alſo a name for *tobacco*. See NICOTIANA.

HYOSCIAMUS ALBUS, Linn. WHITE HENBANE. Its leaves are ſmaller and more woody than thoſe of the black ſpecies; the plant is a native of the ſouthern parts of Europe; its qualities are ſimilar, but not ſo powerful as thoſe of the common ſort. SAUVAGES ſays, that the daily uſe of the hyoſciamus albus, beginning with the third part of a grain, and gradually increaſing it, ſo long as there is no dryneſs of the œſophagus and fauces, is the moſt efficacious, and almoſt only remedy by which a cataract can be reſolved, as he has repeatedly experienced. A prieſt, affected with this complaint in his right eye, after the uſe of this medicine, for eight days, in which time the doſe was increaſed to three grains, could read ſmall print, who before could only perceive large letters. The cryſtalline lens was, at firſt, white; afterward, became bluiſh, and nearly pellucid; the myodal ſuffuſion under which he laboured, vaniſhed, but the appetite and ſleep, at firſt languid, were perfectly reſtored. From the uſe of this medicine, he ſaw another cured by *D. Coulas*, whoſe cryſtalline lens became perfectly diaphanous. SAUVAGESII Noſologia Methodica, vol. i. p. 724.

—— LUTÆUS. See NICOTIANA MINOR.

HYOSCIAMUS NIGER, called alſo *apollinaris*, *altercum*, *faba ſuilla*, *agone*, *altercangenon*, COMMON OR BLACK HEN-BANE. It is the HYOSCIAMUS NIGER *foliis amplexicaulibus ſinuatis*, *floribus ſeſſilibus*. CL. PENTANDRIA. ORD. MONOGYNIA. LINN. Gen. Plant. 247. It is one of the poiſonous vegetables that are indigenous in Great Britain. The root is long, tough, white, and when recently cut through, ſmells like liquorice; the ſtalks are thick, round, woody, irregularly branched, and covered with a hairy down. The leaves ſurrounding the ſtalk at their baſe, ſtand irregularly: they are large, ſoft, and downy, pointed at the ends, and very deeply indented at the edges; their colour is a greyiſh green, and they have a viroſe diſagreeable ſmell. The flowers are monopetalous, divided into five obtuſe ſegments, and when accurately examined, are not without beauty, although they have a diſagreeable appearance on the plant: they are large, of a dirty yelloviſh colour, reticulated with violet-coloured veins. The ſeed-veſſels follow, one after every flower: they are large, and contain a great quantity of ſeeds of a brown, rough, and irregular figure.

This is the only ſpecies of *henbane* that is a native of Great Britain; and it is a dangerous poiſon. The ſeeds, leaves, and roots, if received into the ſtomach, are all poiſonous. The root, in a ſuperior degree, produces various diſorders; madneſs is one effect of this vegetable; if the ſtomach does not reject what it has received, a ſtupor and apoplectic ſymptoms, terminating in death, are the uſual conſequences.

Henbane, in its external appearances, much reſembles parſnip, from the uſe of which we are often told that ill effects follow: it is probable that in thoſe inſtances the roots of *henbane* have been miſtaken for thoſe of parſnips, for *henbane* is often found on dunghills, and with the dung is carried into gardens, where it vegetates, and may eaſily be miſtaken for parſnips, particularly as with them it grows up.

The ſymptoms which ariſe in conſequence of ſwallowing this ſpecies of *henbane*, are, madneſs of the furious kind, which endures for ſome days; in ſome inſtances it produces apoplectic diſorders, with a hard full pulſe, red face, an abolition of the ſenſes and voluntary motions, and difficult reſpiration; in others, ſtupidity or an appearance of intoxication are the conſequences. Some, on ſwallowing the ſeeds, have complained of thirſt, giddineſs, dimneſs of ſight, raving, and profound ſleep; a dilated pupil is often the effect of this poiſon. The poiſon of *henbane* is very ſimilar in its effect to that of opium when taken in large quantities, and like opium, if adminiſtered with ſkill, it is a valuable ſedative anodyne, and moderates exceſs of irritability. It poſſeſſeth the advantages of opium with the additional one of keeping the bowels lax: but then it muſt be given in large doſes. Hence has it been laid aſide, for in full doſes is is apt to create delirium much more than opium. It has been given as far as twenty-four grains; but it is generally begun in ſmall doſes, as, of one or two grains, and gradually increaſed; it ſeldom produces its anodyne effect till the doſes are eight or ten grains, ſometimes fifteen, or twenty. Dr. Collin has extended it to thirty grains a day.

Its ill effects are relieved, as directed in the article AMANITA, which ſee.

Dr. Stork preſſed out the juice from this plant, and with a gentle heat inſpiſſated it to an extract: of this he gave from one grain to twenty, every twenty-four hours; thus he relieved many from palpitations of the heart, a tendency to melancholy, coughs, and other ſpaſmodic diſorders and convulſions, and this after other means failed; though Greeding tried it in forty caſes of melancholia, mania, and epilepſy, without ſucceſs. In cancers, and ſcrophula, it has been tried with various degrees of ſucceſs. In chordees, which have reſiſted the uſe of opium, Bell has uſed it with advantage, giving the extract, from one to three, or more grains, three times a day. See Stoerck de Hyoſciamo. Lewis, &c.

Lewis's Mat Med. p. 315. Wilmer's Obſ. on the Poiſonous Vegetables in Great Britain. Withering's Bot. Arrangement. Memoirs of the Med. Society of Lond. vol. i. p. 310. Cullen's Mat. Med.

HYOTHYROIDES. Theſe muſcles are alſo called *thyro-hyoides*. They run from the thyroid cartilage to the os hyoides; they are attached to the knobs of that cartilage, and the line between them. Their uſe is to bring theſe knobs nearer to each other.

HYPALEIPTRON. A ſort of ſpatula for ſpreading ointments with.

HYPALEIPTON. See LINIMENTUM.

HYPERÆSTHESES. See DYSOREXIA.

HYPERARTETISCOS. Supernumerary parts, or members.

HYPER-

HYPERCATHARSIS, from ὑπερ, a prepoſition ſignifying *exceſs*, and καθαρσις, *purgation*; alſo *hyperinesis*, and *hyperinos*. It is an exceſſive purging from medicine. It is a variety of the diarrhœa mucoſa of Dr. Cullen.

It happens when too violent purging medicines, or exceſſive doſes of milder ones, have brought on a diſpoſition to frequent diſcharges by ſtool; other cauſes of irritation in the bowels may produce the ſame effect. For the cure, proceed as in violent diarrhœas. Gentle anodynes, frictions and perſpiratives were much depended on by the ancients. See Oribaſ. Med. Col. lib. xiv. cap. 42. P. Ægineta, lib. vii. cap. 7. Actius Tetrab. i. ſerm. 3. cap. 118.

HYPERICHOIDES. See HYPERICUM SAXATILE.

HYPERCORYPHOSIS, from ὑπερ, *above*, and κορυφη, *the vertex*. A PROMINENCE, or PROTUBERANCE. See JECUR and PALMO.

HYPERCRISIS, } from ὑπερ, *above*, and κρισις, *a*
HYPERECRISIS, } *criſis*. An HYPERCRISIS, or SUPEREXCRETION. It is when nature, oppreſſed with her burden, makes ſuch efforts to free herſelf by ſuch exceſſive evacuations as endanger the patient.

HYPEREPHIDROSIS, from ὑπερ, *exceſs*, and ἱδρως, *ſweat*. IMMODERATE SWEATING.

HYPERICUM. ST. JOHN'S WORT, alſo called *perforata*, *fuga dæmonum*, *androſæmum*, and hypericum vulgare. Boerhaave mentions thirteen ſpecies, and Miller enumerates thirty. It is called *fuga dæmonum* on account of its virtue in curing thoſe who were ſuppoſed to be poſſeſſed. The ſpecies in uſe, is the HYPERICUM PERFORATUM, or HYPERICUM *foliis obtuſis pellucido-punctatis, floribus uteis, tryginis, caule ancipiti, caule rotundo*. CLASS POLYDELPHIA. ORD. POLYANDRIA. LINN. Gen. Plant. 902. PERFORATED, or COMMON ST. JOHN'S WORT.

This plant has ſlender, round, woody ſtalks, that are reddiſh; ſmall, obtuſe, oblong leaves ſet in pairs, which when held to the light, ſeem to be perforated, whence the name *perforata*; they bear numerous gold-coloured pentapetalous flowers on the tops of the branches, which are followed by blackiſh huſks, full of ſmall ſeeds. It is perennial, grows wild in the woods and uncultivated places, and flowers in June and July.

The flowers abound with reſin, but yet poſſeſs ſo much mucilaginous matter, that water diſſolves all its active parts. The leaves alſo contain much of the ſame reſinous matter. Diſtilled with water, an eſſential oil is obtained, which much reſembles that of turpentine. To the taſte, the leaves and flowers are bitteriſh and ſubaſtringent; and, from their general qualities, they promiſe to be uſeful as a detergent. Though not much uſed now, it was in great repute with the ancients, in hyſteria, hypochondriaſis, and mania; and, was alſo recommended internally for wounds, bruiſes, ulcers, hæmoptyſis, bloody urine, gravel, dyſentery, agues, worms, and, outwardly, as an anodyne, a diſcutient, and detergent. In the London Pharmacopœia, the flowers are only ordered to be uſed, as they are conſidered to contain the greateſt proportion of the reſinous oily matter, in which the medical efficacy of the plant is ſuppoſed to reſide. The dark puncta of the petals and capſules, afford the eſſential oil of this plant, which is contained in the minute veſicles, or glands, and gives a red colour to rectified ſpirit, and to expreſſed oils; the latter of which has been long known by the name of *oleum hyperici*. See Lewis's Mat. Med. Neumann's Chem. Works. It is alſo a name for the ſpiræa and coris.

HYPERICUM SAXATILE, &c. BASTARD ST. JOHN'S WORT, alſo called *hypericoides*, *coris lutea*, and *coris legitima Cretica*.

The ſeeds are ſaid to be diuretic, emenagogue, and powerfully antiſpaſmodic.

HYPERINESIS. See HYPERCATHARSIS.

HYPERINOS. It ſignifies the ſame as *hypercatharſis*, and alſo the perſon who ſuffers from it.

HYPEROA, from ὑπερ, *above*, and ος, *os*. See PALATUM.

HYPERO-PHARYNGÆI. See PERISTAPHYLOPHARYNGÆI.

HYPEROSTOSIS. According to ſome, it is the ſwelling of the whole bone. In Cullen's Noſology it is ſynonymous with *exoſtoſis*.

HYPERSARCOMA, a fleſhy excreſcence. See alſo POLYPUS NARIUM.

HYPERSARCOSIS, from ὑπερ, *exceſs of*, and σαρξ, *fleſh*. It is a fleſhy excreſcence, or proud fleſh.

HYPEXODOS, from ὑπο, *under* and ἐξοδος, *a paſſing out*. See DIARRHŒA.

HYPEZOCOS. It ſignifies the membranes which are ſpread under other parts, as the pleura, &c.

HYPNOBATES, } from ὑπνος, *ſleep*, and βαινω, *to*
HYPNOBATASIS, } *go*. See SOMNAMBULI.

HYPNOLOGICA. It teaches the due regulation of ſleep and waking.

HYPNOPŒOS, } from ὑπνος, *ſleep*, and ποιεω, *to*
HYPNOTICUS, } *cauſe*. HYPNOTICS, medicines which procure *ſleep*. See ANODYNA.

HYPO, ὑπο. A prepoſition, ſignifying *under*; but, in compoſition, it imports not only inferiority with reſpect to ſituation, but a remiſſion or diminution.

HYPOCAPNISMA. See SUFFIMENTUM.

HYPOCARODES. } One who labours under
HYPERCAROTHIS. } a low degree of a carus.

HYPOCATHARSIS. A SLIGHT PURGING.

HYPOCAUSTUM, from ὑπο, *under* and καιω, *to burn*. See CALDARIUM.

HYPOCERCHALEON, from ὑπο, and κεγχρος, an aſperity of the fauces. A ſtridulous kind of aſperity of the fauces and aſpera arteria.

HYPOCHEOMENOS. One who labours under a cataract.

HYPOCHONDRIA, from ὑπο, *under*, and χονδρος, *a cartilage*. The *hypochondria* are that part of the body, on both ſides, which lie under the ſpurious ribs, and is extended to the ilia, comprehending not only the muſcles but the internal viſcera; becauſe, according to Pollux, they are ſubjacent to cartilages. Celſus, from ſeveral places in Hippocrates, renders the word præcordia. Cœlius Aurelianus often puts præcordia. Cœlius Aurelianus often puts præcordia inflammata for an inflammation of the *hypochondria*.

Affections of the *hypochondria*, according to Hippocrates, are *hypochondrion aneſpaſmenon*, a retraction of the *hypochondrium* inwards, without any proper diſorder of the part; *hypochondria diaborborizonta*, a rumbling of the *hypochondria*; *hypochondrii entaſis*, &c. a ſpaſtiſh tenſion of the *hypochondria*, *hypochondria catexeraſmena*, &c. the *hypochondria* dried up and contracted inwardly: *hypochondria meteora*, tumid *hypochondria*: theſe are raiſed by flatulencies; *hypochondria xyntaſis*, a diſtenſion of the *hypochondria* from inflammation; *hypochondria ſcoliotes*, an inequality of the *hypochondria*; *hypochondrium chronium*, an *hypochondrium* affected with an obſtinate diſorder; and

HYPOCHONDRIACUS MORBUS. The HYPOCHONDRIAC DISEASE; it is alſo called *affectio hypochondriæ*, *paſſio hypochondriaca*, HYPOCHONDRIASIS, VAPOURS, SPLEEN, &c.

Hoffman ſtrenuouſly maintains, that the *hypochondriac diſeaſe* is not the ſame as that called *hyſteric*. He obſerves, *that a ſtrangulation of the fauces, a quick and difficult reſpiration*, ſo as to endanger a ſuffocation, *loſs of ſpeech, and all ſenſe of motion*, are the proper and eſſential ſymptoms of the hyſterics: that the *hypochondriac diſeaſe* is inveterate, and rarely ſo cured as not to be again eaſily excited by the leaſt accidents that can cauſe it, which is not the caſe with the hyſterics; that though many of their ſymptoms are the ſame, yet they each have ſuch as the other is never accompanied with, otherwiſe than by the two diſorders being attendant at the ſame time. On the other hand, many others conſider theſe two diſorders under the general title nervous; and thus they only differ, as peculiarities in the conſtitution vary, or as the flatulencies, &c. which attend the patients thus diſordered, may affect this or the other part. Dr. Cullen places this genus of diſeaſe in the CLASS NEUROSES, and ORDER ADYNAMIÆ; which he defines indigeſtion, with languor, ſadneſs, and fear, from uncertain cauſes, in a melancholic temperament; of which he has only known one idiopathic ſpecies. The ſtate of mind peculiar to *hypochondriacs*, and called vapours, or low ſpirits by ſome, is thus deſcribed by Dr. Cullen. "A languor, liſtleſſneſs, or want of reſolution and activity, with reſpect to all undertakings; a diſpoſition to ſerioufneſs, ſadneſs, and timidity; as to all future events, an apprehenſion of the worſt, or moſt unhappy ſtate of them; and therefore often upon ſlight grounds, an apprehenſion of great evil. Such perſons are particularly attentive to the ſtate of their own health, to every the ſmalleſt change of feeling in their bodies; and from any unuſual feeling, perhaps of the ſlighteſt kind, they apprehend great danger, and even death itſelf. In reſpect to theſe feelings and

fears, there is commonly the moſt obſtinate belief and perſuaſion." The doctor alſo obſerves, that it is only when the ſtate of mind juſt deſcribed is joined with indigeſtion, in either ſex, ſomewhat advanced in years, of a melancholic temperament, and a firm and rigid habit, that the diſeaſe takes the name of *hypochondriac*.

The ſeat of the *hypochondriac paſſion* is in the ſtomach and bowels, even though diſturbed paſſions were the cauſe; for firſt, theſe parts are diſordered, then the other parts in conſequence. In this Hoffman thus far agrees, by ſaying the periſtaltic motion in the bowels is retarded by ſpaſms.

The cauſes are, ſorrow, fear, or exceſs of any of the paſſions, too long continued watching, irregular diet; in ſome there is an habitual diſpoſition to this diſorder, and ſuch people have generally a ſallow or brown complexion, and a downcaſt look, a rigidity of the ſolids, and torpor of the nervous power. Whatever may give riſe to nervous diſorders in general, may be a cauſe of this in particular: whatever may be the foregoing cauſes, ſuch as paſſions, indigeſtion, increaſed or diminiſhed ſenſibility, &c.

The ſigns of this diſorder are ſo various, that to deſcribe them is to deſcribe almoſt every other diſeaſe; but in general there is *an inſurmountable indolence, dejectedneſs of ſpirit, dread of death, coſtiveneſs, a ſlow and ſomewhat difficult inſpiration, flatulencies in the primæ viæ, and various ſpaſmodic affections*, &c.

Whatever ſtomach generates acidities from fermentation, or a putrefactive diſpoſition in the alimentary ſolids and fluids mixed, there will ever be more or leſs of the *hypochondriac* diſorder; the gas ſeparated by either of theſe cauſes, is ſuddenly diffuſed here and there, and its peculiar property is to repel the vital heat wherever it is preſent in any conſiderable degree; and from this circumſtance alone, may all the ſymptoms be accounted for; but yet it is allowed that the ſame effects may be produced by other cauſes, whence attention is neceſſary to diſcover, whether a difficult paſſage of the blood through the veſſels in the ſtomach and guts, as Hoffman hath aſſerted, or certain flatulencies, as others relate, or whatever elſe may be an adequate cauſe, in order to the adapting of proper remedies. The *hypochondriac diſeaſe* is very difficult to cure; it rarely occurs early in life, generally in more advanced years only, and when once it hath taken place, it often increaſes as life advances. It ſhould be diſtinguiſhed from indigeſtion, eſpecially when indigeſtion is accompanied with vapours.

THE PRINCIPAL INDICATIONS OF CURE ARE, 1ſt, To correct the vicious cauſe in the ſtomach. 2d, To increaſe the vital heat.

The diet ſhould be light, eaſy in the ſtomach, agreeable to the palate, cordial, and nouriſhing. In general, animal diet; and ſpirituous liquors lowered with pure water, for the common drink.

The cure is always ſlow, therefore hope ſhould be ſupported by every probable artifice.

Whatever be the cauſe, begin with an emetic, and repeat it at proper intervals to two or three times; then purge with the pil. ex. aloe cum myrrha, or the tinct. aloes; and by leſſer doſes of theſe, or of the ſaline purges, as circumſtances may indicate, keep the bowels eaſy through the whole of the cure. After theſe, proceed with bitters mixed with aromatics and chalybeates; and thus, if a due degree of exerciſe is uſed, a cure may be expected. Here Dr. Cullen obſerves, that in the hypochondriac diſeaſe, there is a want of activity, which is to be remedied; there is not a loſs of tone in the fibres, but on the contrary a rigidity in them: whence he recommends warm bathing; the drinking of tea and coffee; exerciſe, not ſo much as it excites the activity of the ſtomach, but as it operates on the mind, and diverts it from its deſpondency. In managing the minds of hypochondriacs, carefully avoid any intimation that their complaints are imaginary, and as carefully avoid both raillery and reaſoning in addreſſing them. Be ever watchful to interrupt his attention, by engaging it with any object but his own feelings. Divert them with any employ that is neither attended with emotion, anxiety, nor fatigue. Diverſion, in which ſome ſkill is required; exercite in the air, which requires ſome dexterity, are both to be admitted: riding is better than either walking, ſailing, or travelling in a carriage; and to ride a journey is the beſt mode of uſing it.

AN EXCESS OF ACIDITY is a prevalent ſymptom for the moſt part, and requires a cloſe attention to all the means of obviating acidity as well as the uſe of antacids.

COSTIVENESS, an afflictive ſymptom, is beſt relieved by ſuch gentle laxatives as juſt ſolicit nature's uſual office, without exciting extraordinary diſcharges.

If the pulſe is quick, and heat of the body inclining to feverithneſs, omit the aromatics and ſteel, but let the bark and elixir of vitriol be adminiſtered.

If, during the fits, THE MIND IS HARRASSED, give a gentle anodyne in a carminative water. IF PAIN AND FLATULENCE, accompanied with AN HEAD-ACH, attend, the ſame means is alſo effectual.

If SPASMODIC SYMPTOMS are conſiderable, tending to convulſions, relief may be obtained by means of opiates joined with fetid gums, or with muſk, according as each may beſt agree with the reſpective patients.

Warm bathing in pure water, heated ſufficiently to raiſe Fahrenheit's thermometer to ſixty or ſixty five, ſhould be continued until the cure is nearly effected, and then gradually approach to the cold-bath.

Chearful company conduces much towards relief; but running into mirth, or any exerciſe uſed ſo as to fatigue, are injurious.

A dry warm air is almoſt univerſally proper. See NERVOUS DISEASES in the following pages. Hoffman on the Morb. *Hypochond.* Shebbeare's Theory and Practice of Phyſic. Cullen's Firſt Lines, vol. iii. edit. 4. Alſo HYSTERIA-HYPOCHONDRIACUS MORBUS.

HYPOCHONDRIASIS See HYPOCHONDRIACUS MORBUS.

HYPOCHYMA, } from ὑπὸ, and χυω, *to pour*. See
HYPOCHYSIS, } CATARACTA.

HYPOCISTIS. The RAPE of Ciſtus. Alſo called OROBANCHE. The ſpecies uſed in medicine is the CYTINUS HYPOCISTIS, Linn. The juice of this plant only is in uſe: it is of a firm conſiſtence, and a bright black colour; it is a mild aſtringent, of ſimilar medical virtues with the Egyptian acacia; though different from it in one of its pharmaceutic properties; for the *hypociſtis* almoſt totally diſſolves in rectified ſpirits of wine, but the acacia is unaffected by that menſtruum. See Raii Hiſt. Plant. Lewis's Mat. Med. Both this and the acacia are now thrown out of uſe.

HYPOCLEPTICUM VITRUM, from ὑπὸ, *under*, and κλεπτω, *to ſteal*, becauſe it, as as were, ſteals away the water from the oil. It is the ſame as SEPARATORIUM; which ſee.

HYPOCŒLON, from ὑπὸ, *under*, and κοιλια, *a cavity*. It is the cavity under the lower eye-lid, See Ruffus Epheſius, lib. i. cap. 4.

HYPOCOPHOSIS, a leſs degree of *cophoſis*.

HYPOCRANIUM. A kind of abſceſs, ſo called, becauſe ſeated under the cranium, between it and the dura mater.

HYPODERIS. In Ruffus Epheſius, it is the extremity of the fore-part of the neck.

HYPODERMIS. See CLITORIS.

HYPOGASTRICA SECTIO. See LITHOTOMIA.

HYPOGASTRICÆ ARTERIÆ. See ILIACÆ ARTERIÆ, for the external *hypogaſtric arteries*. The *hypogaſtric*, or internal iliac artery, dips into the inſide of the pelvis, juſt over the ſhoulder of the ſacrum; when it arrives at the ſide of the pelvis, it throws down branches to the contents of the pelvis, and then goes through the ſciatic notch. In the fœtus, the internal iliac is larger than the external, becauſe it goes to the placenta, whence, after birth, it daily ſhrinks, and makes the chord, which was the umbilical veſſels.

—— VENÆ. Theſe *veins* run the ſame courſe with their correſponding arteries, except that they do not ſend off the vena umbilicalis. The *hypogaſtric veins* are the internal iliac branches.

HYPOGASTRIUM, from ὑπὸ, *under*, and γαστηρ, *the ſtomach*; called alſo *aqualiculus*; *etron*; ſometimes the term *imus venter* is applied to it; it is the lower external region of the fore-part of the belly; it extends from the lower extremity of the regio umbilicalis, to the bottom of the oſſa innominata. It is divided into three parts, viz. the pubes before, and the groins on each ſide. When the integuments are removed from this region, you diſcover the linea alba, the lineæ ſemilunares, and the lineæ tranſverſæ.

HYPOGASTROCELE. See HERNIA VENTRALIS.

HYPOGLOSSI EXTERNI, vel MAJORES, NERVI; alſo called *linguales* and *guſtatorii*. They are the

the ninth pair of nerves; they have their origin juſt above the foramen magnum, and go out at the holes on the ſides of the ſame great hole, above the condyles of the os occipitis. As ſoon as they are paſſed out of the cranium, they run betwixt the carotid artery, and the internal jugular vein, to the tongue, on the ſide of the digaſtric muſcle.

HYPOGLOSSIS, HYPOGLOSSUM. } from ὑπο, *under*, and γλωσσα, *the tongue*. It is that part of the tongue which adheres to the lower jaw, and the ſeat of the diſeaſe called rana, whence Actius names it ὑπογλωσσιος βατραχος, *the frog under the tongue*. See RANULA.

HYPOGLOTTIDES. They are a kind of medicine to be held under the tongue until they are diſſolved.

HYPOGLUTIS, from ὑπο, *under*, and γλουτος, *the nates*. It is the fleſhy part under the nates towards the thigh. Some ſay it is the flexure of the coxa, under the nates.

HYPOMIA, from ὑπο, *under*, and ωμος, *the ſhoulder*. In Galen's Exegeſis it is the part ſubjacent to the ſhoulder.

HYPONOMOS, from ὑπονομος, *a mine*, perhaps from ὑπο and νομος, *a ſettlement*, or from ὑπο, *under*, and νομη, *a phagedenic ulcer*. It is a deep ſinuous phagedenic ulcer.

HYPOPEDIUM. A cataplaſm for the ſole of the foot.

HYPOPHASIA, from ὑποφαινομαι, *to appear a little*. It is a ſort of winking when the eye-lids are nearly cloſed.

HYPOPHASIS. The name of a ſymptom which conſiſts of cloſing the eyes during ſleep, but only ſo, that a part of the eye appears, and a ſlight motion of the eye is perceived.

HYPOPHORA, from ὑποφερομαι, *to be carried*, or *conveyed underneath*. A deep fiſtulous ulcer.

HYPOTHTHALMION. The part under the eye which is ſubject to ſwell in a cachexy or dropſy.

HYPOPHYLLOSPERMI, from ὑπο, *under*, φυλλον, *a leaf*, and σπερμα, *ſeed*. Such plants as bear their ſeed on the back ſide of their leaves.

HYPOPHYSIS. See TRICHIA.

HYPOPIA. Sugillations in the part under the eyes.

HYPOPLEURIOS. See PLEURA.

HYPOPYON, from ὑπο, *under*, and πυον, *pus*. It is a collection of matter under the cornea. Though Mr. Bell conſiders it an affection of ſome of the coats of the eye. It is alſo called *pyoſis* ABSCESSUS OCULI. It proceeds from an extravaſation of blood, or a tranſlation of pus, after an inflammation, the ſmall-pox, &c. In the beginning it is attended with acute pain in the head and eye; and, according to the degree of this diſorder, it is followed by dimneſs of ſight, blindneſs, or death.

The cure is effected in the beginning by reſolvent medicines, ſuch as frequent application of a decoction of ſage, in wine, with bleeding and purging; or if theſe fail, rub the diſeaſed part with your finger, to looſen the matter, and then let the patient lay in a ſupine poſture in a coach which is driven over rough roads; this is ſaid to have frequently diſperſed the matter. Or, ſometimes an operation is neceſſary, and is thus performed; place the patient as in couching a cataract, depreſs the lower eye-lid, while an aſſiſtant elevates the upper; then, with a lancet, cut through the cornea below the pupil, and about the ſpace of a line from the white of the eye, make the aperture large enough to diſcharge the matter, and, the better to empty the abſceſs, preſs it gently, ſo as to force out the pus, or other contents. Dreſs the wound with the mucilage of quinces, mixed with a little camphor. The operation ſhould not be deferred too long, leſt the eye, by the pus remaining, ſhould be ſo injured, as to prove deſtructive to viſion. See St. Yves on the Diſeaſes of the Eye. Heiſter's Surgery. Bell's Surgery, vol. iii. p. 313, &c. Wallis's Sauvages's Noſology of the Eyes, p. 176, 186. White's Surgery, p. 232.

HYPORINION. A name for the parts of the upper-lip, below the noſtrils.

HYPOSARCA, HYPOSARCIDIOS. } from ὑπο, *under*, and σαρξ, *fleſh*. See ANASARCA, and PHYSCONIA.

HYPOSPADIÆOS. The urethra terminating under the glans.

HYPOSPATHISMUS. The name of an operation formerly uſed in ſurgery for removing defluxions in the eyes. It was thus named from the inſtrument with which it was performed. See P. Ægineta, lib. vi. cap. 6.

HYPOSPHAGMA, ὑπο, and σφαγη, *jugulo*. A ſuffuſion of blood, and ſugillation in the tunica adnata of the eye.—This diſeaſe, from the want of heat, pain, and inflammation, differs from an ophthalmia; but it proceeds from a blow: it is accompanied with it in the beginning; though ſometimes it ariſes from internal cauſes, as from ſcorbutic virus, in which antiſcorbutics alone are neceſſary for the cure. If it ariſes from a blow or contuſion, bleeding muſt be had recourſe to, and repeated, in proportion to the pain, inflammation, violence of the blow, and number of ſymptoms; leeches may alſo be applied to the eye-lid; and proceed as in caſes of Ophthalmia, with ſuch applications as are calculated to abate the painful inflammatory ſymptoms, and produce the abſorption of the effuſed fluids.

HYPOSTAPHYLE, called alſo *procidentia Uvulæ*, *alinthiſar*; *columella*; *craſpedon*. This is an elongation of the uvula, from relaxation, inflammation, ulceration, &c. attended with uneaſineſs and difficulty in ſwallowing, cough, nauſea, commonly a continual ſpitting, ſometimes a difficulty of breathing, and alſo a pſelliſmus, *ſtammering* or *faulty articulation*.—Of this there are TWO SPECIES: one ariſing from *inflammation*; the other from *relaxation*. In the FIRST, the uvula being ſwelled, hot, acutely painful, of a red or livid colour, is enlarged and falls down in an altered form. Sometimes ſuppuration comes on, and the difficulty both of ſwallowing and breathing is more conſiderable than in the ſubſequent ſpecies. When this complaint is very violent, there is apparent danger of ſtrangulation. It is cured by bleeding and purging; gargling with emollient and ſubaſtringent liquids; and ſometimes ſcarification may be neceſſary.—In the SECOND SPECIES, the uvula, preſerving its natural colour, is relaxed and elongated: ſometimes it is pale, cold, and oedematous. The cure depends upon the application of ſpirituous, ſtrenthening, and aſtringent ſtimulants, with the internal uſe of cathartics, reſolvents, and tonics. The following gargle, called GARGARISMA ALUMINIS, is an excellent reſtringent ℞: aluminis ʒij. decocti hordei, lb. ij; mellis roſæ ℥iij. miſce.—This is not only of uſe in caſes of relaxed uvula, but other caſes requiring the topical uſe of aſtringents; alſo in ulcerations of the throat, ſauces, gums, &c. In caſe of a paralyſis, if it yields not to proper ſtimulant applications exhibited internally, as well as externally, the part muſt be amputated and the hemorrhage, if neceſſary, ſtopped by the uſe of ſome ſtyptic.

HYPOSTASIS, from ὑφιστημι, *to ſubſide*. The ſediment in urine.

HYPOTHENAR, from ὑπο, *under*, and θενας, *the palm of the hand*. See *abductor minimi digiti manus*, No. 2. It is alſo that part of the hand which is oppoſite to the palm.

HYPOTHETON. See SUPPOSITORIUM.

HYPOZOMA. See DIAPHRAGMA.

HYPSILOGLOSSUS, i. e. BASIOGLOSSUS. } See HYOGLOSSUS.

HYPSILOIDES. The *os hyoides*; alſo the *baſioglooſſus* muſcle. } See HYOGLOSSUS.

HYPTIASMOS. A ſupine decubiture, or a nauſea, with inclination to vomit.

HYPULUS, from ὑπο, *under*, and ελη, *a cicatrix*, an ulcer which lies under a cicatrix.

HYSSOPIFOLIA. See ADHATODA.

HYSOPHYLLUM. See BUPLEURUM.

HYSSOPITES. WINE impregnated with HYSSOP.

HYSSOPUS. HYSSOP. From the Hebrew word *ezeb*, *a holy herb*, or a herb appointed for cleanſing holy places. *Symphytum petræum*. It is the HYSSOPUS OFFICINALIS, or HYSSOPUS ANGUSTIFOLIA, *ſpicis ſecundis foliis lanceolatis*, CLASS DIDYNAMIA; ORDO GYMNOSPERMIA. LINN. 709. It is a low ſhrubby plant, with brittle branched ſtalks, ſquare when young, but round when old. The leaves are oblong, narrow, and of a dark green colour. The flowers are in looſe ſpikes, of a blood colour. It is perennial, cultivated in gardens, and flowers in July and Auguſt.

The leaves have an aromatic ſmell, and a bitteriſh, warm taſte. Water extracts the greateſt part of their virtues, but ſpirit extracts them perfectly; and the extract made by evaporating the ſpirituous tincture, ſcarcely loſes any degree of the virtues of the plant. From about ſix pounds of leaves, an ounce of eſſentiol oil is obtained by diſtilling in water.

This plant is eſteemed as an attenuant, corroborant, and expectorant: it is uſeful in humoral aſthmas, coughs, and other diſorders of the breaſt and ſtomach, unaccompanied

panied with inflammatory ſymptoms. However theſe virtues are much diſputed by ſome of our modern writers, particularly Cullen. In theſe caſes an infuſion of the leaves may be ſweetened with honey, and drank at pleaſure. By way of fomentation, and poultice, in contuſions, and for removing the blackneſs occaſioned by the ecchymoſis, hyſſop has been conſidered an efficacious remedy. See Lewis's Mat. Med. Cullen's Mat. Med.

HYSSOPUS CAPITATA. See SERPYLLUM VULGARE.

HYSTERA. See UTERUS; and INVOLUCRA.

HYSTERALGIA FEBRICOSA. A QUOTIDIAN FEVER, with pain in the womb.

HYSTERIALGES, } Any thing that excites pain in
HYSTERIALGIA. } the uterus. See ACETUM. Others ſignify by it, the pains which reſemble labour-pains, and are generally known by the term *falſe pains*.

HYSTERIA FEBRICOSA. A TERTIAN FEVER, with ſpaſms and convulſions.

HYSTERIA, } HYSTERICS, from ὑστέρα, *the womb*,
HYSTERICA. } The midwives in Greece and Italy practiſed medicine among women, and they gave the name of *hyſterics* to this diſeaſe. It is one of thoſe diſorders that ranks among the nervous, and perhaps moſt frequently at firſt ariſes from a preternatural irritability in the uterus; however, a preternatural irritability in ſome part, or in the habit in general, is attendant, when this diſorder is preſent. Dr. Cullen places this genus of diſeaſe in the CLASS NEUROSES, and ORD. SPASMI; which he defines, a rumbling noiſe in the belly; a certain ſenſation of a ball rolling in the abdomen, aſcending to the ſtomach and fauces, and there ſtrangulating, drowſineſs; convulſions; profuſe quantity of pale urine; the mind, though not ſpontaneouſly, fickle and mutable. He enumerates ſeveral varieties, ariſing from the following remote cauſes: 1. A retention of the menſes; 2. Too copious a flux of the menſes; 3. Leucorrhæa; 4. Obſtruction of the viſcera; 5. A defect in the ſtomach; 6. Two great ſalaciouſneſs.—Beſides the ſymptoms above enumerated, a great variety of others attend this complaint. The belly is tumid, but the navel is drawn inward; there is a general ſhivering with coldneſs. Before the fit and after it, many other ſymptoms attend; among which the moſt common are, a frequent diſcharge of very pale or limpid urine, coſtiveneſs, anxiety, a palpitation of the heart, a general tremor, an unequal and languid pulſe, coldneſs of the extremities, a pale countenance, convulſive twitchings, alternate laughing and crying. When the fit goes off, though the patient ſeems to be ready to expire, the whole of the diſorder diſappears, and, in ſome inſtances, a perfect health is reſtored. Hoffman ſays, that hyſteric patients rarely die without the attack of an epilepſy or apoplexy; from both which, as alſo from a ſwooning, it ſhould be diſtinguiſhed.

The cauſes in general are a preternatural irritability of the nervous ſyſtem, or ſpaſmodic kind; or ſuch in general as is productive of nervous diſeaſes.

Girls on the approach of the menſes, and women becoming pregnant, are frequently the ſubjects of this diſorder, ſo are thoſe who labour under a difficult menſtruation.

In order to the cure, if the conſtitution is ſanguine and robuſt, bleed according to the ſtrength of the patient. During the fit, if there are violent ſuffocations, hold pungent acid ſpirits under the noſe; ſuch as ſtrong vinegar, and let moderate frictions be uſed about the præcordia, and on the feet. Endeavour to procure a ſtool by means of a clyſter, which may be made of an infuſion of camomile flowers, and common ſalt; and as ſoon as the patient can ſwallow, give draughts with from ʒ ii. to ℥ ſs. of acet. acer. in each. In tender habits, bleeding and pungent acids are to be avoided: and the fetid gums, or muſk, according to the peculiarity of the conſtitution, are to be preferred: but a clyſter, as already preſcribed, and frictions, alſo a moderately warm bath for the feet, may aſſiſt in relieving from the fit.

To prevent relapſes in conſtitutions that are much diſpoſed thereto, the particular cauſes attended to will generally direct the proper method. Many receive conſiderable help by taking a ſcruple of the bark, night and morning. See MORBUS HYPOCHONDRIACUS, and NERVOSA FEBRIS. Alſo Hoffman and Wallis's Sydenham on the Hyſterics. Cullen's Firſt Lines, vol. iv.

HYSTERIA-HYPOCHONDRIACUS MORBUS, HYSTERIA-HYPOCHONDRIAC DISEASE. In Dr. Wallis's late publication on Diſeaſe and Health, there is an account of this diſeaſe, ſo named, from the appearances, manifeſting a complaint participating of both hyſteric and hypochondriac ſymptoms, which he thus deſcribes: "In this complaint patients chiefly complain of heavy, uneaſy pains in the head, ſometimes fugitive and acute—a dimneſs of ſight; but this temporary—a ſenſe of ſtrangulation—ringing in the ears, and quickneſs of hearing—ſudden ſtarting at any ſlight noiſe, on the opening of a door quickly, or any thing falling in the room—ſometimes they have complained of a coldneſs of the head, particularly the back part, as if water was trickling down it—flatulence of the ſtomach and bowels—ſometimes they are coſtive, now and then otherwiſe—urine is made frequently, in ſmall quantity, then becomes turbid; at other times more copious, and of an amber colour, ſeldom or never purely limpid—they oftentimes complain of an itching, tingling, or pricking in the ſkin, eſpecially if a gentle ſweat is promoted—ſometimes an eruption like the nettle-raſh ſhews itſelf—frequently a general tumefaction of a puffy aſpect, without any ſpots—at others very ſmall veſicular eruptions at the tips of the fingers; and all theſe external appearances are, for the moſt part, attended with great heat, itching, or a ſenſe of pricking—the appetite is very irregular—the mind eaſily diſturbed, and generally brooding over ſome perſonal calamity, chiefly imaginary—the circulation ſluggiſh and languid—the pulſe ſlow—and the extremities, for the moſt part, cold.

CAUSES. Theſe appearances I always ſuſpect from ſome acrimony ſubſiſting in the fluids, and thus far practice has confirmed my opinion, and enables me to reaſon on theſe appearances, and reconcile them to the doctrines laid down.

For the incitability of the nervous ſyſtem ſeems to have been kept up by the ſtimulus of the acrimonious humours, which was not ſufficiently powerful to increaſe properly the action of the vaſcular ſyſtem—hence the internal parts would be loaded, and the acrid particles have a power of exerting their ſtimulus in proportion to the quantity retained—beſides, from the torpid ſtate of the circulation, the acrimony would be greatly increaſed by the retention of ſuch materials as ſhould naturally have been thrown out of the habit; and this I am warranted to aſſert from what occurred on any eruption appearing on the ſkin, or hot tumefaction of the extremities, or by a gentle ſweat being promoted; for at that time the patients were more conſiderably relieved.

CHARACTERISTIC SIGNS. Quick nervous incitability, united with ſtrong mental prepoſſeſſion, and perſuaſion of the patient's own miſery, and fatality of their ſituation, with torpor of the vaſcular ſyſtem.

CURE. The indications are, to render the nervous influence more equable, and take off the vaſcular torpidity; and theſe are chiefly accompliſhed by cordials, aromatics, and *ſtimulating* antiſpaſmodics, by promoting a determination of the fluids to the ſurface.

But, notwithſtanding gentle perſpiration is ſo ſingularly uſeful, for this purpoſe antimonials muſt not be exhibited, nor muſt opiates for alleviating ſpaſmodic affections, for they very often do infinite miſchief, by relaxing the ſtomach, and increaſing the torpor of the ſyſtem—ſtimulants are better, and ſtill more the ſtimulating antiſpaſmodics; ſuch as volatile alkali, aſafœtida, muſk, given occaſionally, and the volatile ſaline mixture intermediately, joined with cordials, inſtead of the Polychreſt ſalt;—and I have often found the ſpirit of vitriolic æther and camphor anſwer every good purpoſe we could expect from opium, without producing its diſagreeable conſequences—the warm bath in theſe caſes is beneficial.

Though it is neceſſary to have the body kept open, ſtrong purging always does harm—occaſionally the aloetic pill, with or without the calomel, may be given—and as for bleeding, we ſhould rarely, if ever, have recourſe to it—if it is ever thought neceſſary, cupping is the beſt mode—perhaps topical bleeding with leeches may now and then be uſeful in fixed local complaints of the head, or other parts where ſevere pain gives much uneaſineſs; but, in order to keep off an increaſe of blood, I ſhould recommend ſetons or iſſues—riding on horſeback, and that *conſtantly perſevered in*, is amongſt the moſt certain remedies—and bitters, with preparations of iron, or in ſome caſes without them, generally muſt cloſe the cure—the Bath waters are extremely uſeful—and, when patients have recovered ſtrength to bear the cold bath, that may be had recourſe to; but

care muſt be taken to proportion the coldneſs of the water to the power of the conſtitution, for baths too cold are highly injurious; indeed in our medical conduct great nicety is required in theſe complicated caſes, in which we muſt obſerve, that the remedies recommended in the hyſteric and hypochondriac diſeaſe muſt be ſelected, as the complaint verges more to one than the other—upon the whole, I found antiſpaſmodics and ſtimulants to be the moſt efficacious auxiliaries; the former when hyſteric, the latter when hypochondriac ſymptoms were the moſt predominant; in which laſt they may be freely uſed; for it is aſtoniſhing in how large doſes ſtimulants may be given without injury, and how very neceſſary they are to produce any good effect."

HYSTEROTOMIA, } and τομος, *a ſection*. See CÆSAREA SECTIO.

HYVOURAHE, } A large tree in Ame-
HYVOURAI BRASILIANIS. } rica, reckoned by ſome a ſpecies of a guaiacum. Its bark is uſed in Braſil as we uſe the guaiacum wood, and for the ſame purpoſes alſo. The name *hyvourahe* ſignifies in the Braſilian language, *a rare thing*. See Lemery des Drogues.

I.

I C H

IAMBLICHI SALES. A preparation with ſal ammoniac. Some aromatic ingredients, &c. ſo called from Iamblichus, the inventor of it.

IATRALEIPTES, from ἰατρὸς, *a phyſician*, and ἀλείφω, *to anoint*. A phyſician who cures diſeaſes by ointments and friction.

IATROCHYMICUS. See CHYMIATER.

IATROLIPTICE. The method of curing diſeaſe by unction and friction.

IATROPHYSICUS. An epithet beſtowed on ſome writings which treat of phyſical ſubjects with relation to medicine.

IBA. See ANINGA.

IBERIS. See LEPIDIUM and CARDAMINE.

IBERIUS. See LEPIDIUM GRAM. FOLIO.

IBIBIRABA. A berry-bearing tree in Braſil. A water is diſtilled from the flowers and leaves that is uſed for cooling inflammations of the eyes. See Raii Hiſt.

IBIGA. See CHAMÆPITYS.

IBIRA, A tree in Braſil, whoſe fruit, when dried, is uſed inſtead of pepper. See Raii Hiſt.

IBIRACE. See GUAIACUM.

IBIRA-PITANGA. See LIGNUM BRASILIUM.

IBISCUS. MARSHMALLOW. See ALTHÆA, and ALTHÆA THEOPHR. &c.

IBIXUMA. See SAPONARIA.

ICHOR, alſo called *ſanies*. It is a thin, but acrid fluid, which diſtils from wounds.

ICHTHYA. The name of an hook for extracting the fœtus, Galen ſays, from its likeneſs to the ſcale of fiſh. Erotion ſays, that this word ſignifies raſpings.

ICHTHYEMATA. The SCALES of FISHES, and the raſpings of the bark of trees, or their ſcrapings.

ICHTHYOCOLLA. ISINGLASS; alſo called *huſo*, FISH-GLUE, and *alcanna*. It is a ſolid glutinous ſubſtance, prepared in Muſcovy from a fiſh of the ſturgeon kind, which is caught in the rivers of Ruſſia and Hungary. The ſkins, fins, &c. are boiled in water, the decoction is inſpiſſated to a due conſiſtence, and then poured out ſo as to form very thin cakes, which are either dried in that form, or cut while ſoft into ſlices, and rolled up into ſpiral and other ſhapes. Chuſe that which is clear, thin, and almoſt tranſparent. See the method of making it in the Philoſ. Tranſ. vol. lxiii.

