naturally from the acacia in Egypt, Arabia, and elsewhere. This forms a clear transparent mucilage with water. 3. Gum Seneca, or Senegal. It does not greatly differ from gum arabic: the pieces are larger and clearer; and it seems to communicate a higher degree of the adhesive quality to water. It is much used by calico-printers and others. The first sort of gums are frequently sold by this name, but may be known by their dark colour. 4. Gum adragant or tragacanth. It is obtained from a small plant, a species of astragalus, growing in Syria, and other eastern parts. It comes to us in small white contorted pieces resembling worms. It is usually dearer than other gums, and forms a thicker jelly with water.

Willis has found, that the root of the common blue-bell, *Scilla nutans*, dried and powdered, affords a mucilage possessing all the qualities of that from gum arabic. The roots of the vernal squill, white lily, and orchis, equally yield mucilage. Lord Dundonald has extracted a mucilage also from lichens.

Gums treated with nitric acid afford the saclactic, malic, and oxalic acids.

II. The fleshy substance which surrounds the teeth. See *Gingiva*.

Gum, acacia. See *Acacia vera.*
Gum, arabic. See *Acacia vera.*
Gum, elastic. See *Caoutchouc.*
Gum, red. See *Strophulus.*
Gum-boil. See *Parulis.*

GUMA. An alchemical name of mercury.

GU'MMA. (*a, atis.* n.; so named from the resemblance of its contents to gum.) A strumous tumour on the periosteum of a bone.

Gummi. See *Gum.*
Gummi acaciæ. See *Acacia vera.*
Gummi acanthinum. See *Acacia vera.*
Gummi arabicum. See *Acacia vera.*
Gummi carannæ. See *Caranna.*

GUMMI CERASORUM. The gum which exudes from the bark of cherry-trees. See *Cerasin.*

GUMMI CHIBOU. A spurious kind of gum elemi, but little used.

Gummi courbaril. See *Hymenæa.*
Gummi euphorbii. See *Euphorbia.*
Gummi galda. See *Galda.*
Gummi gambiense. See *Kino.*
Gummi guttæ. See *Stalagmitis.*
Gummi hederæ. See *Hedera helix.*
Gummi juniperinum. See *Juniperus.*
Gummi kikekunemalo. See *Kikekunemalo.*
Gummi kino. See *Kino.*
Gummi lacca. See *Lacca.*
Gummi lamac. See *Acacia vera.*
Gummi lutea. See *Botany Bay.*
Gummi myrrhæ. See *Myrrha.*

GUMMI NOSTRAS. The name given on the Continent to gums which are the produce of indigenous trees.

Gummi rubrum gambiense. See *Kino.*
Gummi sagapenum. See *Sagapenum.*
Gummi scorpionis. See *Acacia vera.*
Gummi senega. See *Acacia vera.*
Gummi senegalense. See *Acacia vera.*
Gummi senica. See *Acacia vera.*
Gummi thebaicum. See *Acacia vera.*
Gummi tragacanthæ. See *Astragalus.*
Gummosæ pilulæ. See *Pilulæ galbani compositæ.*

GUM-RESIN. *Gummi resina.* Gum-resins are the juices of plants that are mixed with resin, and an extractive matter, which has been taken for a gummy substance. They seldom flow naturally from plants, but are mostly extracted by incision in the form of white, yellow, or red fluids, which dry more or less quickly. Water, spirit of wine, wine, or vinegar, dissolve them only in part, according to the proportion they contain of resin or extract. Gum-resins may also be obtained artificially by digesting the parts of vegetables containing the gum-resin in diluted alkohol, and then evaporating the solution. For this reason most tinctures contain gum-resin. The principal gum-resins employed medicinally are aloes, ammoniacum, assafœtida, galbanum, cambogia, guaiacum, myrrha, olibanum, opoponax, sagapenum, sarcocolla, scammonium, and styrax.

