P R E F A C E.

**A**BOUT twelve months ago, I published an Essay on *The* GENERATION of ANIMAL HEAT, which was preceded by an *Introduction*, pointing out the Elementary Principles of Nature, and the fundamental Laws by which they are Governed; — At the same time, intimating my intentions of publishing, a *full Explanation* of those Principles and Laws.

*That Explanation*, I now offer to the world, in the following Pages.

I meant to have extended it to the particular agents and operations of *Chemistry*, but, being uncertain whether even this will be read, or not, I thought it best to suspend my researches, at least for the present.

*On the Principles of Nature, evidently presenting themselves to the mind; as being essentially necessary, to produce the various appearances, every where offering themselves to its contemplation.*

I F we take a comprehensive view of nature, we cannot avoid perceiving the existence of matter, in all the different states, from the ponderous and impenetrable solid, to the most subtil

and expansive fluid. But whatever be the state in which it is, we still are convinced of its materiality, by its action upon our material organs of sensation; nothing being capable of exciting the perception, or idea of its existence, presence, and action, but what is material.

Every thing therefore which we can perceive, and know to exist, must be material, howsoever rare or expanded; and the only definition of a particle of matter, which I wish at present to give, is, that it is an impenetrable point or atom, indistructible, and consequently by no natural means divisible.

All things therefore existing, must be composed of particles of matter; and their different states, with respect to solidity, must depend upon the manner, in which those particles are combined with each other; the nearer they approach in every direction, the more solid and ponderous the compound. And upon this mode of arrangement alone, all the various states of solidity and fluidity must depend; because we can never conceive

ceive it possible, for a particle of matter, to act at a distance from itself, or where it is not; therefore, there can be no such power existing as repulsion, or attraction, unless the particles attracting, or repelling be in contact.

We may arrange every thing in nature under *four* general *heads* or *classes*, with respect to their states of solidity; these will be Solids, Liquids, aeriform Fluids, and highly expansive Fluids.

The *first class* comprehends every body or substance, whose component particles nearly approach, and are forcibly attracted to each other; so as to strongly resist any power, applied to separate them from the state they are in, and the present connexion they have, with respect to each other. To this class belongs every thing which we in general call a *Solid* body, or substance; for instance, Stones, Metals, Wood, &c.

The *second class* contains those parts of nature, which strongly resemble the former; except in this respect, that the particles of which they are

composed, have little attraction amongst themselves; consequently, by any moderate force, they may be made to recede, and easily move amongst each other in any direction. Of this kind are all liquids, as Water, Quicksilver, Oils, Spirits, &c.

Of the *third class*, are all those rare, expansive fluids, which are known by the names of Gases, Airs, or elastic fluids; and also vapours. These though as evidently material as the other, contain fewer solid particles, with very large interstices; and though they have weight, and a certain degree of solidity, or power of resistance, yet, that weight and solidity are small, when compared with the substances of the former classes; and consequently, the number of solid particles they contain, must be far less, than the number composing a solid, or liquid of equal extent.

To the *fourth class* belong those highly expansive, subtil, and peculiar fluids, Fire, Light, and the Magnetic and Electric fluids. Their existence is known by their actions; and consequently they are as certainly material, as the ground upon  
which

which we tread ; for nothing can act upon matter, but what is material : nothing can produce sensation, or the perception of its action upon our material organs, but what exists ; and whatever we know to exist, must be material.

It appears then, that the most ponderous solid, and most subtil fluid, are composed of particles equally material, and impenetrable ; but the number of solid particles contained in a cubic inch of air, cannot be nearly equal to the number contained in an equal bulk of metal, as is evident from the difference of their specific gravities ; therefore 'tis certain that those solid particles cannot be so near to each other in air, as they are in metals.

But it hath been mentioned, and cannot be disproved, that no particle of matter can act where it is not ; therefore, the particles forming air, must be in contact with each other, from the centre to the circumference ; but as a certain extent, or bulk of air, is not so dense or solid, as an equal bulk or extent of metal : it must contain  
fewer

fewer particles of matter, and more interstices; consequently, if the particles of matter are in contact, from the centre to the circumference of a particle of air, the cause of its *rarity* must be, that the lines of contiguous particles, forming that extent, cannot be in contact, but must form *radii* of particles, diverging from each other, in proportion as they recede from the centre.

Pure air we know when decomposed, so as to lose its aeriform state, affords a small quantity of acid; in a state occupying much less space than before; and much more solid or dense. Those particles of acid therefore, when in the state of pure air, could not be nearly in contact, but were kept from each other at a considerable distance; consequently, not being capable of acting where they were not, in that expansive state, they must have been kept asunder, by the interposition of some *other* particles of matter, surrounding them in lines, like radii, in all directions, diverging from each other as they receded from the acid particles as centres, so as to form atmospheres around them; which resisting each other

other, when brought into contact, kept those acid centres at a certain distance; in the same manner, as two light balls, electrified with the same kind of electricity, repel, or keep each other at a distance, proportionate to the extent of their respective atmospheres of electric fluid; or in the same manner, as two similar poles of two magnets, refuse to approach each other. For lines of particles, forming radii, extending in all directions from different centres, cannot penetrate, or approach each other, nearer than where they come into contact, because, though the lines of particles at the centre of contact, are parallel, or in the same direction, the surrounding diverging radii will act upon each other at certain angles, approaching to a right angle, as they recede from the centre of contact; consequently, two similar atmospheres will not be able to penetrate each other.

It appears therefore, that the acidifying particles forming the base of pure air, excite certain particles of matter, to attract each other, so as to arrange themselves in an atmospheric form, like  
radii,

radii, round each acid particle as a centre; and that the rarity, elasticity, and levity of pure air, depend upon this atmospheric arrangement; where the lines of particles, diverging as they recede from the acid centre leave large interstices, between them, and form a particle of *Air*, light, yielding, elastic, and yet sufficiently solid, to keep every similar particle at a distance, equal to its extent; if not overpowered by pressure ab extra.

If a little nitrous acid be put into a phial, and exposed to the action of solar light; a quantity of pure air will be produced: but not without being exposed to the light; consequently the particles of acid do not produce pure air, by their own arrangement, amongst themselves; but, by their affinity to light, or *something* partly composing it, they attract to themselves atmospheres of that *something*, and form pure air; therefore, a particle of pure air, is a particle of acid, surrounded by an atmosphere of particles of some *other* kind, attracted from light; those particles by the attraction of the acid, being united to it, and excited to attract each other, so as to arrange themselves

felves into lines, like radii, furrounding the particle of acid in an atmospheric form; therefore we may naturally conclude, that there are *two* kinds of matter; a fixed kind, forming the bases of all solid particles, or compositions of solid particles; and an *active* kind, whose particles being attracted by the fixed particles of matter, become excited to attract each other; so as to form lines in an atmospheric form, furrounding the fixed central particles; and diverging from each other, as they recede from their exciting centres; in the same manner, as a number of iron filings when exposed to the action of a magnet, are excited to attract each other, and arrange themselves in a certain manner, like an atmosphere around it.

Inflammable air resembles pure air in its expansibility, rarity and levity, in which last respect it even greatly exceeds it; consequently it contains but few particles of fixed matter, and those particles are kept at a distance from each other, by the atmospheric arrangement of active particles around them.

If a quantity of this inflammable air, be mixt with a proper proportion of pure air, and the attraction of those atmospheres to their respective centres, be weakened by being extended and dilated by a certain degree of heat; they will penetrate, and unite with each other, so as to bring their respective fixed centres into contact; which unite and form water; by which union the atmospheres being disengaged, combine and form fire, or light; consequently the atmospheres of the particles of inflammable air, have an affinity to the atmospheres of the particles of pure air, by which they unite, and draw their respective centres into contact: but atmospheres surrounding particles of pure, or inflammable air, have no attraction, or power of penetrating and uniting with similar atmospheres of the *same* kind of air; therefore the *atmosphere* surrounding a particle of inflammable air, is of a different kind, from that enveloping the acid particle, and producing pure air; as having an attraction of union to it, exceeding the attraction of arrangement among its own similar particles; and resembles the atmosphere surrounding a ball of cork, positively electrified; which

will

will not unite with another, with a similar electric atmosphere; but rapidly rushes into union with a ball surrounded by an atmosphere of the contrary electricity.

It appears therefore, that there are *two* kinds of *active particles*; that the particles of either kind being attracted by fixed particles of matter, become excited to arrangement, in an atmospheric form, round their respective fixed particles; that each hath an attraction for the other kind, when in a similar state: sufficient to destroy its peculiar arrangement; and that the consequence of that union, is, an *united effort*, to draw their respective centres into contact.

The particles of matter, composing the universe, and producing all the phenomena of nature, therefore, seem to be of *two* general kinds.

The *first* kind, are simple, impenetrable, or solid particles of matter, possessed of a powerful attraction, to particles of the other kind; these for conveniency, may be called *fixed* or *solid* par-

ticles of matter; as forming the solid bases, or evident substance of the first and second classes of matter; and affording the fixed centres, round which the particles of the other kind, arrange themselves like atmospheres, to form the aeriform fluids of the third class.

The *second* kind of matter, are simple, solid particles, possessing a kind of polarity; by which, when attracted by the fixed particles of the first kind, becoming excited, they attract each other into close contact, so as to form lines of contiguous particles, extending like radii, in all directions from the centre; which lines must recede from each other, as their distance from the centre increases.

But as their excitement, and arrangement, depend upon the attraction of the fixed central particle: 'tis evident, that their attractive force of arrangement, must be less, as their distance from the exciting centre becomes greater.

The particles of this second kind, I call, for the  
the

the sake of distinction, *active particles* of matter.

But though all the active particles, resemble each other, in being equally attracted by fixed matter; and by that means excited to atmospheric arrangement; they are certainly of *two* different sorts. Active particles of either sort, when excited, attracting similar particles to arrangement; and two atmospheres of the same kind of active particles, having no power of attracting or approaching each other, nearer than where they come into contact; while radii of particles forming atmospheres, of the *opposite*, or *different* sorts, attract each other into parallel lines, extending from one fixed centre to the other; which by their united force, they draw into contact.

That this diversity of active particles, actually exists, is fully proved by both electricity, and magnetism. For instance, two light cork balls, if positively electrified, will not approach near each other; but if one be positively, and the other negatively electrified, they will rush into contact with violence. In like manner the north  
pole

pole of one magnet, will not approach the north pole of another; but will rapidly meet the south pole, and retain it with force.

It appears therefore evident, that there are *two active* powers in nature; or *two active material* fluids, essentially different in their properties, or dispositions. Each of them hath an attraction for fixed or solid matter; but certain circumstances render the same substance, attractive to one active fluid, but not to the other. And 'tis indeed necessary, that there should be *two active principles* of different natures; because, if there were not, the simplicity of solid matter, and the uniform, equal attraction, of *one* simple active fluid, would unite all nature, into one homogeneous, inorganic, lifeless mass.

Since then it is necessary, and natural to conclude, that there are *two active* fluids, in nature, of different properties, and dispositions, though agreeing in subtilty, expansibility, the property of attraction to fixed matter, and atmospheric arrangement around it; we must likewise allow,  
that

that they have an attraction for each other. For if a certain body, positively electrified, or surrounded by an atmosphere of one active principle, will not come near another in the same state; it shews that each body attracts its own electric atmosphere, and recedes, if possible, from the similar atmosphere surrounding the other; but when presented to a body negatively electrified, they mutually rush into contact; because the body negatively electrified, hath an atmosphere formed by the other active fluid. The same in magnetism; the two active fluids, form similar atmospheres, around the opposite ends of the needle; the same fluid, always surrounding the ends of different needles, pointing the same way; in consequence of which, the similar ends will not unite; but the opposite ends will, forcibly; because the active fluids of the two opposite poles of the needles, being different, attract each other. The same reason is to be given, for the union even of a particle of acid with an alkali.

We may therefore conclude, that besides the simple particles of *fixed* matter, there are *two* kinds  
of

of *active* particles in nature; that the *fixed* particles, equally attract *both* kinds of active particles; that either kind by that attraction, becomes excited to *atmospheric arrangement* around the fixed centre: by means of the peculiar property, or polarity, by which active particles of the same kind, attract each other, so as to form lines, extending from the fixed matter, like radii from a centre; that the atmospheric radii of *different* kinds, have an attraction of combination with each other, when in similar states of excitement, by which they draw their respective fixed centres into contact; but that when in the atmospheric state, neither of these active fluids, will attract the *same* kind of fluid, in the same manner surrounding its respective solid centre; because their attraction is exerted upon the centres themselves, which each respectively is united to. But if one centre has a greater atmosphere than the other, that other will attract so much from it, as to make an equilibrium; where each atmosphere will extend to an equal distance from its centre.

Having now found matter, consisting of solid  
or

or fixed particles; and two active fluids, or kinds of active particles, each having an affinity with the solid or fixed particles, round which they form atmospheres: which will not unite with similar atmospheres; but having an attraction for each other, by which, particles of solid matter possessed of atmospheres of the different fluids, are attracted to unite; we must next see, what will be the result of their union with those fixed particles of matter; and then with each other.

These two active principles, being *equally* attracted by the fixed particles of matter, will each attract and unite itself, to the fixed particles exposed to it; and consequently, each solid particle, will form a *centre* to an atmosphere, of one or other of these active kinds of particles, (which for the sake of conveniency when in that atmospheric state of excitement, I shall occasionally call active fluids,) by which the very properties of these fluids, will be united to the particles of solid or fixed matter; and that union will form a compound, where the inertia of the solid particles, and the elasticity and rarity of the active fluids, must be

each diminished, by their mutual attraction and union.

These compound particles, will therefore have partly the same general properties, as the active fluids themselves have. Particles with similar atmospheres will not unite, but with different atmospheres they will. And these active fluids being equally and universally diffused as far as creation extends; and being equally and powerfully attracted by the fixed particles of matter: every fixed particle of matter must have an atmosphere of either one or other of these active fluids; but as they are each equally attracted by solid matter, 'tis evident, that whichever of the fluids is first united to any solid particle, that atmosphere to a certain extent, the particle must for ever retain; because that fixed particle cannot meet with any thing, to which it hath a stronger affinity; and that active atmosphere can never be more forcibly attracted by any other power, than that, with which it is already combined. Consequently, that atmosphere will never be attracted from its solid centre; and that centre cannot be immediately

diately acted upon, but by first destroying its atmosphere; which can never happen, as nothing can attract it more strongly than its centre does, even were it disengaged; but by being already united to it, it must for ever so remain, to a certain extent or distance from its fixed particle; as its attraction for every other matter, is weakened in proportion as it attracts its centre.

Every solid particle of matter, therefore, actuates an atmosphere of one or other of the two active fluids; but as those fluids are different from, and have an attraction to each other; so must the particles, which as atmospheres they actuate; therefore, every particle of solid matter, must be thus actuated; and the whole will form *two classes, or principles*, each possessed of different properties: and each having an affinity, and power of union with the other.

Of one or other, or both of these classes of actuated particles, all the various substances in nature, which contain any fixed matter as their bases or in their compositions, must be formed; such

are those of the *first*, *second*, and *third* classes of matter; and all the other substances, or fluids, existing, howsoever subtil or elastic, must be produced by the two active fluids, separately or conjointly; such are the highly expansive fluids of the *fourth* class.

If we chemically examine the different solids, fluids and aeriform substances in nature, we in reality find, that *all* of them contain an *earthy*, or an *acid* base or matter; an alkali and an earth, are of the same nature, or the same principle, in different states of combination: but the alkali seems to be the strongest in its general affinities, and consequently the most active; but that activity or alkalinity, seems to be a quality depending upon circumstances; therefore, I include *both* under the general title of *earthy* matter; having a strong attraction to the other, the *acid* matter.

These two substances being of *different* natures, and having a strong attraction to, and power of uniting with each other; are the two classes of *solid*, or *fixed* particles, with atmospheres of the

*two different active fluids*; I shall therefore call the fixed particles of matter, surrounded by *one* of the active fluids, the *earthy principle*; and those particles, having an atmosphere formed by the *other* active matter, the *acidifying principle*; and these are the two *solid* principles of nature; compounded of *similar* central particles of solid or fixed matter, as bases or centres, to atmospheres of the *two different* active fluids.

And now, having pointed out the two more *solid* principles of nature, and distinguished them by proper names, agreeable to those which are universally adopted; 'tis necessary, to distinguish the other two, the *active* principles, by their respective names also.

*One* of them is known, admitted, and named already; 'tis therefore only necessary to point it out, and assign to it, the name universally given to it.

To arrive at this distinction, we must first of all say, that the *earthy principle* is a particle of *fixed*  
matter,

matter, with an atmosphere of *one* of the active fluids; that this atmospheric, or compound particle, will not unite with a similar one; but will, with one formed by the other active fluid. A metal, is allowed to be formed of an earth, united to *Phlogiston*; that is, a metal is composed of a number of particles of earth, united together by their general attraction, to the active fluid, of a *different* nature, to their respective atmospheres; which interposed between the earthy particles, attracts each equally, and consequently, draws them into cohesion, or a solid form. But this active fluid, giving cohesion, and metallic properties, to the earthy particles of which the metal is formed, Philosophers and Chemists by general consent, call *Phlogiston*. *Phlogiston* therefore, is the name by which *one* of these active fluids, shall continue to be distinguished, in the following pages, as sufficiently answering the purpose of discrimination.

But, if *phlogiston* be the cementing principle, which attracts the particles of *earth* together, so as to form a metal: 'tis evident, that the *atmospheres*  
of

of the *earthy* particles, must be composed of the *other* active fluid; and likewise, that as the particles of the acidifying, and earthy principles, have *different* atmospheres, it must follow, that an *acidifying* particle, is formed of fixed particles of *matter*, surrounded by an atmosphere of *phlogiston*.

But what name are we to give to the *other* active fluid? Chemistry hath none for it, because it hath entirely overlooked it. What name then shall we select, or fabricate, for a *fluid*, by the Almighty wisdom and power, endowed with active properties, and amazing subtilty and expansibility? What name better than that which the truly great Sir Isaac Newton gave, to a fluid, whose existence he supposed necessary, and possessed of some properties, similar to this now waiting for a name? that there is a fluid of this kind, in nature, Philosophers allow; and with Sir Isaac Newton and others call it *Æther*. By the name of *Æther*, I shall therefore again take the liberty to call it; not from fanciful fondness for the name, but because it is a name given to a fluid of similar subtilty and expansibility, allowed to exist; and I retain

retain that name, because it answers my purpose, of distinguishing it, from the *other* active principle, known and admitted by the name of *Phlogiston*.

And now we are able to say how an earthy particle is composed, for if an *acidifying* particle, hath a *different* atmosphere from an earthy one, and an acidifying particle hath a *phlogistic* atmosphere; 'tis evident, that the *earthy* principle, is a *fixed* particle of matter, actuated, by being intimately attracted by, and surrounded with, an *ætherial* atmosphere.

The *elementary principles* of nature, therefore are *three*; *two active*, and *one* more passive or fixed. The *two* active principles, are *Æther* and *Phlogiston*; and *each* of these, by their union with the more *passive* principle, forms a *secondary* or more fixed principle; a *fixed* particle of matter, with an *æthereal* atmosphere, forms an *earthy particle* or *principle*; and with a *phlogistic* atmosphere, the *acidifying* principle.

All nature is therefore formed, of *solid* or *fixed*  
particles,

particles, and particles possessed of atmospheric arrangement; that is of *matter* and the actuating property of *attraction*. For though there are *two active* principles, yet, they perfectly resemble each other in their affinity to fixed matter, in their power of firmly uniting with it: in a peculiar polarity, or attraction of arrangement of their particles, in right lines, when excited: and in their general attraction to each other.

Were we to suppose, that there were *two* original kinds of solid particles, one earthy, the other acid; that one would unite with one active principle, and the other with the other active principle only; for instance, that an acid particle would combine with the ætherial, but not with the phlogistic principle; the system would be more complex, and consequently less perfect; for then we should have occasion for a principle, or property of *repulsion*, or a power of *choice*, by which one principle could chuse with what other principle to unite, and which to repel or refuse; for instance, the ætherial principle would have an attraction to the acid principle, or solid acid particle,

ticle, to enable it to combine with it; and a repulsion, or power of refusal, by which it would decline any union with the earthy principle. But this would be multiplying causes, principles, and properties, without necessity; for simple matter, possessed of the active property of general attraction, is alone sufficient, to solve all the phenomena in nature; and consequently the most consentaneous to our ideas of the perfect wisdom of the *Deity*; for to produce any *certain* effects, the *fewer* the principles, or instruments employed, the *more* exalted must be our idea, of the wisdom which contrived or employed them.

It appears then, that the simplest, and most perfect idea which we can form of nature, is, that *all things* are produced by *solid* or *fixed* attractive matter, and *active* matter, having the property of attraction and atmospheric arrangement: that the *fixed* particles of matter, are equally capable of attracting every active particle: that the active particles, mutually and equally attract each other; and yet, that by the union of these *fixed* particles, with *one* part or kind of active matter, they become

come possessed of properties, *very different* from those acquired by similar fixed particles, united to *another* part or kind of that active matter; which shews, that, though every particle of active matter, is possessed of an *equal* power of attracting fixed matter, and uniting with it; and likewise of *arrangement* amongst its *own* particles, so as to take an *atmospheric* form, around that fixed particle as a centre: yet, there is this essential difference in those active particles, that *one* fixed particle, with an atmosphere of æther, or phlogiston, will *not* unite with, or come near *another* particle, surrounded with a *similar* atmosphere; but will rush into contact, with a particle possessed of a *different* atmosphere. Thus a particle with an *ætherial* atmosphere, will not approach near another, with an atmosphere of æther; but will rapidly combine with a particle, whose atmosphere is of *phlogiston*. It is evident therefore, that though *all active* matter possesses an attraction to *fixed* matter, yet that there are *two* kinds of active matter, perfectly similar in every respect but this, that *two* atmospheres of the *same* active fluid, when excited by union to two similar fixed particles, cannot at-

tract, or penetrate each other, so as to unite, or occupy a less space than they do already; but, that two atmospheres *one of each* kind of active particles, can attract, and penetrate each other, so as to firmly combine, and occupy a space when united, *less* than when separate,

The reason why *similar* atmospheres, will *not* penetrate each other, must be, that *similar* particles, have only an attraction of *arrangement*: while particles of *different* kinds, have an attraction of *union*, overpowering the attraction of regular arrangement; when the two atmospheres are in a state of equal excitement.

This polarity, or peculiar arrangement of active particles, being excited by their attraction to solid or fixed particles as centres: 'tis evident, that the nearer the centre, the greater the excitement, and the more powerful will be the property of arrangement.

With this difference between the attraction of *arrangement*, and attraction of *union* of the two fluids,

ids, when excited, so as to take an atmospheric form round their respective centres, we shall find no difficulty in solving the various appearances of nature, which may present; without having the least occasion to suppose, that the *same* particle of matter is possessed of both attraction and repulsion: which, cannot, consistently with reason, be conceived as existent at the *same* time, in the *same* particle of matter; for being opposite and equal effects, arising from the same particle or centre, they would destroy each other; neither need we suppose, that the same particle has a power of *choice*, by which it will unite to *one* simple particle, but refuses every union with *another*; for all that is necessary to be proved, is, that *similar* excited atmospheres, in this state of arrangement, *cannot* unite or penetrate each other; but, that excited atmospheres of the *two different* active principles, can; and by that union, occupy *less space* than before their combination; which I would explain in the following manner.

Suppose a quantity of disengaged, or unexcited *æther*, having in that state, no particular property

ty but fluidity, or a tendency to keep itself in an equilibrium. If, *two* particles of *fixed* matter, be introduced to this æther, they will attract it powerfully : and by that attraction, the *contiguous* particles of *æther*, will become excited, so as to attract the surrounding particles, and they others ; something like what takes place, when a number of small needles are arranged so as to form a line, by being applied, the extremity of one, to the end of another ; or when a number of iron filings are promiscuously spread ; in that unexcited state, they have no attraction, or action upon each other ; but, if a *magnet* be applied to one extremity of this line of needles, or filings, that extremity is firmly attracted to the magnet, and all the other needles, or filings, instantly become *excited*, so as to attract each other. So it is with respect to the ætherial particles, the *first* being attracted by the *fixed* particle, becomes *excited* ; and that excitement is communicated to every contiguous particle ; so that lines of particles are formed, extending like radii from the centre, in every direction.

It is evident therefore, that these excited active fluids

fluids will *each* surround its centre in an atmospheric form: that atmospheres of the *same* kind, of *æther* for instance, cannot penetrate each other, mechanically, but must press upon, or resist each other, if brought into contact: and that they have *no* other power of uniting, because the *only* property which these excited ætherial particles have with respect to each other, is that of *arranging* themselves around their respective centres. If one central fixed particle, indeed, possesses a *larger* atmosphere of excited ætherial particles than another, in contact with it; the external particles will be *less* powerfully attracted, or excited to *it*, than by *that* which hath the *smaller* atmosphere; in which case, the latter will by its superior excitement, attract so much of the atmosphere from the first, as to render the *two* particles possessed of *equal* atmospheres.

The same takes place, in similar excited atmospheres of *phlogiston*; which for the same reason, will press upon, or resist each other, when brought in contact; but cannot unite.

But

But if an excited *ætherial* atmosphere, be brought into contact, with an equally excited atmosphere of *phlogiston*: they will attract each other: the radii of *each*, will be attracted to insinuate themselves between the radii of the *other*: the space they occupy, will become gradually *less*, as they approach: till at length, having penetrated, and united with each other, as much as possible, their force of attraction, or cohesion is become as great as it can be, in those circumstances; *each* atmosphere attracting its *own* central particle, and the *opposite* atmosphere also; so that not being able to quit their respective centres, so as to unite and form a disengaged compound: they can only unite so far, as to form the attraction of cohesion, by drawing and holding the centres together.

It appears also, that the force with which *æther* and *phlogiston* attract each other, is always proportionate to the number or quantity of particles; and as their density is *greater* as they approach the central particle, it must follow, that they will attract each other with a force inversely proportionate, to their distances from their respective centres;

tres; the nearer they are to those centres, the greater their force of attraction to each other; in the same manner, as two bodies electrified, the one with positive, the other negative electricity: or the north and south poles of two magnetic needles, attract each other with a force, increasing in a certain ratio, as their distance decreases.

The attraction of arrangement to a *certain extent*, around a *fixed* particle, will *exceed* the attraction of union with the other kind of active particles; unless they are in an *equal* state of excitement: in which case, they will attract each other, so as to draw their respective centres into contact, without being able to separate from them.

If particles of æther, for instance, be *strongly* excited to arrangement, they will form no union, even with particles of phlogiston, *slightly* excited; because their attraction to *each other*, in that state of *nearness* to their exciting centre, exceeds the force of the attraction of union, which the *slightly* excited particles of phlogiston, in that state, are capable of exerting.

In consequence of the superior force of the attraction between the two fluids, to that by which similar particles arrange themselves to each other, when extending beyond a certain distance from the exciting centre, it will follow, that, if a central particle be surrounded by an atmosphere of æther for instance, of that *certain extent*: that *ætherial* atmosphere, will rather unite to a *disengaged phlogiston*, than extend itself, by taking into arrangement, a greater quantity of *æther*; but those *Phlogistic* particles, having no previous excitement or atmospheric arrangement, of particles, will be simply attracted *to*, and united *with* the *external* particles of the *ætherial* atmosphere; and in consequence of that attraction becoming *excited*, they will take their usual form of *arrangement* amongst themselves, and form an *atmosphere* of *phlogistic* particles, whose centre, is an *atmosphere* of *æther*, excited by its central particle of *fixed* matter. In like manner a *phlogistic* atmosphere of a *certain* extent, around its original particle, may have an *external* atmosphere of *æther*.

If these *two different compound* particles, be  
brought

brought into contact, the *external* atmospheres being different, will attract and approach each other: till, by approximation the *internal* atmospheres are brought into contact; they being *different*, will penetrate, unite with, and satisfy *each other*; in consequence of which, they will *lose* their attraction for their respective *external* atmospheres, which will therefore unite, and *separate* from the other compound; and that union, more or less perfect, according to the degree of excitement they respectively had, or acquire, by the circumstances which effected their union, will produce a *compound active* fluid, or fluids, differing in their properties, as the *degree* of excitement, or *intimacy* of the union, between the particles of the two active fluids of which they are composed, shall differ; such are *Fire* and *Light*.

Having now taken a progeffive view, of the *simple principles*, or *elements*, of which the universe is composed; their *properties*, and the *general laws*, by which those principles are governed or actuated; I shall take the liberty to recapitulate, or give the following concise view of the whole.

1. Nothing can *act* or produce *effects*, which does not *exist* as a cause.

2. Nothing can act at a *distance* from itself, because nothing can act *where it is not*.

3. Every thing in nature is produced by *matter*, and *attraction*, when particles of matter are in *contact*; for unless they be in contact, no body, or substance can act upon another; therefore attraction, or repulsion, at a distance from the acting body, can *not* exist, because they imply a power by which matter acts where it is not.

4. There are in nature a number of *solid*, *points*, *atoms*, or *particles*: divested of every property but attraction, and impenetrability, these I have called *fixed* particles of matter.

5. There are *other* particles of impenetrable matter, which when attracted by the former, become excited to arrange themselves in right lines, so as to form an atmosphere of radii diverging from

from the *fixed* particle as a centre; these I call *active* particles.

6. These active particles *only* become excited, so as to exert or shew their attractive power, when they have an opportunity of uniting with *fixed* particles; or with other particles rendered active, by being united to fixed particles, as centres.

7. When active particles of matter are excited, by a particle of *fixed* matter, they then attract *other* particles of the *same* kind of active matter: which therefore become excited; and by a peculiar *polarity* or property, arrange themselves in right lines, surrounding the fixed particle like an atmosphere.

8. Excited atmospheres of active particles forming lines like rays round their exciting central particles, the further they recede from those centres, the less will be their excitement, and the greater their distance from each other.

9. The

9. The active particles of matter are of *two* kinds, similar in their becoming excited by the attraction of fixed matter: and in their polarity, or property of their particles arranging themselves in right lines, in consequence of that excitement. To these *two active* matters, I give the names of *æther* and *phlogiston*: *æther* being an active fluid, adopted by Philosophers, but overlooked by Chemists; and *phlogiston* an active matter, adopted by Chemists, but neglected by Philosophers.

10. These *two* kinds of active matter, when excited, besides their attraction to fixed matter, and attraction of arrangement amongst themselves, have a powerful attraction *mutually* to each other, when in similar states, or degrees of excitement.

11. When a *fixed* particle of matter, is *once* surrounded by an atmosphere of *æther*, they can never more be entirely separated. The *fixed* particle attracting no other matter more powerfully than *æther*; and *æther*, being attracted by nothing more forcibly, than the fixed particle it already surrounds. And this union forms a particle

cle of *earth*; one of the *fixed*, though secondary or compound principles of nature.

12. A particle of fixed matter, enveloped by an atmosphere of *phlogiston*, can never be entirely separated; and that union forms, the *other fixed*, but secondary or compound principle of nature, the *acidifying principle*.

13. Atmospheres of *similar* kinds of active particles, cannot penetrate, or unite; but when in contact, will *press* upon and *resist* each other.

14. But, atmospheres of the *two different* kinds, in a *similar* state of excitement, will attract each other; and by that means *draw* their respective exciting centres into *contact*.

