## PREFACE.

A VERY tedious chronical Arthrodynia having confined me many months, and thereby given me an opportunity of looking over my Notes and Observations, made in the course of many years practice, and of reperufing the works of various Authors, has given occasion to the following Thoughts, which I entitle Physiological, Pathological, and Practical, in the order that the confideration of diseases presented them to my Mind. For as Physiology is the basis upon which found Pathology must be erected, (it being impossible to form a right notion of the nature of diseases, without a previous intimate Anatomical knowledge of the situation, structure, uses, connections, and relations of the feveral Organs of the Body in their found state) I have introduced fo much of it only, as might serve the purpose of Pathology, derived from that copious fource, the lectures and writings of the illustrious De Haller of revered memory, all except that Thought which

which relates to the functions of the nerves, which, with much diffidence, I offer only as a Physiological conjecture, that seems to me not inconsistent with some Phanomena, and which, with respect to Pathology, is of no great consequence. Thus by knowing what are the requisites to produce health, we may be enabled to form probable conjectures and notions of that state, in which some of those requisites are wanting, disease.

Further, to affift us in our Pathological inquiries, we must join the attentive study of practical Authors, fuch especially as have left us faithful and accurate histories of diseases, with all their fymptoms and appearances, and to these add Practical Anatomy, which will be found to be of the greatest use and assistance in enabling us to form right notions of the nature and feat of difeases, and of the most rational method of treating them. But as, in private practice, opportunities of exercifing Practical Anatomy are very rare, and go but a little way, I would recommend a diligent perufal of the works of fuch Authors as have with laudable zeal and patient labour, collected and made public cases and obfervations of Practical Anatomy; Bonetus, Mangetus, and several others, but especially the most excellent

excellent Morgagni, whose inestimable work, "De Causis et Sedibus Morborum per Anatomen indagatis," I would advise the young Practician, "Nocturna versare manu, versare diurna." This noble work, the indefatigable Author, after a great many years labour, sinished in his eightieth year.

Without some practice in such inquiries, even a very intelligent Physician may not always be secure from mistaking appearances, as morbid where there had been no disease, and the contrary. And what is of yet greater importance, he will certainly be the better enabled to form right notions of the nature and seat of diseases, so as not to confound one with another, since there are few that have such Pathognomonic marks as may infallibly denote them. Were it necessary to do more in favour of Practical Anatomy, I should recommend to the reader Morgagni's presatory Epistles to the several books of his work.

Another help to the acquiring of skill, in this important part of medical practice, Pathology, is that which was done by the learned Mons. de Sauvages, and a few more, but much improved and rendered more useful by the late very celebrated Dr. Cullen, Nosologia Methodica, in which

the learned Professor has arranged diseases in orders, classes, and species, with their characters, in such manner as greatly to facilitate their investigation and discrimination.

The reader will find that I have frequently availed myself of this useful work. I should have thought it unnecessary further to insist on the advantages that may be derived from diligent reading of the works of practical Writers, antient and modern, if it were not for this, that the Antients are by fome moderns confidered as not having contributed much to real medical knowledge. By which it feems they would be understood, that the Theory of the Antients for want of more Anatomical and Physiological knowledge, and a more rational Philosophy, was founded in imaginary principles and Hypotheses; and not qualified to produce right notions of the nature, causes, and seat of diseases. But whatever truth there may be in this, the deficiency was compensated by their diligent attention to the fymptoms and appearances that attended the difease throughout. They have therefore not been treated with that respect that is due to them, and that they received from antiquity. Hippocrates,

\* Hippocrates, according to Galen, was diftinguished as the first Philosopher of his time, whose fentiments Plato adopted. Aristotle was confidered only as the Interpreter of Hippocrates and Plato; and his writings merely commentaries on Plato's Philosophy, from whence were drawn his doctrines of the four first qualities. And, moreover, if Hippocrates were not the inventor, he was, after Esculapius and his Sons, deemed the Restorer of the art of healing; and according to +Pliny, the first who clearly taught it. But, what is more certain and of more importance. Hippocrates appears, in almost all his works, to acknowledge one general principle, which he calls Nature, as superior to all others; to which he attributes powers or faculties for the administration of the animal oeconomy and the cure of difeases on which last account he uses this expression " Naturæ Morborum Medicatrices,"

After Hippocrates; Aretæus, Alexander Trallianus, and other Greeks, have left us fuch histories of diseases and their Therapia, as amply display, not only their accuracy in the diagnostic and discrimination of them, but also their skill in the Therapeutic

<sup>\*</sup> V. Le Clerc Histoire de la Medicine, L. iii. c. i. 2.—†Primus Hippocrates Medendi præcepta clarissime condidit. Plin. L. xxiii. c. 2.

Therapeutic part, in which Alexander was eminently diffinguished. To those may be added the elegant Celsus, and the semi-barbarous, but on some accounts useful, Calius Aurelianus, and a few Arabians.

However defective the Theory of Hippocrates may be thought, it was founded not on imaginary Hypotheses, but on Philosophical and Anatomical principles, and especially on Clinical observation. And well had it been if Galen and his followers had, by practical observations and anatomical refearches, endeavoured to find out the Physico-Mechanical laws and powers of the animal oeconomy, instead of pursuing vain speculations and the imaginary principles of Aristotle and Des Cartes; and the fanciful and unfubstantial Hypotheses of Chymists and Metaphysicians, expressed in terms not more intelligible, fuch as Archeus, Duumviratus, Occultum Vitæ regimen, &c. &c. of Helmont, and others, and various other Hypotheses, for which vid. cel. Hoffmann. \*

Of modern Theories, one of the latest is that which was adopted by the ingenious and justly celebrated

<sup>\*</sup> Prefationem, T. 1, Medecinæ rationalis Systematicæ et Prolegomena de vera Therapiæ natura, &c. Cap. xi.

mans; the principle of which is supposed to be Natura sive Anima, rationis, consilii, intentionis et scientiæ interioris particeps; medicinæ et omnium motuum qui vitam tuentur et morbos curant, Principium; vel Anima medica.

An Hypothesis that has some resemblance to that universal principle which Hippocrates calls Natura. But Stabl and his followers feem to have attributed greater powers to their Anima medica, than Hippocrates did to his Natura medica. For though in his Epidemics, he feems, after ordering a proper diet, to have attended only to the phanomena, and left the rest to Nature; yet in inflammatory and other difeases, he was an active " Naturæ Minister," and in chirurgical cases bold and enterprising. Whereas the Stablians feem to have had fo much dependance on the Autocratia Natura, as to have been fometimes inactive spectators of the mistakes and errors which they allow this wonderful principle to be liable to; and on this account to require the corrections of the skilful Physician. \*

Among

<sup>\*</sup> Vide Clariff. et experientifs Werlhof Cautiones Medicæ 1734, et Observationes de Febribus, Ed. ii. 1745, Hanoveræ.

Among the modern practical writers of distinguished name, are Ballonius, Hollerius, Duretus, Lommius, Sennertus, Riverius, Piso, Sydenham, Willis, Boerhaave, Hoffmann, Stahl, Lancis, Baglivi, Ramazzini, Torti, Werlhof, Mead, Huxham, Pringle, Fothergill, Cleghorn, and many more whom I forbear to name, least I should be thought oftentatious, when I only mean to acknowledge my obligations, and to prevent or save the trouble of frequent references.

If the following Thoughts should prove of use to young practitioners, for whose service they are intended, the Author will hope his labour has not been in vain.

THOUGHTS

## THOUGHTS

PHYSIOLOGICAL, PATHOLOGICAL, and PRACTICAL, &c.

BOOK I.

SECTION I.

The HEAD, BRAIN, and NERVES.

A SI do not mean to give an anatomical description of the brain, I shall only observe that it is composed of two substances, different in some respects from each other. The first which is in general external and is immediately covered by the pia mater, is of a brownish colour, and is thence called the cortical or cinericious substance. It is about two or three lines in depth or thickness, and covers the other,

which is white with a faint red tint, called the medullary fubstance, which constitutes the greatest part of the brain.

The cortical fubstance feems to be formed of the ramifications of the blood vessels. The medullary part appears to be fibrous or vafcular, being probably made up of a finer order of veffels, containing a very fubtile fluid. The nerves being evidently productions of the medullary fubstance, if this be vascular, they may with reason be supposed to be so likewise. What seems to justify this supposition, is the great quantity of blood that is fent to the brain, much more than can be fufficient for its nourishment only; and there being no refervoir there to contain the fecreted fluid, allow me to fuppose that a considerable quantity of a very fine fluid fecreted from the blood by the medullary veffels, is constantly passing along the nerves, which are productions of the medulla, to their extremities in the various organs, the muscles, and the skin, from whence

whence and from the feveral cavities it exhales, and is again, probably, in part reabsorbed.

sinclothics and being in general furrounded

Whether it be to this fluid or to the different modification of the fibres or vessels of the medulla, or to both, that the nerves owe their wonderful influence, I shall not take upon me to determine. Thus much however appears to be certain, that as they are productions of the medulla, the impressions made by objects, on the fenses, are by the nerves conveyed to the medullary centre or fenforium, where the mind perceives, and from whence its volitions are, by them also, conveyed to the feveral moving powers: How the impressions, made on the senses, are carried to the fenforium, and the volitions of the mind, from thence to the moving powers, I pretend not to determine.

If by vibrations, as by some is supposed, they must be of a kind very different from those of musical strings, the nerves being, on no account capable, of fuch vibration; confidered either in their substance or situation; their substance being very soft and unelastic; and being in general surrounded by and connected with soft parts, they are quite incapable of tension and vibration.

My idea of the matter, if I be happy enough to make it intelligible, is this, that the nerves being productions of the fensorium, the impressions made on the organs of the senses and on the fensorium, are synchronous; and the volitions are, in the same manner, synchronous with the action of the moving power.

I no fooner will, for example, to move my hand, but it is that instant in motion: For if the impression and the perception of it, are supposed to be successive, I cannot understand how they can be so instantaneous as they really seem to be, especially from the extreme parts to the sensorium, against the natural course of the nervous sluid, which which passes from the brain to the extremities, but does not circulate, if I may be allowed that expression, back again.

Moreover, I would observe, that I feel at the extremities of the nerves in my singers, in the same manner as I taste with my tongue, smell with my nose, &c. but not in the intermediate part of the nerves. This may seem not to agree with that common observation of a patient's feeling pain in his toes, some time after the leg had been taken off, but it is supposed to be owing to this, that impressions made upon the sensorium remain, for a longer or shorter time after their cause ceases to act.

If I should seem to attribute too much to organization and to extend the sensorium too far, I beg that I may be understood to consider it only as the medium or organ by which the Mind perceives and acts; and to carry it no farther than what seems to me, consistent with the phanomena physiologically considered.

considered. For as to the mind or soul, its nature, place, &c. that is a speculation I must leave to Psychologists, who are possessed of more penetration than I pretend to. And in respect to our future existence, I have the consolation to think, that the Gospel gives us a more substantial ground of hope, than any that Philosophy or Psychology can supply us with. But this by the way.—

The brain being fupplied, by the carotid and vertebral arteries, with a great quantity of blood, perhaps not much less than a fixth part of the whole, is subject to many disorders; some of which are owing to excess of quantity or motion, or both; others to some fault of its quality, as being too viscid or too thin, or acrimonious; each of which will come under consideration as we proceed to treat of the several affections of the brain, &c. In the mean time I would observe, that the dura mater, not being furnished with nerves, is supposed, when in a found state, to be insensible; but this as well as tendons, ligaments,

ments, &c. which when found, shew little fensibility, become very fensible when they are diseased.

# APOPLEXIA.

Apoplexy is, of all the affections of the brain, the most formidable. It attacks a person suddenly, depriving him of all sense and motion, except of the heart and muscles concerned in respiration, which in them seems to be increased, the pulse being full, and the breathing laborious, with snoring and prosound sleep.

The most common species of idiopathic apoplexy are the sanguineous and the serous. To the former are most subject, persons of a sanguine habit; a florid countenance; who are short and corpulent; who indulge themselves too much in good eating and drinking, indolence and sleep.

As this difease is generally mortal, or if the patient escapes with life, he remains deprived of the use of some of his limbs, it is of the utmost importance, to persons of the above description, to be upon their guard to prevent it. They ought therefore to be very temperate in both their eating and drinking, and especially of strong inebriating liquors; they should rife early and use exercife both on foot and on horseback. Temperance will also have the good effect of moderating the passions, which is of great importance. But if notwithstanding this caution, fuch a person should feel a dull pain or heaviness in his head, attended with listleffness or drowfiness, he must, without loss of time be freely bled, take a cathartic, use fpare diet, and whatever elfe may be thought necessary, until he finds himself free from the alarming appearances. Thus much for prevention.

But in case of actual invasion of apoplexy, the patient must be immediately bled at the arm fters must be injected to empty the bowels; vesicatories must be applied and sinapisms to the feet; these to be removed at the end of three or four hours; the feet to be then washed with warm water, and the sinapisms repeated, if necessary; in the mean time, cupping glasses with scarification must be applied below the Occiput. Should the patient become able to swallow, a brisk cathartic will be adviseable; but beware of emetics, volatiles, and sternutatories.

Upon opening the heads of persons who died of this kind of apoplexy, more or less blood has been found, sometimes under the dura mater coagulated and covering part of the brain; sometimes in the ventricles or in the substance of the brain.

### Serous.

The persons most disposed to serous apoplexy, are also the short and corpulent, but

who instead of being rofy and sanguine, are pale, bloated, leucophlegmatic, drowsy, inactive, and who indulge themselves in the pleasures of the table and in sleep. The prophylactic cure differs not much from the former. Bleeding, however, may not be always necessary, but brisk cathartics will, and must be repeated; as will also frequent exercise on horseback; universal friction with a sless-brush or coarse slannel; early rising; and temperance in eating and drinking.

But should they happen to be seized with apoplexy, it will be necessary to take away blood, though not so much as in the sanguineous. For though the accumulation of the serous sluid is generally slow and gradual, yet as it takes up more or less room, the vessels of the brain are in some degree compressed, and in case of violent exertion; excess in eating and drinking and the like; the circulation through the brain will be retarded and a rupture or stagnation occasioned.

fioned. Moreover the water in the ventricles is fometimes found to be \* faline and acrimonious; and thus may irritate and constringe the vessels. On these accounts it will be advisable to take away some blood; to inject cathartic clysters; to apply vesicatories to the back and legs; and, when the patient can take them, brisk cathartics, diuretics, &c. Afterwards stimulants, with tonics and chalybeats together with the prophylactics already mentioned, will have good Beside the two species of apoplexy spoken of, practical anatomy has discovered others occasioned by collections of matter; and fome in which the veffels have been found diftended with air, and even the longitudinal finus containing nothing elfe.\*

There are, moreover, feveral forts of both idiopathic and fymptomatic apoplexy, noticed by Nofogolists, for which I must refer to Dr. Cullen's Nosolog. Meth. v. 11.

B<sub>2</sub> PHRE-

<sup>\*</sup> Vid. Excellent. Morgagni Epist. de Causis et Sedibus, &c. Epist. v.

# PHRENITIS.

From the great quantity of blood fent to the brain, it is rendered subject to inflammation. The symptoms of which are great pain and heaviness in the head; a quick full pulse; great heat; the countenance florid; redness of the conjunctiva; Delirium, Typhomania.

Some authors suppose a difference between inflammation of the brain, *Phrenitis*, and that of its membranes, which they call *Phrenismus*, but they seem at a loss how to distinguish the symptoms of one, from those of the other.

Inflammation of the brain is a difease of the most alarming nature, and requires our utmost attention and most speedy remedy. Blood must be taken away freely and repeatedly, according to the urgency of the inflammatory symptoms; nitrated clysters must

must be repeatedly injected, and cooling laxatives administered. The feet must be bathed in tepid water; the head must be shaved, sponges with tepid water applied to it, and after that a vesicatory. The medicines must be cooling and diluting, such as barley water with vegetable acids, nitrated emulsions, and other neutral antiphlogistics, which must be continued so long as may be thought necessary, to procure a compleat resolution of the inflammation, as any other termination must prove fatal. Collections of matter have been found in the substance of the brain, of those who died of this disease.

# CEPHALALGIA.

An oppressive pain in the head with heaviness, which though frequently symptomatic, yet may not unfrequently be considered as idiopathic, in young persons especially,

especially, and those of sanguine habits; in whom it is often brought on by too much exposure to the heat of the sun, hot rooms, too violent exercise. Should it become frequent and troublesome, it will, in general, be soon removed by bleeding, gentle laxatives, and a temperate, cooling, and diluting regimen. In this head ach, the proximate cause seems to be distraction, more or less, of some part of the brain, by the distension of the blood vessels; for the membranes not being furnished with nerves are supposed to be insensible.

The head ach is not unfrequently sympathic, as in the case of indigestion, in which case a gentle emetic or drinking warm-water or chamomile tea and bitters are effectual.

Young persons, approaching to the time of puberty, are very subject to head ach, of which nature relieves them, often by spontaneous bleeding at the nose, &c.

## CEPHALEA.

This is a fevere pain of the tensive kind, in the external parts of the head, affecting mostly the membranes, the Pericranium and the Aponeuroses of the temporal and frontal mufcles, extending to the face and jaws, where the pain is often very violent; those parts being copiously supplied with nerves, from the second branch of the fifth pair, which also furnishes the principal nerves to the teeth, whence arises the sympathy so remarkable in those parts. It often attacks one half of the head, and is then called Hemicrania; or a very fmall part or point as it were, and is then termed Clavus, and very often the temples and forehead. It is generally chronical; and fometimes periodical of the quotidian type.

It is very prone to return, upon changes of the weather and getting cold; to prevent which, care must be taken to guard the parts from cold, especially in the night.

Internal

Internal medicines are, in these cases, seldom of much use; except when the severity of the pains calls for anodynes. Veficatories applied to the part or behind the ears, often give relief. Where these cannot well be applied, warm plaisters well charged with Opium; Linament. Sapon. cum Opio; epithems of warm stimulants, as pepper and ginger moistened with brandy; or mustard, have often given eafe. When the pains are periodical, the Bark often proves efficacious. And that the patient may be fortified against relapses, and be the better enabled to bear the viciflitudes of weather, Buxton, fea-bathing, and exercise on horseback when the weather is fair and dry, cannot be too much recommended.

### VERTIGO.

This is an affection of the Senforium, in which objects at rest, seem to be in motion; which appears to be rotatory, or undulating

ing or falling. The patient too feems to turn round with the room or bed, even when his eye-lids are closed. If he be up, he grows dizzy and blind; he staggers and at last falls.

This affection is in general fymptomatic or sympathic. Sometimes it is occasioned by indigestion, or the too free use of inebriating liquors; by turning frequently round in a small circle; by the motion of a vessel, as at sea; or in a carriage going over uneven, undulating ground.

When it arises from indigestion, an emetic will be adviseable, first taking away some blood, if the patient be plethoric. After these a laxative of Tinet. Rhei. and Tinet. Aloes, and after all some bitter tonics.

The other species cease, when the occafion ceases.

# EPILEPSIA.

The immediate cause of this affection seems to be irritation of the medullary substance, but what the nature of the irritating cause is, either in the idiopathic or sympathic Epilepsy, does not appear. Violent affections of the mind; sudden frights; hurts of the head; some poisons; the repulsion of cutaneous eruptions; and several other exciting causes are mentioned by Authors, which it would be to little purpose to enumerate, as the treatment must be directed by the judgment of the Physician.

The Fit comes on for the most part suddenly, and without giving the patient the least notice of its approach, so as to secure himself from accidents that he is thereby liable to. But it is sometimes announced by a pain or spasm in some part of the body, or its extremities, from whence it proceeds upwards, in such manner, that

the person has time to secure himself from the fall.

In respect to the treatment, nothing can be done in the Fit, more than to prevent the patient from being hurt by the violent convulfive agitation; and to take care that his stock and other ligatures be let loofe. When he is pretty well recovered from the fatigue of the Fit, the cure may be attempted. And in the first place, if the patient be of a fanguine complexion, and in some degree plethoric, it will be proper for him to lofe blood, which will be a mean of preventing what fometimes happens in the violence of the Fit, the rupture of blood vessels in the Brain and the confequence an Apoplexy. After that, it may be proper to carry off any offenfive matter that may be lodged in the first passages, by gentle emetics, and proper cathartics. This done, trial may be made of Nervines and Antispasmodics, as the fetid gums, Campbor, Caftor, Musk, &c. though it is to be lamented, that these too often disappoint

our wishes, and seldom do much good. I have sometimes thought my patient has received benefit from Zincum calcinatum.

If the difease should return periodically, the Bark ought to be tried, and may be of great use, as in fact it has been found to be. It should be given eight or ten days before the return of the period; in the quantity of two or three ounces, and then be left off; and again repeated before the next periodical time; and be thus continued, so long as it appears to be of use.

Should there be reasons to suspect worms in the case, Anthelminthics such as Pulv. Stanni, &c. must be tried, and epithems or plaisters to the Epigastrium.

In case of sudden repulsion of eruptions on the skin, or scorbutic acrimony, Issues will be adviseable, to be kept open a long time. Harrogate and Scarborough waters and Sea-bathing, under judicious direction, promise considerable advantages.

SPASMUS.

## S P A S M U S.

This is a violent, irregular contraction of the muscles, or some part thereof. If it affect the whole body with rigid stiffness, it is called Tetanus; if the muscles of the forepart chiefly, Episthotonus; if the back part Opisthotonus.

It is a difease which seldom happens with us, but is frequent in the *Indies*, both East and West, and in the Islands.

I shall, therefore, beg leave to refer to those Authors who have seen and treated the disease,—Hillary—Chalmers—London, Med. Observat. and the celebrated Cullen, Nosolog. Method.

TRISMUS; or, LOCKED JAW.

This is a very extraordinary though too common affection, of which I have had the

the mortification to fee some instances that proved fatal, even where the accident appeared at first, to excite not much attention. It has been observed in cases of complicated fractures; wounds by fire arms, or their bursting and lacerating the hand; wounds and punctures of the joints, tendons, aponeuroses, &c. of the hands and feet, and fome of these little thought of, until some stiffness of the jaw, by degrees increasing, gave the alarm, but too late to be remedied. And it is to be lamented that this is too frequently the cafe. Opium taken liberally, and frequently repeated, has fometimes been fuccessful, \* but has often failed. In cases where the hand has been much lacerated by . the bursting of the piece, the danger is great. But if there be a probability of the hand being in the least useful, both the patient and the Surgeon wish to try to fave it, otherwife amputation at the first, would be the only mean to obviate this fatal symptom.

CHOREA,

<sup>\*</sup> London Medical Observ. vol. 1. &c.

# CHOREA, S. Viti. - SYDENHAM.

This is an involuntary convulsive motion of some or all the muscles of the body. It happens, generally, to young persons of both sexes, but mostly to females before or about the time of Puberty, after which time it generally goes off; in the mean time, it is the cause of much anxiety to the patient and their friends, by its long continuance, but it seldom fails of being cured. The cure is effected by medicines of the nervine class, and Tonics such as the Bark and mild Chalybeats.

Thus far I had written, when a cafe of Chorea happened in my own family, to a girl, about twelve years old, who, without any previous complaint, was surprised one morning by a bleeding at the nose, which returned three successive mornings about the same time, and then ceased spontaneously; for I did not think it adviseable to check it,

fo long as I faw that she bore it without complaint; and the whole together was only about eight ounces. She then appeared to be well, but rather pale. Some days after the began to be unsteady, and to have involuntary motions in her fingers, head, and feet, which increased gradually, until she became unable to walk, or hold any thing in her hands; her face was affected, and her tongue, fo that she could not speak intelligibly; in short, her whole body was in constant agitation, so that in bed, means were necessary, to prevent her throwing herself out of it. For feveral nights fhe got no fleep, nor feemed to want it; for she had no other complaint; but eat her victuals moderately, and was almost as chearful as before. I gave her fome of the usual nervines, the fetids, Campbor, Castor, &c. I also made trial of Æther, but without any sensible effect. I thought of Musk, but first I determined to try Opium. I gave her at first eight drops of Tinet. Opii. at bed-time, but without effect; however, I continued it, increasing the dose gradually

until she got up to twenty-five drops; this did not make her sleep, but her agitation began to abate. I then gave her the twentyfive drops about fix in the evening, and fifteen more about nine, this produced no fleep till the morning, when she slept two or three hours; she was, however, less and less agitated, and the complaint feemed to be giving way. After a few days I increased the dose to thirty-five drops, which she took at fix in the evening, and no more. She yet got no fleep until the morning, but by degrees became quite still in bed, though awake, and began to walk, but not steadily; her hands yet very much agitated, when she wanted to take hold of any thing that required steadiness; so that she sometimes laughed at the gestures that the attempt produced. She took Tineture of the Bark twice a day, while she used the Tinet. Opii. The dose of which was gradually lessened until it seemed no longer necessary.

# PARALYSIS.

This is a fulpension or diminution of the power of motion and fensation, accompanied often with drowsiness.

If it affect most of the lower parts, it is called Paraplegia; if one fide only, Hemiplegia, in which the face and the organs of speech are often affected; but these seem only different degrees of the same difease. Partial Palsies are sometimes cured, but often return. They, however, fometimes continue for many years, while the patient is in all other respects well. Even Hemiplegia is frequently observed to continue in this man-The greater degrees are feldom cured, but fometimes end in Apoplexy. As the proximate cause is in that part of the brain or Medulla Spinalis, where the nerves of the part affected have their origin, or between that and their termination, the cure is difficult. The constitution and habit of

of the patient must therefore be attended to. If the patient appear to be plethoric or of a fanguine complexion, it will be proper to take away fome blood; but if, on the contrary, he look rather pale and bloated, bleeding had better be omitted; and the medicines must be warm and stimulating. In both cases, blistering is adviseable; the veficatories should be applied to different parts of the spine, successively; and to the part affected, as well as other stimulants. Though external applications feem to contribute but little to the cure: even that feemingly fubtile and powerful agent Electricity, has fallen very short of what might be expected from it; but as it has in fome cases been useful, it deserves to be tried in fimilar cases.

The Bath waters have often been fuccefsful, but they should be used under the direction of a Physician upon the place.

### HYDROCEPHALUS internus.

While the affections of the brain and nerves are under confideration, I shall take the opportunity of employing a few thoughts on Hydrocephalus internus; that especially, which feems to have been little known before the time of the ingenious D. Whytt. It has appeared from diffections, that water has been found in the heads of fome, who have died apoplectic or paralytic; and I have feen more than one instance, where I suspected it to be the cause of a violent pain in the upper part of the head, attended with spasmodic affections of the eyes and face in adults; but have not had opportunity to verify my conjectures by diffection. But what I have chiefly in view at prefent is that species described by D. Whytt, whose description agreed very much with what I observed in two or three cases that occurred to me fome years fince, but which I could not examine after death. The symptoms were restlesines;

lessing; pain in the head, as appeared by the frequent motion of the hand up to the head, with starting and sudden crying out; strabismus; dilatation of the pupil; convulsions, &c. and it proved for the most part mortal. As a convulsive affection attended with feverishness, it had been treated with saline febrifuges, nervous medicines, vesicatories, &c.