GUNDE'LIA. (*a, æ.* f.; the name given by Tournefort, in honour of his companion and friend, Andrew Gundelscheimer, its discoverer, in the mountains of Armenia.) A genus of plants. Class, *Syngenesia;* Order, *Polygamia segregata.*

GUNDELIA TOURNEFORTII. The young shoots of this plant are eaten, but the roots are purgative and emetic.

GURGU'LIO. (*o, onis.* f.) This is set down in most lexicons as a name of the *uvula*, but it properly means the *wind-pipe.*

Gustati'vus. See *Gustatorius.*

GUSTATO'RIUS. (*Gustativus;* from *gustus*, taste.) Gustatory. Gustative. Appertaining to the sense of taste.

GU'STATORY NERVES. The nerves which minister to the sense of taste. See *Taste.*

GU'STUS. (*us, ûs.* m.; from γευομαι, to taste.) See *Taste.*

GU'TTA. (*a, æ.* f.) 1. A drop. Drops are an uncertain form of administering medicines, and should never be trusted to. The shape of the bottle, or of its mouth, from which the drops fall, as well as the consistence of the fluid, occasion a considerable difference in the quantity administered. See *Minimum.*

2. A name of apoplexy, from a supposition that its cause was a drop of blood falling from the brain upon the heart.

Gutta gamba. See *Stalagmitis.*

GUTTA NIGRA. The black drop. Called also the Lancaster black drop and Quakers' black drop. A preparation of opium, formerly kept secret. The true receipt for making it came into the hands of the late Dr. Armstrong, who published it. It is as follows: — "Take half a pound of opium, sliced; three pints of good verjuice (juice of the wild crab); one ounce and a half of nutmegs, and half an ounce of saffron. Boil them to a proper thickness, then add a quarter of a pound of sugar and two spoonsful of yeast. Set the whole in a warm place near the fire for six or eight weeks, then place it in the open air until it becomes a syrup; lastly, decant, filter, and bottle it up, adding a little sugar to each bottle."

In this preparation an acetate of morphia is

formed; it is therefore thought to be more directly sedative, and less apt to derange the digestion, than the tincture of opium. The black drop is considered about three times as strong as the tincture of opium; the dose must, therefore, be regulated accordingly.

Gutta opaca. A name for the cataract.

Gutta serena. (So called by the translators of the Arabians.) See *Amaurosis.*

Guttæ rosaceæ. Red spots upon the face and nose. See *Acne.*

Gutta'lis cartila'go. The arytænoid cartilage.

Gutti'feræ. Drop-bearers. A natural family of plants, including the genus *Stalagmites,* and others.

Gu'ttur. (*ur, uris.* n.) The throat.

GU'TTURAL. *Gutturalis.* Belonging to the throat.

Guttural artery. The superior thyroideal artery.

Gutturiformis cartilago. The arytænoid cartilage.

Guttu'rnium. The same.

Guttu'ro-maxilla'ris. A name given by Chaussier to the internal maxillary artery.

GYMNA'STIC. (*Gymnasticus; γυμναστικος*; from *γυμνος,* naked, because the athletæ were stripped.) A term applied to that branch of medicine which consisted in the use of various bodily exercises, with a view to the preservation of health or the cure of disease. It formed an important part of the medicine of the Greeks, and is too much neglected by modern practitioners. Gymnastic medicine is said to have been invented by one Herodicus, born at Selymbria, a city of Thrace; or, as some say, at Leutini in Sicily. He was first master of an academy where the youth came to learn warlike and manly exercises; and observing them to be very healthful, on that account he made exercise become an art in reference to the recovering of men out of diseases, as well as preserving them from them, and called it *Gymnastic,* which he made a great part of his practice. But Hippocrates, who was his scholar, blames him sometimes for his excesses with this view. And Plato exclaims against him with some warmth, for enjoining his patients to walk from Athens to Megara, which is about 25 miles, and to come home on foot as they went, as soon as they had but touched the walls of the city.

This was rather sharp practice; but there is little doubt that a very free use of the muscles is highly conducive to health, and that the want of it among the civilised nations of modern times gives rise to great debility of the muscles, and a morbid irritability of other organs.