15. A particle of the *earthy* principle, being composed of a fixed particle of matter, with an *ætherial* atmosphere, that æther will at a certain distance from its exciting centre, attract the particles of *phlogiston*, rather than those of æther; when by being attracted to the surface of the *ætherial* atmosphere,

mosphere, the particles of *phlogiston* become excited, and arrange themselves in an *atmospheric* form around the *other*. And in the same manner, a particle of the *acidifying* principle, will attract and be surrounded by an *atmosphere* of *æther*. Each of these fixed principles, by means of these *external* atmospheres, acquiring properties, different from what they possess in their simple states.

16. An active *atmosphere*, to a certain extent around its *fixed centre*, is inseparable; it will therefore only attract an atmosphere of the *other* kind, in a similar state, so as to form the *attraction* of *cohesion*: by which, the *two* particles or *fixed* principles, or centres, will be forcibly drawn and kept together.

17. But an *external* atmosphere of *one* kind, meeting with an *external* atmosphere of the *other*, will unite, and by drawing their respective *actuated centres* into *contact*, will become *disengaged*, by the attraction of the internal actuated particles, *satisfying each other*.

18. If

18. If a particle of the *earthy* principle, surrounded by an *external*, or *phlogistic* atmosphere, be brought into contact with a particle of the *acidifying* principle, surrounded by an *external ætherial* atmosphere: the attraction between the two external atmospheres, will cause them to penetrate each other, and unite so far, that the *internal* atmospheres, *essential* to the *earthy* and *acidifying* principles, will come into contact; when, they being of the *two different* fluids, will attract *each other*, and unite also: forming a solid compound, different from either earth or acid; in consequence of which union, the two *internal*, or *essential* atmospheres, being satisfied with each other, lose their attraction to the *external* atmospheres intirely; which therefore will *unite*, and *separate*, in a form different from either of the *simple* active fluids, as being composed of *both*; and the *same* two fluids, under different circumstances, where the *mode*, the *violence* of excitement, or *intimacy* of union is different, will produce compounds of different properties; such are *Fire* and *Light*.

19. No *external* atmosphere, can *separate* from

G

its

its exciting *fixed* principle as a centre, unless it can meet with the *other* kind of active matter with which to combine : at the same time, that the *centre* from which it separates, can attract *its opposite principle*, to supply the place of the disengaged atmosphere.

20. An atmosphere of *either* kind, *slightly* excited, by a surface with which it cannot *intimately* unite, will readily *separate*, to unite with the *opposite* active fluid in a similar state; which will *separate* also; and escape *combined* with the *former*, in the form of an active sensible fluid.

Having now delivered my *general Explanation* of the *elementary Principles* of Nature, and the *laws* by which they are governed; I shall next endeavour to demonstrate their actual existence, and point them out, so that they may be certainly known and readily distinguished from each other.

## SECTION II.

*An Attempt to prove, that the Elementary Principles, proposed in the preceding Section, in reality exist; and to point them out in Nature, so that they may be known, and distinguished from each other with certainty.*

**A**LL the solid bodies or substances in nature, when chemically examined, are found to have *solid* bases of particles, which are either *Earthy* or *Acid*.

An *alkali* and *earth*, in the most perfect state of purity in which we can procure them, so nearly resemble each other in their leading properties, that we may suppose them to be the *same* principle, more or less combined with some *other* principle or principles: however to deviate as little as possible from the common mode of expression, and to avoid prolixity, I shall class them *both* under the same general title, the *earthy principle*; rather than under that of alkali, or the principle of alkalinity.

To enumerate the *distinguishing* properties of acids, and earths, would be superfluous; their existence is universally allowed, therefore I need not spend time in proving what is already granted. All I shall further add at present, by way of explaining my ideas of an acid and earth, is, that an *acid* particle is known by its taste, and other properties, to Chemists and Philosophers; and that the basis of *every* solid, liquid, or aeriform substance in nature, which is not formed of those *acidifying* particles, is composed with an *earthy* base; or with the particles of the earthy and acidifying principles,

principles, combined in certain proportions.

The acidifying particles form one fixed principle therefore, and the earthy the other; *similar* in the properties of solidity, fixity, or substantiality; and in their *mutual* attraction to each other; but *different* in their other properties and affinities.

An earth and acid being granted, as the *two* principles, as bases, giving solidity to all bodies, I shall next proceed to consider, and point out the other two principles.

If a certain quantity of *phosphorus*, be confined in a sufficient quantity of *pure air*, *light* and *heat* will be produced: the *volume* of air will be *absorbed*: and a quantity of *acid* will remain, *exceeding* the original weight of the phosphorus employed. It is certain therefore, that the *additional* acid, was furnished by the *air*. But those additional particles of acid, when in their *aeriform* state, could *not* be in *contact*; because they then occupied a space vastly *greater*, than that which they now possess,

possess; but as no particle of matter can act where it is not, 'tis evident, that they could *not push* each other to that distance: therefore they must have been *surrounded* by *atmospheres* of some kind of *active fluid*; which atmospheres, *pressing* upon each other, kept them asunder; and *this active* fluid, be it what it may, I call *æther*. But since the particles of acid, by combustion with phosphorus, are now *condensed* into a much more solid form, and occupy much *less space* than before, in their aeriform state, 'tis evident, that they are *no longer* surrounded by their ætherial atmospheres. The *æther* must therefore have escaped. Is it not natural then to say, that it passed *off* in the form of *light*, or *fire*, which were evidently produced, so long as the æther continued to separate from its acid base, during the combustion of the phosphorus?

Again, If *mercury* be dissolved in *nitrous acid*, the *acid* will unite with the *earth* of the mercury, and form a *Calx* or *Metallic salt*. This *calx*, is therefore evidently composed of the *earth* of the mercury, and the *acid*. Expose this calx to the  
action

action of fire, in *close* vessels; the result will be, that the *mercury* will recover its metallic state, and the receiver be filled with pure air. What change then hath the mercury undergone?—It hath *lost* the acid with which it was combined when in the form of calx.—What can have become of that acid?—it must be contained in the pure air. It is evident therefore, from this and the preceding observation, that the *base* of *pure* air is an acid.

But the *acid* employed, was not possessed of *æther*, *sufficient* to surround it in an atmospheric form; and the particles of *that* acid, combined with the mercury in a solid form, could still *less* retain it; from *whence* then, had those solid particles of acid, the *æther* sufficient, to give them their elastic form of pure air, by keeping them asunder? they could acquire it from nothing but the *fire*, necessary to the operation. It appears therefore, that *fire* was *produced* by means of *æther* in the first case: and that *æther* was furnished by the *fire* in this case.

But

But what is this elastic, subtile fluid, which separates the particles of acid, at such a distance from each other, as to give them the rarity, and elasticity of pure air, and which hath been called æther? Is it fire?—if it be, *every thing* which can give to particles of acid, this *ætherial atmosphere*, must be, or contain in its composition, *fire*. It is well known, that *fire* will give this *ætherial atmosphere* to nitrous acid, when it separates it from the mercury, as hath just now been mentioned; that light will give it the *same* kind of atmosphere, if the nitrous acid be exposed to it, in the state of vapour: and that the *electric* fluid, taken in sparks or shocks through the same, will give the ætherial intermedium also; in *each* case, giving the acid the *same* form, and properties, those of pure air. It is evident therefore, that fire, light, and the electric fluid, equally communicate this *ætherial* fluid, to the particles of acid, to give them the form of pure air; and consequently, that they are either *one* and the *same* fluid: or that *this ætherial* fluid, is an *essential* constituent part, in each.

But if they were one and the same fluid, they  
would

would have no properties, *different*, the one from the other; but they *have* different properties: therefore, they are fluids of different kinds; and one principle, common to them all, is, this *æther*, which united to the acid principle, forms pure air.

But, if fire, light, and the electric fluid, all contain *æther*: and having different properties, require *some other* principle to be joined with that *æther*, to give *those* properties, wherein they differ: what becomes of *that other* principle, when the *æther* separates from it, to unite with and surround the particles of acid, when they take the form of pure air?—it must unite with the substance, or matter from which the acid particles separate; and the *change* produced upon metals, or the nitrous acid, being the *same* when pure air is produced, by *which ever* of the *three* it is effected, shews, that the *other principle*, which they each of them are composed of, besides *æther*, is the *same*; that their *different* properties, depend, upon the *mode* or *intimacy* of union, between the *æther* and the other fluid; and *that other* fluid, we

H

may

may for the future, distinguish by the name of *Phlogiston*; as being an active, elastic fluid, like *æther*; to which it hath an affinity; but they differ in their affinities with the other principles; *æther* only attracting the acidifying, and *phlogiston* the earthy principle.

It appears therefore evident that fire, light and the electric fluid, are composed of the *same principles*: that those are *æther* and *phlogiston*: that their different properties depend upon the mode, or intimacy of their union, or their degree of excitement, or both: and that *one* may be *changed* into the *other*, by altering the mode of their union, or the degree of their excitement. Thus, *light* when agitated, confused, and obstructed in its passage through an opaque body, is altered in the mode of union between the particles of *æther* and *phlogiston*, composing it as light; in consequence of which, those two principles acquire a nearer, or different mode of union, forming *heat* or *fire*, as is evident from experiments with the burning glass. The *electric fluid*, passing through a *slightly* resisting medium, undergoes a change in the state  
of

of combination of the external electric particles most obstructed, and forms *light*; but if the resistance be still *greater*, it becomes *fire*, as is evident from its accending gunpowder, melting metals, &c.

'Tis evident therefore, that neither *fire*, *light*, nor the *electric* fluid, can render solid particles of earth or acid, permanently elastic, but by being decomposed; and that *that* decomposition, cannot take place, unless each principle when separated, hath *another* principle with which to unite. For if any substance, or fluid is thrown into the state of vapour, by heat, without decomposing that heat or fire; so soon as the particles of that vapour come in contact, with any body possessed of *less* heat: they are robbed of it, and *condense* into their *original* fluid or solid form.

But, as a further proof of the actual existence of these *four* principles; and the veracity of the preceding conclusions, I shall bring the following chemical experiment.

If a certain proportion of pure air, and inflam-

mable gas or air, be mixed together, and exploded by any ignited particle of matter; the result will be *fire or heat, light, and water.*

*Pure air*, from the experiments with phosphorus or calx of mercury, mentioned before, we know for a certainty, contains a number of *acid particles*, which cannot be in contact, and therefore cannot act upon each other; consequently they must be kept asunder, by some *active fluid*, surrounding them as *atmospheres*; *this active fluid*, I have called *Æther*; so that *pure air* is composed of *acid particles*, with *ætherial atmospheres*, surrounding and keeping them asunder. But when this pure air is exploded with inflammable air, the *æther* is separated, and the acid particles are condensed: but though the volume of both the airs is lost, we find no residuum of pure disengaged acid; what then can have become of it? it could not escape through the sides of the glass, in which the experiment was made; it must therefore be contained in the *Water*. But water is an insipid, neutral fluid;—yet the *acid* must be there; and must therefore be combined with *something*,  
capable

capable of uniting with, and neutralizing it. That *something*, cannot be æther, because with æther, it formed pure air: which state of elasticity, and rarity, it hath now lost, by being separated from its æther; it must therefore follow, that the *acid* is now combined with the *earthy* principle: with which it is united to saturation; for *earth* is the *only* thing, with which the *acid* could be saturated, or unite, when deprived of æther.

The *water*, then, produced by this operation, is composed of the *acid* particles of the pure air, when separated, at least to a certain degree, from their ætherial atmospheres: united to, and saturated with, particles of *earth*, retaining but little of their atmospheres. But by what was this earth supplied? not by the pure air, because it contained only æther and acidifying particles; consequently, it was procured from the *inflammable* air. These particles of *earth* therefore, formed the *base* of the inflammable air. But when in that aeriform state, they occupied a space *much larger*, than that they *now* possess, as forming part of the small residuum of water: 'tis certain therefore, that they

in

in their aeriform state were far *separated* from each other: that *that* separation, could not be effected by their action upon each other; matter not acting where it is not; 'tis evident therefore, that they were separated, by the interposition of an *active elastic* fluid, surrounding them like *atmospheres*; in the same manner, as the particles of *acid* were by æther, when in the form of pure air.

The particles of matter forming the *base* of inflammable air, must therefore be of the *earthy* principle; and those particles in that *aeriform* state, must be kept asunder by *some* active elastic fluid; but what is that fluid?—what can it be?—It cannot be æther, or that kind of elastic fluid, which separates the particles of the acidifying principle, in pure air; because *that* fluid, *that* æther, hath no affinity with the *earthy* principle; it must therefore be an *elastic, subtile fluid*, possessed of the same attraction to the *earthy*, which æther hath for the acidifying principle; and to distinguish it in future, let it be called *phlogiston*.

Inflammable air then, is composed of particles  
of

of the *earthy principle*, furrounded by *atmospheres* of *phlogiston*; *pure air* of particles of the *acidifying principle*, furrounded by *æther*; these when mixed together, and exploded, produce *fire* and *light*: at the same time that they *lose* their elastic, expanded form: and the residuum is *water*. Water must therefore, be composed, of the *solid bases*, or particles, of the *two airs*; the *acid* and *earthy* particles; which uniting, saturate each other, and form *that* neutral compound; at the same time, the *two* disengaged elastic fluids, the *æther* of the *pure air*, and *phlogiston* of the *inflammable*, unite, and form *fire*, or *light*; according to the circumstances, to which *different* parts, of the two fluids, are exposed, during their combination.

From the experiments, and observations, universally allowed, and established, which are recited in the preceding pages, 'tis impossible to deny, that *pure air*, contains the *principle* of *acidity*, or *acidifying* particles, as its base: that those *acidifying* particles, enter into the composition of the *water*, produced by exploding *pure air* with *inflammable gas*: that in *that* state, they shew no signs  
of

*acidity*, and are therefore neutralized: that the *only* solid, or liquid matter, capable of neutralizing an acid, is of an *alkaline* or *earthy* nature: consequently, that those particles of *acid*, are neutralized by being united with an *earthy* matter: and that *that earth*, was furnished by the *inflammable Gas*. These facts being proved, it must follow, that before any one can disprove the existence of the *two active* fluids, necessary to give these *solid* particles, the *elastic, expanded* form of air: he must *first* of all, demonstrate, that *matter can*, and *does* act where it is not; or that *one* particle of matter, can act upon *another*, at a *distance* from itself, without *any intermedium*. That it *can*, is not possible to be conceived, and therefore ought not to be asserted, or permitted; and that it *does*, there is not one decided proof, and therefore I utterly deny it.

If then matter cannot *per se*, act where it is not:—the *particles* of the *acidifying* principle, entering into the composition of the *water*, produced in the preceding experiment, when *expanded* in the form of *pure air*, could not be in contact; and consequently,

consequently, must have been kept asunder, by the interposition of *some other active*, subtile, elastic fluid; and the particles of *earth*, when expanded in the form of *inflammable* gas, must have been kept separate, by a *similar* kind of active fluid. That these fluids are *different*, is evident from their different properties: from their attraction for, and union with each other: from *that* union producing compounds, possessed of different properties, according to the intimacy or mode of combination, the degree of their excitement, or different proportions: and from each having an affinity to *one* solid principle, and total inability to unite with the other. Indeed, these *two active* principles, are possessed of *similar* properties, to what the two *passive* principles have. The *acidifying*, and *earthy* principles, will unite, and form a compound, different from either; so will the *two active* principles. The acidifying principle will unite with *one* active principle, but *not* the *other*; so will *that other* unite with the *earthy*, but not with the acidifying principle. *That* active principle therefore, which will unite with the *acidifying* principle, I call invariably by the name of *Æther*;

and the *other* active fluid, capable of uniting with the *earthly* principle, is as constantly distinguished by the name of *Phlogiston*.

Again, let us *suppose*, that every aeriform fluid, owes its elastic, expanded form, to *fire*, or that principle which in action produces, the sensation of heat; and consequently, that *fire* is an element, or simple principle, capable of uniting with simple particles of matter, and by removing them to a distance from each other, of giving them the form of elastic fluids.

*Suppose* this simple element of *fire*, the *only agent* in nature, capable of giving the aeriform state to solid particles; for to suppose *another*, is much the same, as to allow the principles for which I contend.

Pure air then, being proved to contain an *acid*, will be composed of a number of acid particles, separated from each other, by being united to the simple element, of *fire*. Mercury then, may be *supposed* a simple substance, as the *Antiphlogistians* pretend;

pretend; and this *mercury*, by means of *fire*, will attract the *acid* base of the pure air, and form a calx. But in this operation does the mercury absorb the pure air, that is the *acid* and *fire* entire, or only the acid?—*Suppose* we say that it only unites with the *acid*, or oxygenous base; the *fire* then must become *disengaged*, and escape in its proper form of fire. 'Tis evident therefore, that the mercury when heated, hath a *greater* affinity to the *acid* principle, than *fire* hath.

But, if this calx, or mercury combined with the acid principle, be heated by itself, in close vessels, preventing any foreign communication, the fire will attract the *acid* from the mercury, and take the form of pure air; while the mercury regaining its metallic state, will remain simple, and pure behind. 'Tis evident in this case that *fire*, hath a *greater* affinity to the *acid principle*, than heated mercury hath; because, it will take it *from* it. But the *first* operation proved, that *mercury* had a *greater* attraction to acid, than *fire* hath; therefore, these *two opposite* conclusions, shew, that *these principles are insufficient and unphilosophical*.

*Suppose* then, that mercury attracts the air *entire*, that is, both the *acid* or oxygenous base, and the *fire* which gives it the form of air. We must then say, that *mercury* when heated, attracts the *acid principle*, and the *fire*, necessary to give it the form of pure air, also, by which union it becomes a *calx*, or compound of *mercury*, *acid* and *fire*. If this compound be cut off, from every external communication, and heated, the acid principle with the fire will separate, in the form of pure air; and the simple mercury will remain, having recovered its metallic properties.

'Tis evident therefore, that *mercury*, when heated, *loses* its attraction to pure air, or a compound of *acid* and *fire*. But the former operation was to prove, that mercury when heated *acquired* the power of attracting pure air; therefore 'tis plain that the opinion of *mercury* being a *simple* or *uncompounded* substance, and *pure air* a compound of the *acid* or oxygenous principle and *fire*, and that *fire* a *simple* substance also, is puerile, and *unphilosophical*.

'Tis evident, that mercury, when *slowly heated*, will attract the *acid basis* of pure air, from its elastic medium; but when *violently heated*, it cannot retain that acid in combination; for which reason also mercury, when violently heated will sublime, or evaporate without decomposition, or becoming a calx.

But if mercury be a *simple substance*, and pure air a compound of *acid particles* and *fire*, the *quantity* of fire thrown into the mercury, *cannot make* any difference, in the *attraction* between the *mercury* and *acid principle*, no more than the quantity of water, combined with an *alkali*, can alter the attraction between those alkaline particles, and the particles of acid combined with water; we must therefore of *necessity*, have recourse to some other mode of explanation.

Pure air *alone*, we know is unchangeable in any degree of heat; so is mercury. But mercury *without* heat, will *not* decompose pure air; with a *certain* degree of heat, it *will* decompose it, by attracting its acid: but in a *greater* degree of heat, will

will lose that attraction for the acid, and part with it. But heat, can produce no change in simple bodies, but that of expansion. An alkali, always retains its alkaline properties, howsoever heated; and an acid is always an acid, in every degree of heat. However, 'tis evident that the acid base of the air, hath sometimes a greater attraction for mercury, than for its elastic principle, and in a greater or less degree of heat, it hath a stronger attraction to the fluid which gives it its aeriform state, than to mercury. But the attraction of the acid to its elastic fluid being always the same: and its affinity to mercury being always the same, it must follow, that when the mercury will not unite with the acid, some change must have taken place in the mercury; that change cannot be the loss of its affinity to the acid, because original natural properties, are unalterable by heat; therefore, its inability to unite with the acid principle, must be owing to its attraction to, and union with some other principle, which in those circumstances, it hath a greater affinity with, than it hath for the acid principle.

Mercury must therefore be a compound; and the  
affinity

affinity of its *base* with the *acidifying* principle, and its appearance when calcined, prove, that *that* base is an *earth*, as hath been universally allowed.

Mercury then is an *earth*, united to some *other* principle; and pure air is an *acid*, combined with *another* principle. Are those two principles the *same*? are they *both* *Fire*? or are they *different* principles, which by their union when disengaged, from their respective bases of Earth and Acid, produce *Fire*?

Let us for a moment *suppose*, that *both* these principles, are the *same*, and that *that* principle is *fire*; and consequently a fluid, simple and uncompound-  
ed.

Mercury will then be an *earth* united to *fire*, and pure air, an *acid* combined with the *same* active principle, *fire*.

By the operation of *calcination*, 'tis proved that the *earth* of the mercury, will *quit* its *fire*, to combine with the acid of the air when heated together;  
but

but when this *calx* or compound of earth and acid, is sufficiently expanded by means of heat, the earth quits the acid, *regains* its fire, and becomes mercury; while the acid also recovers its pristine state, that of pure air; therefore at *one time* the *attraction* of acid to earth, is *greater* than their *united* attraction to *fire*; and at *another time* their *attraction* to *fire*, *exceeds* the *affinity* with *each other*; consequently, the idea of mercury being an *earth* united to *fire*, as a principle, upon which its metallic properties depend, must be erroneous. But it hath been proved, that mercury supposed to be a *simple* substance, is also insufficient, and false: therefore, it must follow, that *mercury* is an *earth*, combined with *some active principle*, different from *fire*; and that *that* principle, may be called by the name of *phlogiston*, by way of distinction, rather than by any other name; because it is a principle, whose existence in mercury, hath been *long* admitted, and *never* disproved.

We are certain then, that mercury contains an *earth*, united to an active principle called *Phlogiston*; which phlogiston is not *fire*, but a something  
proved

proved to be very *different* from it; and we are equally certain, that pure air is composed of an *acidifying* base, combined with *some* kind of elastic fluid.

What is this elastic fluid, which gives the particles of the *acidifying* principle their aeriform state?—is it *phlogiston*?—no—it cannot; for if mercury were *earth* and *phlogiston*, and pure air *acid* and *phlogiston*, the same inconsistency would arise, as was the case when *fire* was supposed united to each in the place of *phlogiston*: that is, *sometimes* the earth and acid, would have a greater attraction for *each other*, than for *phlogiston*; and at *others*, they would attract *phlogiston* with more force than each other; which being *opposite* effects, arising from the *same* causes, declare the supposition at once to be false.

Let us suppose then, that it is *fire*, a *simple principle*, which gives the particles of *acid* the form of *pure air*. We shall then have mercury, an *earth* united to *phlogiston*; and pure air an *acid*, combined with *fire*.

'Tis evident then, that in the *degree* of *heat*, necessary for calcination, the *acid* of the pure air, must have so *great* an attraction to the *earth* of the mercury, that it will *part* with its *fire*, and displace the phlogiston from the mercurial earth. But during the *reduction* of the mercury, the *acid* hath so *powerful* an attraction to *fire*, that it will *separate* from the *earth*, to unite with it. This is inconsistent. Or *suppose* we say, that the *united* attractions between the earth and acid, and the phlogiston and fire, *exceed* the attractions of the earth to the phlogiston, and the acid to the fire, with which they are now combined; in consequence of which, a *double* decomposition takes place, and *two new* compounds are produced: the earth and acid combine and form a *calx*; and the disengaged *fire* and *phlogiston* unite, and escape in the form of what? —not fire—because, the compound is fire and phlogiston—what then?—say any thing—say *light* for instance.

If this compound of earth and acid, then, be exposed to the action of fire in close vessels, the attractions of the acid to fire, and of the earth to phlogiston,

phlogiston, will now *exceed* the attractions of earth to acid, and fire to phlogiston, *which* were the *most* powerful in the former case; in consequence of which, the acid and fire will again become pure air, and the earth and phlogiston, mercury. But if *fire* be a *simple* substance, whence had the earth its *phlogiston*, so as to become mercury? — to avoid this difficulty, we will say that the degree of heat, or fire necessary to the operation, was accompanied with *light*, which furnished the phlogiston——at present be it so, still the facts *contradict* each other, admitting those principles: therefore *those* principles are *false*, which make *pure air* a *compound* of *acid* and *fire*. For the earth and phlogiston of mercury, being unalterable principles, in every situation possessed of the *same* properties; and the *acidifying* principle of pure air, being possessed of certain properties, by *no means* destructible: it must follow, that if the *acidifying principle* hath a *greater* attraction to earth, than to *fire* at *one* time it must at *all* times; and consequently, since it will at *one* time *quit* its elastic fluid, to unite with the *earth* of the mercury; and at *another*, will quit the earth to reunite with its *elastic fluid*, 'tis evi-

dent, that *that elastic fluid*, is not fire, but *some other principle*: which is *more*, or *less intimately* combined with its *acidifying base*, as it contains *less or more* of the matter of fire in its *interstices*; that when *intimately* united to its base, it will attract *that acidifying base more* forcibly, than the *earthy particles*, united to their phlogiston will; but when the quantity of fire penetrating it, is *so great* as to separate it at a greater distance *from*, or weaken its attraction *to* its base: and the phlogiston of the earth is in the *same state*, by the *same means*: its attraction then becomes *greater* for the *phlogiston* of the earth: and the attraction of its *acid* becomes also *greater* to *that earth*; in consequence of which, this *elastic fluid* of the pure air, will unite with that *phlogiston*, and form *fire* or *light*, or *both*; and the acid and earth, will *combine* and form a *calx*.

'Tis evident therefore, that the *fluid* which gives the particles of the *acidifying principle*, the form of pure air, *cannot* be *fire*; and from the preceding reasons, 'tis equally certain, that it cannot be *phlogiston*; but it *must be*, and *is, something*; and  
that

that *something* ought to have a *name*: and *that name* may be what you please; only preserve the idea of a *subtile elastic fluid*, capable of *uniting* with the *principle of acidity*, and forming an *aeriform fluid*, which is able to support the combustion of *inflammable matter*, and the respiration of animals: and of uniting with *phlogiston*, when separated by heat, from the substances which contain it, and forming *light or fire*. That this fluid, may not want a name to distinguish it by, I have ventured to call it *æther*, 'till some one shall find a *better*; and give *sufficient reasons* for the change.

Having therefore been under an absolute necessity, of admitting and adopting *two different active, or subtile elastic fluids*, and an *acidfying* and an *earthy principle*: let us apply them, to the explanation, of the very operations, which could not be *consistently* accounted for, by *any other theory*, and with *any other principles*, different from these.

Mercury is composed of the *earthy principle*, intimately combined with *phlogiston*; pure air of the

*acidifying principle*, united to *æther*. In this state, in the *common temperature* of the air, they have no sensible action upon each other; which shews, that phlogiston hath a *greater* affinity with the earthy principle, when closely united with it, than with *æther* when combined with the acidifying principle. But if the degree of heat necessary to promote combustion, or calcination, be applied, that *fire* will *penetrate every* part of the mercury, and pure air: by which the active principle in each, will be *expanded*, and consequently less forcibly attracted, and detained by its base, or fixed centre. The *æther* and phlogiston being therefore more at liberty, their attraction to each other, will become *greater*, than their power of attraction to their *respective bases*; therefore they will penetrate and unite into *attractive lines* of particles, drawing their respective bases into *contact*; those solid bases will attract each other, and unite, so as to form a *calx*; and by their union the two active fluids will be *disengaged*, combine, and form *fire* or *light*, in which state they will escape.

If this calx be exposed to a still *greater* degree  
of

heat, in close vessels, preventing every external communication with the air, and the volatilization and dispersion of the calx: the quantity of fire now employed, will insinuate itself so *copiously*, into every part, and between every particle, as to *separate* the particles of *earth* and *acid*; by which separation, or disunion, they can *no longer* attract each other. But though their union is broken, by the interposing fire, their properties of attraction are not altered or diminished: therefore, as they cannot in so violent a degree of heat, *unite with each other*: *each* will attract its *proper active principle*, by *decomposing* a part of *the fire*; the earth will unite with phlogiston, and form mercury; and the acid with the æther, and produce pure air.

The æther of pure air therefore, will *never quit* its acid, to unite with the phlogiston of mercury, but when the *quantity* of fire employed, is *so great* as to separate the phlogiston and æther from their bases, or expand them so much as to render their attractions for their respective *bases*, *less* than their affinity for *each other*; but *not so great* as to keep the *earth* and *acid* from *uniting*, by its interposition.

For

For if the earth and acid cannot unite, on account of the quantity of heat interposed, they will never separate from their active principles; for that decomposition can *never* take place, but when the *united* attractions of the æther to phlogiston, and the earth to the acid, *exceed* the *united* force of the attractions of æther to its acid, and earth to phlogiston; which never can happen, but when the *degree* of *heat*, by rarifying the active principles, *weakens* their union to their respective bases, by *expanding* them: without being so copious, or great, as to *prevent* the union of the earthy and acidifying principles.

I have said, that æther, and phlogiston, escape in the form of *fire*, or *light*; and that by uniting, they form *one*, or the *other*, or *both*, according to circumstances; and every operation where fire and light are concerned, tends to corroborate it, and no one instance offers to disprove it.

*Mercury* hath been proved to contain phlogiston; and *all* inflammable matters, are capable of furnishing *phlogiston* to its calx, so as to revive it; 'tis evident

evident therefore, that *inflammable* or *combustible* substances, contain *phlogiston*. When this phlogiston is weakened in its union to its base, by a sufficient degree of heat, if in contact with pure air, it burns: a great quantity of *fire* and *light* are produced: and at the same time, the air *loses* its bulk, its æther, and the inflammable substance its phlogiston; the acidifying and earthy particles, remaining *entire* in the residuum; or else forming water, by the heat rarified into vapour, and in that state passing away, if in the open air. The fire and light, must therefore be produced, by the union of æther and phlogiston.

Again, the earth of mercury, and the acid forming a calx, when separated by heat, so as to be no longer able to attract, and remain united with each other, *decompose* part of the *fire* itself, as already mentioned; the earth acquiring phlogiston, and the acid æther; therefore, the *fire* supplied both the *phlogiston* and *æther*: and consequently, was composed of them.

The calx of Gold, or Silver, is composed of *earth*, and the *acid* principle. By being exposed to the action of *light*, the earth regains its *phlogiston*, and becomes Gold, or Silver, at the same time that the *acid* acquires *æther*, and becomes pure air; consequently, *light* furnished *phlogiston* to the one, and *æther* to the other, by its decomposition; and must therefore be composed of *those two principles*. And if *pure nitrous acid* be exposed to the *light*, in a phial which it does not fill: a quantity of pure air is produced, and the acid becomes phlogisticated, which again proves, that *light* is composed of *æther* and *phlogiston*, because it gives *æther* to the acid now in the state of pure air, and *phlogiston* to the residuum.

If a number of *rays* of *light* be collected into a *focus*, by means of a concave mirror, or convex lens, in a *transparent* medium, through which they can pass undisturbed: the light passes through it, unaltered; but, if *that focus* of condensed light, be thrown upon an *opaque* body, through which it cannot pass readily, and undisturbed: the confusion and condensation, arising from the resistance  
of

of the opaque body, and their velocity together, alter the *mode* of combination, of the two component principles, of the light, the *æther* and *phlogiston*; in consequence of which, they are mixed together, and form a closer or *different* union, producing *fire*. This *fire* must be produced by the *obstructed particles* of *light*: therefore, *light* and *fire* must be composed of the *same principles*, in a *different mode* of combination.