It is one of the fineſt of the animal glues, and has no particular ſmell or taſte. When beat into ſhreads, it readily diſſolves in water or milk, and ſo forms a mild nutritious aliment. This is reſtorative and agglutinant; and is uſed in the fluor albus, continued diarrhœas, and other weakneſſes. A ſolution of it in water, if nicely ſpread upon ſilk, is an elegant plaſter for ſlight injuries to the ſkin: joined with ſome balſams and reſins, it takes the name of *court plaſter*. See EMLP. ADHÆSIUM NIGRUM. It is ſaid to agree with the gum tragacanth in its medical virtues, but that is rather diſputable, for it, like all other animal mucilages, ſoon runs into a ſtate of alkaleſcency, and belongs therefore more to the claſs of nutrientia, becoming more irritating than the mucilages of the vegetable claſs, and conſequently not ſo demulcent when entering into the circulation, if any power of that ſort is preſerved in them when entering the blood-veſſels, and mixed along with the general maſs of fluids. See Lewis's Mat. Med. Neumann's Chem. Works. Cullen's Mat. Med.

ICICA. } GUM ELEMI. See ELEMI.
ICICARIBA. }

ICON. The abbreviation of icones plantarum.

ICOSANDRIA, (εἴκοσι, *twenty*, and ἀνὴρ, *a huſband*.) The name of the twelfth claſs of the Linnæan Syſtem; comprehending thoſe plants which have hermaphrodite flowers, with twenty or more ſtamens, growing on the inſide of the calyx, not on the receptacle. The ſituation, and not the number of ſtamens, is here to be attended to. The calyx is alſo monophyllous and concave in this claſs; and the claws of the petals are fixed into the inſide of the calyx. MARTYN.

ICTERODES. The BILIOUS ARDENT FEVER. See BILIOSA FEBRIS.

ICTERITIÆ. Diſcolourations, or diſeaſes which occaſion an unuſual colour of the whole ſkin, and this without an acute fever.

ICTERUS. The JAUNDICE. It is alſo called *morbus arcuatus*, or *arquatus*, *aurigo*, *morbus regius*, *cachexia icterica*, ictericia, *ictericia*, *morbus*, by Paracelſus, &c. It is a vitiated ſtate of the blood and humours from the bile regurgitating, or being abſorbed into it, by which the functions of the body are injured, and the ſkin is rendered yellow, and almoſt black. Dr. Cullen places this genus of diſeaſe in the CLASS CACHEXIÆ, and ORD. IMPETIGINES, which he defines, a yellowneſs of the ſkin and eyes; white fæces; the urine of a deep red colour, tinging a white rag, of a yellow colour, when dipped into it. He diſtinguiſhes five ſpecies. 1. *Icterus calculoſus*, when there is acute pain in the hypogaſtric region, which increaſes after eating, and when bilious concretions paſs through the inteſtines. 2. *Icterus ſpaſmodicus*, when there is no pain, and the yellowneſs of the ſkin happens after ſpaſmodic diſeaſes and affections of the mind. 3. *Icterus hepaticus*, it is without pain, and follows a diſeaſe of the liver. 4. *Icterus gravidarum*; it ariſes during pregnancy, and gives way after delivery. 5. *Icterus infantum*. It happens ſoon after their birth. A yellowneſs of the ſkin may ariſe, either from bile not excreted in the uſual manner, but received into the blood veſſels, and then effuſed under the cuticle, or from the ſerum of the blood being often yellow, occupying the ſame place, as in ecchymoſis. In ſome caſes, whether the yellowneſs ariſes from one or other of theſe cauſes, is not among phyſicians always clear, but the genuine jaundice only ariſes from the firſt, and a different diſeaſe from the latter; which diſtinction it is proper ſhould be made.

The genuine *jaundice* is when the bile is obſtructed by gall-ſtones, or viſcid bile, plugging up its paſſage into the duodenum. Sydenham ſpeaks of a ſymptomatic *jaundice* which is produced by hyſteric ſyptoms, but this is not obſerved in preſent practice, without the *icterus ſpaſmodicus* may be conſidered of this ſpecies. Many cachectic patients have a very yellow ſkin, but then they have not yellow eyes, and dark-coloured urine, nor aſh-coloured ſtools, which never happen but when the gall duct is obſtructed by bilious concretions, viſcid bile by ſcirrhi, or ſpaſm. Infants often have a remarkable yellowneſs in their ſkin, but their eyes are not tinged. This ſeems to ariſe from the meconium, or from ſome cauſe which, by diſtending the duodenum, ſo contracts the paſſage of the gall as to form an obſtruction. The yellowneſs from the bite of a viper is not a ſpecies of *jaundice*.

The cauſe of the true *jaundice* is the bile mixing with the

the blood, from gall-ſtones, ſpaſms, a ſcirrhus, &c. obſtructing its paſſage into the duodenum. A ſcirrhous liver is the cauſe of the worſt kind. It has been long agreed, that the obſtruction of the ductus communis choledochus, preventing the bile from paſſing into the duodenum, and, from thence being reabſorbed into the blood, was the ſole cauſe of the jaundice. But, in a late publication, by Dr. GOTTLIEB RICHTER, this does not always appear to be the caſe; for, ſays he, "to me it ſeems probable, that the moſt *common cauſe* of jaundice, is a ſtimulus or irritation acting upon the hepatic ſyſtem, which prevents the afflux, ſecretion, and excretion of the bilious fluids; or, rather ſo deranges the circulation in the hepatic ſyſtem, that the ſeveral parts do not reach their deſtined places, according to the laws of health, but are again mixed with the general maſs." In proof of which, he recites ſeveral caſes; one we ſhall here ſubjoin. "A woman died, in the hoſpital, in the higheſt degree of jaundice. On inſpecting her body, *no gall bladder was found*; but, in its place, only a ſkinny ſubſtance of a very ſmall ſize, in which no cavity could be diſcovered. The whole liver was full of white concretions, apparently of the nature of calcareous earth of different ſizes, from that of a pea, to that of a cherry, and which floated in water." Afterwards he ſays, "I am perſuaded, that the cauſe of jaundice is, for the moſt part, of a ſpaſmodic nature;" and reſts his opinion on the following authorities: CHAUX, in the 74 volume of the *Journal de Medicine*, proves by experiments, that the jaundice can be cured by ſedatives alone. SELLE, *Medicina Clinica*, p. 202, imputes the jaundice alſo to a ſtimulus; and VOGEL, in his Treatiſe on Jaundice, publiſhed at Wezlar in 1791, has proved, in ſo convincing a manner, that the jaundice is occaſioned by a ſtate of irritation in the liver, that any thing can ſcarcely be added to the reaſons he has adduced. See RICHTER's Medical and Surgical Obſervations. However, when the jaundice affects the habit, the ſigns in common are, the ſkin and whites of the eyes are yellow; the excrements moſt frequently white, and the urine depoſits a copious dark ſediment. Beſides theſe, an inactivity, anxiety, ſickneſs, uneaſineſs at the pit of the ſtomach, itching in the ſkin, and other ſymptoms occaſionally attend.

When a ſcirrhous liver is the cauſe no cure can be expected. An hæmorrhage is a dangerous ſymptom, for then the blood is both acrid and thin. In adults this diſorder often continues many months, even years, and if no other diſorder attends, great danger is not to be apprehended. If the gall-duct is obſtructed by a ſcirrhus, either in it, or in the duodenum, where it enters that inteſtine, danger is very great, and a cure not to be expected.

During the whole of this diſorder, the patient ſhould uſe frequent exerciſe, but not to fatigue himſelf much; a warm bath, and chearful company, alſo relieve; the diet ſhould be attenuating and aperient.

As to medicines, it is proper, when other cauſes are not manifeſt, to preſcribe with a view to gall-ſtones being the cauſe.

If pain is conſiderable in or about the pit of the ſtomach, proceed as directed for a ſtone in the bile-duct.

If ſickneſs and vomitting attend, the ſame method muſt be attended to as when a ſtone is paſſing from the gall-bladder. See CALCULUS.

If a purging attends, prevent its exceſs; give now and then as much of the ol. ricini as will be neceſſary to quicken the diſcharge by ſtool: and to ſtrengthen, give bitters two or three times a day.

If the itching is ſo troubleſome as to prevent ſleep, an opiate muſt be given at bed-time.

If the diſorder is in its beginning, and if there is any feveriſh ſymptoms, bleed according to the ſtate of the pulſe; then caſe the ſtomach with an emetic of the antimonial kind; after which proceed with ſaponaceous and alkaline medicines, or in their ſtead the acetated kali.

If a viſcid bile gives riſe to their diſorder, after bleeding, and an emetic, give aloetic and mercurial purges; after theſe the kali acetatum is the beſt attenuant and deobſtruent; it hath all the advantages of ſoap, without its diſagreeable taſte; and if any extraordinary heat attends, it is ſtill a moſt uſeful aſſiſtant, for while it allays accidental ſymptoms it carries on the principal work. It may be given to a dram, or a dram and a half, three times a-day.

If a mere redundancy of bile produces a *jaundice*, it is known by the ſtools being highly coloured with the bile, and by their acrid and ſtrong ſmell; in this caſe, the proper remedies are lenient, cooling purges, ſuch as manna, tamarinds, or the ol. ricini. Acids and demulcents are alſo neceſſary helps.

When the hæmorrhage is a troubleſome ſymptom, the blood is in an acrid and diſſolved ſtate; aloetics and attenuants are now to be forborn; on the contrary, acids, demulcents, and particularly the ol. ricini, made into the form of an emulſion, alſo a decoction of hempſeed in milk; and if a feveriſhneſs requires it, a little blood may be taken from the arm.

In caſe of a ſcirrhus, the extr. cicutæ is, perhaps, the beſt palliative.

As an attenuant the rubia tinctoria is of ſingular efficacy. The waters of Bath and Harrowgate are uſually eſteemed as almoſt ſpecifics. Under the idea of jaundice being created from irritation, and ſpaſmodic affections in the hepatic ſyſtem, ſmall doſes of ipecacuanha, tartarized antimony and valerian, aſſafœtida, cataplaſms of cicuta, and hyoſciamus, with linſeed-tea for common drink; bliſters, locally applied, in caſe of pain, and opiates, have been ſeverally adminiſtered, and been attended with ſucceſs. Many agreeable and uſeful forms of medicines adapted to this diſeaſe in general, or to particular ſymptoms, may be ſeen in Dr. Brooke's, and the London Practice of Phyſic. See alſo on the *Jaundice*, F. Hoffmun. Petermannus's Diſſ. Scrutinio *Icteri*, &c. Huxham de Aere & Morb. Epid. p. 143, &c. Wallis's Sydenham, &c. Dr. William Heberden's Obſ. in the Lond. Med. Tranſ. vol. ii. p. 123, &c. Med Muſ. vol. i. Cullen's Firſt Lines, vol. iv. Decoe, on Biliary Concretions.

ICTERUS ALBUS. See CHLOROSIS.

ICTUS. A STROKE or BLOW. It ſignifies alſo the pulſation of an artery, and the ſting of a bee, or any other inſect.

—— SOLARIS. A STROKE of the SUN. Alſo called *inſolatio*; and by the French *coup de ſoleil*. This name is given to diſorders that ariſe from too violent an influence of the ſun's heat, particularly on the head. A long expoſure of the head to a hot ſun hath often produced an inflammation that was ſpeedily fatal.

The diagnoſtics are a violent head-ach, a hot dry ſkin a redneſs and heavineſs of the eyes; ſometimes there is a continual involuntary motion of the eye-lids, a loſs of ſleep, drowſineſs, in ſome with outrageous awakenings, a violent fever, faintneſs, loathing, thirſt, &c.

Perſons not accuſtomed to labour in the ſun, are ſometimes ſtruck by its heat whilſt on journies, &c. and die on the ſpot; others fall into a lethargy, and die in a few hours with ſymptoms of raving madneſs. If a patient eſcapes with his life, he is frequently attacked afterwards with violent head-achs, which in ſome inſtances affect the eye-lids greatly. In other inſtances a delirium is brought on without a fever, gutta ſerena, &c.

In infants this diſorder manifeſts itſelf by a heavy, deep, drowſineſs; which continues ſeveral days, frequent ravings, by convulſive twitchings, periodical head-achs, frequent vomiting, &c.

The effects of too much culinary fire are the ſame with that of the ſun; ſleeping with the head near the fire hath produced a mortal apoplexy during ſleep.

The method of cure is much the ſame as is purſued in the ſanguineous inflammation. Firſt bleed as freely as the ſtrength will admit; after this the legs, or, if the diſorder is violent, the whole body may be put into a warm bath, which ſhould not be much hotter than new milk. Emollient clyſters ſhould be frequently injected, almond emulſion, lemonade, and ſuch like demulcent cooling drinks ſhould be freely given: linen cloths wrung out of vinegar and water may be applied on the face and ſcalp. See Tiſſot's Advice.

IDÆUS DACTYLUS. See PÆONIA.

IDÆA. See OPHIOSCHORDON.

IDEALES. A FAULTY JUDGMENT. ALIENATION of MIND. And diſeaſes in which the judgment is chiefly affected.

IDIOCRASIA. See IDIOSYNCRASIA.

IDIOPATHEIA, from ἴδιος, *private*, or *peculiar*, and πάθος, *an affection*. A PRIMARY AND PROPER AFFECTION OF ANY PART. Thus the head is affected *idiopathically* in a lethargy, and the lungs in a pleuriſy; but when theſe parts ſuffer by conſent, that is by diſorders reſiding in other parts, they are then ſaid to ſuffer by ſympathy.

IDIOSYN-

IDIOSYNCRASIA. *Idyofyncrafia*, from ἴδιος, *peculiar*, συν, *with*, and κρασις, *to mix*, alſo *idiocrafia*, *idiotropia*. Every individual hath a ſtate of health peculiar to himſelf; and as different bodies ſeem to vary from each other, both with reſpect to the ſolids and fluids, though each may at the ſame time be in a ſound condition; this peculiarity of conſtitutions, by which they differ from other ſound bodies, is called IDIOSYNCRASY, or peculiarity of conſtitution. Diſorders from *idioſyncraſy*, are conſidered as incurable, having their cauſe in the original formation. It alſo means peculiar conſtitutional antipathies.

IDIOTROPIA. See IDIOSYNCRASIA.

IDOU MOULLI. The name of a tall plum-tree growing in the Eaſt Indies. Its fruit is cooling, and the bark is uſeful in many chronical diſeaſes.

IGASUR. See NUX VOMICA.

IGBUCAINI BRASILIANORUM. A tree in Braſil, whoſe fruit reſembles apples, and its kernels are a preſent remedy againſt the dyſentery.

IGNAME. See CARA.

IGNIS. FIRE. Some, as Bacon, Des Cartes, Boyle, ſir Iſaac Newton, &c. conſider *fire* not as an element, or as a real exiſtence, but as an adventitious and neceſſary property, reſulting from the inteſtine motion of the inſenſible particles of matter. On the other hand, Homberg, Boerhaave, Lemery, s'Graveſande, &c. conſidered *fire* as a real exiſtence, or a proper element. Whether heat is occaſioned by matter or motion, is a queſtion not well ſettled. The motion of friction or percuſſion, either generates, or collects heat; and, if the ſuppoſition of the mere vibration of parts could adequately account for the effects, it would, doubtleſs, be more ſimple than to call in the aſſiſtance of a material ſubſtance endued with peculiar properties; but, on the other hand, the appearances are ſolved with great eaſe and ſimplicity by the ſuppoſition of ſuch a ſubſtance. However, theſe phenomena of heat ſeem to ſtand ſingle, ſo as not eaſily to admit of compariſon with any other of the appearances in nature: and, conſequently, that all reaſoning by analogy promiſes very little elucidation of a ſubject which can only be proſecuted by experimental reſearch. Notwithſtanding which, the judgment of Homberg, Boerhaave, &c. is ſuppoſed, by ſome, to ſtand confirmed as a moſt ſolid truth, ſince the improvements made by the electric machine; beſides, as *fire* is the ſubſtance of all the ſenſes, being light to the eye, ſound to the ear, ſulphureous to the noſe, acid to the taſte, and painful to the touch, every property required in an element is evidently the property of *fire*. The reality of *fire* is further evident, by thoſe things which have a power of increaſing its quantity, and thoſe which can repel it. In the living human body, whatever increaſes the quantity of craſſamentum in the blood, increaſes the degree of heat alſo; animal diet, aromatic drugs, do this: a permanent heat is produced by antimony, iron, and the elixir of vitriol; but nitre, crude ſal ammoniac, the ſubtle gas from mines, from fermenting vegetable, or putrefying animal ſubſtances, powerfully repel all *fire*, and extinguiſh it whatever ſtate it is in. In PHYSIOLOGY, TRUE FIRE is underſtood, that ſubtile inviſible cauſe by which bodies are expanded or enlarged in bulk, and become hot to the touch; fluids are rarefied into vapour; ſolid bodies become fluid, and, at laſt, are diſſipated; or, if being incapable of being carried off in vapour, are at length melted into glaſs. It ſeems, likewiſe, to be the chief agent in nature on which animal and vegetable life have an immediate dependence; and, without which, it does not appear that nature could itſelf ſubſiſt for a ſingle moment. See CALORIC.

For the influence of *fire*, with reſpect to life, health, and diſeaſe, ſee CRASSAMENTUM, CALIDUM INNATUM, ANIMALIS MOTUS.

Many diſtempers have been named *ignis*, or *fire*, but principally the CAUSUS, or *burning fever*, which Hippocrates often calls πυρ, *fire*.

—— CALIDUS. A HOT FIRE, ſome have called a gangrene. A violent inflammation hath been called a gangrene when it is juſt about to degenerate into it; hence it received the name of *ignis calidus*.

—— FRIGIDUS. A COLD FIRE. A *ſphacelus* hath been thus called; becauſe the parts that are ſo affected become cold as the ſurrounding air.

—— PERSICUS.
—— SACER.
—— SANCTI ANTONII. } See ERYSIPELAS and HERPES EXEDENS.

IGNIS SYLVATICUS. See IMPETIGINES.

Ignis is alſo a name of ſeveral medicines, as *ignis vivus*, and the eſſential oil that ſwims on the top of diſtilled waters, &c.

The chemiſts uſe *fire* in different modes in performing their operations; whence their

—— SAPIENTIUM, or HEAT of HORSE-DUNG.

—— REVERBERATORIUM. REVERBERATORY FIRE. It is made in a furnace covered with a dome, that thus the heat, or the flame, which hath always a tendency to eſcape upwards, may be reverberated, or beat back on the veſſels immediately expoſed to it.

—— ROTÆ, or FIRE for FUSION. It is when a veſſel which contains ſome matter for fuſion, is ſurrounded with red-hot coals.

The chemiſts formerly regulated their *fire* by different degrees, which they called the *firſt*; this was ſcarcely to be perceived; the *ſecond* was, when the heat was manifeſt, but not ſufficient to hurt the ſenſe; the *third*, which was when the heat was painful to the ſenſe; the *fourth*, when the heat was ſufficient to deſtroy the body; and *fifth*, when the heat would cauſe gold to evaporate fumes. Boerhaave was the firſt who regulated the heat of *fires*, by means of a thermometer; and when the degrees of heat are mentioned in his writings, they are to be underſtood according to Fahrenheit's thermometer.

IGNYS. }

ILAPHIS. See BARDANA.

ILATHERA. See THURIS CORTEX.

ILECH. By this word Paracelſus ſeems to mean a firſt principle.

ILEIDOS. In the Spagyric language it is the elementary air.

ILEUM INTESTINUM, ſo called from εἰλεω, *to turn about*, becauſe it makes many convolutions; called, according to GORRÆUS, *eilion*; *ilion*. It is one of the ſmall inteſtines. Where the jejunum ends, the *ileum* begins. Its convolutions ſurround thoſe of the jejunum, on the two lateral and inferior ſides, and it winds about from the left ſide by the hypogaſtrium to the right ſide, where it terminates in a tranſverſe manner at the fleſhy brim of the pelvis, and forms the firſt of the great inteſtines, called cœcum. Winſlow obſerves, that the *ileum* is of a paler red than the jejunum. In all the length of this inteſtine, it is wide and eaſily dilatable; but at its extremity, as it enters the colon, it is narrow, and its ſides are more firm and ſolid.

ILEUM CRUENTUM. Hippocrates deſcribes it in his de Intern. Affect. In this diſeaſe, as well as in the ſcurvy, the breath is fetid, the gums recede from the teeth, hæmorrhages of the noſe happen, and ſometimes there are ulcers in the legs, but the patient can move about his buſineſs pretty well.

ILEUS. See ILIACA PASSIO. It is an ancient name for the colic in the large inteſtines. See COLICA. The chief of the varieties of *ileus* are varieties of *colica ſpaſmodica*.

ILEX. The name of a tree of the oak kind, of which Boerhaave names three ſpecies.

—— ACULEATA BACCIFERA. See AQUIFOLIUM.

—— ACULEATA COCCIGLANDIFERA, alſo called *ilex coccigera*, *ilex aquifolia*. The SCARLET OAK. Its berries are the CHERMES, which ſee.

—— FOLIO ROTUNDIORI MOLLI MODICEQUE SINUATO. The GREAT SCARLET OAK. It is common in Italy and Languedoc. The bark, leaves, and acorns, called *aculeæ*, or *acules*, are more aſtringent than thoſe of the oak.

—— OBLONGO SERRATO FOLIO; alſo called *ilex* anguſtifolio, and *ilex* arborea.

ILIA. The plural of *ile*. The FLANKS. They are the ſpace between the loweſt of the falſe ribs and the upper edge of the os ilium on each ſide; they are the two diviſions of the regio umbilicalis.

ILIACA PASSIO. The ILIAC PASSION, alſo called *miſerere mei*, *ilios*, *ileus*, *convolvulus*, *enterſio*, *eileos*, *chordapſus*, *volvulus*, *tormentum*, AN INTROSUCEPTION of the ILIUM, and the diſeaſe of the ſmall inteſtines. Dr. CULLEN makes it ſynonymous with colica, and arranges its different ſpecies under different ſpecies of that diſeaſe.

It is a violent pain in the ſmall inteſtines, under which the

the periſtaltic motion of the bowels is inverted, and all their contents, in deſperate caſes, are thrown up by vomit.

This diſorder is of the acute, and generally, if not always, of the inflammatory kind. It is divided by ſome into four ſpecies, as may be obſerved below.

The cauſes are various, but the ſymptoms are ſo ſimilar, that it is generally impoſſible to diſtinguiſh them. The immediate cauſe is, an inverted periſtaltic motion of the inteſtines; and the cauſes producing the immediate one, are generally ſaid to be, obſtruction of the paſſage through the inteſtines, or irritation of the ſame. But ſome obſerve, that *one ſpecies is cauſed by a phlegmonous inflammation* in the inteſtine; and this cauſe is known by the pulſe being large, ſtrong, ſomewhat hard, but not very quick; the blood being fizy; the patient rarely vomiting in the firſt ſtage of the diſorder; his having no ſickneſs or anxiety at the præcordia; and being relieved much by bleeding. The *ſecond ſpecies hath for its cauſe an eryſipelatous inflammation of the ilium*; it is known by the intolerable pain at the ſeat of the diſeaſe; it is attended with vomiting ſoon, but not always at its firſt onſet; there are extreme ſickneſs or anxiety in the præcordia, inſatiable thirſt, great and ſudden debility, and a pale dejected countenance; the pulſe is ſmall, weak and quick; the febrile heat inconſiderable, and moſt remiſs in the extremities; ſometimes there is a ſenſe of great heat in the bowels; whilſt the exterior parts are cold and bedewed with a cold clammy ſweat, at leaſt in the ſecond ſtage, when a mortification in the inteſtine is about to commence. *The third ſpecies is moſt incident to youths betwixt fifteen and twenty years of age; it is of a middle nature, betwixt the other two ſorts juſt deſcribed*; in this caſe the blood is florid and unfizy, the face is flushed, the febrile heat is pretty uniformly diſtributed throughout the body; the tongue is whitiſh, and the thirſt is great; the pain is vehement; but the patient hath little or no anxiety or languor, and rarely vomits in the firſt ſtage of the diſeaſe. *The fourth ſpecies is produced by an introſuſception of the inteſtine*, called *introſuſceptio*, or *intuſſuſceptio*, which is a preternatural ingreſs of a portion of an inteſtine into another, or a reduplication of the inteſtine, which ſoon produces inflammation, or indeed may follow after an inflammation is begun. This laſt ſpecies ſome call the true *iliac paſſion*. Dr. Hunter takes notice of a diſeaſe to which children are more particularly ſubject, becauſe their meſentery having ſcarce any fat upon it, eaſily ſlips with the gut, and this he calls the *valvulus* or *volvulus*, of which he obſerves there are two kinds; the firſt is when a part of a gut is received into the part next above it; the other is when a part of the gut is received into the part of the gut next below it.

A coſtiveneſs uſually precedes this diſorder for ſome days, and pain ſoon is perceived in the belly about the navel; theſe pains increaſe; an inflation and diſtention of the belly gradually increaſes, then a hard tumor is felt in the umbilical region, which ſurrounds the belly like a cord; not even the leaſt flatulence can paſs downwards; but after much affliction it at laſt finds a way (though a fatal one) by the mouth.

The *iliac paſſion* ſhould be diſtinguiſhed from the cœliac paſſion, and from pains in the colon.

The prognoſtics are favourable, whilſt inflammation is abſent, and clyſters can be thrown up the anus, and are returned by ſtool; whilſt the pains ſhift from place to place, and the pain and vomiting are only at intervals, there may be hope of a recovery; hope is yet better founded, if a laxative, taken by the mouth, paſſes by the anus; but when the violent ſymptoms appear, there is but little room for hope. An entire ſuppreſſion of urine is a mortal ſymptom.

The principal indication of cure is to allay the pain which lays a foundation for an inflammation.

Though the different ſpecies are not eaſily diſtinguiſhed, it is a favourable circumſtance in the cure that the method is nearly the ſame in them all; however, as in the ſecond ſpecies, bleeding is not ſo freely to be admitted of, an attention to the diſtinctions of the ſpecies may be followed by advantage.

Begin the cure by bleeding, and repeating it as the pulſe will admit. For the patient's drink, barley water, a decoction of marſhmallow-roots, an infuſion of linſeed or other demulcent liquors may be made; but, in preference to all other, let freſh butter-milk be made by ſhaking cream in a bottle, ſo that the patient may take a tea-cupful frequently. The warm half bath is alſo peculiarly uſeful. Give purging medicines by the mouth and clyſterwiſe, as follows:

℞ Calom. ℈ i. extr. colocynth. comp. ʒ i. opii pulv. gr. iii. m. f. pil. No. xii. quarum ſumat. iii. ſtatim. & repet. iii. quaq. hora poſtea vel pro re nata.

℞ Hauſt. ſalin. cum ol. ricini ver. ʒ ſs. poſt ſing. doſ. pilular. ſumend. If inflammation is ſuſpected, add nitre to the draught.

Firſt, adminiſter the more ſtimulating kind of clyſters, and then the emollient ones. Clyſters of tobacco-ſmoak are not to be omitted. It rarely happens that clyſters are ſufficiently repeated.

Though the above cathartics are propoſed, the ſal cath. amar. or the natron vitriolatum are ſometimes of more efficacy.

Apply a bliſter over that part of the belly where the pain is particularly complained of, or if the pain is general, the plaiſter may be applied on any part of the belly, or on the upper part of the thigh.

After each vomiting, the ſaline mixture may be given in the act of fermentation, and mint-water may be taken with xv. or xx. drops of the tinct. opii. Theſe may be repeated as oft as they may ſeem neceſſary, in order to allay this diſcharge upwards.

If the fever increaſes, bleed as often and as freely as the pulſe will admit of, and give nitre with camphor at proper periods.

If a rupture is the cauſe, make no attempt to reduce it before the ſpaſm and tenſion is removed.

If theſe means are ſucceſsful, after the ſymptoms are abated, continue a cooling, emollient, and ſparing diet for ſome days.

See Hippocrates de Morbis; Aretæus; Cœlius Aurelianus; Celſus; F. Hoffman; Wallis's Sydenham; and the Lond. Med. Obſ. and Inq. vol. i. p. 223, &c. Edinb. Med. Comment. vol. ix. p. 266, 278.

ILIACA MINOR, ARTERIA. It is the moſt poſterior branch of the hypogaſtric artery. Sometimes it is the branch of the *glutæa arteria*.

—— VASA. The ILIAC VESSELS, ARTERIÆ and VENÆ, which ſee.

ILIACÆ ARTERIÆ. The ILIAC ARTERIES. They are formed by the biſurcation of the aorta, at about the fourth vertebra of the loins. They deſcend about three fingers breadth from their origin; and when they are arrived to the pſoas muſcle (on each ſide), or rather are upon it, they each divide into two, an external and an internal; the external hath no particular name; the internal is called HYPOGASTRICA. See HYPOGASTRICÆ ARTERIÆ.

The external *iliac*, on each ſide, runs down to the ligamentum Fallopii, under which it goes out of the abdomen. In this courſe it gives off only a few ſmall arteries to the peritonæum, and parts near it; but, as it paſſes out of the belly under the ligament, it detaches two conſiderable branches, one internal, the other external; the inner is called EPIGASTRICA, which ſee; the external is called INNOMINATA, which ſee; beſides theſe two branches, the external *iliaca* gives off a ſmall branch internally, under the ligament, which runs to the vagina of the ſpermatic chord, and ſometimes another ſmall twig goes from the outſide of the os ilium.

The internal *iliac* artery. See HYPOGASTRICÆ ARTERIÆ.

—— VENÆ. ILIAC VEINS; called *titillares venæ*. Theſe are formed by the biſurcation of the vena cava, about the laſt vertebra of the loins. Preſently after their leaving the vena cava, they each divide into two principal branches; one of theſe ſubdiviſions is named iliaca externa, or anterior; the other iliaca interna, or poſterior; the external is alſo ſimply named iliaca; the internal is called hypogaſtrica. The external ſeems to be the true continuation of the trunk; they run the ſame courſe as the arteries of the ſame name. The external *iliac veins* lie more or leſs on the inſide of the arteries, and from a little before they leave the abdomen, they accompany their correſponding arteries, both in their courſe, and in their diviſions into branches.

ILIACUS EXTERNUS, MUSC. See PYRIFORMIS.

—— INTERNUS, MUSC. It lies upon the concave part of the ilium, and takes its origin likewiſe from the anterior edge of the bone; it runs down before the pſoas muſcle, and makes one maſs with it; it then runs over the head of the bone, and paſſes inwards, to be inſerted into the little trochanter. It helps to lift the thigh upwards.

ILIADUM, } It is the firſt matter of all things, con-
ILIADUS. } ſiſting of quickſilver, ſalt, and ſulphur. Theſe are Paracelſus's three principles. *Iliadus* is alſo a mineral ſpirit, which is contained in every element, and is the ſuppoſed cauſe of diſeaſes.

ILIASTER. Paracelſus ſays it is the occult virtue of nature, whence all things have their increaſe.

ILINGOS, from ειλω, *a vortex*. See VERTIGO.

ILION. See ILEUM INTESTINUM.

ILIOS. See PASSIO ILIACA.

ILISCUS. Avicenna ſays it is madneſs cauſed by love.

ILIUM, Os. Alſo called *os innominatum*, but it is only the upper part thereof. It is called *ilium*, becauſe it ſupports the parts that are called *ilia*. The *ilium* forms the upper and poſterior portion of the pelvis; it reaches as far down as a tranſverſe ſection of one third of the acetabulum. The external ſide is convex, and called its dorſum; the internal part is named its coſta; the ſuperior ſemicircular edge is called the ſpine. All the cavity of the *ilium* is called *cholas*, or *cholago*, becauſe it contains the liver, which is the ſtrainer of the gall. Between the os ſacrum and the *ilium* is the ſciatic notch, where the ſciatic nerve and poſterior crural veſſels paſs free from compreſſion.

ILLECEBRA. See SEDUM.

ILLEGITIMUS. ILLEGITIMATE. An epithet for the falſe ribs, alſo for ſome anomalous fevers.

ILLINCTUS. See LINCTUS.

ILLISSIO. See ENTHLASIS.

ILLISIONES AQUARUM. See CATACLYSMUS.

ILLOS. See OCULUS.

ILLOSIS. See STRABISMUS.

ILLUMINABILIS LAPIS. See BONONIENSIS LAPIS.

ILLUTATIO. ILLUTATION. It is a beſmearing any part of the body with mud, and renewing it as it grows dry, with a view of heating, drying and diſcuſſing. It is chiefly done with the mud found at the bottom of mineral ſprings.

ILLYS. A perſon who ſquints, or looks with eyes diſtorted.

ILYS. The FÆCES of WINE. It is alſo an epithet for ſediment in ſtools which reſembles *fæces* of *wine*; alſo the ſediment in urine, when it reſembles the ſame.

IMAGINARII. Diſeaſes in which the *imagination* is principally affected.

IMAGINATIO. IMAGINATION. To the power of the mother's *imagination* many peculiarities in the fœtus have been aſcribed. Much hath been ſaid on both ſides, but though much of the error is confuted, the whole of the ſubject is not cleared up. See Philoſ. Tranſ. Abr. vol. ii. p. 222. Med. Muſ. vol. iii. p. 273, &c.

IMBECILITAS. Alſo ARRHOSTIA. It is often taken for a diſeaſe, but generally means a debilitated ſtate of the habit, and ſometimes the word *arrhoſtia* is made uſe of to expreſs mental imbecility.

IMBECILITAS OCULORUM. See AMBLYOPIA. NYCTALOPS.

IMBIBITIO. In chemiſtry it is a kind of cohobation, when the liquor aſcends and deſcends upon a ſolid ſubſtance, until it is fixed therewith. Sometimes it ſimply ſignifies cohobation, and any ſort of impregnation.

IMBRICATUS. The leaves or ſcales of plants are ſaid to be *imbricated* when they are diſpoſed ſo as to lie one on the edge of the other, after the maner of tiles on a houſe. The term is applied to leaves, and their ſerratures in the bud, or a term in foliation: to the ſtem, when covered with ſcales; *tectus ut nudus non appareat*; to the calyx, as in *hieracium*, *ſonchus*, and other *ſyngeneſia*; to the ſpike, having flowers ſo cloſe, as to preſs orve each other.

IMMERSIO. Chemical *immerſion* is a ſpecies of calcination, when a body is immerſed in any fluid, in order to be corroded; or it is a ſpecies of lotion, as when any ſubſtance is plunged into a fluid, in order to deprive it of a bad quality, or to communicate a good one to it.

IMMERSUS. See INFRASCAPULARIS MUSCULUS.

IMPASTATIO. IMPASTATION. The making of dry powders into paſte, by means of ſome fluid. See INCORPORATIO.

IMPATIENS HERBA. See MOMORDICA and PERSICARIA SILIQUOSA.

IMPERATORIA. MASTERWORT. Alſo called *aſtrantia*, *magiſtrantia*, *oſtruthium*, imperatoria major, imperatoria aſtruthium, *ſtruthium*, *ſmyrnium*. It is the IMPERATORIA OSTRUTHIUM. CLASS, PENTANDRIA, ORD. DIGYNIA. LINN. Gen. Plant. 356. L. Spec. Plant. 371.

It is an umbelliferous plant, with large winged leaves, divided into three indented ſegments, producing thick, oblong, ſtriated ſeeds, ſurrounded with a narrow leafy margin; the roots are oblong, thick, knobby, jointed with ſeveral lateral fibres, brown on the outſide, and whitiſh within. It is perennial, a native of the Alps and Pyreneans. Mr. Lightfoot found it growing in ſeveral places on the banks of the Clyde in Scotland.

The root is warm, grateful, and aromatic, nearly of the nature of angelica. Infuſed in water, or digeſted in ſpirit of wine, it impregnates both menſtruums ſtrongly with its ſmell, warmth, pungency, and bitterneſs. On inſpiſſating the ſpirituous tincture very little of its flavour exhales; but water carries off nearly all the ſpecific flavour of the root in evaporation. If the root is held in the mouth it provokes ſaliva, and if ſwallowed it purges; whence it is called the countryman's purge: an infuſion of it in water, and ſweetened with honey, is an expectorant. The roots ſhould be taken up in the middle of winter in the ſecond year. It was conſidered as an alexipharmic and ſudorific; and in ſome diſeaſes employed with ſo much ſucceſs, as to be called *divinum remedium*. At preſent, it is only conſidered as an aromatic of inferior order. This is alſo a name for ANGELICA.

IMPERATORIA NIGRA. BLACK MASTERWORT, alſo called *aſtrantia nigra*, *aſtrantia major*, and *ſanicula fœmina*. This plant is kept in the gardens of the curious. It flowers in July. Its black and fibrous roots only are uſed.

See Raii Hiſt. Plant. Lewis's Mat. Med. Neumann's Chem. works.

IMPERIALIS AQUA. See FLUOR ALBUS.

IMPETIGINES. Diſeaſes which occaſion blemiſhes or deſœdations in the ſkin. Hence, *impetigo* is called *terna*, *derbia*, *ignis ſylvaticus*, *volagrius*, or *volaticus*. It is uſed likewiſe for *ſerpigo*. See LEPRA, PRURITUS, HERPES, and MENTAGRA.

Dr. Cullen ranks the *impetiginous* diſeaſes as an ORDER of the CLASS called CACHEXIÆ, and defines the *impetigines* to be thoſe diſorders from a general bad habit, manifeſting themſelves principally by diſfiguring the ſkin and other external parts of the body. The itch, &c. though affecting the ſkin, yet not being connected neceſſarily with the habit, Dr. Cullen places in the claſs locales.

IMPETIGO of Celſus. Blancard ſays it is the *lepra Græcorum*.

—— PLINII and ARABUM. Blancard ſays it is that ſpecies of *impetigo*, or of the leproſy of the Greeks, that is known by the name of *lichen*.

IMPLUVIUM. See EMBROCATIO.

IMPOTENTIA. IMPOTENCE. With reſpect to men it is the ſame as ſterility in women, that is, an inability to propagate their ſpecies.

IMPREGNATIO. IMPREGNATION. Alſo INGRAVIDATIO. The ſtate immediately after conception, continuing to delivery. A woman uſually perceives the child to move at different periods; the ſooneſt at the end of forty days, the lateſt at the end of five months. But ſome women, without being pregnant, perceive a motion like that of a child. La Motte thinks that a large child and a ſmall quantity of water may be a reaſon why a pregnant woman ſometimes hardly perceives the motion of the child. The *impregnation* of plants, ſee FARINA FŒCUNDANS.

IMPRESSIO See DEPRESSIO.

IMUS VENTER. See ABDOMEN and HYPOGASTRIUM.

INAIA GUACUIBA. See PALMA COCCIFERA.

INCANTAMENTA. See AMULETA.

INCARNANTIA. Medicines which remove the obſtructions to nature's filling up wounds or ulcers with fleſh, called alſo ANAPLEROTICA, which ſee.

INCENDIUM, } A BURNING FEVER, or ſometimes
INCENSIO. } any burning heat, alſo a hot inflammatory tumor.

INCERATIO. INCERATION. It is the reduction of any dry ſubſtance to the conſiſtence of wax, by the gradual admixture of any fluid therewith.

INCERNICULUM. A STRAINER or SIEVE. In anatomy it is a name for the pelvis of the kidney.

INCI-

INCINERATIO. INCINERATION, alſo *aſtiphora*. It is the burning of the teeth, or any thing to aſhes. See CALCINATIO.

INCISIO, from *in* and *cædo, to cut*. INCISION. The opening of abſceſſes by means of a lancet or ſcalpel. For the beſt modes of making them, or extracting matter with the moſt eaſe and ſecurity. See Bell on Ulcers, edit. 4. p. 76, &c.

INCISORES DENTES. CUTTERS, from *incidere, to cut*. A name of the four anterior teeth in each jaw from their uſe in cutting, called alſo *ctenes*. *Dentes lactei, riſorii, dichoſtores*. The edges of the *inciſores*, by uſe and friction, in ſome people become blunt and thicker; and in others they ſharpen one another, and become thinner. Theſe teeth are convex externally, and concave internally; ſo that by their wrapping over one another when they are wore, it is the internal concave ſurface of the upper ones, and the external convex ſurface of the lower ones, that are waſted. See DENS.

INCISORII DUCTUS. Theſe are two canals which go from the bottom of the internal nares, acroſs the arch of the palate, and open behind the firſt and largeſt of the dentes *inciſorii*; their lower orifices are in the foramen palatinum anterius, called *naſopalatini ductus*.

—— INFERIORES COWPERI, MUSC. They ariſe from the alveoli of the lateral *inciſores* of the lower jaw, and are inſerted into the middle of the ſemi-orbicularis of the lower lip.

—— LATERALES, MUSC. called alſo *canini minores*. A ſort of biceps muſcles, which unite into one at their lower end: they ariſe from the os maxillare, below the middle tendon of the orbicularis palpebrarum, and below the edge of the orbit in the os maxillare, near the union of this bone, with the os malæ; theſe two portions (on each ſide) unite about the lateral dentes *inciſorii*.

—— MEDII, MUSC. Alſo called *inciſorii minores Cowperi*, or *inciſores minores ſuperiores*. They are two ſmall ſhort muſcles ſituated near each other below the ſeptum narium; they riſe from the os maxillare, on the alveoli of the firſt *inciſores*, and are inſerted into the middle and upper part of the upper lip.

INCISORIUM. A table whereon a patient is laid, in order to have an inciſion made on any part.

—— FORAMEN. This lies behind the *dentes inciſores* of the upper jaw, which divides into two, as it opens into the noſe on each ſide of the *ſeptum naſi*.

INCITABILITAS. INCITABILITY. In a practical view, it has appeared neceſſary to make a diſtinction between this term, and irritability; becauſe, though it is allowed, that to theſe two powers, the exiſtence of the machine, in a living ſtate, and the action of its moving ſolids with reſpect to their continuance are entirely owing; yet, they do in ſome degree certainly exiſt independent of each other, notwithſtanding their intimate union, and conjunct action. It is therefore by this knowledge, that we ſhall in ſome caſes be able to diſcover how, from particular defect in theſe two powers, ſeparately attended to, diſeaſes put on different appearances, and are to be prevented, alleviated, or cured by applications made to them diſtinctively, as well as unitedly. Thus then are they diſcriminated. By INCITABILITY, is meant that power in the brain, and nervous ſyſtem, which may be put into action by mental affection, as well as local irritation, and which produces thoſe affections we call ſympathy. By IRRITABILITY, that power is meant which may be put into action by material ſtimulus, locally exerted; yet is obedient to the influence of the nerves in general, and cannot in the living machine exiſt for any conſiderable time without this union. See WALLIS on Health and Diſeaſe. IRRITABILITAS, and SENSIBILITAS.

INCONTINENTIA. INCONTINENCE. In medicine it is when there is an inability in any of the organs to retain what ſhould not be diſcharged without the concurrence of the will.

INCORPORATIO. INCORPORATION. It is much the ſame as *impaſtatio*; it alſo ſignifies the uniting oleous and terebinthinate ſubſtances with water into one equal body by the mediation of a third body added to them.

INCRASSANTIA, alſo *pycnotica*. INCRASSATING MEDICINES, theſe are ſuch as reduce the too fluid blood and juices to a proper conſiſtence.

INCRUSTATIO. INCRUSTATION. In ſurgery it is the induction of a cruſt, or eſchar upon any part.

INCUBO, INCUBUS. The NIGHT-MARE. It hath alſo been called *ephialtes*, or *epialtes*, from ἐφάλλομαι, *to leap upon*; *epibole*, from ἐπιβάλλω, *to preſs upon*; becauſe the patient imagines that ſomething leaps or preſſes upon him, and *babuzicarius*, from βαβύζω, *to ſpeak* inarticulately. There is alſo a ſpecies called *ſuccubus*. The INCUBUS is ſynonymous with *oneirodynia*.

Thoſe who are diſturbed by indigeſted crudities in the ſtomach are generally the ſubjects of this diſorder. It lays a foundation for the epilepſy.

Under this complaint, which always happens during ſleep, the patient cannot ſtir himſelf but with difficulty; he is ſeized with a ſenſe of weight, a dread of ſuffocation, an oppreſſion as from ſomebody falling ſuddenly upon him, with an intent to deprive him of life and ſenſe, not ſuffering him to cry out; hence it is uſual with theſe patients to ſtart up and cry out with a confuſed inarticulate voice.

This diſorder hath generally been ſuppoſed to proceed from a ſtagnation of blood in the brain and lungs; *but it is a nervous affection, and riſes chiefly from indigeſtion*: hence we obſerve that thoſe with weak nerves, who lead ſedentary lives, and feed heartily, are the moſt commonly affected with it. Nothing tends more to produce it than a heavy ſupper eaten late, or juſt before going to bed. Wind is a frequent cauſe, deep thought, anxiety, or any oppreſſion on the mind, alſo produces it.

None are attacked with this diſorder but when laid on their backs; and if any perſon would awake the patient, the complaint would immediately vaniſh.

If the patient hath a ſanguine plethora, bleed, direct a ſpare diet, and aloetic purges. Dr. Whytt ſays that he generally found a *glaſs of brandy a cure, if taken at bed-time*.

A ſlight ſupper, chearfulneſs before bed-time, due exerciſe during the day, are the beſt remedies.

See Cœlius Aurelianus Morb. Chron. lib. i. cap. 3. Lommii Med. Obſ. iii. P. Ægineta, lib. iii. c. 15. Soranus's Aitiologoumena.

INCUS. The ANVIL. The name of one of the bones in the ear. It is broader than it is thick; it is articulated with the malleus, behind the manubrium, and from hence a ſhort thick proceſs projects backwards, and a long proceſs downwards, which runs down parallel to the long proceſs of the malleus, but rather more backward. The ſhort proceſs is thick at its beginning, but decreaſing it ends in a point, which is turned backwards and joined to the edge of the opening of the cellulæ maſtoideæ. The long proceſs at its extremity is rather bent inwards, by which we may diſtinguiſh the *incus* of one ear from that of the other; for, turning the ſhort proceſs backwards and the long proceſs downwards, if the bending in of the long leg be towards the left hand, it belongs to the right ear, and vice verſa. See AURIS.

INDEX, from *indicare, to point*. See DIGITUS.

INDIÆ ORIENTALIS, RADIX GENUINA. See GENSING.

INDIANA RADIX. See IPECACUANHA.

INDICATIO. INDICATION, alſo DELATIO, *endeixis*. The diagnoſtics of a diſeaſe and its pathognomonic ſigns, are collections of particulars that occur to obſervation. *Indications* are concluſions that ariſe from reaſoning on theſe particulars called ſigns. The *indication* of cure, in all diſeaſes, is to remove the proximate or immediate cauſe, for this the term *accuſatio* is uſed.