And the difease happening most frequently to children, the symptoms have been supposed to be occasioned by worms, which are known to produce very Anomalous appearances; hence, among other medicines, small doses of Calomel were occasionally recommended to be made use of, as an Anthelminthic only. But since Hydrocephalus internus became more known, the ingenious Dr. Percival, and some others, have employed Mercury in the cure of it, both internally and externally, and have published some cases in which it has been successful.

It is certainly an affection that demands the most serious attention and judgment of the Physician, to distinguish this from other cases, in which some of the symptoms are much alike: The frequent motion of the hand to the head, strabismus, and dilatation of the pupil, seem to me to come nearest to be Pathognomic symptoms of this affection.

SECTION II.

#### SECTION II.

# AFFECTIONS of the EYES.

# OPHTHALMIA.

mull be exerted to avert the

A SI propose to take notice of those affections of the Eyes only, that do not, in general, require the topical aid of a Surgeon, I shall begin with that which happens most frequently, Instammation. This disease is attended with symptoms more or less painful and dangerous, according to the degree and extent of it.

The most common is that in which the external parts, I mean the Conjunctiva, Cornea, and the eye-lids are chiefly affected;

in which case the usual symptoms, are pain and a fenfation, as if dust or some other extraneous body were lodged under the eyelids; redness of the conjunctiva; impatience of light; and, in general, profusion of tears. When the affection is to a greater degree, the above fymptoms are increased; the Choroidea is affected; the Eye is swelled; great pain is felt at the bottom of the orbit; the pupil looks red; and the fight is cloudy. When this is the case, our utmost attention must be exerted to avert the bad consequences that may enfue. This is to be attempted by copious venesections, from the arm and the jugular veins; the application of leeches to the temples; brifk Cathartics; Anodyne fomentations; warm vapour and Cataplasms; Vesicatories behind the ears, and the neck; and warm Pediluvia.

The milder degree of Ophthalmy, will require a treatment somewhat similar, but more gentle; when the inflammatory symptoms and pain are much abated, it may be proper

proper to use a Collyrium, such as the following B. Aq. Ros: Mift. Campborat: a a 3i. Extract. Saturn. gutt. xii. of which two or three drops warm may be dropped into the eye, three or four times a day. To two parts of this may be added one part of T. Opii. occasionally. In some cases of Ophthalmy, I have made use of Calomel, with manifest advantage. In others, I have found the Bark and other tonics useful; especially in patients of scropbulous, and relaxed habits. And with the view of preventing the return of the diforder, I would recommend the washing of the face and eyes, every morning, in cold well-water; of the good effects of which, among other instances, one is related by the indefatigable Morgagni, as experienced by himfelf. \* Who, from being fubject, in his younger years, to weak and frequent fore eyes, was, by this means, enabled to carry on, and finish, his great work at the age of eighty, without spectacles. The

\* De Causis et Sedibus Morborum, &c. Ep. xiii. art. 24.

The bad consequences of inflammation of the internal parts of the eyes such as matter between the laminæ of the Cornea; adhesion of the Uvea to the Cornea; opacity of this, by small papulæ or ulceration, must have the aid of a skilful Surgeon. I shall only add, that small specks on the Cornea, often wear off by degrees, or with the assistance of some mild detersive collyrium.

# AMAUROSIS.

This alarming affection, known by the barbarous name of Gutta Serena, is sometimes preceded by Gephalalgia, and sometimes comes on suddenly. Its approach is sometimes announced by the appearance of black spots or films, or hairs, floating in the air; especially when the person looks upon white paper, snow, or other white objects; but this criterion is fallible, as persons often have such appearances for years, without that consequence.

This

This affection is a deprivation of fight, without any other apparent change in the Eye, than dilatation of the pupil, and its want of contraction, on the approach of strong light. The cause is something that affects the optic nerve.

This has been found to be fometimes a fluid in the lateral ventricles, by its quantity, compressing, or by its acrimony, irritating the Thalami Nervorum Opticorum, the Corpora striata, or the Optic nerves, at their origin, or in their progress to the orbit: this nerve, having, in these cases, been found to be sometimes compressed by tumours; its substance changed and dissolved, or wasted; and sometimes even twisted as it were, in cases where the globe has been much turned about by the convulsive action of its muscles.—V. Morgagni.\*

It has fometimes come on fuddenly without any evident cause, as happened some E 2 years

<sup>\*</sup> De Causis et Sedibus Morborum, &c. Ep. xiii. art. 24,

years fince to a Miner, in the copper-mines near Richmond, a young man, about thirty, who was struck blind on a fudden, about ten days before he came to the Hospital; without any previous indifposition, as he faid. In him the Pupil was fo much dilated, that very little of the Iris was to be Various stimulating nervous medicines, and applications were tried; among the rest Electricity for some time; but finding no benefit, he grew impatient and left the Hospital, as he came in. Mercury has been advised in this case, and deserves to be tried. Millepedæ too are extolled by fome, and may be fafely tried, though, I fear, their efficacy is not very confiderable.

If dimness of sight happen to persons of a plethoric habit, and be attended with dull pain or heaviness; Venesection and Cathartics will be highly necessary. And as a preservative, temperance and a due degree of labour or exercise will be most adviseable.

SUFFUSIO.

### SUFFUSIO.

Cataract is an opacity of the Chrystalline Lens, a substance which consists of thin laminæ and a very fine fluid; both of fuch extreme tenuity, as to form a body of the most perfect transparency, like the purest chrystal, from which it has its name. It is of the utmost importance to perfect vision: fo that in proportion, as that transparency is impaired, the fight is more or less imperfect. This is often the case in old age when, from being perfectly transparent and invisible, it becomes whitish or yellow, and renders the fight dim. Thus it is in the Cataract, and to fuch a degree as to refuse a passage to the rays of light: having paffed through feveral gradations of confistence, until at last, it becomes folid. In some cases it has been found foft and pulpy; in others its fubstance has been wasted, nothing but a pellicle remaining. Other examples of opacity of the Chrystalline, are to be found

in the works of the egregious Haller; \* Morgagni, &c.

All that can be done here is to remove the opaque body from behind the pupil, either by couching, or extraction; the choice and performance of which must be left to the skill and dexterity of a Surgeon.

### LIPPITUDO.

This is an affection of the Eye-lids, but especially of the Tarsi. The edges are swelled, and the ciliary glands discharge a more than ordinary quantity of their fluid, which with the discharge from the excoriated parts, forms a yellow matter that causes the palpebræ to stick together, so as not to be separated without great CARE.

This affection is fometimes very troublefome

<sup>\*</sup> Opuscula Pathalog. Obs. iii. - Morgagni Ep. lxiii.

fome and tedious; more so in general than Opthalmia.

The cure may be begun by Venefection, if the person be inclined to Plethora, for it is not always necessary; mild purgatives, preceded by small doses of Calomel, are in general useful; those to be succeeded by Alteratives; such as Æthiops Mineralis, Spongia usta, Decoet: Lignorum.—Aq. Calcis. comp: In the mean time some external applications will be adviseable; such as warm-water with a little brandy; sea water warm, &c. At bed-time the application of Unguent: Tution or Ung: Cerussa acetata, spread very thin upon old rag, and laid upon the edges of the Eye-lids. To consirm the cure, sea-bathing, and sometimes an issue may be necessary.

Pustules; simall encysted Tumors; Hordeola, &c. I must leave to the care of the Surgeon, whose assistance they sometimes require.

STRABISMUS

# STRABISMUS-DIPLOPIA.

The little I have to fay upon Squinting, and double vision, I include in the same article, because of their affinity in their proximate cause, which I suppose to be a paralytic affection of fome of the muscles of the eyes, or a preternatural contraction or convulsion of their antagonists: by which the Optic Axes are not exactly directed to the object. The causes of double-fight are nearly fimilar; but this to me, feems more owing to a paralytic, than to a convulfive affection, if it be always (as it was in the cases that I have met with) attended with a falling-down of the upper eye-lid; a cafe that is very troublesome and inconvenient, as well as alarming to the patient, from the apprehenfion of worfe confequences. However, in the cases that I have seen, the patients were, in every other respect, perfectly well; fo that in them it was purely local.

As to the method of cure; internal medicines feem to have but little effect. It may, however, happen that venefection may be proper and necessary, as in case the patient should be plethoric; and it cannot be amiss to try some nervines and slimulants. External applications to the eye-lids, forehead, and temples, must be slimulant, such as Sp. Rorismar. Sp. Vin. campborat. animated with a moderate portion of Sp. volat. aromat. which may be applied two or three times a day.

It might be expected that *Electricity* would be useful in this case; but I have known it tried, not only without the desired effect but the contrary, the eye-lid being still more let down by it, which I should not have supposed; but I was assured of the fact, by the patient himself.

#### SECTION III.

# the E A R. OTALGIA.

HIS wonderful organ is subject to various affections, fome of which are attended with very alarming fymptoms; and others by which, though life be not endangered, yet the sense of hearing is often irrecoverably destroyed.

Diseases of the Ears may be divided into external, that is to fay, fuch as affect the Meatus auditorius externus only; and internal, or those that attack the Membrana Tympani, the muscles of the Malleus, Incus, Stapes, &c.

the membrane that lines the Tympanum, the Vestible, the Cochlea, and the semicircular Canals; together with that important part the expansion of the Portio mollis of the serventh pair, or Auditory nerve, on the several parts just mentioned.

The Ear is subject to rheumatic affections, from catching cold, which occasions violent pain, and even some degree of fever. But this may be removed, by the application of warm vapour, an anodyne somentation, a poultice of white bread put into a slannel bag, or a boiled turnip, applied in the same manner.

But should these not succeed, and the pain be very violent, attended with sever, watchings, &c. the patient must have some blood taken away, and this repeated, according to the violence of the symptoms and constitution of the person; the belly must be emptied by clysters, to which Nitre should be added, and moderate cathartics.

His drink may be fmall fubacid liquids, nitrated emulsions; externally, fomentations, warm vapour, cataplasms, and pediluvia. In short, every thing that may tend to check the inflammation, and promote resolution, must be done; as suppuration would probably injure the organ so much as to occasion the loss of that sense.

This is what fometimes actually happens in fevers, by translation of the morbific matter. Of which I have seen some instances; one of which I shall relate. Being defired to visit a boy about eleven years of age, who had been feveral days in a Fever, I found that the Fever was declining, but there was a confiderable discharge of matter from both his ears. I was apprehensive that irreparable mischief was done to the internal ear, and all that I could do now, was to endeavour to heal the ulcer. This I attempted to do by the use of balfamics, such as Balf. copaiva, Balf. traumat. tempered with vitell. ovi, of which three or four drops were dropped

ped in two or three times a day, with a little cotton wool upon it. The discharge diminished gradually, and at last totally ceased; but the boy became quite deaf; and in confequence of that, in the course of a very sew months, his speech was so inarticulate as to be a mere unintelligible gabble. More such instances might be mentioned, but the case is, I fear, so common, as to make it unnecessary for me to dwell any longer on the subject. Another cause of deafness, I shall just mention, and that is concretion of the Tuba Eustachiana in venereal cases, noticed by Boerhaave.\*

Deafness is sometimes occasioned by indurated cerumen, or other extraneous bodies. When it is caused by hardened wax, it is easily removed by dropping in warm water, alone, or animated with a little brandy, or a few drops of Sp. volat. aromat. about twelve to an ounce of water. This to be dropped

<sup>\*</sup> Prælect. in Inflit. \ 563.

dropped into the ears, alternately, every night, and after that, if it should be thought necessary to syringe the ear, it may be done with an infusion of rosemary or sage.

In complaints of deafness, the ears should always be looked into. Some years fince a country-man came to me to be cured of hardness of hearing. After some inquiry, I examined one ear, in which I perceived fomething black, which, with a pair of fmall pincers, I extracted; the other ear was then examined, and treated in the fame manner. The man immediately faid he could hear very well, and thought it a miraculous cure. The obstruction was formed by filaments of black wool, that he had long been in the habit of wearing, which mixing with the cerumen, had formed a hard ball that filled up the Meatus, fo as to exclude all ordinary founds.

#### SECTION IV.

# INSANIA.

HIS subject may be thought to be misplaced, and that it might have been more properly considered among the affections of the Brain. But the truth is, I thought to have omitted it entirely; and if I should be asked the reason for passing over a malady so peculiarly affecting, I should have faid that persons in these circumstances are for the most part put into the hands of those who make it their business to take care of, and treat such patients. And this, not always on account of their supposed superior skill, but because of their being

being provided with the means to be employed, when coercion is necessary; and without which little is to be done. Indeed I am perfuaded that, in many cases, the Keeping alone, does more towards the cure than any thing elfe. This is, especially, the case with patients of superior rank and fortune, and for this fimple reason, that having been long in the habit of commanding, and of being implicitly obeyed, by their family and fervants, they cannot bear to be contradicted by them, and upon the least opposition are put into a violent fit of rage: fo that we daily fee fuch patients, in general, much more placid and composed, and more easily governed by ftrangers, and those who seem to difregard their anger, than by their friends. Thus, by degrees, they acquire a compofure which at last becomes habitual, and thus they are often cured with very little medicine. This leads me to fay a little more on the fubject.

Coercion then, if necessary, is the first step

from:

to be taken. The next thing to be confidered, is the constitution, babit, and temper of mind of the patient. If he be of a firm habit, strong and sanguine, Venesection, Emetics, and Cathartics will be adviseable; in the mean time, he must have spare diet, and water or small beer for drink. This method is often successful in occasional Insanity, brought on by excessive drinking, which sometimes will continue for weeks, and at last leave the patient perfectly sound of mind, so long as he keeps himself sober.

When the patient's strength has been thus reduced to a more moderate state, we must temporize, and endeavour to find out what are the most prevailing ideas that occupy his mind. For it is often so much engaged with some one object or train of ideas, on which the person is continually intent, as absolutely to exclude all others. This train or chain we must endeavour to disturb and break into. We may attempt this by naufeating medicines, such as Tart. Emeticus, or Ipecacuanha, in small doses: to be repeated

from time to time, according to the effect they may have; and at the same time endeavour to apply to his understanding, whenever there is an opportunity. Such is the treatment that may be proper in maniacal Infanity.

When it is of the melancholic kind, evacuations must be very sparingly used. The patient must be treated with gentleness and kindness, and must be encouraged. The medicines must be Nervine, Antispasmodic, and Cordial. Amongst others Campbor has been considered as a sedative in cases of Insanity; and in this species may be joined to other nervines or cordials—but in the maniacal species, it should be joined with Nitre.

Infanity is fometimes owing to a translation of morbid humours from the furface of the body to the brain, such as eruptions of various kinds, ulcers, &c. &c. In such cases, it will be adviseable to use vapour and warm baths; vesicatories to be kept open for some time; and issues in the most commodious

commodious places, as the infide of the thighs, &c. Convalescents will receive great benefit from air and exercise, whose recovery it will accelerate and tend to confirm.

Sometimes it has been known to arife from violent mental affections, fuch as, Love, Terror, Despondency, &c. And in some it feems to be purely mental, and without any procatarctic cause whatever, that can be recollected; and fuch kinds of Infanity are, for the most part, incurable.

The violently maniacal are fometimes obliged to be treated with rigour and close confinement, but this treatment must be tempered with Humanity, and carried no farther than fecurity requires. Campbor feems, in this species, to be a fedative that deserves to be tried; fifteen grains, with as much Nitre, may be repeated once in fix or eight hours, according to the effect that it has.

#### SECTION V.

# HYDROPHOBIA.

READ of water, that formidable symptom that happens to perfons who have had the misfortune to be bitten by a mad dog, cat, or other mad animal, is one of the most difficult to account for, as it is of all affections the most dreadful. And what renders the case truly pitiable is this, that the patients are often too fenfible of their condition. This, added to the confideration, that it is a malady which having, in general, refisted the power of all the remedies hitherto recommended, however dignified with the specious title of specifics; many Physicians of experience and eminence in their profession, among others the late Dr. Fothergill,

Fothergill, have candidly declared their diffidence of the virtues of them all. And this they feem to have done with the laudable intention of preventing the loss of that time which should be employed immediately in using the most rational means, that can be thought of, to prevent the intromission of the Virus into the blood. For we find that its progress is in general slow. In two cases that came under my notice, the symptoms did not come on until about five or six weeks after the persons were bitten; and I am inclined to think, that is the most usual time of the symptoms coming on.

The most rational means seem to be, either to cut out the wounded part entirely, or if that should not be practicable to enlarge the wound, or make scarifications and apply cupping-glasses to promote a free discharge of blood; after that to apply balfamics mixed with irritants, to promote a large discharge of matter; and not to suffer the wound

wound to heal, but keep it open fix weeks or more. This feems to be preferable to cauterizing the wound. But should this be preferred, it ought to be done immediately, and if practicable to fuch a depth, as to destroy not only the wounded part, but with that, fome portion of the found flesh, least any particles of the Virus should be shut in, before a free discharge can be brought on. To these, or similar means, may be added the rubbing in Mercurial ointment about the wound, to the quantity of one drachm every fecond or third day, but not fo long as to falivate the patient. It will be right likewife to give the patient fuch medicines as have been thought successful; such as Pulv. antilyflus; the Tonquin medicine, confifting of Musk and Cinnabar; Campbor; Opium, &c. which must be given in a solid form. Antispasmodics seem to be the most likely to be of use; for not only the affection of the Gula feems evidently spafmodic, but the Heart itself feems to be peculiarly affected, the pulse being irregular, and fometimes flow, except when

when it is accelerated by the violent efforts that the afflicted fometimes make, feemingly to fly from the inexpressible terror that by turns feizes them: of this I faw two instances. One was in a man, affiftant to the huntsman, who was flightly wounded between his finger and thumb, as he was endeavouring to give a medicine to a hound. Three days after he went to Colne, where he took Hill's, or, as it is also called, the Ormskirk specific, and strictly observed, as he told me, the regimen after he came home for a fortnight, which was the time prescribed to him. He went on with his business, which was that of a cobler, for about five weeks from the time of the accident. One evening he complained of pain in his back and limbs, as if he had got cold, and went to bed. His wife, upon this, got him fome ale, which she made warm to make him fweat; but upon offering it to him, he bid her keep off, as he could not bear the fight of it. The next morning I faw him. He had about twelve ounces of blood taken away, which appeared to be perfectly well

well conditioned, and he was ordered into the Hospital. A warm-bath was prepared into which he was put; this feemed to make him very uneafy, especially when it rose up to his breast, or his face was sprinkled with it: He feemed to fuffer fo much, that I had him taken out of the bath and put to bed. I should have mentioned, that the ground being covered with fnow and the air brisk, in coming out of his house, he shrunk back, as if the light from the snow and the air affected him, and appeared terrified. When he got to bed he feemed quiet, until I defired him to let me give him a little beer, which I perfuaded him to do, though with apparent uneafiness. I took the beer in my hand, and drawing near to the bed, he started up in the utmost terror, so that. his hair stood on end, and he crept into a corner as if trying to get away; I persuaded him, however, to try to take the beer, upon which he took the vessel in both his hands, hurried it to his mouth, and swallowed some of it; he then got under the bed cloaths,

and

From this time nothing fluid, nor scarce any thing could be got down. He gradually grew worse and worse, and died in about eight and forty hours. While he lived, and in the intervals of his paroxysms of terror, he was perfectly sensible, so as to give his directions about the work he had in hand. The paroxysms would be brought on by seeing any of his friends, whom he then would desire to keep away from him. His voice towards the last grew very hollow and hoarse, and he spit out, as the saliva formed.

The other case was in a school-boy who was bitten in the lip by a favourite hound as he was caressing him; but his being mad not being suspected at the time, little notice was taken of it, and the lip being but slightly wounded, soon healed. About five weeks after, he was sent home with symptoms of Hydrophobia. An eminent Physician was sent for, who did all that was possible, but without effect. I was then desired to see him. All our endeavours were fruitless; and he

died about the third day. It was shocking to see him in the paroxysms, jumping over the bed, backwards and forwards; swarming up the bed posts; leaping up and down, until he was quite exhausted, and then sitting down and talking rationally, sensible of his condition, and praying God to deliver him out of his misery.

Bathing by furprize and half drowning the patients, in this calamitous state, having often proved pernicious, always dreadful, and often fatal to the poor *sufferer*, has lost much of the credit it formerly had, and that not without very good *reason*.

Throwing the patient into a pond, as being the only remedy against this terrible malady, and proposed by Celsus, has not succeeded with Physicians, as might have been expected, from the praises bestowed upon so many of them as are mentioned by Etmuller. The experience of Forestus and Tulpius, which is referred to, shews it to have been meant, rather as preservative than curative.\*

<sup>\*</sup> Vid. Morgagni de Cauf. et Sedib. Ep. 8. art. 26. &c.

# THOUGHTS, &c.

The T H O R A X.

BOOK II.

SECTION I.

The HEART.

HIS wonderful organ, the primum mobile in the animal Oeconomy, is from the beginning to the end of life in perpetual motion. And though it be a muscle, composed of fibres, apparently similar to those of other muscles, yet there is this material difference, that whereas all other muscles after much action, require long intervals of repose, this little organ never rests, but continues

tinues acting day and night, not less than eighty times in a minute, for seventy years, and often many more.

From this general fupposition of muscles requiring intervals of rest, to recruit and enable them to renew their action, Physiologists suppose, that during sleep, something is restored to them which had been dissipated during their action, but allowing this, that alone does not seem to evince the necessity of sleep, since whether we use little or much action, or even sit still, we become sleepy, and if we are in health cannot long do well without it. Moreover we know that the Heart never rests.

When the Brain was under confideration, I took notice that it is by means of the nerves that the Mind perceives, and executes its volitions. But the Heart is not, as other mufcles are, subject to the will, but is endued with a property prior to the nervous influence, by which it may be excited to motion even after death; though that influence be necessary

to enable it to act with force and energy. This property is called Irritability, which belongs chiefly to the Heart and Intestines, and remains for some little time after death in Man; but in some animals much longer, even after the head and all possible communication with the nerves has been cut off. To this principle is probably owing, the constant motion of the heart, and that of its motion being capable of being excited again, after it had entirely ceased. As to the matter of respiration being carried on during sleep, we are not to infer from hence that those muscles are not under the controul of the will.

# ANEURYS M.

Though the heart is in general able to bear so many years constant action, yet it sometimes happens, whether from original weakness or from accidental injury, that the sibres are insensibly stretched, the ventricles

are enlarged, their fides grow thin, and the Heart becomes aneurysmatic. A sense of weight and oppression is felt; pain in the region of the heart; palpitation; Cardiogmos; fainting.

When this is the case, all that art can do, is to prevent the increase of the disease; as, if that cannot be prevented, it may sooner or later end in disruption of the heart and instant death. The patient must be let blood once, twice, or more in the year; he must live in the strictest temperance, avoiding all strong liquors and stimulants, and all violent exertions whatever.

#### INFLAMMATION.

The Heart is also subject to Inflammation, the signs of which are heat; quick pulse; pain; palpitation; syncope. The great importance of the part, demands the most speedy remedy. Blood must be taken away freely and

and repeatedly, according to the urgency of the fymptoms and state of the pulse. The medicines must be cooling and sedative, with plentiful aqueous diluents.

These means must be continued until the symptoms of Inslammation go off. For it is of the greatest importance not only to obviate the present danger, but to prevent the Inslammation from terminating in an abscess or ulcer, and adhesion of the pericardium, which would very much embarrass the heart in its action; and occasion palpitation and other uneasy symptoms.

### PALPITATION.

The flighter and transient kinds of this affection, or fuch as are occasioned by sudden furprise and emotions of the mind; the smell of certain effluvia, such as perfumes and sweet-smelling flowers; or their contrary, putrid exhalations—those which are symptomatic

matic of Gout; Exanthemata; Affectio bysterica; or sympathic, as when owing to some affection of the stomach and bowels, from their being both supplied with nerves from the eighth pair and the intercostal, I shall not here dwell upon.

The idiopathic diforders of the heart, in which palpitation is observed, such as inflammation, and aneurysmatic enlargement of its ventricles, and the large blood-vessels, having been already taken notice of, I proceed to observe, that whatever may be the occasional cause of palpitation, the proximate seems to be either a diminution of the force of the heart, or the resistance of some obstacle, that prevents the expulsion of all the blood out of the ventricle by one systole, so that repeated efforts become necessary.

It is mentioned by Authors as an attendant on Hydrops Pectoris, but they are not agreed in its being a symptom of Hydrops Pericardii. This leads me to mention a case that occurred

curred to me. The patient was a middleaged man, who had for some time appeared leucophlegmatic. He complained of shortness of breath; and a heaviness about his heart, with a beating. The motion of the heart was not a palpitation merely, but rather feemed an undulation of a fluid, with a rolling motion. Having the opportunity of examining the case after death, I found the Heart enlarged to an uncommon fize, and fix or eight ounces of water in the pericardium.

### LEIPOTHYMIA-SYNCOPE.

Those affections which are owing to the diminution of the animal and vital powers and the fenfes, though called by different names, feem to have nearly the fame origin, and to differ in degree only. In as much as the beart and senses are affected by some evident cause, such as violent perturbations of the mind; inanition; too great plethora; they

they are called *Idiopathic*. But when they are fymptoms of some other disease, they are termed symptomatic; hence, *Syncope Arthritica*, *Exanthematica*, *Stomachica*, &c.

The treatment is much alike in all, only due attention must be paid to distinguish well between those that arise from *Plethora* and *feverish* indisposition, which may require bleeding; from those that are occa-fioned by *inanition*, great fatigue and the like, where it would not be adviseable.

### ASPHYXIA.

This is a total ceffation of the motion of the heart. It is fometimes caused by sudden and violent emotions of the Mind, and other occasional causes. But the most frequent causes are suffocation or drowning; the sumes of charcoal; of fermenting liquors; Mephitis; foul air, &c. which were formerly much more fatal than they are now. Thanks to those

Affociation, for the express purpose of affisting such as might have the missfortune to be
in any of the above mentioned circumstances; and who must feel ineffable pleasure, in having been the means of saving
the lives of bundreds, who without the judicious and persevering application of the means
recommended by that Society, would now
have been in their graves.

are, design foldivided into annalier and

fraction folders wattly of lafty they refeasinged

SECTION II.

# The LUNGS.

FAUCES, &c.

HE fubstance of the Lungs consists chiefly of a loose cellular membrane, which is divided into lobes; which are, again, subdivided into smaller and smaller lobules, until, at last, they terminate in very small cellules, that communicate all one with another, and are full of air; which exhales from the extreme ramifications of Aspera arteria, and by their general communication, pervades the whole Lungs. In these very small cells, terminate also, the pulmonary Arteries and Veins; into which, the former exhale an aqueous vapour, that is again

again re-abforbed by the veins. The Lungs are nourished by the bronchial arteries which are accompanied by the bronchial veins, and both communicate with the extreme branches of the Bronchia. The Aspera arteria is lined with a soft irritable membrane, which is moistened by a mild, watery mucus, that is furnished by numerous simple glandules, situated in the interstices of the Cartilages, and opening by very small ducts, into all the cavity of the wind-pipe and its branches.