GYMNA'STICE. (*e, es.* f.; *γυμναστικη.*) Gymnastics. Gymnastic medicine. See *Gymnastic.*

Gymnastics. See *Gymnasticus.*

GYMNOCA'RPI. The second division in Persoon's arrangement of mushrooms, such as bear seeds embedded in an appropriate dilated, exposed membrane, denominated *hymenium,* like *helvella,* in which that part is smooth and even; *boletus,* in which it is porous; and the vast genus *agaricus,* in which it consists of gills.

GYMNOSPE'RMIA. (*a, æ.* f.; from *γυμνος,* naked, and *σπερμα,* a seed.) The name of an order of the class *Didynamia,* of the sexual system of plants, embracing such as have added to the didynamial character four naked seeds.

Gynæci'a. (*Γυνεικεια*; from *γυνη,* a woman.) The menses, and also the lochia.

GYNÆCOMA'NIA. (*a, æ.* f.; from *γυνη,* a woman, and *μανια,* madness.) That species of insanity which consists in an extravagant desire for women.

Gynæcomy'stax. (From *γυνη,* a woman, and *μυσταξ,* a beard.) The hairs on the female pudendum.

Gynæcoma'sthon. (*Γυναικομασθον*; from *γυνη,* a woman, and *μασθος,* Doric for *μαστος,* the breast.) A preternatural magnitude of the breast in either sex.

GYNA'NDRIA. (*a, æ.* f.; from *γυνη,* a woman, and *ανηρ,* a man, or husband.) The name of a class in the sexual system of plants. It contains those hermaphrodite flowers, the stamina of which grow upon the pistil, so that the male and female organs are united, and do not stand separate as in other hermaphrodite flowers.

Gynanthro'pus. (From *γυνη,* a woman, and *ανθρωπος,* a man.) This name has been given to an hermaphrodite, in which the characters of the male predominate.

Gynida. (From *γυνη,* a woman.) An hermaphrodite has been so called.

Gyno'basis. (From *γυνη,* a woman, and *βασις,* a base.) Decandolle thus designates the base of a solitary style, which is tumid and divided into separate cells.

GY'PSUM. (*um, i.* n.) Sulphate of lime. Gypseous alabaster substance is found in nature in great abundance in compact, foliated, and fibrous forms, and sometimes crystallised, when it is called selinite. Prepared with water, it constitutes the well-known substance called plaster of Paris. Gypsum forms an ingredient in the unguentum alabastrinum. See *Alabastrinum unguentum.* Plaster of Paris is used by artists and anatomists for taking casts; it has also been employed to make a mould for a fractured limb, to keep it in the proper position.

H.

HABE'NA. (*a, æ.* f. A bridle.) A bandage for keeping the lips of wounds together. An uniting bandage.

HA'BITAT. (A contraction of *habitatio*, habitation.) Used generally by naturalists to express the natural abode or locality of an animal, or the nature of the situation in which a plant grows.

Hacub. See *Gundelia tournefortii.*

Haddock. See *Gadus æglefinus.*

HADID. An alchemical name of iron.

HÆ'DUS. (*us, i.* m.) The kid, or young of the goat. See *Capra hircus.*

HÆ'MALOPS. (*ops, opis.* m.; from αἷμα, blood, and ωψ, the eye.) An effusion of blood in the eye-lids or eye-ball.

HÆMA'NTHUS. (*us, i.* m.; from αἷμα, blood, and ανθος, a flower: so called from its colour.) A genus of plants of the class *Hexandria*, and order *Monogynia*. The blood-flower. The juice of the bulb of a species of this genus is used by the Hottentots to poison arrows.

HÆMASTA'TICA. (From αἷμα, blood, and στατικη, the science which treats of the weight of bodies.) Hæmastaticks. The name given by Hales to that department of physiology which treats of the laws which regulate the movements of the blood in the vessels of the living body.