If an opaque body, be suspended in *vacuo*, in a glass receiver, and *light* be thrown upon it in a *focus*, or condensed state: the quantity of *heat* or *fire* produced, will be *intensely great*, though the *opaque body*, suffers *no change* in its principles, or no *decomposition*; therefore *this fire*, must be produced by the *light*, condensed, confused, and violently agitated, so as to *lose* its *natural* combination, or state of existence; and not in the least, by the opaque body, which produces that change by its *resistance*; and *this fire* must be composed, of *æther* and *phlogiston*, because all fire is so: as hath been proved by its reducing the *calx* of mercury, and producing pure air with the acid; and because it

is produced from condensed and obstructed *light*; which light is known to be composed of æther and phlogiston, because it will give the *latter* to the *earth* of *Gold*: and the *former* to the *acid* separated from that earth, when it is revived, by uniting with phlogiston. And consequently, since *fire* is produced by the intimate combination, of the *æther*, and *phlogiston* of *light*: the heat or *fire* produced during *combustion*, is produced, by the *same* means, the union of the *æther* of the pure air, with the *phlogiston* of the inflammable substance; *both* being *disengaged* by that operation, *must unite*; and that union, will always produce the *same* compound, with the *same* kind, or degree of excitement, and *intimacy* of union; a violent excitement, and intimate union, will always produce *fire*; but if the disengaged æther, and phlogiston, combine *less* intimately or with *less* force, or in a different manner, they will produce *light*; which *light*, may again be changed into *fire*, if it hath *velocity enough* when it meets with resistance, and is thrown into confusion, to produce motion, or excitement sufficient, to take the union, which is necessary to change it into fire.

The

The doctrine of *latent* or *absolute heat*, which accounts for *every* production of sensible heat, by some change, in the capacities, of the bodies giving out this sensible heat, must therefore be *false*.

That *some* solids, and fluids, have a *greater attraction* for heat, and have a *greater capacity* for containing it than others, is undoubtedly true; and that these when they *alter* their form, state, or modes of combination, will either require *more heat*, or *give out* part of that they were before possessed of, accordingly as their *capacities* are altered by this change, is also true; and consequently, that *some sensible heat*, will be produced, when that capacity for containing it is *diminished*. But this is by no means a proof, that *all sensible heat* is produced by that *change of capacity*; and that it is not so, the *condensation of light*, most abundantly proves. For an *opaque body*, in *vacuo*, by means of a *focus of condensed solar light*, may be *intensely heated*, without suffering any *change* in its *capacity*, or any *decomposition* of its *principles*; consequently, the *heat must be produced*, by the particles of *light*; the principles of which they are composed, in consequence  
of

of the resistance of the opaque body, acquiring a different, or more violent, or intimate combination, and thus producing *fire*, or the *matter of heat*.

'Tis evident therefore, that light and fire are composed of the *same principles*: that those principles are *æther* and *phlogiston*: and that *æther* and *phlogiston*, when *separated* from their respective bases by means of heat, always form by their union, light or fire.

But there is *another* active fluid, *very different* from *either* of these, in its properties as a fluid; that is, the *electric fluid*, whose production and properties, come next under consideration.

*Glass*, is a substance, which in no chemical operation whatever, gives any signs of its containing *phlogiston*. *Sulphur* is a matter, which evidently contains a *great quantity* of *phlogiston*: therefore *Glass* and *Sulphur*, are *two* substances, *very different* from each other.

If a tube of *Glass*, be excited by *friction*, it acquires an *electric atmosphere*; and if *two light* bodies be suspended near it, by filaments of silk, they will be *attracted* to it: and acquiring *similar electric atmospheres*, will *recede* from it; 'till the *surfaces* of the atmosphere surrounding the *tube*, and *those* of the *light* bodies, only touch each other; and so long as the electric fluid retains its excitement, around these respective centres; so long will *those atmospheres*, prevent the light bodies from approaching near to the tube or each other.

If a stick, or globe of *sulphur* be excited, by friction, it will acquire, in like manner, an *electric atmosphere*; which will attract *light bodies*, of a similar kind, and suspended in the same manner as the former; in consequence of which, *they* will acquire similar electric atmospheres, and recede from the globe, and from each other, in like manner and upon the same principles as the former.

If the two light bodies, which acquired their electric atmospheres from the *glass* tube, be brought near each other: they will *not unite*, but *repel* or  
*push*

*push each other* to a distance, proportionate to the *extent* of their electric atmospheres; which shews, that *those* electric atmospheres, have *no attraction* for *each other*; but only for the solid substances as centres, round which they take the form of atmospheres.

The two light bodies, possessed of electric atmospheres from the excited *sulphur*, in like manner will *not unite*, or *approach*; those atmospheres having no attraction to each other.

But, if the two light bodies, with their electric atmospheres, from excited *glass*, be brought near the two others, electrified by means of *sulphur*: they will *rush* into *contact*; their atmospheres will *unite*: and *that* union, will *destroy* every appearance of *electricity*; the light bodies, having now *no* properties, *different* from what they had, previous to their being surrounded by atmospheres of the electric fluid.

But, if the *electric fluid* were a *simple* substance, or matter: when excited, *similar atmospheres*, formed

ed around *similar bodies*, as centres, to which they were attracted by excitement, would *always* *repel* each other; as is the case, when the electric fluid is produced by friction, from substances of *similar chemical* properties, and composition. But, the electric fluid produced by means of *glass*, will *not* *repel*, but *forcibly attract* and *combine*, with the electric fluid produced by *sulphur*: therefore 'tis evident, that the *electric fluid*, is not a *simple* substance, but is *composed* of *two principles*, *different* from each other: that *glass* will excite *one* of them, to become active, and take an atmospheric form, and *sulphur* the *other*: that in *that form*, *each* *resists* an atmosphere *similar* to *itself*, and by *pressure*, keeps it at a *distance*: but that *each* will rapidly *unite* with a similar atmosphere, formed by the *other principle*, to which it hath an *attraction*, producing *union*, and a *destruction* of those properties, which they have *contrary* to each other, when excited around their respective centres.

Electricity being therefore of *two distinct* kinds, called improperly positive and negative, or more properly vitreous and resinous, must be composed

of *two equally active fluids*, of *different properties* when excited, by friction; *each* having the property of *arrangement*, in an atmospheric form, around its respective centre, and an *attraction* to the *other*. *Positive* electricity, is always produced by *one* of those active principles, when excited: and *that* particular fluid, is always excited by means of *glass*; and *negative* electricity, by the *other*, which is invariably excited by means of *sulphur*.

The *electric fluid*, is therefore evidently composed of *two active principles*; and *those* two principles, are as evidently, no other than *æther* and *phlogiston*; and consequently, the electric fluid is composed of the *same principles*, as fire and light are,

Fire and light, are produced by the combination of *æther* and *phlogiston*, when *separated* from their *respective bases*, by means of heat or fire; but the *electric fluid* is produced whenever *æther* and *phlogiston* are excited to become *active*, and capable of *separating* from their respective exciting bodies,

dies, to *unite* with *each other*, by *any other means*, than *chemical decomposition* by heat.

That it is composed of the *same principles* as fire or light, is certain, because when passed in sparks or shocks through *nitrous acid* vapour, it affords *æther* to the acid, so as to enable it to take the form of pure air; and it communicates *phlogiston* to the *calces* of metals, so as to *revive* them; and because when it meets with a *slight* resistance, as in passing through air, it changes the *mode* of combination of its principles, and becomes *light*; and when it meets with *still greater* resistance, as in passing through gun-powder or the powder of resin, the resistance of the substance to its rapid motion, causes its principles to unite *still more intimately*, and take the form and properties of *fire*.

But if the *electric fluid*, changes *nitrous acid* into *pure air*, and *revives* metallic *calces*, it *must* afford *æther* to *one*, and *phlogiston* to the *other*; and consequently, must be composed of *those two principles*; therefore, it cannot be *different* from fire or light, but in the *mode* of combination, and *intima-*

cy of union, which takes place between those *two principles*, when in *those different states*, or forming those *different fluids*; which is fully confirmed, by its being *convertible* either into light or fire, by *different* degrees of resistance, producing a *different state of combination*. Indeed, unless we allow *two ætieve principles*, or *fluids*, each capable by excitement, of assuming an *atmospheric electric* form, around the bodies excited, or immersed in that atmosphere, but having an *affinity* to *each other* in that excited state, *greater* than to the bodies they surround: 'tis impossible to conceive, or explain, why *glass* by means of friction, will always produce *positive*, and *sulphur negative electricity*: why atmospheres of positive or negative electricity, will *not* admit the near *approach* of *similar* atmospheres: why an atmosphere of *negative* electricity, will eagerly or violently *rush* into *union*, with another of *positive* electricity: or why, by *that union*, every appearance of electricity, whether positive, or negative, is *destroyed*. Two *ætieve, different fluids* therefore, there must be, and are, *which*, when excited by friction, produce the phenomena of *electrical attraction and repulsion*; and by their *union*, form

form the *Electric shock*. By this violent union, according as circumstances differ, light or fire, may be produced: the calces of metals may be revived: and the acid principle acquire the properties, and form of pure air.

*These two principles* therefore, of the electric fluid, are the *same*, as *those* composing fire or light; and *one* of them uniting with the metallic earth, so as to revive it, must be *phlogiston*; and the *other*, combining with the disengaged acid, and giving it the elastic form of pure air, must be the *active principle* which I have called *æther*.

Fire, light, and the electric fluid, are therefore evidently composed of *two active principles*, distinguishable from each other, by the names of *Phlogiston* and *Æther*, as well as by any other; which principles, by the difference of the intimacy or mode of their combination, produce the *three* fluids, of *different* properties, in their *intire* states. *Each* of these compound fluids in certain circumstances, is capable of *decomposition*, and of *decomposing* certain other compounds: thus metallic calces,

ces, consisting of earth and acid, will decompose them: and they the calces. The earth will combine with the *phlogiston*, and form a metal; and the acid will unite with the *æther* and produce pure air. And *these two active principles*, when by interposing heat or fire their *intimate union*, or *close connexion*, with their respective bases of earth or acid is prevented, and their attractions to those bases weakened, will *again unite* and form *fire or light*, and leave the acid to combine with the Earth.

Thus have I proposed the *Elementary Principles of Nature*, and brought arguments, supported by facts, to prove their existence; such arguments, as bring full conviction to my own mind, and make me ready to defend them, as being the real *primary instruments* in the hands of the Deity, by which alone all the phenomena of nature are produced; and consequently, 'till those arguments and *facts* shall be *disproved*, and the *non-existence* of those elements *demonstrated*, I make no scruple to insist upon and apply them, as *principles*, whose  
existence

*existence is fully proved, and whose sufficiency to account for every appearance in nature, is convincing and satisfactory.*

Having therefore taken a *general view* of nature, the *principles* of which *all things* are composed: the *laws* governing those principles: and the facts *proving* their existence; assuming them as granted, I shall proceed to examine them more particularly, and first of all, the *Earthy Principle*.

---

### SECTION III.

#### *On the Earthy Principle.*

THE existence of an earth, as a fixed principle in nature, hath never been called in question. 'Tis known by its *solidity* or the firmness, and impenetrability, of its ultimate particles: by its *affinity* to *acids*, in different proportions, producing saline matters of different kinds, perfectly neutral when saturated: and by its capability of *uniting* with *phlogiston* in various proportions,

portions, producing *metals*, and *combustible* or *inflammable* substances, of different kinds, according to their relative proportions.

Every substance in nature, capable of *combustion* in *pure air*, must contain the *earthy principle* and *phlogiston*; for by *combustion*, pure air is decomposed. But pure air cannot be decomposed, but by a double affinity: the acidifying principle, will never part from its æther, but when it is attracted by the *earthy principle*: nor the æther from its acidifying principle, but when it is attracted by *phlogiston*; and when those united attractions, overpower the attractions of the æther to its acid, and the earth to its phlogiston, a decomposition must take place; the *earth* and acid will unite, and form the residuum: while the æther and *phlogiston* produce the *fire* and *light* attending combustion, and produced by it.

Every solid substance then, composed of the *earthy principle* and *phlogiston*, is *combustible* or destructible in *pure air*, in such a degree of heat, as is necessary to weaken the affinity, between the

earth and phlogiston, by insinuating itself betwixt them, and expanding the *phlogiston* to a greater distance from its earthy base; by which, its affinity will be lessened, as the expansion increases; till at length its attraction to the æther of the pure air, will *exceed* the attraction of its centre.

The earthy principle, *saturated* with the *acid principle*, forms a neutral compound, having no attraction to acids or earth: shewing no signs of *phlogiston*, when heated in pure air: nor any of *æther* in inflammable air, by decomposing them: an earth *supersaturated* with the *acid principle*, forms the different *acids*. But if *not* saturated with it, the compound will be an alkali or earth, having an avidity to unite with *acids*.

But, earth may enter into a number of compositions very different from these simpler states; for instance, an earth may be partly saturated with acid, and partly with phlogiston, and that in an infinite variety of proportions; in which case, it will partake of the properties both of the inflammable, and neutral saline combinations; or it may be

be combined with some phlogiston, and some acid not wholly divested of æther; and these in a variety of proportions, which at present it is not necessary to consider. However, we may say that *every solid particle* of fixed matter, capable of *uniting* with an *acid* or with *phlogiston*, is a particle of the earthy principle.

Every solid or fluid matter, capable of *combustion* in *pure air*, contains the *earthy principle* combined with *phlogiston*; and every solid or fluid matter, having *no affinity* with either acid or earth, and not destructible or combustible in either *pure* or *inflammable air*, is composed of the *earthy principle*, combined to saturation with the *acidifying principle*, and by these *general properties*, the *earthy principle* may be always known when present.

Having pointed out its distinguishing properties, let us next endeavour to acquire the simplest idea possible, of this earthy principle, consistent with reason, and the properties it must possess as a principle, subject to certain invariable laws.

The simplest idea we can form of matter, is, that of a *solid point* or *particle*, ultimately small, possessed of *no* property but *impenetrability*. A particle of this kind, I would call a *particle of inert matter*; but to render these particles *useful* in nature, 'tis necessary that they be also possessed of the *simple property of universal attraction*.

But a particle of the *earthy principle*, gives a more complex idea, as requiring the *properties of attraction* to the *acidifying principle* and to *phlogiston*, and *repulsion* or *inability to unite with æther*.

In like manner, a particle of the *acidifying principle* differs from a particle of fixed matter, in having an *attraction* to, or power of uniting with the *earthy principle* or with *æther*, but refusing every connexion with *phlogiston*; and the same may be said of *æther* and *phlogiston*, each *will* attract *one* solid principle, but *not the other*, though they will attract each other.

But if a particle of the *earthy principle*, consists of a *simple particle of matter*, attracting *phlogiston* but

but refusing æther, it must be *different* from a particle of the acidifying principle, attracting æther and refusing to unite with phlogiston ; we must then admit of *four kinds* of simple particles of matter ; any one of which, will unite with *two* certain others, but not with the *third* ; thus æther will unite with phlogiston, or with the acidifying principle, but not with the earthy ; and *each* of these simple particles, must have a *power* of *choice*, or *two properties*, one of *attracting*, and the other of *refusing* to unite with certain other particles of matter. But, this is departing from the beautiful simplicity of nature, and multiplying properties without necessity, or gaining any advantage by it, nay even involving ourselves in inextricable perplexities.

The *simplest* idea therefore, which we can form of nature, is, that *every thing* is produced by *simple matter*, and *attraction* : that the bases of all solid bodies are formed of particles of *fixed matter*, divested of every property but *impenetrability*, and *universal attraction* : that these fixed particles, as bases, are actuated by particles of matter possessed  
of

of the property of *universal attraction* to themselves, and to fixed matter indiscriminately: that these active particles, when attracted by fixed particles of matter, *arrange* themselves in *right lines*, so as to form *atmospheres* around them, and that the phenomena produced by these *two distinct active principles*, depend upon their *attraction* to each other, being *greater*, than the *attraction* of *arrangement* existing between *similar particles*, when in states of *equal excitement*, and extending beyond a *certain distance*, from their *exciting centres* of *fixed matter*; for to *that certain extent*, they are *inseparable* from their fixed centres, and can only *draw* those centres into *contact*, without being able to *separate* from them.

That there are *solid* particles of matter, none can deny: that there is an *attractive* power, no one can refuse assent to, and that there is a *polarity* or *mechanical arrangement* in particles of matter, none can deny who hath ever seen, and paid attention, to the regular arrangement of the particles of water, salts and metals, when losing their fluid state, they become solid, and unite with each other at  
certain

certain angles, so as to produce crystals, or *regular* figures.

The *active* particles of matter, therefore, being of *two kinds*, must form *atmospheres* around the *fixed particles* of matter, which they meet with, disengaged; and this *first simple union*, nothing hath power to entirely separate or destroy: *each* active principle, having an *equal* attraction to these *fixed* particles, would *originally* unite itself to its share of them: and *that* union would produce *particles* of *fixed matter*, with *active atmospheres*, different from each other, as being composed of the *two* different *active fluids*.

A particle of the earthy principle therefore, as before concluded, is a particle of *fixed* matter, surrounded by an *ætherial* atmosphere; consequently it will attract *phlogiston*, because *æther* and *phlogiston* have a strong affinity to each other; and for the same reason, will it unite with a particle of the acidifying principle, because it is composed of a particle of matter, with a *phlogistic* atmosphere.

I by no means wish to *insist* upon the particles of *matter* forming the *bases* of the earthy and acidifying principles, being *exactly similar* in every property: nor, that a particle of earth, is a particle of *fixed matter*, surrounded with an atmosphere of *æther*: and a particle of the acidifying principle, a *similar* particle of matter, with a *phlogistic* atmosphere; but every circumstance conspires to make me believe it.

All that I insist upon is, that a particle of the earthy principle, will attract and unite with a particle of the acidifying principle, or with phlogiston, but not with æther; a particle of the acidifying principle with earth, or æther, but not with phlogiston; and æther and phlogiston with each other. But to avoid multiplying causes, properties or principles without necessity, it appears *reasonable* and *necessary* to me, that, the *base* of an earthy and of an acidifying particle, be a particle of the *same kind of fixed matter*: and that their earthy or acidifying properties, as *principles*, depend upon their being *united* to, or *surrounded* by *one* or *other* of the two active principles, by which they become active

tive principles, a fixed particle having a *phlogistic* atmosphere, becomes possessed of the properties attributed to the *earthy principle*, and with an *ætherial* atmosphere, it acquires the properties which distinguish the acidifying principle.

By admitting this explanation, we have in reality, no occasion for *more* principles than *three*; *fixed* particles, and *two* active fluids: each of which active fluids is composed of particles, which being attracted by fixed matter, become excited, to *attract each other* into atmospheric arrangement, around the exciting fixed centres: or the particles of the *other* kind, in a similar state of excitement, into *union*, by which their respective fixed centres, are drawn and held firmly together. The two active principles of nature, therefore, are *æther* and *phlogiston*: each of these when combined with *fixed* particles of matter, becoming active, can never more be intirely separated from those exciting fixed particles, and will therefore form *two* other *more solid principles*, the *earthy* and *acidifying*; *æther* combined with or surrounding fixed particles, forming the *earthy principle*, and *phlogiston* with the

same kind of fixed particles, the *acidifying principle*; and the earthy and acidifying principles must, on account of their actuating atmospheres, have the *same* affinity to *each other*, that æther and phlogiston have.

'Tis evident likewise, that a particle of the acidifying principle having a phlogistic atmosphere, will attract æther also, as well as the æthereal atmosphere of the earthy particles; and that particles of the earthy principle, will attract *phlogiston*, as well as the phlogistic atmosphere of a particle of the acidifying principle; and for the same reason, that is, the attraction of union, existing between the two active fluids, æther and phlogiston.

But similar principles, or particles of fixed matter possessed of similar atmospheres, as hath before been shewn, will *not* unite: because, similar particles, of the same active fluid, when excited by their union with fixed matter, have *no attraction*, but to that fixed matter, except the attraction of *arrangement*, with respect to each other: by which  
they

they unite, so as to take an atmospheric form, around the fixed substances, or particles, as centres; consequently, two similar particles will not unite: each atmosphere tending to its respective centre.

To explain my idea of these *four* principles, and their mode of action still further, and at the same time, prove that they are perfectly consistent with nature, let us *suppose four* cork balls, suspended by silk cords, to represent *four* particles of *fixed* matter, having no powers, or properties, but impenetrability, or solidity: the *two electricities*, will represent the *two* active fluids: *positive* electricity being supposed to be *æther*, and *negative* to be *phlogiston*.

If two of these balls be *positively* electrified, they will represent two particles of the *earthy* principle, having each a fixed or solid centre, surrounded by an *ætherial* atmosphere.

If the other two be *negatively* electrified, like

two particles of the acidifying principle, they will have atmospheres of *phlogiston*.

The two balls positively electrified, will *not* unite, but recede from each other, like two particles, of the earthy principle: and the two negatively electrified balls, will refuse to come in contact with each other, in the same manner, as two particles of the acidifying principle refuse to unite.

If one of the balls *positively* electrified, be brought between the two *negative* balls, they will attract, and unite with each other, in the same manner, as two particles of the *earthy principle* unite, and form a solid, by the interposition of *phlogiston*. And a ball negatively electrified, will forcibly attract another positively electrified, in the same manner, as a particle of the earthy and acidifying principle, will attract and unite with each other. And the light and heat, produced by the union of these two opposite electric atmospheres, when uniting, and separating from their respective centres of matter, is just *the same*, as the light and heat produced, when the phlogiston of  
one

one substance is disengaged from its base, and combines with the æther separated from another substance, of a different and opposite nature.

I have been thus explicit here, that my meaning might be perfectly understood; and have made the preceding comparison, not only by way of elucidation, but also to shew, that the ideas I have formed, with respect to the *acidifying* and *earthy principles*, being possessed of *similar* particles of *fixed matter*, as *bases*, surrounded by *atmospheres* of the *two different active fluids*, are similar to, and perfectly consistent with the operations of nature, and properties of matter, every moment presented to our view.

But according to the general laws laid down and explained in p. 34, and p. 39. prop. 15. it appears that either æther or phlogiston, when surrounding a fixed particle of matter, so as to form a compound or solid principle, to a *certain extent* around that centre, is excited to attract *similar particles* to atmospheric arrangement, *so powerfully*, as *never more* to be separated; but *beyond* that certain extent

extent, the active particles have a *greater* attraction or disposition to unite, with the *opposite kind* of particles, than to extend themselves, by taking more similar particles into arrangement; consequently, the atmosphere of *either principle* being naturally *violently excited*, and always surrounded by the opposite active fluid in some state or other, will constantly attract it in that state; thus, the *earthy principle*, being a fixed particle of matter, surrounded by *æther* to that certain extent, will unite itself either to the *phlogistic* atmosphere of the acidifying principle, and form a neutral compound: or to disengaged *phlogiston*, with which it will envelope itself as a *second* or *external atmosphere*. And in the same manner, the *phlogistic* atmosphere of the acidifying principle, will either satisfy itself with the *ætherial* atmosphere of the *earthy principle*, or will take an *external* atmosphere of *æther*. So that on account of the *violent* degree of excitement, of the atmospheres, surrounding the fixed centres *as principles*, we can never procure those principles, totally disengaged, either from the opposite *fixed* principle, or the *active* principle  
of

of the contrary kind. The earthy principle therefore, when in the state the *most disengaged* from the acidifying principle, which we can procure, will still *not* be the *pure earthy principle*: because its *ætherial* atmosphere will then attract a *phlogistic* one; and upon *that phlogiston*, its *alkalinity* seems to depend. If the quantity, or extent of phlogiston be *small*, its excitement, and activity will be so much the *greater*, rendering the earthy particle *caustic* or *alkaline*; if the phlogiston be *more* abundant, its *alkaline* properties will be *less* powerful, or evident,

Thus *volatile alkali*, when deprived, as much as possible, of acid, and phlogiston, by any other substance having a greater affinity with them, as for instance quick-lime, is rendered powerfully *caustic* and *alkaline*; but if heated, it will decompose the fire, by attracting its *phlogiston*, and become *alkaline air*, (for if it did not *decompose* the fire, it could not become *permanently elastic*) in which state, it is *less* caustic or alkaline than before; and if this alkaline air, hath an opportunity, of acquiring *still more phlogiston*, from the electric

tric fluid, passed through it in shocks, it will still *further expand* itself, and become *inflammable*; in which state, the *quantity* of *phlogiston*, surrounding the *ætherial* atmospheres of the earthy principle, is *so great*, and consequently *so little excited*, as to shew *no* signs of causticity or alkalinity.

The *alkaline* properties therefore, of the *earthy principle*, depend upon the *phlogiston* surrounding its *ætherial atmosphere*; and the degree of alkalinity, must be *inversely* proportionate to the quantity of *phlogiston*: or directly so, to the excitement of that *phlogiston*.

I shall now conclude this Section with the following definition.

A particle of the *earthy principle* is a particle of *fixed* matter, surrounded to a certain extent, by an atmosphere of *æther*; in consequence of which, it hath an *affinity* to the *acidifying principle*, on account of its *phlogistic* atmosphere: and also to *phlogiston*, by which being surrounded, it acquires the properties which constitute an alkali.

## SECTION IV.

*On the Acidifying Principle.*

**H**AVING entered so largely into the nature of the more fixed principles of nature, or those forming the bases, of all solid substances, generally so called, in the preceding Section, where this principle of acidity was also taken into consideration, so far as it was related to the subject, by its affinity with the earthy principle, there treated upon: and having there given my reasons, for

P

suppo-

supposing, that *both* the earthy and acidifying principles, are composed of *similar* particles of fixed matter, surrounded with atmospheres of *different active* fluids; by which union they become *active principles*, resembling the fluids which give them their activity, and different properties, and their attraction to each other, I shall have less to say upon the present subject.

*Acids* are universally known, and their existence consequently generally allowed, as admitting no denial, and wanting no demonstration.

The acidifying principle, is capable of taking different degrees of fluidity or solidity, according to circumstances, and its mode of combination; for, a pure uncombined acidifying particle was never seen, nor ever can be, no more than a particle of the earthy principle, pure and uncombined; yet, an acid in every state, sufficiently manifests the existence, solidity and impenetrability of its particles.

'Tis

'Tis known, in *certain states*, by its taste: also by its affinity to earthy or alkaline substances, and by its attraction to æther.

With the earthy principle, combined to saturation it forms neutral compounds: if the *acid* principle predominates, different acids are formed: if it be insufficient to saturate the earth, the composition is known by the names of calcareous earths, alkalis, &c. and by the property of attraction to acids.

With æther it forms pure air, and the different kinds of acids, which differ in the *quantity* of æther they contain; so, that the *differences* between the various kinds of *acids*, depend upon the proportion of æther they retain: the quantity of *earth* united with them, or *both*; and the neutral salts, formed by the combination of these different acids, with earthy substances of different degrees of purity, will differ from each other also. So that the acidifying principle, may be partly or wholly saturated, either with *earth* or *æther*: or it may be partly saturated with earth, and partly with æther:

or it may be combined with æther, and an earth partly saturated with phlogiston, producing an infinite variety of compound substances, of different properties, according to the different principles, or proportions of those principles, entering into their composition.

Every fluid or solid substance in nature, capable of effecting the *decomposition* of *inflammable* matters, or phlogistic substances, or supporting their combustion, must contain the *acidifying principle* and *æther*. For the earth and phlogiston of inflammable, or phlogistic substances, will never separate, neither will the acidifying principle and æther, unless *each* of *them*, can meet with the *other* principle to which, *in those circumstances*, it can more *intimately* unite, than to *that* with which it *now* is combined; therefore, every substance capable of promoting, or effecting the decomposition of inflammable matters, must contain, and furnish *æther*, to combine with the phlogiston, disengaged from the earth; by the union of that earth with the *acidifying principle*, deposited by the æther; the earth and acid forming a *calx*, or residuum;

duum: and the æther and phlogiston, *fire or light*.

If the earthy principle contains a *superabundance* of phlogiston, and that phlogiston during combustion, be saturated with æther, the *quantity* of acid disengaged from that æther, if the æther and acidifying principle were combined to saturation, as in pure air, will *as much exceed* the point of saturating the earth, as the *phlogiston* did, which is now separated from it; and consequently, the residuum must be an *acid*, or an earth *supersaturated* with *acid*.

But, if the earth be *not* saturated with phlogiston, the quantity of æther required to saturate that phlogiston, will deposit a quantity of acid, *not sufficient* to saturate that earth; therefore, the residuum will still have a power of attracting more acid.

Indeed, an infinite variety must take place, not only in the *residua* or combinations of the two fixed principles, but *also* in the combinations of the *two active principles*, and the admixture of fixed

ed principles they may retain after certain decompositions, according to the different proportions, which they bear to each other, in the substances employed, and producing those decompositions, and new combinations.

*Every solid or fluid matter, therefore, capable of effecting the combustion of inflammable substances, or substances composed of the earthy principle and phlogiston, must be composed of æther and the principle of acidity; and every substance having an affinity with either the earthy principle or æther, is a particle of the acidifying principle.*

But, for the reasons delivered in the last Section, on the earthy principle, and in the former parts of this work, it appears, that this acidifying principle is composed, of a *fixed particle of matter*, surrounded by an *atmosphere of phlogiston*, to a *certain extent*; to which distance from the fixed exciting centre, its particles are *so strongly excited to arrangement*, and so powerfully attracted by that fixed centre, as to be *inseparable*. But *beyond* that extent, the phlogistic particles being less forcibly excited

excited to attract their centre, acquire a *stronger* disposition to unite with *æther*, than to take a *greater* extent of *phlogistic* particles into arrangement; consequently, the acidifying particles, will forcibly attract the *earthy particles* on account of their *ætherial atmospheres*; or if those are absent, they will attract the *æther*, every where present, which will form an *external atmosphere*, around the *essential phlogistic* one. Upon this external atmosphere of *æther*, the *acidity* of the particles depend: the *more extensive* the *ætherial atmosphere*, the *less* the degree of excitement, and manifest acidity; but when the quantity of *æther* is small, its excitement must be great, and its activity and acidity powerful.

Thus, particles of the acidifying principle, with *large* external *ætherial atmospheres*, form *pure air*, where no signs of acidity are perceived: but if part of that *æther* be taken away, by combustion, or any other means, the *acidity* will become evident, and the particles no longer capable of preserving their aeriform state, will be condensed into that of a *liquid acid*. We may therefore give the following definition:

A *particle* of the *acidifying principle*, is a *fixed* particle of matter, surrounded by an atmosphere of *phlogiston*, to that extent, where it ceases to be inseparable, and acquires a *strong attraction* to *æther*; consequently, it will have an *affinity* with the *earthy principle*, on account of its *ætherial* atmosphere; and also an attraction to *disengaged æther*, which being excited to surround it, acquires all those properties which constitute an *acid*.

Having now pointed out the *distinguishing*, or *characteristic* properties of the *earthy* and *acidifying*, or the *two fixed principles*, forming the *bases* of all *solid bodies*; and endeavoured to shew their *natures* and *affinities*, and to trace them to the *simplest* state, of which we can form any idea of them, consistent with reason: I shall next proceed, to consider the *two active principles*, *Phlogiston* and *Æther*, in order.