The necessity of free, uninterrupted respiration, to life and health, is universally known; but how or upon what principle this necessity rests, or what it is that the air communicates to the Lungs, or receives from them, I do not pretend to determine. I would, therefore, recommend to the reader the observations of the ingenious D. Priessley, Crawford, and other excellent Philosophers who have, with so much pains and ingenuity, investigated the constitution and properties of the air, and its influence in the animal occonomy.

I would

I would farther just observe, that the cavity of the Thorax is lined with a thin dense membrane, rather stronger than the Peritoneum, called Pleura, which is attached by a cellular fubstance to the inside of the ribs; it is extended all over the Lungs, the Pericardium and the Diaphragm, on one fide; is attached to the middle of the Sternum above, where it becomes double by the junction of that of the other fide; fo that the two taken together, may be compared, in some fort, to two large bladders or bags inflated; connected at the sternum and the spine; this connection forms the mediastinum; leaving a space in which are lodged the Thymus, fome conglobate glands, fat, &c. The mediastinum being attached to the middle of the sternum above, but inclining to the left as it descends, it adheres to the cartilages of the ribs, and thus the right cavity becomes a little larger than the left. They are completely feparated into two, which have no communication at all with each other, fo that one balf of the Lungs may be very much difeased,

eased, while the other is perfectly found. Of this I met with a remarkable instance, some years ago. A Sheep-stealer being difcovered by a person upon the watch, with a sheep upon his back, and not being willing to furrender, in attempting to escape, was fired at from a piece loaded with flugs. Having on a great coat of strong cloth, though he was beat down, he was not fupposed to be much hurt. He was taken and committed to the Castle; where having been about three weeks, he died. An inquest being ordered, the Surgeon defired me to be present. I could not find that the man had made much complaint until a few days before he died. The cavity on the right fide was full of a brown ichor, but nothing remaining of the Lungs, except the ragged remains of the Bronchia and the blood veffels. In the left fide every thing appeared perfectly found, without even fo much as the flightest adhesion of the Lungs to any part. By the strictest fearch, I could not find that any of the flugs had penetrated; but there had

had been a confiderable contusion below the the right fcapula, and some degree of extravasation of blood in that side, occasioned by the shock, which had corrupted and dissolved the substance of the lungs.

### PERIPNEUMONIA;

# PLEURITIS; PARAPHRENITIS.

Though these affections of the Thorax are treated on by Medical Authors as distinct from each other, the first being supposed to be an inflammation of the Lungs; the second of the Pleura; yet in enumerating the symptoms, they are so much alike, as to leave the distinction very ambiguous. Both are attended with fever; pain in some part of the chest; dissinctly of breathing; cough and hard pulse; this, however, is not constant in Peripneumonia. In the Pleurisy, the pulse is hard; the pain in the side is pungent; increased by breathing; coughing is very painful;

painful; and lying on the Side affected very troublesome, &c.

Upon the whole, I am inclined to think that the *Pleura* alone, is fcarcely ever *inflamed*, but becomes fo by its connection with the *Lungs*, *Diaphragm*, *Pericardium*, &c.

In inflammatory affections of the Thorax, the attention of the Physician is to be directed to the preservation of the Lungs whole and entire; that the inflammation may be carried off, by Resolution of the Obstruction. To this end, blood must be taken away freely, according to the constitution of the patient; and this must be done repeatedly, in the beginning, or in the course of the first two or three days, to about eight or ten ounces at a time, as the strength of the pulse and urgency of the fymptoms may require. Three or four bleedings will, in general, be fufficient; for as free Expectoration is in these cases to be encouraged, the vital strength must not be too much depressed. It is to be remembered that the foftness of the pulse is not,

in this case, a reason for not repeating Venesection, if other circumstances demand it. The Medicines most proper are the neutral faline draughts; nitrated diluents, taken frequently, warm; campborated Nitre; and clysters of warm barley water nitrated. Applications to the side are sometimes useful for easing pain; fuch as Lin. volatile; fomentations with bladders, half filled with bran-pultice; and a Veficatory to the part pained, when the other means fail.

Paraphrenitis or inflammation of the Diaphragm, may perhaps be distinguished by the pain being chiefly about the ends of the short ribs, and by the patient's feeling himself as if tightly girded.

The method of cure is, in general, the fame. I have sometimes thought that Angina Pectoris, may be in part occasioned by some fimilar affections of the Muscle triangularis Sterni, though it is generally supposed to be the Mediastinum that is affected.

PHTHISIS.

# PHTHISIS.

I have already faid, that Refolution is the most fafe and defirable termination of inflammation of the Lungs; if, however, the means proposed for that end should fail, Suppuration is next to be expected and wished for, as Mortification would be inevitably fatal. If Suppuration take place, deep in the fubstance of the Lungs, it will form Vomica, in which difficulty of breathing and a dry cough continue; with great uneafinefs, and fometimes Impossibility of lying on the found fide; shiverings; bettic Fever, &c. If the collection of matter be large, and many confiderable branches of the trachæa Arteria open into it, the quantity of matter rushing into the Wind-Pipe, is fometimes fo great as to occasion Suffocation; but if that do not happen, and the matter be freely discharged and well conditioned, the beetic gradually declines, and the patient recovers. The termination by Refolution is generally at-K 2 tended

tended with free Expectoration, which relieves the obstructed vessels. But if the cough and spitting should not gradually diminish, if the Fever should continue, with Exacerbations about Noon, or in the Evening; circumscribed redness in the cheeks; heat in the slesh; thirst; and these succeeded by profuse Sweats, it becomes Phthiss; the cough and purulent spitting continue; the body becomes emaciated and weak; and Death closes the Scene.

All that art can do in these Circumstances is to endeavour to palliate the most urgent symptoms; to let the patient change his Air; to ride in the open Air, as much as his strength will bear; but not to be too much fatigued; to live upon Milk chiefly. To drink milk diluted with Bristol or Seltzer waters; whey; butter-milk, &c. And to use ripe, subacid fruits, with due regard to the state of the Bowels. One thing more, I would observe, concerning the change of Air or Place, whether to Bristol; Wales; Scotland;

land, or to the Continent, that it be done foon as possible, and not deferred, as is too often the case, until the patient's strength be so much exhausted, as that he either dies by the way, or in a foreign country, to the accumulated grief of his family and friends.

Balfamic medicines are very often used in these cases, but I believe, in general, to very little purpose; as their nature must be so changed before they can possibly reach the part affected, as to be no longer what they were. Benesit has been said to have been received, when they are conveyed to the part in the form of vapour by the medium of athereal Spirit. That they may be thus carried in small quantity to the Lungs immediately, I believe, and have known it tried; but as to their Success, I can say little.

## EMPYEMA.

When the inflamed part of the Lungs, is in contact with the Pleura, they soon adhere, and the matter, in time, makes its way between the Ribs; but is still covered by the external parts; which grow thick and ædematous; this points out the seat of the Disease, and the Place where an opening may be made, and the matter be discharged. It often becomes fistulous, and the matter is, from time to time discharged; a tent being kept in it for that purpose. The matter is often very fetid, and on that account disagreeable; but the Patient is, in the mean time, tolerably easy. The other side being probably found and well.

When matter is contained in the cavity of the chest it forms Empyema, the symptoms of which, are cough; breathing difficult; bestic fever; lying-down very trouble-some; a sense of sluctuation is felt in the Thorax;

Thorax; and other figns like those of Dropsy of the Breast. Copious Expectoration might feem to carry off the matter, but this is not the case; for though it may give some relief, yet large Quantities of matter have been found in the Thorax; though Expectoration had been very copious. And indeed the symptoms and signs are, sometimes, so equivocal, that the utmost Circumspection is required to prevent mistakes, since we sometimes see patients able to lie in any position, with little Cough, or other apparent affection of the Breast, in whom, after Death, the Lungs have been much decayed and turned to matter.

Empyema has sometimes been formed sooner than might be expected, and one lobe of the Lungs turned into matter in a fortnight; while the other remained entire and sound.

Phthisis is not only the consequence of the diseases of the Lungs above-mentioned; but also

also of Hæmoptysis; catarrhal Fevers; Influenza; repulsion of cutaneous Eruptions; Scrophula; especially in young persons. Some Constitutions are, more than other, disposed to it; especially those of a delicate Complexion; rapid growth; who are subject to catarrhal complaints; Cough, &c. and who, too frequently neglect the care that is necessary on such occasions. It is astonishing to see how rapid the progress of the disease sometimes is; becoming fatal in the course of two or three months.

The abdominal Viscera are also subject to inflammation and its consequences, of which notice will be taken as we go along; but beside the cases in which Suppuration has been the consequence of evident Phlegmasia; matter is sometimes formed in so secret and surreptitious a manner as never to be suspected.

Those large Abscesses which sometimes form in the thigh; baving their source in the

the Hypogastrium, and that are generally thought psoadical, are not always suspected, until by the descent of the Matter into the thigh, it becomes sensible to the Touch.

A case of this fort which came under my inspection a few years since, deserves, I think, to be related.

A young woman, aged about twenty, apparently in perfect health, was fent to the County Hospital, on account of a swelling in her Groin, supposed to be a Rupture.

The tumour was about the fize of a Tennis-ball, but very foft and yielding; perfectly free from pain, and the skin not the least discoloured. At the Surgeon's request, I examined the patient; and for this purpose desired her to be laid on her back. While with one hand I pressed the tumour, my other hand was laid upon the Hypogastrium; and pressing with each alternately, I perceived a very great Fluctuation. The dis-

charge of the fluid being resolved, Mr. Fell proposed the doing it by a caustic of a moderate size. The quantity of matter discharged, was little less than a quart; it was about the colour and thickness of Cream, and perfectly inodorous.

I had been particularly inquisitive respecting her health before the appearance of the swelling; but she assured me that she had never had any Fever, Pain, or Sickness, nor Shiverings whatever; nor any other Indisposition before or since its appearance.

After the first Discharge, matter continued to flow in smaller and smaller quantity, and grow thin. About the end of ten or twelve days, all which time she seemed to be going on very well, she began to complain of loss of Appetite; Languer; Thirst; her pulse became quicker than usual, and the matter not much, but ichorous. Those appearances grew daily more and more alarming, so that there seemed only one thing to give

give her the chance of—her own country Air. She went home directly, where I heard she died tabid, in a few weeks.

To what shall we attribute this great change?

The matter was let off by a fmall opening; the dreffings were quite fuperficial. Could the action of the external Air on the cavity from whence the matter had been difcharged, occasion such change? Psoadic absceffes have often terminated in a manner similar to this, especially when discharged by a large opening; to which the fatal Issue of the case, has by Surgeons been generally attributed; and on this account they have thought it best to make the opening small; which they have found to succeed better.

2. In fuch cases as these, might not some kind of injection, especially a balsamic one, be adviseable?

Tabes from internal ulcers are generally accompanied with Hectic Fever, Marafmus, colliquative sweats, Urine high coloured, and depositing a red fediment, which last I have ever found to attend them.

## A S T H M A.

Great difficulty of breathing, Stricture and Anxiety, with wheezing and dry cough, returning at uncertain intervals, are the usual marks of this chronical disease. But though it is chronical, its attacks are sometimes so violent as to be very distressing and alarming; so as to require Bleeding, Vesicatories, and attenuating stimulants, such as Gum Ammoniac. Asafetida, Acet. Scillæ, Mel. Scillæ, &c.

Difficulty of breathing, with Oppression and a sense of fullness in the breast; frequent cough, and sometimes a great quantity of Mucus, is often occasioned by taking cold, and for that reason is called Catarrhal. This may

may in some require bleeding, but in general, attenuating stimulants, Emetics, and Venicatories are the most useful.

When there is a quantity of vifcid mucus, I have feen great relief obtained by the powder of Squills, given in fuch dofes as to procure a difcharge from the Stomach; as recommended by Hoffmann and others.

There are yet many other species of idiopathic Dyspnæa; as there are various occasional causes; due attention to which must
be had, in drawing the curative indications; which I shall not take up my reader's
time to enumerate, but beg leave to refer
him for these, and also for a copious list of
Symptomatic Dyspnæa to Dr. Cullen's Nosolog.
Method. the cure of which will likewise depend on due consideration of the nature
and state of the primary disease.

#### SECTION II.

# Trachæa Arteria and Fauces.

ANGINA; INFLAMMATORIA.

HE intimate connection there is between the Trachæa arteria and the Fauces, leads me to the confideration of Angina, a difease in which they are both affected, more or less, at the same time.

Angina is usually considered as being of three species; namely, inflammatory; apb-thous or ulcerous; and malignant or gangrenous. Other differences are mentioned by Authors, but they are more or less allied to these. This Alliance, however, makes it a matter

matter of very great importance rightly to distinguish, at the Beginning, one species from another; as the proper treatment of one, would be very pernicious in another. The inflammatory, for instance, requiring the taking away of blood freely and repeatedly, and antiphlogistic medicines, both which must be used with great caution, in the ulcerous; and which, in the gangrenous, would be very detrimental.

In order, therefore, to make a right Diflinction, we must take into consideration the Constitution of the Year and the Season; the Age and Sex of the patient; and the nature of the prevailing diseases, &c.

The inflammatory species happens mostly to young men of strong constitutions, sanguine complexions, and who lead active or laborious lives. It comes on with pain in the neck and throat; redness and swelling of the Fauces and Tonsils; pain and difficulty in swallowing; Head-ach; a full and quick pulse;

pulse; Febris Synocha. The cure, as has been already hinted, requires that blood be taken away at the first, freely, and to be repeated in the course of the first and second day, according to the Urgency of the Symptoms, and State of the Pulse. To this must be added, Clysters; or if the patient can swallow, Laxatives, to empty the Bowels; and Vesicatories to the Neck and Throat.

In the mean time the patient must endeavour to bold in his mouth, and to swallow, very frequently, warm, small, nitrated liquids; and to draw in warm Vapour, by way of fumigation; and thus to pursue the faline, cooling method, so long as may seem necessary. But if, notwithstanding all this, the Swelling should be, as it were, at a stand, though the symptoms of Fever, &c. be abated; and the Tumour instead of Resolution should tend to Suppuration, that must be encouraged; as it is the next most defirable Termination. For though it be sometimes alarming to the patient, the cure is often more speedy, than it is by Resolution.

ANGINA

### ANGINA APTHOSA, &c.

This Species is most frequent in Children, young persons, and Women. The same parts are affected with swelling, redness, and whitish or brown spots; which spread and ulcerate. The Fever is rather of the Typhus kind; and the skin affected with a red Efflorescence or Eruption.

The method of cure most proper here, is to keep the patient in bed, but not too warm; to let him drink freely of small Tea, or Barley-water moderately acidulated with Lemon juice or the best Vinegar; and frequently to hold in the mouth and endeavour to swallow, a mixture of Sage tea, Tincture of Myrrh, and Honey, very moderately acidulated with Sp. Salis, so as not to be unpleasant to the taste. If the patient should not be able to take it in that manner, some of it must be injected frequently by a small syringe, and a Vesicatory must be applied

The patient must be supported by proper liquid nourishment, to which Port Wine may be added, in such manner and proportion, as shall seem advisable. Or if the patient cannot swallow what is sufficient, the same may be injected as a Clyster once a day or twice, if thought necessary.

The Angina Maligna, or Gangrenofa, seems to differ from the last only in degree. It is ordinarily Epidemic and contagious. The Fever, with which it is attended, being of the Typhus kind, is not very considerable at the first; nor does it often increase much, so that bleeding is seldom required, and is not to be employed without great Circumspection.

The Fauces, Tonfils, Uvula, and Palatum Molle, are of a deep red; inflamed and painful; with yellow or brown spots, which become deep Ulcers, casting off sloughs; and are attended with great Fætor and Putrefaction.

As the case, even at the first, seldom admits Venesection; the patient must keep his Bed, but must be kept cool. He must be liberally fupplied with finall tepid drink, acidulated with Lemon-juice; Vinegar; or Spirit of Salt, &c. a Veficatory must be applied to the Throat. He must gargle with Sage tea, Tinet. of Myrrh, Mell. Despumat. and Port Wine. And now and then fwallow a spoonful of this or some such mixture, B. Balf. Traumat. Muc. Gum. Arab. aa 3 fs. Mell. desp. 3i. Infus. Salviæ, 3v. Sp. Sal. Mar. Gutt. quot Suff. iciunt ad gratan Ociditz.

A decoction of the Bark, with the addition of one fourth part of red Port, may be taken every four hours. In the mean time he must, from time to time, take a small bason of Panada or Sago, with Port Wine; a glass of which may be also necessary occasionally, in case of Languor. His chamber must be frequently ventilated, campborated Vinegar should be sprinkled about the Bed; and the

room fumigated with Frankincense or other Rosins.

### ANGINA TRACHEALIS.

There is yet another species of Angina, called Trachealis or Laryngæa, in which the membrane which lines the Trachæa Arteria and the Larynx, are supposed to be inflamed. This chiefly happens to young Children, whom it feizes fuddenly with a fense of Strangulation, excessive Oppression, and Difficulty of breathing; and instead of a Cough, which they feem to be irritated to, they have a Wheezing, and a fort of crowing, with great Anxiety and Distress. The attack is, for the most part, so sudden, and its Progress so rapid, as to require the most speedy Assistance. And as by the circulation through the Lungs being fo much embarraffed, the veffels must be greatly diftended, it will be adviseable to take away fome blood immediately; to apply apply a Vesicatory round the neck; to put the Patient's feet into warm-water; and to give him the following, or some such mixture, B. Oxymel. Scitl. Vin. Ipecacuan. āa 3 ss. Aq. pur. 3iii. Sp. C. C. gutt. xx. one spoonful every quarter or half hour until some relief be obtained. In the mean time let the patient try to sip some warm liquid, as Tea, and endeavour to inspire the warm vapour.

The great difficulty of breathing, and firidulous voice, are so sudden in this case, that I should apprehend these symptoms to be owing rather to some spasmodic affection of the musculi arytænoidei of the Glottis, than to inflammation of the Trachæa Arteria, and an excess of Mucus there, which seem to belong rather to the suffocating Catarrh.

### OESOPHAGUS.

We have feen how the Pharynx is liable to be affected in cases of Angina, which fometimes

fometimes and in some degree, affect the Oesophagus also. But independent of this connection, the Gula is subject to Instammation, Ulceration, Constriction, &c. which are often occasioned by external causes, such as swallowing too large morsels, bones, splinters of bones, pins, &c; but not unfrequently when such causes could not be supposed or suspected.

I have met with feveral cases of Constriction of the Gula, for which the patient could give no reason; and which by a slow gradual Increase, have, at last, arrived at such a degree as not to leave a passage for, even, liquid food, sufficient to support the Patients; who, at last, died miserably, for want of Nourishment.

In one or two instances, I thought some benefit was obtained by Mercurials, administered with such caution, as not to cause too great Fluxion upon the part; but I am forry to say that it is in general incurable.

CASE

# CASE of ULCER in the Oesophagus.

I had once an opportunity of examining the parts, in a woman who died in this case; after having been for some time supported by nourishing Clysters.

I found a large ulcer in the Oefophagus, the fides of which were, in that place, fo much thickened as scarce to give passage to a Probe, for near two inches downwards; the broad part of the cricoid Cartilage was great part of it consumed, by a Caries, and more of the Trachæa Arteria ulcerated.

This affection comes on infenfibly, the patient feeling nothing more at first, than as if he had swallowed too large a Morsel. As it increases, he feels as if what he swallowed, stopped about the bottom of the Sternum; and what he had taken down, comes up by mouthfuls, with something like a Hiccup. By degrees, the difficulty increasing,

creafing, he is obliged to fubfift wholly on liquids, and at last cannot take a quantity of them sufficient to support him.

The Oefophagus is liable also to Compreffion from the swelling of the Glands in and about it; and at its lower part, from spafmodic affections of the lower Muscles of the Diaphragm, between which it passes. In the latter case antispasmodics, such as T. fætida, Spt. volat. fætidus and Sedatives, are useful.

the broad page of the critoid Cartilage was

BOOK III.

# THOUGHTS, &c.

ON THE

### ABDOMINAL VISCERA.

The STOMACH, &c.
BOOK III.

SECTION I.

BEING copiously furnished with nerves, the Stomach is extremely sensible; hence it is no wonder that it is so frequently the Seat of pain, especially when we consider its office in the animal Oeconomy. For being the common Receptacle of all that we eat and drink; and our Food and Drink frequently consisting of most beterogeneous compositions, we ought not to wonder at the astonishing N catalogue

catalogue of affections, idiopathic and symptomatic, to which this organ is exposed, that to enumerate them would be almost as difficult as, with Juvenal, to tell, "quot Themison "agros autumno occiderit uno." \*

The most common of these affections, which happen without any difease in the organ itself, are chiefly owing to Indigestion, or Dyspepsia, fuch are Cardialgia or pain in the Epigastrium; Inflation of the Stomach; Eructations; Nausea; Vomiting; loss of Appetite, &c. These are, in general, to be removed by fuch means as the nature of the occasional cause may require. If the Pain and Distension be owing to Excess of Fruit or cold Vegetables, some warm stomachic and laxative TinEture, or Spirit, will be of use; but should that fail, it will be adviseable to endeavour to dislodge the offending matter, by drinking warm-water, Chamemile tea, &c. and affift the Operation by stimulating teregracous compolitions,

<sup>\*</sup> Lib. 10. v. 221.

lating the Fauces. After the Stomach is cleared, it will be adviseable to take Tinet. Rhab. zi. Vin. Aloes, zs. And to continue bitters with Tonics, in smaller quantities, for a few days, or as long as they are of use.

In order to prevent these disorders, nothing is so much to be attended to, as a well regulated Diet, and yet, in general, nothing is so little regarded.

I might here declaim against the various compositions that the Art of Cookery furnishes, to folicit Appetites, which that Art has rendered so fastidious, as not to be pleased with plainer and wholesome Food, but that it would be labour lost.—"Noncanimus surdis."

I cannot, however, omit this Opportunity of faying, that Food confisting of a due proportion of animal and vegetable substances, dressed in the most simple manner, with the addition of salt, pepper, &c. so as to render them more palatable; and for Drink, the

best is, in general, Water, to which, in some cases, a moderate portion of Wine or some good Spirit may be added; Table-beer, Porter, &c. and then a sew glasses of sound Wine; would be the most wholesome. And if the more exalted Compositions of Cookery; and the incongruous mixtures "frigida cum calidis," &c. which a variety of Dishes presents, were avoided, we should not hear so much of Dyspepsy, and the numberless train of Ills, of body and mind, occasioned by Intemperance.\*

It must, however, be acknowledged, that fome Stomachs are liable to Indispositions, under the most careful Attention to Diet; according as the Food is disposed to one or other kind of Acrimony, acescent or alkalescent; from whence arise Soda, or Hearthurn, and other pains of the Stomach.

They who are subject to acid Acrimony, should

<sup>\*</sup> Innumerabiles esse mortos miraris? Coquos numera. Seneca, Epistol. 95.

should avoid excess in such things as have that Tendency; such are farinaceous and other vegetable substances, especially sweet things. On this account Puddings; Pastry; nay even Bread must be used with moderation. The animal part of their food should be Mutton, Beef, wild Fowl, Shell-Fish, &c. in preference to Veal, Lamb, or Chicken, though any of these may be eat. Mild Ale, or sound Porter, or Water with or without a small quantity of Spirit; and a glass of sound Port, will be the properest.

Should the acrimony be alkalescent, which may arise from eating much animal Food, and especially wild, putrescent, or of haut Gout; high seasoned meats; baked Fish; fried Eggs; it will be adviseable to drink warm-water, and endeavour to discharge it, and to take Lemon-juice, or other vegetable acid properly diluted; and then a dose of T. Rhab. and Vin. Aloes. Soda from acid Acrimony may require the Stomach to be cleared first, and then the acid Matter may

be corrected and carried off by Magnefia calcinata, joined with T. Rhab. Vin. Aloes, &c.

The Stomach is fometimes overloaded with Saburra, or thick viscid Mucus, occasioning Pain, Sickness, Anorexia, &c. Vomits are, in thefe cases, often necessary, but we must remember, that a confiderable quantity of Mucus is natural to that Organ, to defend it from the Acrimony, which it fometimes is exposed to, and which, were it not for that defence, would be fometimes intolerable; we fhould not, therefore, be over folicitous about every appearance of Phlegm or Mucus, least we should deprive it of what is necessary.

This Organ is also subject to various idiopathic Affections, fuch as Inflammation; Abfcefs; Ulcer, &c.

The fymptoms of Inflammation, are pain in Epigastrio, or Gastrodynia; with a sense of Heat; Nausea; Hiccup; Fever; and Thirst. The most speedy relief must be attempted,

by Bleeding; emollient Clysters nitrated, without any other Stimulus, unless a stool be thought necessary; a warm Bath; and Barley-Water, or Milk and Water moderately nitrated, which is to be taken in small quantity, but frequently, warm, until the Symptoms abate: In the mean time, he may take now and them a small bason of Chicken-Broth, which with a Clyster of Milk or Broth, once or twice a day, will be sufficient to support the Patient, as long as such support will be wanted.

# and am cloudd as ULCER . Hideo bauch asb

laye peen tinged mach, and the Gall-blad-

An Ulcer in the Stomach is generally accompanied with agnawing or smarting pain, frequent Nausea and Vomiting; a sense of Smarting and Soreness upon taking almost every thing, but especially things that have more or less of Acrimony, either saline, aromatic, or spirituous. The matter thrown up by Vomiting, is for the most part brown, or of the colour of Chocolate, and sometimes inclining to black, without any disagreeable smell

fmell, but often in greater quantity than could have been expected from what the Patient had taken in. It has been by some, thought to be formed of Bile. But in the cases that I have seen, it appeared rather to be Blood, that ouzed, more or less, from the Ulcer, in such quantity only, as not to excite Vomiting, until by its Increase it produced that effect; but in the mean time, it had lost its vivid colour, and was more or less changed. Instances, indeed there are, where the Stomach and Duodenum have been tinged black, and the Gall-bladder found containing a fluid as black as Ink—an Bilis atra Hippocratis?

In the cases, that occurred to me, the Patients became besical, lingered for some months, and at last died tabid; and I had to regret the not having an Opportunity of examining the Bodies after death. Such an Opportunity, however, I had in another Patient who died with the Symptoms above mentioned, in whose Stomach I sound an Ulcer almost the bigness of half a Crown, near

near the *Pylorus*, the fides of which were thick and uneven; the *Pylorus* was much thickened, and the passage greatly straitened. The rest of the Viscera appeared sound.

The Stomach though in itself found, suffers fometimes from Diseases of Parts adjacent to it, which I shall have occasion to notice, when I come to speak of the Liver, Pancreas, &c.

From the Pylorus, begins that part of the Intestines called Duodenum, which tends rather backwards and to the right side, where it touches the neck of the Gall-Bladder. From thence it descends obliquely towards the right, and is received in the Mesocolon, about the place where the Ductus choledochus enters it. From thence it ascends, passes behind the Pancreas and large Mesenteric Vessels to the left; gets out of the Duplicature of the Mesocolon; then descends and becomes Sejunum.