INDICATOR. See EXTENSOR INDICIS.

INDICON. See MYRTIDANON.

INDICUM. The INDIGO BLUE PLANT; alſo called *Indico-indigo, anil, caachira, nil, iſatis Indica, coronilla Indica, emerus Americanus, agnil, glaſtum Indicum, Ameri, coaachira Indorum, colutea Indica herbacea, enger, gali, herva de anil Luſitanis, hin-awaru*, &c. It is a plant which is a native of South Carolina. In ſix weeks to two months from ſowing the ſeed, the plant is ready for cutting up, in order to make the blue colouring matter called *indigo*. The *indigo* is a fæcula, made by means of water and olive oil, from the juice of the leaves of this plant and the ſmalleſt branches. The beſt ſort of *indigo* bears the ſurname of *ſurquiſſe*. The beſt is made at St. Chriſtopher's and Martinico; it is in flat cakes, of a moderate thickneſs, not too ſoft nor too hard, of a deep violet colour; it ſwims on water, and when broken hath no white ſpots in it; ſuch as is copperiſh or reddiſh, on being rubbed with one's nail, and hath the leaſt duſt and broken pieces in it, is not genuine.

There is a ſort which is made from the leaves and the ſtalks, which is named *guatimala*.

The plant is ſaid to be detergent, and of ſome uſe when powdered and applied to ulcers.

There

There is another plant which is called *anil*; it is uſed by way of decoction in nephritic colics, and ſuppreſſions of urine.

See Raii Hiſt. Plant. Neumann's Chem. Works.

INDICUM BALSAMUM. See PERUV. BALS.

—— LIGNUM MONTANUM. See CAMPECHENSE LIGNUM.

INDICUS. See COSTUS.

INDIGA SPURIA. See COLINIL.

INDIGNATORIUS MUSCULUS, from *indignor, to ſcorn*; becauſe this muſcle, though not without the help of another, produces a ſcornful look. See ABDUCTOR OCULI, No. 5.

INDIGO. See INDICUM.

INDUSIUM. A SHIRT OR SHIFT. Some diſpute about changing the linen when the patient is ſick. Clean linen promotes perſpiration, and it may be renewed as often as the patient pleaſes, whether the diſorder be of the acute or the chronical kind.

Except *during a criſis in fevers*, whilſt the patient is in a ſweat, a change of linen, if well dried and warmed, may be daily uſed.

INDUSIUM. See AMNION.

INERTIÆ VIS. The power of inactivity. By this ſir Iſaac Newton means that paſſive principle in matter, by which bodies reſiſt, to the utmoſt of their power, any change or alteration of their ſtate, whatever it be, either of reſt, motion, or its direction; and this reſiſtance is always equal in the ſame body, and in different bodies, is proportional to the quantity of matter they contain. Hence in medicine it means when powers of the conſtitution are torpid, or inert, and for want of their exertion leave the habit, both ſolids and fluids in a ſtate almoſt of inactivity.

INFANS. An INFANT or CHILD. Fred. Hoffman ſays, that the human ſpecies are *infants* until they begin to talk, and children to the age of puberty.

ANATOMY diſcovers to us, that during *infancy* there is much imperfection in the human frame, becauſe its parts are diſproportioned, and its organs incapable of thoſe functions which in future life they are deſigned to perform. The head is larger in proportion to the bulk of the body than that of an adult. The liver and pancreas are much larger in proportion than in advanced life; their ſecretions are more in quantity alſo. The bile is very inert; the heart is ſtronger and larger than in future life; the quantity of blood ſent through the heart of an *infant*, in a given time, is alſo more in proportion than that in adults. Now, though theſe circumſtances have their important uſefulneſs, yet the imperfection attending them, ſubjects this age to many injuries and dangers from which a more perfect ſtate is freed.

Hippocrates enumerates the diſorders of *infants* and *children* in his Aphoriſms, lib. iii. aph. 24—26. Dr. Percival obſerves in his Eſſays Med. and Exp. that of all who are born alive, two-thirds of them live not to be two years old.

Infants have a larger proportion of brain than adults, hence are more ſubject to nervous diſorders, and hence the diagnoſtics of diſeaſes are in many reſpects obſcure or uncertain, as particularly thoſe taken from the pulſe, which from the irritability of the tender bodies of *infants*, is ſuddenly affected by a variety of accidents too numerous, and ſeemingly too trivial, to gain our attention. However, no very great embarraſſment ariſes to the practitioners from this; for the diſorders in this ſtate are generally acute, leſs complicated than thoſe in adults, and are more eaſily diſcovered than is generally apprehended.

The vigour of *children*'s conſtitutions depends moſt on that of their mothers. Healthy women, who accuſtom themſelves to exerciſe and air, and whoſe diet is more ſuited to the robuſt than the delicate, alone bring forth healthy *children*.

As ſoon as a *child* is born, the mucus with which its body is covered, is beſt waſhed off with ſoap and water. The care of ſome nurſes to clear away all the mucus at the firſt dreſſing of the *child* is imprudent, for the degree of rubbing which is ſometimes required, produces inflammation, and much other uneaſineſs in the *child*; moderate cleanlineſs at the firſt prevents ſuch ill effects, and the next dreſſing will eaſily and ſafely complete this buſineſs.

After examining the new born *infants* with a view to diſcover any accidental injury, or natural imperfection, wrap the navel-ſtring in a rag, ſufficiently folded, to prevent the coldneſs of the navel-ſtring from affecting the bowels and producing gripes.

The heads of *infants* are differently formed by the birth; but the nurſe ſhould dreſs them looſely, and leave their future formation to the action of the dura mater.

The next cuſtom is to pour oil of almonds, and ſyrup of violets, or to thruſt ſugar and butter into the child's ſtomach; but this practice induces coſtiveneſs, by weakening the bowels: until the mother's milk begins to flow, which may be accelerated by applying the *child* to the breaſts, it is rarely neceſſary to give the *child* any thing; for there is a mucus in the ſtomach of a new-born *infant*, which is generally a ſufficient nouriſhment, until the mother can afford what is further needful. If any thing is done before the mother's milk can be obtained, let a tea ſpoonful of the ol. ricini ver. be the medicine, and after it give only lukewarm water with an equal portion of new milk.

If the *child* is to be nurſed without the breaſt, the thinneſt diet is the beſt; milk and water alone ſuffices, and is leſs ſubject to turn ſour than thicker meat; as the ſtrength increaſes, more ſolid diet may be given.

The cloathing of *infants* ſhould be looſe and cool; but not ſuch as ſubjects them to the cold. Clean linen may be allowed every day, for it imbibes ſuperfluous moiſture, which otherwiſe might offend. Peculiar attention ſhould be given to prevent their continuing wet, after they void their urine.

The diet ſhould be in general as directed in the articles ABLACTATIO, and LACTATIO. If the ſtools are of a green or yellow colour, add now and then magneſia to the food, or give three or four drops of liquor c. c. in a ſpoonful of milk and water; freſh broth, from which the fat is ſkimmed, may be given once a day.

The nurſery ſhould be a large room, and more than two ſhould not be in the ſame bed. Small or crowded rooms greatly relax the inhabitants, and ſubject them to take cold.

Exerciſe is of the greateſt importance; it conduces both to preſent health, and future vigour; but avoid much motion, except of the gentler kind, before the ſtomach hath digeſted, in ſome meaſure, its contents; and at all times avoid the dangerous practice of hoiſting and toſſing children high and violently, for thus their victuals ſoon are ſoured in their ſtomachs, and digeſtion is much injured, and not unfrequently the tender ribs are bent, or broke, and thus irremediable ills ariſe, though the cauſe at firſt was never noticed. Gently dandling, and rubbing the whole body before a fire every time it is dreſſed, waſhing with cold water, and afterwards drying it well, are ſufficient exerciſes during the firſt few months.

As to the diſorders that are proper to the *infant* ſtate, they are chiefly inward fits, teething, the rickets, the thruſh, watery gripes, and convulſions; theſe are common to all ages. In *infants*, all theſe diſorders generally ſpring from one common cauſe, viz. an acid in the ſtomach and bowels. This, in proportion to its degree, and according to the reſpective peculiarities in the conſtitution of an individual, produces one or other of theſe diſeaſes. To remedy theſe, give from gut. v. ad x. vin. antim. and if it does not operate upwards in half an hour, repeat the doſe. It generally operates both ways, and then it is the moſt uſeful; as the *child*'s ſtrength increaſes give a larger doſe. Repeat this kind of emetic as often as the ſymptoms may require, and keep the *child* always as dry as poſſible, not neglecting to rub it as above hinted, every time it is dreſſed and undreſſed. See the reſpective articles under which the above named diſeaſes are treated; alſo Percival's Eſſays Med. and Exp. ed. 2. p. 363—367; Armſtrong on the Management and Diſeaſes of *Children*. Hoffman on the Diſeaſes of *Children*. An Eſſay on the Management of *Children*, by Dr. Cadogan. A treatiſe on the Diſeaſes of *Children*, by Dr. Harris: it is tranſlated by I. Martin, F. R. S. and is excellent on the ſubject it contains. Directions for the Management of *Children*, by Dr. Clark. Moſs on Nurſing, &c. Wallis on Health and Diſeaſe.

INFECTIO. See CONTAGIO.

INFELIX. Thus Virgil calls darnel. See LOLIUM.

INFELIX. Lignum. See SAMBUCUS.

INFERNALIS LAPIS. Cauſtic made by evaporating ſtrong ſoap-leys almoſt to dryneſs. See CAUSTICUM COMMUNE FORTIUS. It is ſometimes uſed inſtead of the Cauſticum Lunare, and by ſome ſo called. See ARGENTUM.

INFIBULATIO. INFIBULATION. This operation is the reverſe of circumciſion, for it confines the prepuce ſo over the glans penis, that it cannot be drawn back. The operation is thus performed. Extend the ſkin which is above the glans, and with ink mark the part on each ſide through which the perforation is to be made; then let it retract itſelf. If the marks recur upon the glans, too much of the ſkin hath been taken up, and the marks muſt be made nearer to the end of the prepuce, but only ſo as that they may not return upon the glans; and thus the ſeat of the fibula is determined. Then a needle, armed with a waxed thread, is paſſed through, and moved backward and forward every day, until a cicatrix is formed. After this the *fibula* is fixed.

Thus the ancient Romans were uſed to preſerve their ſinging boys from all premature and prepoſterous ideal venery, and to preſerve their voices longer. See Celſus, lib. vii. cap. xxv. The *fibula* ſeems to have been a kind of ring.

INFLAMMATIO. Alſo *Phlegmone*; *Phlogoſis*; INFLAMMATION. HIPPOCRATES often applies the word *Phlegma*, in this ſenſe; it is properly defined to be an increaſed circulation in any part, from irritation, external or internal, local or univerſal. An acute inflammation is termed *Oxyphlegmaſia*.

THE IMMEDIATE CAUSE of *inflammation* is irritation. It does not depend on the quantity of craſſamentum, nor the ardency of the blood: ſpaſm and *inflammation* mutually produce each other. Putrid matter is amongſt the varieties which irritate the nervous and ſenſible parts, and ſo excite *inflammation*. The kinds of irritation are, perhaps, as various, as are the different cauſes thereof; the matter of the ſmall-pox produces one, that of the itch another, &c. More fluid circulates through, and is more ſecreted, in a part that is inflamed, than when it is in a natural ſtate. Senſibility and irritability are increaſed by *inflammation*, and are produced in parts that did not manifeſtly poſſeſs them before.

The MEDIATE CAUSE of *inflammation* is the increaſed ſenſibility, or irritability of the fibres; whence irregularity in the excreta and retenta.

The REMOTE CAUSES are wounds, bruiſes, ſudden and exceſſive cold, luxations, aromatic aliments, &c. Dr. Cullen conſiders ſpaſm as the ſole proximate cauſe of *inflammation*, and ſays "That a ſpaſm of the extreme veſſels takes place in *inflammation*, is preſumed from what is at the ſame time the ſtate of the whole arterial ſyſtem. In all conſiderable *inflammations*, though ariſing in one part only, an affection is communicated to the whole ſyſtem; in conſequence of which, an *inflammation* is readily produced in other parts beſides that firſt affected. This general affection is well known to phyſicians, under the name of *diatheſis phlogiſtica*. It moſt commonly appears *in perſons of the moſt rigid fibres; is often manifeſtly induced by the tonic or aſtringent power of cold; increaſed by all tonic and ſtimulant powers applied to the body; always attended by a hardneſs of the pulſe; and moſt effectually taken off by the relaxing power of blood-letting.* From theſe circumſtances it is probable, that the diatheſis phlogiſtica conſiſts in an increaſed tone, or contractility, and perhaps contraction, of the muſcular fibres of the whole arterial ſyſtem." Firſt Lines of the Practice of Phyſic.

Inflammations receive different names, according to the different parts on which they manifeſt themſelves, as in the inſtances of a quinſy, pleuriſy, &c. called *phlegmonous inflammations*; and a catarrh, diarrhœa, &c. called *inflammations* of the mucous membrane.

However various may be the diviſions and ſubdiviſions of *inflammation*, like fever they are all but *inflammation*, differently circumſtanced. If the ſanguineous veſſels, in thoſe membranes that are inflamed, are the ſeat of the irritation (as in *inflammations* of the ſtomach, brain, &c.) the *inflammation* is then called *phlegmonous*; but when the irratation is on the ſurface of the membranes, it ſtimulates the ſecretory mucous glands to the accumulating and diſcharging more than in a natural ſtate they uſually do. So an irritation, and its conſequent an extraordinary afflux, or circulation of humours through the part, conſtitutes *inflammation* in both caſes.

All the *inflammations* that come under the name of *phlegmonous*, have the ſame ſeat; they are all in the ſanguinary arteries of the part inflamed. Dr. Boerhaave, to ſupport his doctrine on this kind of *inflammation*, ſpeaks of the red blood being obſtructed by an error of place (ſee ERROR LOCI); but obſtruction is not a cauſe, though it may be an effect of this diſorder. The mucous membrane is the ſeat of thoſe *inflammations* which come under the denomination of *inflammations of the mucous membrane*. If there are tumors, the *inflammation* is *phlegmonous*, and theſe are diſtinguiſhed into *phlegmonous* and *eryſipelatous*. The ſeat of the plegmonous is in the *ſanguinary arteries*, and the *cellular membrane*; the ſeat of the eryſipelatous *is in the ſkin*, or *other internal membranes, not cellular*.

Dr. Cullen uſes the term PHLOGOSIS, for this genus of diſeaſe. He places it in the CLASS PYREXIÆ, and ORDER PHLEGMASIÆ; and defines it to be a fever, redneſs of an external part, with heat, and a painful tenſion. The ſpecies he points out are, 1. *Phlogoſis phlegmone*, the phlegmonous *inflammation*. This is attended with a bright redneſs; a circumſcribed tumor, moſt frequently elevated, and terminating in a point, often ſuppurating, and is attended alſo by a throbbing pain. It puts on different forms, and in different ſituations; hence its two varieties. 2. Phlogoſis erythema, erythematous *inflammation*. This has for its aſſociates a red colour, diſappearing on preſſure; its extent is not circumſcribed, but irregular, and ſpreads: there is ſcarce any perceptible tumor; it produces ſcales at the cuticle, phlyctenæ, an ſmall bliſters, and there is alſo a burning heat attends. Of this there are three varieties; proceeding, 1ſt, from its degrees of violence; 2d, remote cauſe; 3d, from its being complicated with phlegmonous inflammation, œdema, or being ſymptomatic. This ſpecies ſometimes is but ſlight, appearing on the ſkin without the perſon being ſenſible of any other diſorder, and it moſt commonly breaks out on the face, or one leg. This complaint encreaſes for two or three days, continues at its height one or two, then abates, and terminates in large cuticular ſcales which fall off.

The conſequences which frequently ſucceed phlogoſis, are; 1. ABSCESS; 2. GANGRENE; and, 3. SPHACELUS. They are known by the following appearance: The FIRST, after inflammation has taken place, and continued ſome time, the pain and pulſation in the part remits, the tumor becomes whitiſh and ſoft, manifeſting a ſenſe of fluctuation on being preſſed; and is attended with an itching or rather pricking pain. The SECOND, after inflammation, the part becomes livid, ſoft, has little ſenſibility, and is often attended with ichorous veſicles. The THIRD, after a gangrene has come on, the parts grow black, flaccid, are eaſily lacerable, without ſenſe, or heat, and with the fœtor of putrid fleſh; the diſeaſe ſpreading very rapidly. See ERYSIPELAS; ABSCESSUS; MORTIFICATIO. However, the principal effects of *inflammations* are heat, pain, ſwelling, redneſs, an accelerated pulſe, a dryneſs of the ſkin, and an itching.

The heat is excited by the reciprocal action and re-action of the ſolids and fluids. *The irritation on the fibres* increaſes the action of the veſſels; *the velocity of the fluids* are thereby quickened through them, and thus heat is excited in proportion as there is craſſamentum in the blood.

PAIN. This is excited by the diſtenſion of the veſſels in a part already become preternaturally ſenſible.

SWELLING. This is not cauſed by obſtructed blood, but by the exceſs of heat diſtending the cellular membrane; but a ſwelling is not eſſential to an *inflammation*.

REDNESS. This proceeds from the quantity of blood brought to the part.

THE QUICKENED PULSE is from that law in nature, by which the heart always increaſes its efforts, to free its ſubſervient veſſels from any injury they ſuſtain from accidental, or preternatural irritation.

DRYNESS OF THE SKIN. This is from the ſtricture in the capillaries, whoſe uſe is nearly aboliſhed by the irritation on them.

ITCHING. This is but the beginning of what ends in pain by its increaſe.

The prognoſtics are more or leſs favourable in proportion to the dignity of the part affected, the conſtitution of the patient, the intenſeneſs of the ſymptoms, the attendance of other diſorders, as the ſcurvy, pox, &c. In a part that is of a firm texture, and that hath but few veſſels, ſuch as the ligaments, glands, &c. the cure is often tedious, and a proper cure is not always effected, for a ſcirrhus is ſometimes the conſequence. If the ſymptoms of *inflammation* ceaſe ſuddenly, the epidermis is raiſed into bliſters full of ichor, or ſinks, and the colour of the part becomes livid, whilſt at the ſame time the pulſe is ſmall, and the ſenſibility of the part is leſſened, a gangrene is then approaching.

Sometimes an *inflammation* ſoon goes off, at others it is removed with difficulty, and often it terminates in other diſeaſes. An *inflammation* can only terminate by a removal of its immediate cauſe, viz. the erethiſm of the veſſels, or rather the irritating matter. But generally it is ſaid to end in a reſolution, ſuppuration, gangrene, ſcirrhus, or cancer; though with reſpect to the two laſt all practitioners are not agreed that they are the reſult of inflammation.

Resolution, is ſaid to be accompliſhed, when, upon removing the cauſe, the ſymptoms diminiſh gradually, and at laſt the patient is in the ſame ſtate as before the diſorder began. And, unleſs morbific matter was the cauſe, this is the moſt deſirable way of termination. A reſolution may be brought about by ſome increaſed evacuation happening by nature's efforts, or by thoſe of art; a fever coming on; or by a metaſtaſis. But theſe are not properly the modes of the reſolution of *inflammation*, bnt the methods which nature or art hath taken to remove the irritation which was the immediate cauſe. In all theſe ſpecies of reſolution calloſities are ſometimes left.

Suppuration, is more properly a conſequence of *inflammation* than a mode of its termination. It happens when a quantity of blood is thrown out into ſome cavity (the *inflammation* continuing), it ferments and is converted into pus, which afterwards acts as a ferment on the ſolid parts, and gives occaſion for the converſion of the whole into a matter ſimilar to itſelf, the ſymptoms of *inflammation* going off.

A gangrene may be a conſequence of *inflammation*, but never can be conſidered as a mode of *inflammations* going off: for now ſenſation is deſtroyed, and life, with reſpect to the part that mortifies, is extinguiſhed; whence no morbid cauſe can any longer be productive of effects.

Laſtly, a scirrhus and cancer ſeem to be peculiar diſeaſes, not the modes by which *inflammation* terminates. Mr. Sharp obſerves, in his Introduction to the Operations of Surgery, that "A ſcirrhous gland is generally mentioned as a fourth termination of *inflammation*; but with impropriety, ſince it ſeldom or never occurs but in venereal, ſcrophulous, or cancerous caſes; when it is the forerunner, and not the conſequence of an *inflammation*, the tumor generally appearing before the diſcoloration."

One general method of cure is that which is proper in all the denominations of phlegmonous *inflammations*, however diſtinguiſhed by phlegmon, eryſipelas, hot œdema, or whatever elſe. And in general there are but two indications; the *firſt* is to leſſen or remove the irritation; the second to abate the increaſed afflux of the humours.

Though *inflammations* of all parts have the ſame general treatment in order to their cure, yet regard ſhould be had to their ſtructure, ſituation, and connection of the parts, to the antecedent cauſes of the diſorder, and the conſtitution of the patient.

It is obſervable that a phlegmon, on its decline, aſſumes ſucceſſively the forms of an eryſipelas and œdema, and then it vaniſhes; this would not happen ſo ſoon if they proceeded from inſpiſſated blood, ſerum, or lymph, wedged in ſmaller veſſels than are deſtined to circulate through them; whence, as theſe different appearances of *inflammation* are known to ariſe ſucceſſively in the ſame place, it ſeems very certain that they proceed from the ſame cauſe, viz. from the ſame kind of humours in the ſame ſeries of veſſels, and that they are nothing elſe but the different degrees of intenſity of the ſame diſeaſe, alſo that the ſame general method of cure is proper for them all.

To anſwer the first indication, viz. *to remove the irritating cauſe*: 1. Endeavour to remove all that can continue the morbid irritation. 2. When ſpaſms are the cauſe, opium is the propereſt remedy. 3. When a ſtimulating fluid is ſecreted on a ſenſible membrane, its action may be hindered by the application of oily, unctuous, or mucilaginous matters. The morbid acrimony may be deſtroyed by proper alteratives, or mercury, &c. 5. Deſtroying or leſſening the irritability of the part, by means of the bark, preparations of lead, &c. 6. The diſtenſion of the internal veſſels is removed by reſtoring the circulation on the external ſurface of the body, or giving internally medicines to relax the ſmall veſſels throughout the ſyſtem, by their action on the ſtomach; ſuch as nitre, ſal ammoniac, all the neutral ſalts, ipecacuanha, ſeneca root, antimonial preparations, cold water, external applications, ſuch as ſinapiſm, bliſters, &c.

The second indication, viz. *to abate the increaſed flux of the humours*, is anſwered, 1. *By bleeding*. 2. *Purging with neutral ſalts*. 3. *By the application of ſedatives to the ſtomach*, as acids mixed in the patient's drink, and narcotics given at proper intervals in ſmall doſes. 4. Sedatives, ſuch as the preparations of lead, &c. may be applied externally. And, 5. By *inflammation excited on the ſkin, near the part originally affected* (except the ſkin itſelf is the part inflamed); to this end frictions, the volatile liniment, or even bliſters, may be applied.

Mean while let a cooling attenuating diet be directed: barley-water, in which the true gum arabic is diſſolved, is among the firſt for the common drink, and, in order to its free diſcharge by urine, add to each draught juſt ſo much nitre as produces a due diſcharge that way; though ſometimes the nitre, by irritating too much, rather checks than facilitates the diſcharges by the kidneys.

If the external *inflammations* are to be removed without a ſuppuration, emollients ſhould never be applied; they increaſe every degree of tumor, by adding to the quantity of matter there accumulated, and rendering the veſſels both more yielding to their impulſe, and leſs able to carry them off; thus they counteract every intention of cure. The increaſed action of the veſſels is to be allayed, and the ſenſibility of the part abated, by ſuch ſedatives as neither increaſe the tumor, the pain, the heat, or the tenſion; to this end ſaturnine topics, or in their ſtead the ſimple aſtringents and ſtimulants in common uſe, ſuch as the uſual mixture of vinous ſpirit with vinegar, poſſeſs the deſired efficacy. Lotio ammoniæ muriatæ cum aceto. ℞ ammoniæ muriatæ ʒ ſs. aceti ſps. vinoſi rectif. āā lb. i. m. Lotio aluminis. ℞ alumin. ʒ ſs. aquæ diſtillat. lb. i. This ſtops the progreſs of external inflammation. When the ſeat of *inflammation* is a lax glandular part, applications that are ſtrongly ſtimulant are the moſt ſafe and advantageous. And where there is but little ſenſibility in the part, as in the ſcrophulous tumours of the lymphatic glands, bliſters exceed all other topical remedies.

The belly ſhould be kept lax in all kinds of *inflammations*; and internal ones are much relieved by a frequent uſe of clyſters.

Vapours and warm baths contribute much to relief, by leſſening the irritation of the fibres, and by retarding the motion of the blod.

When the *inflammation* abates, attenuants and aperients, ſuch as guaicum, ſaſſafras, &c. are uſed with ſome advantage. Bell on Ulcers, edit. 3. p. 17—36. 47—53. Cullen's Firſt Lines, edit. 4. vol. i. p. 211. Kirkland's Med. Surgery, vol. i. p. 235. Pearſon's Principles of Surgery, vol. i. &c. White's Surgery, vol. i.

1. Inflammatio Articuli. Inflammation *in a joint.*

The rheumatiſm is an inſtance of this kind, but no great danger is to be apprehended from it, as it is ſeated only in the ligaments. In this caſe bleeding, mild cathartics, ſudorifics, and a prudent uſe of opiates, are beneficial; and if the joint is rigid, a warm bath will relieve it much.

The danger of a ſuppuration in a joint is from the length of diſcharge, and the abſorption of the matter, which rarely fails to bring on a fatal hectic; therefore, by all means, if poſſible, let this accident be preventd.

2. Inflammatio Cordis. Inflammation *of the Heart*, called Carditis.

Dr. Cullen has placed the *inflammatio pulmonis Lommii*, and *pericarditis*, as ſynonymous, under this head; and, includes this genus of diſeaſe in the CLASS Pyrexia, and ORD. Febres, and defines it to be fever, with pain in the region of the heart, anxiety, difficulty of breathing, cough, unequal pulſe, palpitation of the heart, and fainting; beſides, in this caſe, the pulſe is ſmall, irregular, and intermittent; the patient frequently ſwoons; and if not ſpeedily relieved by art, this diſorder ſoon becomes fatal. The method of cure is the ſame as that in the peripneumonia, and pleuritis. See Inflammatio Pericardii, N° 15.

3. Inflammatio *Faucium*. Inflammation *of the Fauces*. See Angina.

4. Inflammatio Femoris. Inflammation *of the Thigh.*

The faſcia lata femoris, is followed by very unkindly ſuppura-

ſuppurations; and whenever matter is formed under it, we ſhould give it vent as ſoon as it is diſcovered.

5. Inflammatio Hepatis. Inflammation *of the Liver*. See Hepatitis.

6. Inflammatio Intestinorum. Inflammation *of the Inteſtines or Guts*: called Enteritis.

Dr. Cullen places this genus of diſeaſe in the Cl. Pyrexiæ, and Ord. Phlegmasiæ; and, defines it, a typhodal pyrexy, attended with pungent tenſive pain of the abdomen, running round the umbilicus; a vomiting, and obſtinate conſtipation. He diſtinguiſhes two ſpecies. 1. Enteritis phlegmonodea, *inflammation* of the bowels, with acute pain, ſtrong febrile affections, vomiting, and coſtiveneſs. 2. Enteritis eryſipelatoſa; *inflammation* of the bowels, with pain and fever, more mild than the former, without vomiting, and an attendant diarrhœa.

It is the *inflammation* of the exterior coats of the inteſtines that is here treated of; it differs greatly from an *inflammation* of the inner villous coat, or mucous membrane, in which caſe there is either aphthæ, or a dyſentery. See Dysenteria. According to the different parts of the inteſtine in which the *inflammation* is ſeated, different names have been given, as iliaca paſſio, enteritis, &c. but in all, the treatment is the ſame.

If a ſharp pain, with a fever and nauſea, is above the navel, and below the ſtomach, the colon under the ſtomach is the ſeat of the *inflammation*.—If the pain is in the right hypochondrium, under the ſpurious ribs, then that part of the colon which joins the ilium may be inflamed.—If the pain is in the middle of the belly about the navel, the ſmall guts are affected.

The cause may be, external cold, indurated fæces, heavy or hard bodies lying in the inteſtines, introſuſceptions, adheſive ſtimulants, hernias, wounds, or any other cauſe of internal *inflammations*.

The uſual ſymptoms are, a ſhivering, and acute burning pain in the belly, which is fixed in the part where it was firſt perceived; ſometimes it increaſes a little, and then remits, but moſt frequently it is continually the ſame. Generally the whole belly is affected at the ſame time with ſpaſmodic pains, which extend to the loins; and flatulencies are often troubleſome. The pulſe is ſmall, hard, frequent, and often it becomes at laſt irregular and intermittent. There is a coldneſs in the extremities, alſo a ſudden and great proſtration of ſtrength. Sometimes a watery diarrhœa attends, but more frequently the muſcular fibres of the inflamed part contract ſo ſtrongly, that nothing can paſs through, although a motion returns very frequently;—ſometimes the anus is ſo contracted that a ſmall pipe can hardly be introduced.—Flatulencies in the ſtomach, ſickneſs, violent reachings, and vomiting, frequently attend.—The tongue is dry,—thirſt great,—the urine often pale and obſtructed, ſometimes it is high coloured, and diſcharged with heat and difficulty.—The breathing is quick.—The patient bends forwards, frequently compreſſes his belly, becauſe the abdominal muſcles are ſpaſmodically contracted;—the face is flushed. At length a delirium comes on, and convulſions, by which the patient is deſtroyed.

Inflammation in the bowels frequently terminates in a mortification; in which caſe the pain goes off, and the patient appears to himſelf for a little relieved; his face grows pale, the under eye-lid becomes livid; but the pulſe continues frequent, ſmall, and often irregular; the extremities are cold, delirium and convulſions now come on, and carry the patient off. Juſt before he expires, it often happens that he diſcharges very fetid ſtools.

If this diſorder is left to nature, it ſometimes kills in a few hours, and almoſt always before the end of three days; ſo that there is rarely a ſuppuration. But if an abſceſs is formed, the pain abates, and is converted rather into a ſenſe of diſtenſion, and irregular cold fits, with the other ſymptoms of internal ſuppuration, ariſe; the contraction of the muſcular fibres of the inteſtines, the great frequency of the pulſe, and other ſymptoms, go off. When this abſceſs burſts, the patient ſwoons, and ſeems freed from a ſenſe of weight in the part where it was.

Inflammation in the external membrane of the inteſtines ſhould be diſtinguiſhed from the ſtone in the kidneys, or in the ureters,—from *inflammation* of the kidneys or other of the abdominal viſcera,—from ſpaſmodic pains of the belly,—and from other obſtructions there, in which no *inflammation* attends; it ſhould alſo be carefully diſtinguiſhed from the colic,—the hæmorrhoids,—and from the iliac paſſion.

If the pain ſhifts, the vomiting returns only at intervals, and while the clyſters paſs downwards there is hope. If the patient ſurvives three days, and the pain abates ſuddenly, with chilneſs and ſhivering, a ſuppuration is forming, which in about fourteen days will break; then if the patient becomes tabid, the only help is a palliative one for a ſhort time. When all paſſes upwards, the patient is very weak, the pulſe fluttering, the countenance pale, the breath offenſive, then danger is very great. Clammy ſweats, a ſmall intermitting pulſe, fetid or black ſtools, a total abatement of pain, are ſigns of mortification being begun, and then death ſoon follows.

On the firſt attack, bleed freely, notwithſtanding the ſmallneſs of the pulſe and ſeeming weakneſs; for the pulſe becomes fuller, and the proſtration of ſtrength goes off as the *inflammation* abates. Repeat the bleeding at ſhort intervals, until the pulſe becomes ſoft.

Acids ſhould be joined with every draught of the patient's common drink.

The antimonial powder ſhould be given in ſuch doſes as the ſtomach will eaſily retain, and a ſaline draught ſhould be repeated every hour or two.

If acrimony is a ſuſpected cauſe, bleed, give a doſe of the ſal. cath. amar. with as much of the vin. antim. as will cauſe it to operate upward and downward; then give the miſtura cretac. Ph. Lond. and the decoction of calcined hartſhorn for common drink.

Cooling laxative clyſters ſhould be given every two or three hours, until a ſtool is procured. It ſhould be obſerved that though the ſal marin is the beſt purgative in general for clyſters, it is improper if any *inflammation* is ſuſpected in the bowels. But tobacco-ſmoak may be injected, and repeated at ſhort intervals, until the deſired effect is obtained.

Purges are contra-indicated by the contraction of the inflamed part; though when all other means fail of obtaining a paſſage, purges with opiates muſt be tried; the ſal cath. amar. is the beſt, of which two ounces may be diſſolved in ℔ i. of water, and given by two or three ſpoonfuls every half hour, and to prevent vomiting give the tinct. opii, gt. xxv. in aq. cinnam. vel. aq. menth. pip. If no liquid ſtays on the ſtomach, give pills, ſuch as the following: ℞ Pulv. jalap. & kali vitriolat. ää ʒ ſs. opii, gr. i. ſap. Venet. q. ſ. f. pil. vi. ſtatim ſumend. If theſe do not operate in two or three hours, repeat them.

Immediately after bleeding apply a bliſter on the pained part; it often cauſes both clyſters, and purgatives taken by the mouth, to paſs downwards.

Put the patient into a warm bath; let him ſit there, with the water as high as his breaſt, as long as he can, without fainting; repeat it if required; but be careful that the water be not too hot. In bringing him from the bath great care is required to guard againſt the cold. If the bath cannot be had, the legs may be put into warm water, and bladders of warm water may be applied to the belly, and the like may alſo be laid to the feet.

If the vomiting is ſevere, or to prevent a purging medicine from returning, opiates may be admitted, otherwiſe their uſe is not adviſable until all other means fail, and then give the following: ℞ Antimonii tartariſati, gr. ½ ad ¾, ſyr. papav. albi, ʒ ii. ad ʒ vi. aq. menth. ſat. ʒ ii. m. f. hauſt. See Iliaca Passio.

In caſe of an abſceſs, ſee Abscessus Intestinorum.

The erythematic *inflammation* of the guts may be treated as that of the ſtomach. See Inflammatio Ventriculi. Cullen's Firſt Lines, vol. i. p. 372. edit. 4. Edinb. Med. Comment. vol. iii. p. 122.

7. Inflammatio Mammarum Mulierum. Inflammation *in the breaſts of Women*; called Mastodynia.

Dr. Cullen places this as a variety of the Phlogosis Phlegmone.

This may happen at any other time, but generally it is the attendant of thoſe who give ſuck. A ſhivering is moſt frequently a preceding ſymptom; then follows the *inflammation*, with more or leſs fever; a quick pulſe, thirſt, head-ach, and difficult reſpiration.

As the uſual methods to prevent the afflux of milk in the breaſt are uncertain; to guard againſt *inflammation*, the mother ſhould conſent to ſuckle her child, at leaſt during the firſt month; and during this time, to order her diet ſo as that the diſcharge by urine may be ſomewhat increaſed,

increaſed, and the bowels kept lax; the breaſts ſhould alſo be kept as empty as poſſible, by means of glaſſes or other contrivances for this purpoſe. But if, notwithſtanding this, an *inflammation* actually takes place, bleed, direct a thin ſpare diet, give laxatives, and apply the following embrocation by means of linen rags, which ſhould be moiſtened with it as often as they dry: ℞ aquæ ammoniæ ʒ ſs. ſpt. camph. ʒ i. ſs. m. If this is too irritating, add to it half an ounce or more of olive oil: ℞ ammoniæ muriatæ ʒ i. ſps. rotiſmarini ℔ i. in pulverem redige ammoniam, et in ſpiritu ſolvatur: this is called LOTIO AMMONIÆ MURIATÆ, ſo much recommended by Mr. Juſtamond in the cure of the milk breaſt. In the early ſtage of this diſeaſe, the LOTIO AMMONIÆ ACETATÆ is recommended. ℞ aquæ ammoniæ acetatæ ſps. vin. rectif. aq. diſtillatæ āā ʒ iv. m. Some prefer the aquæ ammonia acetata alone; or, a fomentation may be uſed, which generally ſucceeds, made of a decoction of poppy heads, in a pint of which let there be diſſolved an ounce of crude ſal ammoniac. If the *inflammation* does not yield to this management in four or five days at the moſt, the beſt method is to encourage a ſuppuration without delay. See ABSCESSUS PECTORIS, and MAMMÆ, N° 31. &c. Bell's Surgery, vol. v. p. 396.

8. INFLAMMATIO MEDIASTINI; called *Mediaſtina*; INFLAMMATION *of the* MEDIASTINUM.

The cauſe is the ſame as in the pleuriſy, and the ſymptoms are alſo in many inſtances the ſame. The pain ſtrikes obliquely from the ſternum through the breaſt to the back; there is a difficulty of breathing, and cough, attended ſometimes with a ſpitting. Theſe ſymptoms are not ſo violent as in a pleuriſy, nor is the pain on inſpiration ſo much increaſed, or the inflammatory diatheſis ſo great. The cure is the ſame as in a pleuriſy; but ſuppuration is very difficultly avoided, and when it happens it is always fatal.

9. INFLAMMATIO MESENTERII. *Enteritis* & *Peritonitis Meſenterica*. INFLAMMATION *in the Meſentery*. See PERITONITIS.

When the meſentery is inflamed, there is a languid flow fever, without any thirſt or other violent ſymptom, a loſs of appetite, a ſenſe of tenſion, and weight below the ſtomach, without much hardneſs, and only diſcoverable by preſſing upon it. This tenſion is without much pain, becauſe the meſentery hath but a ſmall degree of ſenſation. The ſtools are often chylous, and ſucceeded by a diſcharge of thin ichor, without any ſenſe of pain; ſometimes pure and unmixed, and ſometimes mixed with the fæces. Theſe ſymptoms are mild and gentle, if the meſentery only is inflamed; but if the liver, ſpleen, or any of the inteſtines are alſo affected, they are more violent.

Theſe *inflammations* generally terminate in abſceſſes, or bring on a corruption of the meſentery; the morbific matter is alſo ſometimes tranſlated to other parts, without being removed from the habit; hence the diſorder often recurs, and ſo continues for years; in which caſe ſometimes the fever returns, and is ſometimes changed into a colic.

When the preſence of this kind of *inflammation* can be diſcovered, the method of cure will be the ſame as that for an inflamed liver or ſpleen.

10. INFLAMMATIO MUSCUL. ABDOMINIS. INFLAMMATION *of the Muſcle of the Belly*. Named by VOGEL, MYOCOILITIS.

When theſe parts are inflamed, the ſkin over them is greatly ſtretched, ſo that it cannot be pinched up with the fingers; and if they are ſwelled, the figure of the reſpective muſcle is preſerved; the inflamed muſcle is very hard, and more ſo as it tends to ſuppurate, there is generally more or leſs of fever; during any action of the diſeaſed muſcle the pain is conſiderably augmented, as in caſe of ſneezing, ſtraining at ſtool, or even in breathing.

The rheumatiſm is ſometimes fixed in theſe muſcles; they alſo ſuffer from preſſure, as when patients with a ſtone in their bladder ſeek for relief by reſting their weight upon their belly when it is placed upon ſome hard body, &c.

This complaint ſhould be diſtinguiſhed from a colic, an inflammation in the liver, or any of the ſubjacent viſcera.

If this kind of *inflammation* terminates in an abſceſs, and it is diſcharged inwardly, it proves fatal. And if any tendency to a mortification appears in theſe muſcles, the iſſue is to be dreaded.

If the hardneſs is conſiderable, and a throbbing pain is perceived, an abſceſs is forming, and ſhould be encouraged with all ſpeed, and if poſſible the diſcharge ſhould be made outwardly. Heurnius obſerves that theſe muſcles have ſo thick a membrane, that tumors there require opening, and if the opening is neglected, they ſometimes turn to a ſtony hardneſs. Hildanus ſays, theſe tumors ſhould be opened more early than is uſually in other inſtances, in order to a diſcharge outwardly being ſecured. For the matter is apt to paſs betwixt the muſcles, forming ſinuous ulcers, as bandages cannot well be applied to prevent ſuch effects. The cold air particularly offends in caſes of this kind; hence, when the opening is made, or the ſubſequent dreſſings are applied, the air in the room ſhould be moderately warm.

As a ſuppuration is ſo dangerous, and at the beſt is ſo very difficultly managed, to remove the *inflammation* by the ſpeedieſt methods, before a tendency to the forming of an abſceſs can be manifeſted, will neceſſarily appear to be the moſt eligible method. Bleeding, then, with purging, and ſuch other means as are uſed in other inſtances of *inflammation* in the external parts, ſhould be applied, and ſteadily purſued.

11. INFLAMMATIO OCULI. INFLAMMATION *of the Eye*. See OPHTHALMIA.

12. INFLAMMATIO OESOPHAGI. INFLAMMATION *of the Oeſophagus*.

This is ſometimes a ſymptom attending a quinſy. See ANGINA. Beſides other general methods of cure for *inflammations*, waſh the mouth frequently with the following, and let a little of it be gradually ſwallowed as often. ℞ Albuminis ovi (bene conquaſſati ad liquorem aquoſum) ʒ ii. aq. roſar. & ſyr. moror āā ʒ i. nitri purificati, gr. xv. m.

13. INFLAMMATIO OMENTALIS. See PERITONITIS.

14. INFLAMMATIO OSSIUM. INFLAMMATION *of the Bones*.

The blood-veſſels carried from the perioſteum to the bones, run between their laminæ, whilſt others paſs through particular perforations to the diploe of the cranium, and the marrow in the bones: hence the ſeparation of the corrupted parts, and the reſtitution of ſuch as are loſt. *Inflammation* may therefore be ſeated in the bones, whence ariſe violent pains, obſtinate, and ſeeming to the patient to be deep-ſeated. Hence alſo a ſpina ventoſa, &c. See INFLAMMATIO *perioſtei*, N° 16.

15. INFLAMMATIO PERICARDII: *Pericarditis*: INFLAMMATION *of the Pericardium*.

Dr. Cullen conſiders this as ſynonymous with *carditis*, or *Inflammatio cordis*; and ſays, "the pericardium has been known often to be inflamed, without any other ſymptoms attendant, except thoſe of a peripneumony." But it muſt be obſerved, that the pain ſeems to be deeper ſeated, and is not ſo much increaſed upon inſpiration. If a cure is attempted, proceed as in the pleuriſy or peripneumony.

16. INFLAMMATIO PERIOSTEI. INFLAMMATION *of the Perioſteum*.

Beſides the other uſual cauſes of *inflammation* in other parts of the body, the venereal diſeaſe and the ſcurvy are cauſes of *inflammation* in this part. The venereal poiſon is a frequent cauſe, when the perioſteum within the bone is the ſeat of the diſorder.

The external perioſteum, that is, the membrane which covers the bone, and lies betwixt it and the fleſh; or the internal perioſteum, that is, the membrane which lines the cavities of the cylindrical bones, and which is ſituated betwixt them and the marrow contained in them.

When the *external perioſteum* is inflamed, a deep-ſeated pain and heat is felt, and ſometimes a pulſation; and, when the part is not covered with much fleſh, the pain will be augmented by preſſure; muſcular motion, however, increaſes the pain.——That the *inner membrane* is the ſeat of the *inflammation*, is ſuggeſted from the want of pain on preſſure, or on moving the muſcles of the reſpective part, by not perceiving any pulſation; by receiving

no

no relief from any poſition of the pained part; and, *particularly, by a ſenſation like the ſplitting of the bone from within outwardly.*

Inflammations in both membranes of the bone proceed from the ſame cauſes, produce the ſame effects with reſpect to the part of the bone they adhere to, and terminate in the ſame manner, viz. in an abſceſs or a gangrene; but when the inner membrane is affected, and becomes gangrenous, the caſe is always deſtructive of the whole marrow and bone.

If *inflammations* of theſe kinds are not ſpeedily removed, the bone will be injured, and the perioſteum upon the injured part deſtroyed; and it cannot be renewed until the bone exfoliates, and is renewed; during which time the incumbent parts will be irritated by an acrid ſanies, by which malignant and incurable ulcers are often produced, eſpecially if it happens where a large portion of fleſh covers the bone, and hinders a ſafe incition on the part.

In general the cure is, as in other *inflammations*; but the particular intention will be to carry the peccant matter outwards by fomentations and incitions. As a ſuppuration near the bone is to be dreaded, endeavours to draw the diſorder to the external part muſt be attempted, if it cannot be diſcuſſed by bleeding, ſtrong purges, &c. To invite, to the external parts, ſoftening fomentations and poultices may be applied: but if theſe methods fail, the only remaining one is to cut down through the fleſh to the bone, if the part admits of it.

When an abſceſs begins to form itſelf, it is known, and treated, as in the article Abscessus *Perioſtei*, N° 35.

Theſe caſes generally end in amputation.

17. Inflammatio Recti. Inflammation *of the Rectum.*

It is rarely ſo acute as that of any of the ſmall inteſtines; nor ſo apt to produce ſmallneſs of the pulſe, or coldneſs of the extremities, or to affect the ſtomach; nor is there ſuch a ſtricture as to render the inteſtines impervious. The cure is the ſame as in *inflammation* in any of the other inteſtines, except that purgatives are uſed with advantage, and laxatives ought always to be employed.

18. Inflammatio Renum. See Nephrites.

19. Inflammatio Splenis, vel Lienis. Inflammation *of the Spleen*; called Splenitis; alſo *Pleuritis Splenica.*

Dr. Cullen places this as a genus of the CLASS Pyrexia, and ORD. Phlegmasiæ; and defines it febrile affections, attended with tenſion, heat, tumor of the left hypochondrium, and pain increaſed on preſſure, without ſigns of a nephritis.