## SECTION V.

*On Phlogiston.*

IN the former parts of this work, I have endeavoured to shew, not only the absolute necessity there is, to admit of *two active principles* in nature, but also, that they do in reality exist.

These two active principles or fluids, with solid or fixed particles of matter, form *two* secondary, or compound, but *more fixed principles*; those com-

Q

pound

pound fixed principles in *certain* states, are universally called *Earth* and *Acid*, and the two active fluids I call *Phlogiston* and *Æther*.

These *two active fluids* must be material, because they exist, and are capable of uniting with fixed matter, and giving it new properties; and of uniting with each other and producing effects evident to the senses; nay even when excited *alone*, they are capable of manifesting their *existence*, and *materiality*.

But when they form magnetic, electric, or aëri-form atmospheres around *solid matter*, though evidently material, they have not that solidity, and visibility which solid substances have: consequently, their particles must have large, and numerous *interstices* between them, which must arise from the *peculiar arrangement* which takes place, amongst those particles, when excited; and the power of resistance, and force of attraction must diminish, in proportion to the distance from the solid centre, as it is natural to suppose, from the arrangement the active particles take in right lines  
like

like radii, in every direction, round their centres: the distance between those lines being inversely proportionate to their excitement, and, *that* to their distance from the centre.

This arrangement of active particles, at once explains the nature of elastic or aeriform fluids, with solid bases; and also the power of excited atmospheres, either to resist or attract, being greater as the lines approach each other and the centre; and unless we admit this mode of explanation, 'tis impossible to account for a number of phænomena, which we cannot deny.

The calx of antimony, consists of particles which will not even unite into a solid form; but supply the requisite quantity of phlogiston, and they will become a solid, where the methodical arrangement of its particles, at certain angles, with respect to each other when consolidating, producing a figured form, is too evident to be denied. Here then, as well as in many other instances, we have a peculiar polarity, or arrangement taking place, between the particles of matter; and that proper-

ty of methodical arrangement, evidently depends upon the *phlogiston*; consequently, I have authority from nature to suppose, that particles of *phlogiston*, have a certain *polarity* or *arrangement* amongst themselves, when excited by *fixed matter*; and the crystallization of acids, proves that particles of *æther* have so too.

Allowing therefore that active particles of matter, by excitement, take an atmospheric form: that their activity depends upon their property of universal attraction to each other, and to fixed matter; and finding that *some* atmospheres will *resist* each other, while *others* will *attract* and *unite*, as before more largely considered, we must conclude, nay we are certain, that these *active* atmospheres are of *two* kinds: similar in attraction to each other, and to fixed matter, but differing when excited, in this, that *similar* atmospheres, or atmospheres of the same kind of active fluid, will *not* come nearer than simple contact; but, atmospheres of the two *different* kinds, will *penetrate* each other, and *unite*.

Phlogiston therefore is a subtile, elastic fluid, composed of particles of matter, actuated by the property of attraction; when these particles are excited, they have an attraction for each other, producing an arrangement in right lines: in consequence of which, they assume an *atmospheric form*, around the solid substance, or particle as a centre.

These phlogistic particles, are powerfully attracted by *fixed* particles of matter; by which attraction of union, they become excited to arrangement, and form atmospheres around those fixed particles never more to be separated intirely. These *fixed* particles with *phlogistic* atmospheres, being *unalterable*, form the fixed or solid principle of nature called the *acidifying principle*.

The particles of phlogiston, have an attraction to the particles of *æther*, when disengaged, or in a similar state of excitement: by which, they can unite; and if at the same time they become disengaged from their solid bases, they form *fire*, or *light*, according to the degree of intimacy with which they combine. Phlogiston hath also an attraction

to particles of the earthy principle, because they are composed of particles of fixed matter, with ætherial atmospheres.

Particles of phlogiston, furrounding a solid centre of fixed matter, will to a certain distance attract that centre, more powerfully than æther; but beyond that distance, they will have a more powerful attraction to the particles of æther, in a disengaged state, than to their fixed bases; in consequence of which, the æther will be excited to take an atmospheric arrangement around them.

Particles of phlogiston, when excited to arrange themselves round solid substances, with which they *cannot* enter, into *close* or *chemical* union, will *leave* those substances, and *lose* their atmospheric arrangement, to combine with *æther* in similar circumstances.

Disengaged particles of phlogiston, when they meet with ætherial excited atmospheres, which cannot quit their bases, become excited by the external

external particles of æther, and form a *phlogistic* atmosphere, around the *ætherial* one.

Every substance therefore, capable of yielding *light* or *fire*: or every *combustible* or *inflammable* matter, capable of being *decomposed* in *pure air*, must contain *phlogiston*, united to the *earthy principle*; and consequently,

Phlogiston united to the earthy principle, produces according to the different proportions, in which they enter into composition, *all* the substances, which are *inflammable* or *combustible* in pure air, or with substances containing the *acidifying principle* and *æther*.

Phlogiston with *æther*, forms *fire* or *light*, according to the mode, or force of combination.

Phlogiston with the acidifying principle, will *not* unite; because an acidifying particle, is already surrounded by an *atmosphere* of *phlogiston*.

Phlogiston

Phlogiston may therefore be known, by its uniting with particles of the *earthy principle*, and giving them solidity, or cohesion, or when *more* abundant, by giving them the elastic form of air: and by its power of *decomposing pure air*, or compounds of the acidifying principle and æther, by uniting with the *æther*, and passing off in the form of fire or light, and leaving its earth, to unite with the acid left by the æther.

But besides these simpler states, phlogiston may exist in a great variety of compositions; it may be *partly* united to the earthy principle, and partly with æther; or to an earth, or to æther part-saturated with the acidifying particles; or to an earth, and at the same time, partly to æther not wholly divested of its acidifying particles.

We may therefore conclude this Section, with the following definition.

Phlogiston is a principle, composed of particles of matter, possessed of the *active* property of  
attraction;

*attraction*; when excited by their affinity to *fixed* matter, they have an attraction of *arrangement* amongst themselves, forming lines of particles, around their exciting centres, of fixed matter, in an atmospheric form; with *æther* it will *unite*: and likewise, with the *earthy principle*; but *not* with a particle of the *acidifying* principle, because, it is a particle of fixed matter, already united to a surrounding atmosphere of phlogiston.

## SECTION VI.

*On Æther.*

ÆTHER is that active matter, which when united to particles of the acidifying principle, in a full proportion, gives that inestimable fluid, *pure air*. Pure air, we know, contains a small quantity of *acid* particles, as its base, which in that *aeriform* state, must be very distant from each other, and possess a wonderful elasticity; were the surrounding pressure removed, they would

would expand into a bulk still much more extended, where the particles of acid, would be still further removed from each other, as I have before insisted. A particle of matter cannot act where it is not, consequently, the expansive power, by which these particles of acid are kept asunder, at a distance, inversely proportionate to the pressure, or resistance, they meet with, must be a *something, different* from the acidifying fixed particles themselves, forming an atmosphere around each of them: which atmosphere, is capable of condensation, or extension, and therefore must be elastic; and as the particles of which these atmospheres are formed, must be solid matter, and consequently impenetrable, 'tis certain, that these particles, do not *touch* each other, in *all directions*, as they then would form a solid, opaque mass: but they do not, because they are penetrable to light, fire, and solid matter of every kind, when in motion, to which they give little resistance. But though they touch not each other, in *all* points, or directions, they must in *some*, because they attract and unite with each other, and therefore must be in contact: consequently, they must form *lines* of active par-

ticles, around the *acidifying particles*, as *centres*, diverging as they recede from those centres.

Whatever this *active something* may be, which can give to particles of the acidifying principle, an aeriform state, I call it *æther*. That it is not phlogiston, many operations of nature, and chemistry, prove; though phlogiston is a principle, *equally active*, and possessed of the *same* property of atmospheric arrangement, when excited by fixed matter: yet they differ in their affinities.

Whatever therefore, is capable of giving the acidifying principle an *elastic* form, by uniting with it, so as to be able to support, and effect the *decomposition* and combustion of inflammable substances, must contain *æther*; which, uniting with the *phlogiston* of the inflammable or combustible body, will form *fire* or *light*, and deposit its acidifying particles, to combine with the earth, disengaged from its phlogiston.

*Æther*, with a *superabundance* of acidifying particles, will not be able to support *that* quantity,  
in

in an *aeriform* state, in a moderate temperature of heat; the compound will therefore, be a *liquid*, and that liquid evidently *acid*. Acids will differ from each other, in proportion to the quantity of æther they contain, in any certain quantity of acid; and they may have other different properties, arising from the admixture of pure earth, in different proportions; or even of earth, partly combined with phlogiston.

Neither æther, nor phlogiston *alone*, can produce heat; but we know that they will attract each other: and that when they separate from their respective bases, and are lost as such, their escape is always in the form of *fire* or *light*.

Light we know, may be changed into fire, by condensation, and violent commotion; as is evident, from the fire, or heat produced by the rays of light, condensed in a focus upon any opaque body, in the open air, or in vacuo; which proves, that *æther* and *phlogiston*, are capable of uniting, with *different* degrees of force, or intimacy: perhaps, the most violent, or intimate union, producing

ducing fire; and the revival of metals, and production of pure air at the same time, by means of fire or light alone, fully proves, that *either* of them must impart *phlogiston* to the earthy, and *æther* to the acidifying particles, to give them their metallic, or aeriform states; and consequently, that both fire and light, are composed of *æther* and *phlogiston*.

Æther therefore, will unite with *phlogiston* or the acidifying principle: but it hath no affinity with the earthy principle. But, if the particles of *æther*, are actuated by the property of *universal* attraction to matter: and a particle of earth be a *simple* particle of matter: *æther* ought to attract *that particle* of the earthy principle; but it will not: consequently, either the particles of *æther*, have a power of *chusing* with what they will unite, and what they will not, or otherwise, a particle of the *earthy* principle, is *not* a *simple* particle of *matter*. But, to allow the former, will be granting to matter, different and inconsistent properties, without any necessity for departing from the more simple, and single property, *universal*  
*attraction*:

*attraction*: therefore, I conclude, that a particle of the *earthy principle*, is *not* a *simple* particle of matter; and indeed after shewing that *fixed* particles of matter do exist, and likewise two *active* fluids, equally powerful in their attractions to those fixed particles, 'tis impossible to deny that those *active* principles, when once united to those *fixed* particles, can never more be separated entirely; and consequently, that the particles of *fixed* matter, surrounded by, and united to *æther*, will by that means acquire active properties, different from those actuated by *phlogiston*; in the same manner, as *æther* and *phlogiston* differ from each other.

But, as *æther* is known to have an affinity to *phlogiston*, and an attraction for the *acidifying* principle, 'tis evident, that a particle of that kind being a particle of fixed matter, must have a *phlogistic* atmosphere; and a particle of the *earthy principle*, only differing from an acidifying particle, in its actuating atmosphere, must have an atmosphere of *æther*; with which, particles of *æther* have no affinity, but that of *arrangement*.

*Æther* therefore, is an *active principle*, composed of particles of matter, endowed with the property of *attraction*, to every other kind of matter, existing in nature; and in consequence of *that* attraction, becoming *excited*, they attract each other, and *arrange* themselves in *right lines*, so as to assume the forms of *atmospheres*, around the *solid centres*, by which they are attracted. A particle of *fixed matter*, thus surrounded by *æther*, forms an *inseparable compound*, which is called the *earthly principle*.

The particles of *æther*, when excited by a body whose particles already possess *atmospheres* of *phlogiston* of a certain extent, with which they cannot enter into *intimate* or *chemical* union, will form themselves into an atmosphere, around the *phlogistic* one: which external atmosphere will separate from that body, entirely, to combine with an atmosphere of excited phlogiston, in a *similar* state.

An atmosphere of *æther*, *considerably* excited around a body, with which it *cannot* intimately combine, will attract the surrounding *phlogiston* disengaged,

disengaged, or *lightly* connected with other bodies: to which however, in *this* state of excitement, it hath *less* attraction, than to the *exciting body*; consequently, it will *not* quit its *atmospheric arrangement*, but attracting the *phlogiston* to the *surface* of its atmosphere, *those* particles of *phlogiston*, will become *gently excited*, and form an *atmosphere* of *phlogiston*, around the *ætherial* one; in like manner, an excited atmosphere of *phlogiston*, may be surrounded by an atmosphere of *æther*.

The definition, of the *ætherial principle*, with which I shall conclude the Section is *this*.

*Æther* is a *principle*, composed of particles of *matter*, actuated by the property of attraction, or the power of uniting, with *every other* kind of matter: by which union, they become *excited* to *attract each other*, and *arrange* themselves in *right lines*, forming *radii* around the solid centres, extending in every direction, like an *atmosphere*. It hath an attraction to *phlogiston*, and to the *acidifying principle*: with *both* of which it will *unite*, in any proportion; but, it hath *no* affinity with the *earthy*

S principle,

*principle*, because, its properties as a principle, depend, upon its being *already united*, to a surrounding *atmosphere* of *æther*; to which, it therefore, can have no affinity of union.

Having now taken a view, of the *simple principles* of nature: their *properties*, and the *laws* by which they are governed: and given such definitions of them, as cannot fail, to enable us, with certainty, to distinguish them, from each other; I shall next proceed, to consider, the *different states* of compound bodies, with respect to *solidity* and *fluidity*.

---

## SECTION VII.

*On the Attraction of Cohesion, and the Causes on which the different degrees of Solidity, or Fluidity of Bodies, in the common temperature of heat, depend.*

**S**IMPLE particles of homogeneous matter, having no attraction of union for each other, can never *per se*, become solid; therefore, the attraction of cohesion, must depend upon some other principle,

*principle, being interposed, having an attraction to those simple particles.*

The base of every solid substance, is either of the earthy or acidifying principle; consequently, *particles of either* of them may be rendered *solid*, by means of a certain proportion, of *either* of the *two other principles*, to which they have an affinity.

Thus, particles of the *earthy principle*, may be united together, by means of *phlogiston*, or the *acidifying principle*; and particles of the *acidifying principle*, by the interposition of *æther* or *earth*.

Particles of the earthy principle with *phlogiston*, not sufficient to surround them, with *complete atmospheres*, mutually attract *those interposed* particles of *phlogiston*, by which they become *united, firmly* to each other. Thus, Metals are composed of particles of the earthy principle, united by a *small* proportion of *phlogiston*; hence their great solidity, and specific gravity.

Particles of the earthy principle, with a *greater*  
quantity

quantity of phlogiston, cannot attract with so much force as the former: therefore they will form compounds, *less solid* or *ponderous*, and *more inflammable*; such are the *solid* inflammable substances in general, as Bitumens, Refins, Wax, &c. But, if the proportion of phlogiston be *still greater*, the particles will have a freedom of motion amongst themselves, and form inflammable *liquids*; as for instance, Alcohol, and Oils of different kinds.

But, with a quantity of phlogiston, sufficient to give the earthy particles *complete* atmospheres, they will become *elastic*, or *aeriform fluids*; as for example, Inflammable Air.

When particles of the earthy principle are united by means of *phlogiston*, the *smaller* the proportion of phlogiston, if sufficient to interpose between each earthy particle, the *firmer* and *more solid*, the union; because, if the phlogiston were sufficient, to form a complete atmosphere, around each particle, those elastic atmospheres would no more unite, and form a solid, than the particles of earth themselves.

But

But yet, though *similar* atmospheres have no power of penetrating or uniting firmly with each other, they have an attraction of arrangement, which may give their external particles, a *slight* degree of attraction: for, the external particles of each atmosphere, being excited, have an *attraction* of *arrangement* for each other, which attraction still subsists between them, though neither of them can quit their present state of arrangement, around their respective centres: and the smaller the atmosphere, the stronger its excitement, and the greater its attraction of arrangement, to the external particles of a similar atmosphere.

Particles of the earthy principle therefore, with a *small* quantity of phlogiston, form *solid* substances: with a *greater* quantity, *liquids*; and with *large* phlogistic atmospheres, they take the form of *elastic fluids*, or *gases*; all of which, are inflammable, or combustible in pure air.

But, particles of the earthy principle, are *differently* circumstanced, when combined with the acid principle: the *most solid* compound being produced,

ced, when the particles of earth, and acid, are equal, and *alternately* interpolated between each other, forming a *neutral, fixed, solid* mass; such a simple combination is *glass*. For instance, a metal, its *earthy base* by calcination in *pure air*, loses its *phlogiston*, and *acquires* an *acid*: which acid and earth, being *intimately* applied to each other, by a degree of heat, sufficient to *fuse* them, form a *Glass*.

If the particles of the earthy principle have *not acid enough* to saturate, and firmly unite them, they form compounds *less solid* and *compact*: having still an attraction to *acid particles*; such are *calcareous earths*. But if the quantity of acid be very small, the earthy particles will attract phlogiston also, and become alkalis.

Earthy particles with a *superabundance* of *acid*, form compounds, likewise *less solid*: such are known by their affinity to earth; as the various *chemical* and native *acids*, or *acid* compounds, solid and fluid.

But, on account of the attraction, which the  
particles

particles of the earthy principle have to phlogiston, and to the acidifying principle, and they to æther, we perhaps have *few* compounds of the earthy principle, and phlogiston, without an *admixture* of æther, or *acidifying particles* and æther; nor of the earthy and acidifying principles, without *some phlogiston*, or æther, or *both*; which variety of principles and proportions, produces that wonderful diversity of substances, of different forms, states, and properties, which every where present themselves to our contemplation.

The particles of the *Acidifying Principle*, being particles of *fixed* matter, with *phlogistic* atmospheres, can have *no* attraction, or power of uniting *firmly*, with each other; but, if a certain quantity of æther be added, *not* sufficient to *surround* the acid particles, they will mutually attract it, and by *that* attraction, be *united*, and form solid compounds; such for instance, I suppose *vitriifiable* substances to be.

With a *greater* quantity of æther, the acidifying particles take a less solid, or *liquid* form, producing

cing the different kinds of *acids*; which however, in general, are not without *some admixture* of *earth*, and frequently of *phlogiston* also. If the quantity of *æther*, be still greater, the particles of the acidifying principle, will be surrounded by it, in an *atmospheric* form, taking the state and properties of *pure air*.

The fixation of the acidifying particles by means of particles of earth, hath already been mentioned; and likewise the infinite variety of compound substances which must result, from the endless diversity of proportions, in which *two*, or *more* of the principles, may be employed.

It appears therefore, that particles of the earthy or the acidifying principles, or both, form the bases of every *solid*, *fluid*, or *aeriform* substance in nature: that the *less* the quantity of *phlogiston*, or *æther*, combined with either the earthy or acidifying principles, singly, the *more solid* they are: that particles of the earthy principle chiefly consolidated, or combined by means of *phlogiston*, form the different kinds of *combustible* or *inflammable* bodies:

T

that

that particles of earth united by means of the *acidifying* principle, *not* sufficient to saturate them, form *alkalis*, *calcareous earths*, and *all those earthy substances*, capable of uniting with acids; which however in general, contain *more* or *less phlogiston*, to which the earth hath a great affinity, and oftentimes by means of that acid and phlogiston, *more* or *less æther* is united into the mass, which entering in different proportions, give the properties, wherein *earths differ* from *each other*: that particles of earth, consolidated by means of the *acidifying* principle, combined to saturation, produce the different kinds of *neutral salts*, differing in their properties, from the *same causes*, as the different earths and acids do, that is, the proportions of phlogiston, or æther, which were united, to the earth or acid, which by their combination, are not wholly separated: that particles of the acidifying principle, united by means of a *small* proportion of æther, produce all kinds of *vitriifiable* substances, *indistructible* in *pure air*, but capable of *neutralizing earths* or *alkalis*; which will unite to their acidifying bases, and form *neutral* compounds or *glasses*: and indeed, the *acidifying principle* and *æther*, form eve-  
ry

rything, which is *unalterable* by means of *fire*, in *pure air*: and even *pure air itself*, when the æther is sufficient to give *complete atmospheres*, to those particles of the acidifying principle. But when the acidifying particles are not *volatilized* by atmospheres of æther, but yet have such a proportion of it, as is *more than sufficient*, to attract them to *close and solid union*, by simple interposition, the particles being only attracted to each other by the attraction of *arrangement*, which *each* atmosphere exerts, upon the *contiguous* atmospheres, will form the different kinds of *acids*, which are capable of different degrees of solidity, and fluidity; and at the same time, are seldom *free*, from a considerable proportion of *earth*, and very frequently, have some share of *phlogiston*; upon which principles and proportions, their different properties depend.

Perhaps, *another* cause of the different degrees of solidity, and specific gravity, may be the *quantity* of *essential atmosphere*, furrounding a particle of *fixed* matter, giving it the properties of an earthy, or an acidifying particle; for instance, a

particle of the earthy principle, by change of circumstances, being *deprived* as much as possible of its original quantity of *æther*; *that* æther, will be *strongly excited*, by its nearness, and attraction to its fixed base; consequently, its attraction to phlogiston, will be *greater*, than it would be, were its ætherial atmosphere *larger*, or more extended; and the attraction of union between similar particles, will be *more solid*, and the mass *more ponderous*, by their force of attraction to the *interposed phlogiston*.

Particles of the earthy principle then, form a *solid substance*, by their attraction to a quantity of *phlogiston* present; *which* phlogiston is prevented from *arranging* itself around any *one particle*, by the *equal* attraction, of *two or more* particles, to which it hath an *equal affinity*, and which are therefore firmly united, by that attraction to the *phlogiston* interposed between them.

If the quantity of phlogiston be *greater*, the force of cohesion will be *less*; but on account of the equal attraction of every particle of the earthy principle,

to the phlogiston, and the *strong* attraction of *arrangement*, existing between those phlogistic particles, by reason of their *nearness* to the exciting particles of earth, their arrangement will be imperfect around the earthy bases: and that force of attracting each other to arrangement, *sufficiently great*, to produce that *slighter combination* or *union*, between *neighbouring particles*, which is called *fluidity*, on account of the *facility* with which the particles may be *moved*, from their situations, with *respect* to each other.

If the quantity of phlogiston, as before mentioned, be *so great* as to form *complete atmospheres*, around each earthy particle, they become *elastic*, and take the form of *air*.

What hath been said of the earthy principle and phlogiston, in a similar manner, takes place between the acidifying principle and æther.

The acidifying and earthy principles, are capable by interposition and mutual attraction, of fixing each other.

But

But it appears, that a particle of the acidifying principle, when possessed of a sufficient quantity of æther, to form a complete atmosphere, as in *pure air*, loses every appearance of acidity; but when deprived of a certain quantity of that æther, so as to lose its elastic form, and become a liquid, it regains those properties, which we call *acid*; but even in this state, it evidently retains *some æther*; therefore, it appears, that the *quality* which we call acidity, depends upon the *degree of excitement*, or *state* of the æther surrounding a particle of the acidifying principle, as before mentioned. When the æther is *so abundant*, as to extend to a *great distance* around the acidifying centre, its excitement is *so small*, as to have *no sensible action*. If a *part* of that atmosphere be taken away, the *external particles* then exposed to action, being *nearer* the centre, and *more excited*, shew their activity, by producing the *sensation of acidity*, and by readily uniting with alkaline *earths*, or *phlogiston*; which are the *chemical characteristics* of acidity.

In like manner, a particle of the earthy principle, manifests the property of *alkalinity*, when the  
atmosphere

atmosphere of *phlogiston* surrounding it, is *not extensive*, and consequently is *much excited*; in which state, it will *strongly* attract *acids* and *æther*.

The acidifying principle, on account of its powerful attraction to the earthy principle, and to æther, can never be procured *intirely free* from *one* or *both*: neither can the earthy principle, be found free from acidifying particles or phlogiston: by the *different* proportions of which, the *different* states or degrees of *solidity*, and *fluidity* of *all bodies* are produced.

Particles of the earthy principle therefore, are fixed particles of matter, actuated by a quantity of æther; if those particles are not combined with particles of the acidifying principle, their ætherial atmospheres will attract surrounding phlogiston in different proportions, producing atmospheres of different extent, and consequently, of different degrees of excitement; and the properties produced by that degree of excitement, being those we distinguish by the name of *alkaline*, must be greater,

er, as the quantity of surrounding phlogiston, and its distance from the earthy centre diminishes.

And a particle of the acidifying principle, being a fixed particle of matter, actuated by phlogiston, will always be more or less completely combined either with the earthy principle or with æther.

If it be surrounded by a *large* atmosphere of æther, the external particles being but little excited, will be scarcely active; but as the quantity of æther is diminished, the particles nearer the centre, being more excited, proportionately manifest their activity; which, from its *effects* is called *acidity*. The degree of acidity or activity, of a particle of the acid principle, will therefore, be inversely proportionate, to the quantity of æther surrounding it.

A particle of *earth* in proper circumstances, or in a certain degree of heat, will *part* with its *phlogiston*,

giston, and all its *alkaline* properties, to combine with a particle of acid: which at the same time, will disengage its *external ætherial atmosphere*, and lose its *acid* properties, to unite with the earthy principle, and form a solid compound, neither acid nor alkaline.

When particles of the earthy or acidifying principle are firmly united, by the interposition of a *small quantity* of phlogiston, or æther, they shew no appearance of *alkalinity* in one case, or *acidity* in the other; because, the active principle interposed, being *equally* attracted by *each* surrounding particle of earth, or acid, is *prevented* from assuming *that atmospheric excited state*, whose *properties* are distinguished by the name of *alkalinity* in *earthy* matters, or *acidity* in the *other* principle.

The attraction of cohesion, or degree of solidity of all bodies, therefore, depends *either* upon the *proportion* of one or other, or both of the *active principles*, phlogiston and æther, when combined with

the two solid principles, the earthy and acidifying; or upon the union of the *two active*, or *two fixed* principles, *alone*. The *two fixed* principles together, or with a *small* proportion of the active principles, produce the *most solid* and *ponderous* substances: with a *greater* proportion they form *liquids*: and with a *still greater*, *aeriform fluids*; while the *two active principles*, by uniting, produce those extremely subtile and elastic fluids, *Light* and *Fire*.

But, independant of the principles, of which bodies are composed, their state of solidity, or power of cohesion, by which one particle attracts another, is liable to very great alterations, from causes, foreign to themselves. Thus, solid substances, may be reduced to small parts, by *mechanical* means: *acids*, *alkalis*, and many *saline* matters, may be *dissolved* by means of *water*; and almost every substance in nature, undergoes some change in its solidity, state of aggregation, or existence, when exposed to the action of *fire*. But, as *these last*, are only accidental changes, chiefly produced by the mechanical action of water, or fire, and which disappear, and leave those substances

stances in their natural state, when the water or fire is again withdrawn: I shall at present pass over them, without further notice, and proceed to the next Section; in which, I shall endeavour to explain, the *power* or *property* of *Gravitation*, or the *universal attraction* of matter, upon the principles here delivered.

---

### SECTION VIII.

*On Gravity, or the Power by which distant Bodies attract each other.*

**T**IS very evident, that distant bodies have a power, by which they attract, or have a tendency to approach each other: that the sun, the earth, and every planet in our solar system, have a mutual tendency to, or attraction for each other; for were not the attraction for instance, betwixt the sun and the earth, sufficient to counter-act

act the natural tendency of the earth, actuated by its given motion, to move in a right line, it would not be drawn from that line, so as to move in the nearly circular orbit, in which we know it does.

This attraction is called the attraction of *gravitation*, or the power, which if not counteracted, by the direct tendency of motion, would bring the earth into contact with the sun, in the same manner, and from the same cause, as a stone raised on high, when left to itself, will fall, or be attracted to the earth.

To point out the laws, relative forces, and mathematical proofs of gravity, and its influence upon moving bodies, is not consistent with my plan: they are already known; and 'tis sufficient for me, that the existence of an attraction, or gravitating power, producing a mutual tendency in all bodies to come into contact, is universally admitted: the attraction of the earth to the sun, or the moon to the earth, is an instance in larger masses of matter; and the falling of a stone, or its being attracted

ed

ed to the earth, when removed from it, shews that the same property exists in smaller bodies.

But, as no body can act where it is not, 'tis evident, that *two distant* bodies can have no action upon, or attraction to each other, but by means of *something* interposed; *that* something we know is not air, fire, light, or any thing grosser than these: it must therefore be something else, more subtile and rare, even than they are.

Whatever this something may be, 'tis evident, that it hath an universal attraction to matter: that it is extended from the sun to the earth, to Herschels planet, and most probably far as creation itself: that its power is excited by matter, and consequently, that the quantity or degree of that power or the force of attraction, is in a compound ratio, to the quantity of matter, and nearness to the exciting body: and that it penetrates all bodies.

If two bodies have each of them radii of these attracting particles, extending from one to the other; each body must move towards the other,  
because

because each succeeding particle of these excited intermediate lines of attracting particles, being *nearer* to the distant body, must be *more excited*, and attract with *greater force*, than the preceding more distant particle: consequently, each body will be drawn towards the other; and the force and velocity will increase, as their distance decreases, till at length they rush into mutual contact; and as every solid particle of matter, is capable of giving an equal degree of excitement, to this active medium, 'tis evident, that a body composed of 100 solid particles, will attract with 10 times the force, of a body containing but 10; therefore, the lighter or smaller body, will move with 10 times the velocity, and consequently, through 10 times as much space, when attracting each other to union, as the heavier body will; as being only attracted, with one tenth of the force, with which it attracts the smaller body.

This attracting or gravitating power, must therefore be a subtile active fluid, whose particles attracting matter, are excited to attract each other, and form lines, or radii, surrounding the body in every

every direction.—What is it?—is it æther?—or is it phlogiston, both of which in a similar manner, attract matter and become actuated, so that their particles attract each other?—no—it cannot; because the globe of the earth, equally attracts all bodies, whether they have atmospheres of æther or phlogiston: it therefore cannot be æther, because this gravitating power acts upon a particle surrounded with an ætherial atmosphere; neither can it be phlogiston, because a particle of matter is equally attracted by it, to the earth, although enveloped by an atmosphere of phlogiston. But if it is neither æther, nor phlogiston, what then is it? — It is an effect arising from *both*, which when excited, *attract each other*; and by that means, the *solid bodies*, to which they are connected, and by which they are excited; and is effected by the same general laws, by which a particle of the earthy principle, with its ætherial atmosphere, attracts a particle of the acidifying principle, with its phlogistic atmosphere; two atmospheres of the two different fluids, in a similar state of excitement, attracting each other, from one centre to the other, and forming contiguous lines of particles,

cles, whose *only property* is, that of *attraction*, by which, they *draw* their respective centres together.

If then an atmosphere of æther, uniting with another of phlogiston, have the property of *drawing* the two solid centres which they separately surround, forcibly into *contact*, in a *direct line*: in that state of combination, they must be arranged in lines, extended from one solid centre to the other: and be possessed of the very properties, which produce the phenomena of attraction, or gravitation. But the *effects* being the *same*, the *causes* must be so too; consequently, the *active power*, which *attracts all bodies*, and *draws* them to *each other*, is no other, than the attraction of *combination* of the two active principles, *æther* and *phlogiston*; which being *excited*, by attraction to solid bodies, so as to form right lines, extending in every direction, to all distances, those radii of *different kinds*, will *attract*, and *draw each other* into *parallel lines*, immediately extending from one solid centre to the other; *which centres*, by those *attractive lines*, will also be *drawn towards each other*.