The Duodenum is lax and rather large;
O and

and by its ascending, after receiving the Ductus choledochus and the Pancreatic Duct, it gives some opportunity for the Bile and Pancreatic Liquor to mix with the Food.

The Pancreas extends from the Spleen to the right, almost transversely, over the Vertebræ; is received between the Laminæ of the transverse Mesocolon; and its round Extremity is almost surrounded by the Duodenum to which it is attached.

As I shall have occasion to mention the *Pancreas* and the *Duodenum* hereafter; this short account of their situation, may not be thought superfluous; and will answer my purpose as well as a more *detailed* and more accurate description.

#### LIVER.

The great Importance of this Organ in the animal Oeconomy may be supposed from its Magnitude,

Magnitude, being the largest of all the Viscera. And as its office is to separate the Bile from the Blood, we may thence infer, that it is to that the Liver owes its Importance. And in fact, we find, that whenever the Bile is deficient or depraved, the due Assimilation of the Food is prevented; the Chyle becomes imperfect; Nutrition fails; the Body becomes by degrees cachectic, anasarcous, dropsical.

The large quantity of Blood that passes through the Liver, but especially that by the Vena Portarum, which performs the office of an Artery, but without its contractile Power, is retarded in its progress; and hence probably the disposition to Obstructions and Schirrous Tumours so frequently found in this Part.

The mesenteric and the splenic Veins, of which the former is the largest, together from the Vena Portarum, which is dispersed through the Liver, accompanied by the ramifications of the bepatic Artery, the Vena cava and the Ductus bepaticus; these communicate

one with another, the Vena Portarum with the Porbiliarii, and the branches of Vena cava; and this too, with the bepatic Artery.

The blood brought by the mesenteric Vein, is supposed to be charged with oily, fetid, and alcalescent Particles, absorbed by the mesaraic and internal bæmorrboidal Veins; and thus being, by its nature and retarded motion, rather too viscid, is supposed to require being diluted, which is thought to be performed by the Blood brought from the Spleen; the whole fubstance of which, being formed of the ramifications of Blood Veffels, and having no excretory Vessels, and being at the same time lodged in a part, where the warmth is confiderable, becomes alcalescent; is attenuated, and mixing with the mesenteric Blood, not only dilutes it, but fupplies it with fomething necessary to the completion of the Bile; and this too, at a time when it is most wanted; when the Stomach is diffended with Food; which preffing upon the Spleen, urges on and accelerates the motion of the Blood from it.

### The DISEASES of the LIVER,

are Inflammation; Abscess; Schirrous Tumours, &c.

Inflammation of the Liver is attended with Fever; pain and Tension of the right Hypochondre, which extends to the Shoulder; highcoloured Urine; Thirst; dry Cough; Hiccup; Faundice, &c. As Resolution is the most defirable termination, this must be attempted by free and repeated Bleedings; fmall nitrated diluents; Clysters; mild laxatives; and proper diet. But should Suppuration take place, the Event will be doubtful; unless the Abscess should be in Contact with and adhering to the Peritoneum; and then it may be discharged outwardly; or, by some Communication with the Intestines, may be carried off by Stool, which I have known to happen.

#### CASE of an ABSCESS.

A remarkable instance of an Abscess in the Liver came under my Notice. A middle-aged man was admitted into the Hospital, with a large Tumour in the right Hypochondre. Before this appeared, he had great pain in the part, with Fever, Shiverings, &c. He was now much emaciated, pale and bectical. He had been but a few days in the Hospital, when he was, one morning, seized with violent Vomitings, soon after which, the Tumour disappeared, the whole Belly became swelled; and after languishing two or three Days he died.

Upon opening the Body, I found a great quantity of matter in the Abdomen, which had been discharged from a large Cavity formed of almost the whole right Lobe of the Liver; the outer covering of which was the Sac, which was lined with a white Sub-stance of some thickness, not much unlike buff

buff leather. In the Cavity I found a great number of Hydatids of various fizes, from that of a large Goofeberry, to that of an Apricot or Peach. I had some of them boiled, but that produced little Change in them, except that the Shell seemed a little thickened, but the Fluid was like pure Water.

Schirrous Tumors in the Liver are not unfrequent, but are feldom discovered during the Life of the Patient, unless the whole Vifcus be much enlarged, of which I have met with some Instances.

#### CASE of a Schirrous Liver.

Case—An elderly Man was sent to the Hospital on account of a pain at his Stomach
and frequent Vomiting, by which he was
become much emaciated. Finding that his
Pain and Vomiting were constantly brought
on by taking Food, he lived chiefly on small
quantities of warm Milk, the Yolk of Eggs
diluted with warm water with a little sugar,
and things of this kind.

The

The Stomach was suspected to be diseased, until death gave me an opportunity of discovering the Seat of the Malady. The Stomach appeared to be pretty sound; but the concave surface of the Liver which pressed upon it, had a number of hard white bodies like Steatomata in it; the Apices of which were prominent, and seemed capable of irritating the Stomach so as to occasion the Symptoms.

#### CASE of DISEASED LIVER.

I take this opportunity of mentioning a case affecting the Liver, very different from the above.

Case—A youth of about eighteen years of age, was brought to the Hospital with a very large swelling of the Epigastrium, towards the right side. Upon inquiry, he told me that some weeks before, he had received a violent kick of a Horse, which gave him great pain. He could not tell me what had been done, but whatever it was, it did not prevent

prevent the Swelling, which by degrees increased so much, that he was at last advised to come to the Hospital. The principal part of the Swelling was, as I have said, on the right side of the Epigastrium extending to that Hypochondre. There was a very sensible Fluctuation, similar to what we feel in Ascites, but it was not perceivable below the Navel.

The case appeared to be very unpromising; so that I had no encouragement to meddle with it, but as without discharging the Fluid, nothing could be of use; and as it appeared to me, that it might be discharged with safety, though with little prospect of more than a little temporary Relief; even this consideration determined me to try it. I proposed its being done by the Trocar, which was accordingly passed into the most prominent part of the Swelling, and where the Fluctuation was the most sensibly felt; by which were discharged about two gallons of thin brown Ichor, not fetid, which seemed to have been contained in the Covering of the right Lobe

of the Liver, the fubstance of which was dissolved. The Patient was relieved by the Operation, and was upon the whole easier while he lived, which might be about four-teen days after he left the Hospital.

# CASE of MATTER DISCHARGED by STOOL.

Having occasionally mentioned the matter of internal Abscesses being sometimes difcharged by Stool, I take this Opportunity to relate the case of a Patient, who had been afflicted feveral days with great pain in his Belly, which was much fwelled, with great Tension, attended with Fever. His Apothecary in the country, had used very proper means, fuch as Bleeding, laxatives, fomentations, &c. but still the swelling continued; the Patient loft his strength, so that his life was thought to be in great danger. Such was the state of the case when I was sent for. In examining the Belly, and taking into confideration the attending symptoms, I suspected matter to be formed among the abdominal abdominal Muscles, but so deep that I durst not propose an opening then, but advised perseverance in the use of proper outward Applications, and in the mean time to endeavour to support the Patient. About a week after, I had a letter from the Apothecary, informing me that the Patient had voided a large quantity of Matter by Stool, from which time he began to recover and did well. He had a Return of the complaint about two years after, which terminated in the same manner, since which he has continued well.

## PANCREAS.

Having already mentioned its fituation, I have only to add that being a true falivary Gland, its fluid has the fame use in digestion as the Saliva; only being so very large, it is supposed to furnish triple the Quantity, that the other salival Glands do, of a thin aqueous, insipid Fluid, neither acid nor alcalious, which it pours into the Duodenum, at the

place where the Bile enters it. The Bile, which is of a more viscid Nature, is hereby diluted, and the mixture of both, with the Aliment descending from the Stomach, is promoted and chylification completed.

Besides this important use of the Bile, it stimulates the Intestines, and promotes the descent of the Feces, which, when the Ductus choledochus is obstructed, is very much retarded.

#### CASE of SCHIRROUS PANCREAS.

It appears then that the pancreatic Liquor is so necessary to perfect Chylification, that this must be imperfect when the Pancreas is diseased; an Instance of which, I had an Opportunity of seeing, in a poor Man who was admitted into the Hospital in a very languishing State. He had long suffered violent pain in the Epigastrium and Stomach; constant Indigestion; frequent Vomitings; Cossidered in the Indigestion in the

pressure of which, he at last was brought to the Grave.

Upon opening his Body, I found no particular affection of the Stomach, nor the Intestines, nor the Liver. But proceeding to the Duodenum, I found the Pancreas much enlarged, schirrous and ulcerated. Having discovered this, and being pressed for time, I was obliged to desist; not, however, without the satisfaction of having found out the real Source of the complaints.

# JAUNDICE.

The Pori biliarii in their progress towards the Portæ, joining their ramifications, form the Ductus hepaticus, which descending to the lest, enters the posterior part of the Duodenum, at the bottom of its second Flexure, about six inches from the Pylorus. But while it is in the Portæ, it is joined by a similar but smaller duct, which is inserted

into

into it, under a very acute Angle, coming from the Gall-Bladder; hence it is called the cyflic Duct. By this Duct the hepatic Bile is carried to the Gall-Bladder, whenever it is prevented, by any obstructing cause whatever, to pass by the Ductus choledochus into the Duodenum; in which case, the Gall-Bladder is sometimes enormously enlarged.

It does not appear that the Gall-Bladder can receive the Bile any other way than from the bepatic Duct, by the cyftic.

The Bile stagnating in the Vesicula, grows thicker and acquires a greater degree of Bitterness, and a deeper Colour; and in these chiefly, does it differ from the hepatic Bile, which is less bitter, less viscid, &c. And that this difference is produced by its stagnation is easy to conceive. But the great utility of the Gall-Bladder seems to be, its receiving the Bile when the Stomach is empty; and discharging it most abundantly by the pressure of the Stomach after a meal, to mix with the aliment as it passes into the Duodenum.

BILIOUS

#### BILIOUS CONCRETIONS.

By its stagnation in the Gall-Bladder, the Bile becomes not only thicker, but Concretions are formed of various forms and fizes. I once saw in the Gall-Bladder of a stout man of about fixty, bilious Concretions of a cubical shape, perhaps not exceeding the weight of two or three grains each, but in number more than fifty. I never understood that he had the faundice, or other complaint, but he had been in prison above a year. Could such numerous concretions have been formed during that state of Inactivity? A too sedentary life does undoubtedly savour the Stagnation and Inspissation of the Bile; which may in time form Concretions.

These Concretions stopping in the Ductus choledochus in the Duodenum, may occasion that species of Jaundice, which is preceded by violent pain in the Epigastrium, and straining to vomit; and which continues only a few

few days, and even goes off fpontaneously; but which frequently returns, after longer or shorter Intervals. This is the case when the Stones are not very large; for when that happens, the Symptoms continue so long as sometimes to exhaust the Patient's strength; which, however, has many times expelled them, of such a size as one would have thought that they could not possibly have passed.

The Jaundice being thus occasioned by viscid Bile or Concretions, is often very successfully treated at the first by Emetics. But these should not be immediately given, if the Symptoms should be strongly spasmodic. In that case, it is most adviseable to begin with the milder Deobstruents and saponaceous Laxatives, and in case of Plethora, to take away some Blood: and in due time Emetics may be more safely tried, and with greater prospect of Advantage. As to specific Solvents, I believe little dependance is to be had on any of them, because they can hardly ever come into contact with the Stones.

The

The Bile in persons of certain constitutions and habits of body, as the cold and phlegmatic, and those as are subject to frequent acidities, feems to want Energy; hence arise Indigestion; Cardialgia; Soda; excess of Mucus; Flatuosity; four Eructations, &c. In fuch cases, after an Emetic and some warm laxatives, fuch as Vin. Rhab. Vin. Aloes, Tinet. Sennæ, &c. Bitters, especially Aloetics, (which will in some fort be a Substitute for the Bile) joined with Tonics, will be most advisable. In the mean time the Patient must use exercise on Horseback, and observe fuch a regimen of diet as the nature of the cafe requires, and which has already been recommended in cases of acid Acrimony.\*

The Jaundice is sometimes occasioned by Spasmodic constrictions in the Duodenum, from violent emotions of the Mind. In which case antispasmodics and Sedatives may be useful. In Children it is often occasioned by acid acrimony in the Duodenum, constringing

Q the

<sup>\*</sup> Vide page 100.

the ducts, and here Magnesia with Rhubarb, Soap, and other Antiacids are very useful.

## AFFECTIONS of the SPLEEN.

#### INFLAMMATION.

Having endeavoured to explain the use and importance of this Viscus, according to the opinions of the most celebrated Physiologists; I come now to mention its diseases. These are, in general, similar to those of the other Viscera; Inflammation; Enlargement; Schirrosity, &c. Pain; Swelling and Tension of the left Hypochondre; Fever; difficulty of lying on that side, without Nephritic symptoms; are the most common attendants on inflammation: which is accompanied with more or less danger, according to the greater or less violence of the symptoms.

The

The treatment of this is so very similar to that of all other internal *Phlegmasiæ*; that having already taken occasion to repeat it, over and over, more repetitions would be superfluous and unnecessary.

### SPLENALGIA.

This too is mentioned by Authors, as an affection in which the Spleen is enlarged, attended with a dull, heavy, tensive pain, without Fever. But being a case that I have seldom met with, and never had an opportunity of verifying the nature of by diffection; for further satisfaction in this and many other affections of this organ, I must refer my reader to the incomparable Morgagni, where he will find several examples of the Spleen being so increased in length and its other dimensions, as to reach down to the Hypogastrium.

## Of the INTESTINES.

#### ENTERITIS.

Having confidered the principal Chylopoietic organs and their affections, I now proceed to the Intestines, which being of the fame nature with the Stomach, and endued with great Sensibility, especially Duodenum, Fejunum, and Ilium; and exposed to various irritating causes mechanical as well as physical, they are also liable to similar affections, some of which are fo dangerous as to require the most serious Attention. Such is Inflammation, the fymptoms of which are Pain in the Belly, about the Navel, with Swelling and Tenfion; Naufea, Vomiting, Costiveness and Fever. To obviate the fatal Confequences of which, the Patient must be let blood freely and repeatedly; the Abdomen must be fomented assiduously, and continued, as the Patient can bear it; emollient Clysters must be repeatedly injected.

injected. The Patient must take frequently in fmall quantities at a time, chicken water, Barley water warm, with a moderate quantity of Nitre. He must also endeavour to get down, by fmall repeated doses a Solution of Sal. Cathart. Sal. Rupellensis, or Soda Phosphorata, dissolved in Mint Water; Decoet. Tamarind cu Senna, or Ol. Ricini, to procure stools. Should these be rejected, ti may be adviseable to give the Patient 25 or 30 drops of Tinet. Opii, or Opium, gr. i. ii. and half an hour after, try the laxatives again. A warm Bath should, in the mean time, be getting ready. Should the Conflipation of the Belly and Vomiting still continue, I should advise trial to be made of crude Mercury, which may be given in doses of three ounces, and repeated one or two hours after; or fix, eight, or more ounces may be given at once. To a Lady, a patient of mine, fome years ago, I ordered three ounces, to be repeated as mentioned. She took only a fecond dose, soon after which she began to have stools; having before taken feveral feveral Laxatives and clysters without effect, fo that this success seemed due, in part at least, to the Mercury.

The Mesentery, and Omentum too, are sufceptible of Inflammation, but how to distinguish that of those parts from each other, and from Inflammation of the Intestines? I should suppose the former would be less painful at least.

Whether the Peritoneum be inflamed, independent of the Abdominal Muscles, it is not easy to determine; but the latter we know are subject to Inflammation; the signs of which are pain, soreness, and tension of the Abdomen, especially when the Muscles are in Action, or the part is compressed, and Fever. After what has been said on the treatment of Enteritis, which is quite applicable to this; I shall only observe that as this Inflammation often tends to Suppuration, if that cannot be prevented, we must endeavour to procure the discharge of the Matter outwardly. For should

should it open into the Cavity of the Belly, it might prove fatal.

I before mentioned the case of a Patient, who had an Abscess in the Belly, which was discharged by stool; and he recovered.

### COLICA-ILEUS.

The Colic is a pain in the region of the Navel, attended with vomiting and costiveness, and often with a sense of Fullness and Tension of the Belly, from Air pent up in a small part of the Intestine by Constrictions occasioned by Irritation from some kind of Acrimony. The Nerves being distracted, by the Distension of the Bowel, pain more or less severe ensues. This seems to be that species of Colic that is called spasmodic or statulent, and is sometimes attended with Retraction of the Navel and Spasms of the Abdominal Muscles.

This disease often arises from overloading the Stomach, especially with a variety of things, hot and cold; sweet and sour; and seasoned with all the art of Cookery; and then swallowing down a quantity of cold Fruit, Creams, Fellies, Ices, &c. with no less variety of Liquors. For from such beterogeneous Mixtures, the powers of Digestion are oppressed, Fermentation is increased, whence arise flatulency, Distension of the bowels, and Pain.

In fuch cases, two or three spoonfuls of Brandy, Spirit of Juniper, or Nutmeg, with a spoonful or two of warm water are often useful. But should it fail, the best Way will be to endeavour to discharge the load by irritating the Fauces, and drinking Chamomile tea, or warm water, and after having cleared the Stomach, give Tineture of Rhubarb and Vin. Aloes, a sufficient dose to procure stools.

Some stomachs are easily offended, particularly

cularly in persons subject to gouty and nervous Affections. They should therefore be very careful how they indulge themfelves in eating crude Vegetables and Fruits.

A few years fince, in the course of not many hours, a Gentleman died here of a violent Colic, brought on by eating too freely of Sallad and Fruit to Supper.

In all cases of Colic and Ileus we should ever remember to inquire whether or no the Patient have any kind of Hernia.

### I L E U S.

This affection feems to differ from Colic only in degree. They being both attended with pain in the Belly and Costiveness, but in this they are to a greater degree. In this too the Constipation of the Bowels is more fixed, with constant vomiting of every thing that is taken down and contained in the finall Intestines. Even Faces are brought up; but these, I suppose, may have been formed in the Ilium, which has been found, after Death, to contain solid Faces in no small quantity. Not only Excrements are mentioned by Authors, as having been vomited up, but also Clysters and even Suppositories. But in Ileus with obstinate Costiveness, in which the Colon is supposed to be loaded with hard Faces, this cannot possibly happen; the Valvula Baukini presenting an unsurmountable Obstacle.

We are told by some, indeed, that what they call Bilious Colic, which is accompanied with bilious Vomiting and loose Stools, does sometimes bring on the Iliac affection; and in that case there may be supposed a free passage from the Colon upwards; but admitting this, what reason then could be given for using a Suppository. Moreover, violent Vomiting and at the same time Looseness, are more properly symptoms of Cholera, than of Colica or Ileus.

SIMPLE

#### SIMPLE COSTIVENESS.

Though fimple Costiveness is sometimes, and in some Persons, so habitual, as that they have a stool every third or fourth day only, yet enjoy perfect health; and though it may be confidered as a fign of complete digestion in healthy persons; yet it is often very troublesome, and, if not attended to, is productive of ferious confequences; occafioning Hernia, the Piles, and even Death. As happened to a Gentlewoman here, not many years fince; in whom Costiveness, not being attended to at first, became in a few days so obstinate as to refist the utmost efforts of her Physician, a man of the first eminence, to relieve her; Vomiting coming on, and preventing all passage of the medicines downwards; fo that she died about the fourteenth day without ever having the least Fever, merely from Infarction of the Colon with Faces.

Persons of this habit, should endeavour R 2 to

to accommodate their diet to prevent it, by eating Bread containing Rye,—boiled Vegetables, and ripe Fruits of all forts, fresh and dry; and drinking Malt liquor, as small Beer, mild Ale, &c.

#### WORMS.

The worms which infest the human body are ordinarily of three forts, to wit, Lumbrici; both the Ascarides; and Tania. To the first and second fort, children after being weaned, and young perfons, are the most fubject. Tania chiefly affects grown perfons; but they are likewise subject to both the other kinds. I have not yet mentioned cucurbitini, because I am inclined to consider them as parts of Tania, as I never faw them in any Patient who had not the Tania. Or may I be permitted to confider one cucurbitinus as the Parent of the fucceeding ones, each of which produces its fuccesfor, which though entire and distinct from each other, yet

yet are by some fort of Gluton attached one to another, so as to form one continued band sometimes of wonderful length.

I have in my possession, a quantity of Tania which was discharged by a woman, my Patient, at different times, by feveral yards at a time, amounting together to not less than fifty yards, which was not all that she had passed; several small portions and many fingle cucurbitini having been thrown away, before I defired them to be taken care of, as she had been ill some time before the came under my care. The fymptoms she chiefly complained of were pain in the Bowels, Faintness, Nausea, &c. which with fome others, would not have positively ascertained the presence of Tania, had not the discharge of cucurbitini fully fatisfied me, as to the true nature of her difeafe.

At the first I ordered her cathartics with Calomel; and on the intermediate days she took

time, but her complaint returning, I ordered for her an Electuary of Rafur. Stanni; Conf. Ruta, and Pulv. Aloetic, by which, in a few days, her pains greatly abated, and after passing several Portions of Tania, she was for some weeks free from pain or other complaint. A return of it, however, obliged us to have recourse again to the same means, which again relieved and finally cured her. I thought it, however, adviseable for her to take two or three doses of a Mercurial Cathartic as before, and to finish with some tonic Bitters.

## LUMBRICI.

Lumbrici affect Children and young Perfons mostly, but persons of more advanced age are not wholly exempt. They inhabit chiefly the small Intestines and the Stomach; occasioning pains in the Bowels; Paleness of the Face; Itching of the Nose; Bulimia; Spasms; Spasms; Fever, &c. They sometimes pierce through the Intestines and Abdomen; two instances of which I met with in two young Persons: in the one the Worm appeared at the Navel; the other in the Groin; each forming a small Abscess, from which they issued. They were alive. Both the Patients recovered.

The method of cure as mentioned above, will, in general, be of use here. Various other means there are, a detail of which I shall not enter into here; but just take notice of the celebrated Swiss remedy against Tania, made public by order of the French King—the root of the Fern, Polypodium, filix mascula Linnai; but this I have not had occasion to try.

#### ASCARIDES.

These small Insects inhabit the rectum, and occasion intolerable itching in the Podex; from

from whence they often creep out, upon the Thighs. The usual Anthelminthics may be employed here with advantage; but in general Clysters made of a decoction of Worm-wood, Rue, &c. with a moderate quantity of Salt; or of Aloes, succeed best. Harrogate Water, both drunk and injected has very happy effects.

After these it will be proper to purge away the Faces, and finish the cure by Tonics, aided by Aloetics.

## DIARRHOEA.

In this Stools are very frequent, the contents of which are simply feculent; bilious; mucous; whitish or Chylous; or half digested Food; or thin and bloody; which appearances have given names to different species: hence Diarrhæa biliosa, mucosa, cæliaca, Lienteria, Hepatirrhæa. There are besides many symptomatic differences, as Diarrhæa febrilis, Variolosa,

riolofa, Arthritica, &c. Attention to these differences is of no small Importance towards forming a right method of Cure; which however is, in general, much the same in all.

As the most frequent causes of Diarrhaa are lodged in the Stomach and Duodenum; being either acrimonious fubstances taken down, or generated there by Intemperance; or beterogeneous mixtures, in eating and drinking; the Cure must be directed to the difcharging the acid or nidorous Crudities, by drinking Chamemile tea, or warm-water; by Emetics of Ipecacuanha; and gentle purging with Rhubarb; Magnesia; T. Rhab. Vinos; Vin. Aloes, &c. which must be repeated if necessary. Should the Diarrhaa still go on, fmall doses of Ipecac: with xx or xxv gr. of Conf. Opiata, may be given twice a day. The Patient in the mean time drinking Decoct. Corn. Cervi. &c. His diet may be Rice; Sago; Salep, &c.—Externally, an Epithem of Conf. Opiata to the Epigastrium may be useful.

## DYSENTERIA.

Frequent Griping, mucous and bloody Stools, Tenesmus, and Pyrexia, are the most common attendants on this disease. And as it, for the most part, depends more or less on the Constitution of the year, the Season, or fome local Disposition, it is more or less prevalent, or epidemical, contagious, and dangerous. It is most frequent in Autumn. It begins with Chillness, and more or less of Fever, Naufea, and slimy or bloody Stools; while folid Faces remain in the Colon, and by irritating the Gut, which may be fupposed to be affected with some degree of Phlogosis, increase the pain and incessant want of going to Stool, so as to be mistaken for loofenefs. For this reason we ought to be particular in our inquiries, how the Patient had been, in respect to Stools, a little before and at the Accession of the disease; that if he had been disposed to Costiveness, we may by clysters and laxatives endeavour to remove the folid Faces and Scybala, the retension of which would have bad effects.

Though this Difease is attended with Pyrexia and Pain, in which case bleeding the Patient may be fometimes adviseable, this must be done with caution. Clysters of Decoct. pro Enemate, Mutton water and the like, without any Stimulants, must be repeated often. In the mean time fome gentle Laxative, as Sal. Cathart. Sal. Rupellens; Soda Phofphorata; Decoct. Tamarind. cu Senna, must be taken in fmall repeated dofes, as the Stomach will bear, until any folid Faces or Scybala that may lodge there, be removed. In case of the pain being violent, an anodyne will be necessary. Should it happen that there be but little of Faces in the Gut, the method will be fafe, and may carry off any acrimonious matters that might and often do, in these cases, irritate and corrupt the Intestines.

In Epidemic Dysentery there is generally more or less of Putrescency, and sometimes S 2

to fuch a degree as to occasion very fetid Stools, with lumps of reddish or brown mucous, which is a sign of the Bowels being in a putrid, gangrenous State.

Some Cases of this fort I met with in the year 1758, when fuch a Dysentery was very frequent at Hull. In one especially, which proved mortal to a middle-aged man; thefe appearances were followed by a total ceffation of Pain, but the Languor, cold Sweat, and Hiccup announced a Mortification, in which State, nevertheless, he lived two or three days longer than I expected. This case induced me to try the Bark, after having obtained a free passage by the means before mentioned, which I gave in Decoction, and occasionally with the addition of Tinet. Opii, which feemed to have a good effect. I must observe that the Bowels were in general fo very tender in this Dysentery, as to be much irritated by very fmall doses of Rhubarb, in powder.

The Patient's diet must be Panada; Sago; Salep, and the like, seasoned with a little Sugar, Wine, and moderately acidulated with the juice of Lemon, Chicken broth, Beef tea, &c. The drink may be Barley water; Toast water; small Lemonade. The Patient must keep his bed, but the room must be kept temperately cool, and ventilated. It should also be fumigated, and sprinkled with Camphorated Vinegar. And in order to promote Perspiration, it will be adviseable to place Bladders or Bottles with hot water at a little distance from his Feet.

## CHOLERA.

Comes on with Nausea; Anxiety; Griping; Vomiting, and frequent Stools, which are often very bilious and sharp, or thin and watery; returning so very quick and harrassing the Patient to such a degree, as to occasion cold Sweats; Cramp in the Legs; and Syncope. In some cases the discharges have been so copious

copious, as to exhaust the Patient in a few Hours.