Lommius obſerves, that this diſorder rarely happens; that when it does, there is a hard and a throbbing tumor, a pain in the left hypochondrium, a continual violent fever, extreme heat, unquenchable thirſt, the tongue is covered with a blackiſh mucus, a total loſs of appetite, with a difficult, and, as it were, imperfect reſpiration, like that of children when they ſob through anger. Aretæus further ſays, that the pain attending *inflammation* in the ſpleen is not conſiderable. If the diſtemper be not accompanied by an ulcer, but continues for a long time, the patients have an averſion to food, are ſwollen, have a bad habit, and a diſagreeable aſpect, and have many round, livid, hollow, foul, and incurable ulcers over the whole body, but eſpecially on the legs, which entirely emaciate and kill the patients; but ſuch as have only a ſmall, hard, and ſcirrhous tumor, feel little or no pain, and conſequently live longer. But if the diſtemper overpowers the patient, a dropſy, a conſumption, or a colliquation of the whole body, are the certain conſequence.

The general methods of removing other violent internal *inflammations* muſt be uſed in this caſe. If the *inflammation* can be diſcuſſed, the patient is ſafe; but if a ſuppuration, or any other kind of termination follows, the conſequence is fatal ſooner or later.

20. Inflammatio Testium. See Henria Humoralis.

21. Inflammatio Uteri. Inflammation *of the Womb*, called alſo, Hysteritis; Metritis.

Dr. Cullen places this genus of diſeaſe in the CLASS Pyrexiæ, and ORD. Phlegmasiæ; and defines it, febrile affections, attended with heat of the hypogaſtric region, tenſion, tumor, and pain; the os uteri painful on being touched, and vomiting.

Women, after-child-birth, when the lochia are impeded, are the moſt frequent ſubjects of this complaint.

The cauſes, beſides the common ones of internal *inflammations* in general, are tearing, bruiſes, external ſtimuli, obſtructed menſtrua, or obſtructed lochia. It often happens after abortion, and child-birth, eſpecially when the lochia are prevented by cold, or other cauſes, and is then attended with ſymptoms different from thoſe which appear when an uterus, not lately impregnated, is inflamed.

In the firſt caſe there is a pain at the bottom of the belly, which, for the moſt part, is neither throbbing nor conſtantly acute; the pulſe is frequent, eſpecially after child-birth, often ſmall, ſometimes irregular; in ſtrong habits, and after early abortions, hard; the patient is affected with delirium, a ſubſultus tendinum, and the other ſymptoms of irritation; the womb gangrenes and mortifies, and the patient ſinks. *In the ſecond*, the pain is more conſtant, bounded, and throbbing; the pulſe is hard, full, and ſtrong, and other ſymptoms of general *inflammation* attend; or if the diſeaſe riſes to a greater height, the pulſe is ſmall and frequent, the ſymptoms of irritation attend, and ſuppuration is more liable to happen.

In both, as different parts of the womb are affected, there is a ſtrangury, or a ſuppreſſion of urine; the little that is diſcharged, is fetid and hot, or a teneſmus attends, with a pain in going to ſtool; or there is pain in moving the lower extremities, or ſwelling, with heat, to be felt by introducing a finger up the vagina, the os tincæ being ſhut; univerſal reſtleſſneſs, thick urine, pain upon external preſſure, the belly is tenſe, a red ſtain extends up to the navel, and turns black when fatal; and, if it occurs in an impregnated uterus, an abortion follows.

It often happens that the woman can only lie on her back; and on turning to either ſide, ſhe feels a painful heavy maſs fall to that ſide; and, at the ſame time, an exceſſive pain in the loins, kidnies, and groin, of the oppoſite ſide. The pains excited by *inflammation* in the womb, ſometimes extend to the inſide of the thighs when the woman turns on her ſide, or it is felt in the loins.

This diſorder may be removed by a ſpontaneous eruption of the menſes, or of the lochia; or, after an abortion, or child-birth, by the patient's falling into a conſtant, equal, gentle, long-continued ſweat; or it may terminate in an abſceſs, or a mortification, both which laſt are almoſt always fatal. Sometimes a metaſtaſis proves a means of relief.

Bleeding, however uſeful in moſt *inflammatory* diſorders, in this particular one, though not wholly uſeleſs, yet, if too freely uſed, only increaſes the weakneſs, without leſſening the *inflammation.*

When *inflammation* attacks a womb not lately impregnated, the common remedies uſed in internal *inflammations* are to be employed, regard being had to whether the attendants are an *inflammatory* diatheſis, or the ſymptoms of irritation.

In abortions and *labours*, where the patient hath not been much weakened, if the pulſe is hard, and not very frequent, the loſs of blood by the arm may be followed with advantage; but it rarely happens that this evacuation can be repeated; therefore, the general method of cure will always depend on relaxants, ſuch as the pulv. antim. and hauſt. ſalin. taking care that they do not produce a purging. To theſe, as neceſſary, may be added, anodyne and antiſpaſmodic fomentations and poultices.

In delicate or feeble conſtitutions, after child-birth, and where there is no hardneſs, but great frequency of the pulſe, this diſorder too often proves fatal. All that can be done is to keep the patient in bed, moderately warm, exciting, if poſſible, a gentle conſtant ſweat by farinaceous decoctions, in ſmall quantities at a time, but frequently repeated, and applying fomentations and poultices.

Perſpiration may be free; the other uſual evacuations by urine and ſtool may be moderately promoted; *but all very extraordinary ones are dangerous.*

Always guard againſt preſſure on the affected part, whether from any thing external, from urine in the bladder, or from fæces in the rectum. Urine, if neceſſary, may be drawn off with the catheter, and the bowels may be emptied by repeated clyſters, which ſhould be watery.

Bliſters generally quicken the pulſe too much, and

ſeem not ſo uſeful in this caſe as in ſome other local *inflammation*.

No diſorder requires more care to keep the patient compoſed in mind, and ſtill in bed.

Until the fever and ſpaſms abate, the ſtimulant aromatics and emmenagogues will be improper; *indeed the lochia are rarely promoted by them at any time.*

If pain continues, notwithſtanding the uſual treatment, opiates may ſometimes be given with ſucceſs, as is directed in an *inflammation* of the inteſtines.

If a ſuppuration comes on, endeavour to procure an exit to the pus as ſoon as poſſible, which, when it points to the perinæum, may be ſometimes managed.

For what hath been taught by the ancients, on the ſubject of *inflammation*, ſee in Fernelius; alſo Mageniſe on Inflammation; and Aikin's Obſervations on the external Uſe of Preparations of Lead, and on Inflammation, as it conſtitutes particular diſorders; likewiſe Fordyce's Elements of the Practice of Phyſic, part the ſecond.

22. Inflammatio Vaginæ. Inflammation *of the Vagina.*

This diſeaſe may occur from any cauſe which produces inflammation in other parts from irritation, and muſt be cured by the ſame means; but emollient, ſaturnine, and opiated injections are here particularly uſeful after proper depletion. But this accident ſometimes happens after delivery. It is occationed by the head of the child being long retained in the pelvis.

If the ſwelling and *inflammation* is not very great, they are generally removed by the diſcharge of the lochia; but, if the internal membrane of the vagina is inflamed, emollient injections muſt be thrown up from time to time, and a piece of prepared ſponge ſhould be introduced, to prevent its coaleſcing. The ſponge may be thus prepared: take a piece of a proper ſize for keeping the vagina open, when it is expanded; ſoak it in warm water; then roll it tight from end to end with a ſtring; cut off any irregularities, or hard lumps, and lay it to dry; when dry, take off the ſtring; the ſponge being then ſtiff, it will remain in that form; anoint it with lard, and introduce it into the vagina, the moiſture of which will expand it.

If the preſſure on this part was ſo long continued as to obſtruct the circulation in it, a mortification will enſue, which may either be total or partial: if it is total, the patient will die; if partial only, the mortified parts will ſlough off. This may be known to be the caſe, if the woman complains of great pain after delivery, a fetid ſmell, and a diſcharge of ſharp ichor at firſt from the vagina, then pus and matter. When this is the caſe, emollient fomentations may be thrown up from time to time; doſſils of lint may be dipped in ſome proper balſam, and applied to the parts to deterge and heal them: and when the ſloughs are all caſt off, great care ſhould be taken to prevent the vagina from growing together, either by introducing doſſils of lint, or pieces of ſponge into it.

23. Inflammatio Ventriculi. Inflammation *of the Stomach*; called Gastritis; alſo *Cardialgia Inflammatoria.*

Dr. Cullen places this as a genus of the CLASS Pyrexiæ, and ORD. Phlegmasiæ; which he defines, a typhodal pyrexy, attended with anxiety; heat and pain in the epigaſtric region, increaſed on taking any thing into the ſtomach; a propenſity to vomit, and immediately throwing up what is taken; alſo a hiccough. He obſerves two ſpecies.—1ſt. *Phlegmonodea*, when it happens from internal cauſes. In this ſpecies, the pain is acute, and the febrile affections violent.—2d. *Erythematica*, when, from external cauſes, the pain and febrile affections are of a milder nature, with an eryſipelatous inflammation appearing in the fauces. To theſe he adds the following comment: That he is certain, from many obſervations, that of the gaſtritis, as well as the enteritis, there are two ſpecies; of which one is phlegmonous, and the other eryſipelatous; and, therefore, he has recited them; though he confeſſes, that the ſymptoms of the eryſipelatous inflammation of the ſtomach, and more ſo thoſe of the inteſtines, are often obſcure and uncertain; but, of theſe he has ſpoken, that poſterity may inveſtigate theſe ſubjects more diligently.

This diſeaſe is alſo called inflammatory colic.

It is produced from nearly the ſame cauſes as the *inflammation* of the inteſtines, except introſuſception, and hardened fæces, and it is more liable to be excited by acrid ſubſtances.

Many of the ſymptoms of an *inflammation* in the inteſtines attend. When the ſtomach is inflamed, there is a pungent, fixed, burning pain in it, with a pulſation, diſtenſion, and tumor; the mildeſt things that are ſwallowed increaſe this pain, and at the ſame time bring on ſickneſs, vomiting, purging, or hiccoughing; there is a continual uneaſineſs about the precordia, a difficulty of breathing and ſwallowing, a pain in ſneezing, the pulſe is ſmall, quick, hard, and intermitting, the extremities are cold; there are clammy ſweats and faintings. When a wound in the ſtomach is the cauſe, there is frequently little or no pain, although all the other ſymptoms take place, and the patient is cut off.

Inflammation in the ſtomach muſt be diſtinguiſhed from a cardialgia, and from an *inflammation* in the convex part of the liver.

This diſorder is of the moſt acute kind; and unleſs the moſt powerful means of relief are immediately employed, it proves fatal.

In general, the ſame method of cure which is propoſed when the inteſtines are inflamed, muſt be purſued in this. The principal difference is, in this internal malady, medicines can rarely be adminiſtered, on account of the great irritability of the ſtomach.

Bleeding is almoſt the only dependence, and it muſt be freely uſed, notwithſtanding the lowneſs of the pulſe, and repeated till the pulſe riſes.

From the weakneſs of the patient, cordials may ſeem to be indicated, *but they are extremely injurious in this inſtance.*

Whatever is given to drink, ſhould neither be cold nor hot, but gently warmed. Demulcents and emollients are the propereſt for the common drink, with ſmall portions of nitre, or of the ſob of currants.

Emollient clyſters, with nitre, ſhould frequently be adminiſtered, and they ſhould be injected in large quantities, that they may act as fomentations, and as nutritives.

Bliſter the region of the ſtomach, particularly over the part aggrieved.

Gentle anodynes, ſuch as ſolution of gum arabic, or ſpermaceti made into draughts, in each of which may be gr. x. of nitre, and from iii. to v. drops of tinct. opii. Theſe may be repeated as often as ſeems neceſſary for moderating the pain, and checking the vomiting. But the violence of the ſymptoms ſhould be firſt abated.

Bladders of hot water ſhould be kept conſtantly upon the region of the ſtomach. *The legs may frequently be put into warm water*, and *ſinapiſms* may be applied to the feet.

If acrid poiſon, or an exceſs of eating was the cauſe, a *gentle emetic may be ventured on*; but on all other occaſions avoid this kind of remedy.

In caſe of an abſceſs burſting, give the balſ. capivi ver. ʒ i. three times a day in a draught of milk, and let a milk diet be enjoined.

The above is the phlegmonic *inflammation*, but the following, viz. the *erythematic inflammation of the ſtomach*, moſt frequently occurs. It often comes on without at firſt manifeſting its preſence; but ſometimes it is evident by the affection of the ſtomach ſpreading into the œſophagus, and appearing in the pharynx, as well as on the whole internal ſurface of the mouth. When, therefore, an erythematic *inflammation* affects the mouth and fauces, and when, at the ſame time, there ſhall be in the ſtomach an unuſual ſenſibility to all acrids, with a frequent vomiting, the ſtomach is affected with the ſame *inflammation*. Even, when no *inflammation* appears in the fauces, yet, if a pain be felt in the ſtomach, if there be a want of appetite, an anxiety, frequent vomiting, an unuſual ſenſibility with reſpect to acrids, ſome thirſt, and frequency of pulſe, we may ſuſpect the preſence of this diſeaſe in the ſtomach. Erythematic *inflammation* often ſpreads from place to place on the ſame ſurface; occaſioning diarrhœa in the inteſtines, and vomiting in the ſtomach.

In order to the cure, the treatment will vary according to the cauſes, &c. When an acrid matter taken in by the mouth is the cauſe, this is to be evacuated by large draughts of warm mild liquids: then ſome general demulcent ſhould be employed; or, if the nature of the acrimony, and its proper corrector be known, it ſhould be adminiſtered. If ſymptoms of *inflammation* are manifeſt, according to their degree, let bleeding, bliſtering

on

on the region of the ſtomach, fomentations on the belly, and frequent emollient laxative glyſters, be uſed. But as the affection often ariſes in putrid diſeaſes, &c. ſo in theſe caſes, bleeding cannot be admitted; all that can be done in ſuch circumſtances, is to avoid irritation, and to throw into the ſtomach as much of acids, and of aceſcent aliments, as it can bear. See Cullen's Firſt Lines, vol. i. p. 356, &c. ed. 4.

24. Inflammatio Vesicæ. Inflammation *of the* Bladder, called Cystitis.

Mezery names it *cyſtiphlogia*. Dr. Cullen places this genus of diſeaſe in the CLASS Pyrexiæ, and ORD. Phlegmasiæ; and, defines it, a febrile affection, attended with pain and tumor of the hypogaſtric region; frequent and painful micturition, or iſchury and teneſmus. He obſerves two ſpecies. 1. Cyſtitis à cauſis internis, when it proceeds from internal. 2. à cauſis externis, from external cauſes.

It is produced by the uſual cauſes of internal *inflammation*; an *inflammation* in its internal coat is ſometimes cauſed by a ſtone lodged in it.

The diagnoſtics are as follow; with a fever, a preſſing and burning pain is perceived in the region of the bladder above the pubes, and in the perinæum; ſometimes a redneſs is perceived in theſe parts, though the pain is deep ſeated. If the *neck* be the part affected, there is a retention of urine, with a conſtant ſtimulus in its evacuation; —if the *fundus*, there is a continual dribbling, with great efforts to throw out a larger quantity at a time, which the patient conceives to be contained in a bladder. Frequent attempts to expel the fæces, with which the rectum appears to the patient to be always loaded; theſe increaſe the pain very much, particularly when any fæces are actually contained, and eſpecially if they are hard. The pulſe is frequent and hard, and the extremities cold: there is great anxiety, reſtleſſneſs, ſickneſs, vomiting, delirium, and other ſymptoms of irritation.

This diſorder uſually terminates ſoon, either in a recovery or death; frequently the latter. A gangrene comes on, by which the pain is removed; but the other ſymptoms continue until death delivers the miſerable ſufferer.

This diſorder may paſs off by an increaſed ſecretion of mucus from the internal membrane, or by a metaſtaſis, or by ſuppuration; in which laſt caſe the matter may be diſcharged into the cavity of the bladder, and paſs off with the urine; or, into the cellular membrane, and ſo paſs externally through the perinæum; or laſtly, into the cavity of the abdomen, where it proves fatal. The ulcer in the bladder and perinæum are difficult of cure.

Inflammation in the external coat of the bladder ſhould be diſtinguiſhed from that of the internal; and *inflammation* in any part of the bladder ſhould be diſtinguiſhed from *inflammation* in the adjacent parts, alſo from that retention of urine which proceeds from other cauſes.

In order to the cure, bleed according to the ſtrength of the patient, and the violence of the ſymptoms.

Relaxant medicines, ſuch as the pulv. antim. and hauſt. ſalin. ſhould be given as early as poſſible, and repeated as often as is convenient; for help muſt be ſpeedy and powerful, or death ſoon puts a ſtop to the means.

Laxative and cooling clyſters ſhould frequently be injected; or, if theſe cannot be complied with, the cooling ſaline purges may be given by the mouth, and repeated ſo as to keep the bowels lax.

If the urine is retained, decoctions of mucilaginous herbs ſhould be freely drank; or, if need be, *the catheter may be uſed*, though much care is required in its introduction.

If, notwithſtanding due evacuations, *ſpaſmodic contraction* with much pain continues, *opiates in ſmall doſes*, ſuch as tinct. opii gt. iii. may be repeated at proper intervals.

If a redneſs appears externally, apply an *anodyne emollient cataplaſm*, and cover it with bladders of warm water. If no appearance of *inflammation* is obſerved externally, rub the region of the bladder, and alſo the perinæum, *with the linim. ammoniæ*, Ph. Lond. to excite *inflammation* in the ſkin.

The patient may be placed in the warm bath two or three times the day.

If by uncertain horrors, and the departure of ſome of the ſymptoms of *inflammation*, a ſuppuration is ſuſpected, haſten its progreſs, in order to as ſpeedy a diſcharge of the matter as poſſible, which, when evacuated, proceed as in caſes of an ulcer in the urinary paſſage.

25. Inflammatoria Febris. See Synocha, Inflammatory *Fever*.

Dr. Cullen places it as a genus under the CLASS Pyrexiæ, and ORD. Febres; and as a ſynonyme with Synocha, which he defines heat, greatly encreaſed; a frequent, ſtrong, and hard pulſe, high coloured urine; the functions of the ſenſorium ſomewhat diſturbed. This fever is the *continua non putris* of Boerhaave; and the *febris acuta ſanguinea* of Hoffman.

When an ardent fever is attended with an *inflammatory* diatheſis, or when actual *inflammation* affects any part during the preſence of a fever, the patient is ſaid to labour under one of an *inflammatory* kind: but according to the different parts on which the *inflammation* is ſeated, different denominations are given to the diſorder, as when it is ſeated in the throat it is called angina, &c.

In ſtrong conſtitutions it is produced by any of the cauſes by which fever may be excited. A prediſpoſition in ſome particular part, is the general cauſe of a partial *inflammation* affecting the lungs of one, the pleura of another, &c. When a fever attacks where this prediſpoſition prevails, the irritation, which is the immediate cauſe of all *inflammations*, acts with moſt power, and there moſt readily produces its effects. In ſome inſtances the fever precedes the *inflammation*, in others, the former is the conſequence of the latter.

The cauſes of *inflammatory* fevers are, in general, whatever are the uſual cauſes of fever, and of *inflammation* ſeparately.

The ſymptoms in the beginning are often ſlight, but they are ſoon followed by a violent hot fit, in which all the ſymptoms indicating ſtrength appear in a great degree, the whole fever being often entirely terminated by topical *inflammation*, or an hæmorrhage, leaving only the *inflammatory* diatheſis; or in a few periods the patient is deſtroyed by the ſtrong action of the veſſels immediately affecting the brain, or depriving him entirely of ſleep, and, in conſequence of that, cauſing delirium, violent convulſions, and death. If none of theſe things happen in the ſecond week, the ſtrength diminiſhes, and the fever goes off with a perfect criſis, or imperfect critical ſymptoms appear after each exacerbation; theſe becoming gradually leſs, the white cruſt on the tongue falls off, but ſometimes leaves little exculcerations behind. *If a local inflammation* begins with the ſymptoms of the firſt ſtage of fever, and they remain after the pain hath ariſen, when the *inflammation* is diminiſhed by any natural or artificial means, it often happens that the fever continues, increaſes, and is attended with weakneſs until the patient dies.

When a pleuriſy, or other partial *inflammation*, ariſes in the hot fit of a fever, it is preceded by horror and rigor, cold, quickneſs of the pulſe, and ſeveral of the other ſymptoms of the firſt ſtage; theſe are followed by the ſymptoms of the next ſtage; together with thoſe of the *inflammatory* diatheſis; after which the pain, and other ſymptoms of the *inflammation* in the ſide, or part affected, take place; and the ſymptoms of the firſt ſtage of fever commonly leave the patient, thoſe of the *inflammatory* diatheſis continuing. Sometimes the ſymptoms of the firſt ſtage of fever are relieved. In this caſe anxiety about the præcordia, tranſparent urine, particular evening paroxyſms, &c. continue along with the *inflammations*, produce a different progreſs and termination of the diſeaſe, and require a variety in the treatment.

The indications of cure are, *firſt*, to reduce the fever by bleeding in the beginning, and repeating it as required. *Secondly*, to remove the increaſed irritability: and, *thirdly*, to promote the ſecretions and excretions.

The diet ſhould be chiefly boiled oats, or barley, or ſubacid fruits; the drink ſhould be taken frequently in ſmall quantities. It may conſiſt of whey, barley-water, water acidulated with vinegar, or the jelly of currants, or other ſuch like fruits. It may be drank warm or cold as is moſt agreeable to the patient. Half a dram of nitre may be diſſolved in every pint of liquor in which no acid juice is mixed.

Let the room be frequently filled with a pure cool air.

If the patient hath any ſtrength, let him be made to ſit up a quarter or half an hour in a day. This leſſens the fever, head-ach, and delirium; but when a ſalutary ſweat comes on, he may lie ſtill. The ſheets may be changed every two or three days, ſo that all putrid or other morbid ſteams may be removed.

For the moſt part, the cure depends in a great meaſure

on

on a due diſcharge of blood. The bleeding may be repeated in many inſtances to a third or fourth time; but when on the firſt bleeding, the blood is rather florid than ſizy, and no relief follows it, the operation ſhould cautiouſly be repeated. Purging alſo, and the ſame general treatment as in an ardent fever, is to be urged in thoſe of the *inflammatory* kind.

If the blood is ſizy, the ſal or liquor c. c. and the ſal ſuccin. purificati, may be repeated at proper intervals. Nitre with camphor are alſo particularly uſeful, or Clutton's febrifuge ſpirit may be given in every draught of the patient's drink.

To promote the ſecretions and excretions, antimonial preparations are to be preferred. The *firſt doſe* ſhould be given in a ſufficient quantity to excite a gentle pukeing: the *next two or three doſes* ſhould keep up a naufea; and ſmall quantities of an opiate, ſuch as the tinct. opii, gt. iii. ad vi. or a proper quantity of the elix. opii camph. ſhould be added. Theſe relax and moderate the irritation preternaturally excited in the conſtitution. In caſes which do not well admit of bleeding, as ſoon as the heat is ſo abated, that a diaphoretic may be admitted, the pulv. rad. contrayerv. may be mixed with ſpermaceti, and to theſe the ſal c. c. may be added, from gr. xv. to ʒ i. in each doſe; though, if there is a very looſe texture obſerved in the blood, acids, with warm cordials, are to be preferred.

After due evacuations by bleeding and purging, if the pain is conſiderable, apply a bliſter over the pained part, when the *inflammation* is local. In all kinds of *inflammatory* fevers, when the patient becomes languid, or, perhaps, comatoſe in the advanced ſtate of the diſorder, bliſters are one of the principal kind of helps; cordials, as camphor, ſaffron, &c. may accompany them.

If when the fever is nearly gone, the delirium, for want of ſleep, continues, the ſyſtem being greatly weakened, after all other means of procuring ſleep are tried in vain, opiates may ſometimes be given with advantage.

Let the patient's mouth and throat be frequently waſhed; his hands and feet bathed in luke-warm water; and fomentations be applied to thoſe parts where the greateſt number of veſſels lie expoſed to the touch.

Sometimes, after the *inflammatory* diatheſis is conquered, this kind of fever ends in a putrid one, in which caſe it is to be treated in the ſame manner as though a putrid fever had attacked the patient at the firſt.

See Fordyce's Elements of Phyſic, part ii. Fordyce's Enq. into the Cauſes, &c. of putrid and *inflammatory* Fevers.

INFLATIO. See EMPHYSEMA.

INFLUENZA. Whilſt it was the general opinion of philoſophers, that all things upon earth were governed by the heavens, phyſicians imputed the epidemical catarrhous ſemipeſtilential fever to the influence of the ſtars; whence, the Italians gave it the name of *influenza*. From Sydenham upwards to Hippocrates, it was known and is mentioned by the name of *catarrhalis febris epidemica*: but Sydenham chiefly calls it *tuſſis epidemica*. Since Sydenham's time it hath been variouſly named, but is now generally known by the name of *influenza*.

Dr. Cullen places this diſeaſe in his Noſology, as a variety of his catarrhus à contagio.

In the year 1673, Sydenham treated of the nature and cure of the putrid fever, by him called *variolus fever*; he found that this fever returned every ſummer afterwards, and was ſucceeded by the *cholera morbus*, and *bilious fever*, (by him called the new fever). In 1675, theſe fevers were attended by a new ſymptom, viz. an uncommon degree of *ſtupor*, which frequently ended in a *coma*, and was for that reaſon by Sydenham called the comatous fever. In the beginning of November of the ſame year, this fever was complicated with a *cough*, and was deſcribed by Sydenham pretty nearly as follows:

"This fever proceeded in this manner during the autumn, ſometimes ſeizing the head, at others the bowels, every where raging under the appearance of ſymptoms peculiar to thoſe parts, till the end of October; when the weather, which till now had continued in a manner as warm as ſummer, changed ſuddenly to cold and moiſt; whence catarrhs and coughs became more frequent than I remember to have known them in any other ſeaſon. But it is of moſt moment to obſerve, that the ſtationary fever of this conſtitution uſually ſucceeded theſe coughs, and hence became more epidemic, and likewiſe varied ſome of its ſymptoms. For whereas ſome little time before, it attacked the head and bowels, now it chiefly ſeized the lungs and pleura, whence aroſe peripneumonic and pleuritic ſymptoms; though it was ſtill preciſely the ſame fever that began in July 1673, and continued without any alteration of its ſymptoms till the riſe of theſe catarrhs.

"Theſe catarrhs and coughs continued to the end of November, after which they abated, but the fever ſtill remained the ſame as it was before the catarrhs appeared; though it was neither quite ſo epidemic, nor accompanied with quite the ſame ſymptoms, theſe depending accidentally upon the catarrhs.

"In 1675, the ſeaſon having continued unuſually warm, like ſummer, till towards the end of October, and being ſuddenly ſucceeded by cold and moiſt weather, a cough became more frequent than I remember to have known it at any other time; for it ſcarce ſuffered any one to eſcape, of whatever age or conſtitution he were, and ſeized whole families at once; nor was it remarkable only for the numbers it attacked (for every winter abundance of perſons are afflicted with a cough), but alſo on account of the danger that attended it; for as the conſtitution, both now and during the preceding autumn, eminently tended to produce the epidemic fever above deſcribed, and as there was now no other epidemic exiſting, which by its oppoſition might in ſome meaſure leſſen its violence, the cough made way for, and readily changed into the fever. In the mean while, as the cough aſſiſted the conſtitution in producing the fever, ſo the fever on this account attacked the lungs and *pleura*, juſt as it had affected the head even the week preceding this cough; which ſudden alteration of the ſymptoms, occaſioned ſome, for want of ſufficient attention, to eſteem this fever, an eſſential pleuriſy or peripneumony, though it remained the ſame as it had been during this conſtitution, i. e. ſince July 1673.

"For it began now as it always did, with a pain in the head, back, and ſome of the limbs; which were the ſymptoms of every fever of this conſtitution, except only that the febrile matter, when it was copiouſly depoſited in the lungs and *pleura*, through the violence of the cough, occaſioned ſuch ſymptoms as belong to thoſe parts. But, nevertheleſs, as far as I could obſerve, the fever was the very ſame with that which prevailed to the day when this cough firſt appeared: and this likewiſe the remedies to which it readily yielded plainly ſhewed. And though the pungent pain of the ſide, the difficulty of breathing, the colour of the blood that was taken away, and the reſt of the ſymptoms that are uſual in a pleuriſy, ſeemed to intimate that it was an eſſential pleuriſy; yet, this diſeaſe required no other method of cure than that which agreed with the fever of this conſtitution, and did no ways admit of that which was proper in the true pleuriſy, as will hereafter appear. Add to this, that when a pleuriſy, is the original diſeaſe, it uſually ariſes betwixt ſpring and ſummer; whereas the diſtemper we now treat of, begun at a very different ſeaſon, and is only to be reckoned a ſymptom of the fever which was peculiar to the current year, and the effect of the accidental cough.

"Now, in order to proceed in a proper manner to the particular method of cure, which experience ſhews to be requiſite both in this cough and in thoſe which happen in other years, provided they proceed from the ſame cauſes, it is to be obſerved that the effluvia which uſed to be expelled the maſs of blood by inſenſible perſpiration, are ſtruck in, and thrown upon the lungs, from the ſudden ſtoppage of the pores by cold, by irritating the lungs, immediately raiſe a cough; and the hot and excrementitious vapours of the blood being hereby prevented from paſſing off by perſpiration, a fever is eaſily raiſed in the maſs; namely, when either the vapours are ſo copious that the lungs are unable to expel them, or the inflammation is increaſed by the adventitious heat ariſing from the uſe of overheating remedies, or too hot a regimen, ſo as ſuddenly to cauſe a fever in a perſon who was already too much diſpoſed to one. But of whatever kind the ſtationary fever be, which prevails the ſame year, and at the ſame time, this new fever ſoon aſſumes its name, becomes of the ſame kind, and in moſt particulars reſembles it; though it may ſtill retain ſome ſymptoms belonging to the cough, whence it aroſe. In every cough, therefore, proceeding from this cauſe, it is ſufficiently manifeſt that regard muſt be had not only to the cough, but likewiſe to the fever that ſo readily ſucceeds it.

"Relying on this foundation, I endeavoured to relieve ſuch as required my aſſiſtance by the following method: if the cough had not yet cauſed a fever, and other ſymptoms, which, as we ſaid, uſually accompany it, I judged it ſufficient to forbid the uſe of fleſh meats, and all kinds

of

of ſpirituous liquors, and adviſed moderate exerciſe, going into the air, and a draught of a cooling pectoral ptiſan to be taken between whiles. Theſe few things ſufficed to relieve the cough; and prevent the fever, and other ſymptoms uſually attending it. For as by abſtaining from fleſh and ſpirituous liquors, along with the uſe of cooling medicines, the blood was ſo cooled, as not eaſily to admit of a febrile impreſſion, ſo by the uſe of exerciſe thoſe hot effluvia of the blood, which ſtrike in, and occaſion a cough as often as the pores are ſtopped by ſudden cold, are commodiouſly exhaled in the natural and true way, to the relief of the patient.

"With reſpect to quieting the cough, it is to be obſerved that opiates, ſpirituous liquors, and heating medicines uſed for this purpoſe are equally unſafe; for the matter of the cough being entangled and ſtiffened thereby, thoſe vapours which ſhould paſs off from the blood, in a gentle and gradual manner, by coughing, are retained in the maſs, and raiſe a fever: and this frequently proves very fatal to abundance of the common people, who, whilſt they unadviſedly endeavour to check the cough, by taking burnt brandy, and other hot liquors, occaſion pleuritic or peripneumonic diſorders; and by this irrational procedure render this diſeaſe dangerous, and often mortal, which of its own nature is ſlight, and eaſily curable. Neither do they err leſs, though they ſeem to act more reaſonably, who endeavour to remove the cauſe of the diſeaſe by raiſing ſweat; for, though we do not deny that ſpontaneous ſweats frequently prove more effectual than all other helps in expelling the morbific cauſe, yet it is apparent that whilſt we attempt to force ſweat, we inflame the blood, and may poſſibly deſtroy the patient, whom we deſire to cure.

"But it happens ſometimes, not only when the diſeaſe has been unſkilfully treated, in the manner above deſcribed, but alſo ſpontaneouſly, at the beginning of the illneſs, or in a day or two afterwards, eſpecially in tender and weakly perſons, that the cough is ſucceeded by alternate intervals of heat and cold, a pain in the head, back, and limbs, and ſometimes a tendency to ſweat, eſpecially in the night; all which ſymptoms generally followed the fever of this conſtitution, as it were, of the lungs, which occaſioned a difficulty of breathing, ſtopped the cough, and increaſed the fever.

"According to the beſt obſervation I could make, the fever, and its moſt dangerous ſymptoms, were beſt relieved by bleeding in the arm, applying a bliſter to the neck, and giving a clyſter every day. In the mean time, I adviſed the patient to ſit up ſome hours every day, to forbear fleſh meats, and ſometimes to drink ſmall beer, ſometimes milk and water, and ſometimes a cooling and lenient ptiſan. If the pain of the ſide abated not in two or three days, but continued very violent, I bled a ſecond time, and adviſed the continuance of the clyſters. But with reſpect to clyſters, it muſt be carefully obſerved, either in this or other fevers, that they are not to be long and frequently uſed when the diſeaſe is in its decline; eſpecially in hyſteric women, and in men that are ſubject to the hypochondriac diſeaſe; for the blood and juices of ſuch perſons are eaſily changed, and ſoon agitated and heated; whence the animal œconomy is diſturbed, and the febrile ſymptoms continued beyond the uſual time.

"But to return to our ſubject; whilſt by theſe means we allowed time that the blood might gradually free itſelf from thoſe hot particles that were lodged in the pleura and lungs, all the ſymptoms uſually went off in a gentle manner; whereas, when the diſeaſe was treated in a rough way, by giving abundance of remedies, it either deſtroyed the patient, or rendered it neceſſary to repeat bleeding oftener than the diſeaſe required, or would ſafely bear, in order to ſave life. For though repeated bleeding anſwers every purpoſe in the true pleuriſy, and is alone ſufficient for the cure thereof, provided there be no hindrance from a hot regimen and heating medicines; yet, here, on the contrary, it ſufficed to bleed once, or at moſt twice, in caſe the patient refrained from bed, and drank cooling liquors. And I never found it neceſſary to bleed more frequently, unleſs the ſymptoms relating to the *pleura* and lungs were much increaſed by ſome adventitious heat, and even in this caſe the practice was not wholly void of danger.

"Upon this occaſion, I ſhall briefly deliver my ſentiments with reſpect to a very trite and common opinion, viz. that a pleuriſy is found to be of ſo malignant a nature in ſome years, that it will not then bear bleeding, at leaſt not ſo often as this diſtemper ordinarily demands. Now, though I conceive that a true and *eſſential* pleuriſy, which, as ſhall hereafter be obſerved, happens indifferently in all conſtitutions, does in all years equally indicate repeated bleeding; yet, it ſometimes happens that the peculiar epidemic fever of the year, from ſudden alteration of the manifeſt qualities of the air, readily throws off the morbid matter upon the *pleura* and lungs, while the fever notwithſtanding continues exactly the ſame. Wherefore, in this caſe, though bleeding may be uſed to abate this ſymptom when it is very violent, yet, generally ſpeaking, little more blood ought to be taken away than is required by the fever whereon this ſymptom depends; for if the fever be of a kind that will bear frequent bleeding, it may likewiſe be repeated in the pleuriſy, which is a ſymptom thereof: but if the fever will not bear repeated bleeding, it will be prejudicial in the pleuriſy, which will go off with, or laſt as long as the fever does. And in my judgment this was the caſe in the ſymptomatic pleuriſy that accompanied the fever which prevailed here at the time the cough began, namely in winter, 1675; and, therefore, I muſt obſerve, *that whoever, in the cure of fevers, hath not always in view the conſtitution of the year, inaſmuch as it tends to produce ſome particular epidemic diſeaſe, and likewiſe to reduce all the contemporary diſeaſes to its form and likeneſs, proceeds in an uncertain and fallacious way.*

"In the month of November of the above mentioned year, I attended the eldeſt ſon of ſir Francis Wyndham in this fever. He complained of a pain in his ſide, and the other ſymptoms that attended thoſe who had this diſeaſe. I bled him but once, applied a bliſter to his neck, injected clyſters every day, gave him cooling ptiſans and emulſions, and ſometimes milk and water, or ſmall beer, to drink; and adviſed his ſitting up a few hours every day: and by this method he recovered in a few days, and a purge completed the cure.

"But it muſt be remarked, that though theſe were the ſymptoms which ſucceeded the cough, during this winter, yet the cough, unattended with theſe ſymptoms, was more prevalent at the ſame time. But this required neither bleeding nor clyſters, provided a fever was not occaſioned by a hot regimen, or heating medicines; it ſufficed to allow the benefit of the open air, and to forbid the uſe of fleſh, wine, and ſuch ſpirituous liquors which are apt to cauſe a fever." Wallis's Sydenham.

In the month of July, 1775, the putrid fever came on; was ſucceeded by the cholera morbus in Auguſt, and the bilious fever in September, as uſual; this bilious fever, however, was attended with a degree of *ſtupor*, which went off with the other ſymptoms when properly treated; but was eaſily turned into a *coma*, when improperly treated at any period of the diſeaſe. See Dr. Grant's Account of the Epidemic Cough and Fever, 1776, from Sydenham.

This ſubject hath engaged the attention of many ſince the year 1775; and in 1782, Dr. J. C. Smyth gave his obſervations of this diſorder, in the firſt volume of Medical Communications, p. 71, &c. the ſubſtance of which is as follows:

"The late *influenza* was very generally accompanied not only with the uſual catarrhal ſymptoms, but with others no leſs diſtreſſing to the patient, and which were ſtill more alarming to the phyſician; ſuch as great languor, lowneſs, and oppreſſion at the præcordia; anxiety, with frequent ſighing, ſickneſs, and violent head-ach. The pulſe was uncommonly quick and irregular, and the ſick were frequently delirious, eſpecially in the night. The heat of the body was ſeldom conſiderable, particularly when compared with the violence of the other ſymptoms; the ſkin was moiſt, with a tendency to profuſe ſweating; the tongue white or yellowiſh, but moiſt. Some perſons complained of ſevere muſcular pains either general or local, others had eryſipelatous patches or efflorescences on different parts of the body, which in one inſtance terminated in gangrene and death. I obſerved petechiæ but once, and then only two days before death. Thoſe attacked with the *influenza* were in general taken ſuddenly ill; and the ſymptoms in the beginning, or for the firſt twenty-four or forty-eight hours, were extremely violent, bearing no proportion either to the danger or duration of the diſtemper. Children and old people either eſcaped entirely, or were affected in a ſlighter manner. Women with child, when ſeized with the diſeaſe, were apt to miſcarry; or if far advanced in their pregnancy, to be delivered before their time; in either caſe the hæmorrhage was conſiderable, and ſeveral died. Patients ſubject to

pulmonic complaints, ſuffered much from the cough, difficult breathing, and other peripneumonic ſymptoms, and to them alſo the diſeaſe proved dangerous or fatal.

The head-ach which accompanied the *influenza* may be diſtinguiſhed into three kinds.

1ſt. The uneaſy weight, foreneſs, and diſtenſion, of the forehead, uſual in common colds.

2dly. The violent ſick head-ach, ariſing from the affection of the ſtomach, and relieved by vomiting.

3dly. The head-ach, during which the patients complained of a ſenſation as if their head was ſplitting, with a ſevere ſhooting pain at the vertex: this laſt head-ach was moſt uſual in peripneumonic caſes, and ſeemed chiefly occaſioned by the violence of the cough.

The fever began with irregular chilline ſs, had conſiderable exacerbations and remiſſions, and was always greatly increaſed towards night; but even then the heat of the body and thirſt were ſeldom ſo great as might have been expected, and the acceſſions of fever were chiefly marked by the increaſed quickneſs of pulſe and delirium. The frequency of the pulſe was greater than is common in fevers; (it was often 120, even in the remiſſions of fever, in the acceſſions 140, and ſometimes ſo frequent, that is was impoſſible to reckon it; in many inſtances it was irregular and intermitting); nor do I remember to have felt ſo frequent, and at the ſame time ſo irregular a pulſe, (*the irregularity of the pulſe is in a great meaſure characteriſtic of malignant contagious fevers,*) in any fever attended with ſo little danger, and of ſo ſpeedy and eaſy a termination; the violence of this being commonly over in twenty-four or forty-eight hours. Many, from the beginning, were delirious in the night-time and during the exacerbation of fever, who were perfectly recollected and diſtinct in the day and during the remiſſions; but even where the delirium continued, it was not a conſtant one, as the ſick knew thoſe who ſpoke to them, would anſwer ſome queſtions diſtinctly, and a few minutes afterwards talk incoherently: a fixed ſtare of the eyes at the time, and a kind of wildneſs in the countenance, were alſo very expreſſive of this ſtate or condition. The delirium which we have juſt now deſcribed, though unnoticed (ſo far as I know) by any practical writer, is not unuſual in the putrid fever, and differs as materially from the low delirium incident to the laſt ſtage of that diſeaſe, as it does from the phrenetic delirium of the febris ardens, or of any inflammatory fever. During the whole of the *influenza*, I met only one inſtance of true phrenetic delirium, and it may not be foreign to the purpoſe to remark, that it happened to a patient who had been three times bled, had ſwallowed no heating cordials, and who was taken every day out of bed, conformable to the judicious practice of Sydenham (vid. De Febre Comatoſa), expreſsly with the intention of preventing this termination of the diſeaſe. Reſpecting the danger of the *influenza*, phyſicians, I find, have entertained ſomewhat oppoſite opinions; poſſibly owing to the difference of place and ſituation. In London, although the diſtemper doubtleſs proved fatal to many, yet it could hardly be accounted a dangerous one, if the number who died be compared with the prodigious number of thoſe who recovered.

The late *influenza* might very properly have been named the ſweating-ſickneſs, as ſweating was the natural and ſpontaneous ſolution of it, and reſt, abſtinence, and warm diluents, were, in moſt inſtances, all that were neceſſary for the cure; yet, amidſt ſuch an amazing number and variety of caſes, many occurred which required ſome further medical aſſiſtance, and when that became neceſſary, it was of the utmoſt importance that it ſhould be procured early; for the diſeaſe, when neglected or improperly managed in the beginning, ſometimes ended in a malignant fever of difficult treatment, and of very doubtful termination. And although the tendency to profuſe ſweating often continued, it now only weakened the patient, and a critical or ſalutary ſolution of the diſeaſe, in conſequence of this evacuation, was no longer to be expected; nor do I recollect a ſingle example of profuſe ſweating being attended with any advantage after the firſt forty-eight hours.

The medicines which I found moſt ſerviceable in abating or carrying off the fever were ſmall doſes of an antimonial powder, compoſed chiefly of tartar. emet. the julep e camphora, with about a fourth part of the ſpt. Mindereri; the common ſaline draught, with ten or fifteen grains of the pulv. contrayerv. c. or, what I commonly preferred, from twenty to forty drops of the liquor anod. min. Hoffmanni, adding occaſionally, a ſmall quantity of the paregoric elixir.

In caſes of great lowneſs, beſides the drinks and nouriſhment uſual in fevers, I allowed the ſick white-wine whey, wine and water, and weak veal broth.

For removing the oppreſſion at the præcordia, ſickneſs, and head-ach, no means were ſo certain as vomiting with tart. emet. giving it in ſmall doſes, largely diluted, and repeated every ten or fifteen minutes, until it produces the deſired operation. This medicine, adminiſtered in this manner, had alſo a very remarkable effect in bringing on a remiſſion of the febrile ſymptoms, and in accelerating the termination of the diſeaſe. It likewiſe commonly opened the body: when that was not the caſe, ſome gentle laxative was given.

The cough required not only plentiful warm dilution, but opiates and bliſters were alſo very neceſſary; and where the ſick were attacked with ſtitches, or acute pains about the cheſt, with difficult or laborious breathing, and other peripneumonic ſymptoms, the propriety of bleeding was, in my opinion, clearly and evidently pointed out; nor can I think any phyſician juſtifiable in neglecting the uſe of the lancet under ſuch circumſtances. At the ſame time, I am ready to acknowledge, that bleeding, though neceſſary to obviate the fatal conſequence of a particular ſymptom, was by no means conducive to the general cure of the diſeaſe; that, on the contrary, the lowneſs and dejection were often increaſed by it; that the blood taken away had not always an inflammatory appearance, but was ſometimes florid, and the craſſamentum tender; that the relief afforded by bleeding was neither ſo conſiderable, nor ſo certain as in other ſimilar caſes of peripneumony; and that in the courſe of the diſeaſe there frequently appeared unequivocal ſigns of a putrid tendency. But admitting the whole of theſe facts, and granting that they ought to make a phyſician cautious of taking away blood ſo freely, perhaps, as he otherwiſe would do, and as the urgency of the ſymptoms might ſeem to juſtify, yet they ſurely do not lead to an entire prohibition of the uſe of the lancet, at leaſt in thoſe caſes where there was evidently no alternative, and where, although the effects of bleeding might be doubtful, the conſequence of omitting it was certain. Upon ſuch occaſions, the advice of Celſus is the voice of reaſon, "Satius eſt enim anceps auxilium experiri quam nullum." Beſides bleeding, bliſters applied as near as poſſible to the parts affected were here, as in ſimilar caſes, of very eſſential ſervice, in removing the ſtitches in the ſide, and in relieving the difficulty of breathing, ſo that we may juſtly apply to them what an eminent author ſaid of the Peruvian bark, that he found it moſt ſerviceable where it was moſt wanted; for in caſes purely inflammatory, where bleeding of itſelf will commonly do every thing, bliſters are leſs neceſſary; but in thoſe of a mixed nature, where the aſſiſtance of bliſters is more immediately required, the relief afforded by them is in general more certain.

Some may think it ſtrange that amongſt the remedies employed in the treatment of this diſeaſe, I have made no mention of oily medicines, ſuch as emulſions, linctuſes, &c. nor of the Peruvian bark. In regard to oily medicines, I have often obſerved, that the advantage derived from them in caſes of catarrh, attended with heat and fever, was extremely equivocal; and that wherever there were naufea, oppreſſion, and uneaſineſs at the ſtomach, with a bitter taſte in the mouth, and nidorous eructations, they did more harm than good; as theſe ſymptoms ſo frequently occurred in the *influenza*, I thought it ſafeſt to omit their uſe entirely.