HÆMATAPO'RIA. (*a, æ.* f.; from αἷμα, blood, and απορια, defect.) Sagar uses this term synonymously with *anæmia.*

HÆMATE'MESIS. (*is, is.* f.; from αἷμα, blood, and εμεω, to vomit.) A vomiting of blood. Hæmatemesis is readily to be distinguished from a discharge from the lungs, by its being usually preceded by a sense of weight, pain, or anxiety in the region of the stomach; by its being unaccompanied by any cough; by the blood being discharged in a very considerable quantity; by its being of a dark colour, and somewhat grumous; and by its being mixed with the other contents of the stomach.

The disease may be occasioned by any thing received into the stomach, which stimulates it violently or wounds it; or may proceed from blows, bruises, or any other cause capable of exciting inflammation in this organ, or of determining too great a flow of blood to it; but it arises more usually as a symptom of some other disease (such as a suppression of the menstrual or hæmorrhoidal flux, or obstructions in the liver, spleen, and other viscera,) than as a primary affection. It is seldom so profuse as to destroy the patient suddenly, and the principal danger seems to arise, either from the great debility which repeated attacks of the complaint induce, or from the lodgment of blood in the intestines, which, by becoming putrid, might occasion some other disagreeable disorder.

This hæmorrhage, being usually rather of a passive character, does not admit of large evacuations. Where it arises, on a suppression of the menses, in young persons, and returns periodically, it may be useful to anticipate this by taking away a few ounces of blood, not neglecting proper means to help the function of the uterus. In moderate attacks, particularly where the bowels have been confined, the infusion of roses and sulphate of magnesia may be employed: if this should not check the bleeding, the sulphuric acid may be exhibited more largely, or some of the more powerful astringents and tonics, as alum, tincture of muriate of iron, decoction of bark, or superacetate of lead. Where pain attends, opium should be given freely, taking care that the bowels be not constipated; and a blister to the epigastrium may be useful. In all cases the food should be light, and easy of digestion; but more nourishing as the patient is more exhausted.

HÆMA'TICA. (From αἷμα, blood.) Diseases of the sanguineous function: the third class in Dr. Good's Nosology.

Hæmatine. See *Hæmatoxyline.*

HÆMATI'TES. (*es, is.* m.; from αἷμα, blood: so named from its property of stopping blood, or from its colour.) *Lapis hæmatites.* A species of iron ore called bloodstone. Finely levigated, and freed from the grosser parts by frequent washings with water, it has been long recommended in hæmorrhages, fluxes, uterine obstructions, &c., in doses of from one scruple to three or four.

HÆMATI'TINUS. (From αἱματιτης, the hæmatite.) A collyrium, in which was the hæmatite.

HÆ'MATOCE'LE. (*e, es.* f.; from αἷμα, blood, and κηλη, a tumour.) A swelling of the scrotum, or spermatic cord, proceeding from or caused by blood. The distinction of the different kinds of hæmatocele, though not usually made, is absolutely necessary toward rightly understanding the disease; the general idea or conception of which appears to Pott to be somewhat erroneous, and to have produced a prognostic which is ill founded and hasty. According to this eminent surgeon, the disease, properly called hæmatocele, is of four kinds: two of which have their seat within the tunica vaginalis testis; one within the albuginea; and the fourth in the tunica communis, or common cellular membrane, investing the spermatic vessels.

In the passing an instrument, in order to let out the water from a hydrocele of the vaginal coat, a vessel is sometimes wounded, which is of such size as to tinge the fluid pretty deeply at the time of its running out: the orifice becoming close when the water is all discharged, and a plaster being applied, the blood ceases to flow from thence, but insinuates itself partly into the cavity of the vaginal coat, and partly into the cells of the scrotum; making, in the

space of a few hours, a tumour nearly equal in size to the original hydrocele. This is one species.

It sometimes happens in tapping a hydrocele, that although the fluid discharged by that operation be perfectly clear and limpid, yet in a very short space of time (sometimes in a few hours) the scrotum becomes as large as it was before, and palpably as full of a fluid. If a new puncture be now made, the discharge, instead of being limpid (as before) is either pure blood or very bloody. This is another species; and, like the preceding, confined to the tunica vaginalis.