It appears therefore, that *æther* and *phlogiston*, are the two subtile, active principles of nature, equally expanded, far as the universe extends, and equally present in every part of Creation. By their *equal* attraction to fixed matter, and power of *in-*finuating themselves into the *interstices*, or *spaces* left between the atmospheric lines surrounding fixed particles, they become *gently excited*: so that every solid body, of whatsoever kind, will communicate a *certain degree* of excitement, to *one* or *other* of these surrounding fluids; *which* by that attraction, becoming active, will attract the particles of the *other* kind, excited by *another body*; in consequence of which, those *two distant bodies* will be *drawn* in a right line, *into contact*.

'Tis well known, that the gravity, or weight of any body, is not always in proportion to its surface, but to the quantity of matter it contains: therefore, the active fluids, are capable of *permeating every solid body*, and of receiving a certain gentle excitement, from *every particle* of either, or both of the *fixed principles*, forming the bases of those solid bodies: consequently, the greater the number  
ber

ber of fixed particles contained in any body, the greater will be the number of excited lines of active particles, extending in every direction, from that body: and the greater must be its force, or power of attraction, when *those* radii, meet with *others* of the opposite kind, extending from some other exciting body.

Since then, the specific gravity of any body, is proportionate to the number of solid particles composing it, it is natural to conclude, that *every* particle, of either of the *solid principles*, is capable of giving this moderate degree of excitement, producing gravitation, either to æther, or to phlogiston: that 'tis highly probable, that the ætherial atmosphere, essential to a particle of the earthy principle, gives this excitement to the disengaged phlogiston surrounding it: and that the phlogistic atmosphere, essential to the acidifying principle, excites æther; consequently, when these slightly excited atmospheres of æther and phlogiston, come into contact, they will attract each other, and draw their respective centres, together; and any smaller body, will be forcibly

drawn to another much larger, composed of both the fixed particles, as for instance, a stone to the earth, because of whichever kind the atmosphere of the smaller body may be, it will meet with an infinite number of lines of particles of the opposite kind, extending from the larger mass of particles, by which it will be most powerfully attracted.

Æther and phlogiston therefore, are universally diffused, and every particle or every mass of fixed matter, gives to one or other, or both of them, some excitement: the consequence of that excitement is, an arrangement in right lines of similar particles; and a line of particles of *one* kind, extending from *any* body, meeting with a similar line of particles of the *other* kind, excited by *another* body, will attract and be attracted by those particles, in a progressive motion from the particles more distant, or less excited, to those more excited, and nearer to the distant body, till at length, the opposite or exciting centres, are drawn together.

A fixed particle of matter, surrounded by an atmosphere of æther, or of phlogiston, so as to become a particle of the earthy, or acidifying principle, may without any interruption excite the phlogiston, or æther every where present, so as to enable them to produce the phenomena of gravity: because, æther or phlogiston, *strongly* excited by the fixed central particle, can have no power of uniting *with*, or disturbing the arrangement of phlogiston or æther, in this *slighter* state of excitement; no more than an atmosphere of the *electric* fluid, can interrupt, or destroy the arrangement or power of a *magnetic* atmosphere; both of which attractive powers we know may exist in full force, at the same time, in the same needle; for if a magnetic needle, be electrified, it will shew all the phenomena, of *electric* attraction and repulsion, that another needle, not magnetic, will, in the same circumstances: and at the *same time*, it will attract or repel another magnet, and shew, that it is still possessed of its *magnetic* power of attraction.

'Tis

'Tis evident therefore, that the globe of the earth, and every large mass of compound matter, being furrounded by the *æther* and *phlogiston universally diffused*, and being composed of both the fixed principles, will excite that *æther* and *phlogiston*, to arrangement in right lines: that those *ætherial*, and *phlogistic* lines of particles, will like *radii*, extend, *diverging* as they recede from the earth as a centre, to the *most distant* parts of *creation*, unless they meet with lines of *phlogistic*, or *ætherial* particles, in a similar state of excitement, from some other mass of matter; for instance, the sun; in which case, the lines of *phlogistic* and *ætherial* particles, excited by the earth, will attract the *ætherial* and *phlogistic* lines, from the sun; and by that union, would *draw* their respective centres, the earth and sun *into contact*: did not the direct tendency of the earth's motion, and the force or degree of that motion, counteract the power with which the *ætherial* and *phlogistic* rays of particles, by their mutual attraction, draw them to each other; and in the same manner, the attraction of the earth to the moon, and between lesser masses of matter must be accounted for;

for; as well as the attraction of a particle of the earthy, to a particle of the acidifying principle.

We may conclude therefore, that the *attraction* of universal gravitation, is the *same*, as the attraction between an acid and an alkali; and that *both* are produced by the *same cause*, the attraction of excited particles of *æther*, to particles of *phlogiston*, in a *similar* state of excitement: that *æther* and *phlogiston* are *universally diffused*, and *every where* present, and are, capable of being *so much excited*, by the fixed principles of either kind, as to become *atmospheric*, and *attractive* to *each other*: and that when they come *into contact*, in that state of excitement, by their affinity to each other, they progressively *unite*, and form *lines* of particles, strongly *drawing* the *solid centres*, around which they are excited, *into contact*; because, the *next* approaching particles of *æther*, or *phlogiston*, being *nearer* to their respective centres, than the *present* particles, will attract with *more* force, than they do; consequently, the solid centres will be drawn together, with a force increasing, as their distance diminishes, till they are brought into contact; where  
they

they will remain *firmly united*, as neither of them, on account of their solidity, can penetrate the other.

This *progressive attraction* of combination therefore, of the *two active* principles, *æther* and *phlogiston*, forms that attractive power called *Gravity*, or the *attraction* of gravitation; by which, *every* part of nature, is *connected* with *every other* part; forming *that whole*, whose beauty, order, and harmony, strike us with wonder and admiration!

---

---

SECTION IX.*On Magnetism.*

**M**AGNETISM is that property peculiar to *Iron*, by which one particle or mass of it, is capable of attracting, or forcibly uniting with another. This magnetic virtue, is capable of acting at a *considerable distance*: but the greater the distance, the less the force, or power of attraction.

This property depends upon the *principles* of which iron is composed, and *their proportions*; for if it be decomposed, or deprived, to a certain degree of its phlogiston, and acquires a certain addition of the acidifying principle in its place, it is no longer capable of magnetic influence.

If a piece of iron be *magnetic*, it hath a general attraction to iron *not* in the same magnetic state; but if two bars, or needles of iron, be magnetic, they will not attract each other, unless one of them be *inverted*.

A magnetic needle, when not interrupted, will always arrange itself, with *one certain end* to the *north*, and *the other* to the *south*.

If another needle not magnetic, be applied in the same direction, with *its south* end, to the *north* end of the *excited* needle, it will be attracted, and in consequence of that attraction, will become magnetic; so that when separated, *that end*, which was applied to the north pole of the other, will still point to the south; and consequently, the further

ther end to the north. Or if it be applied to the south pole of the magnetic needle, it will still acquire the magnetic virtue, and that end which touched the south pole, will point to the north.

If two magnetic needles be suspended, so as to have freedom of motion, and the north pole of one be brought near to the south pole of the other, they will attract each other at a considerable distance, and mutually rush with accelerating force, and velocity into contact; but as two needles, *cannot* act upon each other at a *distance*, when *not magnetic*, 'tis evident, that this attractive property, must depend upon *some other principle* or *active fluid*, surrounding the needle in an *atmospheric* form, when *magnetic*.

This magnetic fluid therefore, is an atmosphere of active particles, surrounding the excited pole, and attracting, or drawing towards it, with a certain force, any particle or particles of iron, within a certain distance.

If the *north pole* of an *excited* needle, therefore,

be brought near another needle *not* excited, it will draw it to it: but, if *that north pole*, be brought near to the *north pole* of another excited needle, they will *not* approach, but *recede* from each other; the same if two south poles, be brought near each other. We have then a *magnetic needle*, whose north pole will attract *either end* of a needle *not excited*, with a certain force: which will attract the *south pole* of an *excited* needle, with a still greater force, and to a much greater distance: but which will *not* attract, or come near to the *north pole* of an *excited* needle; though *that north pole* itself, will attract an unexcited needle, in the same manner as the other north pole will.

'Tis evident therefore, that *each pole* of a magnetic needle, is surrounded by an *atmosphere* of magnetic fluid: that *each atmosphere*, hath an *equal* attraction to iron in general: that the atmosphere surrounding the *south* pole, will strongly attract the *north* pole of another magnet: but that the atmosphere surrounding the *north* pole, will not come near, but *recede* from the *north* pole of the other magnet; consequently, the atmosphere surrounding

rounding the *north* pole, must be a fluid, *different* from that, enveloping the *south* pole, though similar in its attraction to iron, and power of assuming an atmospheric form.

It appears therefore, that similar atmospheres will not approach, but that opposite atmospheres, will forcibly unite, and attract each other: that the pole of *every* excited needle, pointing to the *north*, hath a *similar atmosphere*: as have all those pointing to the south: but that the atmosphere of the *north* pole, is a *different fluid*, from that, actuating the *opposite pole*, of every *magnetic* needle.

The magnetic fluid is therefore of *two different kinds*; or rather, *two different fluids* when rendered active, by excitement, are capable of forming themselves into *atmospheres*, around certain particles of *iron*, by *which* excitement, they become *attractive* to iron and to each other. These *two active subtile fluids*, being exactly *similar* in their properties, to *æther* and *phlogiston*, can be no other; therefore, if the *north pole* of a *magnet* be surrounded by  
an

an atmosphere of *æther*, the *south pole* must have an atmosphere of *phlogiston*.

The natural composition of iron is such, that it strongly attracts around it, a considerable quantity *both* of *æther* and *phlogiston*: if by any means, such as a smart stroke upon one end of a needle, or an electrical shock passing through it, either the *phlogiston* or *æther* be *peculiarly excited*, at *that end*, it takes an *atmospheric form* around it; and the *other* active fluid, will immediately assume a *similar* active state of arrangement, around the *other end*; in consequence of which, the needle will become *magnetic*; *one* atmosphere or pole pointing to the north, the *other* to the south.

If the end of another needle, *not excited*, be applied to the north pole of this *excited* needle, if that excited pole be surrounded with *æther*, it will attract the *phlogiston*, naturally surrounding the *un-excited* needle, to *that end* which is applied to it; *which phlogiston*, by that attraction, will become *excited*, and take an *atmospheric form*: while the *æther*, being disengaged, becomes *equally excited*,  
and

arranges itself around the *opposite end* of the needle; by which it becomes magnetic also; its æthærial atmosphere always pointing to the north, and the phlogistic pole to the south.

The north and south poles of two magnetic needles, will attract each other, and unite; because, one hath an æthærial atmosphere, and the other a phlogistic one; therefore, they will penetrate each other, unite, and destroying each other's regular arrangement, will form *lines* of attracting particles, *drawing* their respective poles into *contact*, in the same manner, as when by a *more moderate excitement*, they produce the attraction of gravitation, or tendency to unite between other bodies.

But two *similar* atmospheres of æther or phlogiston, furrounding similar magnetic poles, *cannot* penetrate or unite with each other, as having *no attraction*, but that of arrangement; consequently, those atmospheres will *press upon*, and *resist* each other; having no power to leave their respective centres, or poles, round which they are excited to arrangement.

The

The *two poles* of a magnet therefore, very much resemble the *two fixed principles* of nature, the earthy and acidifying particles; if the ætherial pole of a magnet, be that which always points to the north, like a particle of the earthy principle, it will be a centre of *fixed matter*, with an *ætherial* atmosphere; and the south pole, will be like a particle of the acidifying principle, a *fixed* centre, with an atmosphere of *phlogiston*; the fixed centres being the *same*, in each pole, or each fixed principle: and their peculiar properties, produced by the *active atmospheres* around them.

The north and south poles readily, and forcibly attract each other: so do the earthy and acidifying principles.

Two *similar* poles will *not* attract each, other: neither will two particles of the *same* fixed principle.

Two ætherial, or north magnetic poles, may be made to unite, if a phlogistic, or south pole be brought between them: so two ætherial, or earthy particles,

particles, will unite, if phlogiston, or a particle of the acidifying principle with a phlogistic atmosphere, be introduced between them.

Indeed, the properties of a particle of the earthy and a particle of the acidifying principle, and their relation to each other, so *strongly resemble* the properties of the *two contrary poles* of a magnet, and their relation to, and influence upon each other, that there can be no doubt, that both depend upon the *same causes*, and that *those causes*, are the *two active principles*, *æther* and *phlogiston*, which being excited to arrange themselves like atmospheres around them, as centres, give the properties of the earthy or acidifying principles to fixed particles of matter, and the *polarity of magnetism*, to the poles of the needle; the pole surrounded by one active fluid, always pointing to the north, while the pole surrounded by the other, as constantly points to the south; in the same manner, as a particle of fixed matter surrounded by æther, acquires the properties of the earthy, and a similar particle, with an atmosphere of phlogiston, acquires the properties of the acidifying principle,

strongly tending to combine with the earthy principle, as the north pole of a magnet, rushes into contact with the south.

Magnetism, and all its phenomena therefore, depend upon the two active principles, *æther* and *phlogiston*; which, by the peculiar nature of *iron*, which they naturally surround, are capable *either* of them, *singly*, of becoming *excited* to such a degree, as to surround one end of a needle, or bar, like an *atmosphere*; but which ever of the two active fluids is so excited, the *other* by separating from its common union with it, becomes excited also, and surrounds the opposite end of the needle; which being robbed of its natural quantity of the *other* fluid, attracted and excited to the other end, strongly attracts *this other fluid* into an atmospheric form also; so that a bar of iron, hath a *natural quantity* of the two active principles, equally diffused around it. If one of those fluids, for instance *æther*, be excited at *one end* of a needle, it will attract into arrangement, *all* the particles of *æther* naturally surrounding that needle, and form an atmosphere around that end; and in this state of excitement,

citement, it attracts the needle with *more force*, than it does phlogiston: therefore, the phlogiston being disengaged, will become *equally* excited, and form a *similar* atmosphere around the other end; and the needle thus having *all its æther* at one end, and *all* the *phlogiston* furrounding the other, will become *magnetic*; that is, similar poles, or poles furrounded with atmospheres of the same kind of fluid, *cannot* attract or come near each other: but a north and south pole, of two magnetic needles, having atmospheres of the *different fluids*, one being ætherial and the other phlogistic, will attract, and be *drawn* forcibly to each other. *Either* of these atmospheres will attract iron, on account of the opposite principle naturally furrounding it; but if either of these excited poles, suppose the *ætherial* one, be applied to the end of a needle, of *unexcited iron*, the æther will attract *all* the *phlogiston* naturally belonging to the non-magnetic needle, to that end; in consequence of which, the *æther*, naturally attending the phlogiston attracted by the magnetic pole, will *recede* to the *other end* of the needle; therefore, *each* being excited, will form *atmospheres*, around their respective ends;

and this needle also, will be a *magnet*; that end by which it was excited, always having an atmosphere of the *opposite fluid*, to that of the magnetic pole applied; and consequently, pointing in a *contrary direction*.

The reason why the two different atmospheres of a magnetic needle, will not unite so as to *separate* from their fixed centres, since they have so great an affinity to each other, is owing to the *degree* of their *attraction* to their respective poles of iron, being *greater*, than the force of attraction for each other; as is evident, from this, that though the north and south poles of two magnets will forcibly unite, yet if drawn asunder, the ætherial and phlogistic atmospheres will *part* with *each other*, rather, than from their exciting poles of the needles; in like manner, the æther around one pole of the needle, will attract the phlogiston around the other, but that attraction is not so great, as the attraction to the poles of the needle, therefore they will not *leave* their respective poles; but their attraction to each other, will *destroy* the *regularity* of their *arrangement*: those particles be-  
ing

ing *most* deranged, which are the *most opposed* to the contrary atmosphere.

It appears therefore, that a needle, in its common state, hath the *same quantity* of æther and phlogiston furrounding it, as when excited; and that the *only difference* is, that in the *natural* state, the æther and phlogiston are *promiscuously* and *equally* united, on every part of the surface: but when that needle is *excited*, so as to become magnetic, *all that* natural quantity of æther, is collected and intimately attracted to *one end*, and *all the phlogiston* to the other; and that this is in reality the case, every property of the magnetic needles corroborates, and the following circumstance sufficiently proves. If an iron rod, of *considerable* length, and thickness, be rendered magnetic at one end, it will be magnetic to the other; suppose that the *excited* end hath an atmosphere of æther, and will attract the *south* end of an *horizontal* magnetic needle, at the distance of *three inches*: if it be moved, nearer to the needle, *upwards*, in a perpendicular direction, it will attract that south end, for *three inches* of its length; therefore, the ætherial atmosphere

mosphere, is *six inches* in diameter; three inches from the end, or pole, each way. If the rod be still moved upwards, the *north* end of the magnetic needle will become attracted, which shews, that *then* the *phlogistic atmosphere* commences: and the same *north pole* will be attracted, till *six inches* of the rod pass by it; which shews, that the phlogistic atmosphere extends six inches also, that is, three inches each way, from its centre or pole. If now the rod be still moved upwards, the *south pole* of the needle will be *again attracted*, as at first; which proves, that the *ætherial atmosphere* *again* commences, and extends *six inches* as before.

But, if a *smaller rod* be employed, the *extent* of those atmospheres, will be *less*; and consequently, the *poles*, or *centres* of those atmospheres, will be *nearer* to each other.

But a magnet in vacuo, will render a needle magnetic, without losing any of its own power: consequently, the needle acquires *no* additional principles; and its acquired magnetic power is produced, by its naturally surrounding fluids, being

ing separated, and becoming atmospheric, *one* at *one* of its *ends*, and the *other* at the *other*; and the *greater* the *surface* of the needle, the *greater* must be the *quantity* of those fluids, naturally surrounding it; and therefore, the *more extensive* will be the *atmospheres*, formed by those fluids, the æther and phlogiston, when excited to the *magnetic* arrangement; and the *more distant* must be their poles.

Whatever can destroy this arrangement, as a smart stroke, an electric shock, the action of fire, or the decomposition of the iron, immediately deprives the needle of its magnetic properties, which, in all cases may be recovered, by the touch of a magnet; except, when the iron is decomposed; in which case, it is incapable of magnetic excitement, unless its principles, and their proportions be restored as at first; without which, it cannot give that excitement, and attraction to the surrounding æther and phlogiston, which constitute the magnetic power.

The reason why a magnet will attract no other substance but iron, is because no other body composed

posed of *different principles*, or of the same principles in *different proportions*, hath so strong a natural attraction to *both æther and phlogiston*, as iron hath; therefore, if the ætherial pole of a magnet, be brought near to another body, although surrounded by phlogiston, it will *not* attract *that body*, unless it attracts its phlogiston so as to give it an *excitement, similar* to the magnetic state, or so *strongly*, that it will *not part* with it; in which case, the ætherial pole of the magnet, attracting the phlogiston, must draw the body along with it also; but no other substance can be attracted by the magnet: therefore, *no other body is* so powerfully attractive to surrounding æther and phlogiston, as iron is; and consequently, can neither be attracted by the magnetic atmospheres, nor become magnetic.

For if iron, in its natural, or in its magnetic state, gives to æther or phlogiston a *much more powerful excitement* than other bodies do, as appears from the power of magnetic attraction: 'tis evident, that the *weaker* excitement given to them, by other bodies, will *not* enable either of them, in that state,

state, of slight excitement, and weak *attraction* of *union* to its opposite, to overcome the *stronger* attraction of *arrangement* in this *magnetic state*, of *great excitement*; consequently, the *magnetic arrangement*, will not give way to the *feeble* attraction of *any other* state of excitement, around *any other* kind of matter whatsoever, having *less* attraction to æther and phlogiston, than *iron* hath.

Having now examined *æther* and *phlogiston*, in *two different* states of excitement, forming atmospheres around solid bodies, as centres; in the *simpler* state of excitement, producing the *attraction* of *Gravity*: and when *more strongly* and peculiarly excited by the attraction of iron, producing the *attraction* of *magnetism*; it next follows, to consider the *third state* of their excitement, in which, they are capable of taking an *atmospheric* form, around their exciting bodies, producing the *third* kind of *attraction*, that of *electricity*; which will form the subject of the ensuing Section.

---

## SECTION X.

### *On Electricity.*

**E**LECTRICITY is that state, or property communicable to bodies, by which they attract, or repel each other, according to circumstances; independent of either gravity or magnetism. Every appearance therefore of attraction, or repulsion, which is not the effect of either gravitation or magnetism, is produced by *Electricity*. But as  
bodies

bodies by means of electricity, are capable of acting upon each other, at a considerable distance: 'tis certain, that all the phenomena of electrical attraction or repulsion, are produced by some subtle active medium, extending from the excited body, to the body acted upon; and that active medium, is universally called the *Electric fluid*.

If *glafs* be excited by friction, it will acquire an atmosphere of this electric fluid, which will attract a light ball of cork, or any other substance suspended by a silk thread, at a considerable distance; and drawing it to itself, will communicate a similar atmosphere of electric fluid, to the cork; in consequence of which, it will be repelled; which shews, that the *electric atmosphere* of the glafs, hath a general attraction to all unexcited matter, by which it draws it to the excited glafs: that the body, by that attraction brought to the surface of the glafs, becomes surrounded by that electric atmosphere, unites to a part of it, and is then repelled; and consequently, that *two bodies*, possessed of the *same electric fluid*, acquired from the excited glafs, will repel each other.

If a piece of *fulphur* be rubbed, it acquires an atmosphere of electric fluid, which in like manner, will attract a cork or other body, and then repel it; therefore, the *electric fluid* excited by means of *fulphur*, hath an attraction to all unexcited bodies; and *two bodies* furrounded by it, will repel each other.

*Two balls* therefore, furrounded by atmospheres of electric fluid, excited by *glass*, will *repel* each other; so will two balls electrified by means of *fulphur*. But a ball electrified by excited *glass*, will *attract* a ball electrified by means of excited *fulphur*; and every appearance of electricity will vanish, in the form of light, accompanied with a snapping noise: consequently, the electric fluid produced by exciting *glass*, is *different* from that produced from *fulphur*; because, they forcibly *attract, unite, and destroy each other's electric properties*: therefore, they are two different fluids of different properties: each capable of being excited, and of attracting, and furrounding all bodies like atmospheres: in which state, neither of them can unite with, or come near to bodies possessed of similar

similar atmospheres: but, atmospheres of the two different fluids, will attract, unite, and by uniting, *destroy* those electric properties, which each had when separately excited. It appears therefore, that their attraction to each other, is greater than their attraction to the bodies by which they are excited, or round which they take an atmospheric form: that they possess the properties of attraction or repulsion, which we call electric, when excited singly: but, when they unite, every electric property ceases, they separate from their exciting surfaces, and light or fire is produced, metallic calces may be revived by acquiring *phlogiston* from them, and the acid principle become pure air, by their supplying it with *æther*. These things considered, and their attraction to matter, their atmospheric arrangement, the inability of similar atmospheres to coalesce, and the attraction and union of the two different kinds of atmospheres, being so exactly similar to the two active fluids, *æther* and *phlogiston*, leave no room to doubt, that they are the *same principles*, rendered active, or having acquired the properties which we call *electric*, by a certain mode or degree of excitement.

citement. For, if metals contain *phlogiston*, and pure air *æther*, which I think I have sufficiently proved, then the union of the two electric fluids producing a spark, which is composed of both *æther* and *phlogiston*: and *that* electric spark being produced by the union of the two opposite electric fluids, which in their separate electric states, possessed different properties: one of them *must* have been *ætherial*, and the other *phlogistic*; therefore, positive and negative, or vitreous and resinous *electricity*, are no other than *æther* and *phlogiston* separately, in that state of excitement which we call electric.

But, if *glass* be excited by means of a rubber, the electricity of the glass will be opposite to that of the rubber: that is, the one will possess *æther* in an electric state, and the other *phlogiston*.

If the *inside* of a jar, properly coated, be connected by means of such bodies, as readily conduct the electric fluid, with the excited glass, and the *outside* coating of the jar, be connected with the rubber, the jar will acquire a quantity of the *same* kind

kind of electric fluid as the excited *glass*, on its *inside* surface: while the *outside*, will become electric by the contrary fluid, the same as the *rubber*; one side having the ætherial electricity, and the other the phlogistic.

If a conductor, or substance of any kind, be surrounded by an atmosphere of either ætherial, or phlogistic electricity, that atmosphere will attract any other body, which, if light will be drawn to it, and then repelled; and it will have *equally* the *same effect*, if a piece of *glass* be *interposed*, between the excited body and the body attracted; which fully proves, that either the ætherial, or phlogistic electricity, *readily penetrates glass*, and loses none of its electric properties; still attracting, and then repelling the light body, the *same* as when *no glass* is interposed.

Again, if the *inside* of a coated jar, communicates with an exciting body, while the *outside* is *insulated*, or not connected by conducting substances with the rubber, the electric fluid produced  
by

by the globe, will *diffuse* itself over the inside of the jar, but will *not unite* with it, so as to *charge* it; but is loosely expanded upon the surface of the coating, forming an atmosphere in the same loose state, as that surrounding the conductor; which keeps flying off from the surface, or some edge, point, or corner, as fast as it is generated by the globe; the form in which it escapes, is that of *light*, accompanied with a hissing noise, and phosphoreal smell.

But, if the *external* coating of the jar, be connected by conductors to the *rubber*, the electric fluid thrown into the jar, will become *fixed*, and *condensed* there; and the jar will be *charged*; while the *outside* will be equally charged, with the *contrary* kind of electric fluid. Here again, the action of *either* or both of the electric fluids, *through glass*, is evident; for by their attraction to each other, they become *fixed* to the *opposite surfaces* of the *glass*: though neither of them could fix to it, when *not attracted* by the *contrary fluid*, on the *other side*.

If a communication be made, by means of conductors, between the two opposite surfaces of the jar, the two fluids will rush into union, with violence and noise, and produce *fire* or *light*; by which, both the fluids lose their electric properties.

But if the two opposite electric fluids, have a greater attraction to each other, than to the surfaces on which they are excited, and each of them is capable of readily penetrating glafs, what is the reason, why, when excited, one on each surface of the jar, they do not attract each other through the glafs and unite; in the same manner, as they would through an equal, or much greater thickness of metal?

But if, as is certainly the case, the electric *æthereal* fluid be on one side the glafs, and the electric *phlogistic* fluid on the other surface: and each acts through the glafs, so as by its attraction to the opposite fluid on the other side, to become fixed and condensed on its respective surface: the reason why they do not rush into union through the

B b

glafs,

glafs, must be, that *each fluid* is as much attracted by *some other* matter, with which it is combined, as it is by the *opposite* fluid on the other side the glafs. It is not the opposite surfaces of the glafs that attracts them, because, they will leave those surfaces, to rush into union; it must therefore, be *some fluid* of some kind or other, by which *each* is attracted so *strongly*, as to be *prevented* from passing through the glafs, to unite with its opposite.

What is this other fluid? — we know that when either a globe of glafs, or sulphur is excited, or when *either* the electric ætherial, or phlogistic fluid is copiously produced, that it appears *luminous*, or escapes in the form of *light*.

But light we know will communicate phlogiston to metallic earth, and æther to the acid principle, and is therefore composed of *æther* and *phlogiston*; consequently, as light is always composed of the same principles, the light produced by the excited electric fluid, when escaping from the exciting globe, whether the fluid be of the negative, or positive kind, shews, that *each* of the *two opposite*  
*electric*

*electric fluids*, is composed of *both æther* and *phlogiston*: and consequently, the *positive* or *negative* state; depends upon *which* of the two active principles, is *excited* by the *surface* of the globe, and *which* forms the *external atmosphere*.

Sulphur we know, contains much *phlogiston*, which when excited by a sufficient degree of heat, readily attracts the æther from pure air, with which it will unite and fly off in the form of fire or light; we may therefore naturally suppose, that when *sulphur* is *excited gently* by friction, it will attract the *æther* excited on its surface by that friction; for æther as well as phlogiston, are always, and every where present, in some state or other. But, since the phlogiston of the sulphur, *cannot* in the moderate degree of heat produced by this friction, *separate* from its chemical union with the other principles, with which it is combined to form sulphur: neither can it enter into chemical union with the surrounding æther; the consequence of their excitement therefore will be, that the *æther* will be attracted by the *phlogistic surface* of the *sulphur*, and assume an *excited atmospheric* form.

But the *phlogiston* which was *naturally* present, and united to that æther, becomes *equally excited* by that friction; and being *disengaged* from the æther attracted by the sulphur, becomes as powerfully *attracted* by, and united to the *surface* of the *rubber*; but yet, the excited æther and phlogiston, being in contact, strongly attract each other, as is natural to suppose, from their strong affinity; and as is sufficiently evident, by the attraction subsisting between the globe and the rubber. But, when by the rotation of the globe, or progressive motion of the rubber, their excited surfaces must separate from each other, the *æther* excited by the globe, not being able to enter into chemical union with it, will attract along with it some *phlogiston*, which will surround it in an *atmospheric* form; and the excited *phlogiston*, forced over the edge of the rubber, will take along with it an atmosphere of *æther*, and retreat to the back of it; at the same time, the other parts of the rubber, deprived by this excitement of their natural quantity of æther and phlogiston, attract those principles from the surrounding bodies, to which they are connected by proper conductors; for if the rubber cannot  
acquire

acquire phlogiston and æther, in their natural state of union from surrounding bodies, no electric fluid can be produced, more than just that quantity of æther and phlogiston will afford, which naturally surrounds the globe and the rubber; because, the principles will be wanting, which become electric by being excited by friction.

When a *globe*, or stick of *sulphur* therefore, is excited by friction, so as to attract *æther*, that æther will attract an atmosphere of *phlogiston*, which will exhibit all the phenomena of *negative electricity*; while the *rubber*, possessed of excited *phlogiston*, with an *external atmosphere* of *æther*, will be *positively* electrified.

But, these electric states, of the excited sulphur and its rubber, are directly opposite to those of *glass* and the rubber, by which it is excited: therefore, *glass* by excitement attracts *phlogiston*, which being equally excited, attracts an atmosphere of *æther* around it; acquiring by that arrangement, the properties of *positive electricity*. And at the same time, the *æther* disengaged from its union  
with

with the phlogiston attracted by the glass, will become excited to the surface of the *rubber*; and when by the motion of the globe, the excited glass separates from the edge of the rubber, the excited *æther* of the *rubber*, will attract around it, and take along with it, the *phlogiston* separated from the *external* atmosphere of *æther*, surrounding the phlogiston attracted by the surface of the globe, and flowing over the edge, will recede with it to the back of the rubber.

The whole of *electric* excitement then, is simply this; *æther* and *phlogiston* in a certain *natural* state of union, universally exist; when these are excited by friction, between the rubber and a globe of glass for instance, the glass having a greater attraction to *phlogiston*, on account of the acidifying and *æthereal* principles entering into its composition, than to *æther*, by this excitement attracts some of it to its surface; and the *æther*, naturally combined with that portion of phlogiston, being equally excited, will attract the surface of the *rubber*; when these excited surfaces part, the *phlogiston* excited by the globe, will attract an *atmosphere*  
of

of *æther*, from the remaining part of the compound of *æther* and *phlogiston* naturally furrounding the rubber: and the *phlogiston* disengaged from *that æther*, will be attracted in an *atmospheric* form, around the excited *æther* of the *rubber*. The progressive rotation of the globe, carries these *electric atmospheres* along with it, by its attraction to the *phlogiston* forming the *internal* atmosphere; and the excited *atmospheres* of the *rubber*, at the same time, and by the same motion, are forced over its edge, and retreat to its back parts. The other parts of the rubber, thus deprived of their natural quantity of *æther* and *phlogiston*, constantly attract it from every substance around; and so long as it is supplied with them, from the surrounding bodies, so long will the motion of the globe and rubber, by their mutual friction, excite those principles, to take the states of *positive electricity* around the *glass*, and *negative* around the *rubber*.