As to the bark, I ſhall only remark, that in the *influenza*, the cough, affection of the breathing, and oppreſſion at the præcordia, where they occurred, were to me ſufficient reaſons for not employing it; and that even where theſe ſymptoms were not preſent, and in caſes where the great lowneſs, and apparent putrid tendency, ſeemed not only to juſtify, but even to demand the uſe of the bark, I never was ſo fortunate as to ſee one ſingle inſtance where it produced any ſenſible good effect, either in moderating the fever, ſupporting the ſtrength, checking the diſpoſition to gangrene, or in peventing the fatal cataſtrophe that enſued.

When the fever, and other immediately alarming ſymptoms of the *influenza* had ceaſed, there frequently remain-

ed

ed a teasing cough; and convalescents in general complained of languor, want of appetite, and that their sleep was interrupted and unrefreshing. For removing these complaints, and completing the recovery of the patients, change of air, and riding on horseback, were the most effectual remedies; and to some they were absolutely necessary. A milk diet was recommended where the cough was obstinate; but I did not find it either necessary or of advantage to enjoin so strict an antiphlogistic regimen as is usually done in similar complaints. Neither do I know of any instance where the cough terminated in a phthisis pulmonalis, and I am much inclined to believe that this fatal termination was much less frequent after the *influenza* than after a common cold. For the lowness and want of appetite, chalybeate waters, especially when drank at the spring, were of singular service. I also frequently prescribed, and I think with advantage, the elix. vitr. cum liquor. anod. Hoffmanni, taken to the quantity of thirty or forty drops in a bitter infusion, or in a decoction of the bark.

In this short account of the late *influenza*, I have offered no conjecture with regard to the original cause of the distemper, or the manner in which it was propagated. I apprehend, from the present state of our knowledge, that we can hardly venture to say even what it is not; still less to affirm, with any probability, what it is."

See also Observations on the *Influenza* by A. Broughton, M. D. A Description of the *Influenza* by R. Hamilton, M. D. Dr. Fothergill's Works by Dr. Lettsom, 4to, p. 615, &c. Medical Observations and Inquiries, vol. vi. p. 340, &c. Medical Transactions, vol. iii. p. 54, &c. Medical Communications, vol. i. p. 1, &c. Edinb. Med. Com. vol. ix. p. 393, &c.

INFRASCAPULARIS, Musc. from *infra, below*, and *scapula the shoulder-blade*; also called *infraspinatus, superscapularis inferior, subscapularis*, or *immersus*. It rises from the whole inner surface of the scapula, passes under the coracoid process, runs over the capsular ligament, and is inserted into the outer tuberosity of the os humeri, carrying the arm round, and partly raising it, being the reverse of the supra spinatus.

INFRASPINATUS. See INFRASCAPULARIS.

INFUNDIBULUM, from *infundo to pour in*. It is called *choana, choanes, pelvis, chone*. Between the basis of the anterior pillars of the fornix, and the anterior part of the union of the optic thalami, lies a cavity named *infundibulum*. It runs down towards the basis of the cerebrum, contracting gradually, and terminating in the glandula pituitaria. It also communicates with the lateral ventricles. See CEREBRUM. Likewise it is a name of the pelvis of the kidneys. See RENES. So the Latins call the *pharynx*.

INFUSIO, from *infundo, to pour in*. INFUSION. It signifies either the action of infusing any ingredient in a proper fluid, or the medicine prepared by its action.

By *infusion* in water, the gummy and saline parts of vegetables are extracted: and by the intervention of the gummy part, the resinous is also taken up by the same menstruum, so are the oily; so that in many instances the whole virtue of a plant, &c. is obtained. In general, water takes up more by *infusion* from dry herbs than from fresh ones, particularly the newly dried ones. From animal substances, water extracts the gelatinous and nutritious parts; whence glues, jellies, and broths, are obtained; and along with these it takes up principles of more activity. Water also dissolves some portion of calcareous earth, but it hath no action on any other kind of earthy matter.

In making *infusions*, whether the water is cold or hot, the ingredients are only steeped in it, without boiling. It is the same, whether proof spirit, rectified spirit, urine, or whatever else is the menstruum.

In nervous disorders, infusions are best made in a vinous or a spirituous menstruum. Stomachic *infusions* should be moderately spirituous. Cathartic ones, whether saline or resinous, if for extemporaneous use, are best made with hot water in the manner of tea.

Infusions should not be so fated with the ingredients as to make the medicine unpalatable: though where fetid simples are required, this cannot be attended to.

Such *infusions* as are resinous should be given in wine; so should all those that turn milky when mixed with water. Bitters in wine should be given before and after dinner, for then they affect the head less.

Many *infusions* are most agreeable when made with cold water; and they are stronger thus than when heat is used, as is instanced in the bark, camomile flowers, &c.

This mode in common conveys different substances into the machine by impregnating a watery menstruum with their most active parts. Variety of which will be found under the names of the substances used, as *infusum allii*. See ALLIUM, &c.

INFUSIO. See TRANSFUSIO.

INFUSUM. An INFUSION. Sometimes it is expressed by *dilutum*: it also at others means a clyster, or an injection.

INGRAVIDATIO. See IMPREGNATIO.

INGUEN. The GROIN. The two groins are the lateral divisions of the hypogastric region.

INGUINALIS. See ERYNGIUM.

INHAMÆ ORIENTALES. See BATATAS HISPANICA.

INHAME. See CARA BRASILIENSIBUS.

INHUMATIO. In chemistry, it is a method of digesting, by burying in horse-dung the vessel which contains the ingredients to be digested.

INIMBOIA, or INIMBAY. See BONDUCH INDORUM.

INION. See OCCIPUT.

INJACULATIO. So Helmont calls a disorder which consists of a violent spasmodic pain in the stomach, and an immobility of the body.

INJECTIO. An INJECTION, called also *eisbole*. Liquors to be used by way of *injection*, are contrived for the more immediate application to the part affected, and are adapted to the most latent cavities of the body. They should always be used whilst lukewarm. They may be applied either by a syringe or clyster-pipe.

When *injections* are used in cases of gleets or gonorrhœas, Dr. Swediar advises that the syringe used should have a short, but wide pipe, just as large that its orifice goes into the orifice of the urethra, and the piston to go close to the sides of the tube. If the whole pipe of the syringe be much smaller than the orifice of the urethra, it is attended with two disadvantages: *first*, with a small pipe, if it is not perfectly smooth, the patient easily wounds the inside of the urethra, thereby rendering himself liable to an ulceration of the part, and consequent absorption of the poison. *Secondly*, the liquid *injected*, instead of going into the cavity of the urethra, will, in proportion as the patient presses the piston, run out sideways, through the orifice of the urethra. If the piston itself does not apply closely to the sides of the syringe, even if the pipe is sufficiently large, so that it perfectly closes the orifice of the urethra, the liquor will still gurgitate between the piston and the syringe, instead of going into the urethra; and thus the patient may imagine that he has *injected* the liquor properly, when, perhaps, very little has entered. The syringe being properly made, should be applied closely and exactly to the orifice of the urethra; so that by the conic form of its pipe, all passage may be denied to the liquid betwixt it and the sides of the urethra. If the disorder lies in the usual original seat of gonorrhœas, viz. just under the frænum, the patient should, with one hand, compress the urethra at the first curvature of the penis, where the scrotum begins, while he holds and manages the syringe with the fingers of the other. The piston, which should always go close and easy, ought then to be pressed softly and slowly, till he feels the urethra gently dilated, and thus keep the liquid *injected* for a minute or two in the urethra, repeating the same operation three or four times. By a rash or longer continued pressure of the piston, the irritation produced thereby in the urethra often does more harm than the *injection* does good. By attending to these directions, a double advantage is obtained. The liquid is properly applied to the part affected, at the same time that no danger is incurred of driving some of the venereal poison lower down the urethra along with the *injected* liquid; but this precaution is unnecessary, if the seat of the disorder is lower down. With respect to the liquid itself, it should always, in cases of virulent gonorrhœa, be made lukewarm; but in gleets this is not necessary. *In gonorrhœas*, if the liquid is too cold or too warm, it may easily hurt the patient, either by the retropulsion of the matter, or increasing the inflammation. In all cases before an *injection* is applied, the patient should attempt to make water. There are a variety of *injections* made use of in this complaint; among the most efficacious, are the following:

INJECTION OF ACETATED AMMONIA. To three ounces of diſtilled water, add one ounce of acetated ammonia.—OF ACETATED LITHARGE. To four ounces of roſe water, add eight drops of acetated litharge.—MURIATED INJECTION. To four ounces of diſtilled water, add eight drops of muriatic acid.—OILY INJECTION. To four ounces of oil of almonds, add eight drops of acetated litharge.—OPIATED INJECTION. To four ounces of diſtilled water, add forty, or ſixty drops of tincture of opium.—INJECTION OF GREEN TEA. Infuſe half an ounce of green tea in four ounces of boiling water, and let it ſtand till cold.—COMPOUND INJECTION OF CERUSSA, ſee Plumbum, N° 1.—INJECTION OF MURIATED QUICKSILVER. To four ounces of diſtilled water, add two drops of the liquor of muriated quickſilver. This muſt be weakened if the inflammation in gonorrhœa is great; or, ſhould there not be any, it may be ſtrengthened. Any of theſe may be uſed in the inflammatory ſtage of a gonorrhœa; but the MURIATED is conſidered as the moſt eligible, where the ſcalding of urine is very troubleſome. As aſtringent injections, the following are recommended: INJECTION OF ALUM. Diſſolve four grains of alum in four ounces of roſe-water.—of COPAIBA. See CAPIVI BALSAMUM;—of ACETATED COPPER;—of AMMONIATED COPPER;—of VITRIOLATED COPPER; COMPOUND INJECTION OF VITRIOLATED COPPER. See CUPRUM. Theſe are beneficial in the laſt ſtage of gonorrhœa; gleets; fluor albus; and, perhaps, by ſmall portions of their active ingredients it may be uſeful in the inflammatory ſtage, becauſe there they act as ſedative.—INJECTION OF GALLS. See GALLÆ.

BUT in the uſe of *injections*, it is neceſſary to obſerve, that many who labour under gleets, after having for ſome time made uſe of *injections*, and finding themſelves much better, will grow careleſs in the application, and even ſometimes neglect the *injection* altogether for a day, or half a day. The conſequence of this is ſometimes diſagreeable: many inſtances have occurred in which, by neglecting to uſe the *injection* for a ſingle day, the diſcharge has been greatly augmented, as if it had been a freſh gleet; and the relapſe being more obſtinate than the original diſeaſe, the patients have been obliged to continue the *injections* for more weeks than, perhaps, it would have required days to cure the diſtemper, had they continued the uſe of them without interruption. In general, to prevent all danger of a relapſe, it is proper to apply the *injections* three, four, or, according to circumſtances, ſix times a day during the diſeaſe, and to continue the ſame regularly for ten or twelve days after the running has entirely ceaſed.

IN ANATOMY great improvement hath been made by means of injections. Ruyſch was the firſt who was eminent in their uſe. Rieger publiſhed Ruyſch's method. The properties required in the injecting matter, are, 1ſt, fluidity; but this alone is not ſufficient, they muſt likewiſe, 2dly, grow ſtiff when cold, yet not ſo ſtiff but that they may remain tough and flexible; for were they too hard, the ſmaller veſſels would always be in danger of being broke. The following poſſeſs theſe properties.

Fine INJECTION. *By Dr. Nicholls.*

Take hard white Spaniſh varniſh, and hard brown Spaniſh varniſh, of each equal parts; turpentine varniſh, and vermilion, of each a ſufficient quantity. Mix them.

Coarſe INJECTION. *By Dr Nicholls.*

Take of yellow reſin two pounds; of yellow wax one pound; of turpentine varniſh a ſufficient quantity.

Theſe *injections* may be coloured with vermilion, indigo, blue, or with verdigriſe. Whatever colouring matter is uſed, it muſt be ground extremely fine.

The fine *injections*, when uſed, ſhould be as warm as they can be borne by one's finger if dipped therein. The coarſer ſort ſhould nearly boil.

The ſubjects to be injected, after having their veſſels cleared of their contents, by ſqueezing out the juices, ſhould be made warm, by being ſteeped in warm water.

A fœtus may be injected by the umbilicus; *a child* by the aorta aſcendens from the left ventricle; *an adult* may be injected in the ſame manner as a child. *Injection* by the aorta does little more than fill the arteries: but by the umbilicus of a fœtus, both arteries and veins are filled. When the arteries in the cornea are filled, the *injection* ſhould not be puſhed any longer. As ſoon as the *injection* is finiſhed, put the ſubject into cold water that it may cool ſuddenly.

The younger the ſubjects the farther the matter will run in their veſſels; and if the body is macerated a day or two in cold water, before it is put into warm water, the blood will be more effectually diſſolved, and the veſſels more emptied than by any other method. When put into warm water, it may continue thirty ſix, or forty-eight hours, the water being kept as hot as one can bear a hand in it.

To dry a preparation, hang it where a current of air can paſs free, but guard it from duſt; when dry, let it be well varniſhed. The ſhining varniſh may be laid on it, with a bruſh. Whilſt it is drying, if maggots appear, dab the part with hydrargyrus muriatus, diſſolved in ſp. vin. r.

Acidum muriatum, or nitroſum, diluted, are the beſt for macerating injected preparations in.

The rectified ſpirit of malt is the beſt for preſerving theſe preparations, or any anatomical preparations.

INNOMINATA ARTERIA. It is the external branch of the external iliac artery at its diviſion about the hole in the ligamentum Poupartii. It aſcends outwardly to the inſide of the ſpine of the ilium. It is loſt in the muſcle of the belly, and it ſends branches to the ilius internus.

INNOMINATI NERVI. A name of the fifth pair of nerves. See TRIGEMINI NERVI.

INNOMINATUM, Os. So called becauſe it has no proper name, called alſo *coxæ oſſa*, *os ilii*; ſome called it *coxendix*.

INNUTRITIO. See ATROPHIA.

INOCULATIO. See VARIOLÆ.

INOSCULATIO, from *in* and *oſculum*, *a little mouth* or *orifice*. See ANASTOMOSIS.

INPINGUEDO PORCI. See COSTUS.

INSANIA. DELIRIUM, or MADNESS.

INSECTUM. An INSECT. Theſe animals are thus named from their being marked, or diſtinguiſhed, by variety of parts, ſeparated as it were by inciſions.

INSESSIO. INSESSION. A ſitting over relaxing vapours; alſo a *ſemicupium*.

INSIDENTIA. See EPISTASIS.

INSIDIANS. Inſidious, latent. It is an epithet of diſeaſes, which betray no evident ſymptom, but are ready on any provocation to break forth, as it were, by ſurpriſe.

INSIPIDUS. TASTELESS. See APÆUM.

INSIPIENTIA. A low degree of delirium.

INSOLATIO. INSOLATION. An expoſing any thing to the ſun. The diſeaſe thus named is the ſame with *ictus ſolaris*, which ſee.

INSOMNIUM. A DREAM. Lommius obſerves, that if dreams are different from what may be expected from the buſineſs of the day, they indicate ſome indiſpoſition of body. Hippocrates writ a book expreſsly on this ſubject.

INSPIRATIO. INSPIRATION, alſo *eiſpnoe epipaſmos*. It is when the air is drawn into the lungs. See RESPIRATIO.

INSTILLATIO. It ſometimes imports the ſame as embrocatio.

INSTITA. A FILLET. Alſo a flat worm in the inteſtines.

INSUFFLATIO. INSUFFLATION. The blowing into any cavity, in order thereby to convey any thing medicinal to a part affected.

INSULTUS. The firſt invaſion or acceſs of a paroxyſm.

INTEGASTRUM. A term uſed by Paracelſus, which ſignifies the decuſſation of the optic nerves.

INTEGUMENTA. INTEGUMENTS. Theſe are the cuticle, rete mucoſum, cutis, and membrana cellularis.

INTEMPERANTIA. INTEMPERANCE. Beſides its uſual ſignification reſpecting food, it ſometimes is the ſame as DYSCINESIA.

INTEMPERIES. See DYSCINESIA.

INTENTIO. INTENTION. It is either extenſion or indication.

INTERCEPTIO. See APOLEPSIS.

INTERCOSTALES ARTERIÆ. Theſe come in pairs from the aorta, and run on the lower parts of each rib. There are eight, nine, or ten of theſe. The two or three upper come from the ſubclavian. The intercoſtales of the true ribs anaſtomoſe with the internal mammary; thoſe of the ſuperior go to the muſcles of the belly.

—— MUSCULI, called alſo *meſopleuriοi*. The INTERCOSTAL

TERCOSTAL MUSCLES. They are eleven in number on each ſide externally, and the ſame number are again on each ſide internally; ſo that in all there are forty-four. The *external ones* paſs downwards and forwards; they riſe from the edge of the ſuperior, and are inſerted into the edge of the inferior rib; their fibres run nearly parallel. Near the ſternum they diſappear: theſe elevate the ribs. The *internal ones* are the reverſe of the external: they riſe from the edges of the inferior, and are inſerte into thoſe of the ſuperior ribs; conſequently they decuſſate each other. Theſe depreſs the ribs: now by the alternate action of theſe muſcles, the thorax is in a great degree expanded in inſpiration, and in expiration has its dimenſions leſſened.

INTERCOSTALES NERVI. The INTERCOSTAL NERVES, called alſo *ſympathetici nervi majores*. They are formed of ſome of the dorſal and indeed of all the ſpinal nerves, alſo of branches from the fifth and ſixth pairs from the brain. They run on the other ſide of the ribs.

——VENÆ, *dextræ, ſuperiores, et inferiores*. See AZYGOS.

INTERCURRENS FEBRIS. An INTERCURRENT FEVER. Some fevers are epidemical in certain ſeaſons only, and indeed only prevail in ſuch ſeaſons; other fevers happen in all years, and indeed are ſometimes epidemic. Thoſe which happen only in certain ſeaſons are called ſtationary; but others are called by Sydenham *intercurrents*. See Sydenham's Works.

INTERCURRENS vel INTERCIDENS PULSUS. When between two ſtrokes, at proper diſtances, a third quickly intervenes.

INTERCUS, from *inter*, *between*, and *cutem*, *the ſkin*. See ANASARCA.

INTERDENTIUM. The intervals between teeth of the ſame order.

INTERDIGITUM. A CORN betwixt the toes.

INTERFEMINEUM, from *inter*, *between*, and *femur*, *the inſide of the thigh*. See PERINÆUM.

INTERLUNIUS MORBUS. See EPILEPSIA.

INTERMISSIO. The intervals betwixt two fits of any diſtemper.

INTERMITTENS FEBRIS. An INTERMITTENT FEVER. It is when the febrile ſymptoms quit the patient for a time and then return. When the cold fit is violent, or continues long, or is a principal part of the diſorder, it is called an AGUE. With reſpect to the time of the fits returning, different names are given to this fever; e. g. QUOTIDIAN, which is when the fit returns every day, or after the expiration of twenty-four hours; TERTIAN, when it returns every other day, or after forty-eight hours; QUARTAN, when the fit attends on the firſt and fourth day, the two intervening ones being free; or after ſeventy-two hours; QUINTAN, when every fifth day, which rarely occurs, or after ninety-ſix hours, it is alſo called *pemptæus*. Thoſe are called autumnal which begin in Auguſt, and thoſe vernal which begin in February.

It has been ſaid that one ſpecies partakes very much of the nature of an ardent fever; it prevails in cold dry ſprings, from the ſame reaſon as pleuriſies and peripneumonies do. *Another ſpecies*, which is frequent in moiſt ſeaſons and in marſhy countries, has for a principal cauſe, a defect of vital heat, and an impoveriſhed ſtate of the blood. *A third ſort* is cauſed by infectious effluvia. However, now it is generally allowed that the true cauſe is marſh miaſma. When any of theſe cauſes attend, an irregular or improper diet, diſturbed paſſions, crudities in the primæ viæ, &c. may more readily prove the remote cauſes of *intermittent fevers*.

Dr. CULLEN places this fever under the CLASS PYREXIÆ, ORDER FEBRES, SECT. 1; and defines theſe fevers in general, fevers ariſing from marſh miaſma, conſiſting of many paroxyſms, a total freedom from fever, at leaſt an evident remiſſion, returning with a remarkable exacerbation, and moſt frequently with chillneſs or ſhivering; there being only one true paroxyſm any one day, to which he affixes this remark. Whoever will weigh thoſe things which will ſoon be delivered, concerning remittent fevers, ſtrictly called ſo, to be diſtinguiſhed from continued fevers; and thoſe which continued fevers manifeſt, will readily ſee why I have thought it neceſſary to change the character, formerly given of intermittents, as well as continued fevers which laſt he defines fevers having no intermiſſion, nor ariſing from marſh miaſma, but continuing with only ſlight remiſſions, and exacerbations; there being two exacerbations each day. And for claſſing remittents with intermittents, he ſupplies the following reaſons: he thinks that the noſologiſts, SAUVAGES, LINNÆUS, and SAGAR, have not acted judiciouſly, in inſtituting a ſeparate order for remittents, as if they were altogether different from perfect intermittents. For thoſe fevers which are called remittents, ariſe from the ſame principle marſh miaſma, as intermittents; each of them rages together epidemically, in the ſame places, and at the ſame time of the year; each of them is cured exactly by the ſame remedies; and very often in the ſame ſubject, the ſame diſeaſe which appears ſometimes, exhibits the intermittent, ſometimes the remittent type; diſeaſes, therefore, ſo extremely alike with reſpect to their cauſes, mode of cure, and type, ought neither to be placed under a different order, or different ſection. He therefore conſiders remittent fevers only as a variety of intermittents, and divides them into *tertians*, *quartans*, and *quotidians*. See TERTIANA, QUARTANA, QUOTIDIANA. In this place we ſhall ſpeak of intermittents, of which the ſigns are, at the outſet and in the cold fit, heavineſs, a pain in the head and limbs, pain in the loins, paleneſs in the face, chillneſs in the extremities, yawning, ſtretching, and violent ſhaking, ſmall ſlow pulſe, thirſt, retching, ſometimes vomiting a bilious matter; and, in the hot fit, a heat of the whole body, redneſs, diſtention of the ſkin, a quick ſtrong pulſe, watchfulneſs, ſhort breath, raving, high-coloured urine without a ſediment, &c. Theſe ſymptoms abate by degrees, and an univerſal ſweat appears, which ſoon terminates this fit; this generally continues to 10, 12, or 20 hours. The patient is indiſpoſed the following day: he is chill and apt to ſhiver, hath a weak and ſlow pulſe, his urine is thick and pale, and either depoſits a ſediment, or contains a ſmall cloud ſuſpended therein; the ſediment is of a reddiſh colour, exactly reſembling brick-duſt; the urine is often frothy too, and there is generally a pellicle or very thin filmy ſkin on the top of the urine, which alſo adheres to the ſides of the glaſs that contains it: *this laſt obſervation on the urine peculiarly characteriſes the ſeveral ſpecies of intermittents*. In the beginning of autumnal *intermittents*, they are ſometimes not eaſily diſtinguiſhed from continual fevers. When weakly perſons are the ſubjects, the *intermiſſions* are proportionally leſs diſtinct.

Obſtinate *intermittents* often end in fatal dropſies, or other troubleſome diſorders. Vernal *intermittents* ſometimes go off without any aſſiſtance after the return of a few fits; they very rarely prove fatal. When children have long laboured under autumnal *intermittents*, they rarely recover until their bellies grow hard and ſwell; then the diſorder vaniſhes; the ſame is obſerved with reſpect to the ſwelling of the legs in adults.

THE INDICATIONS ARE, to reſtore the conſtituon to its natural degree of heat, and then to ſupport a due degree of perſpiration.

If the diſorder is owing to that ſtate or habit of which an ardent fever is the uſual conſequent, bleeding ſhould begin the cure; this may be followed by ſub-tepid baths, lenient purges, ſaline medicines, with either the fixed or the volatile alcalies, bliſters, and a ſupply of gruel, in proportion to the degree of thirſt. If, after a few days, this method fails to relieve, the milder alexipharmics will certainly effect a cure.—When this diſorder is produced by dry cooling ſprings, the bark is rarely uſeful, and if imprudently adminiſtered, a continual fever is produced, the cure for which is bleeding and cooling medicines, until the *intermittent* is acquired.—In caſes where the bark is not convenient, Dr. Rutherford adviſes to give an antimonial vomit, and ſo to manage that a ſweat be excited by repeated draughts of ſome aperient diaphoretic drink before the cold fit approaches; the cold fit thus avoided, the hot one is prevented alſo. Hoffman uſed this method, and they both aſſert the happieſt effects therefrom.

Intermittents are moſt frequent when the atmoſphere is cold and moiſt, and when the cauſes of an impoveriſhed blood are or have been preſent. In this caſe, inſtead of bleeding and the other means above propoſed, a vomit may begin the cure; during the rigour of the following fit, give a few grains of the antimonial powder; put the patient in bed, let him be ſupplied with warm wine whey, and when a ſweat comes on, endeavour to ſupport it until the fit declines. In the interval, the bark, a generous diet, and chalybeates, will effect the cure.

If putrid vapours were the cauſe, begin with an emetic in the following fit, when the heat and ſweat ſucceed the ſhivering; ſupply the patient with frequent draughts of

warm wine whey. In the interval let cordials with the bark be given; their doſes ſhould be large, and as frequent as the ſtomach will retain them.

As the bark is the great ſpecific in this diſorder, its uſe ſhould never be reſtrained, except by too great heat; nor need the laterititious ſediment in the urine be waited for, if the pulſe is moderate. When the powder can be taken, its efficacy is moſt to be depended on; or it may be given in decoction, or cold infuſion; but if an averſion to this medicine forbid the internal uſe, a waiſtcoat in which it is quilted may be worn next the ſkin, or a bath may be made of a ſtrong decoction of this drug, or bark clyſters may be adminiſtered.

An opiate often ſucceeds, if given about half an hour before the fit. To an adult the tinct. opii may be given from fifteen to twenty drops, in any convenient vehicle.

When the hot fit is tedious and violent, expoſe the patient to cool air, and let him drink cold water as freely as his own ſenſation will direct; thus the heat will ſoon abate, and a ſalutary ſweat come on.

Arſenic has in this complaint been given with great ſucceſs in the following form. SOLUTIO ARSENICI, ARSENICAL SOLUTION. Take arſenic very finely powdered, and fixed alkaline ſalt, of each ſixty-four grains; (ſome order half the quantity), diſtilled water half a pint; theſe are to be put into a Florence flaſk, and placed in a ſand heat: the water is then to boil ſlowly till the arſenic is perfectly diſſolved; when the ſolution is cold, half an ounce of compound tincture of lavender is to be added, and of diſtilled water, another half pint, more or leſs, ſo that the whole of the ſolution ſhall yield by meaſure a pint, or rather weigh fifteen ounces and a half. Patients *from two to four years of age* may take *from two to four drops*; *from five to ſeven years*, from *five to ſeven drops*; from *eight to twelve years*, from *ſeven to ten drops*; from *thirteen to eighteen* and *upwards*, may take twelve *drops at a doſe*, in any proper vehicle two or three times a-day.

If the ſymptoms of an inflammation are attendant, let thoſe be removed before the bark is given.

Often, by too much purging, a dropſy is induced; whether to this or any other cauſe this ſymptom may be owing, attempt its cure by warm ſtomachic and antiſcorbutic remedies; a mixture of ſome ferruginous preparation may accompany the bark, and after each doſe give a vinous infuſion of freſh horſe-raddiſh root, with the tops of wormwood.

A cough with a hectic fever ſometimes follows after the removal of the *intermittent*; in this caſe, daily gentle purging, &c. as when the belly ſwells and is hard.

In children a hard ſwelled belly is a frequent ſymptom; this is beſt relieved by repeated purging with the pulv. baſilic. an antimonial vomit ſhould now and then be interpoſed, and when the hardneſs and the tumor is abated give the bark with ſalt of ſteel.

If a madneſs ſhould come on, cordials and reſtoratives are the propereſt means; compoſure muſt be indulged, and in general the ſame procedure as when this ſymptom is attendant on a NERVOUS FEVER, which ſee.

In caſe of coſtiveneſs, rhubarb with emetic tartar may be given, ſo as to render the bowels eaſy.

If bile in the blood-veſſels ſeem to render the intermiſſions imperfect, the ſpirit of nitre is convenient, and for the moſt part to be preferred; but if the juices are viſcid, the neutral ſalts muſt alſo be adminiſtered.

For agreeable forms and efficacious preparations in a uſeful variety of modes, ſee Brooke's and the London Practice of Phyſic. Wallis on Health and Diſeaſe.

Thoſe who die of *intermittents* uſually depart in the hot fit.

See Hoffman on *Intermittents*; Wallis's Sydenham; Fordyce's Elements, part the ſecond; Practical Eſſays by D. Lyſſons, M. D.

INTERNODIUM, from *inter*, *between*, and *nodus*, *a joint*. An INTERNODE. In BOTANY it is that part of the ſtalks of plants which are *between* joint and joint, or knot and knot. IN ANATOMY it is the KNUCKLES; alſo the ſpace between one of the joints of the fingers and another.

INTERNUNCII DIES. See CRITICI DIES.

INTEROSSA ARTERIA. The CUBICAL ARTERY, having in its courſe between the heads of the radius and ulna reached the *interoſſeous* ligament, gives off the *interoſſeous arteries*, which are two, one internal, the other external.

The internal one runs cloſe to the ligament till it reaches below the pronator teres, where it perforates the ligament, and paſſes to the convex ſide of the carpus, and back to the hand, where it communicates with the external *interoſſeus*, the radical, and the cubical arteries.

The external pierces the ligament about three fingers breadth below the articulation, and ſends off a branch towards the external condile of the os humeri, under the ulnaris externus and anconæus minimus, to which it is diſtributed, as alſo to the ſupinator brevis. The interoſſeous artery then runs downwards on the outſide of the ligament, and is diſtributed to the ulnaris externus, extenſor digitorum communis, the extenſores pollicis indicis, and minimi digiti. And having reached the lower extremity of the ulna, it unites with a branch of the internal *interoſſeous artery*, which at this place runs from within outwards, and is diſtributed with it on the convex ſide of the carpus and back of the hand, communicating with a radial artery, and with a branch of the cubital. By theſe communications, this artery forms an irregular arch, from whence branches are ſent to the external *interoſſeous* muſcles, and to the external lateral parts of the fingers.

INTEROSSEA LIGAMENTA. The *interoſſeous ligaments* in the fore-arm are fixed by one edge along the ſharp angle of each ulna, and by the other along that of the radius. They are principally made up of two very ſtrong planes of fibres which croſs each other at oblique angles, and leave holes at different diſtances, for the paſſages of blood-veſſels. The ligament ties the two bones cloſely together, and the two planes ſerve for the inſertion of ſeveral muſcles. In the ſupination of the hand it is very tight, but in the pronation it is folded a little lengthways.

INTEROSSEI MUSCULI. There are muſcles of this name both in the hands and feet. There are three in the upper part of the hand, and as many on the inferior; this name deſcribes their origin; they join with the lumbricales, and are blended with them, performing the ſame office. They move the fingers ſideways.

In the feet ſeveral ſmall muſcles fill up the four interſtices between the metatarſal bones, much after the ſame manner as in the hand. Their uſe with reſpect to the toes is ſimilar to that of the ſame ſort of muſcles in the hands.

INTERPELLATUS MORBUS. In Paracelſus it is a diſeaſe attended with irregular or uncertain paroxyſms.

INTERPOLATUS DIES. In Paracelſus theſe are days interpolated betwixt two paroxyſms.

INTERSCAPULUM. See SCAPULA.

INTERSEPTUM. See UVULA and SEPTUM NARIUM.

INTERSPINALES COLLI, — MUSCULI. } Winſlow calls them *ſpinales colli minores*.

Dr. Hunter ſays they lie between the ſpinal proceſſes of the neck and loins, ſerving to erect the body, by bringing the ſpinal proceſſes nearer to each other: he calls them *intraſpinales*.

INTERTRANSVERSALES MUSCULI, or INTRATRANSVERSALES. They lie between the tranſverſe proceſſes of the neck, ſerving to bend it to one ſide. Theſe muſcles appear alſo in the loins. Winſlow calls them *tranſverſales colli minores*. To the firſt of theſe muſcles ſome have given the name *cucutiens*.

INTERTRIGO, from *inter*, *between*, and *tero*, *to rub*, called alſo *attrita*, *atiritio*. A GALLING, or eroſion of the cuticle, or of the ſkin. Children are apt to have excoriations behind their ears, in the neck, and thighs; thoſe on the lower parts are from the urine, or from being too fat. Waſh them two or three times a-day with warm water, and then apply chalk in fine powder, or fuller's earth, after diſſolving it in water. Dr. Cullen places this as a variety of erythematous inflammation.

INTERVERTEBRALES MUSCULI. They ariſe from the body of one vertebra laterally, and are inſerted, after an oblique progreſs, into the back part of the other vertebra, immediately above it. They draw the vertebræ nearer to one another, and a little to one ſide.

INTESTINA TERRÆ. See LUMBRICUS TERRESTRIS.

INTESTINA, from *intus*, *within*. The INTESTINES, commonly called the GUTS, by the poets frequently *chorda*; alſo *pantices*. From the pylorus to the anus is one continued canal, divided into the great and ſmall *inteſtines*, which are furbelowed upon the meſentery and meſocolon. The whole length of the *inteſtines* is between ſeven

ſeven and eight times the length of the body; the ſmall ones are about five parts out of the ſeven or eight, which is the length of the whole. The ſmall *inteſtines*, CORONARIUS and Linden, name *dextron*; they are called alſo *cholades*, becauſe they contain bile, and are named DUODENUM, JEJUNUM, and ILEUM, which ſee. Their diſtinctions are ſomewhat obſcure, though generally marked out pretty nearly; the large *inteſtines*, called *craſſa inteſtina*, are the CŒCUM, the COLON, and RECTUM, which ſee.

The firſt coat of the *inteſtines* is from the peritoneum, and forms the external one, called *cellulosa tunica Ruyſchii*; *tunica externa*, vel *membranoſa inteſtinorum*; the ſecond is the muſcular coat, the third is the nervous or cellular, the fourth is the villous, called *periſtoma*. The villi are of different ſhapes and lengths in different parts of the *inteſtines*, more thick in the ſmall, more long and thin in the large ones; they are thought to be ſecerning and abſorbing organs, as there the arteries terminate, and the veins begin.

The glands of the *inteſtines* called *enteradenes*, are ſuppoſed to be lodged in the cellular coat, next the villous; they are divided into *glandulæ ſolitariæ* and *aggregatæ*; but their exiſtence, notwithſtanding this, is not clear.

In the great *inteſtines* we may obſerve little holes, which when inflated, lead to cells analogous to the ſolliculi of Malpighius and by analogy we may ſuppoſe glands to exiſt in the great *inteſtines* near the anus, to ſeparate a lubricating mucus, for faciliating the paſſage of the fæces.

The arteries and veins run together on the *inteſtines*.

The uſe of the *inteſtines* is to complete the firſt digeſtion, ſtrain the chyle, and carry off the fæces by the anus; all which are performed by the periſtaltic motion, cauſed by their muſcular coat.

The periſtaltic motion of the *inteſtines* is not conſtant, but takes place on proper occaſions, or as theſe bowels are ſtimulated by their contents. The action of the lungs on the diaphragm, and the action of the abdominal veſſels, conduce to the emptying of the ſtomach and guts; the chyle, bile, rarefied air, &c. excite occaſionally the periſtaltic motion, for the moſt ſpeedy deſcent of what is to be caſt out. See Haller's Phyſiology, lect. 29, 31.

INTESTINALIS ARTERIA. See DUODENALIS ARTERIA, and GASTRICA DEXTRA ARTERIA.

INTESTINALIS VENA. See DUODENALIS VENA.

INTESTINORUM SOLAMEN. Thus Hoffman calls the *ſemen aniſi*, and Van Helmont, the *oleum aniſi*.

—— TUNICA EXTERNA, and MEMBROANSA. See INTESTINA.

INTOXICATIO, from τοξικον, *poiſon, venom*. It is properly the ſame as *infectio*, but it is now generally uſed in the ſame ſenſe as *inebriation*.

INTRASPINALES. See INTERSPINALES.

INTRATRANSVERSALES. See INTERTRANSVERSALES.

INTRICATUS, MUSCULUS. See ABDUCTOR AURIS.

INTRINSECI. Painful diſorders of the internal parts.

INTRITUM, from *interendo*, *to rub* or *grate*, ſimilar to *entrimma*. It is a culinary term for minced meats, or rather ſuch as are prepared by pounding, as potted beef, &c.

INTROCESSIO. See DEPRESSIO.

INTROSUSCEPTIO. See ILIACA PASSIO.

INTSIA. A large evergreen tree in Malabar, called alſo *acacia Malabarica globoſa*. The juice of the leaves and bark is uſed to eaſe pains in the belly. See Raii Hiſt.

INTUMESCENTIÆ, alſo *tumidoſi*. Diſorders attended with a puffineſs, or with a ſwelling of the body, or of a conſiderable part of it. It is the ſecond order of the claſs cachexiæ of Cullen's Genera Morborum, which he defines, the whole, or great part of the body ſwelled externally.

INTUSSUSCEPTIO. See ILIACA PASSIO.

INTYBUS. A name for the *cichoreum latifolium* ſive *endivia vulg.*

INULLA. See ENULA.

INUNCTIO. INUNCTION. It is either the action of anointing, or the materials with which a part is anointed.

INVASIO. The ſame as *acceſſio*.

INVERECUNDUM, Os. See FRONTIS, OS.

INVERSIO UTERI. See PROCIDENTIA UTERI.

INVIDIA. ENVY. It is compoſed of deſire, anger, and ſorrow. And as it participates of the debility of the laſt, ſo it likewiſe does of the febrile commotion of the former; hence ariſes an hectic fever, which conſumes the ſtrength.

INVOLUCRA. SECUNDINA; SECUNDINES, from coming next after the child, called alſo *hyſtera*, *hyſteron*, *membranæ*. They form an univerſal covering for the fœtus, and the water in which it floats during pregnancy. They are membranes called CHORION and AMNION, to which ſome add the ALLANTOIS, alſo the PLACENTA, and part of the FUNIS UMBILICALIS; all which ſee.

If in labour the membranes do not break immediately upon their being puſhed into the vagina, they ſhould be allowed to protrude ſtill farther, in order to dilate the os externum.—If they ſuddenly burſt, and diſcharge much water, and the pains become ſlack thereon, the labour, however promiſing before, becomes tedious. To know if the membranes are broke (which is a proper enquiry when the head gets before the waters) obſerve whether the head of the child feels hairy or not; for while it is yet covered with the unbroken membrane, it is ſmooth, ſoft, and ſlippery to the touch. Sometimes the head preſenting, ſo that the fontanel is felt puffy and ſwelled, deceives us, and it is taken for the membranes, but that ſhould be carefully diſtinguiſhed. If during labour the waters puſh the membranes down in an oblong, or in a gut-like form, the birth will be tedious. The beſt form of the membranes, when they protrude through the os internum, is ſhort, broad, or round.

INVOLUCRUM. See PERICARDIUM.

ION. See VIOLA.

IONIA. See CHAMÆPITYS.

IONTHLASPI, called alſo *lunaria*. Boerhaave mentions two ſpecies of this plant; they are found in France, Italy, and Spain; they are ſaid to be deterſive, aperitive, &c. but they are not noted much in practice.

IONTHOS. So the Greeks call thoſe hard pimples in the face which the Latins call by the name of *varus*, and *gutta roſacea*.

IOSACCAR. SUGAR of VIOLETS.

IOTACISMUS. A defect in the tongue or organs of ſpeech, which renders a perſon incapable of pronouncing his letters.

IOUI. A reſtorative alimentary liquor prepared in Japan. It is made from the gravy of half roaſted beef, but as to the reſt it is kept a ſecret.

IPECACUANHA, alſo called *Braſilienſis radix*, ipecacoanha Braſilienſibus, *herba paris Braſiliana*, *polygonos*, *hippecacuanna*, *caa-apia*; *Indiana radix*, *ipepocoanha*, *periclymenum parvum*, IPECACOAN, or BRASILIAN ROOT. It is the PSYCHOTRIA EMETICA, or *pſychotria herbacea procumbens*, *foliis lanceolatis glabris*, *ſtipulis extra foliaceis ſubulatis*, *capitulis axillaribus pedunculatis pauciflorıs*, Linn. Curtis, in his Catalogue of Medicinal Plants, &c. contained in the London Botanic Garden, calls it *viola ipecacua*. It is brought from the Spaniſh Weſt Indies. Four ſorts are mentioned, viz. the grey, brown, white, and yellow. The grey is generally eſteemed the moſt, but Neumann aſſures us that the brown is equally good. The white ſort is much weaker than the other, and the yellow does not act in the leaſt as an emetic, being merely purgative. The Peruvian ſort is called *bexuguillo*.

Ray ſays that the *ipecacuanha* is a ſpecies of the herb paris; it bears a number of berries. Notwithſtanding what has been ſaid by various authors reſpecting this plant, a very late writer, Dr. WOODVILLE, who has made medical botany his ſtudy, ſays, "It ſeems ſurpriſing, that the plant ipecacuanha, which has been in uſe more than a century, ſhould have not been botanically aſcertained.——The younger LINNÆUS thought the PHYSCOTRIA the genus to which it belonged, and has therefore named it *phyſcotria emetica*; ſtill the authority on which MUTIS received the information, cannot be implicitly followed."—He, however, has ſupplied a figure of the true ipecacuanha plant, though not being advanced to a ſtate of inflorescence, it ſtill leaves the matter undetermined. For this plant, preſerved in ſpirits, was ſent by governor Philips from Braſil, to ſir Joſeph Banks. The roots of the GREY SORT are about the thickneſs of a ſmall quill, very unequal and knotty; variouſly bent and contorted, full of knots and wrinkles, and deep circular fiſſures, which reach down to a ſmall whitiſh woody fibre that runs in the middle of each piece; the cortical part is compact, brittle, and looks ſmooth, and reſinous on breaking. They have little or no ſmell, the taſte is bitteriſh and ſubacrid, covering the tongue as it were with a kind of mucilage. The BROWN is ſmall, ſomewhat more wrinkled, of a brown or blackiſh colour without,

without, and white within. This is brought from Brafil. The white is woody, has no wrinkles, and, to the taſte, no perceptible bitterneſs. The *aſh-coloured*, or *grey ipecacuanha*, is that generally preferred for medicinal uſe. The *brown* has been ſometimes obſerved even in a ſmall doſe to produce violent effects. The *white*, though taken in a large one, has ſcarce any effect at all. The root contains a gummy and reſinous matter, though the gum is in much greater proportion, and more powerfully emetic than the reſin; the cortical part is more active than the ligneous; and the whole roots manifeſt an antiſeptic and aſtringent power; the emetic quality is moſt effectually counteracted by the acetous acid; for thirty grains, taken in two ounces of vinegar, produced only ſome looſe ſtools. Theſe particulars have been aſcertained by the experiments of Dr. Irving.

This medicine is the mildeſt and ſafeſt emetic with which we are acquainted; for it readily paſſes off by ſome of the other emunctories, if it does not operate as a vomit.

Chuſe the larger compact roots that have a reſinous appearance. The ſlender, blackiſh brown, and thoſe which are full of fibres, are the worſt.

The *caapia*, commonly ſold under the name of white *ipecacuanha*, is impoſed for the true *ipecacuanha*; but its roots are yelloviſh, or of a yelloviſh white colour. The *aconitum* or *apocynum*, is another impoſition; but the colour of its medullary fibre is of a deep reddiſh yellow colour, whereas that of the *ipecacuanha* is whitiſh, or of a pale grey.

Helvetius firſt brought this root into repute as an antidyſenteric; ſince which time it has been uſed in diarrhœa, menorrhagia, and leucorrhœa; and in diſorders proceeding from obſtructions of long ſtanding; in ſpaſmodic aſthma, where nothing forbids repeated vomiting, it has been efficacious; for, in violent paroxyſms, it has procured relief: where habitual, from three to five grains may be given every morning, or from five to ten every other morning, and continued for four or ſix weeks. Small doſes of one-third to one-half a grain have been of uſe in catarrhal, ſome conſumptive caſes, and various ſtates of fever. It has alſo been employed in the cure of agues as an emetic, given at the time of acceſſion, or at the cloſe of the cold fit. Of all its preparations, the powder is the beſt; two or three grains of which will produce two or three diſcharges by vomit; and, in diarrhœas and dyſenteries, in which perſpiration is defective, after its puking two or three times, it excites a perſpiration, if the patient is wrapped up warm. Its chief operation is conſidered as an emetic in proper doſes; in ſmaller doſes, as a nauſeative and aperient, upon which its antidyſenteric power ſeems to depend. See Cullen's Mat. Medica.

The beſt menſtruum for extracting the whole virtue of the root is one part pure ſpirit, and two or three of water; of wines, the Canary or mountain obtains moſt from it; but the London College directs the following.

Vinum IPECACUANHÆ. *Wine of* IPECACUANHA.

Take of the roots of *ipecacuanha* in powder, two ounces; of Spaniſh white wine, two pints; digeſt for ten days, and ſtrain. Ph. Lond. 1788. Doſe as an emetic, from ʒ ij. to ʒ i. ſs. as a diaphoretic, from 20 to 40 drops, with a fourth part more of tinctura opii.

Dr. Alſton of Edinburgh ſays, that the virtue of this root reſides not in its oil, gum, or reſin, but in its peculiar ſpirit. See DIARRHOEA and DYSENTERIA, for its uſe in thoſe diſorders. If three grains of powdered *ipecacuanha* is added to fifteen grains of jalap, it operates downward both more certainly and efficaciouſly.