The whole vascular compages of the testicle is sometimes very much enlarged, and at the same time rendered so lax and loose that the tumour produced thereby has, to the fingers of an examiner, very much the appearance of a swelling composed of a mere fluid, supposed to be somewhat thick, or viscid. This is in some measure a deception, but not totally so: the greater part of the tumefaction is caused by the loosened texture of the testes; but there is very frequently a quantity of extravasated blood also. If this be supposed to be a hydrocele, and pierced, the discharge will be mere blood. This is a third kind of hæmatocele, and very different, in all its circumstances, from the two preceding: the fluid is shed from the vessels of the glandular part of the testicle, and contained within the tunica albuginea. The fourth consists in an effusion of blood from a branch of the spermatic vein, in its passage from the groin to the testicles; in which case, the extravasation is made into the tunica communis, or cellular membrane, investing the spermatic vessels.

Each of these species, Pott says, he has seen so distinctly, and perfectly, that he has not the smallest doubt concerning their existence, and of their difference from each other.

HÆMATOCE'LE ARTERIO'SA. A name that has been given to aneurism.

HÆMATO'CHYSIS. (*is, is.* f.; from *αἷμα*, blood, and *χεω*, to pour out.) A hæmorrhage, or flux of blood.

HÆMATO'DES. (From *αἷμα*, blood.) Hæmatoid. 1. An old epithet of the bloody crane's-bill. See *Geranium sanguineum.*

2. The epithet of a peculiar form of malignant tumour. See *Fungus hæmatodes.*

HÆMATO'LOGY. (*Hæmatologia, æ.* f.; from *αἷμα*, blood, and *λογος*, a discourse.) The doctrine of the blood.

HÆMATO'MPHALUS. (From *αἷμα*, blood, and *ομφαλος*, the navel.) A tumour about the navel, from an extravasation of blood.

HÆMATOPEDE'SIS. (From *αἷμα*, blood, and *πεδαω*, a leap.) The leaping of the blood from a wounded artery.

HÆ'MATOPHLŒBŒ'STASIS. (From *αἷμα*, blood, *φλεψ*, a vein, and *στασις*, a station.) A suppression of an impetuous current of blood in the veins; and sometimes, according to Galen, a full vein.

HÆMATO'SIS. (From *ἁιμα*, blood.) A hæmorrhage, or flux of blood.

HÆMATOSINE. The colouring matter of the blood. See *Sanguis.*

HÆMATOSPI'LIA. (From *αἷμα*, blood, and *σπιλος*, a spot.) A name given by Alibert to *Purpura hæmorrhagia.*

HÆMATO'XYLINE. The colouring principle of the logwood, also called *Hæmatine*, but less appropriately.

HÆMATO'XYLON. (*on* or *um, i.* n.; from *αἷμα*, blood, and *ξυλον*, wood: so called from the red colour of its wood.) The name of a genus of plants in the Linnæan system. Class, *Decandria;* Order, *Monogynia.*

HÆMATOXYLON CAMPECHIANUM. The systematic name of the logwood tree. Called also, *Acacia Zeylonica.* The part ordered in the Pharmacopœia, is the wood, called *Hæmatoxyli lignum, Lignum campechense, Lignum campechianum, Lignum campescanum, Lignum indicum,* and *Lignum sappan.* Logwood. It is of a solid texture and of a dark red colour. It is imported principally as a substance for dyeing, cut into junks and logs of about three feet in length; of these pieces the largest and thickest are preserved, as being of the deepest colour. Logwood has a sweetish sub-astringent taste, and no remarkable smell; it gives a purplish red tincture both to watery and spirituous infusions, and tinges the stools, and sometimes the urine, of the sand colour. It is employed medicinally as an astringent and corroborant. In diarrhœas it has been found peculiarly efficacious, and has the recommendation of some of the first medical authorities; also in the latter stages of dysentery, when the obstructing causes are removed, to obviate the extreme laxity of the intestines usually superinduced by the repeated dejections. In the form of decoction the proportion is two ounces to 2lb. of fluid, reduced by boiling to one. An extract is ordered in the pharmacopœias. The dose from ten to forty grains.