It has been observed to happen most frequently in Summer; and is occasioned by violent irritation of the Stomach and Intestines from Acrimony, either produced by improper diet; or taken down, fuch as drastic Medicines, and fuch as being improperly given, act as Poisons; eating ripe Fruits of fome forts to Excess; too great a quantity of cold vegetables, fuch as Cucumbers, have often brought on Cholera. The excellent Morgagni\* has related his own cafe, in which he tells us, that in the course of twelve bours, he voided by Stool eight quarts, at least, of Water almost limpid. His Stools were not very frequent, but copious-and he did not know what would have been the confequence, if warned by a troublesome Nausea, he had not by taking a draught of warm gruel, vomited very readily and with fuccefs, by throwing

<sup>\*</sup> De Causis et Sedibus Morborum, &c. Epist. 31. art. 9.

throwing up fomething green which looked like the leaf of a boiled vegetable, but whether it was fo or not or how he got it, he could not find out. But the danger he had been in, appeared the next day in his Face and Hands, which appeared as thin as if he had been in a long illnefs: with great drynefs of his Mouth and Fauces. These, however, and his Lassitude went off in a few days. The Lassitude might have been partly owing to the journey he was upon when the thing happened.

The cure requires attention to the different Causes, Symptoms, and Times of the disease. As Nature operates to the expulsion of the material cause, this must be affished by drinking repeated draughts of Chicken water; thin Water-gruel, which will have the effects too of diluting and weakening the acrimony. In the mean time should the violence of the disease have brought on Spasins, cold sweats, and a tendency to Syncope, it will be necessary to obviate these alarming symptoms

fymptoms by Cardiacs and Anodynes, given in moderate doses and repeated according to the exigency of the case. The Patient in the mean time must be supported by taking frequently finall quantities of Sago, Panada, made of bifcuit, feafoned with aromatics, and Wine or Brandy in decent proportion; and Perspiration promoted by the application of warmth to the Feet, or Pediluvia if the Patient can bear it. Should there remain any marks of Acrimony it will be proper to carry it off by gentle Laxatives, fuch as Magnesia, Rhubarb, &c. and then endeavour to restore the Tone of the parts by Tonics and Bitters. Externally Aromatic Epithems and Plaisters are very useful.

# ILEUS SANGUINEUS, seu HEMORRHOIDALIS.

This is a fymptomatic Colic, occasioned by Plethora in the Mesentery and the Intestines, attended

attended with great pain and oppression, frequent Vomiting and Constipation of the Bowels; and fometimes Hypochondriacifm; fupposed to arise from flagnation or fullness of Blood in the mefaraic and hamorrhoidal veins, thereby irritating the nerves, with which the parts are copiously supplied from the mesenteric and bepatic Plexus; and causing spasmodic affections fuch as a fense of pressure and pain under the Ribs, especially towards the right fide; for the Vena Portarum doing the office of an artery but without its contractile powers, and without the support of Valves, the Blood at the fame time passing from larger into smaller veffels, and being naturally thicker, its motion is retarded, and thus it is disposed to stagnate.

The treatment of this disease must vary according to the nature and violence of the fymptoms, and constitution of the Patient. Bleeding, therefore, will in general be necesfary, more or lefs, according to the strength of the Patient, and the state of the pulse. Emollient Emollient Clysters must be injected repeatedly, and a free passage downwards procured by mild lanatives. Should the pain still continue, it will be adviseable to try a tepid Fomentation, or Semicupium, and if he has before been subject, more or less, to periodical discharges of Blood by Stool, the application of Leeches to the Anus will be adviseable. In the mean time the spasmodic symptoms must be treated with mild sedatives, Tinet. Opii, Sp. Ætheris Vitriolici, vel Nitrosi; Mistur. Campborata, &c.

#### HÆMORRHOIS-PILES.

The Mefaraic Plethora is not unfrequently discharged by Stool, in which case the Blood is pure from Fæces, and in moderate quantity. It then ceases for a time, and returns again, and thus becomes periodical. Or the Hæmorrhoidal vessels in the Reetum become distended and burst, or form Piles, from which the Blood is discharged.

When

When the Hæmorrhoidal Flux is moderate it may be faid to be falutary, by preventing the mischies occasioned by the Plethora.

But when it becomes irregular, frequent, and too copious, it either weakens and exhausts the Patient, or brings on Cachexy, Leucophlegmacy, and Dropfy. To prevent which, great attention on the part of both the Patient and the Physician, is to be had.

The Piles are often attended with great pain, fullness, and even Instammation, so that Bleeding is sometimes necessary, with emollient anodyne Fomentations, Cataplasms, and Liniments. In the mean time the Belly must be loosened by lenitives, such as Manna, Elect. e. Cassa, Fl. Sulph. lot. assisted with emollient Clysters, if they can be admitted.

The abdominal Vifcera that we have hitherto had under confideration, are of the utmost importance, their office being to prepare a Fluid which is to nourish the Body,

T 2

and supply the constant waste to which it is fubject. When we confider the Organization of those parts, and of what consequence it is to preferve their integrity, and at the fame time think of the ill effects of intemperance in eating and drinking; and of the incongruous and discordant mixtures that a luxurious table offers to a wanton, vitiated appetite, to heap upon the Stomach; instead of being furprifed at their frequency, we ought to wonder that diseases of those Organs are not much more frequent: and we ought too to remember, that by Temperance they may often be prevented; but cannot by the most skilful application of the Powers of Art, be always cured.

SECTION IV.

#### SECTION IV.

## On the URINARY ORGANS.

The KIDNEYS, &c.

Proceed now to the Urinary Organs, the principal of which, the Kidneys, are subject to Inflammation, and from their office of secreting the Urine, are liable to concretions formed of its saline and earthy parts, which are attended with pain, more or less acute, from their irritating the Kidneys, Ureters, Bladder, &c. which being all lined with the same very sensible Membrane, sympathize in each others affections; and hence occasion some difficulty in discovering the real seat of the disorder.

#### INFLAMMATION-NEPHRITIS.

Pain in the region of the Kidney, striking down towards the Hypogastrium; frequent making Water with pain or strangury, and Feverishness, are the usual attendants on this complaint. The Urine is sometimes pale, sometimes high coloured.

If the Pulse be full, it will be adviseable to bleed the Patient, to let him have an emollient Clyster; and drink plentifully of Barley water with Manna and Nitre dissolved in it, and frequently take two or three tea spoonfuls of a Linctus, made of equal parts of Ol. Amygd. Muc. Gu. Arab. and Elect. Lenitiv. If the pain continue violent, it will be adviseable for the Patient to go into a warm Bath, and continue there for half an hour if he can bear it; the degree of warmth, about 90, to be kept up by adding hot water from time to time.

Calculous affections of the Kidneys and Ureters produce, in general, symptoms like Nephritis, particularly vomiting, but without Fever.

Instances, however, have occurred, where a Stone has been found in the Kidney, after Death, of which there had not been the least sufficient during life; having been, I suppose, always fixed and immoveable.

The treatment here is very fimilar to that of Nephritis, except that Bleeding may not be always necessary.

#### ISCHURIA Renalis et Ureterica.

This is a total suppression of Urine from some affection of the Kidneys or Ureters. The most frequent causes of which are Calculus; Spasm; Plethora; Inflammation; Matter; coagulated Blood; Palsy. It is a very dangerous case, and more or less so according

to the *Nature* of the cause. That which is owing to a fixed *Calculus* is very bad, and is, in general, *incurable*; though some have been cured.

A total suppression for the most part becomes mortal in seven or eight days, if the Urine be not discharged out of the Habit by copious Sweat, Vomiting, or by Stool: By some or other of these the suppression has been supported ten, twelve days, and even much longer in some cases, and the obstruction giving way, has been at last cured.

Is by Bleeding. The inflammatory is to be treated in the same manner, and the free use of antiphlogistics, and sedatives occasionally; which are useful especially in the spasmodic. The paralytic requires blistering; the good effect of which I have had occasion to observe in this and in similar affections of the Bladder.

ISCHURIA

## ISCHURIA Vesicalis.

This is a total suppression of Urine in the Bladder, with swelling of the Hypogastrium; which is sometimes very large and prominent. It is attended with great pain, and constant urgent Stimulus to make water, and sometimes a dribbling of Urine, forced out by the resistance of the Bladder.

The causes are, in general, similar to those affecting the Kidneys and Ureters. But some there are peculiar to the Bladder, as the Polyurica or that from too long retention of the Urine; the Cystoprostica or compression of the Restum distended with Fæces or Wind; the parts thickened by Inflammation; Abscess; the Piles; and in the Sex, distension of the Vagina by accumulated Menses retained there by the Hymen being imperforate. The cure of these will vary according to the nature of the cause.

In all, the Urine must be drawn off by the Catheter; the lower Bowels must be emptied by Clysters and Laxatives; Venesection may be necessary, and demulcent drink moderately nitrated; emollient Clysters also nitrated, may be injected from time to time, with advantage.

#### ISCHURIA URETHRALIS.

The symptoms are the same here as in the preceding, with the addition of pain in the Urethra. The most frequent causes are tumours in Perinaco, Calculus, Caruncles, Inflammation.

#### DYSURIA.

This is a painful difficulty of making water, or strangury, the different species of which are owing to causes very like those that produce the different sorts of Ischuria. The method of cure is in general the same also.

## Dysuria Mucosa.

be

Difficulty of making water, attended with great pain in the region of the Pubes, and a discharge of mucous, white or coloured. The Urine when first made appears milky, and by degrees, deposits a quantity of mucous, fometimes very copious and inodorous, fo vifcid and ropy as to be with difficulty feparated from the vessel. This disease seldom happens to persons under sifty, and it has been observed, that they who have been most subject to Hamorrhoidal complaints, and have at times made mucous or bloody Urine, are the most liable to this; which is fupposed to depend on the relation or connection between the Neck of the Bladder and the Rectum; the vessels of the former which are numerous, communicating with the external Hæmorrhoidal.

Hence the difease has been by some called\*

U 2

Hæmor-

<sup>\*</sup> Detharding, in illust. Halleri disput. pract. T.vii. p. 11.p. 775.

Hæmorrhoides Vesicæ Mucosæ. The same communication of vessels not taking place in the Sex, because of the intervention of the Vagina, is thought to be the reason that females are little liable to the complaint; though they be not wholly exempt from discharges analogous to these, which, however, are to be attributed rather to suppression of the menstrual than bamorrhoidal discharge. If Hamorrhoids of the Bladder should happen, they are eafily diftinguishable from the renal bloody Urine, the Blood being in this more pure and copious; but in the former more diluted, accompanied with pain and a reddish mucous, and fometimes with Coagula which obstruct the Urethra.

I have already faid that the viscid mucous, which is so copiously from time to time, for it is not constantly discharged in this disease, but more or less by intervals, though not periodical, is in general inodorous. This want of smell and the viscidity distinguish it from purulent matter, as this may be diffused easily in the Urine, which it renders very fetid.

This

This difease is chronical and difficult of cure; the Coats of the Bladder become thickened, and can feldom be restored to their proper Tone. The cure, however, is to be attempted by endeavouring to lessen the congestion on the Neck of the Bladder and the Spafm, by fuch means as the age, and constitution of the Patient, and the symptoms indicate. If the pain be very violent; if the Patient be of a firm, full babit, and have been fubject to the Piles, it may be advisable to take away fome Blood, and to empty the Bowels by emollient Clysters and gentle Laxatives. Should there be any appearance of the Piles, it may be proper to apply Leeches to the Anus.

The diet must be simple and mild; high-seasoned meats must be avoided, as must also beating liquors; Barley-water, Toast-water, to which may be occasionally added, a moderate portion of Wine; mild Malt liquor, not much hopped, may not be amiss, as it is laxative.

HÆMATURIA.

#### HEMATURIA.

Bloody Urine is often caused by calculous concretions, which lacerate the Membranes of the Kidneys, Ureters, or Bladder, especially when put in motion by riding and other violent actions. It is then accompanied with pain in the Back, Side, or in the region of the Bladder, with mucous and filamentous Urine. It is not uncommon in persons advanced in years, especially those who have been subject to Hæmorrhois, and in the Sex from aberration of the Menstrua.

Whether it proceed from the Kidneys, the Bladder, or the Penis, is not hard to determine, but in respect to the Prognosis, this makes no great difference. If the Hæmor-rhage be frequent or copious, it is very formidable to persons of advanced age, to whom it often proves fatal: but even in such I have seen it have no ill consequences, but then it was very moderate. It is not unfrequently caused

caused by Plethora, determined to the Kidneys by something occasional; it is then preceded by a dull pain in the Back, a sense of heat and a total suppression of the Urine. In this case Bleeding has very happy effects; as have also mild, demulcent, nitrated liquids and gentle Laxatives, which method is also proper in calculous cases.

#### DIABETES.

This is an immoderate discharge of Urine, having the smell and sweet taste of Honey. The Urine in general appears crude, but without sediment. The Patient is thirsty; with a dry skin; loss of appetite; wasting of his slesh and strength, but this is slow and gradual.

The idiopathic Diabetes is said to be of two species, one of which Mellitus, is that described above; the other Insipidus, which is a profusion of limpid Urine, but not sweet. The former is the only species that has occurred

curred to me, of which I have seen two cases in two persons of middle age, one a woman, the other a man; in neither of whom could I trace the disease up to its cause.

Systematic Writers attribute it to preternatural relaxation of the renal secretory Vessels, giving passage to half-assimilated Chyle, on which supposition, perhaps, it has been called the Nephritic Diarrhæa and Lienteria. But this supposition does not account for that particular and characteristic mark of the disease, the honey-like slavour and taste of the Urine.

Relaxation of the renal Tubuli having been supposed to be a principal cause of this disease, in order to remedy this, Authors have recommended the use of Tonics, as Bark, &c. And for drink, Bristol Water with a portion of Florence Wine.

The celebrated Mead particularly recommends Serum aluminatum; taken to about a pint pint three times a day. Others have advised Rhubarb as having good effects in this case.

I have given Serum aluminatum with fenfible advantage, advising at the same time a mild nourishing diet, consisting principally of Milk; and Milk diluted with Bristol Water for drink; to which may be added Asses Milk and sweet Whey, interchangeably.

greenment Elloye that have been

SECTION V.

of the Maintain race, the Orerer

## SECTION V.

## The UTERUS.

HE abdominal Viscera that have been hitherto under consideration, are common to both Sexes. I come now to contemplate that very important female organ, by which the amiable Sex is formed, to bear, in obedience to Divine command, a principal part in the perpetuating of the Human race, the Uterus.

The substance of this organ is dense, compact, cellular, and succulent; in which there is an appearance of muscular Fibres upon its Fundus, especially in Child-bearing Women.

Its cavity is somewhat triangular, but so small as to be incapable of containing more than a small almond. In its Neck are many mucous Sinuses and small Vesicles containing a limpid Humour. The Os internum, called Os Tincæ, is prominent in the Vagina, and full of mucous Sinuses. From the angles of the Uterus are produced the Tubæ Fallopianæ, which tend toward the Ovaries, to which they are connected by their jagged extremities. Both the Tubes and the Ovaries are comprehended in the broad ligament, and joined by an expansion of it, so long as to be free or loose.

The substance of the Ovaries is like that of the *Uterus*, firm, white, and cellular. In the Ovary, even of a *Virgin*, there are small round Vesicles formed of a pulpy Membrane silled with coagulated lymph, to the number of about twelve in each Ovary.

The Vesicle, about the time of Puberty, becomes surrounded by a yellow Coagulum,

X 2 forming

forming the Corpus luteum, hollow within, and containing an Ovulum, the feat of the future Man. These Corpora lutea are first observed after conception.

As it is not my purpose to attempt to unveil the mystery of Generation; what I have said being only meant to prepare the way for the better comprehending the pathological reasoning that may arise; I will only just observe, that the Uterus is supplied with Blood by a considerable branch of the hypogastric Artery, similar to the vesical Artery in Man. This, which is common to the Uterus, Bladder, and Restum, forms Anastomoses with the spermatics, which have the same origin as in men, and are distributed to the Ovarium, the Tubæ, and the Uterus.

Another, the Hæmorrhoidea media from the Trunk of the Pudenda communis, goes to the Vagina, Bladder, and Rectum. Besides these, the Vagina and Clitoris have Arteries from the Hæmorrhoidea externa.

The

The veins are from the *Hæmorrhoidea* externa, and from the vesicalis, forming a Plexus which goes to the *Clitoris*.

The Veins have no Valves, except a few in the spermatics.

The Nerves are from the lower mesocolic Plexus, which gives off large branches to the Bladder, Uterus, and Rectum. Hence all these parts, are very sensible.

## MENSTRUA.

In this state things continue until about the age of thirteen or fourteen, or later; when the Blood begins to receive a new impulse; the *Breasts* begin to swell and the *Menses* to appear. This appearance is preceded by various uneasy sensations, and dull pains in the Loins, in the head, and often pimples in the Face, &c. The small vessels of the *Uterus*, which before gave passage to

a ferous Humour only, begin to be distended with, and at last to furnish red Blood for a few days; the pains, &c. then go off, and the Vessels by degrees contract and give out only Serum as before. After an interval of uncertain length in young girls; but by little and little, towards the end of the fourth week, the same appearances return, and this periodical evacuation is repeated, until about the fiftieth year; with considerable variation, however, caused by the temperament, diet, and constitution of the subject.

That the menstrual Blood comes from the Uterus itself, I hope, I need not take up the Reader's time to prove; reason and observation, both concurring to confirm it. The periods when regular, being monthly, have induced some to attribute this to the influence of the Moon; but with how small a share of reason, must be evident, when it is known, that not a day passes in which that evacuation does not happen to several Women.

That

That it is owing to *Plethora* and not to any irritating *Ferment*, feems to appear from this, that in cases of retention, it makes its way by other organs, where no such *Ferments* can be supposed.

The Pletbora feems to arise from this, that the Body having almost attained its full growth, more Blood is generated than is wanted. This furplus is, in males, often carried off by Bleeding at the Nofe; but, in females, it finds an easier passage by the veffels of the Uterus, which being of a foft cellular fubstance, they are more easily extended, and open by fine exhaling veffels into its cavity, more freely than into the veins that accompany them. Six or eight ounces of Blood being thus discharged, the Arteries recover their elastic power; their extremities contract again and give passage only to the ferous Fluid, until by degrees the Plethora is again formed by the same causes as before. Nor need we be at a loss to find a reason for this period being monthly, as it depends on the proportion that is between the quantity and *Impetus* of the collected Blood, and the refistance of the *Uterus* which infensibly gives way. Hence its returns are more frequent when there is a greater quantity of Blood determined to the *Uterus*, as in the *plethoric* and *libidinous*. And they at last cease to flow, when the *Uterus* acquires such a degree of firmness as the force of the Heart, propelling the Blood, cannot overcome.

I have already taken notice of the fymptoms that announce the near approach of the *Menses*, but some there are which seem to give notice of *this* though at some distance. Such are paleness of the *Face*, lassitude, weakness, palpitation of the *Heart*, from quick motion and other exertions, &c.

This state of young women demands great attention, and prudent management; in the dietetic part especially. They should not be too much confined, but have sufficient time

time allowed for exercise in the open air, when it is proper; and for agreeable amusement. Their study must be adapted to their powers of Mind, which while it is usefully informed, must be agreeably recreated and polished by the elegant productions of Genius, fo as not only to qualify them for the important duties they have to perform, but to render them agreeable and pleafing companions. Works of Genius are, however, to be properly and cautiously chosen, Novels especially, scarce any of which should, I think, be permitted at this age, for reasons it is unnecessary to mention. What I now fay is in my own character; the rest I leave to the Moralists.

The fymptoms mentioned above, feldom require much medicine, and infenfibly go off. Should the Stomach appear to be loaded, a gentle *Emetic*; fome *Bitters*; *TinEt*. Aloes comp. &c. may be useful; but the more active stimulants must be used with caution.

## MENSIUM defectus.

Though the menstrual discharge be natural to the Sex, and ought, and generally does, take place at the time of puberty, a little sooner or later, according to the constitution and circumstances of the Person; who, if it do not, seldom enjoys health; yet I have met with instances in young women of good constitutions, and who led active and laborious lives, who at the age of eighteen or twenty, had never had the discharge at all.

When it does not appear in due time, the person becomes indisposed; grows pale; listless; with pains in the Back; Pica; Chloross; Cacheny. If it happen to adults who have already menstruated frequently and in a regular way, the defect is then properly a Suppression. If it slow sparingly, and be attended with pain, it is said to be difficult, Menorrhagia difficilis.

The remote causes of these different states, are supposed to be spasmodic constrictions of the vessels, in persons of nervous habits: Rigidity of the vessels in women of masculine habits, and rather advanced in years; or Relaxation of the parts in persons who look pale, bloated, and who have the Fluor albus almost constantly; or a laxity of the muscular sibres, induced by a sendentary inactive life, which produces stagnation rather than Suppression.

Another cause of Suppression is Pregnancy, but this I should not have mentioned, as a cause of this defect, but with the view of observing the great caution that should be always used in our inquiries into these matters; not only in the cases of married women, where mistakes might have bad consequences; but especially in the unmarried, who are to be treated with the greatest circumspection and delicacy; as in cases of Suppression, they are liable to suffer, for a time, the most cruel and unjust reslections, from such mistakes.

## CASE of ATRESIA.

One cause of this defect that came under my own notice, being not very common, I take this occasion to mention it. A young woman, of about twenty, came under my care in the Hospital, labouring under a total defect of the Menses, which she had never feen; though she had from time to time pains and other fymptoms, that often happen about that period. She was treated with the usual aperitives and deobstruents for about three weeks without any advantage; at which I was much furprifed; and being piqued to find my reasonable expectations of her receiving benefit, thus disappointed, I became still more inquisitive, and defired that the nurse would examine her more minutely. The real cause was now discovered, a compleat Hymen, in which, the Surgeon by a fimple operation with a lancet, made an opening, and discharged about two pounds or more of a fluid, of a reddish colour, about the confiftence consistence of treacle, and perfectly inodorous. She was thus perfectly cured, and left the Hospital two or three days after.

Defect of the Menstrua must be treated according to the nature of the remote caufe. Spafmodic constriction, if attended with Plethora, will require Bleeding; emollient clysters; Semicupia and nervine medicines. Rigidity, as in women of strong habits and advanced years, will require a nearly fimilar treatment. But we must not forget that this discharge ceases sooner in some than in others; and that, therefore, Stimulants may not be always proper but often improper. Too great laxity of the habit from inactivity and a too fedentary life, which give occasion to congestion in the Uterus, must be treated with faponaceous Aperitives; Aloetics; the ferulaceous Gums; Volatile Salts, &c. moderate friction of the Abdomen; exercise in a carriage or on horfeback. A Semicupium with aromatic herbs, has been here found useful. The congestion and load being removed, moved, Tonics, as the Cortex, Chalybeats, and Sea-bathing, promise advantage.

the Hoffmarting or three days after

I hope, I shall be excused for not having entered more minutely into the treatment of these cases, as a right discrimination of the nature and causes of affections of the Uterus, requires the aid of an able and experienced Physician, and to direct the cure.

Though the temporary cessation of the menstrual discharge, in a state of Pregnancy, be in general natural and necessary; it becomes the cause of various troublesome asfections, such as Nausea; Pica; Vomiting; pains in the Back, Thighs, and Legs, &c. which symptoms gradually abate and mostly go off, about the third or fourth month. The Catamenia do not, however, always cease at once, but continue sometimes to return, in diminished quantity, for two or three months; nay I have known it continue, in some degree, the whole time, without any bad consequences.

The

The Vomiting proves often exceedingly distressing, and I have known it in two or three instances, so severe and constant, through the whole time of gestation, as that the woman was scarce able to retain any thing but pure water, so that she was reduced extremely low, but nevertheless did well.

Pains in the Head, fullness and pain in the Stomach, and straining to vomit may sometimes render bleeding necessary and proper in the early months; but this must not be done without great caution, especially in a more advanced stage; but of this more hereafter.

The Menstrua are often irregular, both in respect to their intervals, which are longer or shorter; and in respect to quantity, which in some is small; in others copious; and in those who are advancing towards the final period, sometimes excessive.

I may observe here, that there is some-

from the veins of the Vagina, somewhat similar to that from those of the Anus. This may be even more abundant than the men-strual discharge, but is not, like that, periodical; besides, its being attended with pain too in the part, serves to distinguish it from the menstrual.

#### MENSES devii.

The menstrual discharge deviates sometimes from its natural and proper course, and makes its way at the Stomach, Lungs, Kidneys, Bladder, Intestines, and other outlets. These deviations are occasioned by spasmodic affections of the uterine vessels, excited by violent commotions of the Mind, and agitation of the Body; the application of cold to the extremities, &c. I have seen great quantities of pure blood thrown up by vomiting on such occasions.

## CASE of periodical HÆMOPTYSIS.

A Patient of mine had a periodical spitting of Blood, which succeeded to a Suppression of the Catamenia, and observed the same periodical returns, about once in three weeks. It continued three or four days, in which time she discharged by a gentle cough, without pain, seven or eight ounces of pure blood, and then no more, until the next period. She was in the mean time well and free from the cough.

#### MENORRHAGIA.

This is an excess of the menstrual discharge, attended with pains in the Belly, Back, and Loins, and bringing on Weakness, Fainting, slow Fever, and Cachexy. It is not easily distinguishable from Hamorrhagia uterina; this, however, is often more copious; is attended with more pain, and does not always happen at the stated periodical time.

To this affection are most exposed, women of fucculent and fanguine habits; of florid complexions, and who indulge in luxurious living; who lead fedentary lives; and lie too long in Bed. The method of cure, will require that, in case there be evident figns of Plethora, the quantity be lessened by Venesection, to the amount of seven or eight ounces, taken from the Arm; and this should be done eight or ten days before the expected periodical return. The food should be plain drest, and in moderate quantity. High feafoned and stimulant dishes must be avoided. Soups, broths, and other liquids, as food, should be taken in fmall quantity. The drink should be water with red Port, Porter, or water with a small portion of French Brandy. Tea, and other tepid potations must be taken with moderation. The Patient's bed should not be too foft, and for this reason a mattrass should be uppermost; nor should she lie too long in bed, after having got fufficient rest and sleep. To these must be added, exercise

ing in the open cool air, but avoiding fatigue; and Sea or cold bathing. These dietetic rules well observed will be of great use; and the cure will be further promoted by medicines of the tonic class; such as Cort. Peruvian; mild Chalybeats; Pyrmont or Tunbridge waters.

# MENORRHAGIA gravidarum-ABOR-

But when this is not the cafe, the

# confequence of the NOITen of the Menter,

Abortion being a case of the most interesting nature, not only on account of the disappointment of parents and families; but what is of yet greater importance, the danger into which women are sometimes brought by it; the utmost attention and skill are here required.

It happens most frequently in the early months, at which time, though the danger Z 2 be

be not so great, still there is the disappointment.