To deceive children, mix ℈ i. or ʒ ſs. of powdered *ipecacuanha* with half a pint of boiling water in a tea-pot; diſguiſe it with a little milk and ſugar, and give a tea-cupful every ten or fifteen minutes, till it operates; when thus given, it needs nothing to work it off with. The College alſo orders,

Pulvis IPECACUANHÆ *Compoſitus. Compound Powder of* IPECACUANHA; named alſo *Doveri pulvis.*

Take of *ipecacuanha*, hard purified opium, of each, rubbed into powder, one dram; of vitriolated kali in powder, an ounce. Pharm. Lond. 1788. The doſe is from ten to thirty grains; the former doſe containing a grain of opium. This is very nearly the ſame as the powder of Dr. Dover, and is conſidered as one of the moſt certain ſudorifics in practice, for which purpoſe it is given in rheumatiſm, dropſy, and other diſeaſes where ſweating is neceſſary, and that difficult to be procured by any other means.

See Lewis's Mat. Med. Lond. Med. Obſ. and Inq. vol. i. Neumann's Chem. Works. Woodville's Medical Botany.

IPEPOCOANHA. See IPECACUANHA.

IPHION. See ASPHODELUS LUTEUS.

IQUETAIA. See SCROFULARIA AQUATICA.

IRA. ANGER. It produces a violent ſtricture in the nervous and muſcular parts, and for a time increaſes the tone of all the fibres; it quickens the pulſe and hurries reſpiration. The ſtomach and bowels ſuffer much by this paſſion; and ſometimes the ſtricture on the gall-ducts is ſuch, that a jaundice is the conſequence, though more frequently the gall is determined more copiouſly to the duodenum, producing a variety of diſagreeable ſymptoms. *Anger* alſo produces hæmorrhages from the noſe, the lungs, or the hæmorrhoidal veſſels, particularly in thoſe who are diſpoſed to theſe evacuations, and has occaſioned apoplexy.

During the fit of *anger*, or its immediate effects, carefully avoid vomits and purges, though if, in conſequence of *anger*, much bile is thrown into the duodenum, as ſoon as the patient is compoſed, a little rhubarb, with nitre, may be given to determine it downwards, and abate its acrimony.

The firſt and principal ſtep, when a patient is violently affected with *anger*, is, if the conſtitution is vigorous, to bleed; if the habit will not well admit of this operation, give the following, or other ſimilar antiſpaſmodics. ℞ Sp. ætheris nitroſ. tinct. caſtorei aa ʒ ſs. camphor ℈ i. m. dentur gut. xx. vel. xxx. pro re nata. Sometimes a gentle opiate, mixed with cordials, is required.

IRACUNDUS MUSCUL. See ABDUCTOR OCULI, N° 5.

IRINGUS. ERYNGO. See ERYNGIUM.

IRIS. The fore-part of the choroides is thus named, becauſe of the variety of its colours. It is alſo called *gramme*. It lies floating and looſe: it is convex to the anterior, and concave on the poſterior part; the perforation in the middle of its fore-part forms the pupilla. The *iris*, by contracting or dilating, excludes or admits of light in ſuch proportions as the varjety of circumſtances may require, &c. It is diſputed whether this power in the *iris* is owing to a nervous tenſion, or the action of muſcular fibres; on examination, two orders of fibres are found between the laminæ of the *iris*; one of which is circular, the other radiated; whence it is moſt probable that muſcular fibres produce theſe actions. See UVEA; CHOROIDES; and CIRCULUS ARTERIOSUS.

The operation of cutting the *iris* is required when a cataract adheres to it; and when, from the contraction of its muſcular fibres, the pupil is cloſed up, called *ſynizeſis*, or *caligo pupillæ*. Thus, both theſe diſorders are ſometimes remedied. Mr. Sharp, in his Operations, ch. xxix. directs the operator to proceed as follows: place the patient as for couching; open, and fix the eye with the ſpeculum oculi, then introduce the knife in the ſame part of the conjunctiva that is wounded in couching; inſinuate it with its blade held horizontally, and the back of it towards you, between the ligamentum ciliare, and circumference of the *iris*, into the anterior chamber of the eye; and, after it is advanced to the farther ſide of it, make your inciſion quite through the membrane; and, if the operation ſucceeds, it will, upon wounding, fly open, and appear a large orifice, though not ſo wide as it becomes afterwards. Mr. Sharp further obſerves, that when the pupil is contracted from a paralytic diſorder, this operation can hardly be encouraged.

IRIS. It is a perennial plant, with long, narrow, ſword-like leaves, ſtanding edgewiſe to the ſtalk, and large naked flowers divided deeply into ſix ſegments, of which alternately one is erect, and another arched downward, with three ſmaller productions in the middle, inclоſing the ſtamina and piſtil; the roots are tuberous, irregular, and full of joints. Boerhaave mentions twenty-four ſpecies, and Dale adds two more. See alſo ERYSIMUM. It is a name likewiſe of the *hedge-muſtard*, *hermodactyls*, a kind of *ginger*, a ſpecies of *xiphium*; alſo a ſpecies of *cryſtal*, and of a *paſtil*, conſiſting of alum, ſaffron, and myrrh.

IRIS FLORENTINA. FLORENTINE ORRIS, called alſo *iris* Illyrica, *iris* flore albo, and WHITE FLOWER DE LUCE. It is the IRIS FLORENTINA, *caule foliis altiore*

tiore sub bifloro, floribus sessilibus albis, corollis barbatis. CLASS TRIANDRIA. ORD. MONOGYNIA. LINN. Gen. Plant. 59. It is supposed to be only a variety of the common *iris*, or purple flower de luce. Its roots are brought from Italy, as being superior to those of our own growth. They are in oblong, flattish pieces, freed from the fibres, and brownish externally, but white, with brownish specks, internally. They are easily reduced to a powder of a farinaceous kind.

This root, in its recent state, is nauseous, acrid, and purgative, but loses these qualities by drying. The dry root is unctuous, bitterish, and pungent to the taste, not very strong, but durable in the mouth; hath a light, agreeable smell, which resembles violets, or rather raspberries; and it communicates a flavour to spirits, and to wines, which resembles them. As a medicine, the fresh root is a powerful cathartic; and, for this purpose, its juice has been employed in the dose of ʒ j. and upwards, in dropsies: in its dried state it is an useful expectorant; it attenuates viscid phlegm, and promotes its discharge. What this might do in its more recent, acrid state, Dr. Cullen says he cannot determine; but in the dried state in which we commonly have it in our shops, he considers it as an insignificant expectorant. Mat. Med. It is cut in the form of peas, and used for promoting the discharge in issues.

In distillation it gives over all its flavour with water; its bitter remains in the extract. Rectified spirit brings over a part of its flavour, and the extract is bitter, pungent, and glows in the mouth. See Lewis's Mat. Med. Neumann's Chem. Works.

IRIS TUBEROSA —— BULBOSA. See HERMODACTYLUS FOLIO QUADRANGULO, &c.

—— FOETIDA, also called *spatula fœtida, xyris gladiolus fœtidus*, SPURGE-WORT, STINKING GLADDON, or GLADWYN. This is a wild species of *iris*; its root is thick, and spreading in the earth, with many fibres, from which spring many leaves, longer, narrower, and sharper pointed than the common flower de luce; they have a strong smell. It is found in hedges, thickets, &c. The root is diuretic, but not much deserving notice.

—— PALUSTRIS, also called *acorus adulterinus, gladiolus lutæus, pseudo acorus, pseudo iris, butomus, butomon*, YELLOW FLOWER DE LUCE, YELLOW WATER-FLAG, SEDGES, &c. IRIS PSEUDACORUS, or IRIS PALUSTRIS, *foliis ensiformibus, corollis imberbibus, petalis interioribus stigmate minoribus.* CLASS, TRIANDRIA. ORD. MONOGYNIA. LINN. Gen. Plant. 59. YELLOW FLOWER DE LUCE. It is common by the sides of rivulets and marshes; the roots are reddish, the flowers stand several on a stalk, and are of a yellow colour; the middle ribs of the leaves are prominent.

The roots of this species, when fresh, are more acrid, and strongly cathartic, than the above two species. Eighty drops of the expressed juice, repeated every hour or two, have purged, when jalap, gamboge, and mercurials have failed. The root is without smell, but has an acrid styptic taste; its juice, on being snuffed up the nostrils, in the nose and mouth creates a burning heat, accompanied with a copious discharge from these organs; hence it is considered as an errhine, and sialogogue: from its astringency, it has been used for making ink, and dying black; and also, as a medicine in the cure of diarrhœa. To serpiginous eruptions, and scrophulous tumors, the expressed juice is an advantageous application. BERGIUS says, when *fresh*, it is a hydragogue purgative; when *dried*, an astringent; but, however, like the other *irises*, it is too variable in its strength to be received into general use.

—— LATIFOLIA TUBEROSA. See ZINGIBER.

—— VULGARIS, also called IRIS HORTENSIS NOSTRAS, IRIS *Germanica*, Linn. IRIS PURPUREA, the COMMON PURPLE FLOWER DE LUCE, *iris*, or *orris*. Its blue or purple flowers stand several on one stalk; their arched segments are bearded with a yellowish matter. The plant is a native of the mountainous parts of Germany; it is common in our gardens, and flowers in June. The roots, when fresh, smell disagreeably, and have an acrid nauseous taste; they are a strong irritating cathartic; in which case, the expressed juice hath been given in a dropsy, from ʒ ii. to ʒ iv. diluted with water. By gently inspissating the juice, it is less purging, and irritates less; but, if inspissated to dryness, it loses all its purging quality. The dried root resembles in smell and taste the Florentine species.

IRRADIATIO. See ACTINOBOLYSMUS.

IRRITABILITAS. IRRITABILITY. Irritation is a species of stimulus, expressing a lesser degree of it than vellication or corrugation, &c. and the parts on which stimuli are capable of acting, so as to produce motion, are said to be irritable, and this seems to be confined to the muscular fibres. What is produced on the nervous system, is more properly termed sensibility. See SENSIBILITAS, and INCITABILITAS.

The same species of stimulus, applied to different parts, produces different effects; thus urine does not affect the bladder; but, if it is injected into the guts, it proves purgative, and distension is the chief stimulus that affects the blood-vessels.

Haller endeavours to prove the insensibility of the tendons, membranes, and ligaments. Dr. Hunter is of opinion, that the ligaments, tendons, periosteum, and dura mater, are almost, if not wholly, insensible; however, inflammation soon manifests the *irritability* and sensibility of parts, in which they were not observable in a healthy state; even the bones become sensible when disordered; they also inflame and suppurate; and, in short, the effects of medicines are very often to be deduced from this *irritability*, as they depend on either increasing or diminishing it. In slow fevers, this irritation must be heightened; in ardent ones lessened. The same is observable in many other disorders.

Dr. Kirkland observes, that *irritability* is of two kinds, viz. inflammatory or spasmodic. The first of these he says always arises from distention, or continued irritation: and, always while the inflammation is attended with any considerable degree of violence, produces a fever, and a quick pulse. The other kind is confined to the expanded brain, and never affects the pulse or produces a fever; but these two kinds may exist together.

See Haller's Treatise on Insensibility and Irritation; Dr. Whytt's Answer to Haller's Treatise on Sensibility and *Irritability*; the Difficulties in the Modern System of Physic, with Regard to the Sensibility and *Irritability* of the Parts of the Human Body, by Dr. De Haen; and Kirkland's Dissertations on the Brain and Nerves; also on the Sympathy of the Nerves, and of different Kinds of *Irritability*. Cullen's Materia Medica.

IS, *is*, *a fibre*; its plural is *ises*. Some say that Hippocrates used this word indifferently for *a fibre* and *a nerve*; and it is clear that other writers have done the same.

ISAROS. See ARUM.

ISATIS. *Sativa*;—latifolia;—tinctoria. See GLASTUM.

—— INDICA. See INDICUM.

ISATODES. Of the colour of woad.

ISCA. A sort of fungous excrescence of the oak, or of the hazel, &c. The ancients used it as the moderns use moxa. See MOXA.

ISCHÆMON, from ἰσχω, *to restrain*, and αἱμα, *blood*. A name for any medicine which restrains or stops bleeding.

—— SATIVUM. MANNA GRASS. See GRAMEN.

ISCHIAS. A name of the *sciatica* or *ischiadicus Morbus*, and of two crural veins, one of which is called the greater, the other the lesser. See CRURALIS VENA.

ISCHIADICUS DOLOR. See ARTHRITIS.

ISCHIADICUS MORBUS, also called *ischias*, SCIATICA, *coxæ dolores*. Aretæus ranks this disorder as a species of the gout, and says, "that it comes on the hind part of the thigh, the ham, or the tibia; at other times the pain seizes upon the acetabulum of the os femoris, and then attacks the buttock and loins, and seems to be any thing rather than a *sciatica*." Dr. Cullen ranks it as a synonime with rheumatismus.

The *sciatica* hath three seats: first, *the tendinous expansion, which covers the muscles of the thigh*. Secondly, *the coat of the sciatic nerve*; and here the pain is more acute and violent, attended with a numbness; this is easily accounted for, since it is well known that any compression on a nerve causes deadness. Thirdly, *the capsular ligament*; the depth and severity of the pain leads us to judge of this part being the seat.

In the first case, the usual anti-rheumatic medicines may be given inwardly, and the volatile liniment applied externally. *The second* requires the application of blisters, with what is necessary in the first. *The third* is best removed by mercurial alteratives; and, indeed, the other two, when obstinate, require a similar treatment. Dr. Fothergill recommends the following pills and draught, *as being of all other means the most effectual.*

℞ Calom. gr. x. conf. roſar. r. q. ſ. pil. x. deaur. cap. i. omni nocte, ſuperbibendo hauſt ſeq.

℞ Tinct. opii, gt. xxv. vin. antimonii, gt. xxx. fyr. ſimp. ʒ i. aq. alex. ſ. ʒ i. ſs. ſp. ʒ i. ſs. m. f. hauſt.

If the pain does not abate by the time this quantity is taken, the doſe of calomel may be increaſed to two grains one night, and one the next, &c. alternately. When the pain abates, the anodyne and antimonial are gradually leſſened, until by degrees they are wholly omitted. See Lond. Med. Obſ. and Inq. vol. iv. p. 69, &c. See alſo Brooke's and the Lond. Practice of Phyſic, for a variety of other methods which occaſionally have been productive of the deſired effect. See RHEUMATISMUS. Dr. COTTLIEB RICHTER ſpeaks of ſome caſes of the iſchias nervoſa being ſucceſsfully treated by bliſters often repeated, and ſudorifics. The bliſters were applied on different parts where any pains were felt in ſucceſſion: the ſudorifics were firſt crude antimony, and ſtipit. dulcamaræ in pills; and the warm bath for ſix days; on the 7th, a powder compoſed of camphor, ipecacuanha, and opium, and a tepid bath before it; the bath was continued till the foot became oedematous, and then left off; the other remedies ſtill purſued, which, in about ſix weeks, compleated the cure. His ſymptoms were, pains in his arms, ſhoulders, and back, which ſettled about the hip-joint, continued fixed; and, encreaſing till he could not walk, the whole limb became ſhorter; the pains extended from the hip-joint down to the foot; he felt as if ants were running about in the foot; he was totally unable to move the limb to either ſide, which, in other reſpects, was warm, and properly nouriſhed. A lady and a young man were cured by the application of burning cylinders, and bliſters; on which he remarks, that from this method nothing is to be expected unleſs in ſuch kinds of lameneſs as proceed from the metaſtaſis of any ſtimulating matter, where the lameneſs is accompanied with pains in the ſuffering limb, and chiefly the hip-joint; and this morbific matter, he thinks rheumatic, or gouty; though, in ſome caſes, he had reaſon to believe it was ſcrophulous. See his *Medical and Surgical Obſervations*, p. 169.

ISHCIAS EX ABSCESSU. See ARTHROPUOSIS.

—— SPARGANOSI. See LYMPHÆDUCTUS.

ISCHIATOCELE. Inteſtinal rupture through the ſacro-ſciatic ligaments.

ISCHIOCELE. A rupture between the os ſacrum and the tuberoſity of the os iſchium.

ISCHIO COCCYGÆUS. See COCCYGÆUS ANTERIOR.

ISCHION. A name of the ligament which retains the head of the thigh-bone in the acetabulum coxendicis.

ISCHIUM, Os, becauſe it lies near ἰσχὺς, *the loin*, ἰσχίον, the HIP-BONE. Called alſo *coxendix*, and, by by ſome, *cochone*. The extent of this bone might be marked by an horizontal line drawn through near the middle of the acetabulum coxendicis. The great tuberoſity on which we ſit, as it advances forwards, becomes ſmaller, and gives origin to the corpora cavernoſa, and the erectores penis, and the clitoridis; then the bone mounts upwards with a conſiderable curve, and is ſtretched out into its ſmall leg. It forms the lower part of the pelvis.

ISCHNOPHONIA, from ἰσχνὸς *ſlender*, and φωνὴ, *the voice*. A SHRILLNESS of the VOICE; but more frequently an heſitation of ſpeech, or a STAMMERING. It is the *pſelliſmus hæſitans*.

ISCHNOTIS. LEANNESS.

ISCHURETICA. Medicines that remove a ſuppreſſion of urine.

ISCHURIA, from ἰσχὼ, *to retain*, and οὖρον, *urine*. An ISCHURY, A STOPPAGE OF SUPPRESSION OF URINE. La Motte diſtinguiſhes betwixt a retention, and a ſuppreſſion of urine. *In a retention*, the patient hath frequent motions to make water without being able to void it; or, if he does paſs any, it is in very ſmall quantities, and with difficulty; this is alſo called a STRANGURIA. *In a ſuppreſſion*, there is ſeldom any inclination to diſcharge any urine; but, if there is an inclination, the diſcharge is ſudden.

An *iſchuria* is of two kinds, viz. *the true*, in which caſe the bladder is full; and, *the ſpurious*, in which the bladder is empty, for nothing deſcends from the kidneys.

Dr. Cullen places this genus of diſeaſe in the CLASS LOCALES, and ORD. EPISCHESES, which he defines an abſolute ſuppreſſion of urine. He diſtinguiſhes four ſpecies. 1. *Iſchuria renalis*, where ſome diſeaſe of the kidneys having preceded, there is pain, and an uneaſy ſenſation of weight in the region of the kidneys, without any ſwelling of the hypogaſtric region, or ſtimulus to make water. 2. *Iſchuria ureterica*, where the ſymptoms are ſimilar to the above ſpecies, with this difference, *the ſenſe of pain and uneaſineſs is felt in a certain part of the ureters*. 3. *Iſchuria veſicalis*, when there is a tumor in the hypogaſtric region, pain at the neck of the bladder, and a frequent urging to diſcharge urine. 4. *Iſchuria urethralis*, when there is ſwelling in the hypogaſtric region, a frequent deſire to diſcharge urine, and the pain in ſome part of the urethra. The varieties of each ſpecies may be ſeen below.

The cauſes are various. Etmuller ſays, the moſt frequent is a want of mucus in the urethra. Other cauſes are a ſtone in the kidneys or bladder; caruncles in the urethra; inflammation in any of thoſe parts; a ſpaſm in the neck of the bladder, or in the urethra; pain from the piles in pregnant women, the child's head preſſing the neck of the bladder againſt the os pubis; a tumor, or ulcer, in the proſtate gland; a defluxion of humour on the neck of the bladder; a retention of urine; a palſy in the detruſor urinæ; a retention of hardened excrements in the inteſtinum rectum, &c. A *ſpurious iſchury* is when the kidneys ſecrete no urine, or when the ureters either do not receive, or do not tranſmit it; and this may happen from inflammation of the ureters, or in the kidneys. A view of the different cauſes may be perhaps beſt taken from the different varieties of *iſchury*, noticed under the following words.

VARIETIES OF THE FIRST SPECIES, WITH THE KIDNEYS AFFECTED, ARE:

ISCHURIA *nephritica*, FROM inflammation of THE KIDNEYS;—*nephrolitica*, a ſtone;—*nephropletho rica*, plethora;—*lunatica, periodica*, periodical;—*nephroſpaſtica*, from ſpaſms;—*nephrelmintica*, worms;—*nephrethromboides*, congrumated blood;—*nephropyica*, purulence of the kidnies;—*nephrophlegmatica*, pituite, or mucus;—*nephroplegica*, paralytic affection;—*ſuppleta*, from ſome other evacuation ſupplied.

VARIETIES OF THE SECOND SPECIES, WITH THE URETERS AFFECTED, ARE:

ISCHURIA *ureterica*, FROM inflammation of THE URETERS;—*ureterolithica*, from a ſtone;—*uretero thromboides*, grumous blood;—*uretero phlegmatica*, from pituite;—*uretero pyica*, from pus;—*uretero ſtomatica*, the cloſing of the inferior orifice of the ureters.

VARIETIES OF THE THIRD SPECIES, WITH THE BLADDER AFFECTED, ARE:

ISCHURIA *atretarum*, from the menſtrua retained in the vagina;—*cyſtica*, FROM inflammation of THE BLADDER;—*cyſtoſpaſtica*, a ſpaſm of its ſphincter;—*cyſtolithica*, a ſtone;—*cyſtoplegica*, paralytic affection;—*cyſtepyica*, purulence;—*cyſtothromboides*, from grumous blood;—*cyſtophlegmatica*, mucus;—*cyſtoproctica*, from the rectum ſwelling, with ſcybali, calculus, flatus, inflammation, abſceſs, or hæmorrhoids;—*ectopocyſtica*, from the bladder being diſplaced;—*hyſterocyſtica*, from the uterus;—*paradoxa*;—*polyurica*, from the bladder diſtended with urine a long time retained.

VARIETIES OF THE FOURTH SPECIES, WITH THE URETHRA AFFECTED, ARE:

ISCHURIA *aſpadialis*, FROM cloſing of the urethra;—*carunculoſa*, FROM caruncles, diſeaſes as they are called of the urethra;—*cryptoica*, a retraction of the penis within the abdomen;—*hydrocelodes*, from a rupture of the urethra opening into the ſcrotum;—*perideſmica*, a ſtricture of the penis;—*perinæalis*, a tumor of the perinæum;—*phymoſica*, a phymoſis;—*urethrelmintica*, worms;—*urethritica*, inflammation of the urethra;—*urethrohymenodes*, from a membrane impacted in the urethra;—*urethrolithica*, from a calculus impacted in the urethra,—*urethrophlegmatica*, from mucus, ſtuffing up the urethra;—*urethromboides*, grumous blood;—*urethropyica*, pus.

When the ſuppreſſed urine is lodged in the bladder, a pain and ſwelling is obſerved about the pubes;—*a ſuppreſſion from relaxation* is diſtinguiſhed from *ſuppreſſion from ſtricture*; *firſt*, by the little pain attending the diſorder, when from relaxation; *ſecondly*, by the introduction of the catheter; *thirdly*, from the diſtenſion of the bladder, obſervable from the fulneſs above the pubes; *fourthly*, from no ſtimulus being excited in the bladder to diſcharge any

any fluid wherewith you diſtend it.—If inflammation in the kidneys is the cauſe, the pain and heat are principally in that region.—If a ſtone in the kidneys gives riſe to the complaint, a vomiting is an attendant ſymptom.—If a ſtone in the bladder obſtructs the urine, a pain is felt there, and alſo along the urethra; a mucus, or pus, is excreted with pale urine; and generally the ſtone may be felt, if the catheter is introduced.—If from inflammation in the neck of the bladder, there is alſo pain and a tumor there, the pain will be much increaſed if the perinæum is but ſlightly preſſed; and if a finger is introduced into the anus, and turned towards the bladder, a tumor will eaſily be perceived.

If this diſorder is in a great degree, there is a teneſmus, coldneſs of the extremities, a vomiting, and a febrile pulſe.

If this diſorder is the *ſpurious kind*, there is no tenſion, but rather a ſenſe of emptineſs about the pubes.

If this diſorder continues above ſeven days, it proves fatal; alſo, if from a wound of the ſpine, or luxation of its vertebræ. If the ſmell of urine proceeds from the patient's mouth or noſtrils, there is no hope. An hiccough, and a teneſmus, are alſo unfavourable ſymptoms.

If the urine is lodged in the bladder, and cannot be voided, whether the cauſe be cold, a too long retention of urine, and whatever elſe that could deprive the fibres of the bladder of their contracting power; or *if the ſuppreſſion is from a ſpaſmodic ſtricture in the neck of the bladder*, an immediate recourſe to the catheter is not convenient, for in theſe caſes it cauſes much pain; but ſuch medicines as oppoſe the cauſe ſhould firſt be tried.

If the habit is plethoric, bleed, inject the turpentine clyſter, with a dram of the tinct. opii; an oily mixture may be given, in which is the ſp. nitroſ. ætheris, with the tinct. opii, in proportion to the degree of pain; and the patient may be placed in a warm bath. If theſe fail, a bougie may be introduced, or the catheter may be uſed.

In children, a ſuppreſſion of urine is often relieved by a poultice of raw onions, or of radiſhes, applied to the pubes.

When a long retention of urine is the cauſe, cloths may be wrung out of cold water, and applied round the waiſt and belly; but bleeding ſhould, in ſome conſtitutions, precede.

If a relaxation or paralyſis of the detruſor urinæ be the cauſe, give the bark with nervines, and apply cloths wrung from cold water round the belly and loins, or put the patient into a cold bath. Gentle preſſure on the belly ſhould now and then be uſed.

When caruncles obſtruct the urethra, bougies ſhould be introduced there.

When a retention of urine is produced, let the cauſe be what it may, every patient ſo circumſtanced is ſpaſmodically affected; and generally the introduction of a bougie will increaſe the ſpaſm, produce a ſhivering, and then a fever fit; all which will return as often as the bougie is introduced, and the diſeaſe to be relieved will become proportionably obſtinate. Yet, if the bougie is introduced without pain, and the patient diſcharges his urine more freely, its uſe may be continued.

If there is inflammation in the neck of the bladder, the catheter cannot be uſed before the inflammation abates; diuretics cannot conveniently be admitted; here nitrous medicines, neutral ſalts, the acidum muriaticum diluted in the patient's common drink, and ſmall doſes of camphor, may be frequently given. Decoctions of parſley roots, with a little nitre, may be drank in proportion as the thirſt requires; and bladders of warm water may be applied to the pubes and perinæum, or to the region of the kidneys, if the inflammation is there, and ſuch other medicines as are recommended in the nephritis. Bleeding is here a principal remedy, and as a laxative the ſal cath. amar. or the ol. ricini ver. may be uſed.

If a ſtone obſtructs the neck of the bladder or *the urethra*, puſh it back with the catheter, or cut through the perinæum, and there extract it. Some adviſe never to uſe the catheter in retentions of urine from any cauſe but from a calculus obſtructing its paſſage. But this advice may be too general; the uſe of this inſtrument is rarely required.

When the head of the child, in pregnant women, obſtructs the paſſage of the urine, introduce a finger into the vagina, and puſh back the child's head until a due evacuation is made.

When acrid urine is the cauſe, emulſions made with the ol. ricini, ſhould be the common drink. Nitre mixed in oily draughts, and mucilaginous decoctions, are the proper remedies.

Spaſms are removed by fomentations, the warm bath, demulcents, clyſters, antiſpaſmodics, and anodynes.

When the urine is totally retained in the bladder, it is too common a practice to adviſe to introduce the catheter; but whether this complaint ariſes from inflammation or from ſpaſm, this conduct ſhould carefully be avoided. Mr. Pott obſerves, that the beſt method of relieving this complaint, particularly when cauſed by ſpaſm, is by evacuation and anodyne relaxation. The loſs of blood he ſays is often neceſſary; as to what quantity, the ſtrength and ſtate of the patient will determine. The inteſtines muſt be emptied by ſome gentle cathartic. *But the moſt effectual relief will be from the warm bath, or ſemicupium, the application of bladders half filled with hot water to the pubes and perinæum*; and ABOVE ALL OTHER REMEDIES, *the injection of glyſters*, conſiſting of the decoct. pro enemate ol. and tinct. opii; or if after a due bleeding, if neceſſary, and emptying the bowels, a free doſe of opium is given, and the patient is ſeated in a warm bath during twenty minutes or half an hour, repeating this uſe of the bath oftener or ſeldomer as the caſe may ſeem to require, ſucceſs will very rarely fail to attend; and if by theſe means, the urine begins to drop through the urethra, although but a drop in a minute at the firſt, by perſevering ſteadily and cloſely, the bladder will effectually empty itſelf. Let the whole endeavour be to appeaſe irritation and pain, to accompliſh which, although it may take up three or four or even ſeven days careful attention, it will amply reward the practitioner's care, and the patient's fatigue.

When great pain attends a retention or ſuppreſſion of urine, the perſon called on for his aſſiſtance ſhould firſt be well ſatisfied that the caſe is what it is ſuppoſed to be; he ſhould obſerve whether the kidneys have done their office, and whether in reality there is urine in the bladder, which if full it will be ſo diſtended as to be felt above the os pubis, and by preſſure on it a pain will be excited in the neck of the bladder. Another obſervation deſerves attention in inſtances of this kind; viz. the bladder will contain ſometimes a large quantity, and not be affected by it; at other times a very ſmall quantity will affect it; ſo that when an obſtruction takes place, an inflammation ariſes, and ſymptoms of irritation enſue; and if relief is not immediately given, the patient is ſoon cut off. Dr. George Fordyce obſerves, that much of the difficulty and pain from retained urine is from the more or leſs ſudden filling of the bladder or diſtending it.

When the urine is ſuppreſſed from the kidneys failing to perform their office, diuretics are very cautiouſly to be admitted; attempts may be made to relax the veſſels of theſe organs by putting the patient frequently into the warm bath; and purgings may be admitted, as they increaſe the ſecretions in the inteſtines.

If no other method will ſucceed, a puncture may be made into the bladder, as directed in the article PERINÆUM, *Puncture of the*.

Indeed there are four methods propoſed by different writers for drawing off the urine; viz. 1. By making an opening into the bladder above the os pubis, in the part where the high operation for the ſtone uſed to be performed. 2. By making a puncture in perinæo, and ſo getting into the bladder. 3. By making an opening into the bladder through the parts divided in the lateral operation for the ſtone. 4. By getting into the poſterior part of the bladder through the rectum, with an inſtrument introduced up it for that purpoſe. But from the experience of ſome judicious practitioners, it can hardly be ſaid that their advantages are an encouragement to perform them. If one of theſe methods was determined on, Mr. Pott gives his opinion in favour of opening the bladder above the os pubis; but obſerves, that in his practice he hath not ſeen any of them to be neceſſary; and further, though he does not abſolutely forbid, yet his perſuaſions againſt them do very little leſs.

See an inſtance of this diſorder from a retroverſion of the uterus, in the Lond. Med. Obſ. and Inq. vol. iv. p. 388, &c. See Pott's Chirurgical Works. Lewis's Tranſlations of Hoffman's Practice of Medicine. Bell's Surgery, vol. ii. p. 171. White's Surgery, p. 374. Memoirs of the Medical Society of London, p. 117.

ISLINGTON-WATERS. See AQUÆ CHALYBEATÆ.

ISORA-

ISORA-MUNE. The name of a tree in Malabar. The juice of its root is uſed in diſorders of the breaſt.

ISOTHEON. See DIONYSOS.

ISOTONI. See ACMASTICOS.

ISPIDA. See ALCEDO.

ISTHMION. The narrow paſſage between the mouth and gullet. The *fauces*.

ITHMOIDES. Falſely for ethmoides.

ITEA. See SALIX.

ITINERARIUM. A ſtaff uſed in cutting for the ſtone; it is thus named by Hildanus.

IULUS (plural IULI.) See AMENTACEI FLORES.

IVA ARTHRITICA. See CHAMÆPITYS.

IVABEBA. An ancient ſhrub, the root of which is a good deobſtruent. See Raii Hiſt.

IVA MOSCHATA. See CHAMÆPITYS.

IVA PECANGA. See SARSAPARILLA.

IVRAY. See LOLIUM.

IXIA. *Varix*. Alſo a name of the *carlina*, or ſuch of this tribe as yield a viſcous juice. The *ixia*, or ixias, is repreſented as poiſonous; but it is not clearly known to what plant theſe names belong.

IXIA, IXINE, IXION. See CARDUUS PINEA.

IXUS. See APARINE.

J.

JABATAPITA. A tree in Braſil, which bears yellow flowers, and has a grateful ſmell. The fruit reſembles our myrtle-berries; they are aſtringent, and yield by expreſſion an inſipid oil. See Raii Hiſt.

JABUTICABA. A fine tall tree which grows in Braſil. Its fruit reſembles an apple, and is gratefully cooling.

JACA INDICA. The Indian jacque jaca, or JACK-TREE. See MARUM.

JACARANDA ALBA. It is like the European palm-tree; it is plentiful in Braſil. The Braſilians make a pottage of it, which they call *manipey*, is a good ſtomachic. See Raii Hiſt.

JACARECATINGA. See CALAMUS AROMATICUS.

JACE BRASILIENSIBUS, alſo called *melo Indicus*, *patheca*, and *citrullus*. Ray makes it a ſpecies of *anguria* or *citrullus*, and calls it WATER-MELON; this fruit is as large as a man's head; it hath a green rind, and its pulp is well taſted. See CITRULLUS.

JACEA. KNAP-WEED or MATFELLON. Boerhaave enumerates forty-one ſpecies. The margins of the leaves are not ſerrated; the leaves and ſtalks are deſtitute of ſpines; it is common in paſture grounds, and flowers in July and Auguſt. A flight aſtringency is attributed to it.

—— ORIENTALIS PATULA. See BEHEN ALBUM.

—— RAMOSISSIMA, STELLATA, RUPINA. See CALCITRAPA.

—— STELLATA; LUTEA, &c. See CALCITRAPA OFFICINALIS.

JACOBÆA PRATENSIS. See DORIA.

—— PALUSTRIS. See VIRGA AUREA.

JAGRA. See PALMA COCCIFERA.

JALAPA. JALAP. It is a native of the province of Chalapa, or Xalapa, in New Spain, from whence its name is derived, and written according to the pronunciation of different languages, ſo is called *jalapium*, *gialappa*, *gialapium*, *mirabilis Peruviana*, *chalapa*, *xalapa*, *zalapa*, &c. Some call it *mecoachana nigra*, *convovulus Americanus*, *bryonia Peruviana*. There is ſaid to be a third ſpecies of jalap called *mutaliſta*, by the Indians *mathaliſtic*.

The plant is a ſpecies of convolvulus. The *convolvulus jalapa*; or convolvulus foliis, ovatis ſub cordatis obtuſis obſolato repandis ſubtus villoſis, *caule volubili*, *pedunculis unifloris*. CLASS PENTANDRIA; ORD. MONOGYNIA. LINN. Gen. Plant. 215. The plants raiſed in Europe are not ſo good as the American.

The roots are brought from New Spain in tranſverſe ſlices; they are ſolid, hard, weighty, of a blackiſh or dark brown colour on the cortical part, internally of a dark greyiſh colour, with ſeveral black circular ſtriæ.

Chuſe the hardeſt, darkeſt coloured, and thoſe pieces which have the moſt of theſe reſinous veins; thoſe that break blackeſt, moſt compact, ſhining, and that burn readily at the flame of a candle. Worms rarely touch the reſinous part: ſo when the pieces are deſigned for obtaining the reſin from them, the worm-eaten are as good as the other.

Pieces of briony root are ſometimes mixed with the *jalap*, but are eaſily diſtinguiſhed by their paler colour and leſs compact texture, and by their not readily burning at the flame of a candle.

Jalap hath ſcarcely any ſmell, and but little taſte; when ſwallowed it affects the throat with a ſlight pungency and heat, and occaſions a ſpitting. In doſes from ten grains to half a dram it is an effectual purge, but gripes and nauſeates leſs than the generality of purging medicines in uſe. For children in general, and adults of a ſpongy lax habit, or of a leucophlegmatic diſpoſition, it is more proper than for the robuſt and thoſe with rigid fibres: it is diuretic as well as purgative, whence its preference in dropſies; in which caſe it is beſt given in wine, in which it ſhould ſtand a few hours before the taking of it.

Various are the means of correcting *jalap*. As to peculiar uneaſineſſes complained of by particular perſons, from taking this drug, as they are no other than what is common to all medicines of this kind, they may be relieved by changing the mode of adminiſtration, or ſuch other circumſtance as the ſagacity of the attentive practitioner will eaſily ſuggeſt.

If it be well triturated with cryſtals of tartar before exhibition, it will operate in ſmaller doſes than when taken by itſelf, and at the ſame time very moderately without griping. Rubbed with hard ſugar, it becomes a good or ſafe medicine for children; joined with calomel, and given in large doſes, it is rendered one of the moſt powerful purgatives either as a hydragogue or anthelmintic; and from its general efficacy in dropſies, was called *panacea hydropicorum*. The purgative activity reſides chiefly in its reſin. The gummy part is found to have little or no cathartic power, but as a diuretic is extremely powerful. The doſe of the ſimple powder is from ℈ i. to ℈ ij. The compound powder may be double the quantity.

Reſina JALAPII. *Reſin of* JALAP.

Take any quantity of *jalap* root powdered; pour upon it ſo much ſpt. vini r. as will cover it to the height of four fingers, and digeſt them in a ſand-heat, that the ſpirit may extract the reſin; filter the tincture through paper; put it into a glaſs cucurbit, and diſtil off one half of the ſpirit; add to the remainder a proper quantity of water, and the reſin will precipitate; divide it into little cakes, and dry with a gentle heat. This has no place in the Pharm. Lond. 1788.

It is a pure reſin: but its inſolubility in any aqueous fluid forbids its uſe, except it is previouſly prepared by trituration with an alcaline ſalt, gum, ſugar, or ſuch like intermedium, to fit it for mixture with a watery liquor. If it is thus managed, a doſe from gr. v. to. x. operates with ſufficient eaſe and efficacy.

The *jalap* which remains after this reſin is extracted, gives out, by boiling in water, a mucilaginous ſubſtance which operates by urine, but not in any degree by ſtool.

From ſixteen ounces of good *jalap* Neumann ſays he hath obtained ℥ v. and ℈ iv. of pure reſin.

This reſin is frequently adulterated, and the variety of methods by which the fraud may be practiſed are ſuch as elude every known method of detecting it, ſo that he who will uſe it muſt prepare it himſelf.

The London College direct an extract to be made in the ſame manner as that of the cort. Peruv. cum reſina. See CORT. PERUV.

From gr. x. to ℈ i. is a doſe. The advantage of this extract conſiſts in the nearer equality of its ſtrength than is found in the different parcels of the roots, ſome of which afford only ℥ ii. of reſin from ℔ i. whilſt others afford

℥ v. but this diſproportion is not obſerved in the reſins. However, except for the convenience of form, the tincture with proof ſpirit is made with leſs trouble, and will anſwer every purpoſe propoſed by this gummy-reſinous extract.

Tinct. JALAPII. *Tincture of* JALAP.

Take of powdered *jalap* eight ounces, and of proof ſpirit of wine two pounds; digeſt with a moderate heat, for eight days, and ſtrain off the tincture. The doſe is from ʒ i. to ℥ ſs. or more, mixed with ſyrup it may be given to children with the greateſt ſafety. This is the purgative ſaid to be given by the inoculators who received their inſtructions from SUTTON. Cullen's Mat. Med.

This tincture is tolerably certain in point of ſtrength, for the above proportion of this menſtrum does not take up the whole virtue of any kind of *jalap*. See Neumann's Chem. Works. Lewis's Mat. Med.

JATROPHA. See CATAPUTIA MINOR; and CASSADA.

JECORARIA. A name of the *hepatica vulgaris*; alſo of a vein in the right hand. See SPLENITIS.

JECUR. The LIVER: called alſo *hepar*, the upper part *erix*. Immediately below the diaphragm, on the right ſide, is placed the *liver*, whoſe ſmall lobe is ſtill contiguous to the diaphragm, and goes to the ſcorbiculus cordis. It is divided into two lobes beſides the *lobulus Spigelii*, which Hippocrates calls *hypercheryphoſes*; the large lobe is ſituated on the right hypochondrium, contiguous to the diaphragm; it reaches as far back almoſt as the ſpine, and reſts upon the right kidney; the ſmall lobe runs cloſe to the diaphragm, as far as the ſpleen. The convex ſide of the *liver* is uſually connected to the diaphragm by three ligaments, which are continuations of the peritonæum; one lies near the edge of the extremity of each lobe, and one in the middle, and they are accordingly called the right, and left, and middle ligaments. The *liver* is likewiſe connected to the right ala of the tendinous part of the diaphragm by a broad adheſion, which is the reflection of the peritonæum, and is called the CORONARIUM LIGAMENTUM. Under the great lobe, a little to the right, we ſee the gall-bladder. The ſmaller lobe of the liver is in the left ſide, which is diſtinguiſhed above by a membranous ligament, and below by a large ſciſſure in the ſame direction as the ſuperior ligament. The eminences on the concave ſide of the *liver* belong to the great lobe; the principal one is a triangular maſs, ſituated backwards near the great ſciſſure, which maſs is named *lobulus Spigelii*; this lobe is attached by a little peduncle to the middle of the lower ſide of the great lobe. The *firſt fiſſure* we obſerve, next to the great one, is a notch at the anterior part of the *liver*, for the reception of the ligamentary remains of the vena umbilicalis; the ſecond fiſſure is towards the poſterior part of the *liver*, between the lobulus Spigelii, and the little lobe, where we obſerve the remains of the ductus venoſus, which runs to be inſerted into the vena cava, and is peculiar to the fœtus; upon the right of the lobulus Spigelii, between that and the great lobe, is another fiſſure in which the vena cava runs down; the next fiſſure is a tranſverſe one, ſituated before the lobulus Spigelii: this is called porta; beſides theſe, on the forepart of the great lobe there is a depreſſion, for the reception of the gall-bladder; and we may obſerve on the under-ſide of the great lobe, a ſmall cavity, where it reſts on the right kidney.

The principal veſſels of the *liver* are, 1ſt, From behind the pancreas, a maſs of veſſels and nerves run up to the porta. 2d. The hepatic artery comes off from the cœliaca, and divides into two branches, one of which goes to each lobe. 3d. The vena portæ, when it arrives at the porta, likewiſe divides into two, one of which enters the right, and the other the left lobe. 4th. From the duodenum and pancreas we ſee the *porus biliarius*, ductus communis choledochus, which, at a diſtance from the porta, divides into two ducts, viz. the cyſtic, which goes to the gall-bladder, and the hepatic, which again is ſubdivided into two, which go their reſpective lobes. 5th. The vena cava, in its paſſage through the diaphragm, ſends off ſeveral branches, eſpecially two which go to the *liver*, and are called venæ cavæ hepaticæ: their office is to throw the blood into the vena cava, after the bile is ſecreted. 6th. The blood from all the viſcera is returned to the vena portæ, which ramifies through the *liver* like an artery; the lower part of this veſſel is called vena portæ meſenterica; the upper hath the name of hepatica given to it. Laſtly, we may obſerve, that the greateſt part of theſe veſſels are incloſed in a membranous theath, which from Gliſſon, who firſt took notice of it, is called capſula Gliſſoniana. This author deſcribes it as compoſed of cellular membranes, nerves, and peritonæum, which he alledges not only cover the veſſels at their entrance, but ramifies through the *liver* with them; but the peritonæum muſt be abſolutely excluded, for the nerves and cellular membrane only go through the *liver*.

The external ſurface of the *liver* is ſmooth, and covered with the peritonæum, which membrane is not only tied to the *liver* by the membrana cellularis, but by the veſſels which run out to be ſpread upon it. The *liver*, except for the veſſels, is very ſoft, and like a piece of congealed blood. Malpighi examined this, and brought it out to be a congeries of folliculi, where the veſſels terminate and form the bile. Ruyſch makes it a congeries of veſſels, even in the tendereſt part of it. The penicilli of Ruyſch are a collection of veſſels upon the ſurface; according to this author, the veſſels do not terminate in the penicilli, but become infinitely finer, whence this viſcus cannot be ſtructured as Malpighi imagines. The *liver*, according to the ancients, was the viſcus wherein the chyle was converted into blood, but ſince the knowledge of the lacteals, and the diſcovery of the circulation of the blood, we know that the uſe of the *liver* is to ſecrete the bile. There are two kinds of blood which come to the *liver*, viz. the arterial by the hepatic artery, and the venal by the vena portarum; a greater quantity of blood is ſent by the latter than by the former, as it brings the blood from the ſplenic, meſenteric, &c. veins; this latter alſo is that by which the bile is ſecreted. See Winſlow's Anatomy, and Haller's Phyſiology, Lecture xxvii.

The *liver* is the ſeat of various diſorders, viz. inflammation, abſceſs, ſcirrhus, hydatids, &c. See HEPATITIS; *icterus*; *bilioſa febris*; *cholera morbus*; *hepatalgia*, and in moſt of them the countenance hath a pale colour, or a yellowiſh one, with a greeniſh caſt. Beſides thoſe diſorders of this viſcus, which have long ſince been noted by medical authors, Mr. Crawford mentions one which he denominates an enlargement of the *liver*. See his Eſſay on the Nature, Cauſe, and Cure of a Diſeaſe incident to the *Liver*. The principal ſigns of it are, a great and ſudden ſwelling and hardneſs of the belly, with a difficulty of breathing, which latter is the only very troubleſome ſymptom. Previous to theſe, a general weakneſs, a ſenſe of tightneſs about the breaſt, and a giddineſs of the head on any little motion, are perceived; then an œdematous ſwelling appears in the legs, pains in the back, thirſt, and loſs of appetite attend; the pulſe is ſmall and weak, but on bleeding it becomes more full and diſtinct; the countenance is florid: as the belly enlarges, the breathing is more difficult, and then the ſenſe of oppreſſion about the precordia, and a ſtricture about the cartilago enſiformis, becomes almoſt inſupportable, ſoon terminating in a complete ſuffocation. A violent vertigo, and troubleſome palpitation of the heart, are occaſional ſymptoms. Some ſymptoms of this diſorder reſemble thoſe of the ſcurvy; but the ſore ſpongy gums, always attendant on the ſcurvy, are not obſerved here.

As ſoon as this diſeaſe is apprehended, ſupport the patient with a mild nouriſhing diet, and when he is faint, give him vinous cordials. Bleed as the ſtrength will admit; after which two or three of the following pills are to be immediately given, and repeated once or twice in the ſpace of twenty-four hours, until they operate.