The colouring principle of this root is called *hæmetine.* On the watery extract of logwood, digest alkohol for a day: filter the solution, evaporate, add a little water, evaporate gently again, and then leave the liquid at rest. Hæmatine is deposited in small crystals, which, after washing with alkohol, are brilliant, and of a reddish-white colour. Their taste is bitter, acrid, and slightly astringent.

Hæmatine forms an orange-red solution with boiling water, becoming yellow as it cools, but recovering, with increase of heat, its former hue. Excess of alkali converts it first to purple, then to violet, and, lastly, to brown: in which state the hæmatine seems to be decomposed. Metallic oxides unite with hæmatine, forming a blue-coloured compound. Gelatine throws down reddish flocculi. Peroxide of tin and acid merely redden it.

Hæmatoxylum. See *Hæmatoxylon campechianum.*

HÆMATU'RIA. (*a, æ.* f.; from *αἷμα*, blood, and *ουρον*, urine.) The voiding of blood with urine. This disease is sometimes occasioned by falls, blows, bruises, or some violent exertion, such as hard riding and jumping; but it more usually arises from a small stone lodged either in the kidney or ureter, which, by its size or irregularity, wounds the inner surface of the

part it comes in contact with; in which case the blood discharged is most usually somewhat coagulated, and the urine deposits a sediment of a dark brown colour, resembling the grounds of coffee.

A discharge of blood by urine, when proceeding from the kidney or ureter, is commonly attended with an acute pain in the back, and some difficulty of making water, the urine which comes away first being muddy and high coloured, but, towards the close of its flowing, becoming transparent, and of a natural appearance. When the blood comes immediately from the bladder, it is usually accompanied with a sense of heat and pain at the bottom of the belly.

The voiding of bloody urine is always attended with some danger, particularly when it is mixed with purulent matter. When it arises in the course of any malignant disease, it shows a highly putrid state of the blood, and always indicates a fatal termination.

The appearances to be observed on dissection will accord with those usually met with in the disease which has given rise to this complaint.

When hæmaturia has resulted from a mechanical injury in a plethoric habit, it may be proper to take blood, and pursue the general antiphlogistic plan, opening the bowels occasionally with castor oil, &c. When it is owing to calculi, which cannot be removed, we must be chiefly content with palliative measures, giving alkalies or acids according to the quality of the urine; likewise mucilaginous drinks and glysters; and opium, fomentations, &c. to relieve pain. Uva ursi also has been found useful under these circumstances, but more decidedly where the hæmorrhage is purely passive; in which case, also, some of the terebinthinate remedies may be cautiously tried, and means of strengthening the constitution must not be neglected.

HÆMOCE'RCHNUS. (Αἱμοκερχνος; from ἁιμα, blood, and κερχνος.) This word is rendered in two senses by the translators of the Greeks, according to two different etymologies; for the word κερχνος signifies a *rattling in the wind-pipe*, and also, as an adjective, *dry*. The word hæmocerchnus has therefore been rendered by *spitting of blood with rattling in the throat*, and also by *excretion of dry sanguinolent matters*.

HÆMO'DIA. (Αἱμωδια; from αἱμα, blood, and ὁδους, a tooth.) The Greek word for the sensation commonly called *edging of the teeth*.

HÆMOPLA'NIA. (From αἱμα, blood, and πλανη, a wandering.) A genus of disease in Swediaur's Nosology, embracing vicarious hæmorrhages.

HÆMO'PTOE. (From αἱμα, blood, and πτυω, to spit up.) The spitting of blood. See *Hæmoptysis*.