If the *inside* of a coated jar, be connected by a conducting substance to the *excited glass*, and its *outside* to the *rubber*, the *phlogiston* with its *ætherial* atmosphere, will pass along the conductor, from  
the

globe to the *inside* coating of the jar: and the *æther* with its *phlogistic* atmosphere, will pass from the rubber, to its *outside* coating; the *internal phlogiston* on the *inside* of the jar, attracting the *internal* atmosphere of *æther* on the *outside*, will *fix each other* to their respective surfaces; by which means, the quantity on each side, may be so accumulated, as to render the jar charged. In that state 'tis evident, that the *inside* of the jar, contains an atmosphere of *phlogiston* on *its surface*, surrounded by an atmosphere of *æther*: and the *external* surface, hath an atmosphere of *æther*, surrounded by another of *phlogiston*. The atmosphere of *phlogiston* or the *internal* surface of the jar, cannot pass through the glass, to unite with the *æther*, on the *external* surface, because, it is *equally attracted* by the *æther* surrounding it, in an *atmospheric* form, in the *inside* of the jar. But, if a quantity of *phlogiston*, rendered electric by an atmosphere of *æther*, passes into a jar, it will not *fix* itself to the inner surface of the jar, unless it meets with an equal quantity of *æther*, rendered *electric* by a phlogistic atmosphere, on the *outside* side of the jar; but if *æther* be present, by its attraction to *that æther* on the external surface,

surface, it becomes fixed to the *internal* surface, and may be accumulated till the jar be charged, and can take no more,

If now a communication be made, between the two opposite surfaces, the *two external atmospheres* of æther and phlogiston, of the two surfaces, will first of all attract each other; in consequence of which, the two *internal* atmospheres being drawn from their respective surfaces, will be brought into *contact also*: when, *losing* their *electric* properties and arrangement, the *whole* will unite with violence; some *fire* or *light* being produced, by the new *mode of union* of the *two principles*.

That each state of electricity, is composed of the two active principles, æther and phlogiston, in one, the *æther* being excited to take an *atmosphere* of *phlogiston*, and in the other, *phlogiston* being excited to take an *atmosphere* of *æther*, on which different modes of arrangement, the different properties of negative, and positive electricity depend, is therefore sufficiently evident, and further proved by the following facts.

If a *large* ball of metal, be *positively* electrified, and a *small* cork ball be brought near it, the cork will be *attracted* and then *repelled*; but if the *positive electric atmosphere*, be *one simple* fluid, why is the ball *repelled* after being attracted?—for, when iron is attracted by either phlogiston, or æther, rendered magnetic, by *their simple* excitement round the poles of a needle, it is not again repelled: but the cork is repelled after being attracted: therefore, the *electric atmosphere*, is *not simple*, nor composed of *one homogeneous* fluid. The reason of its *repulsion* after being attracted, is therefore this, the cork is attracted by the *external* atmosphere of æther, by which it is drawn to the *internal* atmosphere of *phlogiston*, immediately surrounding the metal ball; *that internal* atmosphere, is *communicable* from one substance, to another: but the *external* atmosphere is *not*, unless the *internal* atmosphere, *first separates*. As soon therefore, as the cork comes into *contact* with this *internal phlogistic* atmosphere, it becomes surrounded by it, and in consequence of *that*, is again attracted by the æther, *which* gives it an *external* atmosphere around it; and having then no longer an attraction

tion for the ætherial atmosphere in which it floats, by its levity it is pushed to the *surface* of that ætherial atmosphere, surrounding the heavier and greater body.

But, if the ball of metal be large, and strongly excited, by being surrounded by a *great* quantity, or extent of electric atmosphere, and the cork ball be *small*, if it be *forcibly* pushed into the *internal phlogistic* atmosphere, and completely covered by it, it will remain there, firmly united to the ball of metal, and may be moved around it, without separating from it; but if it be *raised out* of that *phlogistic* atmosphere, part of which will adhere to it, so soon as it comes into contact with the surrounding *æther*, it will attract it, and be attracted by it; in consequence of which, it will acquire an *ætherial* atmosphere also, and be *pushed* to the *surface*; so that its external atmosphere, will only touch the utmost verge, of the external ætherial atmosphere of the ball of metal.

Again, if a ball positively electrified, be brought near another negatively so, their *external* atmo-

spheres will attract each other, at a considerable distance. If they be permitted to approach, considerably nearer than where they begin to attract, they still may be drawn asunder, and will be found to possess the same degree of electricity as before; but if they be suffered to approach *so near*, that the *two internal* atmospheres come *into contact*, they immediately rush violently into union with each other, and with their external atmospheres; and every appearance of electricity suddenly vanishes, with the peculiar arrangement of the principles, upon which it depended, and by which it was produced; and the two active fluids, the æther and phlogiston, return to their *natural state*; except *that part* of them, which by the violence of their union, took the form of *light* or *fire*, according to the force, and mode of combination, with which they united together.

Another experiment may be brought, to prove the same, which is, that if a conducting body, communicating with the earth, or not insulated, be brought *within* the *electric atmosphere* of any excited body, it will acquire an *electric* atmosphere  
of

the *contrary* kind: and the nearer it approaches the excited body, the more will it become possessed of the opposite kind of electricity; 'till at length, being brought sufficiently near to each other, the *two opposite* atmospheres will unite, and forming a luminous spark, their electric states, and all the properties depending thereon, will be destroyed, and each body left equally devoid of electric excitement of either kind. Suppose the excited body be positively electrified, it will then have attracted to its surface, an atmosphere of *phlogiston*, surrounded by another of *æther*: this *external ætherial* atmosphere, acting upon the conductor, surrounded by its *natural* quantity of *æther* and *phlogiston*, in their *common* state, will attract the *phlogiston*; in consequence of which, the *æther*, naturally combined with that *phlogiston*, will become *excited*, and adhere to the *surface* of the *conductor*, like an atmosphere; and at the same time, still retain an attraction to *that phlogiston*, which will now surround it like an atmosphere. The two *external atmospheres*, continuing to attract each other, cannot unite perfectly, because they are each still retained, by the attraction of the *internal* atmospheres,

spheres, adhering to the *opposite bodies*: the *nearer* the ætherial atmosphere approaches the conductor, the *more* powerfully will it attract phlogiston from it: and the *greater* must be the *quantity* of æther, displaced from its intimate natural union with *that phlogiston*, and excited to attract the *surface* of the conductor.

The *external ætherial* atmosphere therefore, of the electrified body, will keep attracting the phlogiston of the conductor: and that phlogiston will keep *depositing* its naturally combined æther on the *surface* of the conductor, where it will become *excited*, and attract *that phlogiston* as an atmosphere: till the two bodies approach *so near* to each other, that the *internal phlogistic* atmosphere, of the *electrified* body, can touch the *internal atmosphere* of æther, acquired by the conductor; when, they will *rapidly rush* into union with each other, and with their external atmospheres, mutually; in consequence of which, *light* and *fire*, will be produced, with a *noise* and *shock*; and every appearance of *electricity* of either kind, in *either* body, will at the *same instant disappear*.

The

The phenomena therefore of *electricity*, are produced by the *two active fluids*, *Æther* and *Phlogiston*: when by *friction*, they become *excited* to attract the *surfaces* of *certain* bodies. Those substances which have naturally a *greater* attraction to *æther*, than to phlogiston, such are for instance, amber and sulphur, when rubbed, *attract* and *excite* that *æther*, which then takes an atmospheric form upon that surface; and the phlogiston naturally combined with it, by this separation and friction, becomes equally excited, on the surface of the rubber; and the globe, and rubber, by means of those atmospheres, attract each other.

But, when the two excited surfaces *part*, the *æther* will not *quit* the surface of the globe of sulphur: neither will the phlogiston quit the rubber: but the *æther* not being capable of entering into a close, or chemical union with the sulphur, although strongly excited to it, and in a state of great activity, seizes *that phlogiston*, which in the common, or natural state, is supplied by the rubber: and the globe becomes *electric*; having an atmosphere of *æther* attracted to its *surface*, and that *æther* being

ing furrounded by an *external* atmosphere of *phlogiston*. But, at the same time that the strongly excited *ætherial* atmosphere of the *globe*, when it parts from the rubber, seizes the neighbouring *phlogiston*; the equally excited *phlogiston* on the *surface* of the *rubber*, seizes the *æther* separated from *that* *phlogiston*; with which it envelopes itself like an atmosphere, as it flows over the edge of the rubber.

The opposite takes place with respect to the globe and rubber, when glass is employed.

*Glass* from its chemical nature and composition, hath a greater attraction for *phlogiston*, than to *æther*; when excited therefore by friction, it will attract the excited *phlogiston* to its *surface*; which not being capable of chemically combining with the glass, although strongly excited, will seize upon *æther* sufficient to surround it. And the other opposite principles, disengaged in these cases, will become equally excited to the rubber; the *æther* by means of the exciting glass, deprived of its *phlogiston*, will strongly attract the rubber, and  
that

that excited æther, when forced to separate from the phlogiston, excited by, and attracted to the globe, will assume an *external* atmosphere, composed of the *phlogiston*, separated from the æther forming the external atmosphere of the glass.

It appears therefore, that as the *magnetic* poles, resemble the earthy and acidifying principles, as being *solid centres* of matter, surrounded by atmospheres of *æther* or *phlogiston*: each mutually attracting the other; so, two balls positively and negatively electrified, will greatly resemble the *same two fixed principles*, when in the states of *evident alkalinity* or *acidity*. For the *earthy* principle never manifests its *alkaline* properties, but when surrounded by more or less *phlogiston*; neither does the *acidifying* principle appear evidently *acid*, but when it is surrounded with some *æther*; if that atmosphere of æther be *small*, it will be so much the *more excited*, and that excitement produces the sensation and phenomena of *acidity*; but if it be very *great*, or widely extended, it will be so *gently* excited, as to shew *no evident acidity*, as when in the state of pure air.

A particle of the earthy principle is a particle of *fixed* matter, actuated by being united to, and furrounded by the *ætherial* principle; and when that is furrounded by an *external atmosphere* of *phlogiston*, it becomes evidently *alkaline*: but if furrounded by so large a quantity of phlogiston as to become in an aeriform state, its alkaline properties are not sensibly evident, as in inflammable air; in which state, it resembles a *body electrified* by means of *sulphur*, or of any phlogistic electric; as being a solid body, having an *internal* atmosphere of *æther*, furrounded by an external atmosphere of *phlogiston*.

In like manner, a particle of the acidifying principle, is a *fixed* particle of matter, actuated by *phlogiston*, which phlogiston by being furrounded by an *external* atmosphere of *æther*, forms a particle evidently acid: in which state, this acidifying particle is similar to a particle of matter, *electrified* by excited *glass*; the solid centre attracting phlogiston, and that phlogiston taking around it an atmosphere of *æther*.

The chief difference between the two solid principles, when in that state in which they are aeriform or surrounded with complete external atmospheres, and two bodies surrounded by the two opposite states of electricity, is, that the acidifying and earthy particles, can only be deprived of their *external* atmospheres by uniting, because their internal atmospheres being immediately united to their respective fixed particles, can never more be separated, as being excited by those fixed particles, to attract with the *greatest force* they are capable of exerting.

But, any body will part with *both* its internal and external *electric* atmospheres, when those atmospheres can meet with atmospheres of the contrary fluids, in a similar state of excitement: in which case, each fluid meeting with its opposite, to which it hath a strong attraction, will unite, and by that union, the *arrangement* of *both* kinds will be destroyed, and with it every appearance of *electricity*, as being a property arising from that arrangement; therefore, these excited atmospheres  
of

of the two different kinds, mutually satisfying each other, will destroy the attraction by which they were held to their respective surfaces; because they were not *chemically*, or *intimately* united to those surfaces, but only *slightly* and *simply* attracted by being in *contact*.

Æther or phlogiston have therefore, only a slight attraction to the surfaces of electric substances: and when excited by friction, neither of them can sufficiently attract the electric surface so as to fix itself, or acquire the electric state, unless it can meet with the *opposite principle* to attract around it; by which, and the attraction of the electric surface together, its excited attraction will be sufficiently satisfied, so as to enable it to assume, and preserve *that atmospheric* form, upon which its *electric* properties depend.

The *electric* states of æther and phlogiston, are therefore very different from those states, in which, by the powerful attraction between them and iron, they assume the *magnetic* arrangement. For by  
iron,

iron, they are so equally and powerfully attracted and excited, that *either* of them is capable of forming an atmosphere around it, which by its powerful excitement, will strongly attract the opposite principle, and with it the excited pole, or iron, which it furrounds and attracts; and when the two opposite poles, or one of those poles and iron are in contact, they will remain strongly united.

But, when a body is attracted by an *electric* atmosphere, it is drawn towards the excited body, till it touches the *internal* atmosphere, by which it becomes furrounded, and by that means acquires an attraction to a *part* of the external atmosphere also: which having acquired, it becomes equally electrified, as the excited body, and is no longer attracted, but recedes to the surface of the external atmosphere of the first body.

They differ in this too, that two fluids forming one kind of electric atmospheres, have a *greater* attraction to the *two opposite fluids*, in a similar but  
contrary

contrary atmospheric state of arrangement, than they have for the *surfaces* to which they are attracted; in consequence of which, they *will* leave those surfaces to unite with each other. But when in the magnetic state of excitement round iron, they have a *greater* affinity to *that iron*, than to each other; in consequence of which, they *will not* quit the iron, to unite, so as to destroy their magnetic excitement.

But they resemble each other in this respect, that when *one* fluid is peculiarly excited to *magnetic* arrangement, around one pole of a needle, the *other* fluid assumes a similar state around the contrary pole: in the same manner, as when *one* of them is peculiarly excited to take the *electric* state around the globe, the *other* becomes equally excited and attracted by the rubber.

All bodies are naturally surrounded by æther and phlogiston in their common state of combination, in which state either of them is capable of being attracted by its opposite, in the electric state  
of

of excitement; consequently, an electrified body, will attract another body of any kind; which shews, that the *degree of excitement* in the *common* state, is not *much different* from that in the *electric* state; and that the *chief difference* is, that in the common state, the *two fluids* are *uniformly mixed*, but, in the *electric* state, they are *separated* so as to become *atmospheric*, each to the other. For neither the æther nor phlogiston naturally combined, and attracting all bodies, will separate, or enter into new combinations, unless *the other* can assume a similar state of excitement. But the *phlogiston* surrounding *any other body* than iron, will not have any attraction to the *ætherial magnetic* atmosphere of a needle, because the *magnetic* attraction of arrangement, is *too great* to be affected by the weaker attraction of *union*, of the opposite fluid in the *common* state; but if it *could* be attracted by the magnetic ætherial atmosphere, the *æther* with which it is combined, would not be so strongly attracted by *that body*, as to enable it to take the simple form and force of attraction, necessary, to give it a *magnetic* arrangement; for if the body did not attract the *æther* surrounding it, so forcibly as the  
ætherial

ætherial magnetic atmosphere did the *phlogiston*, they would not separate and form magnetic atmospheres; therefore, which ever were attracted, the other would go along it: consequently, no substance but *iron*, in an unexcited state, attracts the naturally surrounding æther and phlogiston, with so much force as to enable them to be attracted and drawn towards the magnet, by means of their attraction to it: and therefore, no substance but iron can attract an atmosphere of either æther or phlogiston, with such force as to render it magnetic.

That no substance but iron can become magnetic, or be attracted by a magnet, is therefore evident from this, that when either phlogiston or æther is excited, every particle hath its attraction of arrangement to similar particles, and its attraction of combination to the particles of the other kind, in a degree proportionate to that excitement: if therefore two particles of *æther* be excited, so as to attract each other, with the force of 1, each contiguous particle must have nearly the

the same force; therefore, their *mutual* attraction of arrangement, will be with the force of 2, and their attraction of combination to phlogiston will be in the same proportion; but if two particles of *phlogiston* be *each* excited to attract the other, with the force of 2, they will unite together with the force of 4, and their attraction to æther will bear the same proportion.

A particle of this phlogiston therefore, whose excitement is equal to 2, being brought into contact with *one* of *those* particles of *æther*, whose excitement was as 1, they will attract each other into union with the force of 3; but two of those particles of *phlogiston* attract each other to arrangement, with the force of 4: consequently, those phlogistic particles will not separate from their arrangement, to combine with the æther; because, the *mutual* attraction of arrangement, in that state of *great excitement*, is *more powerful*, than the attraction of combination with the æther, *slightly excited*.

The particles of æther or phlogiston therefore, when they form magnetic atmospheres around iron, are *strongly* excited, and *strongly* attract each other to arrangement: but when they form electric atmospheres, around bodies, they are but *gently* excited, and *weakly* attract each other; and consequently, their attraction of combination, with the opposite kind of particles, must be proportionately weak; 'tis evident therefore, that they will attract the opposite kind of particles, strongly excited by the magnetic arrangement, with *less force* than *those particles* attract each other; consequently, the *magnetic* particles will suffer *no derangement*, and the magnetic and electric atmospheres, though formed of the two different principles, being so *differently excited*, and attracting with such *different degrees* of force, will never *derange*, or *unite* with each other.

An ætherial magnetic atmosphere will therefore, not be sensibly attracted by a phlogistic electric atmosphere in a much less excited state, because the magnetic attraction of arrangement between the particles of æther, is much greater *than*,  
and

and will not give place *to* the weaker attraction of union, exerted by the slightly excited electric atmosphere of phlogiston; therefore there can be no approximation of their respective centres: because not being equally excited and active, they cannot destroy each others arrangement, and form lines of attracting particles, drawing one centre to the other.

For the same reason, *that* combination of æther and phlogiston, surrounding all bodies, and producing *universal attraction*, or *gravitation*, being a still *gentler* degree of excitement, cannot derange or be deranged by those fluids, when in different states of excitement they acquire different degrees of attraction, and constitute electric or magnetic atmospheres: because, the gentle attraction of that arrangement, producing universal attraction, can *never destroy* the *stronger* force with which *those* particles attract each other, when they are excited to take the *other modes* of arrangement.

But

But whether *these active principles* are *so excited*, as to produce the attraction of gravity, electricity, or magnetism, they always in the *same state*, have the *same* degree of excitement; so that in any one of these three general states of attraction, they always have a power of acting upon each other; but *not* in any *two different* states; and the difference of force with which they attract in the same state of excitement, is always produced by the difference of the *quantity*, or *number of particles* excited.

The other two states of excitement, resemble that producing general attraction in this respect, that when an atmosphere of either the electric or magnetic excitement, approaches an atmosphere of the other active principle, in a similar state of excitement, they attract and destroy each others *peculiar atmospheric arrangement*, and form lines of the two different kinds of particles, parallel, contiguous, and progressively uniting to each other; and consequently, attracting and drawing into *contact*, the bodies to which they extend; exactly in the same manner, as when in that state producing universal gravitation or attraction.

Having

Having now taken a view of the two active principles, in their different states of excitement, when combined with, or attracted to fixed particles of matter, or bodies containing and composed with solid matter : I shall next examine *them*, in their states of *combination*, *unconnected* with *solid bodies* ; or not depending upon any union with, or excitement *from them* ; which will be the subject of the two following Sections.

---

## S E C T I O N   X I.

### *On Fire.*

**F** I R E is that subtile fluid, which is capable of penetrating and expanding all bodies; and is known likewise by the sensation of *heat* which it produces, by its action upon the body.

A body therefore is heated, or hot, in proportion to the quantity of this fluid contained in its interstices, or flowing from its surface, to restore its equilibrium, by passing into bodies or spaces, containing

containing a less quantity, than the heated body.

That fire is a subtile fluid actually existing, and by its action or motion, produces heat, or that state of bodies which we call heated, is too evident to need insisting upon; for if it were not, an active fluid, like all other fluids endeavouring to restore or keep itself in an equilibrium, how is it possible that a heated body, suspended in vacuo, should communicate a part of its heat, to a colder body at a considerable distance from it? if heat were no other than a violent *motion* of the particles of which bodies are composed, the suspended heated body, could not communicate motion, or heat to another body not in contact, when there is nothing but a *void* between them; or if it could, it must be by means of the substance by which it is suspended: and in that case, the *upper* part of the exhausted receiver to which the suspending substance is fastened, would be *hot*, *sooner* than that part of the receiver opposite to the heated body; but it is not so, the heated body communicates its heat to any other near body, not in contact, through a *vacuum*: therefore, the heated body communicates

municates *something* flowing from its surface, to the colder body; *that something* by its action produces the sensation which we call *heat*, or communicates to bodies, those properties by which we know them to be *heated*; and *that something* is *fire*, whose existence is known by its action and effects; its action we call *heat*; and its affects are those which must arise, when the component principles of bodies are *separated* by the *interposition* of *fire*; consequently, its effects upon different substances must be different: and the *greater* the proportion of the two active principles, entering into the composition of bodies, the *more evident* will be those effects.

A metal consists of particles of the earthy principle, attracted to each other by a small proportion of phlogiston, interposed between those earthy particles. If a number of *igneous* particles insinuate themselves between *those* particles, they will cause them to recede a little from each other, and the consolidating or attractive power of the connecting *phlogiston* will be *weakened*, as *that distance* between the earthy particles *increases*. If  
the

the quantity of intervening fire be considerable, the attractive power of the phlogiston will be so weakened, that the earthy particles will be capable of being *easily moved* among each other, so as to be in a state of *fluidity*; and if the quantity of *heat* be *still augmented*, by insinuating itself between every line of active particles, surrounding the fixed central particles of matter, and between every particle forming those lines, they will be *so far removed* from their centres, and their *attraction* to them *so weakened*, that *both* the *ætherial atmospheres* immediately surrounding the fixed particles, forming the earthy principle, and the connecting *phlogiston*, will be so far dilated, by the fire interposed between every particle, that they will *recede* to *so great a distance*, as to become volatilized, and escape in the form of vapour. But so soon as the igneous particles separating and distending them, are removed, by passing off into surrounding bodies, *less heated*: those *expanded atmospheres* will gradually *contract*, and become *fluid*, or *solid* in progression, as the particles of fire escape from the interstices, betwixt the atmospheric lines which

F f

those

those active fluids form around those fixed particles.

Fire therefore is a fluid, or composed of subtile particles, and its *action* partly *mechanical*, weakening the attraction between the component principles of bodies, by insinuating itself into the interstices, formed by the arrangement of those principles, around their fixed centres; and even between each particle, and increasing their distances from each other; by which, their attractive powers are proportionately diminished.

The particles of fire seem to have but *little attraction* to each other, but a *general attraction* to the *atmospheres* of other bodies, of whatsoever kind: they seem to possess a *fluidity*, or tendency to *equal diffusion*, like water; and consequently, cannot form any atmospheric arrangement around other bodies: from all of which, when accumulated in, or upon them, it seems to flow off, according to the laws of fluidity, seeking to restore itself to an equilibrium.

It evidently differs therefore, from æther and phlogiston in their simple states, or in their states of excitement around bodies producing the phenomena of cohesion, electricity, or magnetism: it can therefore be *neither one nor the other* of them, *singly*; but, there can be no doubt that it is *composed of the two*; as is evident, both from *synthesis* and *analysis*.

The *electric fluids* are phlogiston and æther, in *certain* states of excitement; which, when they unite, form *fire*; as is evident from their melting metals, firing gunpowder, &c.

*Inflammable substances* when ignited in pure air, produce *fire*; at the same time that they lose their *phlogiston*, and the pure air its *æther*; therefore, the *phlogiston* and *æther* uniting, form *fire*.

Certain *calces*, composed of earth and acid, when separated by the interposition of *fire*, so far from each other, as to be no longer attractive, or attracted, are capable of *decomposing* that *fire itself*;

the earth will attract its *phlogiston* and acquire its metallic state; and the acid will combine with its *æther* and form pure air.

*Fire* therefore, is evidently a composition of *æther* and *phlogiston*, combined to saturation, or nearly so; in consequence of which, each fluid loses its general properties of attraction to certain kinds of matter, and of atmospheric arrangement in consequence of that attraction to bodies; and the degree of their attraction and activity, is equal to the degree of their excitement, when they combine with each other; therefore, when *æther* and *phlogiston* are *separated* from their respective bases, by means of heat, and in that state combine, they will still retain that degree of activity, and form *fire*.

But the degree of excitement of each, will in a great measure depend upon the force with which it was combined with its respective base: excitement being always proportionate to attraction; but the *phlogiston* united to certain bodies, so as to render them inflammable, is in general, so strongly

ly

ly excited, as to attract those particles together in a *solid form*, while the æther surrounding the acidifying particles in the form of pure air, is but *loosely combined*, and consequently moderately excited; therefore, 'tis natural to suppose, that when *that phlogiston* combines with this æther, it will be *more excited* than the æther is; but, being *forced* to separate from its earthy base, by the acid of the pure air attracting it, it must of necessity *unite* with the æther, and that union will produce *fire*, a compound of æther and *phlogiston*; in which state of union, however, the *phlogiston appears to be most excited*, and consequently most active.

In consequence of this *greater* excitement of the *phlogiston*, it will manifest its superior power, and have a *greater* degree of attraction to those substances which contain æther, either *simple* or *compound*, *than to those* chiefly composed with *phlogiston*; with such kind of substances therefore, it will form a *slight* union, so as to be *detained* in their interstices, in a combined or *quiescent* state; but with substances containing phlogiston, or more phlogiston  
than

than æther, it *cannot combine*, and will therefore flow through them *simply* as a *fluid*.

*Pure air* therefore, being composed chiefly of *æther*, widely extended in an atmospheric state around its centres of the acidifying principle, will *strongly attract fire*, on account of the *superior activity* of its *phlogiston*, which it will retain in a *quiescent state*, in its interstices, or between its particles; but *inflammable air*, will *not* attract and retain it; because, its aeriform state depends upon atmospheres of *phlogiston* surrounding the earthy particles as centres; therefore, the *quantity* of *fire* attracted by a certain measure of *pure air*, will *greatly exceed* the *quantity* flowing through an equal measure of *inflammable air*.

In like manner, a *metal* containing *phlogiston*, will not attract the fire flowing through its interstices, so as to fix or accumulate it: but if that metal, by calcination, be deprived of its *phlogiston*, and in its place attracts the acidifying principle, the *calx* formed by that combination, will attract the *phlogiston*, and consequently fix a small quantity

tity of the *fire*, which it in part composes; because, the acidifying principle in its acid state, hath an atmosphere of æther of small extent, and therefore the more active.

The superior activity of *phlogiston*, when combined with æther so as to form fire, appears highly probable, and readily accounts for the *different capacities* of different kinds of substances, for containing *heat*; a solid or fluid, containing *much æther*, will *attract* and *fix* a certain proportion of *fire*: but a body containing much *phlogiston*, will *not* attract or retain it: therefore, it flows from it on one side as fast as it is thrown in on the other; if any solid or fluid containing a less quantity, be near to receive it.

*Pure air*, on account of the *æther* in a great measure composing it, contains, or attracts and *detains* a considerable quantity of fire. If a piece of *phosphorus*, containing much *phlogiston*, be put into a certain measure of it, the *phlogiston* of the *phosphorus* will attract and combine with that *æther*,

*ther*, and escape in the form of light and *fire*: by which combination, its *acid* base will be deposited, and the *small quantity* of *fire*, combined with its ætherial atmospheres, now in a great measure lost, will be *disengaged* and become *sensible also*; excepting that small part of it, attracted and detained by the acid.

The *less* the quantity of fire contained in a certain measure of pure air, the *greater* the quantity of heat it will produce by combustion with inflammable substances; because, the *æther* will be *less rarified* or expanded; and consequently, a certain measure of pure air, will contain a greater quantity of *it*, capable of combining with a *greater* quantity of *phlogiston*, and producing *more fire*, than when rarified by a greater quantity of heat.

Fire is never *chemically* produced, but when æther and phlogiston have an opportunity of *combining* together, and *separating* from their respective substances; therefore, an inflammable substance, ignited in pure air, can only produce *fire*  
by

by *decomposing each other*; when the *phlogiston* of the substance, combines with the *æther* of the air, and forms *light* or *fire*: and the *acid* of the air, unites with the *earth* of the inflammable body; and that this is in reality the case, not only the *disappearance* of the *phlogiston* of the inflammable body, and the *æther* of the air, when fire is produced, proves, but likewise, the *decomposition* of *fire itself* by certain metallic calces, where it evidently affords *phlogiston* to the *earth* of the metal, and *revives* it: and at the same time, supplies the *acid* with *æther*, and converts it into *pure air*.

Fire is therefore evidently composed of *æther* and *phlogiston*, combined with each other in a state of great excitement; in which state they were separated from the substances with which they were previously combined; but it seems, that the *phlogiston* entering into the composition of fire, is *rather more excited* and *active* than the *æther* is. Perhaps the nature and properties of fire, depend upon the *phlogiston* being more excited than the *æther* with which it is composed: and when

æther

æther and phlogiston combine, each being *equally excited*, they so perfectly counteract each other, as to produce *no* sensible effects; but, when the *æther* is *more excited*, than the phlogiston, they then by uniting, form light.

However, fire is evidently a fluid, composed of æther and phlogiston, intimately united: where the phlogiston appears to be most active, or most abundant: but yet, they are so closely combined, and mutually saturated, that they destroy each others elasticity, or arrangement, and become a compound fluid, possessed of properties peculiar to itself; and those principles are never decomposed, or separated from each other, so as to form *chemical* combinations with earth, or acids, but when the quantity of fire is so great, and violent, as to *destroy* the power of union, between the *earthy* and *acidifying* particles composing a body; in which case, those particles will seize upon the fire itself: the *earth* will exert its power of attraction upon the *phlogiston*, and the *acid* upon the *æther*, and form two new compounds.

*Fire* then is an active fluid, whose properties as a compound of the two active principles, are very similar to those of *water*, a compound of the two fixed principles. *Water* hath a very general attraction to bodies: so hath *fire*. *Water* hath so strong an affinity with many kinds of solid or more fixed substances, as to overpower their attraction of cohesion, and remove their component particles at a distance from each other, by insinuating itself between those particles; but when the *water* is evaporated, the particles are left unaltered in their natures or properties. Just so it is with *fire*, with respect to the *atmospheres* of *active fluids*, essential to the principles of which bodies are composed, or connecting those principles together; for *fire* hath a general attraction to active particles of *either kind*, and when *either of those* are arranged around fixed principles in either a simple or compound state, so as to form acids, earths, alkalis, neutral compounds, metals, or any other kind of substances: those essential or connecting atmospheres of whichsoever kind, are attracted by this active compound; and if it be present in sufficient

ficient quantity, those atmospheres are as it were dissolved by it, because it insinuates its particles into *every interstice*, and even *between every particle* composing them; in consequence of which, they become more extended, the bulk of the body is increased, the attraction of those atmospheres to their fixed centres, are proportionately weakened, and indeed according to the quantity of fire insinuating itself between the particles forming those atmospheres, solid bodies may be rendered fluid, and fluids expanded into vapour; but so soon as the particles thus separated by the dissolving or interposing fire, are deprived of that fire, by suffering it to escape, they return to the state, and acquire the properties they possessed, before they were heated.