It has been already observed that the periodical discharge sometimes continues, though in a diminished quantity, for two or three months after conception, and even longer. This, therefore, should be kept in Mind. But when this is not the case, the early fymptoms of pregnancy, fuch as Naufea, Vomiting, a sensation of fullness, &c. being fupposed to arise from Plethora, in confequence of the cessation of the Menses, have induced medical Authors to recommend Venefection, as being indispensably necessary, at this time, as preventative; but this, I think, in much too general terms; fince it is a practice that ought not to be followed without very mature deliberation. Cafes there may be, as well as babits and constitutions, that may require it, but these should be well considered, because there are reasons for thinking, that in some Constitutions, the tender and delicate especially; and

in the latter months of Pregnancy, instead of preventing, it has often been the occasion of Abortion. Such delicate women are also liable to it from very slight causes, affecting the mind or the senses, because of the debility and irritability of the system, not to mention external injuries to which all are more or less exposed.

When apprehensions of miscarrying take possession of the Mind, we must endeavour to appease them, by encouraging the Patient; and, as the Stomach may be disordered by acidity, especially if she be costive, it may be adviseable to give Magnesia, with or without a small addition of Vin. Rhabarb, or Tinet. Senn. to which may be added a few drops of Tinet. Opii, which may also be given as a sedative without the laxatives, if they should be thought unnecessary. By such gentle means the symptoms and apprehensions will be quieted and removed.

But if Metrorhagia flooding should hap-

pen about the seventh or eighth month, and become copious and continual, the danger will be very great and must prove fatal, without the manual assistance of a skilful Accoucheur.

Such a case happened two or three years ago, to Mrs. C. a very valuable woman, the mother of feveral children. The Uterine Hæmorrhage made its appearance very early, then ceafed for a time, and returned again about the beginning of the fixth month. Mr. Champney, her Accoucheur, endeavoured, by the most approved means, and cautious management, to gain time and protract as long as he could, what, he forefaw, must probably happen. But towards the end of the same month, finding that the was daily lofing strength, he defired a general Confultation, at which I was prefent. The refult of which was that the delivery of the Patient appeared to be the only means of faving her life, and that as little more time as possible should be lost. This determination

termination agreed fo perfectly with his own opinion, that not thinking it fafe to wait for another day, he performed that difficult business, the same evening, with the most happy success. His Patient continued for some days in a very weak and critical situation, but by degrees grew better, and at last got well.

#### HÆMORRHAGIA UTERI.

Hæmorrhage of the Uterus, is, as has been faid, a disease to which women who are not pregnant are liable. It is sometimes acute, sometimes chronical. The acute is often preceded by Lumbago, or Colic, Shiverings, &c. and is supposed to be owing to spasmodic affections of the vessels of the abdominal Viscera, excited by violent commotions of the mind, too great exertions of the body, &c. The chronical supposes also spasmodic strictures of the Viscera, and too great relaxation of the vessels

of the *Uterus*. They are *both* dangerous and difficult to cure; being very liable to return, and often fatal to women advanced in years, by bringing on Marasmus, Dropsy, &c.

The treatment of this differs little from that of other Hæmorrhages already mentioned, and may require Venefection; fedatives such as nitrated Emulsion with a small portion of Camphor, Tinct. Opii, and emollient Clysters, to which may be added Tinct. Opii gutt. xxx. to moderate the pain and strictures. On the supposition of too great laxity, the Bark has been found useful. Here, too, the utmost attention of a skilful and experienced practician is required.

#### FLUOR ALBUS.

This is nearly allied to the menstrual discharge, being derived chiefly from the same source, and to which it often succeeds and seems feems to stand in the place of. It affects those most who have before had the menstrua most copiously, and who lead inactive, sedentary lives; hence they are generally pale, often bloated and cachectic.

in general fuch as tend to correct the Leurs-

But befide what may be supposed to be derived from the vessels of the Uterus; there is no fmall part that has its fource from the muciferous Sinuses about its neck and the Os internum, and a yet more copious one from the Vagina. Hence it will require no small attention in order to form a just notion of the nature and true fource of the The ferous Humour that is discharge. fupposed to come from the uterine vessels, appears mostly about the periodical time, preceding or fucceeding the Menstrua; that which is of a mucous nature, from Os internum or the Vagina. And though these may be fometimes discoloured, yet they have not in themselves any ill quality. On the other hand, when the discharge is of an unnatural colour, fetid, and attended with Aa tharp SECTION VI

sharp pain or smarting, Ulceration somewhere is to be suspected, the nature of which must be carefully investigated. Sapienti sat.

fedentary lives; hence they are generally

The medicines proper in these cases, are in general such as tend to correct the Leucophlegmatic habit and strengthen the Solids. Moderate purging with Rhubarb, aided with a small portion of Pulv. Jalap, may now and then be adviseable to carry off part of the redundant humidity; and in some cases it may be very proper to add a little Calomel. In the mean time Bark with Aromatics and Chalybeates will be very beneficial.

The Patient must be sparing in the use of small tepid liquids, such as Tea, Broths, &c. and may eat Mutton and Beef, in preference to sowls or chickens. For drink, Porter, Port and Water, and the like. Exercise; friction, and Sea bathing will be useful. Warm rooms, and lying too long in Bed, must be avoided.

#### TUMORES ABDOMINIS.

of the Abaomen that appears at first partial

secreases gradually without Plettarion,

Mance of ereater or less extent, owing

Some particular affections of the abdominal Viscera, have been already taken notice of, I come now to observe that the whole Abdomen is sometimes tumefied to a very great degree. This swelling is in some cases tense and elastic, without Fluctuation. Such is Tympanites, which is supposed to be occasioned by Air, distending either the stomach and intestines, or contained in the general cavity of the Abdomen.

This fwelling fometimes appears in the Hypogastrium, about the seat of the Uterus, and

and is then called *Physometra*. That which is attended with *unelastic* Tension and *Fluctuation*, and is the most common of all is *Ascites*; and when it is in the *Hypogastrium*, *Hydrometra*, or Dropsy of the *Uterus*.

There is yet one more general fwelling of the Abdomen that appears at first partial, increases gradually without Fluctuation, but presenting to the touch, a folid, heavy substance of greater or less extent, owing to the enlargement of the Liver, Spleen, Mefentery, Omentum, or Intestines, which last have been found conglomerated together in fuch manner as to form one large inform mass.\* This folid enlargement of the Abdomen has obtained the name Physconia, of which many species and varieties are enumerated by Nofologists and collected by the learned Cuffon, commended by D. Cullen, as being fumma ad Pathologiam utilitatis. But as the cafes are in general incurable, I shall pass on to fuch fredling lonetimes, appears in the

ogularium about the feat of the U

<sup>\*</sup> V. Morgagni, Epist. 39. n. 26.

fuch as, though frequently incurable, do yet admit of palliation, and fometimes of cure. Such are Watery Tumours, or Dropfies.

#### HYDROPS.

The most common kinds of watery or dropsical swellings are Anasarca; Ascites; Hydrocephalus, &c. for the several species and varieties of which I must beg to refer to the accurate Cullen's Nosologia Methodica.

Anafarca may not, always, be justly attributed to diseased Viscera, as it very often happens from evident causes; such as excessive Hæmorrhages; drinking immoderately of water, when exhausted with heat and fatigue; as often happens to poor labourers in the fields; such also as are employed in draining of marshy grounds, and who often work whole days in water, and are obliged to subsist on poor diet, and seldom drink any thing but water, or some small vapid

vapid liquor. Of fuch cases, I have had the mortification to see several, as they often prove very difficult of cure; the tone of the solids being so greatly impaired, and the Blood become so thin and watery, as the most powerful tonics, with the assistance of the most proper diet, cannot always restore.

I have seen more than one instance of labouring men, in *Peripneumonic* affections, who had been brought into this state by being injudiciously *bled* to such excess, as to be, with difficulty restored to health.

The indication of cure requires warm Cathartics, with Pulv. Jalapii, which in general has very good effects. This should be repeated once in four or five days, and on the intermediate days, I should advise Tonics and Stimulants, and such things as tend to warm the general habit; for which purpose also the diet must be rather generous, and a reasonable quantity of Wine, Porter, or Ale be allowed.

For the purpose of discharging the stagnant Serum, I have known Vesicatories have good effects; not merely by evacuating the fluid, but partly by roufing the action of the muscular fibres. Scarifications also have their advantages; but as they are fometimes attended with untoward consequences, they are not to be had recourse to without the most circumspect attention and estimation of the patient's state of body, complexion, &c. and a retrospect to the origin and causes of the disease; for the attempt should not bemade without some reasonable ground of Hope of the patient's receiving some durable benefit, and of escaping the accidents that fometimes supervene: least after being flattered for fome days with a speedy recovery, by a promifing discharge, he should when it ceases, have the mortification to see the fwelling return, with increase of weakness; or that the scarified part should inflame, which might be followed by the most serious consequences; for which reason the scarifications should be made, and attended to by an able, judicious furgeon.

ASCITES.

For the purpose of discharging the fing-

#### AS CITES.

good effects; not merely by evacuating the

This being an enlargement of the Belly, from a collection of extravalated fluid, either in the general cavity only, or in some cyst, or in bydatids, may be confidered as a fimple or as an encysted Ascites; both which are more or less owing to diseases of the Abdominal Viscera; and on this account are mostly incurable. For that they are not absolutely so, I know by my own experience. Diseases of the Liver, Spleen, or Mefentery, are often discoverable by the touch, as well as by other fymptoms; but as the part affected is not always the object of our fenses, we are sometimes at a loss how to determine. ceafes, have the mornineation to fee

In the simple Ascites the belly swells gradually, and sometimes slowly; it is not always preceded by Anasarca, but as the swelling of the belly increases, the rest of the body wastes; it is attended with almost insatiable

infatiable thirst; sometimes bectic heat and high-coloured urine, which deposits a pink coloured sediment: and this is, I believe, an almost certain sign of diseased Viscera.

As the swelling and tension increase, the skin shines, grows thin, and the sluctuation becomes more and more palpable; the patient now complains of pain in his loins, which grows very troublesome, owing, as it seems, to the distension and weight of the Abdomen.

The cure of this disease requires the expulsion or discharge of the extravasated sluid, for which purpose Authors have recommended strong cathartics and drastics, such as Jalapium, Gumbogia, Elaterium, Antimonials, &c. which so far from being useful, in my own opinion, often do more harm than good in this case. To these I should prefer Diuretics if they could be depended on; but little is to be expected from the most powerful of them; unless the patient

be allowed to drink freely of some small acidulated liquid, to which more perhaps is to be attributed than to the Specific.

The folution of Cremor. Tartar. has had good effects, and it is very pleafant and refreshing, when the thirst is urgent, which is often the most troublesome symptom of all that the patient labours under. And yet among other cures, that by a total abstinence from all liquids, is faid to have been successful; but I believe the instances of its success are so very sew, as to give little encouragement to persevere in so trying a course.

As a diuretic, Tinctura Nicotianæ has been tried with confiderable fuccess, by my worthy friend, the ingenious Dr. Thomas Fowler of Stafford. I had opportunities of trying it in a few cases of Anasarca, in which I generally found it to increase the quantity of Urine considerably for some time, and did more perhaps than any thing else would have

have done, but the cases were too bad to admit of cure.

Digitalis purpurea, so much commended by the ingenious Dr. Withering, I have not tried.

Upon the whole, I am of opinion, that when the Abdomen is much distended with sluid, the most easy way of taking it away, is Paracentesis, as it does no violence to the constitution; and should it not prove effectual in curing the patient, it affords great relief; and I believe the repetition would be less formidable to many patients, than a long continuance of most of the other means that have been recommended. But it does sometimes cure the disease, as I have seen in more than one instance.

CASES of ASCITES cured by TAPPING.

One of which was a Patient in the Hofpital, who had the operation performed
twice. After the fecond operation he did
Bb 2

not fill again, while he remained in the Hospital, nor did I ever hear of its returning
any more. But though he had the disease,
his complexion was good; he had no cachectic appearances, nor any thing that I
much disliked, except that the Urine had a
red sediment, which I have often observed
where any of the Viscera are diseased. But
if they were so, it may be supposed here to
have been not to any considerable degree.

Another instance of cure by Paracentesis was in the case of an unmarried Lady, about forty years of age, who had laboured under an Ascites for above twelve years; in the course of which time, she had been under the direction of several Physicians of eminence, none of whom thought Paracentesis advisable; so that after trying all sorts of things, both internally and externally, she left every thing off, and for several years did nothing at all. Being attacked with a pain in her side, she desired my assistance. As I had not seen her before, I out of curio-

fity, took some notice of her other complaint, which she gave me some account of. She permitted me to lay my hand on her body, covered as it was by her cloaths; through which, however, I thought I perceived a fluctuation. She was induced, by what I observed, to remove part of her covering; and I then was confirmed in my conjecture, and told her, that her case must have been much changed, fince she had been told that it was not a proper one for tapping, for that I could affure her, that the operation was not only practicable, but would probably give her great relief; for fhe was now become fo large, and the Abdomen so prominent, as to be extremely troublesome to her. But I, at the same time, defired the would let me confult with the late eminent Dr. Dealtry. The Doctor was fo good as to meet me, and perceiving the change which had taken place, fince he had last seen her, which was some years, he agreed that the operation should be performed, which it was the next day by the late late Mr. Fell, and by the precautions taken, the Patient bore the whole to be taken away at once; and was in a few days almost well. Seventy-nine pints of a fluid as transparent as pure water were measured, so that there had been not less than ten gallons. I defired some of it might be made to boil in a clean vessel; it became frothy, but had no appearance of containing any thing coagulable. She survived the operation several years, and died at last of an illness, in no wise allied to Dropsy.

I have been the more particular in relating this case, and the appearance of the sluid, because it had been imagined, that from its long stagnation there, it must have become so viscid, or encysted, as that it could not be discharged by the operation.

# CASES of diseased OVARIES.

As the Liver and the Mesentery are the Organs most frequently found diseased, in these

these cases, in Man; the Ovaria are the most fo in Women, which I have had opportunities of observing in two or three cases: in one of which, before the Abdomen became too much distended, the enlarged Ovarium on the right fide, was plainly to be felt; but as the fwelling increased, the Belly became uniformly fwelled. The fluctuation was perceptible enough, but its undulation was fluggish. The operation at last became necessary, for the ease of the Patient. The fluid, which was in quantity about fixteen pounds, was of a dirty dark colour, mucous and quite ropy. The fwelling cameon again, but flowly, however the operation was again to be performed, and the fame conditioned fluid was discharged. Some days after, fhe was feized with a Fever of which she died. On opening the body, I found the right Ovarium very much enlarged, and a great part of it schirrous; what was not so, had fuppurated and contained a mucous matter, much like that which had been discharged.

In another *similar* case, except that the fluid was whiter and more *purulent*; the Ovary was much larger, having formed a large Cyst, and its substance was dissolved into matter.

I have seen many varieties in the appearance of the sluid, sometimes perfectly limpid, sometimes ferous; sometimes it has deposited Pus, or Mucus of different colours, which last are owing to diseased Viscera that have suppurated.

The limpid and ferous are probably owing to difeafed Vifcera too, by compressing and bursting the lymphatic and ferous vessels.

When the matter discharged is of such a complexion as to give reason to suspect some of the Viscera to be in a schirrous or ulcerated state, the operation can only be considered as palliative, and therefore should be put off as long as possible, that is until the uneasiness it gives the patient render it necessary and unavoidable.

SECTION VII.

#### SECTION VII.

## HYDROTHORAX.

HYDROPS PECTORIS.

HE Dropfy of the Breast may originate from causes that occasion Anafarca, Ascites, and other Dropsies. But it may also be supposed to arise from obstruction and inflammation of the Lungs; which it has by diffection been so often found to accompany; that it is not likely that the Patients should all have laboured under Hydrops Pectoris, before the Peripneumonia came on. And, indeed, if we only confider what would follow if the motion of the great quantity of Blood, which is continually paffing through the Lungs, become greatly retarded; it will not be hard to admit, that some of the lym-Cc

not

phatic or ferous part may transude and be separated from the rest. The sluid thus out of the course of the circulation, may also surnish the matter of those various concretions that are found floating in the extravalated Serum; and on the surface of the Heart, and the inside of the dropsical Pericardium.\*

The fymptoms of Hydrothorax are difficulty of breathing, especially in a decumbent posture, hence sudden starting up from sleep, with hurry and palpitation. But this must not be looked upon as a Pathognomonic sign, nor does the absence of this symptom afford any certainty of the contrary. A sense of weight upon the Diaphragm, like being tightly girded; the Face pale and bloated; the Feet and Hands too, sometimes, oedematous; the Urine in small quantity; Thirst, and sometimes a dry Cough, are among the symptoms, some or other of which attend this disease. The Prognosis is, in general, very unfavourable.

The

<sup>\*</sup> V. Morgagni Epist. L. 11. Ep. xx. art. 34. et sequent.

The cure is to be attempted by means, similar to those employed in the cure of Anasarca and Ascites. But in this case, Paracentesis of the Thorax and, si Diis placet, the Pericardium, which some Authors have had the hardiness to recommend, must be a very desperate remedy, especially for that of the Pericardium.

And even that of the Thorax alone, if we confider what, in this case, must be the state of the parts contained in it, the operation ought not to be attempted at all, if the Physician would avoid "Subire speciem ejus ut" occisi quem sua sors peremit." \* Though Hippocrates † himself has pointed out the manner of performing it. Unless he should prefer the spirit of "Quos Ratio non restituit temeritas adjuvat." ‡

Hydrocephalus internus having been noticed, when our thoughts were employed on the Brain: there remain only Hydrorachitis, Hydrotherus, and Hydrocele; but these I must leave to the care of Surgeons, to whose province they more properly belong.

# THOUGHTS, &c.

### BOOK IV.

SECTION I.

#### PYREXIÆ-FEBRES.

THOUGH Fevers are the most common of all diseases, yet they vary so much in their types, causes, and cure; their symptoms are often so complicated, and they are so frequently accompanied by other diseases, as to demand our utmost attention and circumspection.

The character of Pyrexia, according to the accurate Dr. Cullen,\* is not any one symptom,

<sup>\*</sup> Nosologia Method. vol. 11. Cl. 1. et subjunctam notam,

fymptom, as a quick pulse, or encreased heat, but a concourse of several, as borror succeeded by a more frequent pulse; the functions more or less impaired, and the strength of the limbs diminished. And though it may be objected, that Pyrexiæ happen sometimes without any previous borror, and others without acceleration of the pulse or increase of heat, yet this happens so very rarely as not much to affect the character here given.

The frequency of the pulse and increase of the heat seem to be owing to too frequent contraction of the Heart and Arteries, and to the increased attrition, and effervescence of the particles contained in the Blood. The more frequent contraction of the Heart, seems to be owing to slimulus; for the Heart being composed of musquals fibres that are peculiarly irritable, the remoter cause of its spassic affection is irritation; and as the irritating cause is in the circulating sluids, they must be more

or less faline and acrid, even naturally, and in a state of health, since the circulation of the Blood is in part occasioned by that stimulus, and not merely mechanical.

And though the fluids in health are neither acescent nor alkalesent but subsaline, yet they have a tendency to alkalescence and putridity, and, in diseases, become sometimes very acrid, as appears in the discharges by sweat and urine; the last of which I remember to have sound, in a patient of a scorbutic habit labouring under a Typhus, though fresh made, to have an alkaline smell and even to effervesce with Vinegar.

This tendency to putridity is greater or less, according to the nature and violence of the Fever; the habit and constitution of the patient; the season and constitution of the year; the exciting causes, &c.—

Fevers may be confidered under two general divisions, Intermittent and Continual.

The

The intermittent Fever confifts of feveral paroxysms with intervening Apyrexia, or sensible remission and exacerbation, preceded by shivering, and occasioned for the most part by putrid Miasmata, exhaled from marshes, stagnant lakes, ponds, &c.

#### FEBRES INTERMITTENTES.

Of intermittents the most common are the Tertian, Quartan, and Quotidian. The paroxysims of Tertian return every day, coming on generally before noon, and taking up about twelve hours, succeeded by compleat Apyrexia. This is said to be legitimate. If the paroxysm be extended beyond twelve hours it is called Tertiana notha, or Spuria. If the fit return every day with unequal paroxysms, but the alternate ones alike, it is Tertiana duplex. If the fit return on alternate days, but with two paroxysms on the one, it is Tertiana duplicata. If it return daily, but with two paroxysms on one day, plex.

and but one on the other it is Tertiana triplex. If it return daily, but have a longer
remission between the uneven and even days,
imparibus et paribus diebus, than between the
even and uneven, paribus et imparibus, it is
called Semitertiana, and comes very near to
be remittent.

Beside these typical differences, it has symptomatic varieties. If it be attended with comatose affections, it is termed Tertiana Carotica; Hemiplegica, Soporosa, &c. If with spasmodic affections, Tertiana Epileptica; Hysterica; Asthmatica; Tetanodes.

If accompanied with eruptions, T. Petebialis; T. Scorbutica; T. Urticata. If joined with phlegmasia, T. Pleuritica; T. Arthritica; Pleuritis periodica. If complicated with other diseases, Tertiana Scorbutica; Tertiana Verminosa.

If instead of Apyrexia there be a remission only, it is called Tritaeophya; Hemitritæa; Tertiana

Tertiana remittens and continua; Tertiana subintrans; subcontinua; Torti et aliorum.

Some of the principal Tertian Remittents are the following, Causos, Hippocratis.—Febris ardens, Boerhaave.—Morbus, Hungarieus.—Febres epidemicæ, Willis.—Syneches epidemica, Morton.—Febres Autumnales incipientes, Sydenham.—Febres Castrenses et Paludum, Pringle.—Putrida Epidemica, Huxham.—Febres Cholericæ, Hoffmanni.—F. Biliosa Lausan, Tissot.—Continua remittens, Hillary.—Febris remittens Indiæ orientalis, Lind.—Tertianæ perniciosæ iet Pestilentes, Lancisi, &c. &c.

# FEBRIS QUARTANA.

In this the paroxysms return every fourth day, and the Fit comes on generally in the afternoon.

The legitimate Quartan has one paroxysm only, every fourth day. Quartana legitima, Dd Sydenham.

Sydenham. If it have two paroxysms every fourth day, and none on the other, it is Quartana duplicata. If it have three paroxysms every fourth day, and none on the other days, it is Quartana triplicata. And that which out of four days, has only one free from Fever, and the paroxysms every fourth day, similar, is Quartana duplex.

The Quartan which comes every day, with the paroxysms every fourth day, similar, is Quartana triplex.

Besides these, Quartan has symptomatic varieties, as follow, Quartana comatosa, Werlhof—Piso.—Qu. Epileptica, Morton.—Qu. Amens, Sydenham.—Qu. Splenetica, Etmuller.

This Fever is also complicated with other diseases, as Quartana, Arthritica—Musgrave.
—Arthritis febricosa—Werlhos.

Sometimes Quartan is remittent only,

then called Quartana remittens; Tetartophya simplex; Tetartophya semitertiana, Sauvages.

—Tetartophya Carotica, Werlhof.—Tetartophya bepatalgica, C. Piso.

### ERRATIC FEVERS.

These are thought to be either Tertian or Quartan;

Erratica Quartana, Van Swieten. Erratica Septana, Boerh. V. Swieten. Septimana, Morgagni, cum multis aliis.

# QUOTIDIAN.

This Fever comes on every day, generally in the morning. When the accession is at the same hour every day, it is Quotidiana simplex legitima. When it affects some part only, of the Body, it is said to be partial, as Quotidiana Cephalalgica, Morton.—Cephalalgia intermittens; Quotidiana ophthalmica, Morton.

Dd 2 Quotidian

Quotidian is sometimes accompanied with other affections, as *Quotidiana Ischiadica*, Ed. Ess.—*Quotidiana nephralgica*, Morton.—*Quotidiana Epileptica*, Ed. Essays.

# QUOTIDIAN REMITTENTS.

Quotidianæ remittentes et continuæ Auctorum, Amphemerina.

Some are vespertine or symptomatic, as Amphemerina Catarrhalis, Anginosa, Tussiculosa, Arthritica, &c. &c.

This shortened abstract of the different types and varieties of intermittent Fever, I thought might be acceptable to the Reader, but for a more compleat detail I must refer him to the celebrated D. Cullen's very useful work, Nosologia Methodica, v. 11.

#### CURE.

As intermittent Fevers appear under such various forms, in order to discover their true

true nature, we must be particularly attentive to their types, varieties, and concomitant affections; to the constitution of the year; the seasons, their anomalies and prevailing diseases.

We have already observed that the most common cause of intermittents is from the exhalation of putrid Miasmata, from marshy grounds and stagnant waters, which are often infected with putrid animal effluvia. Their cure will, therefore, require change of situation, which is often alone sufficient, and without which other means will prove inessectual.

A pure legitimate Tertian will sometimes go off, after a few paroxysms, by only obferving a proper regimen, without any medicines. And indeed when the symptoms are moderate, it may be safely left to nature. But if it should be attended with great heat, head ach, or other violent local pain, and Plethora, the patient must loose blood; his bowels

bowels must be emptied by clysters, and gentle laxatives; and then saline febrifuges, and cooling, diluting liquids, will be the most adviseable.

After which, the Bark, if it should be thought necessary, may be given to advantage. For though it is in itself perfectly safe, yet as it is so powerful a febrifuge, if the paroxysms be not accompanied with any alarming symptoms, it is best in general, not to begin with it too soon, least it should suppress the febrile commotion, which might have removed incipient obstructions in the Viscera, a circumstance that should be duly considered.

Though the legitimate Tertian be neither dangerous nor very difficult to cure; yet when Epidemic, it is fometimes attended with fuch alarming fymptoms; or the paroxysims are so lengthened, and the remissions so short, as to degenerate into continual, and endanger the life of the patient.

Of fymptoms accompanying Epidemic Tertian the soporous or comatose are very formidable; especially in persons advanced in years; who are the most liable to this Symptom, though instances are not wanting of younger Persons having been thus affected.\*

Drowfines fometimes comes on early, and the patient wishes to sleep; sometimes he speaks imperfectly, one word for another, as if the Tongue were slightly paralytic. Here we must be upon our guard least the Somnolency, which increases with succeeding paroxysms, should about the third or fourth become Carus, and the patient at last die apoplestic, which fatal issue can only be prevented by putting a stop to the Fever.

If the Physician should be called in during the paroxysm, and find the patient to have comatose symptoms, but in a moderate degree, he must endeavour to promote the Crisis

<sup>\*</sup> Morgagni Lib. iv. Ep. 1. Art. 30. et feq.

Crisis of the Fit, by ordering him to drink freely of small diluting drink moderately acidulated, which will abate the heat, thirst, and tendency to putrescence.

In the mean time the drowliness must not be indulged. Veficatories must be applied to the legs, which will take effect on the decline of the paroxysm; some blood must be taken away, if the state of the patient allow, and the fymptoms indicate it; and should the Stomach appear to be difordered, an Emetic may be necessary. For which purpose a proper dose of Vin. Antimonii, will in this case be adviseable, on account of its manner of acting; and its tendency to move downwards; which may be promoted too by Clysters. By fuch means we must endeavour to weaken the force of the next paroxysm, but after that no time must be lost to the Bark, as it is on that alone that we can depend, for preventing the danger arising from future paroxysms.