HÆMO'PTYSIS. (*is, is.* f.; from αἱμα, blood, and πτυω, to spit.) A spitting of blood. An expectoration of florid or frothy blood, preceded usually by heat or pain in the chest, irritation in the larynx, and a saltish taste in the mouth. It is sometimes produced by congestion, or a plethoric state of the vessels of the lungs, which is the most common cause of an idiopathic hæmoptoe, and which also obtains in diseases of the heart, especially in hypertrophy of the right ventricle, which is accordingly a common cause of hæmoptysis. Thus produced it is called *hæmoptysis plethorica:* sometimes it is produced by external violence, and this is called *hæmoptysis violenta:* calculous matter, irritating and eroding the vessels, causes the species denominated *hæmoptysis calculosa:* vomicæ bursting in the lungs, and ulcerating the vessels, gives rise to the *hæmoptysis phthisica;* and when the bleeding is caused by the suppression of some customary evacuation, it is termed *hæmoptysis vicaria.* Hæmoptysis is readily to be distinguished from hæmatemesis by the blood being coughed up in one instance, and vomited in the other: in hæmatemesis also the blood is thrown out in considerable quantities, and is, moreover, of a darker colour, more grumous, and mixed with the other contents of the stomach: whereas blood proceeding from the lungs is usually in small quantity, of a florid colour, and mixed with a little frothy mucus only.

A spitting of blood arises most usually between the ages of sixteen and twenty-five, and may be occasioned by any violent exertion, either in running, jumping, wrestling, singing loud, or blowing wind-instruments; as likewise by wounds, plethora, weak vessels, hectic fever, coughs, irregular living, excessive drinking, or a suppression of some accustomed discharge, such as the menstrual or hæmorrhoidal. It may likewise be occasioned by breathing air too much rarefied to be able properly to expand the lungs.

Persons in whom there is a faulty proportion, either in the vessels of the lungs, or in the capacity of the chest, being distinguished by a narrow thorax and prominent shoulders, or who are of a delicate make and sanguine temperament, seem much predisposed to this hæmorrhage; but in these, the complaint is often brought on by the concurrence of the various occasional and exciting causes before mentioned.

A spitting of blood is not, however, always to be considered as a primary disease. It is often only a symptom; and in some disorders, such as pleurisies, peripneumonies, and many fevers, often arises, and is the presage of a favourable termination.

Sometimes it is preceded, as has already been observed, by a sense of weight and oppression at the chest, a dry tickling cough, and some slight difficulty of breathing. Sometimes it is ushered in with shiverings, coldness at the extremities, pains in the back and loins, flatulency, costiveness, and lassitude. The blood which is spit up is generally thin, and of a florid red colour; but sometimes it is thick, and of a dark or blackish cast; nothing, however, can be inferred from this circumstance, but that the blood has lain a longer or shorter time in the chest before being discharged.

It was long supposed that the discharge of blood from the lungs was always connected with the rupture of vessels; but it is now well ascertained that, in many cases of hæmoptysis, the blood simply exudes from the bronchial membrane without any breach of structure, and

that even a fatal hæmorrhage may arise from this source.

Unless the discharge of blood be excessive, hæmoptysis is seldom attended with immediate danger to life, but it is nevertheless generally a formidable symptom, as being connected with some organic lesion of the thoracic viscera. Sometimes the hæmorrhage is so profuse as to be fatal; and occasionally, owing to the rupture of a large vessel, the lungs are inundated with blood, and the patient dies instantaneously. See *Apoplexy, pulmonary*.