Indeed, Water and Fire seem to be the two grand solvents, and chief agents in nature; *water* being chiefly composed of the *two fixed principles*, hath its attraction, or exerts its dissolving powers chiefly upon them; while *fire*, being a compound of the *two active principles*, shews its attractive  
power

power upon those active particles, by insinuating itself between them, so as to weaken their connection and increase their extent.

Both water and fire enter into the composition of most bodies, in a greater or less degree, or quantity; in which state, their peculiar properties do not appear; but if those bodies be decomposed, or their particles approximated, the water, or fire, or both may become evident.

Though fire hath a kind of dissolving power, upon atmospheres of either kind of active particles, the same as water hath with respect to acids and alkalis, yet it seems to be most attracted by *æther*, or *ætherial* compounds, which have an affinity with it, and a power of combining with a certain proportion of it, so as to keep it in a *latent state*, or in fact, combined with those *ætherial* atmospheres: so acids, or compounds containing much acid, have a strong affinity with water, which they take into their composition, in a *latent state*; and which by decomposition, or concentration

centration by heat, may be rendered evident; in the same manner, as fire may become sensible by condensing or altering the state of a body detaining it, to a more solid form.

*Water* may be *decomposed* by certain bodies, as for instance by iron: the earth of the iron attracting its acidifying particles, and forming a *calx*, or *slag*, while the earthy principle of the water, combines with the disengaged phlogiston of the iron, and becomes *inflammable air*; in like manner, *fire* may be *decomposed* by the calx of mercury for instance, the earth of the calx attracting its phlogiston, and becoming mercury, and the acid disengaged from that earth, combining with its æther, and forming pure air. And an *earth* and *acid* in *certain states*, combining together, as invariably produce *water*: as *æther* and *phlogiston*, when sufficiently excited, by *uniting* form *fire*.

*Fire* therefore, is evidently composed of *æther* and *phlogiston*, in a state of *strong excitement*; and is a *compound fluid*, having a *general attraction* to those principles in an atmospheric state: and a peculiar

peculiar attraction to *ætherial* compounds, with which it can so far enter into combination, as to lose its *active properties*, and become *latent*, or *inactive*.

particular attention to the combination of light with heat, which it can be the cause of, as to the combination of light with heat, and become latent, or in-  

---

## SECTION XII.

*On Light.*

**L**IGHT is an elastic fluid, whose general properties of refraction, reflection, &c. are well known to all philosophers.

It is evidently of different kinds, or composed of particles similar to each other in subtilty, elasticity,

ticity, velocity, &c. but when separate producing different sensations, or ideas of colour different from each other; and the different kinds composing a beam of solar light are seven, (or perhaps but three;) which, when separated, and in that single or uncombined state, falling upon the reticular expansion of the optic nerve, produce the seven different perceptions or ideas, which are called the seven primary colours.

*Light* is evidently composed of *æther* and *phlogiston*, because, it is almost always produced when inflammable substances lose their *phlogiston*, by combustion in pure air, which by that same process, loses its elastic principle, its *æther*; therefore, the phlogiston and *æther* uniting, escape in the form of fire, accompanied with *light*.

And the same is fully proved, by metallic calces acquiring *phlogiston*, by being exposed to the *solar light*; and at the same time, the disengaged *æther* of the light, forming *pure air* by uniting with the *acidifying* principle, displaced from the calx

calx by its acquisition of phlogiston, and becoming a metal. And indeed, so many circumstances tend to prove it, and so much hath already been said upon the subject, in different parts of this work, that I shall only mention this one additional circumstance,

Vegetables by exposure to *light*, evidently *decompose* it, and retain and fix its *phlogiston*, at the same time, that the *æther* the other part of light, is thrown off as useless or excrementitious; it therefore combines with the acid particles in the fluids of the vegetable, and is expelled in the form of *pure air*.

Light is very different from either *æther*, or *phlogiston* singly; because, being composed of *both*, their peculiar attractions, and arrangements, counteract each other; and it will therefore neither form atmospheres around bodies, nor enter into chemical union, *unless* it be *decomposed*.

It differs from fire, though composed of the same principles, as being much more elastic, and  
subject

subject to refraction and reflection, according to circumstances.

However, fire when rapidly flowing off from the surface of any body, in which it is greatly accumulated, is *partly* changed into *light*; and light when thrown in a *condensed* state, upon a body which resists its motion, and refuses it a ready passage through its pores, becomes *partly* changed into *fire*.

Fire and light therefore, are evidently composed of the same principles, æther and phlogiston; but having different properties, those principles must be in different states of combination; in *one state* exciting the sensation of heat, and possessing those properties which we attribute to *fire*: and in *the other*, producing the sensation of colours, lights and shades, and all the phenomena of *light*.

Though æther and phlogiston, when in that state of combination which we call light, destroy each others peculiar affinities to other bodies, and arrangement, so as to form a fluid almost

any chemical affinities, yet it appears, that the *æther* is the *most excited* and *active* of the two; because light will pass readily through bodies chiefly composed of *æther* or acid: but to bodies containing much earth or phlogiston, it seems to have so great an affinity, that it will not easily leave them; and therefore, in passing through them, it *loses* so much of its force and elasticity, as to be *incapable* of exciting the perceptions or ideas of light, and in general is charged into *fire*, and gives the sensation of *heat*; for most *earthy* bodies, and *inflammable* substances, are *opaque* and become *heated* by exposure to light.

It appears therefore, when *æther* and phlogiston combine and form *fire*, that the *phlogiston* is *most excited*; but when they form *light*, the *æther* is the *most active*; and when by any circumstance, they suffer a considerable change in their mode of combination, they may be *converted* from *one state* to the *other*; and when exposed to each others action, in the two different states, they may counteract and destroy each other, as we evidently see  
is

is the case, when the light of the sun falls upon a fire, the superior activity of the *æther* in the light, counteracts the greater excitement of the *phlogiston* of the fire, by which they destroy each other: the fire becomes dull, and is at length extinguished.

But since light is composed of *æther* and *phlogiston*, how does it happen, that different particles of it, are possessed of different properties, and produce different sensations or ideas of colour? It must be owing to *different particles* of the *æther*, having *different degrees* of excitement: or, to the different proportions of *phlogiston* combined with that *æther*.

If *glass* contains *no phlogiston*, but as I have before mentioned, be chiefly composed of acidifying particles firmly united by a small proportion of *æther*, or with a small quantity of earth, it will follow, that the *violet rays* of *light*, being *more refracted* by the prism, than the *red*, must contain *more phlogiston*, or *æther less active*, than the red rays do; as being more impeded, or drawn aside,  
in

in their passage through the phlogistic atmosphere attracted to the surface of the prism.

For if glafs be chiefly composed of acid and æther, it will naturally attract the circumambient *phlogiston*, like an *atmosphere*, to its surface; and this phlogiston will attract the active *æther* of *light*; but, as they cannot combine, the *motion* of the particles of light will carry them forwards; which accounts for the transparency of glafs, which transmits light without reflecting it.

But, inflammable substances, *gold* for instance, being composed of earth and phlogiston, will naturally attract to its surface the surrounding *æther*, every where present, and *that æther* will *repel every particle* of *light*, whose *æther* is in a state of excitement *similar* to itself; gold therefore attracts to its surface an atmosphere of *æther*, which is *excited* by that attraction to a *certain degree*: if a beam of light falls upon this, the *æther* of the *yellow rays*, being *just as much excited* more than its phlogiston, as the *æther* surrounding the *gold* is, will be *repelled*  
or

or *reflected*, and give the perception or idea of a *yellow colour*, in different degrees of light and shade, according to the form of the surface exposed.

But *those rays*, whose æther is either *more*, or *less excited*, than the æther attracted to the surface of the gold, will only be *partly* and *weakly* reflected; part of them having perhaps even a slight attraction of arrangement, to that more or less excited ætherial atmosphere of the gold, will therefore *pass* through it, to the gold itself; where, being attracted by its phlogiston, they will lose their velocity, and the *peculiar excitement* of their æther, upon which the properties of light depend; and *that æther*, will then combine with the *phlogiston* accompanying it, now *equally* active, as itself, or perhaps *more so*; and by that new mode of combination, they will form *fire*.

'Tis evident therefore, that no particles of light will be repelled, or reflected with their full force, or velocity, but *those* whose æther is in a *similar* state of excitement, and equally attracted by *their*

*own*

*own phlogiston*, as the *ætherial* atmosphere of the *metal* is, with respect to the *phlogiston* entering into the *composition* of that *metal*; in which case they cannot unite, or penetrate each other; therefore, those particles of light will be *repelled* by their velocity and elasticity, while the other particles will be *slightly reflected*, or partly retained, and being promiscuously and violently mixed together, will lose their elasticity and form *fire*, and give the sensation of heat instead of light.

Since then the violet rays are the most, and the red the least refracted by glass, it appears, that the violet rays, or particles of light, contain æther in the least active state, and the red rays have their æther in the most excited state; consequently, as excitement is inversely proportionate to the quantity, or extent of atmosphere, it must follow, that particles of light giving the idea or perception of a *violet colour*, are composed of *phlogiston*, with a *large atmosphere* of æther: and *red rays*, of phlogiston, with a *small and more excited* atmosphere of *æther*; and the intermediate rays of the spectrum, have their æther more or less excited,

or

or extensive, as they approach, or recede from those extremities of the spectrum, of separated light.

*Lead* in its native state, contains much phlogiston; that quantity of phlogiston being considerable, and *loosely* united to the earthy base of the lead, will be but *slightly* excited; and in consequence of that, will attract an atmosphere of *æther* to its surface, which will be slightly excited also; when therefore, rays of light fall upon the lead, the *æther* of the blue rays being but slightly excited, and in a similar state with the *æther* surrounding the lead, will be *forcibly reflected*; but the other rays, green, yellow, orange and red, having *æther* in a *more* excited state, and more attractive to phlogiston, will only be partially and weakly reflected; while the other part passing through the atmosphere on its surface, will enter into the substance of the lead; where, they will lose their properties of light; and becoming *fire*, will *heat* the *metal*.

But

But if lead be deprived of part of its phlogiston, by calcination for instance, so as to form minium, that remaining phlogiston will be small in quantity, closely combined, and much excited; consequently, it will attract surrounding *æther* with more force, than in its metallic state; *which æther* will therefore become more excited; in this state it will repel the *red rays*, because, their *æther* is in a similar state of *strong* excitement; but the *other rays* will be partly reflected with little velocity, and partly attracted, and condensed in the lead so as to form fire.

Lead when it contains its *full quantity* of *phlogiston*, is of a bluish white colour: when deprived by calcination of part of it, it becomes *greenish*; when more calcined, *yellow*: then *orange*, and last of all *red*; therefore, the *more phlogiston* it contains, the *nearer* it approaches the *violet colour*: and the *more* it is *deprived* of that phlogiston, the *nearer* it gradually approaches, the *other end* of the natural scale of colours, till at last it becomes of a beautiful red.

The *kind* of rays of light reflected, depends therefore upon the quantity of phlogiston, whose excitement, is *inversely* proportionate to that quantity: and the quantity of æther naturally surrounding the surface of that lead, will be excited always *in proportion* to the excitement of that phlogiston; therefore, as the æther forming *different particles* of light, is in *different states* of excitement, being the *least* excited in the *violet* rays, and proportionately *more and more* so to the *red*, 'tis evident, that the more the lead is deprived of its phlogiston, the more will the remainder be excited, and with it the surrounding æther: and *that* æther, being *repulsive* to particles of light in the *same state* of excitement from phlogiston, as itself, will *repel* first *one* kind of light, and then *another*, in progression; at first when little excited, it will reflect the blue rays: when more excited, the green, or yellow: and when at last the phlogiston of the lead is much diminished, and much excited, its surrounding æther will be in the *same violent state* of excitement as the æther of the *red rays* are; and consequently, the *red rays alone* will be reflected

with their *full force*, or *degree* of *velocity*, upon which their power of exciting the sensation of colour, in a great measure depends.

Gold, as before mentioned, reflects most forcibly the yellow rays; because its ætherial atmosphere, is in a similar state of excitement, with the æther of the particles of light, forming the yellow rays: therefore, they will be repelled with their full force. But the other rays having their æther more or less excited, will not be so fully acted upon by the ætherial atmosphere of the gold, therefore, they will in part, pass through that atmosphere, and be attracted into the gold, so as to form *fire*; and partly be repelled, but with diminished force, producing a *faintish white*, if the yellow rays be intercepted; but if they be not, the *force* with which those others are reflected, being *much diminished*, they will not injure the *more powerful effect* of the *completely reflected yellow rays*; which, will therefore produce the *sensation* of a *yellow colour*.

The solar rays, undoubtedly contain all the different kinds of particles of light. These compound

pound rays, or beams, when *entire*, give the sensation of *whiteness*; therefore, every thing which appears white, reflects all kinds of particles, or rays of light.

A body that appears *red*, must evidently reflect the red rays: but, it will likewise appear blue, green, or yellow, if those kinds of rays be thrown *singly* upon it; which shews, that a body may *appear red*, though it reflects rays of every other colour, as well as the red ones; and the reason must be, that the *red rays* are *more perfectly* and *completely reflected*, than those of any other kind; consequently, their *velocity* and *superior activity* will produce *so strong* an *excitement* of the optic nerve, as to render it *incapable* of perceiving the *weaker impulses* of the *other kinds*, partially reflected, and with diminished velocity.

Bodies containing *no phlogiston*, such as glass, vitrifiable substances, and many kinds of salts, give *no* particular colour: but readily transmit through them rays of light of every kind; such  
kind

kinds of substances, certainly contain the acidifying principle with *æther*, and *that æther* may be naturally supposed to have a *peculiar attraction* to the *phlogiston* universally present, rather than to *æther*; as appears evident from glass, which when rubbed, excites an atmosphere of phlogiston to become electric; therefore we may suppose, that these kinds of substances have an attraction to *phlogiston* in their natural state, *which is gently excited, and attracted to their surfaces.*

The rays of solar light, falling *obliquely* upon this phlogiston, as in experiments with the prism, are all readily transmitted through it, and through the glass itself; which shews, that those rays of light have their *æther* in a *more active state, than* their *phlogiston*; because, they are *not* reflected, but readily transmitted; and as *some* of those rays are *more refracted, or bent* from their direct course, *than others*, it proves, that *some* of them have their *æther* more excited, *than others*. Perhaps the *more excited* the *æther*, the *less* will it be drawn from its direct course through that phlogistic

gistic atmosphere of the prism, as being of *less extent*, and *less resisted*, as is the case with the *red rays*; and the *less excited* and *more extensive* the æther of a particle of light, the *more* will it be *affected* and detained by the slightly excited phlogistic atmosphere, and be drawn *so much the more* from its direct course, or be *so much the more refracted*, as is the case with the *violet rays*.

If light then is composed of phlogiston, and æther in a more active state than that phlogiston, and some rays have their æther more excited than others, 'tis evident, that *phlogistic* substances, attracting the *circumambient æther* to their *surfaces*, will *reflect* those rays, more or less perfectly. If *all* the rays are reflected, the body will appear *white*; but if *one kind* of rays be *more perfectly* or *forcibly* reflected than the others, the body will appear to be of *that colour*, which those *completely reflected rays* naturally excite.

It appears therefore, that every body which reflects rays exciting the idea of one certain colour,  
hath

hath its *ætherial atmosphere* in the *same degree* of excitement, as the *æther* composing *that kind* of rays hath; in consequence of which, they are reflected *perfectly*, and with their *full velocity*; but those substances, reflecting *no certain kind of colour*, have their *ætherial atmospheres* in a state of excitement, *different* from the degree of excitement, of the *æther* composing *any particle*, of *any* of the *different kinds* of light.

Those rays of light which are *imperfectly* and *partially* reflected, will *partly* pass through the *ætherial atmosphere*, *into the body itself*; where, meeting with the phlogiston partly composing it, they will be *detained*, and *mixed together*, so as to lose their velocity, and properties, *as light*; in consequence of which, they will combine in a *different manner*, and form *fire*, as before intimated.

Colouring particles of phlogistic matter, *suspended in transparent liquids*, will act in a similar manner: only instead of those particles of light, whose *æther* is in a similar state of excitement  
with

with that furrounding them, being *reflected* by them, they will in general be *pushed aside*, and pass by them, through the liquid in which they float, and by which they are easily transmitted; so that the *colour transmitted*, is *that*, which is excited by *those rays*, *expelled* by the phlogistic or colouring particles; and *that light*, or colour, may be reflected through the liquor, by any proper surface on the further side, so as to give the idea of light, or colour reflected by the colouring particles *themselves*.

Bodies of a *loose* texture containing a superabundance of phlogiston, and that so little excited, as to have no power of attracting a sufficiently dense ætherial atmosphere around its particles, attract and fix rays of light of every kind on account of their æther; which rays, being confusedly and forcibly mixed together, in the irregular vacuities of the substance, will form *fire*; and no part of them being reflected, the matter appears *black*.

But those substances, of an irregular or *loose* composition, and containing æther in a dense state, or in a state of excitement different from, or greater than that of the æther composing any of the rays of light, will repel or reflect those rays of *every kind*, and produce the sensation of a *white colour*.

That bodies of all kinds, have an attraction to the æther, or phlogiston naturally present: one or other of which, they always excite in some degree or other, to surround them in an atmospheric form, in their natural or common state, is undoubtedly a fact; for rays of light we see, are acted upon, at a considerable distance from the body by whose atmosphere they are attracted.

But, as a full proof, that bodies do attract atmospheres around them, to a considerable extent: and that *phlogistic* substances have an *atmosphere* of a *contrary* nature, or kind, to what *glass* or *æthereal* substances have: and consequently, that most probably a phlogistic substance attracts an ætheri-  
al

al atmosphere, and an ætherial body a phlogistic one: I need only mention the experiment of exposing glass, and metal to *air* when depositing *dew*. The *ætherial* atmosphere surrounding the metal, *repels*, or *drives away* the water in that atmospheric state of vapour, so that not a particle of it can fall within that atmosphere, or upon the *metal*: while the *phlogistic* atmosphere, attracted to the surface of *glass*, attracts those particles of water in their atmospheric state, and *condenses* them upon its surface, in the state of *dew* or *water*.

This mode of explaining the fact, that certain bodies reflect rays of one colour, more forcibly or evidently than others of a different kind, is only offer'd as a *conjecture*; all that I at present insist upon is, that *light* is *composed* of the two active fluids, *æther* and *phlogiston*: that it is produced when *in certain circumstances* they unite: that in *other circumstances*, it is capable of being *decomposed*, and giving *phlogiston* to certain earthy substances, and *æther* to the acidifying principle: and that when *condensed*, and forcibly crowded in certain bodies,

not capable of transmitting it, it becomes *fire*, and evidently *beats* the obstructing body.

Having now given an explanation of the elements, or first principles of nature, and the laws by which they act or are governed, and examined then, in the different states of excitement, in which they can exist *singly*: as well as in their *simpler* states of *combination*: I shall next consider, that other very common state of their existence, where, the *four* principles are *mutually saturated* with *each other*, so as to form that inestimable neutral compound, *Water*.

---

### SECTION XIII.

#### *On Water.*

**W**A T E R is a simple neutral fluid, which in different degrees of heat, is capable of assuming different appearances, and degrees of solidity. If the quantity of heat be diminished to  $32^{\circ}$ , or below that, of Fahrenheit, its particles attract each other, in a certain mode of arrangement,

ment, and in so forcible a manner as to become a *solid* body, which is called *Ice*; but if the heat be increased to  $212^{\circ}$ . or upwards, its particles then become repulsive, and expand with great force into the state of *vapour*.

Water is evidently material, and even manifestly composed of the more fixed principles; yet, it is neither acid nor alkaline: consequently, it must be formed of *acidifying* particles, united with the *earthy principle*.

When the earthy and acidifying particles come into contact, they strongly attract each other, and form a solid ponderous compound, such as glass; but glass is more solid and ponderous, and less fusible than ice: and requires a much more violent degree of heat to render it fluid, or evaporate it, than ice does: therefore 'tis natural to suppose, that the *two fixed principles* composing *water*, are *each* accompanied with the *active principle* to which it hath an affinity, excited to surround it to a *certain extent*: but not sufficient to give it so *complete an atmosphere*, as to render it aeriform.

Ice

Ice will therefore be composed of particles of the earthy principle, surrounded by *small* atmospheres of *phlogiston*, consequently in an active state: united to, and consolidated by particles of the acidifying principle, surrounded by atmospheres of *æther*, of a *certain extent*, and in an active state; those atmospheres firmly attracting, and saturating each other, so as to form the solid neutral compound, *Ice*.

If a quantity of *fire* be applied to this *ice*, it will insinuate itself into *every interstice*, between those atmospheric lines of particles; and by its *general attraction* to the active particles of either kind, when in an atmospheric state, it will insinuate itself *between those particles themselves*, forming those atmospheric lines; in consequence of which, the peculiar attraction by which one *compound particle*, was arranged and attracted to the contiguous particles, so as to form a *solid*, will be *weakened*: and those respective atmospheres so extended, as to readily admit a *freedom of motion* among those compound particles; so that they may be moved  
in

in any direction, by the slightest force. In this state of fluidity, they are called *water*.

If now the quantity of *fire* be much increased, it will insinuate itself so copiously between every active particle, as to increase their atmospheric extent to a great distance from their respective centres; in consequence of which, their attraction to those centres will be greatly weakened, and therefore the attraction between the earthy and acidifying principles must be very much diminished; so that each fixed principle, will be surrounded with atmospheres, so extended, by the particles of *fire* taken into arrangement, and insinuated between the lines of active particles forming those atmospheres, that they will be in an *aeriform state*, or that of *vapour*; each particle on account of its widely extended atmospheres, keeping every other at a considerable distance: and having little attraction of union to particles of the opposite kind, because the natural excitement of those atmospheres are weakened, in proportion as they are removed from their respective exciting centres. At the same time, those particles of *fire*,  
by

by entering into combination with those atmospheric particles, *lose*, in a great measure, their peculiar properties as fire, and only resume them, so as to manifest their *heating* power, when they *leave that combination*, to enter into bodies possessing a less quantity of them; in consequence of which, those atmospheres will again contract: and the fixed principles will gradually approach, so as to regain the state of *water*, and *ice* in progression, as the *igneous particles escape*.

To explain the subject still further, by a comparison, the *fixed principles*, being composed of *fixed* particles of *matter*, surrounded by *inseparable* atmospheres of one, or other of the *active principles*, capable of giving *atmospheric* arrangement to *active particles* of the *opposite kind*, may be compared to particles of *iron* giving *magnetic* excitement, to one or other of the active principles. The *earthy* principle, with a *small* atmosphere of *phlogiston*, will resemble the magnetic pole, pointing to the *south*; and the *acidifying* principle, with an atmosphere of *æther*, will be like the magnetic pole pointing to the *north*. A particle of water therefore, being

composed of a particle of the earthy principle, surrounded by some phlogiston, combined with an acidifying particle, exciting a small atmosphere of æther, will resemble a magnetic needle: the earthy particle being the south, and the acidifying particle the north end of that compound particle of water. If another particle of water, be brought near to the former, the earthy particle of each, will attract the acidifying particle of the other, by which, they will therefore be *firmly attracted together*, and arranged in an *inverted position* with respect to each other; the same as the south pole of one magnetic needle, will attract and forcibly hold in contact, the north end of another. In this state, the needles will resemble *ice*: the opposite poles being firmly united, and peculiarly arranged, to each other.

If those two particles of ice, be *separated*, or pushed to a distance from each other, by the interposition of particles of *fire*, they will resemble the two magnetic needles, when forcibly separated to a small distance; in which state, their mutual attraction being *weakened* by distance, they may  
be

be easily moved, but will still attract each other with evident force; so the particles of ice, now mutually attracting with diminished force, are capable of being easily moved, from their present situations with respect to each other; in which state, they form that fluid called *Water*.

But were those *magnetic* poles totally separated from each other, by any interposing medium combining with their magnetic atmospheres, so as to *extend* them to such a distance, as nearly to *destroy* their magnetic excitement: at the same time, that *every interstice* was *filled* with the interposed medium: 'tis evident, that they would be made to *recede* from each other, by the pressure of that medium surrounding every pole, and have but *little* power of counteracting that separating force, by the attraction of the opposite poles, in that state of debility. So it is with the compound particles of water, when *much fire* is mixed with them; for the interposing *fire*, *extends* the *atmospheres* of the two *fixed principles*; *weakens* their natural *excitement*, and *separates* them nearly into *distinct parti-*

*cles*, each surrounded by its respective *atmospheres*, *extended* and *turgid* with the particles of *fire* interposed, and connected with those *atmospheres*; in consequence of which, *each particle* must be forced to a *distance*, from every other, and the *phlogistic fiery atmosphere* of the *earthy particles*, will have but *little tendency to unite*, with the *ætherial atmospheres* of the *acidifying particles*, as *replete* and *saturated* with *igneous particles* as themselves: therefore, the particles of the water, will expand into the state of vapour.

'Tis evident also, in this state of vapour, where the *fixed* principles, composing water, are so *separated*, as to have scarcely any connection, that they may be readily decomposed; which in fact may easily be affected, and is a proof of the veracity of the principles proposed.

For instance, *iron* is composed of *earthy* particles, rendered metallic, and connected together by means of much *phlogiston*. If this *phlogiston* be *extended*, and its attraction to those *earthy particles*

cles *weakened* by means of *fire*, and in that state be exposed to the action of *water*, in the violent state of *vapour*, by means of *fire* disuniting its component fixed principles, and rendering them *aeriform*, by combining with and extending their respective atmospheres of active particles, 'tis evident, that the *phlogiston* of the iron, will attract the *ætherial* atmospheres of the acidifying particles composing the water, by which those *acidifying* particles, will be drawn into *contact* with the *earthy* particles of the *iron*, and attracted by them: in consequence of which, those *earthy* particles will lose their attraction to their *phlogiston*, which will be *expanded* and eagerly *attracted* by the *earthy particles* of the *water*, now rendered *powerfully active*, by losing those *acidifying particles* attracted by the earth of the iron, with which *they were* before *combined* and *saturated*; but now being entirely separated from them, these *earthy particles* of the *water*, thus left with *small, unsatisfied, and active atmospheres* of *phlogiston*, will eagerly *attract* into arrangement, the *phlogiston displaced* from the earth of the *iron*, so as to surround themselves with complete phlogistic atmospheres;

atmospheres; by which they will acquire an *aeriform* state, and become possessed of those properties, which distinguish them to be *inflammable air*.

It appears therefore, that when violently heated, the attraction of the *earth* of iron, to the *acidifying* particles of water, in an *active* state, and of the *earth* of water not saturated with phlogiston, to the *phlogiston* of iron, together, are *stronger*, than the united attractions of the *earth* of iron to its *phlogiston*, and of the *earthy principle* of water, to the *acidifying principle*; each *fixed principle* being in an *active* state, and, by means of *fire*, *separated*, so as *not* to be capable of saturating or satisfying each other.

Heated iron therefore, exposed to water in the state of vapour, will attract the *acidifying particles* of *that water*, and form a calx or slag; and at the same time, will give its *phlogiston* to the disengaged active *earthy particles* of the *water*; which, attracting that phlogiston around them, will become *aeriform*, or possessed of complete atmospheres,  
so

so widely extended, as to be no longer evidently excited, or possessed of alkaline properties; in which state, they are called inflammable air.

Water therefore, is composed of the *acidifying principle*, surrounded with a *certain* quantity of *æther*, which *æther* is in that state of excitement, which is called *acid*, being strongly attractive, either to phlogiston in a similar state, or to disengaged particles of *æther* themselves; so that the *æther* surrounding each acid particle, by its *attraction of arrangement*, will attract *æther* sufficient to envelope every particle with a complete atmosphere, by which they acquire the properties and name of pure air,

Those particles, in this acid, or active state, combining with particles of the *earthy principle* in a state of great activity, mutually attract and saturate each other, so as to form that neutral compound, *water*; for the *earthy particles*, thus satisfying the acidifying particles, are each enveloped in a *small atmosphere* of *phlogiston*, which in that state,  
gives

gives them the properties which are called *alkaline*; having a strong attraction to *acids*: and also a power of taking into *arrangement*, so great a quantity of *phlogiston*, as to give them the state and properties of *inflammable air*.

Pure air is therefore composed of acidifying particles, *fully* saturated with, and surrounded by *complete* atmospheres of æther; and inflammable air, of particles of the earthy principle, rendered aeriform, by *perfect* atmospheres of phlogiston; each being in a great measure inactive, on account of the great extent of its atmospheres, which become less excited as their distance from their respective actuating fixed principles, as centres, increases.

If these two airs, or gases be mixed together, and their respective atmospheres of æther or phlogiston be still *further extended* by means of *fire*, or any ignited body, the *external* and *less forcibly attracted* particles of *those atmospheres*, will unite, and *separate* from their respective centres; and in that state, they will form *fire*, or *light*, or *both*, and escape;

escape; and at the same time, the fixed *earthy* and *acidifying* principles, *each* still retaining a *certain* portion of those *external* atmospheres, by which they were surrounded, and which, to a certain extent, they too powerfully attract, to be *easily* separated from, are by those remaining atmospheric particles attracted to unite, and form *water*.

The indefatigable, and justly celebrated Dr. Priestley, hath lately doubted the production, or generation of water, by exploding pure and inflammable airs together; because, in his Experiments, the fluid residuum, was not *pure water*, but evidently contained *some acid*. But those Experiments, in reality prove no more than this, that the quantity of inflammable air, necessary to supply *phlogiston* sufficient to saturate the *æther* of the pure air employed, did *not* contain *enough* of the *earthy principle*, deposited by that phlogiston, to *saturate* the *acid particles* separated from the *æther* of the pure air; or, that the quantity of phlogiston in inflammable air, is in *too great* proportion to the *æther* in pure air; in consequence of which, the acidifying particles are too much deprived of

their æther, and the remainder is in that state of activity, which constitutes acidity. So that if the proportion of phlogiston be too great, or of the earth too small in the inflammable air employed, the acidifying particles will be left too active, or not saturated, and the compound residuum will be *water with a slight acidity.*

And that this disproportion, is the cause of the *acidity* of the water generated, is abundantly evident, from comparing the *quantity* of *acid* found in Dr. Priestley's Experiments, with the *much greater quantity*, which the *same measure* of *pure air* would have deposited, had it been decomposed by *phosphorus*. For in the Drs. Experiments, 500 ounce *measures* of *pure air* only afforded as much acid as was equivalent to 12.54 grains of concentrated acid of vitriol; which quantity of acid is capable of saturating as much vegetable alkali as is contained in  $22\frac{1}{2}$  grains of nitre crystallized in mean temperature. The sediment of the same liquor was also supposed to contain, at least, as much acid as the liquor itself. So that the whole quantity

quantity of acid deposited may be supposed to be equal to about 25 grains of concentrated vitriolic acid.

The 500 Ounce measures therefore of pure air, by combustion with inflammable air, deposited so much acid as was equivalent to about 25 grains of vitriolic acid, which would saturate about 15 grains of soda: but had that quantity of pure air been decomposed by combustion with *phosphorus*, it would have deposited about 380 grains of acid, which would have saturated upwards of 1000 grains of soda.