But if the Physician should at his first visit find the patient in a profound fleep or Carus; Blood must be taken away immediately; Vesicatories must be applied to the head, neck, and wrifts; and cupping with fcarification to the back of the head. And fo foon as there is a fensible remission, and that the patient is able to take it, and there appear no circumstances unfavourable to it, the Bark must be given in substance, in doses of one or two drachms, or more, every two hours, if the patient can; and in fuch manner as he can best take it during the remission. Should it appear to have taken some effect, by preventing or weakening the force of the next paroxyfm, the doses may be taken lefs frequently or lessened; but it must be continued fo long as may be thought necessary.

In the case of Cardinal Barbadico, Morgagni\* gave him, as soon as possible, at the first dose zs. and ziss. morein smaller doses, by intervals, with the most happy effect.

Ee

Continual

Continual double Tertians, being of the fame nature as Epidemic Tertians, are happily treated with the Bark, provided the Remissions be long enough, and nothing appear to forbid it. And here the attention and skill of the Physician must be exercised, least vernal and autumnal Fevers, that are in their nature truly Tertian, should degenerate into continual or malignant, attended with very dangerous symptoms.

Tertians accompanied with spasmodic affections; efflorescence on the skin; Phlegmasia or local inflammation; or complicated with other diseases, must be treated according to the nature of the associated affections and symptoms. As must also remittent Tertians, which at times are attended with various symptoms and affections that require the Physician's greatest attention and circumspection; and must be treated with caution, as they bear neither bleeding nor purging in general, though particular cases may require them at the beginning of the Fever.\*

CAUSUS.

<sup>\*</sup> V. Werlhof. Obs. de Febribus, &c. Hanoveræ 1745.

#### CAUSUS.

Febris ardens begins with chillness, fucceeded by excessive heat, especially within, for the extremities do not feem to be fo very hot; the skin and mouth very dry; infatiable thirst; nausea; vomiting; lassitude and restlessness; frequent pulse, hard at first, but becomes weak and irregular. Exacerbations on uneven days, diebus imparibus. They are most like double Tertians. The patients complain of a bitter taste; the countenance is fometimes yellow; and the stools bilious and fetid. Its progress is rapid more or less, according to the violence of the fymptoms, going off by fome critical discharge by sweat, stool, urine, &c. or taking the patient off the third or fourth day, and feldom going beyond the feventh.

The cure is to be attempted by letting the patient drink freely of small, tepid, aqueous, subacid drink; barley water; thin gruel, Ee 2 acidulated

acidulated with lemon juice; currant jelly, and the like.

If there be figns of Plethora, Phlegmafia, or local inflammation, or other urgent fymptoms that require it, blood must be taken away, more or lefs, according to the urgency of the fymptoms, and mild, emollient, nitrated clysters be injected, to remove the dry and hardened fæces. The patient's feet should be bathed in tepid water, his hands too, and other parts of the body with sponges squeezed out of warm water. The medicines must be faline draughts; nitrated emulfions; Sp. Nitri dulcis, and in general the cooling antiseptic method is to be purfued. The patient must be kept cool, and fresh air must be admitted into his apartment frequently.

Symptoms that occur in the course of the Fever, and may be considered as the effects of it, upon the Brain, Heart, Lungs, Stomach, and Bowels, &c. must be carefully attended

to, not only on account of the Prognosis, but that they may be treated according to the rules of art. \*

## QUARTAN.

This Fever, though the longest, has been by some considered as the safest of all Fevers, especially the Autumnal, which is the most

\* Thus far the Impression of these Thoughts was advanced, before I had seen the Treatise on Tropical Diseases, by the very sensible and experienced Dr. Moseley, which I have read with great pleasure and advantage.

The learned Author's comparative view of the Causus of Hippocrates, and the Endemial Causus or Yellow Fever of the West-Indies, which he has not a doubt of being a species of the former, aggravated by the heat of the climate; and the just regard paid to the great Hippocrates and other excellent Greeks, Latins, and Moderns, mentioned by him, in both the Diagnostic and Therapeutic parts, in the Dysentery as well as in this case; not, however, omitting some very necessary cautions respecting evacuants, (bleeding, emetics, and purgatives) in their application to the Causus endemius of hot climates, (the satal effects of which, instanced in Tart. Emetic. he pathetically laments) do great credit to his candour, and the skill, which eminently appear throughout the work.

most frequent. It has not only been thought the fafest, by reason of its long intervals, and compared with Tertian in this respect, it may be true; but it has had the credit too of freeing us from some other diseases, fuch as Epilepsy, Mania, Melancholia, &c. Whatever truth there may be in this, nevertheless, by the long continuance of the febrile paroxyfms, the habit is weakened, and becomes bectic; obstructions are generated in the Viscera; and at last comes on Dropsy.\* Moreover hybernal quartans have been obferved fometimes to degenerate into acute difeases, Catarrhal, Rheumatic, and Exanthematic Fevers, which retaining the quartan Type, by the intervention of its paroxyfm, increase the danger; so that Semiquartans, though less common, may be faid to be not less pernicious than Semitertians.

Whatever blame or praise Quartan has formerly obtained, it is much diminished by

<sup>\*</sup> Quare tuta quoque imprimis ea Quartana que integro Liene hominem tenet.—Idem morbus, si vel tumido Liene est, vel nimium inveterascit, Hydropi corpus exponit, se que æger his casibus oppressus perit.—Lomm. L. i. p. 17.

by the providential gift of the Bark, by which this, as well as other intermittents, are effectually fubdued. But as in the legitimate Quartan the intervals are fo long, we are not under the necessity of precipitating its exhibition; therefore as Quartans are often fuspected to be, more or less, accompanied with vifceral obstructions, it is advisable to confider well the concomitant appearances in the patient; his habit of body; complexion, and the fymptoms: In general I think it is best to begin the cure with the neutral and Ammoniacal falts, and other deobstruent and laxative medicines, and emetics. But should any alarming symptoms appear during the paroxysm, we must have recourse to the Bark, until the formidable appearances are fubdued; after which, if neceffary, the aperients may be again refumed.

There feems to be so much affinity between *Quartans* and *Quotidians*, that I shall now pass on to the latter.

the chylopoietic Organs. Hence

and not unfrequently, buts on the appear-

QUOTIDIAN.

# QUOTIDIAN.

providential gift of the Bark, l

This the most rare of Intermittents, differs little from Quartan, except in duration; being in general more chronical. In its diurnal accessions, it refembles the double Tertian and triple Quartan; but may be distinguished from them by its returns being pretty constantly, at or near the same hour in the morning; and its being mostly vernal. In double Tertian the third accession is similar to the first; and the fourth, which is the milder, is like the fecond. In triple Quartan the fourth is like to the first; the fifth to the fecond, &c. In the Quotidian the fymptoms are in general mild, and the fweats moderate. The accession is, however, fometimes attended with Cardialgia, and not unfrequently, puts on the appearance of Cephalalgia, Colic, Gout, &c. being accompanied with nausea, vomiting, and flatulency; and by its continuance, some times vitiates the chylopoietic Organs. Hence Quotidians Quotidians have been pronounced by Galen, Celfus, and others, as not being free from danger; degenerating fometimes into continual or flow Fever. As both Quartans and Quotidians are prone to return, after having been checked by the Bark, that medicine must, in them, be repeated every third week; but in the Tertian every other week, so long as may be thought necessary.

## FEBRES continuæ, continentes.

Continual Fevers are fuch as have no intermissions; but only remissions and exacerbations every day. Some are inflammatory, and others nervous. Of the former kind is Synocha, which is different in degree, according as the symptoms are more or less violent: hence it is called Ephemera, Diaria, Synochus non putris, et Febris inflammatoria. As in plethoric habits it is often occasioned by overheats, from violent exercise; too much wine, or other faults of the nonnaturals only; if rightly attended to, it is of but

LYPHUS.

fhort duration, going off in one or a very few days, often without any fenfible crifis; the fluids being very little altered, the fymptoms moderate, and the cure requiring little more than a mild, diluting, and cooling regimen. But should the patient be very feverish; the heat great; the urine high coloured, and crude without fediment, and accompanied with Head Ach, or local Inflammation, blood must be taken away, according to the habit of body, strength of the patient, and urgency of the fymptoms; and the patient must be treated with diluting, cooling, subacid drink; Saline Antiphlogistic medicines; emollient clysters with nitre, and gentle laxatives. His food must be water gruel, panada, fago, acidulated with juice of lemons or oranges, currant jelly, and the like; to be taken during the remissions. continuance of the fever is supposed to dispose the blood to putrescency, it has been called Synochus putrida; but Inflammatoria feems to be more proper.

#### TYPHUS.

The nervous continual. In this the pulse is generally weak and quick; the urine little altered; the head is disordered, and it is attended with languor and debility. Dr. Cullen supposes two degrees of it, Typhus miteor and Typhus gravior. Under the former he places Febris maligna, &c. Willis.—Febris pestilens, Fracastorii, Foresti.—Febris nova, Sydenham.—Nervosa, Wintringham.—Lenta nervosa, Huxham.—Contagiosa, Lind, &c.

Under Typhus gravior, he ranks the Fevers, generally termed putrid and malignant, viz. The malignant, peftilential, and contagious Fevers of Camps, Prisons, Hospitals, Ships, &c. of P. Salius Diversus, Alpinus—Sennertus—Riverius—Willis—Huxham—Pringle—Van. Swieten, &c. And the malignant petechial Fevers of Hoffmann and various others.

Another Typhus, cum flavedine cutis, comprehends the yellow, or rather the putrid bilious, Fever of the West-Indies \*and South-Carolina; and the malignant of Barbadoes.

Ephemera Britannica or English sweating fickness, and Febris Sudatoria, La Suette of the French are thought to belong to Typhus.\*

Nervous Fevers are in general contagious and often epidemic; and though the contagion may be supposed to be the same in all, yet in different persons its effects will vary according to the different constitutions, conditions, manner of living, and their apparent state of health at the time of seisure. The first effect of the contagion seems to be such an alteration of the Blood from its sound state, and such depravation of the sluids secreted from it, as renders them unsit for their several functions. Of this depravation,

<sup>\*</sup> Moseley, p. 175.- † Vid. Cullen. Nosologia Method. v. 11.

vation the nervous fluid feems to partake; and this affects the vital and animal functions. To this is, probably, owing the languor; debility; fhivering; oppression of the spirits, and confusion of the head. The Bile and salivary secretions are disordered, hence Nausea, Vomiting, Diarrhea.

In all these Fevers there is, more or less, a tendency to putrescency, which seems owing to the contagion; and though it stimulates the heart to more frequent action, yet by weakening the nervous energy, the febrile commotion is rendered not very strong; but is continued until the noxious particles can be, by the powers of nature, separated and discharged.

The due support of those powers must be a primary object, in the cure of these Fevers, which seldom bear evacuations, except a gentle emetic, Magnesia, and a few grains of Rhubarb, in cases of vomiting and griping stools. But as it is found that by warm moderate sweats:

fweats; copious spitting; eruptions about the mouth; and sometimes by gentle stools, the morbific matter is gradually wasted and expelled, (for we are not to expect a general, formal criss, the urine being for the most part crude and pale) we must endeavour to assist Nature in the way she points out. For this purpose, mild, diluting, subacid, tepid drink, moderately cordial, are most proper. Of cordials, Wine is in general the best, being both cordial and antiseptic, and is to be occasionally added to the patient's drink and food, which must be panada, sago, water gruel, and is to be taken during the remissions.

The medicines too must possess the same qualities, such as saline draughts taken during the effervescence, with the addition of Mistura campborata, Castor, Confectis cardiac. and to render it the more diaphoretic and antispasmodic, a small portion of Elix. Paregoric may be occasionally added. Vesicatories are in these cases very useful, and

are to be repeated from time to time, as the affections of the head and nerves may render them necessary.

In the mean time the patient must not be kept too warm. His room must be ventilated by the admission of fresh, cool air, and fumigated with vinegar, &c.

Miliary eruptions sometimes appear, but they seem to be rather symptomatic than critical, as they are not found to give the relief that might be expected from a critical efflorescence; and therefore the means that are recommended to promote their expulsion, must be used with prudence, since they are often supposed to be the effect of too much sweating, kept up with the view to expel the morbisic particles, but which rather weakens than relieves the patient.

As however eruptions are generally preceded by anxiety and oppression about the pracordia, when these symptoms appear about the seventh, ninth, or eleventh day, some fort of Exanthemata may be expected, and it will be right to favour the exclusion of the morbific matter by mild Diaphoretics. And as nature seems to be relieved not only by the skin, but by the salivary glands, and by slools, those discharges, when critical, are to be promoted by moderate stimulants, such as Oxymel Scillitic, &c. and gentle laxatives of Magnesia, Rhubarb, Dec. Tamarind, Manna, Sal. Rupellens, if nature should seem to want such assistance.

#### Synochus.

Continua putrida, Boerhaavii-Lommii.

This is a fort of continual Fever that happens frequently with us, which is neither wholly nervous nor inflammatory, but a compound of both, being at the beginning Synocha; in its progress, and towards the end, Typhus; to which Dr. Cullen gives the name Synochus, and under it ranks Febris depuratoria,

depuratoria; continua Epidemica, Sydenham.

—Febris continua putrida, Wintringham.

Sauvages, Varietates.

After what has been already noticed on the subject of Fevers, I would only observe that the treatment of this must vary according to the different stages of it. In the beginning, bleeding, and the diluting and cooling method will be proper, which in its advance and towards the end would not be adviseable, and must give place to the mild Diaphoretic, Antiseptic cordial medicines, Vesicatories, &c. as the symptoms may indicate.

#### TYPHUS GRAVIOR.

Malignant, pestilential, and petechial Fevers seem to differ only in degree from those called Nervous. And this may be probably owing to the greater virulence of the contagion, where a greater number of persons are collected together as in Camps, Hospitals, Jails, &c. Hence the symptoms are Gg more

more violent, and the appearances denote a greater degree of putrescency of the Blood, and of depravation of the fluids in general. But the difference of the fymptoms will not depend folely on the degree of virulence, but will be farther modified by the different states and constitutions of the persons affected; and this will occasion some variation in the method of cure. For though the general effect of the contagion is to weaken the nervous energy, fo that bleeding and other evacuations are to be practifed with great caution, yet in persons of full plethoric habits, the fymptoms are fometimes fuch as not only to justify the taking away of blood, but even of repeating it. As the stomach and first passages are more or less affected, and their contents corrupted by contagious miasmata taken in by the mouth, a gentle emetic, and if there be reason to suspect that the intestines are loaded, a moderate dose of Rhubarb, or other mild laxative will be adviseable. tient is to be supplied with mild, antiseptic, fubacid

fubacid drinks, and nourished with panada, water gruel, sago, &c. to which wine must be added with a liberal but prudent hand, according to the circumstances. By such means a mild Diaphoresis must be supported; which may be affished with Sp. Minderer: Pulv. Contrayerv.c:Conf. cardiac. Mistur. Campborat: Elix. paregor. As these Fevers are observed to go off partly by the skin and partly by stools, the latter are to be prudently promoted, when they come on about the seventh, ninth, or eleventh day.

Should Petechiæ appear early, or other marks of putrescency, the mineral acids must be freely taken.

### FEBRIS HECTICA.

This Fever comes on about eleven o'clock every day, with chillness, paleness of the face, and very great thirst, succeeded by a quick pulse, heat and slushing in the cheeks. These symptoms decline gradually,

Gg 2 ft me

but increase again towards night, continue some hours, and are followed towards morning by copious sweat, which carries off the the heat, and the patient gets a sew hours sleep. The Fever, however, does not entirely leave him, and the exacerbation comes on again about the same hour, as before, in the forenoon, but not always in the evening. The morning sweats are generally very profuse; the urine is high coloured, and deposits a pink coloured sediment, which I have often found to be a symptom of internal Ulcers; the patient's slesh and strength waste away, and he dies tabid.

This happens most frequently in diseases of the Lungs, which of all the viscera are the most subject to ulceration, and I have generally found the urine depositing a rose or pink coloured sediment to be an almost infallible sign of an internal ulcer, and together with Hestic Fever and Marasmus making up a fatal Prognosis.

The fymptoms, excepting cough, are very fimilar in cases of matter formed in the joints, as I have seen in that of the Os Femoris with the Ischium, and with the Tibia, and that with the foot; in Psoadic abscesses, &c.

A fymptomatic flow Fever often attends Worms; Scropbula; Chlorosis; but it has not the character of the true Hectic.

#### SECTION II.

# EXANTHEMATA.

rious kinds, of which fome are owing to a specific Seminium, and make their appearance at or about one certain time of the disease occasioned by contagion. Of this kind especially are the Small-Pox and Measles, to which we may add the Scarlet Fever, though less remarkable than the other. These eruptions are critical, the contagious particles being by them discharged upon the skin. By the way we may here remark the different effects of disferent contagion upon the skin, one kind producing papulæ that instame and suppurate,

as Variolæ; another causing small red spots like flea-bites, forming patches or clusters that are fcarcely perceivable by the touch, and vanish in a few days, leaving upon the skin a branny roughness only, the Meafles; another in which the spots are red, cause a considerable roughness of the skin, and by degrees fade and go off with defquamation of the skin, such is the Rash; another in which the spots are at first white veficles, fome fmall and round, other rather larger and lenticular, this is the Miliary, by fome called Purpura alba; another called Petechia, which are spots in the skin that are of a deep red, brown, or purple, that appear about the fixth or feventh day, in malignant, pestilential Fevers, Small-Pox, &c. and are more or less alarming as their colour approaches more or less to black. Petechiæ are fometimes succeeded by the Miliary, in malignant Fevers, &c. and often with bad omen. Some of these are manifestly idiopathic and critical: though the Meafles

Measles are by some thought symptomatic, as well as the Miliary and Petechia. even the last, though they mostly attend malignant and pestilential diseases, and denote great putrescency of the fluids, yet when they are only of a deep red, brown, or purplish colour, and gradually fade away, with fuch abatement of the fymptoms as are often followed by the patient's recovery, they may be reasonably supposed to be in fome degree critical. As to the Measles, though their eruption does not immediately remove all the fymptoms, but that on the contrary the cough and difficulty of breathing are upon the turn increased, sometimes to an alarming degree; and fo as often to injure the Lungs; yet these may be owing to mismanagement, or to the malignancy of the disease, since it is well known that a premature retrocession of the eruptions is always dangerous.

VARIOLE.

## VARIOLÆ.

Of all Exanthemata, owing to specific contagion, the most remarkable is the Small-Pox. It was formerly one of the most formidable too; but by the practice of Inoculation, it has been rendered in general fomild as to create very little trouble or apprehenfion. But though daily experience of its uniform fuccess evinces the great advantage of Inoculation, yet in a matter fo very interesting, it is no wonder that many find it difficult to overcome their fears of giving their child a difease of which he may die, who yet would think it wrong not to give him the best chance of passing well through a difease which he must once have, at the most eligible time of life, and with the choice of the most favourable circumstances, of season; quality of the matter; mode of infection; (which feems to be of great importance) and the having an opportunity of preparing him for it, where Hh that

where that may feem necessary; which, however, is very little wanted in children of good habits, and who are properly educated.

Should the difease however, whether by natural or artificial infection, be attended with symptoms unfavourable, the assistance of an able and experienced Physician will be necessary.

### RUBEOLÆ.

The Measles begin very much like a Catarrhal Fever, with heaviness of the head; watery eyes; sneezing; hoarseness and fever. The eruption appears about the fourth day, in red spots and papulæ visible, but so little elevated as to be scarcely perceptible by the touch. About the fifth or sixth day they fade and by degrees go off, leaving a branny roughness upon the skin.

When the difease is of a benign kind, the symptoms

fymptoms are mild and favourable, and the patient gets through without much trouble, little more being wanted than to keep moderately warm; to drink fmall tepid liquids, fuch as barley water with raifins; baum, or fmall green tea; lemonade and the like.

The patient's room must not be made too warm, nor must he be much loaded with bed-cloaths, more than what may be fufficient to encourage mild perspiration. But as the difease is often more or less epidemic, the fymptoms vary according to the constitution of the year; the season; their anomalies and prevailing difeases, and the difference of age, habit of body and strength of the patient. If the difease come on with much head-ach, cough and fever, and the patient be plethoric, he must lose blood according to his strength and the urgency of the inflammatory fymptoms; which render it necessary even in children. And though it should not seem to be required at the beginning, yet it often happens about the fixth day, when the eruptions begin to fade, that the cough increases, and is accompanied with such oppression and difficulty of breathing, as to endanger the patient's life, or to injure the lungs so as to lay the foundation of a *Phthisis*. Here bleeding is become absolutely necessary, without which no other means would avail, and it must be repeated if necessary; a vesicatory must be applied, and the patient must sip frequently some small tepid liquid, such as an infusion of raisins, liquorice, and pennyroyal, and endeavour to inhale the warm vapour from the tea-pot.

When this difficulty is overcome, little more will be wanted than two or three doses of rhubarb or other mild laxative, and if a cough should remain, change of air and asses milk to compleat the cure.

the inflammatory fyntpionis; which ren-

Lord west in children

SCARLATINA

# SCARLATINA, Sydenbam.—SCARLATINA SIMPLEX, Cullen.

This as well as Small-Pox and Measles, is preceded by a Synocha, and is contagious. The symptoms are, however, sometimes so mild, as to give the patient very little trouble or sickness. There is indeed some Fever, but very moderate. Such was that taken notice of by Sydenham. The face, about the fourth day appears rather swelled, and large red spots or patches come out here and there, which run together, and in three days more gradually go off in branny scales, but leaving an anasarcous swelling.

This difease is peculiar to children and young persons, especially girls. It comes on with shivering, pain in the head, anxiety, redness and soreness of the eyes, and other catarrhal symptoms, very much like the Measles; and is like that to be treated with small warm diluting drinks, such as with-

Vid. och Collen Nofologia Method. 11.

out heating, tend to promote perspiration. The patient must in the mean time be kept in bed, in a moderate degree of warmth.

When the disease is over, and the defquamation has taken place, it will be proper to give the patient some gentle cathartics, which must be repeated at proper intervals, as the case may require, after which some mild tonics will be adviseable.

SCARLATINA CYNANCHICA, Cullen.

But there is another Scarlatina which is Epidemic, and which being almost always accompanied with Ulcers in the throat, Dr. Cullen calls Scarlatina cynanchica; which as in most of the patients it very much refembled the malignant fore throat; and as in all that were affected, he never observed Epidemic Scarlatina to be simple; he has often doubted whether every Scarlatina be not Cynanchica, and almost always the same disease with Cynanche Maligna.\*

But

<sup>\*</sup> Vid. cel. Cullen Nosologia Method. 11.

But he fays, there are many reasons for his not adopting this opinion: For, that Scarlatina is fometimes fimple, that is without a Quinfey, and that therefore there is a fpecies of contagion that produces a fcarlet efflorescence only, is certain from the obfervations of Sydenham and others. And if contagion affecting the fauces, often produce the fearlet also; this only proves that it is the nature of fome contagions to affect both the skin and the throat. Though these contagions may yet differ, so as that the one should primarily more affect the fkin, the other more the fauces; and this difference he thinks, there always is between the contagion of the fcarlet, and that of the malignant fore throat.

In the epidemic which he confidered as Scarlatina, some of the patients had no fore throat, and in those who had, it was in almost all, benign; the ulcers on the Tonsills small, not spreading; the matter mostly good, and the disease rarely mortal.

In the malignant Angina, the fick were feized at the first with fore throat; the ulcers were foul, spreading, malignant, and gangrenous; and the disease was for the most part mortal.

This distinction between the malignant fore throat, and the fcarlet Angina agrees with what I have observed, and, as a thing of no small importance, should be kept in mind. The treatment of Cynanche Maligna, has been already considered.

# ERYSIPELAS

This is an affection of the skin, in which it appears of a bright red, with swelling, considerable heat, and often pustules or vesicles, accompanied with Synocha. It frequently attacks the face, and after dying away there, shews itself again on the legs, the redness spreading sometimes very considerably; it continues seven or eight days, then

off. The Fever is often accompanied with dorwfiness, and sometimes with delirium; it continues only a few days in common cases; but when the Erysipelas is symptomatic, in putrid and malignant Fevers, it lasts longer, and the inflammation sometimes ends in suppuration or gangrene.

Erysipelas requires different treatment, according to the different degrees. When it is Idiopathic, the inflammation, great, and the swelling considerable; bleeding, antiphlogistics, mild diaphoretics, with small tepid liquids, and clysters or mild laxatives, in case of costiveness, will be the best. In the mean time the patient must be kept moderately warm, so that moderate perspiration be promoted. Should the inflammation increase, it will be advisable to sometiment the part with soft slannel wrung very dry out of Decost. pro Fotu, and sprinkled with Sp. Vin. Campborat. taking care that they be not applied too hot. The

Fever, if putrid or malignant, must be treated as such.

CASE of ERYSIPELAS PHLEGMONODES.

I take the opportunity here to mention what happened to me in the course of, and apparently unconnected with the Arthrodynia, which had fo long confined me. On the 24th of December, being in perfect health and good spirits when I went to bed, about three o'clock in the morning I awoke in a shivering Fit, which was soon after succeeded by Pyrexia, but in no great degree. A day or two after I felt a foreness in the calf of my left leg, where the skin appeared red and hot, in short an Erysipelas shewed itself, which I flattered myself would prove merely fuperficial; but I foon found that it was Phlegmonodes, attended with burning heat. And fuch was the acrimony of the humour there deposited, as to produce the effect of a Caustic, (a black Eschar) which destroyed the Cutis, &c. and upon the the whole was more like an Anthrax than any thing else. The feverishness soon went off, and I became perfectly well in health; but the Eschar was long before it separated, and the Ulcer which was about the size of a crown piece, is not yet healed. I was not a little surprised at the virulence of the humour, as I never had in my life any cutaneous eruptions, or other marks of acrimony; nor was the disease that afflicted all my joints, attended with any appearance of inflammation. The Erysipelas was entirely under the management of my Surgeon, being in so good health, that medicine was perfectly unnecessary.

# MILIARY FEVER.

This fever made its appearance about the middle of the last century at Leipzig, where it proved fatal to the greater part of women in Child-bed that took it, for they only were attacked with it.

\* Dr. Welsch, the first who wrote upon it, looked upon it as a new difeafe, and expresses himself as having laboured under great anxiety on account of its fatality, and his having no precedent to direct him in the cure. From analogy, therefore, he was led to confider it as a malignant Fever, and as fuch treated it, giving it the name of Febris maligna miliaris, the eruption causing the skin to feel as if sprinkled with millet feed. By others it was thought to feel like the cloth called frize, and they called it der Friezel, red, or white, according to the colour of the spots. To some they appeared of the fize of lentils, and they called it Lenticular.

At its first appearance it affected lying-in women only; but some years after, 7341-5, it raged with great violence at and in the neighbourhood of *Strasburg*, under the name

in Child-fed that took it, for they letty were

<sup>\*</sup> V. Ill. Halleri Disputationes, vol. 5.

name of \* Purpura meliaris alba; though Purpura belongs properly to the red fpots; and not at all to that in which the white fpots are not preceded by the red.