℞ Aloes Soccotor. ℥ ſs. rad. jalap. pulv. ʒ i. calomelas, ſap. Venet. ää ʒ ii. balſ. Locatel. q. ſ. ut f. maſſa, ex cujus ſingulis drachmis, formentur pilulæ, No. xii.

The patient is greatly relieved a few hours after bleeding; and by means of theſe pills, repeated at proper intervals, the complaints gradually abate, and the cure is generally completed in the ſpace of nine or ten days.

People who return from warm climates are ſubject to an encreaſed ſecretion of bile in the primæ viæ: this is attended

tended with general langnor of the body, nauſea, foul tongue, loſs of appetite, indigeſtion, and frequently diarrhœa. The ſkin becomes yellow, and the general aſpect of the patient is extremely unhealthy. Bath waters are in theſe caſes of ſervice; or drinking from half a pint to a pint of warm water, may anſwer the purpoſe.

JEJUNUM. One of the ſmall inteſtines, ſo called, becaute it is generally found empty; named likewiſe *neſtis*. Where the duodenum ends, it begins, and is attached to the meſocolon at its beginning; then it proceeds downwards from the left ſide to the right, and obliquely forward, and makes ſeveral convolutions, which are chiefly ſituated in the upper part of the regio umbilicalis.

JEMOU, or JEMU. See GAMBOGIA.

JESUITARUM PULVIS. JESUIT'S POWDER. See CORT. PERUVIAN.

JETAIBA. The Braſilian name for the locuſt-tree, See ANIME, GUM.

JETICA BRASILIENSIBUS. See BATTATAS HISPANICA.

JETICUCU. See MECHOACANA NIGRA.

JOVIS FLOS. See CROCUS.

JOVIS GLANS. See JUGLANS.

JUBA. In botany, it is a paniele, ſo called, from its reſemblance to a horſe's mane.

JUDAICA ARBOR. See SILIQUASTRUM.

JUDAICUM BITUMEN. See BITUMEN.

JUDICATORIA. A ſynocha of four days.

JUGALE OS, vel JUGAMENTUM, from *jugum, a yoke*. See MALARUM OSSA.

JUGALIS SUTURA. The SAGITTAL SUTURE is ſometimes thus called. It is alſo the future by which the os jugale is articulated to the bone of the upper jaw.

JUGIS VITA. See AYE VITA.

JUGLANS, from *juvo, to help*, and *glans, a nut*; or rather from *Jovis glans, the nut of Jupiter*. The WALNUT. The tree is called *Carya*, as are walnuts rendered black by boiling. The rob of theſe is called *diarcarryon*. It is alſo called *nux regia, nux baſilica, nux Perſica, nux Euboica, caryon, caryon baſilicon*, Perſicon. The tree which produces this nut, is the JUGLANS REGIA, foliolis ovalibus glabris ſubſerratis ſubæqualibus. CLASS MONŒCIA: ORD. POLYANDRIA, LINN. Species Plantarum, pag. 997. EDIT. Holmiæ, 1753.

Boerhaave mentions five ſpecies. The kernel is of the ſame nature as that of almonds; the ſhells are aſtringent; the oil expreſſed from the kernel is of the ſame nature alſo as that of almonds; an ointment made by boiling the leaves of walnut-tree in lard is a uſeful application to old ulcers; the bark of the tree is a ſtrong emetic; the catkins are emetic; the juice of the root purges briſkly; the powdered leaves deſtroy worms in the human body.

The unripe fruit which has a bitter aſtringent taſte, is the part employed for medicinal purpoſes as an anthelmintic; laxative, and uſeful in aphthous affections, and ſore throats. Two drams of the inſpiſſated juice in four drams of cinnamon-water, of which from 20 to 50 drops are to be given, two or three times a day, for ſix days, a purge with calomel on the 4th day, forms the mode of its exhibition. Gargles alſo made of the rob diſſolved in any convenient vehicle may be uſed in aphthæ and ſore throats. Vinegar in which walnuts have been pickled, *is ſaid* to have been found a very uſeful gargle.

JUGULARES VENÆ. The JUGULAR VEINS. They are the external and internal. They correſpond with the carotid arteries. Theſe are alſo called *Venæ apoplecticæ*. The internal one which aſcends by the ſide of the aſpera arteria is called *apoplecta*. The ancients ed theſe veins *ſoporales*.

JUGULUM. The THROAT, or anterior part of the neck. In Celſus, lib. viii. cap. 8. it ſignifies the clavicle.

JUJUBA. Alſo called *zizipha, ziziphus*. The *jujube-tree*. The *rhamnus zizyphus*, Linn. *Jujubes* are an half-dried fruit of the plum kind, about the ſize and ſhape of an olive, conſiſting of a thickiſh, reddiſh, yellow ſkin, a whitiſh fungous pulp, and a wrinkled ſtone pointed at both ends. They are the produce of a prickly tree, with three-ribbed leaves, and herbaceous or yellowiſh flowers, ſometimes found wild, but commonly cultivated in the ſouthern parts of Europe.

This fruit is incraſſant and demulcent, and hath been uſed in pectoral decoctions.

JUJUBA INDICA. See LACCA.

JULAPIUM, called alſo *julap, juleb, julepus*; JULEP. This form of medicine the Arabians invented. It is a liquid medicine that is clear and ſweet. It is ſo called becauſe uſually prepared of ſweet ingredien's, or at leaſt with ſugar. The word *julep*, or *juleb*, in the Perſian language, ſignifies *a ſweet potion*.

A *julep* among the ancients was a ſweet apozem, prepared as it was wanted.

A *julep* is an agreeable form for adminiſtering cordials, and ſome other claſſes of medicines; but it is generally only a vehicle for other articles, or to render them more eaſy in the ſtomach, or otherwiſe more effectual, on which account they ſhould not only be contrived to be agreeable, but alſo of articles concurrent with the intention of the principal medicine. In this form are many medicines conveyed into the machine, and named after the material uſed, as Julepum; 1. e Camphorâ; 2. Cretâ. 3. Moſcho; but this term is now almoſt rejected.

JULAP,
JULEB,
JULEPUS. } See JULAPIUM.

JULEP. A name for ſyrupus

JULUS, catkin or ament. See AMENTUM.

JUNCARIA. ITALIAN RUSHY HORSE-TAIL. Lemery mentions this as vulnerary, deterſive, &c. but it is not known in preſent practice.

JUNCTURA, from *jungo, to join*. See ARTICULATIO.

JUNCUS ODORATUS, called alſo *fœnum* vel *ſtramen camelorum, ſchœnanthus, holoſchœnos, ſquinanthum*, juncus aromaticus, *palea de mecha, gramen dactylon aromaticum*, SWEET-RUSH, or CAMEL'S-HAY. This is the principal, a dried herb of the graſs kind, brought from Turkey and Arabia. It reſembles barley-ſtraw. It is full of a ſungous pith. It is the ANDROPOGON SCHŒNANTHUS, Linn.

When in perfection it is agreeable to the ſmell; warm, bitteriſh, and not unpleaſant to the taſte. An extract poſſeſſes the chief of its virtues; but other more valuable articles ſuperſede its uſe.

JUNIPERUS. JUNIPER. JUNIPERUS COMMUNIS; or, JUNIPERUS fol. ternis patentibus mucronatis, bacca longiore, CLASS DIOECIA. ORD. MONODELPHIA. LINN. Gen. Plant. 1134. It is alſo called *arceuthos*. Its berry *acatalis*. With us this is only a buſh, but in Norway it grows to the ſize of a large tree. The wood of which is called *cedrinum lignum*; *lignum juniperinum*. It is an evergreen. Its leaves are ſlender, narrow, ſtiff, and ſharp-pointed; the flowers are a kind of catkins; the berries have each three oblong irregular ſeeds The young fungi on this tree are called *calicta*, or *coliette*.

The berries are chiefly brought to us from Holland, or from Italy. They ſhould be choſen freſh, not much ſhrivelled and free from mouldineſs. They have a moderately ſtrong, but not diſagreeable ſmell; a warm pungent ſweetiſh taſte, which, if they are long chewed, or previouſly bruiſed, is followed by a conſiderable bitterneſs. The ſweetneſs ſeems to reſide in the juice, or pulpy part of the berry; the pungency, in the bark; the bitterneſs, in the ſeeds; and the aromatic flavour in the oily veſicles ſpread throughout the pulp, and the ſeeds. In the dried berries this oil is hardened into a reſinous ſubſtance, which is viſible on breaking the ſeeds; which ſeeds are called *ebel*.

They give out nearly all their virtue both to water and to ſpirit. Diſtilled with water, they yield a yellowiſh eſſential oil, called *alchitran*, which much reſembles that of turpentine in its medical qualities.

Theſe berries are carminative, ſtomachic, detergent, and diuretic, approaching in quality to that of turpentine.

The London College order the ſpiritus *juniperi* comp. COMPOUND SPIRIT of JUNIPER, formerly called *aq. juniperi compoſita*, to be thus made:

Take of *juniper* berries, bruiſed, one pound; carraway and fennel ſeeds, bruiſed, of each one ounce and a half; proof ſpirit of wine, one gallon; water, quantity ſufficient to avoid an empyreuma;—diſtill off a gallon. Pharm. Lond 1788.

The coriander ſeeds alſo anſwer the ſame purpoſe as thoſe herein ordered; but to a pound of the berries there ſhould be half a pound of theſe.

ROB BACCARUM JUNIPERI. *The* ROB *of* JUNIPER BERRIES.

Boil *juniper* berries well bruiſed in water, or take the decoction, after diſtilling them for the oil, and inſpiſſate

to the conſiſtence of thick honey. This is ſo eſteemed among the Germans, as to have obtained the name of *theriaca Germanorum*. It may be uſed in catarrhs; weakneſs of the ſtomach and inteſtines, and difficulty in making water, to which old people are ſubject. Hoffman highly recommends its uſe; though by ſome it is conſidered as an inactive preparation.

The followig formula was preſcribed by Van Sweiten: ℞ Rob bacc. juniperi ℥ij. dilue in aq. juniperi *ſimplicis* ℔ij, ſpiritus juniperi ℥ij, et ad ſitim ſedandam. Sps. ætheris nitroſi ℥ſs; m. doſis cochl. ij. vel 4r. tertia hora. However, the infuſion of the berries, either alone or mixed with a little gin, is *in dropſies* a very uſeful drink. *In uterine obſtructions, ſcorbutic affections*, and *cutaneous diſeaſes*, the utility of the juniper has been ſpoken of, but in the two laſt complaints, the wood and tops have been preferred. The eſſential oil is found to be an active ſtimulant, a warm carminative, alſo to poſſeſs diuretic and deobſtruent power. Doſes fram 2 drops to 10.

The wood of the *juniper* tree, is ſudorific, and of ſimilar qualities with that of guaiacum and ſaſſafras, but much inferior to either.

JUNIPERI GUMMI. The reſin which is obtained in warmer climes, particularly in Africa, where there is a large ſpecies of *juniper* tree, is ſemipellucid, and of a pale yellowiſh colour; it is in glebes, reſembling maſtich, but larger. It is the *ſandaracha* of the Arabians, and the gum *juniper* of the ſhops. From the uſe it is put to, ſome call it *vernix*. This reſin hath a light agreeable ſmell, and not much taſte. It diſſolves in ſp. vini r. if violently ſhook in it; and in oils both expreſſed and diſtilled, but it gives nothing to water. See Lewis's Mat. Med. Cullen's Mat. Med.

JUNEPIRUS. A name of ſeveral ſpecies of cedar. See CEDRUS FOLIO CYPRI, and CEDRUS PHOENICIA.

—— LYCIA. See OLIBANUM.

—— SABINA. See SABINA.

JUPICANGA. See CHINA OCCIDENTALIS.

JUPITER. See STANNUM.

JUS, *broth*, called alſo *brodium*. *Broths* made of the lean parts of beef, mutton, &c. are very nouriſhing, when uſed as aliment; but it ſhould be obſerved, that in weak, worn-out conſtitutions, ſtrong *broths* cannot be digeſted, and that the ſtrength thereof ſhould always be proportioned to the digeſtive powers of the patient.

JUSTICIA See ADHATODA.

JUVANTIA, ADJUVANTIA. Whatever relieves under a diſtemper, whether it is an aliment, medicine, or any of the non-naturals, are thus named. Alſo, things that help; and *lædentia*, things that offend. Two technical terms. When the nature of a diſtemper was doubtful or unknown, the ancients preſcribed ſome innocent medicines which they were well acquainted with, and according as they did either good or hurt, though in a ſmall degree, they formed a judgment of the method by which the cure was to be attempted.

JUVENTUS. See ÆTAS.

JUXTANGINA. A ſpecies of quinſy. See PARACYNANCHE.

K.

KAATH. See TERRA JAPONICA.

KABALA, } See CABALA.
KABALLA. }

KABOLOSSA. See CHINA OCCIDENTALIS.

KACHIMIA. See CACOCHYMIA.

KADALI. Ray takes notice of four ſpecies of this ſhrub; they grow in the Eaſt Indies. The fruit, when ripe, is eaten, and calicoas are dyed with the juice.

KADANAKU. See ALOES HEPATICA.

KÆKURIA. See ELEMI.

KÆMPFERIA ROTUNDA. See ZEDOARIA.

KAHA. See CURCUMA.

KAKA-MOULLON, KAHA MULLU. An Eaſt Indian ſiliquoſe tree. The bark is boiled in milk, and is ſaid to cure a diabetes and gonorrhœa. Raii Hiſt.

KAKA-NIARA. An Eaſt Indian tree, the leaves of which deſtroy worms. See Raii Hiſt.

KAKA-TODDALI. A ſmall ſhrub growing in Malabar, and much uſed there in various diſorders from a redundancy of ſerum. Raii Hiſt.

KAKIMIA. A barbarous word for *cachymia*.

KALENZI-KANSJAVA. See BANGUE.

KALI, alſo called *ſalſola*, *ſalicarnia*, *alga marina*, SALT-WORT, and SNAIL-SEEDED GLASS-WORT. Miller enumerates eighteen ſpecies It is the SALSOLA KALI, herbacea decumbens, foliis ſubulatis ſpinoſis, calycibus marginatis axillaribus. CLASS. PENTANDRIA; ORD. DIGYNIA. LINN. Gen. Plant. 311.

Kali is a plant with ſpreading, reddiſh, pretty thick branches: oblong, narrow, pointed, fleſhy leaves, like thoſe of houſeleek. The flowers are imperfect in the boſoms of the leaves, are followed each by one ſeed ſpirally curled, and incloſed in the cup. It is annual, grows wild on the ſea-coaſts in the ſouthern parts of Europe, particularly of the Mediterranean.

The herb is juicy, taſtes bitteriſh, and remarkably ſaline. The expreſſed juice, and infuſions, or decoctions of the leaves, are ſaid to be powerfully aperient and diuretic, and in this intention have been much recommended in dropſies; but the *kali* is principally regarded on account of its yielding copiouſly the fixt alkaline ſalt, called ſoda, or ſoude. The plant is cultivated about Montpelier, for the ſake of the ſalt. Much of this ſalt is prepared at Alicant in Spain, from a different ſpecies of *kali*. Different marine plants contain this ſalt, and what is made in Scotland and Ireland is called KELP. See Woodville's Medical Botany, pag. 387, 388.

From the *quercus marina*, alſo called *fucus veſiculoſus*, *fucus maritimus*, *alga marina*, SEA-OAK, SEA-WRACK, or SEA-TANG, much alkaline ſalt is obtained by incineration; the juice of its veſicles, left to putrefy, yields on evaporation a portion of acrid pungent ſalt.

This plant is a ſoft ſlippery one, common on rocks that are left dry at the ebb-tide; the leaves reſemble thoſe of the oak-tree in ſhape, the ſtalks running along the middle of the leaves, and terminated by watery bladders, containing either air or a ſlippery matter. The veſicles begin to fill in March, and burſt about the end of July, and diſcharge a matter thick as honey.

If the putrid juice of this plant is applied to the ſkin, it ſinks into it immediately, excites a ſlight ſenſe of pungency, and deterges like a ſolution of ſoap. One of the beſt applications at the decline of glandular ſwellings, for perfectly diſcuſſing them, is a mixture of the juicy veſicles on the leaves of this plant, gathered in July, with an equal quantity of ſea-water; they ſhould be kept in a glaſs veſſel for ten or fifteen days, until the liquor becomes of the conſiſtence of thin honey. The parts affected are to be rubbed with the ſtrained liquor two or three times a day, and afterwards waſhed clean with water.

They apply alſo a cataplaſm of the quercus marina made by bruiſing a quantity of this plant, the chief uſe of which is in caſes of ſcrofula, white-ſwellings, but more particularly glandular tumors. Where this cannot be got, ſea-water and oatmeal formed into a poultice has ſupplied its place.

KALI AERATUM. AERATED KALI.

Take prepared kali, half an ounce; diſtilled water, five drams; diſſolve the kali in a water-bath, then add a dram of prepared ammonia, and when the mixture ceaſes to efferveſce, ſet it by to cryſtallize. This is uſed as a lithontriptic, two drams diſſolved in a pint of diſtilled water taken twice a day.

KALI ARSENICATUM. ARSENICATED KALI.

Let equal quantities of arſenic and purified nitre be powdered and well mixed together, then put into a retort and placed in a ſand-bath, the heat of which is to be increaſed gradually, until the vapours ceaſe to iſſue from the mouth of the veſſel. The maſs muſt then be diſſolved in four pounds of diſtilled water, a proper quantity of which muſt be evaporated, and the reſiduum ſet aſide to cryſtallize. Doſe $\frac{1}{4}$th of a grain, three times a day. This is uſed for the ſame purpoſes as the ſolutio arſenici. See INTERMITTENS FEBRIS. CANCER.

The fixed alkaline ſalts obtained from theſe plants are the ſame as the mineral fixed alkaline ſalt. See ALCALI and ALGA.

KALI, vice SAL ABSINTHII. See ALCALI and CINERES CLAVELLATI.

KALI ACETATUM. See SAL DIURETICUS.

KALI PRÆPARATUM. See ALCALI, in pag. 40.

KALI TARTARIZATUM. See TARTARUM.

KALI PURUM. PURE KALI. *Formerly the* ALKALI VEGETABILE FIXUM CAUSTICUM. FIXED VEGETABLE CAUSTIC ALKALI.

Take the water of pure *kali* one gallon; evaporate it to dryneſs; afterwards melt it by fire, and let it be poured off. Ph. Lond. 1788. This has a diſpoſition to liquefy, which renders the application very inconvenient; to remedy which, is uſed an addition of quick-lime. See CAUSTICUM COMMUNE FORTIUS.

KALI SULPHURATUM. SULPHURATED KALI, *commonly called* HEPAR SULPHURIS. LIVER *of* SULPHUR.

Take flowers of ſulphur one ounce, *kali* five ounces; mix the ſalt with the ſulphur melted by a ſlow fire, by conſtant ſtirring, till they perfectly unite. Ph. Lond.

1788. The dose is from five grains to a scruple. In tetters, and other cutaneous affections this has been recommended. Some have employed it dissolved in water, as a bath for the psora; and in cases of tinea capitis it has often been used by way of lotion, and has been strongly recommended to prevent the effects of mineral poisons.

KALI TARTARIZATUM. TARTARIZED KALI, formerly *Tartarum solubile*. SOLUBLE TARTAR. See TARTARUM.

KALI AQUA. WATER *of* KALI, *formerly* LIXIVIUM TARTARI. LEY *of* TARTAR.

Take *kali*, one pound; set it by in a moist place, till it dissolves, and strain it. Ph. Lond. 1788.

This has the same medical properties as the *kali* præparatum, and is nothing more than that substance in a dissolved state; which may be made more extemporaneously by dissolving the salt in a proper proportion of distilled water.

KALI PURI AQUA. WATER *of* PURE KALI, *formerly* LIXIVIUM SAPONARIUM. SOAP LEY.

Take of *kali* four pounds; quick-lime six pounds; distilled water four gallons; add to the lime four parts of water, and let them stand for an hour; then add the *kali*, and remaining part of the water; boil them for a quarter of an hour; let the liquor cool, and strain: a pint of this liquor ought to weigh sixteen ounces. If the liquor raises any effervescence by the addition of any acid, then add more lime. An earthen or glass vessel should be used in the process, and the liquor strained through linen. Pharm. Lond. 1788.

KALI VITRIOLATUM. See NITRUM VITRIOLATUM, N° 6.

KANDEL. Ray takes notice of six species of this shrub. Some of them are used for staining linen with; some have medical virtues attributed to them, and others none.

KANELLI. A name of two East Indian trees. They are evergreens. The flowers are used in diarrhœas. See Raii Hist.

KANNAGHORAKA. See CARCAPULI LINCOTANI.

KAPA MATA. See ACAJAIBA.

KARABE, i. e. CARABE. See SUCCINUM.

KARABITUS. See PHRENITIS.

KARATAS. The PENGUIN, or wild ANANAS. It is common in the West Indies; the juice of the fruit is used to sour punch with, but it is too austere to be swallowed alone.

KAREMYLE. See OROBUS.

KARFE. See CINNAMOMUM.

KARIN-TAGERA. An evergreen tree in Malabar; it resembles an hazel. The oil from the root prevents the hair from falling off. Raii Hist.

KARI-VETTI. A tree in Malabar; the juice of its leaves is emetic. Raii Hist.

KARVA. See CASSIA LIGNEA.

KATKIN. See AMENTACEI FLORES.

KATO-CŒLIA. See CŒLIA.

KAYL. SOUR MILK.

KEIRI. See CHEIRI.

KELLO. See PLUMBUM NIGRUM.

KENNA. See LIGUSTRUM INDICUM.

KERATOPHYTON, also *lithophyton*. The name of a submarine plant, which is of a viscid or glueish consistence, pellucid like horn, and often covered with a cretaceous crust, sometimes of elegant and various colours. Boerhaave mentions sixteen species, but none of them have any medical virtues attributed to them, except one, which is the *corallium nigrum*.

KERMES. See CHERMES.

KERVA, OL. See CATAPUTIA.

KERMES MINERALIS. CHERMES MINERALIS. See ANTIMONIUM, N° 15.

KETMIA. The leaves resemble those of mallows, or of vervain-mallows. The flower is like that of the mallow; the fruit is divided into many partitions, the top of which opens when ripe, and discloses many seeds. Boerhaave enumerates twenty-two species. All the species, except those which taste like sorrel, agree in virtues with mallows. This genus, called *ketmia* by Tournefort, is the *hibiscus* of Linnæus.

KETRAN. See CEDRIA.

KEYSERI PILULÆ. KEYSER'S PILLS. According to an account of them given in the Edinb. Med. Commentaries, they consist of pure quicksilver, reduced to a red calx by a proper degree of heat, which being dissolved in vinegar (one part of the former to eight of the latter) is lastly to be mixed with manna, of which two pounds will be required to each pint of the solution. This composition being dried gently by the fire, is rolled into pills, and recommended as the most effectual remedy of all the mercurial kinds, against the venereal disease. See HYDRARGYRUS ACETATUS.

KHADIRA, vel KHEIR. See TERRA JAPONICA.

KIK, or KIKI. See CATAPUTIA.

KILBURN WATERS. See AQUÆ CATHARTICÆ AMARÆ.

KINA, or KINA-KINA, also *kin-kina*. See CORT. PERUV.

KINA-KINA AROMATICA. See THURIS CORTEX.

KINKINA EUROPÆA. See GENTIANA.

KINO. See GUMMI RUBRUM ASTRINGENS.

KIPPAKELENGU. See BATTATAS HISPANICA.

KIRIBUNNAWELL. See CHINA OCCIDENTALIS.

KNAWEL. ALCHIMILLA *supina gramin. folio*. TOURNEFORT calls it the CHAMÆLINUM VULGARE *folio affines glabro floſculis plurimis*. GERMAN KNOTGRASS. It is somewhat astringent. There are two species of it.

KOLERUS. A dry ulcer.

KOLTO. See PLICA POLONICA.

KRAUT SAUER, pronounced by the English SOUR KROUT. See BRASSICA.

KRIEBEL KRANKHEIT. See RAPHANIA.

KRIMNA. See ALPHITA.

KURUDU. See CINNAMOMUM.

KUTUBUTH. An Arabian name for a water-spider, an insect perpetually in motion. Hence the name hath been transferred to a species of melancholy, called by Sennertus *melancholia errabunda*. See LYCANTHROPIA.

KYMIA. See CUCURBITA

KYMIT ELEVATUM. WHITE SUBLIMED CINNABAR.

KYNA. See OPOPONAX.

KYNANCHE. See ANGINA.

L.

LAB

LABARIUM. Looſeneſs of the teeth.

LABDANUM. See LADANUM.

LABELLA LEPORINA. See LABIA LEPORINA.

LABEO. See CHILON.

LABIA. See PROCESSUS.

LABIA, } A LIP. The *lips* are all that are looſe be-
LABIUM. } fore the gums; the red part is called *prolabium*; the ſphincter is named *orbicularis labiorum*. When the cuticula, which here is called epithelium, is taken off, there is a villous appearance, as in the glans penis.

LABIA LEPORINA. The HARE-LIP; called alſo LABELLA and LABRA LEP. LAGOSTOMA; *roſtrum leporinum*; *lagocheilos*. It is when there is a fiſſure in the upper lip, with a want of ſubſtance, like that of a hare, whence its name. The diviſion is ſometimes double, like the letter M; it is then called the DOUBLE HARE-LIP. When this caſe happens to the under lip, it is called the SPURIOUS HARE-LIP. But ſome late profeſſors ſay that this laſt never occurs.

If an operation is required, firſt divide all its adheſions internally with an inciſion knife, then with a ſtraight pair of ſciſſars cut off all that is callous, ſo that you make an angle at its upper part; then pierce the *lip* with two ſilver pins, ſo as that the ſides of the fiſſure may be brought and kept in contact by them and the thread which is to be applied over them. Begin the thread on the upper pin, to hinder the *lips* from ſeparating under the heads and points; apply little bolſters to prevent their ſitting uneaſy upon the adjacent parts. Apply a pledgit of digeſtive over the whole, ſo as to keep the thread ſoft.

Mr. Pott obſerves, that when the *hare-lip* is double, it ſometimes happens that the middle portion contracts itſelf up, and the bone projects. To begin the cure in this caſe remove the projecting bone by means of a chiſſel; when this is done the contracted part of the *lip* is to be brought down and detained there by bandage; afterwards proceed as in the *ſingle hair-lip*, operating on one ſide at time, which is to be thoroughly healed before youproceed to the other. The pins ſhould not be moved before the ſixth or ſeventh day, and then firſt cut the ſtitches to ſee that the fleſh is ſecurely joined before you move the pins. When a part of the bone is cut away, wait the healing thereof before you proceed with the *hare-lip*. See Le Dran's Operations. Heiſter's Surgery. Sharp's Operations. Bell's Surgery, vol. iv. p. 149. White's Surgery, p. 269.

LABIÆ PUDENDÆ. Called alſo CREMNOI, LABRA. They ariſe from the mons Veneris, lying on the fore part of the pubes, and extending down under the edge of the oſſa pubis, whoſe ſymphyſis is exactly between them. They are more prominent and thick above than below, and unite below at the perinæum. They are compoſed of ſkin, cellular membrane, and fat; red within, and outwardly are covered with hair at the age of puberty. The angles of the labiæ above, and below; or the point where the lips meet, are called *commiſſures*.

LABIALES ARTERIÆ. See MAXILLARIÆ ARTERIÆ.

—— GLANDULÆ. The LABIAL GLANDS. The membrane which covers the inſide of the lips is a continuation of that on the cheeks; it is alſo perforated by many ſmall holes, which anſwer to the ſame number of ſmall glands. See Winſlow's Anatomy.

LABIATUS. See FLOS LABIATUS.

LABIS, from λαμβανω, *to lay hold of*. Any forceps.

LABIUM. See LABIA.

LABRA. See LABIÆ PUDENDÆ.

LABRISULCIUM. A CHAP IN THE LIP, or the ſame as *cheilocace*. It is a ſcrophulous ſymptom.

The *labriſulcium*, or *chapped upper-lip*, as it is a ſcrophulous ſymptom, it requires the ſame treatment as is uſual in that diſeaſe; thus the ſwelling of the lip is taken down, at leaſt for a time, until a freſh cold, or other error of the non-naturals, occaſion a new fluxion. The cleft or *chap* itſelf may be rubbed with the ol. ceræ, or with the ol. amygd. and ſpermaceti.

Arnoldus Boot treats of this ſymptom particularly in his tenth chapter, under the name of *cheilocace*, where he obſerves that children are the uſual ſubjects of it. See Turner's Surgery. This alſo is the name given to the CANCRUM ORIS.

LABRUM. See DEXAMENE.

LABRUSCA. See BRYONIA ALBA.

LABYRINTHUS The LABYRINTH. The ſecond cavity of the ear, called alſo *fodina*. It lies in the pars petroſa of the temporal bone, which runs forward and inward. It is an oblong body, divided into three parts, called the *veſtibulum*, the *cochlea*, and the *ſemicircular canals*. The *veſtibulum* (in which the ſtapes ſtands) is ſituated in the middle; the *cochlea* is the anterior, and lies forward and inward: and the *ſemicircular canals* which compoſe the poſterior part, lie backward and outward. The three parts of the *labyrinth* are lined by a fine perioſteum, which ſpreads over and ſhuts the two feneſtræ of the tympanum.

LAC

LAC. MILK. *Milk* is very little if at all different from the chyle, as when it is taken by the lacteals. See CHYLUS. It is a fluid prepared and ſecreted in the bodies of animals, but not completely elaborated into an animal nature. On a chemical analyſis it yields the ſame general principle with ſubſtances of the vegetable kingdom.

Milk differs in degrees of goodneſs in the following order; the beſt is *woman's*, the next is *aſs's*, *mare's*, *goat's*, *ſheep's*, and the worſt is *cow's*, becauſe it is the ſtrongeſt and moſt difficultly digeſted.

When *milk* is gone cold, like moſt other animal fluids, it loſes much of its excellent qualities, and warming it is ſo far from reſtoring them, that they are totally deſtroyed by it. When *milk* is boiled, it becomes a very improper aliment for weakly perſons, and for thoſe who have weak ſtomachs.

If *milk* is directed for a nouriſhing diet, and the patient is reduced to extreme feebleneſs, it ſhould be ſucked from the breaſt of a middle-aged woman, of a good habit of body, who lives ſoberly, and uſes moderate exerciſe; let the patient ſuck four or five hours after the woman hath taken her uſual meals; much before or much after are alike improper. Galen often hints at the advantage of uſing milk before it is mixed with the circumambient air; for then it poſſeſſes its greateſt degree of perfection, as retaining its fineſt parts, it will be rendered more ſalutary by the animal heat.

When a *milk* diet is uſed by perſons whoſe ſtrength is not ſo extremely reduced as to render a breaſt neceſſary,

it

it ſhould, if poſſible, be drank while warm from the cow; and in ſuch diſorders, or in ſuch circumſtances of the conſtitution, as are relieved by a total diet of *milk*, at leaſt four pints ſhould be taken every day. This will not ſuffice for making or keeping the body robuſt; but for the valetudinary, the ſedentary, and ſtudious, it is not only ſufficient, but the moſt proper.

When *milk* ſeems to diſagree, a tea-ſpoon-full of the ſpirit of hartſhorn to a pint,—or a draught of lime-water, if drank as ſoon as it is clear, and before the heat is diſſipated, which is excited on mixing the lime and water together,—or the chewing of bark in a morning, and a little rhubarb at night, will render it eaſy on the ſtomach, and promote its digeſtion.

Milk is demulcent and nutritious; but whatever diſpoſes it to curdle, renders it in proportion indigeſtible; it is an improper aliment in febrile and bilious diſorders; but gall, as well as lime-water, when taken into the ſtomach, powerfully diſſolves *milk* that is coagulated there.

Milk conſiſts of *oil*, *mucilage*, *ſugar*, *water*, and *air*. The oil ſpontaneouſly ſeparates, and is called *cream*; the mucilage is the coagulable part, which is ſeparated by mixing rennet with it; and of this they make cheeſe: that it poſſeſſes air, is proved by placing it under the receiver of an air-pump, after having heated it a little; and as to the ſugar, it is ſeparated by the following method.

Saccharum Lactis. Sugar *of* Milk.

Take the whey of cow's *milk* (made with calf's rennet): clarify it with the white of an egg, and, if not perfectly limpid, paſs it through a filter; then evaporate it in a glaſs veſſel, in the heat of a water-bath, and ſet it in a cool cellar to cryſtallize. The cryſtals are to be waſhed with cold water. This is as directed in the Ph. Pariſ. but Dr. Lewis recommends the following:

Take aſs's *milk*, whilſt new, and evaporate it to dryneſs, and digeſt the dry matter in water till all its ſoluble parts are extracted; then inſpiſſate the filtered liquor. This preparation is ſweet, though neither white nor cryſtalline; nor is it perhaps in the pure cryſtalline part of the *milk* that the virtue of it lies. The medicinal quality is in the ſaccharine part, whence women's and aſs's are moſt medicinal; but the nutritive quality is in thoſe parts which abound more in the *milk* of goats and cows, whence, as a nutritive, their *milk* is preferred.

According to Hoffman's obſervation, twelve ounces of woman's *milk* leaves on evaporation eight drams of ſolid matter, of which boiling water diſſolves ſix drams; this ſolution yields a rich ſweet ſalt. He obſerves the ſame of aſs's *milk*. The ſame quantity of cow's *milk* leaves thirteen drams of ſolid matter, from which water extracts only one dram and a half; the ſalt it affords is not very ſweet, and it diſſolves difficultly. All other *milks* are of an intermediate nature.

Serum Lactis. *The* Whey *of* Milk.

Whey from *milk* is cooling, diluent, and aperient; it promotes the natural excretions, and increaſes the action of the purgative ſweets, as caſſia, manna, &c. It contains the nutritive and moſt of the ſaccharine part of *milk*, though it is freed from the more indigeſtible caſeous part. A more agreeable whey may be made by the following method than by that which is uſed in ſeparating the curd for cheeſe.

Evaporate new *milk* over a very gentle heat to dryneſs; then pour upon the remaining yellow grumous powder as much pure water as there was of milk, then boil them until the powder is diſſolved, and ſtrain it for uſe.

If whey is taken medicinally, it ſhould be drank for ſix or eight weeks, at the rate of four or five pints a-day.

A pint of cow's milk being evaporated, about an ounce and a half of yellow powder remained, of which a dram and a half diſſolved in water.—From *a pint of woman's milk*, hardly an ounce of dry matter remained, but water diſſolved more than one half of it. The proportions were the ſame, when aſs's *milk* was uſed.

Milk is ſuppoſed to contain a portion of animal matter: and as the animals which afford it feed almoſt wholly on vegetable ſubſtances, it is concluded to be an aliment of an intermediate nature between animal and vegetable; and thus ſhould it be conſidered in our application to valetudinarians. Dr. Cullen has given a long account of *milk*, and the ſeparate parts of which it is compoſed, which is well worthy of being conſulted. See his Mat. Med. 1789.

See Dioſcorides, lib ii. cap. 64. Hoffman's Diſſ. de Mirabili *Lactis* Aſinini in Medendo Uſu. Hoffman's Diſſ. de Salub. Ser. *Lact.* Med. Muſ. vol. iii. p. 361, &c. Percival's Eſſays, Med. and Exp. ed. 2. p. 251, &c. Fordyce's Elem. p. 1, 19, &c. Cullen's Mat. Med. See alſo Caper.

Lac actosum. See Alcaol.

—— amygdalæ. Milk of almonds. See Emulsio.

—— asininum artificiale. See Eryngium.

—— calcis. Milk of lime. So ſome call the water which is whitened by a ſolution of quick-lime in it.

—— Spumosum. See Aphrogala.

—— sulphuris. See Sulph. præcipit.

—— virginale. See Benzoinum.

LACCA. Lac, or gum lac; *anoſa*. It is a concrete brittle ſubſtance, of a dark red colour, brought from the Eaſt Indies; the beſt from Ceylon: it is incruſted on pieces of ſticks, internally divided into cells. It is ſaid to be the reſinous juice of the jujube-tree. (See Jujuba Indica, which is alſo called *Ziziphus Indica*; and—*Zeylanica*; *Perinteddati*; and *Æmbella*); but moſt probably it is met with on different kinds of trees. It is ſaid to be collected by winged red inſects of the ant kind; or it is their wax, and is impregnated with their colouring matter, and is either depoſited by them on branches of trees, or on ſticks placed for them; this is called stick-lac. In the cells, ſmall red bodies are often obſerved, which appear to be the young inſects. If the stick-lac is broken into ſmall pieces, and infuſed into warm water until it ceaſes to give any tincture to the liquor, the remainder appears of a tranſparent, yellowiſh brown colour, and is called seed-lac: and on raiſing the heat ſo as to melt the seed-lac, it riſes to the ſurface, and is formed into what is called shell-lac.

The *ſeed* and *ſhell-lacs* being robbed of the colouring animal matter, ſeem to be of an intermediate nature between that of wax and reſin, and to partake of the nature of both. They crumble on chewing, and do not ſoften or ſtick together again; laid on a hot iron, they catch fire, and ſoon burn away. If diſtilled like wax, they yield an acid ſpirit, and a butyraceous oil. Alkaline lixivia, and volatile alkaline ſpirit, diſſolve them into a purpliſh liquor. With the help of heat, they diſſolve in ſp. vini r. Alum promotes their ſolution in boiling water. Lac is not uſed in medicine; the colouring matter ſerves as a paint, and the reſt is employed for ſealing-wax. See Neumann's Chem. Works. Dict. of Chem. Lewis's Mat. Med.

LACCOPEDON. See Scrotum.

LACERATURA. See Vulnus.

LACERTULI, } Bundles of fibres. In every muſ-
LACERTUS. } cle, long, ſlender, ſoft fibres are found, poſſeſſed of ſome elaſticity, running univerſally parallel with each other, which, ſurrounded with a plentiful portion of cellular membrane, are collected into what are called lacertuli, that are in ſhape like the arm from the elbow to the wriſt:—theſe, bound together with a looſer, and for the moſt part fatty membrane, run into large bundles, which are always divided by cellular ſtripes, or partitions, then called Lacerti; which alſo running parallel, or inclined, ſurrounded with a thin cellular membrane, continuous with the partitions, and ſeparated by a thicker cellular texture from the neighbouring fleſhy parts, are conſidered as one muſcle. See alſo Brachium, where the word Lacertus is uſed in another ſenſe.

LACERUM FORAMEN. It is one of the inner holes in the head, through which the third, fourth, firſt branch of the fifth, and the ſixth pair of nerves paſs.

LACRYMA ABIEGNA. See Terebinthina.

—— Jobi, alſo called *lithoſpermum*, *millium arundinaceum*, reed millet, Job's tears. The ſeeds reſemble tears, whence one of the names above given to this plant, which hath the appearance of a reed. The ſeeds are ſaid to be lithontriptic, but they are not in much uſe. Raii Hiſt.

LACRYMALIA OSSA. See Unguis Ossa.

—— puncta. At a little diſtance from the internal angle of the eye, on the edge of the eye-lids, may be ſeen two ſmall holes, which are the orifices into the *lacrymal* channels and bag, and they are thus named.

LACRY-

LACRYMALIS GLANDULA. See GLANDULA LACRYMALIS.

LACRYMALIS NERVUS. The fifth pair of nerves from the head, divided into branches, the firſt of which is called the orbitary branch; and this is ſubdivided into three more, the third of which is called the *lacrymal* branch; it goes chiefly to the *lacrymal* gland.

LACINIA *corollæ*. Any part into which the border of a monopetalous corolla is cut. It is applied alſo to monophyllous calyxes: and a calyx which has two laciniæ is ſaid to be bifidus, &c. or it ſignifies jaggs on the borders of leaves: hence are they called,

LACINIATI, *jagged*; which word implies an irregularity in the diviſion, and ſubdivition; whereas Lacinia, according to Linnæus, is the ſame with a part, ſegment, or cleft.

LACONICUM. See CALDARIUM.

LACTARIA. See LACTICINIA.

LACTATIO. LACTATION, or GIVING SUCK. The mother's breaſt, if poſſible, ſhould be allowed the child, at leaſt during the firſt month; for thus the child is more peculiarly benefited by what it ſucks, and the mother is preſerved from more real inconveniences, than the falſely delicate imagine they would ſuffer by compliance herewith. But if, by reaſon of an infirm conſtitution, or other cauſes, the mother cannot ſuckle her child, let dry-nurſing under the mother's eye be purſued.

When women loſe their appetite by giving ſuck, both the children and themſelves are thereby injured. Wet nurſes are to be preferred, who, during the time they give the breaſt, have rather an increaſed appetite, and digeſt more quickly. The former are apt to waſte away, and ſometimes die conſumptive. In ſhort, thoſe nurſes, with whom *lactation* may for a while agree, ſhould wean the child as ſoon as their appetite leſſens, their ſtrength ſeems to fail, or a tendency to hyſteric ſymptoms is manifeſt.

For no woman can be a proper nurſe, whoſe appetite is not good, and digeſtive powers ſufficiently ſtrong to elaborate, and convert her food into ſound juices, notwithſtanding the waſte ſhe muſt ſuffer from the neceſſary ſupply of milk for the infant.

When the new-born child is to be brought up by the mother's breaſt, apply it, in ten or twelve hours after delivery, thereto; thus the milk is ſooner and more eaſily ſupplied, and there is leſs hazard of a fever, than when the child is not put to it before the milk begins to flow of itſelf.

If the mother does not ſuckle her child, her breaſts ſhould be kept warm with flannels, or with a hare-ſkin, that a conſtant perſpiration may be ſupported: thus there rarely will ariſe much inconvenience from the milk.

The child, notwithſtanding all our care in dry-nurſing, ſometimes pines if a breaſt is not allowed. In this caſe, a wet-nurſe ſhould be provided; if poſſible, one that hath not been long delivered of a child. She ſhould be young, of a healthy habit, and an active diſpoſition, a mild temper, and whoſe breaſts are well filled with milk. If the milk is good, it is ſweetiſh to the taſte, and totally free from ſalmeſs: to the eye it appears thin, and of a bluiſh caſt. Should the woman have her menſes, if in other reſpects objections are not made, this need not be any: and as to the cuſtom with many, of abſtaining from venery while they continue to ſuckle a child, it is ſo far without reaſon to ſupport it, that the truth is, a rigorous chaſtity is as hurtful, and often more pernicious, than a moderate uſe of venery. Amongſt the vulgar errors, is that of red-haired women being improper for wet-nurſes

If the menſes do not appear during the firſt months, but, after ſix or eight months' ſucking, they begin to deſcend, the child ſhould be weaned.

Wet-nurſes ſhould eat, at leaſt, one hearty meal of animal food every day; with this a proper quantity of vegetables ſhould be mixed. Thin broth, or milk, is proper for their breakfaſts and their ſuppers; and if the ſtrength ſhould ſeem to fail a little, a draught of good ale ſhould now and then be allowed; but ſpirituous liquors, muſt, in general, be foreborne,—not but a ſpoonful of rum may be allowed in a quart of milk and water, (i. e. a pint of each) which is a proper common drink.

Though it is well obſerved by Dr. Hunter, that the far greater number of thoſe women who have cancers in the breaſt or womb, are old maids, and thoſe who refuſe to give ſuck to children; yet it is the unhappineſs of ſome willing mothers not to be able; for inſtance, thoſe with tender conſtitutions, and that are ſubject to nervous diſorders; thoſe who do not eat a ſufficient quantity of ſolid food, nor enjoy the benefit of exerciſe and air: if children are kept at their breaſts, they either die whilſt young, or are weak and ſickly after childhood is paſt, and ſo on through remaining life.

LACTEA FEBRIS. The MILK-FEVER. This frequently happens after delivery. It is the cuſtom of many, not to apply the child to its mother's breaſts before the milk flows freely of itſelf; thus, by the third or fourth day after delivery, a fever is brought on, with a train of other ill effects. This *milk-fever* rarely happens to any but thoſe who have deferred letting the child ſuck for two or three days after delivery; then the breaſt is ſo full that it cannot eaſily be emptied; conſequently, it becomes inflamed, and the evacuation that way being ſuppreſſed, a fever is excited. Where there is a ſecretion of milk, its due diſcharge is as neceſſary as that of the lochia; the ſtoppage of either produces the ſame complaint, viz. the *milk-fever*; by occaſioning a plethora. Other imprudences may give riſe to this diſorder, or accidents, that were not to eaſy to avoid, may be the preceding cauſes.

The more immediate cauſes are a diſtenſion of the nerves in the breaſts, which is readily diſtinguiſhed by the ſwelling of the glands; and an abſorption of milk, which hath become acrid by ſtagnating in the breaſt, and is known by a rigor and looſeneſs coming on after the breaſts have been inflamed and painful.

The uſual ſymptoms are pain and diſtenſion in the breaſts. Theſe extend often to the arm-pits, where the pain is very conſiderable. Sometimes the breaſts become hard, hot, and inflamed; then thirſt, head-ach, and fever ſoon follow.

If the diſorder is not violent, it continues a day or two, then ſpontaneouſly vaniſhes by a copious perſpiration.

If the patient is ſanguine and robuſt, blood may be taken from the arm; but as this is rarely required, ſome caution ſhould attend its uſe. Apply the child to the breaſts; and linen cloths, dipped in freſh cool-drawn linſeed oil, muſt be laid over them: the bowels ſhould be emptied by means of a clyſter; or a gentle cooling purge may be given. Theſe, with the ſaline mixture, and the uſual modes of adminiſtering antimonial preparations, rarely fail to carry off the diſeaſe.

A thin, cooling diet, conſiſting chiefly of panada, barley-water, and ſuch like, ſhould be uſed, until the violence of the ſymptoms is removed.

If the breaſts ſhould ſuppurate, proceed as in an ABSCESS of the BREAST. See Abſceſſus Pectoris, and Mammæ, No. 31.—Alſo Kirkland on Child-bed Fevers.