But in Dr. Priestley's experiments, that quantity of pure air, when decomposed by inflammable air, produced only 25 grains of acid, in the liquor and sediment; which together, if we suppose of the *same kind*, and strength, as that generated by combustion with phosphorus, would only saturate 70 grains of soda: therefore, as the whole quantity of pure air is nearly equally decomposed in both cases, the other 355 grains of acid must be contained in the *liquor produced* by the operati-

on; where being *not evident*, as an *acid*, it must be combined to saturation with *something* capable of neutralizing it; and that something must either be *æther*, or *earth*, or *both*; but if it were *æther*, the acid would still be aeriform which it is not, therefore, it must at least in part be the *earthy principle*, in a state of great activity, or in that state which we call *alkaline*; and *that earthy principle* in its *alkaline* state, must be supplied by the 1000 ounce measures of *inflammable air* employed in the experiment, *partly* deprived of its *phlogiston*, by that phlogiston's uniting with the *æther* of the pure air and producing light and fire; in consequence of which, the *earthy principle* with its *active* residuum of *phlogiston*, combines with the *acidifying principle* with its *active* residuum of *æther*, and forms *water*.

But 1000 ounce measures of inflammable air, weighing about 60 grains, exploded with 500 ounce measures of pure air weighing about 380 grains, produce about 440 grains of water, containing about 25 grains of acid; consequently, if

those

those 25 grains of acid are abstracted, the remainder will be *water* in its perfect, or *neutral* state.

It appears therefore, that if the 25 grains of acid furnished by the pure air, be deducted from the weight of the pure air employed, the remainder of that pure air, about 355 grains must enter into the composition of the water. Of what do those 355 grains consist?—If 100 grains of pure air be decomposed by phosphorus, the phosphorus will gain 100 grains in weight, and those 100 grains are *acid*, and capable of saturating 280 grains of soda: consequently, the weight of pure air is that of its *base*, and *that base* is *acid*; therefore, the 355 grains, entering into the composition of the water, in the former experiment, are 355 grains of acid: and that quantity is combined with the *base* of the *inflammable air*, and neutralized so as to form *water*. But an acid can be neutralized, or dispossessed of its acid properties, by nothing but the *earthy principle* in an active or alkaline state, or by *ether*; therefore, the base of inflammable air is an *earth*.

But

But the inflammable air only weighed about 60 grains, therefore could not afford more than 60 grains of earth to combine with, and saturate those 355 grains of acid: consequently, the proportion of the earth to the acid in water, cannot be greater than about 1 to 6. But, *water* is a *neutral* fluid, neither evidently acid nor *alkaline*: therefore, the *acid* composing it, must be *partly saturated* with the *earthy principle* in an *active* state, and *partly* with *æther*.

But, from Mr. Kirwan's Experiments, pure air it seems may contain about one eighth of its weight of water, and inflammable air about one half; therefore, if those proportions be deducted, the 355 grains of pure air, will be found to contain about 310 grains of acid, and the 60 grains of inflammable air, about 30 grains of earth; which uniting, will form water, and mix with that which they contained already formed.

Water therefore, in reality, seems to be composed of a greater number of acid than of earthy particles; the proportion, without pretending to ascertain

ascertain it, may be supposed, for conveniency, to be 10 of the former, to 1 of the latter; and consequently, the ætherial particles forming atmospheres around those acidifying particles, must be *so far extended*, as to have only about *one tenth* of the *activity* or *excitement*, which the *phlogistic particles*, furrounding the earthy particles to a proportionately less extent, have: by which proportion, the *activity* of those *ætherial* particles, will be *so diminished*, as to render their acidity imperceptible; and the water they compose, by combining with the *more active phlogiston* of the earthy particles, will still be *neutral*.

When water contains but *little fire* in its interstices, *each earthy particle* with its small phlogistic atmosphere, if unaccompanied with other earthy particles, would attract 10 *particles* of the *acidifying principle*, to its surface; and they would arrange themselves around it, in angles of about 60 degrees, so as to equally divide the surface of that atmospheric earthy particle amongst them; and in that case, the external phlogistic atmosphere of the earthy particle, would unite with the external ætherial atmospheres of the acidifying particles,  
and

and draw each of them towards it, till their respective *internal essential* atmospheres came into contact; by which, they would become firmly fixed to each other, in that particular mode of arrangement, so as to form a solid particle of *Ice*.

It appears therefore, when a number of acidifying particles with ætherial atmospheres, of moderate extent and excitement, are mixed with a smaller number of earthy particles, with phlogistic atmospheres, of less extent and greater excitement, in a certain proportion, that they counteract each other, so as to produce a *neutral* compound.

If these neutral or compound particles, be mixed with a number of *igneous* particles, sufficient to weaken their mutual attraction by expanding their atmospheres, each *earthy* particle, will be surrounded, by its proportion, of the *acidifying* particles, moderately attracted to its surface; but not so firmly united, but, that every particle can be moved with the gentlest force; so that the whole, will be in that state of *fluidity* which we call *water*. In this state, each acidifying particle  
being

being furrounded by *ætherial* rays, extending in all directions, *those on that side* next its *particular earthy centre*, will be attracted with considerable force, by the *phlogistic* atmosphere of *that centre*; while *those* extending *outwardly*, or in a contrary direction, will attract the *phlogistic* rays of the *neighbouring earthy centre*, extending *through that space* left between the acidifying particles, (attracted at certain angles, or distances to that surface,) *which* is opposed to those *ætherial* rays: in consequence of this, the particles of water, have a *mutual attraction* to each other.

If the quantity of *fire*, commixt with these particles, be *diminished*, till the respective atmospheres furrounding each particle, be sufficiently contracted and active, the *phlogistic* atmospheres of the earthy centres, will gradually attract the *ætherial* atmospheres of the furrounding acidifying particles, till their respective *internal*, or *essential* atmospheres come into contact; when, they will be *suddenly* and *violently* drawn into *close union*, so as to become a *solid*, or *ice*; and the fire, before con-

ned with those atmospheres, will become *disengaged* and be *expelled*.

But in the state of water, the particles were so slightly connected, as to move in any manner, or direction, so as to give the most space to the moving body, and occupy the least room; but now, each atmosphere acquiring its proper force, by becoming disengaged from the interposing particles of fire, a certain *arrangement* takes place, at the moment of congelation; every *earthy* centre *attracts* and *firmly fixes* its proper number of *acidifying* particles to its surface, at certain *angles* or *distances* from each other; and as the ætherial atmospheres of those distant acidifying particles, attract the phlogistic rays of the neighbouring earthy particles, extending from the *spaces* between *their* respective acidifying particles, 'tis evident, that at this moment of congelation when each acidifying particle becomes fixed in its proper place, to its own proper centre, that it will attract the neighbouring particle of water, to arrange itself so, that it may attract the centre of the unoccupied *space*, or *that part* of the neighbouring

bouring earthy particle, which is *most distant* from the acidifying particles *properly* surrounding it; and in *that position*, or *mode of arrangement*, the two particles will become *firmly united*, and capable of taking *others* into a *similar arrangement*, so as to form a *solid mass of ice*.

But, if the water, instead of being robbed of the quantity of fire necessary to its fluidity, be exposed to the action of a *still greater* degree of heat, equal to  $212^{\circ}$  or upwards, that increased quantity of fire, will distend every atmosphere, of every particle composing that water, and enter into atmospheric arrangement with them, by attracting and insinuating itself, between every active particle, forming those atmospheres of either kind; by which, they will be so extended, and their activity so weakened, that their respective fixed centres, will be very far removed from each other; and the contrary kinds of particles, forming each particle of water, will be but *slightly connected*.

When

When the quantity of fire becomes so great, as to *expand* those atmospheres to a *certain extent*, the ætherial atmospheres extending from the surrounding acidifying particles of *one* particle of water, will lose *their* power of attracting the phlogistic rays extending from the central earthy particles of the *neighbouring* particles of water; partly on account of each atmospheric ray being *weakened* by extension, and partly by the ætherial atmosphere of each acidifying particle, surrounding each earthy centre, being so *turgid* and *expanded*, as to *press* upon *each other*, and fill up *those spaces* naturally left between them in their state of water; by which, the *egress* of the *phlogistic rays* extending from each respective earthy centre, will be *perfectly intercepted*, and every attraction between the particles of water must cease; and each compound particle of water, being thus *prevented* from having *any attraction* to those near it, the turgid atmospheres of each, at *that moment* when every counteracting attraction of consolidation ceases, will *instantly* and *forcibly expand*, and *recede* to their *full extent* from each other, so as to assume the state of *vapour*.

At

At the very moment too, when those *atmospheres* cease to be confined by the attraction uniting one particle of water to the other, they will attract into arrangement a number of the particles of *fire*, which before were only crowded into the interstices of the lines of particles forming those atmospheres; by which, they will become still more extended, and expand into the state of vapour; and the quantity of *active fire* or *sensible heat* will be *diminished*, by the number of its particles attracted by those atmospheres into combination with them; in which state, the igneous particles must lose considerably of their activity, and become *latent*: till those atmospheres be again contracted so far, that one compound particle can attract another, and become water; by which attraction, the atmospheres will be condensed, the fixed centres approximated, and the interposed particles of fire pressed out, so as to flow off in their active disengaged state, and produce sensible heat.

It appears therefore, when for the sake of giving a general idea of *water*, I compared one of its particles,

particles, composed of the earthy and acidifying principle in active states, to a needle, rendered magnetic by having all its phlogiston excited at one of its ends, and all its æther to the other, that the comparison was not strictly just; for although the particles of water are held together, by means of the phlogistic atmosphere of the earthy principle of one, attracting the ætherial atmospheres of the acidifying particles of others, as before asserted, yet there is this difference, that instead of a particle of water being formed of one earthy particle, united to one acidifying particle, so as that each may form one end of the particle of water they compose, the earthy particle with its atmosphere of phlogiston, resembling the south pole, and the acidifying particle with its ætherial atmosphere the north pole of a magnet, in reality, *each earthy particle* with its excited *phlogistic* atmosphere, is surrounded on every side by a certain number of *acidifying* particles, actuated by *ætherial* atmospheres; and those acidifying particles are arranged to that earthy centre at *certain angles* with respect to each other.

Suppose

Suppose the angle formed, by the rays extending from any two acidifying particles to that earthy centre, be  $60^{\circ}$ . those *two* particles with their *ætherial* atmospheres, and the *phlogistic* atmosphere of the earthy particle in the centre, will resemble an iron rod of a certain length and proper thickness, having an *ætherial magnetic* atmosphere at *each end*, and a *phlogistic* one in the *centre*, particularly, if it be bent at its centre to an angle of  $60^{\circ}$ . If another rod of the same size and figure, and in a similar state of excitement, be brought near and parallel to it, 'tis evident, that it cannot be attracted: but if either of its *ætherial* ends be brought into the *middle* of the *space* between the two ends of the former, it will *pass between* them, and be *attracted* to their *phlogistic centre*. In like manner, the *acidifying* particle of one particle of water, will pass between the *ætherial* atmospheres of any two acidifying particles partly composing another, and its *own ætherial* atmosphere will be so attracted by the *phlogistic* atmosphere of the *earthy centre* of the others, that it will be *held* in that *certain position*, or *arrangement*; and be immoveably fixed there, if the quantity

quantity of fire be not so great, as to prevent their *internal* atmospheres, from being drawn into contact.

Water appears therefore, evidently to be composed of particles of the earthy principle, with small atmospheres of phlogiston in a very active state, combined with a greater number of acidifying particles, with more extended atmospheres of æther, consequently, in a less excited state, than the phlogiston of the earthy particles with which they are united: the greater activity of the phlogiston, making up for the deficiency of the number of earthy particles, so as to enable them to saturate those acidifying particles, and form with them this neutral fluid, water. Their proportions I at present have not data sufficient to enable me to determine.

The decomposition of water when violently expanded by means of fire, so as to be in the state of *vapour*, or *steam*, by iron made hot; sufficiently proves these principles; for the earth of the iron attracting the acid of the water, becomes a calx,  
and

and at the same time gives out its *phlogiston*, which is seized upon by the active *earthly* particles of the water, then perfectly disengaged, and attracted by *them* into arrangement, so as to form *complete phlogistic atmospheres* around them; by which, they become expanded into *inflammable air*. The additional weight acquired by the earth of the iron, and the weight of the inflammable air produced, together, being equal to the weight of the water disappearing.

And as a further proof, I shall just mention the production of *pure air*, when pure nitrous acid is exposed to the action of *light*.

Nitrous acid is evidently composed of water, with a superabundance of acidifying particles with small ætherial atmospheres; consequently, in an active, or acid state. In this compound, the acid particles strongly attract the *earthly* particles of the *water*; in consequence of which, they must retain their proper acidifying particles with a force *less* than natural. In that state, if they be exposed to *light*, which is a compound of æther and phlogis-

ton, those acidifying particles will attract the æther of the light; and the phlogiston separated from that æther, will be attracted by the earthy particles, which, by being thus satisfied with phlogiston, will lose their attraction to their natural acidifying particles, at the very moment when those acidifying particles attract æther from the light, sufficient to give them *complete atmospheres*, and enable them to *expand* and become *pure air*.

Those earthy particles, with their acquired phlogiston, will be attracted by the particles of nitrous acid, and dissolved or equally diffused among them.

Water is produced, when pure air, which is certainly composed of particles of the acidifying principle, and æther, and inflammable air, which is composed of particles of the earthy principle with phlogiston, are mixed together in certain proportions, and exploded: it is decomposed when iron, in proper circumstances, attracts its acid, and at the same time gives out *phlogiston* enough to surround its *earthy particles*, with complete

plete atmospheres, which in that state become *inflammable air*: and it likewise is decomposed by nitrous acid, which attracts its earthy particles, if at the same time its *acidifying particles* can meet with *æther*, enough to give them sufficiently extended atmospheres; as is the case when the mixture of nitrous acid and water, is exposed to the action of *light*, with room to expand; in which case, the *acidifying particles* of the water, will resign their earthy particles to the nitrous acid, and attracting the *æther* of the *light*, will expand and become *pure air*; the disengaged phlogiston of the light being at the same time attracted by the earthy particles of the water, and equally diffused amongst the nitrous acid: consequently, *water* is composed of particles of the *earthy principle* with *phlogiston*, united to *acidifying particles* with *æther*, mutually saturating each other: where, however, the *acidifying particles* seem to be *most numerous*, and their *ætherial atmospheres most extended*; and consequently, *less active* than the phlogiston surrounding, and actuating the earthy particles with which they are combined.

I have now explained what I mean by the elements of nature; and attempted to demonstrate their existence; to point out the general simple properties which each is possessed of, and to shew, that those simple elements and properties, singly, or combined, produce those powerful agents of nature, whose wonderful effects strike us with awe, or fill us with admiration!

I shall here therefore conclude the subject; but for the sake of bringing the whole, as much as possible, into one point of view, shall add the following Recapitulation.

RECAP-

---

---

*Recapitulation.*

1. **E**VERY thing is composed of *matter*, actuated by the property of *attraction*; by which alone all the operations and phenomena of nature are produced.

2. Matter is of two kinds, one of which may be called *fixed*, and the other *active*.

3. Particles of *fixed* matter have no property but *impenetrability*, and *general attraction*: but,

4. Particles of *active* matter, when attracted by particles of fixed matter, become excited to attract  
each

each other into *arrangement*, so as to form *lines* extending like *radii* around the fixed particles; and receding from each other as their distances from those fixed centres increase, so as to form expanded *atmospheres* around them.

5. The particles of *active* matter are of *two kinds*, each being equally attracted by fixed particles, and in consequence of that, excited to attract particles of its own kind, into *atmospheric arrangement*. One kind of these active particles I call *Æther*, and the other *Phlogiston*.

6. *Fixed* particles of matter, surrounded by atmospheres of *æther*, will form *compound* particles, which cannot be decomposed, because that *æther* can never be attracted with greater force, by any thing, than by the fixed particle which it already is united to: these compound particles being therefore *indestructible*, will form a *fixed*, or *solid* principle; which I therefore call the *Earthy principle*.

7. In

7. In like manner, *fixed* particles of matter attracting atmospheres of *phlogiston*, will produce the indestructible compound particles, which form the *acidifying principle*.

8. The *active* particles of matter, besides this attraction of arrangement amongst similar particles, when excited to become atmospheric around fixed centres, have likewise an *attraction mutually* to *each other*, when in similar states; by which, their particles move into union from their circumferences, *progressively* to their centres, until those respective fixed centres are drawn into contact. This attraction between atmospheres of the different active particles, drawing and holding their fixed centres together, is called the *Attraction of Cohesion*: therefore,

9. Particles of the *earthy* principle, by means of the ætherial atmospheres essential to them as principles, will attract the phlogistic atmospheres, of particles of the *acidifying* principle, by which their respective fixed centres will be drawn into contact, so as to form a solid mass.

10. Æther and phlogiston being universally diffused, in their unexcited fluid state, are capable of penetrating between the lines of active particles, arranged around fixed particles, or fixed principles; in consequence of which, one, or both will receive a certain degree of excitement from every fixed particle, or fixed principle; which excitement, will cause them to attract similar particles to arrangement, and form lines of ætherial, or phlogistic particles, which would extend in all directions, far as creation itself, if they were not to meet with rays of the opposite kind, in a similar state of excitement, from other bodies. But when rays of æther, or phlogiston, excited by the fixed particles of *one* body, meet with lines of the contrary active particles, excited by *another*, they will *draw* those bodies into contact: the greater the number of *fixed* particles, the greater will be the number of *active* particles thus excited; and consequently, the more powerful their attraction. Thus is produced the *Attraction* of *Gravity*; by which every mass of matter is connected with every other.

11. Fixed particles of matter, give to active particles their excitement, by which the active particles of one kind, become attractive to those of the other; consequently, the attraction between fixed and active particles when in contact, is most powerful: but, as that attraction is weakened by distance, those atmospheres, at a certain extent from their fixed centres, will begin to have a *greater* attraction of *union* to active particles of the *other* kind, *than* of *arrangement* to *similar* particles; in consequence of which, they will attract an *external* atmosphere of the *opposite* kind, rather than extend themselves, by taking *more* particles of *their own kind* into arrangement Therefore.

12. The *ætherial* atmosphere surrounding a particle of fixed matter, so as to form a particle of the *earthy* principle, when of a *certain extent* around that fixed particle, will attract an atmosphere of *phlogiston*, by which it will acquire the property which is called *Alkaline*; if that phlogistic atmosphere be fully, or widely extended, its excitement will be small, and its alkaline proper-

ty scarcely evident; but, if it be of little extent, the particles will be powerfully alkaline.

13. In like manner, the *phlogistic* essential atmosphere of a particle of the *acidifying* principle, of a certain extent, will envelope itself, with an external atmosphere of *æther*; which will manifest its activity, by a proportionate degree of that property called *Acidity*.

14. The *essential* atmosphere of every fixed particle of matter, rendering it a *fixed principle*, being at such a distance from its exciting centre, as to have its attraction to the opposite active fluid, greater, than its attraction of arrangement to similar particles, will *attract those* particles of a *contrary* kind, into *arrangement* around them; and to a *certain extent*, their attraction of *arrangement*, will be *greater* than their attraction of *union*, to the *contrary* active particles.

15. A particle of *either* of the fixed principles, will therefore, if possible, surround itself with an atmosphere of the opposite kind of active particles, to *that extent*, where the attraction of arrangement, *ceases* to be most powerful; in which state, the particle becomes *aeriform*. Consequently,

16. An earthy particle, with its *full external* atmosphere of phlogiston, or in the state of inflammable air, will not sensibly act upon a particle of the acidifying principle, with a complete atmosphere of æther, forming a particle of pure air; because, each is in *that state*, in which, their *external* particles have *no decided tendency*, either to *arrangement* with *similar* particles, or to *unite* with the *opposite* kind. But,

17. If those external atmospheres be *extended* by heat or *fire*, with that increased distance, from their respective centres, they will acquire a tendency to *unite*, as being removed to *that distance* from those respective centres, *where*, the *attraction of union*, *exceeds* the force of arrangement.

18. A particle of the earthy principle, with a *partial*, or *small* external atmosphere of *phlogiston*, will, therefore, be in that state of activity which we call *alkaline*; having an attraction of *union* to the acidifying principle, whose æther is in a similar active, or acid state, but having a *still greater* attraction of *arrangement* to phlogiston, which if it can meet with, in proper circumstances, disengaged, it will attract, in preference to the acidifying principle: as is the case when water in the state of *steam*, is exposed to the action of *iron*, properly heated; the *earthy* particles of the water, will separate from the acidifying particles with which they were combined, to attract into arrangement *complete atmospheres* of *phlogiston*, from the iron; by which the earth of the iron, will be left to unite with the acidifying particles of the water, and the earthy particles of that water with their complete phlogistic atmospheres, will expand and become *inflammable air*. So likewise, when the *earthy* particles of water, are attracted by nitrous acid, its *acidifying* particles will attract into arrangement, the *æther* of *light*, and become *pure air*,

air, rather than remain united to the earthy particles. Therefore,

19. When those external atmospheres of the earthy and acidifying principles, are *very small*, and very active, they will unite, and draw their internal atmospheres into contact, and union also, so as to form neutral compounds, if each be in proper proportion: If they be each of *moderate extent*, when their external atmospheres are drawn into contact, and rush into closer union, *part* of those external atmospheres will be *disengaged*, and unite and escape: but, if each be *widely* and *fully extended*, they will be so inactive as to form no union with each other, capable of separating them from their present connexions; unless by means of *fire*, they be so far removed from the centres by which they are respectively attracted, as to acquire an attraction of union, greater, than that of arrangement: in which case, part, or all of both will unite and form fire, or light; and the more active remaining particles of each, if any remain, being strongly retained by their fixed principles,

will

will unite also, and draw those centres into combination; as is the case with pure and inflammable air, when by means of fire, they combine and produce Fire, Light, and Water.

20. No fixed principle will part from its external atmosphere, unless it can acquire the opposite fixed principle, to attract and satisfy it, in the place of its active principle disengaged; neither will that active atmosphere, separate from its fixed principle, unless it can meet with the other active principle wherewith to combine, at the same time, that their respective fixed principles unite: unless the principles be disproportionate, in which case, the *active* principle disengaged from *one*, may be attracted to *arrangement* around those particles of the *fixed* principle of *another*, to which it hath an affinity, so as to give them *complete atmospheres* and render them *Aeriform*.

21. *Compound bodies*, may contain both the fixed and active principles, in such proportions, as to have a strong attraction, to *both æther* and *phlogiston* in their common state; in which case, they will resemble two *fixed particles* of matter, surrounded with a *compound* of æther and phlogiston; if the æther were excited particularly to surround one fixed particle, the other, being deprived of its share of that æther, would exert its *full force*, upon the phlogiston, and attract it around itself. Thus,

22. *Iron*, is such a composition, that it naturally attracts *both* æther and phlogiston. If *one* of those active fluids be excited at *one* end of a rod of iron, it will attract all the similar particles, near it, into arrangement; while the *other* fluid will become *more* powerfully attracted, at the other end of the rod, than usual, by the whole attraction of that end, being then exerted upon *it alone*; therefore, it will form an atmosphere at that end, and the rod will become *magnetic*.

23. If

23. If the *ætherial* end of this magnet, be applied to the end of another iron rod in its natural state, it will attract and excite all the *phlogiston* of that natural rod to *that end*, and all its *æther* will recede to *the other*, and form an *ætherial atmosphere*; in consequence of which, this second rod will become a *magnet* also.

24. The *ætherial* pole therefore, is like a particle of the earthy principle, as being a fixed centre with an atmosphere of *æther*; inseparable, on account of the strong natural attraction of the iron: and the *phlogistic* pole, will resemble a particle of the acidifying principle. The opposite poles, like the contrary principles, strongly attracting each other, but refusing every connexion with similar poles.

25. These two different *magnetic* atmospheres, cannot *separate* from their respective poles, by *uniting*, because, they *both* are *equally* attracted by the iron, *either singly*, or *combined*: therefore, their attracting each other, does *not prevent* their being *still attracted*, and *retained*, by the iron.

26. Com-

26. *Compound bodies*, containing *either æther*, or phlogiston in a state of some activity, in some measure resemble the *fixed principles*, as having an *attraction to active particles* of the *contrary kind*; and by a proper excitement, they may be made to attract those *opposite* particles, into an *atmospheric* form around them. For instance,

27. *Sulphur*, contains much phlogiston; and being always naturally surrounded by both æther and phlogiston in their *common* state, when its surface is excited, it will attract an atmosphere of *æther*; and the phlogiston, naturally combined with that æther, by being thus separated, will become equally excited; but the sulphur hath no attraction for *phlogiston*, therefore it must *unite* itself to the *surface* of the *rubber*.

But in this case, the quantity of *æther* being great, and the degree of excitement, which the phlogiston of the sulphur is capable of giving, being small, the attraction of arrangement of *that æther* must be less, than the attraction of union to

Q q

phlogiston;

phlogiston; as being *extended further* from the exciting surface, *than where* the attraction of arrangement, *ceases* to be *most powerful*: in consequence of which, its external particles will strongly attract the external particles of the phlogiston separated from it, or excited to the surface of the rubber; and when that union is destroyed by the separation of the rubber, from the surface of the sulphur which it excites, the attraction of union, of the æther, to the opposite principle, being *left in full force*, it will immediately attract an *external atmosphere* of *phlogiston*, from the æther and phlogiston supplied by surrounding bodies, in their common state; which phlogiston it will take along with it: at the same time, that the *phlogiston* excited to the *rubber*, will surround itself with the *æther*, disengaged from *that* phlogiston which now forms the *external atmosphere* of the *sulphur*: so that the *sulphur* will have attracted to its surface, an atmosphere of æther surrounded by another of phlogiston, and be negatively electrified; while its rubber, will possess an atmosphere of phlogiston, with an external one of æther, and be positively electrified.

28. *Glass*, on the contrary, by friction, will attract to its surface an atmosphere of *phlogiston*, which will assume an external atmosphere of *æther*; while the opposite active principles, separated from those, will form an *electric* atmosphere of *æther*, enveloped with an external one of *phlogiston*, on the *rubber*. So that,

29. Sulphur, in its electric state, resembles a particle of earth in its alkaline, or aeriform state; being a fixed centre, with an internal atmosphere of *æther*, attracting an external one of *phlogiston*: and glass, when excited to become electric, is like a particle of the acidifying principle, in its acid, or aeriform state. The two fixed principles, in these states, will attract each other, unite, and disengage, at least part of their external atmospheres: but the *opposite electric* atmospheres, will *both unite* with their *contraries*, and *totally separate* in the state of *fire*, or *light*; because, they were not so strongly attracted, by their respective exciting surfaces, as to be inseparable; those surfaces, in reality, only exciting them by virtue of the active principle, most excited and powerful in each.

30. Æther and phlogiston in very different states of excitement, have no action upon each other; for if æther be *greatly* excited, and phlogiston but *gently* so, the *attraction of arrangement* between the particles of æther, will not give place to the *weaker attraction of union*, of the slightly excited particles of phlogiston: so that in fact, a needle may be surrounded with a magnetic atmosphere, an electric atmosphere, with light, with fire, with air, and at the same time, with odorous particles, flowing off, or surrounding it in every direction, none of which, interfere with the other, but all preserve their peculiar properties, and produce their proper effects, without interrupting each other.

31. When *æther* and *phlogiston* combine and separate, form solid bodies or principles, they may become *exciting bases* to each other; in such a case, if the *phlogiston* be most excited, or active, it appears probable, that they form *Fire*, which, be that as it may, is certainly a compound of the two active subtile principles, and is capable of *pervading* every substance, and is subject to the laws of *fluidity*; having however, a peculiar attraction, or  
power

power of combination with the *active principles* of all bodies.

32. By this general attraction to *active* particles, of *both* kinds, fire not only flows readily into the *spaces* left between the lines they form by arrangement, but also insinuates itself between *each particle*; in consequence of which, the atmospheres they form, become *extended*, and their attraction to their respective centres *weakened*; so that atmospheres of the contrary kinds, which *before*, were inactive, having as great an attraction to their respective centres, as to each other, *now* being further removed from those centres, their attraction of *union*, or *tendency to unite* with each other, becomes *greater*, than their attraction of *arrangement*; in consequence of which, they will now attract and decompose each other, first *drawing* their respective centres, or fixed principles into *contact*, and then *leaving* them, *combined together*, to unite *themselves*, and *pass off*, in the state of *Fire*, or *light*. In every case however, its combinations seem to be those of *necessity*, owing to the *quantity* of it present, as it readily *leaves* bodies, howsoever accumulated,

accumulated, to *flow* into *other bodies*, containing a *less quantity* of it: except *those*, containing much *æther*, with which it seems to have a peculiar affinity; and which seems to prove the conjecture, that the *phlogiston*, entering into its composition, is *more excited*, or *active*, than its *æther*.

33. When *æther* and *phlogiston* are separated from their fixed principles, and combine, in a *certain manner*, they form *Light*; which, passes unaltered, and uninterrupted through bodies containing much *æther*, as seeming to have no attraction to them. But those substances which contain *much phlogiston*, *attract* and *detain* it in its passage through them; by which detention, it *loses* its peculiar arrangement and properties, and is *changed* into *heat*, or *fire*; which gives sufficient room to conjecture, that the *æther*, partly composing *Light*, is *more excited*, or *active*, or *exposed to action*, than its other part, its *phlogiston* is: and, as fire and light are composed of the *same principles*, and are *convertible* the *one* into the *other*, it seems probable, that their *peculiar properties* as fire, or light, depend upon the *phlogiston* being  
most

most active, or most exposed to action when forming *fire*, and when the *æther* is most so, they become *Light*. Therefore we may suppose, that

34. *Different particles of Light, have different proportions of æther; and that the different states, or degrees of excitement of that æther, produce rays of light, acting upon the optic nerves with such different degrees of force, as to produce the sensations of different colours; therefore,*

35. Bodies, composed with *phlogiston*, will naturally attract to their surfaces, the every where surrounding *æther*, and *that æther* will be in *different states of excitement*, according to the state of the combined *phlogiston* of the body. When a ray of light falls upon a body of this kind, *those particles* of that light, whose *æther* is in a *similar state of excitement*, with the *æther* surrounding the body, will be *completely repelled, or reflected*, and the body will appear to be of the *particular colour*, which *that reflected ray*, naturally excites in the eye: while the other rays, will be *partly absorbed*, and by being mixed together, will produce  
*heat,*

*heat, or fire; and, being partly reflected, but with less force, or velocity, than the other particular kind, would produce a dull white, did not that other ray, more perfectly and potently reflected, overpower it. Therefore 'tis probable, that,*

36. No bodies reflect any certain ray, or appear of any distinct colour, but those surrounded with *æther*, in a state of excitement, *similar, and equal* to the excitement of the *æther*, of *some certain rays, or particles of light*; which particles, by that means are *reflected* with that degree of force, or velocity necessary to produce the sensation, or distinct idea of a certain colour; in all other states, the rays of light are so reflected, as to produce the sensation of *white*, of different degrees of intensity, proportionate to the force with which they are reflected; or if a *phlogistic* body, hath no *ætherial* atmosphere, or none capable of reflecting any of them, they will be *absorbed* and *changed* into *fire*, and the substance will appear to be *black*, and become *heated*, in proportion to the quantity of light absorbed.