Sir D. Hamilton thought it ought to be called a "Vesicular Fever, because the pusuales are vesicles or little blisters, filled at "first with a limpid Serum, and afterwards "with a whitish one, not unlike the colour of pearls."

As the Leipzig Fever affected only lyingin women, that of Strasburg happened mostly to middle aged men, and those especially of plethoric, sanguine habits of body, to whom it was more dangerous than to the phlegmatic. The symptoms being more or less violent at different times, it has been divided into benign and malignant; the former called by † Etmuller, Scorbutica; and by Hoffmann into Acute and Chronical; the latter having

no

no Fever, nor being dangerous, but rather falutary, though very troublesome from the itching it occasions. This seems to agree with what we call a Rash. The acute is dangerous, either simple, having miliary pustules only, which \* Hoffman calls idiopathic; or complicated with purpura rubra; Variolæ; Morbilli; or Petechiæ; which sometimes come on in the increase or decrease of the disease, seldom at the beginning. The miliary sometimes joins itself to putrid, ardent, and spotted Fevers too, and then he calls it Symptomatic.

What has been already faid, being chiefly Historical, I shall now enter into a detail of the phænomena, or symptoms attending this Fever. At the first, when it affected childbed women only, it began generally within the first four or five days after delivery; sometimes about the seventh, seldom later.

Its

and Chronical; the latter having

Its beginning was attended with shivering, then general heat; anxiety about the pracordia; pain in the head; redness of the eyes; restlessness; a partial sweat about the face, neck, and pracordia; the urine was, for the most part, as in health, or very little changed; the belly bound, or stools flow. Its increase was accompanied with increase of heat; redness and roughness of the skin about the breast, neck, and back; and here and there over the whole body; the pulse full; little fleep, and that uneafy and difturbed; the urine clear, orange coloured or red; and the symptoms, in general, decreased; the Lochia diminished. The state was about the fifth or fixth day of the disease, when the symptoms attained their height. Such in general were the diagnostic figns. The prognosis was in general unfavourable. Anxiety; a weak unequal pulse; difficult Respiration; prostration of strength; restlessness; delirium; dimness of sight; bleeding at the nose; tremor; spasms; were symptoms which, with more or less violence, according to the difference

difference of babit and constitution of the patients announced a fatal termination; to some even in the beginning or increase, but mostly about the state. But if at this time there came on a moderate sweat about the præcordia, and from thence extended over the whole habit; with remission of the heat and other symptoms; gentle quiet rest; the urine becoming thick and turbed, depositing a copious sediment, with spontaneous setid stools, the patient recovered, his strength gradually returned, and by moderate sweats and perspiration, the itching and roughness of the skin goes off, with desquamation of the cuticle.

Sir David Hamilton's account of this difcase about the year 1710, agrees very much both in respect to the phanomena, and to his notions of the nature of it, which he considered as malignant. But I think it appears that by miliary, he means the white vesicles, as he calls them; for where he says that this kind of sever is twofold, simple "and compound. I call it fimple, as often as no "putules befide the miliary appear, whereof "I am going to difcourfe; but compound, "when red papillary pufules are interspersed "with the miliary; and which, when they are folitary, are commonly called a Rash. "And it is farther to be observed, that the "miliary pustules are sometimes intermixed "with the small-pox, and while the small-pox "rifes up, those gradually wither away; "but remain standing after the papillary "are dried up.

As in his general notions of the nature of the disease, so in his description of the Symptoms, and the Prognosis, Sir David agrees materially with the German Physicians. In respect to the prognostic signs of this sever, he says, "a Prognostic is thus to be made of "this fever: If the sick hath not observed "a due Regimen in the Beginning, or the "Physician prescribed beating medicines, not "raising a sweat, although the symptoms "were milder from the beginning, yet the Kk "distemper

"distemper often turns to the worse, and "threatens either death or a lingering dif-"ease." In his caution too against the use of " beating medicines, usual in Hysteric " paroxysims, without Diaphoretics, whence "in lieu of a mild procedure of nature, ex-"pelling the matter by gentle sweating, a "rapid fermentation throws down the same "into the Guts;" Sir David agrees with them, as well as in the treatment recommended by them; founded as appears on the supposition of its being an Idiopathic difease; and that the offending matter is best carried off by moderate sweating, thick concocted urine, and spontaneous gentle tho' fetid stools.

Great and profuse Sweats sometimes precede the miliary eruption, which may be considered rather as Symptomatic; and to denote a greater quantity or more irritating quality of the morbisic particles in the blood, by which the powers of nature are put into greater commotion, and thereby weakened;

fmothered with bed cloaths and hot rooms. But that the miliary eruption is the creature merely of a heating regimen and heating medicines, is an idea that the Authors mentioned disclaim; and which is not supported either by their practice or their observation. It is, however, allowed to be sometimes Symptomatic.

It seems to have been very frequent and dangerous in persons of all ages and sexes about the year 1741.—Vide an anonymous Pamphlet on the cure of the Miliary Fever, with extracts from Sir David Hamilton and Sir Richard Blackmore. London, printed for C. Say, Newgate-street, 1751.

admired by a very fucciolated senseed

action, he sain't insects

#### MORBI PUERPERARUM.

#### FEBRES.

The Fevers that happen to lying-in women, may have for causes, injury done to the Uterus in difficult parturition; great emotions of the Mind, occasioning spasins and suppression of the Lochia; getting cold; retention of the milk from neglect of having the breafts drawn; whence arises a fudden Plethora, which, where there is already a phlogistic Diathesis, causes inflammation and great danger to the patient, as has been proved by diffection, not only the Uterus, but the Peritoneum or Epiploon, having been found in an inflamed and gangrenous state. But to none of the causes mentioned may it be more frequently attributed than to the retention of the milk, as I have been affured by a very fuccessful Accoucheur; who informs me also, that it is a case that, in very extensive practice, he rarely meets with with, and may be prevented in a great meafure by giving attention to have the milk regularly drawn off, which prevents also any degree of milk Fever. Hence the ingenious Mons. de Sauvages, among other species of inflammation of the Uterus, ranks \* Metritis Lactea; and † Lieutaud, after the enumeration of various affections, excited by the milk, fays "Telles font les maladies " dont sont menacées les femmes, qui veulent se " soustraire aux loix établies par la naturé." This one would think should have induced him to have recommended instead of a number of infignificant topics, &c. the breafts to be drawn, which he does, indeed, by compulfion it feems, and apologifes by faying " on est obligé d'avour recours au tettement d'un " enfant ou a la suction de toute autre personne: " ce parti peut entretenir, a la verite, la dispo-" sition a l'engorgement, mais en remediant aux " doulears presentes il donne le tems d'user d'autre " moyens."

<sup>\*</sup> Cullen. Nosologia Methodica, v. ii. p. 118.

<sup>†</sup> Precis de la Medicine pratique, L. iii. p. 650.

"moyens." So that he proposes it only as a temporary expedient to give time for the employment of other means. This is at least acknowledging its utility.

Should, however, any of the causes mentioned occasion Fever, accompanied with pain and tension of the Hypogastrium; vomiting, &c. Blood must be taken away, and that, more than once, according to the urgency of the fymptoms. Emollient clysters must be injected, and tepid fomentations applied to the Abdomen; her drink must be small tepid liquids, such as barley water; baum, or fmall green tea, and the like, to promote gentle perspiration, for which purpose also three or four grains of James's Powder may be given, and repeated with discretion. In the mean time she must not be kept too warm, but only fo as to favour free perspiration. And as it sometimes happens, on these occasions, that the Bowels are affected with spasins, from which arise flatulency and pain, it will be proper

to move them now and then by injecting a proper clyfter, or if necessary, giving some very gentle laxative, but with due caution of not exposing the patient to a check of perspiration. In the mean time the breasts should be gently drawn from time to time, as it is a matter of considerable importance.

It is not my intention to go into the confideration of many other affections and accidents to which lying-in women are liable. I would, however, observe that the pains that often succeed *Parturition*, are not always owing to the contraction of the Uterus, to expel *Coagula*, &c. but often to flatulent distention of the Intestines from spassic affections, in sympathy with those of the *Uterus*.

For which reason, if the woman complain of great pain and a sense of fullness, without symptoms of *Phlegmasia*, it will be adviseable to give her one or more Clysters, if necessary, which will frequently produce produce discharge of wind, and ease the patient. Should similar pains return, the same means may be used; and then something Diaphoretic, as Sp. Minderer. 3iii. Aq. Menth. Sativ. 3i. Pulv. Contrayerv. c: gr. xv. Tinct. Opii. gutt. xv. Syr. Groci. 3i. Tinct. Castor. 3i. may be taken at bed time. Should it seem necessary to procure a passage downward, Magnesia, and Rhubarb with the addition of Tinct. Sennæ, or some other gentle laxative will be proper.

One thing more I would have noticed, especially by the assistants and those who may be about Women in Labour, that they be extremely cautious in saying any thing that might in any degree affect her mind; the bad essects of which have been too often experienced. Such a case is related by \*Morgagni, of a woman of a nervous habit, who apprehended that she should die upon that occasion. She was also very anxious

to

<sup>\*</sup> V. Morgagni, Epist. xlviii. art. 43.

to have a Son. She was fafely delivered of a Daughter, which was carefully kept from her by all the attendants, but her husband coming with joy to congratulate her, on her fafe delivery, inadvertently discovered the truth; she was instantly affected to such a a degree, that her pulse sank, she became cold, and without any material discharge from the Uterus, that could be supposed to sink her, she died about an hour after. \*

\* Morgagni, Ep. xliv. art. 43.

#### SECTION III.

## MORBI ARTUUM et ARTICULORUM.

## ARTHRITIS.

the disorders of the Limbs and the Joints are in general so perplexed and indistinct, that it appears to me to be no easy matter to give to each its proper marks. \* Dr. Cullen whose characters of diseases are, in general, very accurate, defines Rheumatism a disease owing to an external, and for the most part an evident cause, attended with Pyrexia; pains about the

<sup>\*</sup> NofologiaMethod. v. ii. p. 125.

the joints, following the tract of the Mufcles; affecting the knees and larger joints more than those of the feet; and exasperated by heat and motion. Now, however just this character may be so far as it regards the joints, it certainly does not perfectly apply to the varieties noticed by the learned Professor, they being chiefly muscular, fuch as Lumbago\* Rheumatica; Ischias Rheumaticum; Pleurodyne Rheumatica; Pleuritis Spuria, Boerhaav. which are not always attended with Pyrexia; to these, therefore, I would apply the term Rheumatism; and to that in which the joints, with their ligaments, and other furrounding parts of the shoulders, elbows, wrifts, fingers, knees, feet, &c. are affected with fwelling, tenfion, redness, and great pain, the name Arthritis might not be improperly given. To the supposition of the tendons, ligaments, and membranes, being the feat of the pain in these cases, it has been objected that Ll 2 those

<sup>\*</sup> De Caus. et Sed. Mor. Ep. Ivii. art. 17.

those parts are insensible; that this has been proved by irritating them with both mechanical and chymical irritants, in living animals, who shewed no signs of suffering pain. But even admitting this to be true, when they are sound; it is quite otherwise when they become diseased, (swelled or instance) as was proved some years since by the ingenious Professor, Whyte, of Edinburgh, in his dispute with the excellent De Haller, upon the subject of irritability.

The names Podagra, Gonagra, Cheiragra, or Gout, seem most applicable to that disease, which though it affects the same parts as Arthritis, yet it differs so materially from it in some particulars, as to seem to be of a different Genus; it being generally preceded by a sense of fullness at the Stomach; Flatulency; Dysorexy; Dyspepsy; coming on without any evident cause, and being for the most part Hereditary and Periodical. When the Gout is regular, these symptoms are commonly followed by swelling of the great

great toe, and other joints of the feet, which is intenfely red, and exquisitely painful, even when not moved. The rose or pink coloured redness and the ardent pain, seem to distinguish the Gouty from the Rheumatic swelling. The Fever is sometimes very brisk; the urine is high coloured, and on the decline of the Fit deposits a great quantity of red sediment, and is followed with desquamation of the cuticle of the parts affected.

As these affections of the Limbs and Joints have symptomatic differences, some difference must be observed in the treatment of them. Rheumatic pains in the Side, Loins, and Coxa, not attended with Pyrexia, are soonest removed, by slannel and local applications, such as somentations, Liniment. Volatile; warm plaisters, and vesicatories.

Arthritis being a difease that young and middle aged persons of strong habits, and sanguine

fanguine complexions, are most subject to, may require repeated venesection, antiphlogistics, attenuants, and mild diaphoretics; small tepid liquids nitrated; saline draughts; Sp. Minderer. Vin. Antimon. to which may be added Tinet. Opii occasionally. In the mean time the patient's food must be light and not heating, such as water gruel, panada, sago, chicken, and the like.

In those cases that are attended with great pain in the Loins, and difficulty of standing erect, the Muscles Psoas and Iliacus internus are not unfrequently diseased and suppurate, of which I have seen several instances. And for an example of the state and condition of the Muscles, in a Rheumatic disease of the Loins, as it appeared on dissection, Vide Morgagni, Ep. lvii. art. 17.

niment. Volutile; warms glaifters, and velica

PODAGRA

#### PODAGRA-GOUT.

The Gout being, as already observed, of a nature different from that of other Arthritic affections, the treatment of it may require particular attention. It happens, for the most part, to persons who have indulged in what is called good living; and been in the habit of feeding upon strong high feafoned meats, and drinking largely of wines of various forts; "Arthritis morbus fere Divitum, "rarissime Pauperum," \* by which a peculiar kind of acrimony of the humours is generated. which being carried about by the circulation, affects, in its course, the joints, tendons, ligaments, &c. and produces swelling, violent pain, and other fymptoms as before stated, until by the powers of nature it is fo changed as to be separated and discharged, by free perspiration and turbid urine, which in the declination of the Paroxysm, depofits

fits a large quantity of red sediment, and thus the Fit terminates; and is said to be regular.

But if the usual symptoms of Gout, should not be succeeded by swelling and inflammation; or that they should be slight and transitory coming and going, as the fymptoms come and go, Podagra is then called Atonica, but thefe are not eafily diftinguished from each other. When the inflammation and fwelling go off prematurely, and the Stomach becomes difordered, the Gout is denominated retrograde. And if some internal Phlegmasia suddenly cease, and inflammation of the joints fucceed, it is faid to be wandering. It is fometimes joined with other diseases; but for these and some others I must refer to Cullen's Nofologia Method. \* from which some of these characters are partly taken.

The Gout, in general, attacks persons about

<sup>\*</sup> Gen. Morbor. p. 128.

about the middle time of life of the above description. In those of more advanced years, the Fits become less violent, but they are less regular and more extended. Young persons and even children are not wholly exempt; and it is generally hereditary.

The regular Gout requires little more than patience, flannel, and a proper regimen; that is fuch a one as shall tend to favour perspiration, and support the vital powers, without heating the patient too much; and to empty the Bowels by clyfters or gentle warm laxatives. As Nature is here the principal agent, that by degrees prepares, and at last separates and throws off the morbific matter by repeated finaller paroxyfms, which at last terminate in one general paroxysm, about the fourteenth day, fometimes fooner, and often taking up much longer time:\* it behoves us to watch ber operations, and to Mm affift

<sup>\*</sup> Vide Sydenham de Podagra.

assist and direct them by such means as may feem best adapted to the nature of the case.

Should the Gout prove atonic or retrograde, we must endeavour to obviate the confequences, by promoting the expulsion of the morbific matter, and to determine it to its proper feat, by warm stimulating Pediluvia, cataplasms and vesicatories, and such other means as the fymptoms may indicate; not omitting venefection if Phlegmasia, or other affection of the Brain, Lungs, or other principal Viscera, should indicate it. Sudden and violent affections of the Mind have fometimes occasioned a fatal retrocesfion of the Gout, as happened to a Cardinal Bishop of Padua, on receiving the sudden afflicting news of his Brother's death, as related by \* Morgagni. Who also mentions another case of retrograde Gout, without any evident cause, cured.

The moderating future paroxysins can only

<sup>\*</sup> Morg. Ep. lvii. art. 10, 11.

only be done by observing a temperate regimen; having at the same time due regard to the patient's age, constitution, and state of health: For the powers of Nature must not be too much depressed, in those especially who are advancing into years; with whom too spare and abstemious a diet of milk, pultaceous food, and the like, would very probably disagree. A steady perseverance in such diet and total abstinence from wine has, in some instances, produced a radical cure.\* Though in others it has proved but short and transsent; and its return more severe than before.

#### ARTHRODYNIA.

The AUTHOR'S CASE.

This affection of the joints, according to Dr. Cullen, succeeds to the Rheumatism, or to some violent strain or effort, and consists in pain of the joints or muscles, more or M m 2 less

<sup>\*</sup> Vide Morg. Epist. lvii. art. 7 et auctores ibi allegates.

less transient; is increased by motion, and relieved by warmth; the limbs are weak and stiff, and often cold; but there is no Pyrexia, nor for the most part any swelling.

This character agrees but in very few fymptoms with my case, which being, properly, neither Rheumatic, Arthritic, nor Podagric, might, I thought, be not improperly denoted by the general term Arthrodynia, it being a chronic affection of the joints, attended with some pain, stiffness, and swelling, but without redness or tension of the skin; not attended with Pyrexia, nor much pain except upon motion, and then not very severe.

In my case, all the joints, except those of the Dorsal and Lumbar Vertebræ, (for those of the neck were not free) and the toes were affected. Particularly the instep, the knees, the hands and singers, the wrists, the elbows, the shoulders, the articulation of the lower jaw, on the left side only, so that at times, it was not without difficulty I could open

open my mouth to eat. I could not be fure that any of the muscles were affected, but that the tendons were, I had very sensible proof of, in the tendons of the Gastrocnemii, which have been all along swelled and very painful, though the muscles seemed to have no share in it.

The joints became gradually enlarged, those especially of the knees, hands, wrifts, and elbows; but the fwelling even of the knees, did not apparently affect the fkin. This swelling seemed to be partly in the Cartilages, as well as the ligaments, tendons, &c. for as it increased, the knees became more and more stiff, till at last, they creaked audibly like a door moving on rufty hinges that wanted oil, and this feems to have been the Acme of the disease, in which state the parts continued for a very long time. This stiffness I attributed partly to enlargement of the joints, and partly to a defect of Synovia, from some indisposition of the glands, by which it is fecreted.

That

That the swelling was purely in the joints, is yet evident, in two or three fingers in which the fwelling yet remains, though fome of them are at present distorted, manifestly by the fwelling of the joints, upon which the skin is perfectly free and wrinkled. The fwelling of the joints has been as flow in its declenfion as it was in its increase. It is greatly abated in the knees, which move with ease and freedom; the great tendons of the Gastrocnemii are almost well; the wrifts, elbows, and shoulders are yet rather stiff, and somewhat painful, though they are growing better, and will, I flatter myfelf, be cured by warm bathing, though it was before ineffectual,

There being no apparent reason for venefection, I never thought it necessary. The medicines I chiefly made use of, were Sp. Minder. Vin. Antimon. James's Powder, and warm bathing of different degrees of heat, from about 110 to about 84 at different times, from none of which I ever found any fensible benefit, though I constantly obtained a free perspiration, especially in the extremities. Perceiving, therefore, that it would prove chronical, and that it would have its course, I gave up all medicines, except Vin. Antimon. and Tinet. Opii. of which I took about twenty-five drops, on account of restlessness; this had the desired effect.

The Tinet. Opii not only procured me rest, but seemed to favour the free perspiration, especially about the feet and legs, that has uniformly continued the whole time. Nevertheless the stiffness was so tedious, that I fometimes apprehended that the Opium might rather favour it by making me lie longer still; and on that account I left it off, from time to time; but further attention gave me reason to think otherwise, so that I have, for many months, continued it once in twenty-four hours, in a dose of thirty or thirty-five drops, and no more, with undoubted advantage. I cannot omit observing, that during this long confinement, (two years)

years) I have, for the greatest part of the time, enjoyed perfect health. My appetite has been in general good, though moderate, as I could wish. My digestion complete; not having so much as the least eructation or any other sign of indigestion. My drink at meals has been chiesly water with rum, of a moderate strength, and sometimes a glass or two of wine. The Erysipelas which I have already given the history of, was an incidental matter that surprised me, as I should not have imagined that there could be such caustic acrimony in my blood.

### ARTHROPUOSIS.

This, as Dr. Cullen observes, is undoubtedly of a nature very different from either Gout or Rheumatism; the disease being, in the cases at least that I have seen, within the capsular Ligament, where matter had been formed in consequence of Instammation, which by becoming acrid, had eroded the Cartilages,

Cartilages, and rendered carious the bones. I have already mentioned two cases of this fort, which it would be superstuous to repeat. I cannot, however, omit to mention what occurred to me in examining the knee joints of an old woman, who died of a Fever; and who had, independent of that, complained of stiffness and grating in those joints; the cartilages of which I found to exhibit small surrows, that seemed to have been formed by the friction of small particles of an earthy concretion, like small gravel or sand, which I found in the joint.

Whether or no she had the Gout, I know not, but it seems that particles capable of concretion are secreted by the synovial glands, or from the surface of the cartilages; or that the Synovia may occasionally degenerate and form them. But which is most probable, I cannot say.

### APPENDIX,

Confisting of a second case of Chorea St. Viti, that happened when this work was nearly finished; and because it differed materially from the former, the Author thought an account of it might be acceptable, especially as the cure of the first, which was esfected in about a month, was supposed to have been forwarded by the use of opium. Vid. p. 23.

The fubject of this fecond cafe, had just completed her fourteenth year. For two or three preceding years she had been pale, languid, and unable to use much exercise, but was in other respects tolerably well. Not long before this disease came on, she appeared to be recovering her looks, and to be more healthy than she had been for some time.

The

The affection came on with some unsteadiness in her hands and feet, which she thought was a trick, and jestingly said she had got the Fidgets. The agitation, in the mean time, was increasing gradually, so that in a few days she could not sit upon any thing, but was obliged to be kept in bed altogether, and that could only be done by attendants, who were constantly present; notwithstanding which, she more than once sprang from the bed upon the floor.

The Convulsions were universal and incessant, day and night, without intermission and without any sleep. I regretted that on account of the agitation of her hands, her pulse could not be well judged of; but I suppose the motion of the heart must have been irregular, for the organs of speech were affected so much, that she became almost quite unintelligible, and this inability, to make herself understood, seemed at times to increase the agitation.

But to come to the treatment: nervines, antispasmodics,

antispasmodics, and sedatives, were evidently indicated; but evacuants, had they been practicable, were not. For though the patient was fourteen, there appeared, yet, no figns of fullness of the wessels, or other tokens of a very near approach of an event that may foon be expected. Beside this, as in the first case, the attack had been preceded by, but not prevented by, bleedings at the nose; I thought I had little reason to expect benefit from venefection had it been practicable. I therefore thought it advifable, first to try the usual nervine medicines, Caftor, Campbor, Musk, Alether, &c. for some days, but this was to no manner of purpose: On which account, and because of her not having had for many days and nights any fleep, I determined to try Opium; of the tincture of which I gave her, in the evening, fifteen drops. She flept most of that night, but without any abatement of the agitation, which was as violent as before all the next day. However, as I had some reason to think that it had been useful on the former occasion, and as it had feemingly procured

procured the patient fo much sleep, I repeated the same dose again in the evening, but this had no effect at all. I was, nevertheless, determined now to give it a fair trial. I increased the dose, therefore, by little and little, by intervals, until I got up to twentyfive drops at least, and this was repeated once in fix or eight hours, for one day only; for finding that, instead of abating the agitation and making her fleep, it heated her and rendered her even more irritable and reftless than before; and being now fully convinced that Opium would not do, I gave her no more, but thought it advisable for her to take fome faline draughts in the act of effervescence, and fmall diluting liquids. She, by degrees, grew rather more composed, and for two or three days feemed to be growing fomewhat better, fo as to give hopes of the affection declining; but still she got very little fleep. She took nothing but now and then a neutral effervescing draught, Mift. Campborat. Tinet. Caftor, &c. The agitation that seemed to abate a little, again increased; and the inceffant friction against the sheets, by

the

by ruffling the cuticle, made the prominent parts very tender, which added to her restleffness. About this time, she one morning asked for some boiled milk, which she took very plentifully, and with pleafure feveral times in the morning and forenoon; it agreed very well with her, and she has continued to take more or less ever fince; indeed it has been her principal fubfistance. The convulfions and the reftleffness still, however, continued. I therefore once more tried Tinct. Opii in fmall doses, four or five drops, with as many of Sp. C. C. about once in fix or eight hours, but without any effect; it was therefore now entirely left off; and except Tinet. Castor, which she took a little of in her asses milk twice a day, all medicines were laid aside. She kept to her milk diet, and gradually began to be more still, but for many days got only an hour or two fleep in the morning, but feldom any in the night; however, she grew more and more composed, and to sleep better; her speech at the same time improved; and at the end of about fix weeks, from the first seizure,

she was able to walk about, and take the air in a carriage. She is now persectly well, though rather thin.

We have here instances of the different effects of Opium in two subjects labouring under similar nervous indispositions, differing only in degree; in the first of which, (the younger) it was seemingly beneficial, but in the second it manifestly increased the irritability and watchfulness.

Upon the whole, the Chorea appears to me to be an affection that requires great attention in the Physician, and due regard to the age, constitution, complexion, and other circumstances of the patients; without which mischief may be done. For though it generally goes off in time, and the patient gets well, it is nevertheless exceedingly distressing, when the symptoms are so violent as they were in these cases, especially the second. The reader will permit me to say a few words on the method of cure, as recommended and practised by our excellent

lent Sydenham; Venesection and Cathartics, which he orders to be done alternately, and to be repeated at proper intervals, three or four times in the course of a few weeks. I must confess that in the case just related, had fuch evacuations been practicable, I should not have ventured on one bleeding, much less on that and purging repeatedly, on any Authority whatever, for reasons which I have partly hinted at above. And I can hardly conceive upon what confiderations our very experienced countryman founded that practice. He supposes, indeed, that this affection depends on some humour rushing upon the nerves, and that by irritating them, it produces those preternatural motions; on which account he thought that the indications of cure were to be directed, first, to the subtraction of that bumour, by bleeding and purging, and after that to the strengthening of the nervous system, &c. V. Sydenbam. \*

<sup>\*</sup> Schedula Monitoria de novæ Febris ingreffu, &c. ann. 1635, p. 661.

But there is reason to think that this affection is in some manner the Prodromus of an Event that must 'ere long be expected; yet as that Event takes place at different times, in different persons, owing to some difference in their constitution, manner of life, education, and other circumstances, so that we cannot fay when it will be, until it has once happened; we cannot be too cautious, least, while we wish to relieve, we should, by mistimed evacuations, retard; or by stimulants, Emmenagogues, &c. irritate, fo as to force Nature on some unnatural efforts; to the great detriment of the patient. So that in these cases the precept "Festina lente" ought always to be carefully remembered.

orth to the Tuberaction of that humour, in