—— VASA, called alſo *galactophori ductus*, (from γαλα, *milk*, and φερω, *to carry*) the LACTEAL VESSELS. They ariſe by imperceptible beginnings from the inteſtines, and ramify upon them as the arteries; they run through the meſentery in long ſolitary trunks; and, in their way to the receptaculum chyli, through the lymphatic glands at the root of the meſentery, they unite with each other, and with the lymphatics, about the laſt dorſal, or firſt and ſecond lumbar vertebræ, to form the receptaculum chyli, which ſee. The *lacteals* are furniſhed with many valves, and ſo is the thoracic duct; ſo that every lacteal preſſure will force up the chyle, as that by inſpiration and the pulſation of the aorta.

The *lacteals* are the abſorbent of the bowels, beginning in their inner ſurface. The ſame kind of veſſels are called abſorbents, or lymphatics, in other parts of the body, and take their riſe from the ſurfaces of the reſpective parts; ſo that the *lacteals*, lymphatics, and abſorbents, are all the ſame kinds of veſſels. Dr. Hunter ſays that the *lacteals* and lymphatics are the ſame veſſels, only differing in their ſituation; and they both terminate in the ſame duct.

The CHYLIFERA VASA are alſo called VENÆ LACTEÆ, becauſe their valves are diſpoſed as thoſe of the blood-veins are, and becauſe, like them, they convey their contents from ſmaller to larger tubes.

Dr. Harvey diſcovered the lymphatics in the year 1616. In 1627, they were publiſhed by another author. Uzzalius diſcovered the *lacteals* in a dog, running to the meſenteric glands; this was in the year 1662. See Winſlow's Anatomy.

LACTESCENTIA. See LACTIFERUS.

LACTICA. See TYPHOS, and TYPHODES.

LACTICINIA. Aliments prepared of milk, called GALACTINA, LACTARIA. It is uſed in another ſenſe alſo. See ANIMELLÆ.

LACTIFERI DUCTUS, vel TUBULI. LACTIFEROUS DUCTS or TUBES. The glandular body of the breaſt contains a white maſs, which is merely a collection of membranous ducts: they are narrow at their origin, broad in the middle, and contract again as they approach the papillæ, near which they form a kind of circle of communication. See MAMMÆ.

LACTIFERUS. *Lactiferous* plants are thoſe which abound with a milky juice. The term is applicable to thoſe which abound with other coloured juices, as *Lactescentia* comprehends the different coloured fluids, which flow copiouſly from particular plants on being wounded; which is either white, red, or yellow. In *euphorbium*, *papaver*, *aſclepias*, &c. *campanula*, and many of the plants in the firſt diviſion of the claſs SYNGENESIA, *they are white*; in *chelidonium*, *bocconia*, *ſanguinaria*, and *cambogia*, *yellow*; and in rumex ſanguineus, red.

LACTIS FLOS. See APHROGALA.

LACTUCA. LETTUCE, called alſo *marullium*, *eunuchion*. It is a plant with ſlender but firm ſtalks, which yield, as do the leaves, a milky juice on being wounded. The flower conſiſts of a number of flat floſculi, ſet in a ſmall ſcaly cup, followed by ſhort flat ſeeds, which are pointed at both ends, and winged with down. It is alſo the name of ſeveral ſorts of *chondrilla*.

—— AGNINA, alſo called *locuſta*, *valeriana campeſtris inodora major*, *valerianella arvenſis præcox humilis ſemine compreſſo*, *album olus*, LAMB'S-LETTUCE, and CORN-SALLAD.

—— HORTENSIS. GARDEN-LETTUCE.

—— LACTUCA MARINA. See FUCUS.

In general, *lettuces* are emollient, refrigerating, faponaceous, reſolvent, diuretic, and laxative. They are better to be eaten raw than boiled; though in this ſtate they afford little nouriſhment, but when boiled they prove more ſweet and mucilaginous, and therefore may be conſidered as more nutritious. They are eaſily digeſted, but afford very little nouriſhment. Their milky juice inſpiſſated is a kind of opium; but, as a medicine, they are not celebrated.

LACTUCA VIROSA. STRONG-SCENTED WILD LETTUCE. It is the LACTUCA SYLVESTRIS, *capitis odore vehementi ſoporifero et viroſo* of MORISON. LACTUCA *ſylveſtris odore viroſo* of CASP. BAUHINE, and of LINNÆUS, the LACTUCA VIROSA, *foliis carina aculeatis dentatis*. CLASS, SYNGENESIA; ORD. POLYGAMIA ÆQUALIS, Spec. Plant. vol. 2. pag. 795. The upper leaves of this plant are jagged about the edges; the lower are not. In Britain it is indigenous; found in hedges, and by the ſides of ditches, and flowers in June. It differs widely in its qualities from the garden lettuce: it ſmells ſtrongly of opium, and appears to participate, in no ſmall degree, of its virtues. The narcotic power reſides in its milky juice. It is ſaid to quench thirſt, to be gently laxative, powerfully diuretic, ſomewhat diaphoretic, and not diſagreeable to the ſtomach: but, during its operation, plentiful dilution is allowed. It is given in form of extract made from the expreſſed juice. Out of twenty-four dropſical patients, twenty-three were cured with this medicine, according to the account of Dr. Collin, of Vienna. It is recommended in ſmall doſes; though in dropſies of long ſtanding from viſceral obſtructions, it has been adminiſtered to the quantity of half an ounce a-day.

LACTUCIMINA. See APHTHÆ.

LACTUMEN. See ACHOR.

LACTUMINA. Little ulcers, or cruſty ſcabs in the ſkin, ſo called becauſe they chiefly happen to children at the breaſt.

LACUNÆ. Certain excretory ducts in the vagina are thus named, ſo are the glands or their excretory ducts, in the urethra. They are any drain or furrow (from *lacus*, *a ſtanding-poſt*).

LADA. See PIPER NIGRUM.

LADA CHILLI. See PIPER INDICUM.

LADANI EMPLASTRUM. See EMPLASTRUM STOMACHICUM

LADANUM, alſo called *labdanum*, *ciſtus*, *ciſtus ladaniſera*, *ledon Creteniſe*. The TRUE LADANIFEROUS SHRUB. CISTUS CRETICUS, *arborescens exſtipulatus*, *foliis ſpatulato—ovatis petiolatis enerviis ſcabies*, *calycinis lanceolatis*. CLASS POLYANDRIA; ORD. MONOGYNIA, LINN. Gen. Plant. 673. The *gum labdanum* is a reſinous juice which exudes upon the leaves of this ſhrub: it grows plentifully in Arabia, Candia, and other parts of the Archipelago. The juice is collected during the ſummer heats, with a kind of rake, which hath ſeveral leather thongs fixed to it inſtead of teeth, with which the leaves of the ſhrub are lightly bruſhed backwards and forwards; the unctuous juice adheres to the thongs, and is afterwards ſcraped off with knives, and formed into regular maſſes for exportation. The plant grows in ſandy places on the ſea-ſhore; which accounts for the quantity of ſand that is mixed with the gum.

There are two ſorts of *gum labdanum*. The beſt is in dark-coloured black-maſſes, of the conſiſtence of a plaſter, and that grows ſtill ſofter on being handled: the other is in long rolls curled up. It is harder than the former, but of a paler colour.

In general, this gum agrees in virtues with the balſam of Peru; but is rarely uſed otherwiſe than in external applications, and amongſt perfumes. It hath an agreeable ſmell, and a light, pungent, bitteriſh taſte. Rectified ſpirit of wine diſſolves nearly the whole of the pure gum: water takes up by infuſion much of its ſmell and taſte. By diſtillation with water, an eſſential oil ariſes, leaving behind it a brittle reſin.

Heat ſoon and eaſily deſtroys the ſpecific flavour of this gum. This reſin was formerly given as a pectoral, and aſtringent in catarrhal affections, dyſenteries, and other diſeaſes: it is now confined to external uſe in form of plaſter. See EMPLASTRUM STOMACHICUM: ſometimes it is uſed by way of fumigation. See Lewis's Mat. Med. Neumann's Chem. Works.

LÆDENTIA. See JUVANTIA.

LÆMOS. See ŒSOPHAGUS.

LAGAROS. See COR.

LAGOCHEILOS, from λαγος, *a hare*, and χειλος, *a lip*. A perſon with a hare's lip. See LABIA LEPORINA.

LAGON. The FLANK.

LAGONDI. See BERIBERI.

LAGOPHTHALMIA, } from λαγος, *a hare*, and
LAGOPHTHALMUS, } οφθαλμος, *an eye*. See ECTROPIUM.

LAGOPODIUM, } called alſo *pes leporinus*, *trifolium*
LAGOPUS, } *avenſe humile ſpicatum*, HARE'S-FOOT, or HARE'S-FOOT TREFOIL, HERB TRINITY, or TRINITY-GRASS. Boerhaave reckons it a ſpecies of trifolium. It is a low, ſpreading plant with narrow hairy leaves; the flowers are of a purple colour; the root periſhes in winter. It grows amongſt corn, and in fallow fields; it flowers in June and July. The whole plant is reckoned aſtringent; but is rarely uſed.

LAGOPUS. HARE-FOOTED, (ſee ATTAGEN); alſo a name of ſome ſpecies of trifolium.

LAGOSTOMA. See LABIA LEPORINA.

LAIT REPANDU. See LYMPHÆ DUCTUS.

LALO. See BAOBAB and COUSCOUS.

LAMAC. See GUM. ARABICUM.

LAMBDACISMUS. A defect in ſpeech, which conſiſts in an inability to pronounce certain conſonants.

LAMBDOIDES. The name of the future which runs betwixt the oſſa occipitis and parietalia. It is ſo called from its reſemblance to the Greek letter Λ, lambda. It is alſo a name of the *os hyoides*. This future has likewiſe the appellation *Pectæ futura*.

LAMINA CRIBROSA. The cribriform lamella. It is the horizontal plate of the os ethmoides, through which the olfactory nerves paſs.

LAMINÆ SPONGIOSÆ INFERIORES. See CONCHÆ NARIUM INFERIORES.

LAMIUM. DEAD NETTLE. Boerhaave mentions ſeventeen ſpecies.

LAMIUM ALBUM, Linn. Alſo called *urtica mortua*, *Archangelica flore albo*, *urtica alba*, *urtica iners*. WHITE ARCHANGEL, or DEAD NETTLE.

—— LUTEUM, called alſo *galeopſis*, *leucas montana*. See GALEOBDULON. YELLOW ARCHANGEL.

—— MACULATUM, called alſo *galeopſis lutea*, *mitzadella*, *urtica lactea*. SPOTTED ARCHANGEL.

—— RUBRUM, alſo called lamium purpureum fœtidum, *galeopſis*. RED ARCHANGEL, or SMALL DEAD NETTLE.

Theſe plants are well known every where. Infuſions of them are commended as almoſt ſpecific in the fluor albus; but experience hath not manifeſted any great uſefulneſs from them.

LAMPATAM. See CHINA ORIENTALIS.

LAMPOURIS. See CICINDELA.

LAMP-

LAMPSANA, alſo called *papillaris herba*, *napium*, *endivia erecta*, &c. DOG-CRESSES, NIPPLE-WORT. It is a roughiſh plant, bearing ſmall yellow floſculous flowers. It is annual, grows wild in fields, and by the ſides of the roads. It is one of the bitter lacteſcent plants, nearly ſimilar in virtues to dandelion, endive, and others of the ſame claſs. It hath been applied to ulcerations on the nipples, whence the names *papillaris* and *nipple-wort*.

The preſent practice does not notice it. It is alſo a name of *rapiſtrum*.

LANA. WOOL. Burnt *wool* is eſcharotic.

LANA SUCCIDA. SORDID WOOL, or that which is greaſy with the ſweat of the ſheep, called *aplytos* by the Greeks.

LANARIA. A name of the *lychnis ſylveſtris*, of the *ſapenaria*, and *verbaſcum*.

LANGUOR. DEBILITY of SPIRITS.

LANGUOR PANNONICUS. See AMPHEMERINA HUNGARICA.

LANIGERUS. *Lanigerous* trees are ſuch as bear a woolly or downy ſubſtance, as is commonly contained in the catkins of the willow.

LANTANA. See VIBURNUM.

LANUGINOSUS, *Lanuginous*, or *downy*, as the quince, &c.

LANUGO. DOWN. The ſeeds of plants which have a downy ſubſtance faſtened in them, which ſerves as wings to tranſport them, are termed *lanuginous*. They are alſo called pappous. See CHNUS.

LAONICA CURATIO. A method of curing the gout by evaporating the morbid matter by topics.

LAPARA, the FLANKS, from λαπαξω, *to empty*, becauſe this part falls in as if empty.

LAPAROCELE. A rupture through the ſide of the belly.

LAPATHUM. DOCK. It is a perennial plant, of which Boerhaave enumerates eighteen ſpecies.

—— ACUTUM; alſo called *rumex*; *oxylapathum*; SHARP-POINTED DOCK. It is the RUMEX ACUTUS, Linn. *Docks* are ſo generally known as to render a deſcription needleſs. This ſpecies, whoſe leaves are ſharper pointed than the common ſort, hath a bitter aſtringent taſte, but no remarkable ſmell: the roots of the other common *wild docks* are nearly of the ſame quality: equally diſcover their aſtringent matter, both by the taſte, and by ſtriking an inky blackneſs with a ſolution of vitriol: but of the two, the ſharp-pointed is to be preferred. The roots of both have a laxative as well as a corroborant quality; but the former quality is poſſeſſed in a very ſmall degree. Water takes up all their virtue, and in ſpring they are uſed with moſt advantage.

—— ALPINUM, alſo called *hippolapathum rotundifolium*, *lapathum montanum*, BASTARD MONKS RHUBARB. The leaves are very broad like thoſe of burdock; the root is brown outwardly, and intenſely red within. This and the true ſpecies may be uſed indifferently.

—— AQUATICUM; called alſo *hydrolapathum*; *herba Britannica*, lapathum paluſtre; GREAT WATER-DOCK. RUMEX HYDROLAPATHUM, floribus hermaphroditis, valvulis integris, *graniferis*, *foliis lanceolatis acutis*. CLASS, HEXANDRIA; ORD. TRIGYNIA. LINN. Gen. Plant. 451. This is the rumex criſpus of Linnæus. The hydrolapathum of the Edinburgh Pharmacopœia is referred to the *rumex aquaticus*, *foliis cordatis acutis*, *floribus hermaphroditis*, *valvulis integerrimis nudis*. MUNTINGIUS has taken great pains to prove it is the herba britanica of the ancients; not from Britain, but from *britanicus*, a Teutonic word, which ſignifies a power to faſten looſe teeth. However, the leaves of the RUMEX HYDROLAPATHUM are from two to three feet long, and are ſaid to be laxative, but have upon trial been proved to be very inconſiderably ſo: the roots are blackiſh on the outſide; internally they are white, having a faint reddiſh tinge, which, in drying, changes in ſome parts to a yellowiſh or brown.

This ſpecies of *dock* is found in moſt parts of England by river-ſides.

It is a powerful antiſcorbutic, if freely taken internally; and a ſtrong decoction of it puts a ſtop to eating ulcers in the mouth and tonſils, cures ſpongy gums, &c. Boerhaave extols it from his own experience, as uſeful in ſcorbutic, rheumatic, and cutaneous diſorders, alſo in diſorders from obſtructed viſcera. From the experience of others, it is evidently uſeful in flatulent diſorders, and a good aſſiſtant to the ſtomach in its office of digeſting. LINNÆUS ſpeaks highly of its uſe.

If the root is dried and powdered, it is a powerful antiſeptic, and in general is a good ſubſtitute for the bark. It is uſeful in many nervous diſorders. MURRAY ſays the powdered root is an excellent dentifrice. But where the powder is unacceptable as an internal medicine, the following decoction may be uſed:

℞ Cort. e rad. hydrolap. lb. ſs. coq. lenit. in aq. pluvialis lb. vi. ad lb. iv. & cola. cap. lb. ſs. tepid. quater in die.

The bark of the root contains the greateſt proportion of the active parts; but the whole plant may be uſed, as it all contains the ſame medical virtues with the root. See Med. Muſ. vol. i. p. 46, &c. However, notwithſtanding the high character it has maintained among ſome phyſicians, there are others that think it does not materially differ from other aſtringents, and therefore are doubtful about the virtues aſcribed to it by Muntingius.

LAPATHUM HORTENSE, called alſo *rhabarbarum monachorum*, *patientia*, *hippolapathum*; MONKS RHUBARB. The ſtalk of this dock is red, and branched towards the top: the root is thick at the head, but ſoon divides into ſeveral branches of a brown colour outwardly, and a deep yellow within. The virtues of the root are ſimilar to thoſe of the root of rhubarb, only differing in being leſs purgative and more aſtringent.

—— CHINENSE ORIENTALE. See RHABARBARUM.

—— RUBRUM; alſo called *lapathum* ſanguineum, *ſanguis draconis herba*, BLOOD-WORT.

The leaves are recommended as laxative, and the ſeeds for reſtraining uterine fluxes.

—— UNCTUOSUM. See MERCURIALIS.

—— VULGARE; *anaxyris*; BROAD-LEAVED WILD DOCK, or COMMON DOCK. The leaves are very large, roundiſh at the points, and are ſouriſh to the taſte. The root is bitter, aſtringent, and of a pale or yellowiſh colour. In France, the root is in common uſe, and that for moſt of the ſame purpoſes as the great water-dock. The largeſt grow in moiſt grounds, the ſmalleſt are moſt aſtringent in dry.

LAPIDILLUM, or LAPIDILLUS. The name of a kind of ſpoon, formerly uſed to take out ſmall ſtones and fragments from the bladder.

LAPILLI. See OCULI CANCRORUM.

LAPIS. STONE. The foſſiliſt divides *ſtones* into two claſſes; but according to the chemiſt, *ſtone* is formed by a mixture of an acid with earth, which is hardened by ſubterranean heat, or petrified by cold. From the different proportions of earth, ariſe different kinds of *ſtones*; the different kinds of earth diſſolved by the acid afford another variety. A ſolution of ſome metallic matter uſually gives the colours. Stahl divides all *ſtones* into calcareous and vitreſcible; but this arrangement is very exceptionable. All that hitherto have been examined, conſiſt of cryſtalline, calcareous, argillaceous, talcky, or gypſeous earths: there are rarely any of theſe pure, but mixed in different proportions with other mineral ſubſtances. CHAPTAL, who has beſtowed much labour on this ſubject, conſiders the various earths beneath our feet as combinations in general; and that the earthy elements moſt extenſively diſtributed are five in number. 1. Lime; 2. Magneſia; 3. Barytes; 4. Alumine; 5. Silex: and out of theſe primitive earths, nature ſeems to have formed all the mixtures and combinations which conſtitute ſtones. From conſidering the nature of theſe mixtures and combinations, three habitudes or modes are diſtinguiſhable, which eſtabliſh three grand diviſions. For it is perceptible, 1ſt, That theſe earths are, in ſome inſtances, combined with acids; 2. In other inſtances, they are mixed with each other; 3. Theſe ſtones, ſo formed by the mixture of primitive earths, in other inſtances, are united together, or fixed in a gluten, or cement. From hence there is lithology diſtinguiſhed into three claſſes. The *firſt* will comprehend SALINE STONES; *Second*, STONES properly ſo called, or EARTHY MIXTURES; *Third*, Rocks, or ſtony admixtures. See Newmann's Chem. Works; Bomare's Dict. of Nat. Hiſt. Chaptal's Elements of Chemiſtry, vol. 2. It is alſo a name annexed to many natural and artificial preparations, as the *lapis bezoar*, *infernalis*, *prunellæ*, &c.

LAPIS IPSE. See ADROP.

—— ANIMALIS. See CHIFFER.

—— AMPELITES. See AMPELITES.

—— ALCHERON. See BEZOAR BOVINUS.

LAPIS BENZAHAR. See BEZOAR FOSSILE.

—— BEZOAR. See BEZOAR ORIENTALIS.

—— PERUVIANUS. See BEZOAR OCCIDENTALIS.

—— PORCINUS et MALACENSIS. See BEZOAR HYSTRICIS.

LAPPA. See BARDANA MAJOR, MINOR, and ARCTIUM.

LAPPAGO. See HIPPOPHÆS; and, according to Blancard, it is aparine.

LAPPULA CANARIA. See CAUCALIS

LAQUEUS. See BROCHOS.

LAQUEUS GUTTURIS. A malignant inflammation of the tonsils.

LARBASON. See ANTIMONIUM.

LARDUM. BACON. It is a proper food for those who use strong exercise.

LARIX. The LARCH-TREE. The leaves are long and narrow, produced out of little tubercles, but fall off in winter; the cones are small and oblong; the branches are regular as those of the fir-tree. This tree is very common on the Alps, and in several parts of Germany; and from it is produced the Venice turpentine. Raii Hist. It is also a name for several species of cedar. See CEDRUS.

LARVA. A MASK. When the face is burnt with gunpowder, &c. the application is a linen mask, with holes for the eyes, nose, and mouth; this mask is mollified with proper remedies, and applied to the face: it is tied behind with six tapes.

LARYNGÆÆ ARTERIÆ. See GUTTURALIS ARTERIA.

LARYNGOTOMIA from λαρυγξ, *the throat*, and τεμνω, *to cut*. See TRACHEOTOMIA.

LARYNX. See ASPERA ARTERIA.

LASCIVUS. See CHOREA SANCTI VITI.

LASER. LASERPITIUM. See ASAFŒTIDA.

LASERPITIUM, is a name of the *sesoselinum*, and of the *silphium*, called by the ancients *altilis*.

LASERPITIUM VULGARE; called also *bupleuron arborescens salicis folio*; *gentiana alba*, *cervicaria alba*, *Libanotis*, *Thapsia*, *seseli Æthiopicum*, *cervaria nigra*, the LESSER HERB FRANKINCENSE. LASSERWORT.

It is a plant which is found in great plenty in Switzerland, and on the Pyrenean mountains. The root is recommended as an alexipharmic and uterine; the seeds are somewhat acrid. It is met with in the gardens of the curious, and flowers in August. Boerhave enumerates sixteen species.

LASSITUDO. MUSCULAR DEBILITY.

LATA LIGAMENTA. The *broad ligaments* of the womb are properly only a duplicature of the peritonæum, reflecting from the loins to the uterus, and are long enough to admit it to hang down into the vagina.

LATER. A BRICK. *Bricks* are heated and applied to various parts of the body, or on cataplasms, to continue their heat. And an oil is made by quenching hot *bricks* in olive oil, until all the oil is imbibed, and then distilling them in a retort until all the oil is drawn off; after which the spirit must be separated. This oil is named *oleum lateritium*,—*philosophorum*,—*sapientiæ*—*perfecti magisterii*,—*divinum*,—*benedictum*. It used to be employed as a remedy in many diseases, but is now properly laid aside.

LATERALES MUSC. See MASSETER, MUSCULUS.

—— MUSC. NASI. See OBLIQUUS NASI MUSC.

—— PROCESS. OSSIS SPHENOIDES. See SPHENOIDES OS.

LATERALIA. LIGAM. On the body of the os humeri, there are two particular ligaments, which may be called *lateral* or intermuscular: they are long, flat, thin, narrow, fixed on one edge along the two lower thirds of the bone, and reaching to both condyles. They are braced pretty tight, and are very narrow at the upper part, but broader towards the condyles, from whence they are expanded like a goose's foot, and form the brachio-cubital, and brachio-radial ligaments.

LATERITIUM OL. See LATER.

LATHYRIS. See CATAPUTIA MINOR, OCHRUS.

LATISSIMUS (so called, because it is the broadest) DORSI, also ANISCALPTOR, because it is in use when the breech is scratched. This muscle rises from the fascia lumborum at its lower part; higher from the sixth, seventh, or eighth vertebræ. At its anterior part, it rises from the ninth, tenth, eleventh, and twelfth ribs: its fibres run round the posterior and inferior angle of the scapula; and its tendon is inserted into the posterior ridge of the groove of the biceps. Its office is to pull the arm backwards, and close to the body.

LAUCANIA. See ŒSOPHAGUS.

LAUDANUM, from *laus*, *praise*. The name implies that the medicine is worthy of praise; it is generally confined to preparations of opium. See TINCTURA OPII, under OPIUM.

LAUREOLA FŒMINA, also called *mezerion*, *mezereum*, *meserion*, *chamælæa*, *thymelæa laurifolia decidua*, MEZEREON, SPURGE-OLIVE, WIDOW-WAIL. DAPHNE MEZEREUM, or DAPHNE *floribus purpureis sessilibus ternis confinis*, *fol. lanceolatis deciduis*. CLASS OCTANDRIA. ORD. MONOGYNIA. LINN. Gen. Plant. 485. It is a small tree or bush, with pale, purplish, or white flowers, which are followed by bay-shaped leaves. It grows plentifully in the woods near Andover, in Hampshire; and about Laxfield, in Suffolk. The flowers appear in January. In August or September the berries, called *cocci cnidii*, ripen. This plant, when fresh especially, if retained in the mouth, and chewed a little, is so very acrid, that it occasions great and long-continued heat and inflammation in the fauces and throat. The berries have also the same effects, and, when swallowed, prove a very corrosive poison, not only to man, but dogs, wolves, foxes, &c. The bark and berries have been long used externally, in different forms, to old ulcers and ill conditioned sores. The former is strongly recommended in France as an application to the skin, which produces, by proper management, a serous discharge, without blistering, which may be continued, and answer the purposes of a perpetual blister, as far as evacuation can be useful, and this with less pain and inconvenience. It has been used as a seton to discharge the humours in inflammation of the eyes. The mode of applying the bark is as follows: The recent bark, about three-quarters of an inch broad, and one inch long, after macerating a little time in vinegar, is applied to the skin, over which is placed an ivy or plantain leaf. This is renewed night and morning, till it bring on a serous discharge, by cauterizing the part; after which, a renewal once in 24 hours is sufficient to continue the discharge for any period.

A decoction of the cortical part of the roots is a powerful remedy in many venereal symptoms, especially when assisted by the hydrargyrus muriatus. This bark should be gathered fresh as it is wanted. The best grows in a light soil. Boil an ounce of the fresh-gathered bark from the roots of mezereon, in twelve pints of water, to eight; at the end of the boiling, an ounce of liquorice root may be added: of the strained liquor half a pint may be drank four times a day. Dr. Russel strongly recommends the use of this decoction, particularly when nocturnal pains are violent in the venereal disorder; also for washing those nodes which proceed from a thickening of the membrane of the bones. See Lewis's Mat. Med. Lond. Med. Obs. and Inq. vol. iii. p. 189, &c. The following decoction is also made use of:

DECOCTUM MEZEREI.

Take of bruised mezereon root, two drams; bruised liquorice-root, one ounce; distilled water, two pints: boil the mezereon till the water is reduced to half the quantity, adding, a little before removal from the fire, the liquorice. Dose one-half pint to one pint within the 24 hours.

It is said to cure other remains of the lues venerea, where mercury has failed; and Dr. Cullen recites one (where many ulcers continued) entirely cured by the use of a decoction of mezereon for two or three weeks. Dr. Home has found it not only cure scirrhous tumors, which remain after the venereal disease, and after the use of mercury, but that it healed some scirrhi from other causes. In cutaneous affections it has sometimes been successful. The bark of the root should only be used. Cullen's Mat. Med. In the case of a difficulty of swallowing, thought to be occasioned by a paralytic affection, by the order of Dr. Withering, a woman was cured, by chewing a thin slice of this root, as often as she could bear it, within a month, though the complaint had been of three years standing.

—— MAS, also called *chamædaphne*, *cupetaton*, *thymelæa laurifolio semper-virens*, *daphnoides*. SPURGE LAUREL. It is the *daphne laureola*, Linn. It is a small shrub: its leaves resemble those of the laurel, but are less; the flowers consist of one leaf, which is greenish.

The

The leaves, berries, and bark, are acrid and hot, burning and inflaming the mouth: if ſwallowed, they vomit and purge. In March or April, the flowers appear; in September, the berries open. See Raii Hiſt. Lewis's Mat. Med.

LAURIFOLIA MAGELLANICA. See WINTERANUS CORTEX.

LAURINUM, OLEUM. See LAURUS VULGARIS.

LAURO-CAMPHORIFERA. See CAMPHORA.

LAURO-CERASUS, alſo called *padus-ceraſus, avium nigra*, CERASUS RACEMOSA *fructu non eduli, ceraſus folio laurino, ceraſus trapezuntina*, BAY CHERRY, or the LAUREL CHERRY, or CHERRY-BAY. It is the PRUNUS-LAURO-CERASUS of Linn.

The root of this tree or ſhrub, is large, rough, and furniſhed with many fibres. The branches are woody, numerous, brown on the outſide, and white within. The leaves are large, fleſhy, oblong, ſhining, pointed at both ends, and ſlightly ſerrated at the edges: their upper ſurface is ſmooth, and of a beautiful dark green colour; the under ſide is rough, ſtrongly marked with fibres, and of a light green complexion. The flowers appear towards the ſuperior part of the branches; they are pentapetalous, in five-leaved cups. They are followed by cluſters of berries reſembling cherries, and containing an oblong ſtone within the pulp of the fruit. It flowers in May, and ripens its fruit in September.

The leaves have a bitter taſte, with a flavour reſembling that of bitter almonds, and the kernels of peaches and apricots; this flavour is communicated to water and to vinous ſpirits, either by infuſion or diſtillation. Theſe preparations are ſo extremely deleterious, and ſometimes ſo ſudden in their operation, as to occaſion inſtant death. Dr. Mead relates, that a few ſpoonfuls of laurel water killed a large dog while it was paſſing down his throat, before it could be ſuppoſed to have reached the ſtomach. It is the moſt expeditious means of killing dogs and almoſt all kinds of animals; given by the mouth, or injected into the rectum, its operation is equally certain, and it acts the moment it touches the ſtomach, or is received into the inteſtines. It is ſpeedily mortal to ſmall animals, if applied to wounds of the muſcles. It is a ſedative of the moſt powerful kind, and tends plainly to deſtroy the mobility of the nervous power, and thereby the vital principle; and, when employed in ſufficient quantity, it does this very ſuddenly, without exciting inflammation on the part to which it hath been applied, and without producing any ſenſible change in the ſtate of the fluids. This poiſon is of that claſs which produces epileptic ſymptoms; it generally produces very ſtrong convulſions, and in a ſhort time death. The ſpaſmodic motions of the whole body are extremely violent on taking it. Two tea-ſpoonfuls of *laurel* water were given to middle-ſized rabbits; in half a minute they were convulſed, and in leſs than a minute they were dead. When it is given ſtrong, and in large quantities, they die almoſt inſtantly, and without convulſions, a ſudden and univerſal paralyſis coming on. Given in leſs quantities, the convulſions are more or leſs ſtrong. On diſſection, after this poiſon has been taken, no uncommon appearances are obſerved in the ſtomach or inteſtines; the arteries are found empty, and the veins turgid with blood. The ſinuſes in the brain, and the veins in the pia mater are diſtended; but this ſeems to be occaſioned more by the convulſions, than by the particular properties of the poiſon. Dr. Rutty of Dublin relates, that a girl of eighteen years of age, very well and healthy, took a quantity leſs than two ſpoonfuls of the firſt runnings of the ſimple water of *laurel* leaves; and, within half a minute after ſhe fell down, was convulſed, foamed at the mouth, and died in a ſhort time.

Although the poiſon of *laurel* appears to conſiſt in the eſſential oil which it affords in diſtillation, yet it is ſtrongly ſuſpected that an infuſion of the leaves is alſo injurious.

It hath been generally obſerved, that if the animals that had ſwallowed this poiſon, vomited it up readily, they generally recovered; but its action ſeems too ſpeedy to hope for relief by any means if ſwallowed by mankind. See VENENUM. Wilmer on Poiſonous Vegetables, and Cullen's Mat. Medica.

—— CASSIA. See FOLIUM.

LAURUS ALEXANDRINA, alſo called *hippogloſſum, epigloſſum, bis-lingua, daphne, digloſſon, epiglottis, ruſcus latifolius*, LAUREL of ALEXANDRIA. *Bonefacia, coracobotane gazar; uvularia.* It is the *ruſcus hippogloſſum of* LINN. and nurſed up in gardens chiefly as a curioſity. The root of this plant is knotted at the head: the ſtalks are tough and pliant: the leaves are placed alternately; on the middle of the back part of each, grows a ſmall moſſy flower, which is ſucceeded by a red berry.

This plant grows in the mountainous parts of Italy and Hungary. It is diuretic. See MILLER'S BOT. OFF.

LAURUS VULGARIS, *dihexapela, diahexapte*, COMMON LAUREL, or BAY-TREE. The LAURUS NOBILIS, or the LAURUS *foliis lanceolatis venoſis perennantibus, floribus quadrifidis*. CLASS ENNEANDRIA. ORD. MONOGYNIA. LINN. Gen. Plant. 505.

The *bay-tree* is generally well known: it is an evergreen, with oblong, ſtiff, ſmooth leaves; the flowers are of a paliſh yellow colour, and are followed by oblong dry berries, containing, under a thin black ſkin, an horny ſhell, within which are lodged two dark brownith ſeeds joined together. It is a native of the ſouth of Europe, and common in our gardens. The flowers appear in April or May, the berries ripen in September, and thoſe which are uſed in the ſhops are generally brought from up the Streights, and are the fruit of the *laurus Alexandrina*.

The leaves have a light agreeable ſmell, and a weak aromatic rough taſte. In diſtillation with water, they yield a ſmall quantity of a very fragrant eſſential oil; with rectified ſpirit they afford a moderately warm pungent extract. They are, however, ſo limited in the preſent practice, that they are rarely employed except in the way of enema; and in the decoctum pro fomento, Pharm. Lond. Though ſometimes they are uſed in infuſion, and drank by way of tea. The berries are ſtronger than the leaves, and yield more eſſential oil: on preſſure they give out an inſipid oil that is fluid; but when they are full ripe, and boiled in water, they afford a thicker oil of a yellowiſh green colour, which is ſcummed from the ſurface, and is the green OIL OF BAYS. This is bitter, acrid, and uſeful as a topical application in palſies, and other nervous diſorders. The oil of bay-berries is called *daphnelaon* and *oleum laurinum*. With regard to the berries, they are an ingredient in the emplaſtrum cumini; and, BERGIUS ſays, they are ſtomachic, reſolvent, promoters of the menſes, urine, and ſweat, who recommends them only in hyſteria. They have long been thought to act with peculiar power on the uterine ſyſtem; hence improper to be uſed during pregnancy. The eſſential oil of the berries may be taken in doſes of from one to five or ſix drops on ſugar, or mixed with mucilage, or in ſpirit of wine.

LAURUS CASSIA. See FOLIUM.

LAURUS ROSEA. See NERION.

Laurus is a name for the *camphor, cinnamon, caſſia lignea*, and *ſaſſafras*.

LAVACRA. WASHES. Such as are uſed to improve the ſkin.

LAVANDULA, } from *lavando, waſhing*, becauſe it
LAVENDULA, } was uſed in baths on acccount of its fragrancy. LAVENDER, called alſo *ſtœchas*, FRENCH LAVENDER.

LAVENDULA LATIFOLIA, called alſo *nardus Italica, ſpica mas, pſeudonardus aſpic*, COMMON BROAD-LEAVED LAVENDER, or SPIKE LAVENDER. LAVENDULA SPICA, or *lavandula* foliis ſeſſilibus lanceolato-linearibus margine revolutis, ſpica interrupta nuda. CLASS DIDYNAMIA. ORDER GYMNOSPERMIA. LINN. Gen. Plant. 711.

Lavender is a ſhrubby plant, with its leaves ſet in pairs, the ſtalks ſquare whilſt young, and round when grown old; on the tops of the branches are naked ſpikes of bluiſh flowers, and ſometimes of white. The common broad-leaved ſort hath by much the larger ſpike, though the flowers are leſs. The name of *ſpica, ſpike*, is given to *lavender*; becauſe of all the verticilated plants, this alone bears a ſpike. Some writers give the name of *ſpike* to the broad-leaved, and others to the narrow-leaved ſpecies. The broad-leaved is common in the ſouthern parts of Europe; it is ſtronger both in ſmell and taſte than the narrow-leaved; by diſtillation it yields near thrice the quantity of eſſential oil, which is both heavier and hotter than that from the other kind, but the flavour is not ſo grateful. The water and ſpirituous extracts made from each ſort are very nearly alike.

In the ſouth of France, where both ſorts grow wild, the broad-leaved is only uſed for obtaining the oil called

OIL of SPIKE, named *daverdon*, and OIL of ASPIC, which, if genuine, is pale coloured, even limpid, though ſometimes it is yellowiſh. The flowers contain almoſt all the oil; they ſhould be macerated ſome days, and then diſtilled. This oil is adulterated with oil of turpentine, and with rectified ſpirit of wine; but, if it is genuine, it diſſolves ſandarac, and indeed it is the beſt known ſolvent of amber.

LAVANDULA ANGUSTIFOLIA, called alſo SPICA FŒMINA, SPICA VULGARIS, PSEUDO-NARDUS, *lavandula* minor, COMMON LAVENDER, SPIKE, or NARROW LEAVED LAVENDER. The leaves of this ſpecies are very narrow, and ſomewhat hoary; native in the ſouthern parts of Europe, but it grows in our gardens very vigorouſly. The flowers appear in June or July.

The flowers are very fragrant and agreeable to moſt people; they are bitteriſh, warm, and pungent to the taſte; they are ſometimes uſed as a mild ſtimulant and corroborant, in vertigos, palſies, tremors, and other debilities of the nervous ſyſtem, both internally and externally; and, in general, in all diſorders in which is a lax fibre.

Dr. Cullen aſſerts, that whether applied externally or internally, it is a powerful ſtimulant of the nervous ſyſtem, and that it will ſeldom go further than exciting the energy of the brain to a fuller impulſe of the nervous power into the nerves of the animal functions, and ſeldom into thoſe of the vital; hence may be more ſafe in palſies than the warmer aromatics, eſpecially if not given in a ſpirituous menſtruum, or along with heating aromatics.

Water extracts by infuſion, near all the virtue both of the flowers and leaves; but the flowers are ſo far preferable to the leaves, that the latter are not much uſed. *Lavender flowers* afford the moſt oil when ready to fall off ſpontaneouſly, and the ſeeds begin to ſhew themſelves.

The eſſential oil when freſh, and from flowers that were in perfection, is of a pale yellow colour, of a pungent taſte, very fragrant, poſſeſſing, in an eminent degree, the peculiar ſmell which is admired in the flowers.

The flowers may be ſeparated from the plant by drying them a little, and then gently beating them; they ſhould then be immediately committed to the ſtill, and the proceſs conducted with a well regulated gentle heat. This oil is given internally as a cordial, from one drop to five. It is alſo uſed as an internal ſtimulant in palſies, lethargies, and other debilities of the nervous ſyſtem, and various affections proceeding from a want of energy in the animal functions. Murray diſſuades from its uſe, where there is any danger from a ſtimulus applied to the ſanguiferous ſyſtem. If ſoft paper is moiſtened with this oil, and applied to any part infeſted with cutaneous inſects, as the pediculi inguinales, &c. they will ſoon be deſtroyed.

Rectified ſpirit extracts the virtue from *lavender* moſt completely, and in diſtillation carries ſome of the odoriferous part over with it.

The London College directs a ſimple ſpirit from theſe flowers. ℞ Florum recentium *lavendulæ*, p. lb. i. ſs. ſpt. vinoſi tenuioris congium unum: diſtilla in balneo aquoſo m. libras quinq. And a compound ſpirit, ℞ ſpt. lavendulæ m. libras tres, roriſmarin. m. lb. i. corticis cinnamomi contuſi, nucis moſchatæ contuſæ ſingulorum, p. unciam dimidiam; ſantali rubri, p. ʒ i. Digere per dies decem & cola. Ph. Lond. 1788. This laſt uſed to be called the Engliſh PALSYDROP, or ENGLISH DROP. The doſe is from ten drops to a tea-ſpoonful. See Lewis's Mat. Med.

LAVAPRATAS. See MAMANGA FRUTEX.

LAVER. A name for the *becabunga*, *ſium*, *naſturtium aquaticum*.

LAVIPEDIUM. See PEDILUVIUM.

LAXA CHIMOLEA. In Paracelſus it is a purging medicine, principally deſigned for the venereal diſeaſe. Johnſon ſays it is a ſalt which grows on ſtones, and is like the anatron, or ufnea lapidea.

LAXATOR MEMBRANÆ TYMPANI. This muſcle ariſes from the upper part of the bone, above the membrana tympani, runs inward, and is inſerted into the thick proceſs of the malleolus. Winſlow calls it the *mallei muſculus internus*.

—— EXTERNUS; *externus tympani auris*. It riſes in the upper ſinus of the auditory paſſage, and is inſerted in the membrana tympani with a ſlender tendon to the malleus, and draws the membrane upward and outward.

LAZARI MORBUS, or MALUM. See ELEPHANTIASIS.

LAZCHER. See BEZOAR.

LAZURIUM ARGENTI, or LAZURINUS PULVIS. It is the SAFFRON of SILVER.

LECHENEON. See CEREBRUM.

LECTUALIS MORBUS. A diſeaſe which confines a patient to his bed.

LECTULI. COUCHES. In theſe chaff is mixed, with proper ingredients coarſely powdered, that their qualities may be abſorbed into the body whilſt the patient is laid on them.

LECTULUS. See EPITHEMA.

LEDON CRETENSE. See LADANUM.

LEDUM PALUSTRE; called alſo *ciſtus ledon*; *roſmarinum ſylveſtre*; MARSH CISTUS, or WILD ROSEMARY. It is the LEDUM *foliis linearibus ſubtus hirſutis, floribus corymboſis*. CLASS DECANDRIA; ORD. MONOGYNIA. LINN. Gen. Plant. 546. Of this there is but one ſpecies; it riſes with a ſlender ſhrubby ſtalk about two feet high, dividing into many ſlender branches, garniſhed with narrow leaves, not much unlike thoſe of heath. The flowers are produced in ſmall cluſters at the end of the branches, and are ſhaped like thoſe of the ſtrawberry-tree, but ſpread open and wider at top. Theſe are of a reddiſh colour, and, in the natural places of their growth, are ſucceeded by ſeed-veſſels, filled with ſmall ſeeds which ripen in autumn. It grows naturally upon bogs and moſſes in many parts of Yorkſhire, Cheſhire, and Lancaſhire. The *calyx* is quinquefid; the *corolla*, plain, and quinque partite; the capſule quinquelocular, and opening at the baſe. It hath a ſtrong, though fragrant, ſmell, and is bitter to the taſte. It is conſidered to be poſſeſſed of ſedative powers, from its narcotic and inebriating qualities. It has been known, without any previous evacuation by emetics and purgatives, alone, to cure the dyſentery. See LINNÆI Mat. Med. and Medical Obſervations, &c. by Goetlieb Richter.

LEGUMINOSA. See FABAGO.

LEGUMEN. Thoſe ſpecies of plants which are called PULSE, ſuch as peas, beans, &c. They are ſo called becauſe they may be gathered by the hand, without cutting. Ray reckons all thoſe plants to be *leguminous*, which have a papilionaceous flower. See FARINACEA.

LEIOPODES. EVEN-FOOTED. Thoſe are thus called, the ſoles of whoſe feet are without the uſual hollow part. Or rather, as Vogel deſcribes it, when the middle of the inſide of the foot is not hollow but plane. It is called *planeæ*, SPLAY-FOOT.

LEIPHÆMOI, from λειπω, *to be deficient*, and αιμα, *blood*. Thoſe are thus called who have too little blood.

LEIPODERMOS, from λειπω, *to be deficient*, and δερμα, *the ſkin*. See PREPUTIUM.

LEIPOPSYCHIA, from λειπω, *to leave*; and ψυχη, *the ſoul*, or *life*. A FAINTING FIT, a LANGUOR, &c. It is ſynonymous with *adynamia*.

LEIPOTHYMIA, from λειπω, *to leave*, and θυμος, *the mind*. A FAINTING FIT, a SWOONING.

LEIPYRIA, from λειπω, *to leave*, and πυρ, *heat* or *fire*. A dangerous ſpecies of ardent fever, wherein the internal parts are ſcorched with heat, whilſt the external parts are cold. It is a kind of tertian.

LEMNIA TERRA EARTH of LEMNOS. See BAOLAR.

LEMPNIAS CALCIS, SCALES of BRASS, which ſeparate when beat with a hammer.

LENOS. In Hippocrates it ſignifies a channel or excavation, made in ſome machines for making extenſion, and reducing fractured bones. See alſo CEREBRUM.

LENS. The LENTIL, called alſo *phace*, or *phæos*. Boerhaave mentions three ſpecies; they are ſhaped like tares, but are leſs; they are a flatulent ſort of food, and not eaſily digeſted. It is the ERVUM LENS of Linnæus, that was formerly uſed as a medicine.

LENTA FEBRIS. See HECTICA.

LENTICULARIA. See MILLEFOLIUM.

LENTICULÆ, LENTIGENES. FRECKLES on the face or breaſt. See EPHELIDES; EFFILA; and alſo PETECHIA.

LENTICULA PALUSTRIS. DUCK-MEAT, called alſo *lens paluſtris*; *aquatica*; *lenticularia minor*. It grows on the ſurface of water that is not ſubjected to much agitation. Its appearance is ſimple and foliaceous; its roots are ſlender, capillaceous, and pellucid. It is cooling if uſed as an external application. BOERHAAVE mentions three ſpecies.

LENTI-

LENTICULA PALUSTRIS MAJOR, } alſo called *he-*
—— AQUATICA TRISULCA, } *derula aquatica*. Theſe are of qualities ſimilar to the former.

LENTICULARE. A LENTICULAR. It is alſo called a RUGINE.

LENTICULARE OS. A name of the fourth bone in the firſt row in the wriſt. It is alſo called *orbiculare*, and *piſiforme*.

The *os lenticulare*, or *orbiculare*, in the ear, Dr. Hunter thinks is part of the incus, as its extremities ſtand upon a narrow neck, and is ſoon broken off, and in the adult is one continued bone with the incus.

LENTICULARES, GLANDULÆ. They are the ſmall glands of the inteſtines; and are ſo called on account of their ſize. See PETECHIÆ.