In this hæmorrhage, which is mostly of the active kind, the antiphlogistic regimen must be strictly observed; particularly avoiding heat, muscular exertion, and agitation of the mind; and restricting the patient to a light, cooling, vegetable diet. Acidulated drink will be useful to quench the thirst, without so much liquid being taken. Where the blood is discharged copiously, but no great quantity has been lost already, it will be proper to attempt to check it by bleeding freely, if the habit will allow: and sometimes, where there is pain in the chest, local evacuations and blisters may be useful. The bowels should be well cleared with some cooling saline cathartic, which may be given in the infusion of roses. Digitalis is also a proper remedy, particularly where the pulse is very quick, from its sedative influence on the heart and arteries. Antimonials in nauseating doses have sometimes an excellent effect, as well by checking the force of the circulation, as by promoting diaphoresis; calomel also might be added with advantage; and opium, or other narcotic, to relieve pain and quiet cough, which may perhaps keep up the bleeding. Emetics have, on some occasions, been successful; but they are not altogether free from danger. In protracted cases, internal astringents are given, as alum, kino, &c., but their effects are very precarious: the superacetate of lead, however, is perhaps the most powerful medicine, especially combined with opium, and should always be resorted to in alarming or obstinate cases, though, as it is liable to occasion colic and paralysis, its use should not be indiscriminate; but it acts probably rather as a sedative than astringent. Sometimes the application of cold water to some sensible part of the body, producing a general refrigeration, will check the bleeding. When the discharge is stopped, great attention to regimen is still required, to obviate its return, with occasional evacuations: the exercise of swinging, riding in an easy carriage, or on a gentle horse, or especially sailing, may keep up a salutary determination of the blood to other parts: an occasional blister may be applied, where there are marks of local disease, or an issue or seton perhaps answer better. Should hæmoptysis occasionally exhibit rather the passive character, evacuations must be sparingly used, and tonic medicines will be proper, with a more nutritious diet.

HÆ'MORRHAGE. (*Hæmorrhagia, æ.* f.; from αἷμα, blood, and ῥήσσω, to break out.) A bleeding, or flow of blood. Blood, from whatever organ it flows, may have two causes for its issue. The vessels may be ruptured by a morbid distension and impetus; or they may give way from debility and relaxation, their tunics breaking without any peculiar force urged against them, or their exhalents admitting the flow of red blood, instead of the more attenuate serum. To the former description of hæmorrhages, Dr. Cullen has given the name of *active;* to the latter, that of *passive*. The active hæmorrhages he places amongst febrile diseases, because, although only an accidental symptom, it is generally present; and all those which are evidently without fever, he refers to other parts of his system.

The great predisponent cause of active hæmorrhage, wherever it makes its appearance, is congestion or plethora. A plethoric diathesis will, however, only predispose to a bleeding somewhere or other; and hence there must be a distinct local cause that fixes it upon one particular organ, rather than upon another. The chief local cause is a greater degree of debility in the vessels of such organ than belongs to the vascular system generally. But there are other and more extensive causes that operate upon some organs, and which consist in an unequal distribution of the blood, and its peculiar accumulation in some vessels rather than in others. See *Epistaxis, Hæmoptysis, Hæmatemesis, Menorrhagia*, &c.

Hæmorrhage from the lungs. See *Hæmoptysis.*

Hæmorrhage from the nose. See *Epistaxis.*

Hæmorrhage from the stomach. See *Hæmatemesis.*

Hæmorrhage from the urinary organs. See *Hæmaturia.*

Hæmorrhage from the uterus. See *Menorrhagia.*

HÆMORRHA'GIÆ. Hæmorrhages, or fluxes of blood. The name of an order in the class *Pyrexiæ* of Cullen's Nosology. It is characterised by pyrexia with a discharge of blood, without any external injury; the blood on venesection exhibiting the buffy coat. It contains the following genera, viz. epistaxis, hæmoptysis, hæmorrhois, and menorrhagia.

HÆMORRHŒ'A. (From αἷμα, blood, and ῥεω, to flow.) The name given by Swediaur to passive hæmorrhage.

HÆMORRHŒA PETECHIALIS. A name given by Dr. Adair to *purpura hæmorrhagica.*

HÆMORRHOI'DAL. (*Hæmorrhoidalis.*) 1. Of or belonging to the hæmorrhoidal vessels.

2. The trivial name of some plants which were supposed to be efficacious against piles; as *Carduus hæmorrhoidalis*, &c.

HÆMORRHOIDAL ARTERIES. *Arteriæ hæmorrhoidales.* The arteries of the rectum are so called: they are sometimes two, and at other times three in number. 1. The upper hæmorrhoidal artery, which is the great branch of the lower mesenteric continued into the pelvis. 2. The middle hæmorrhoidal, which sometimes comes off from the hypogastric artery, and very often from the pudical artery. It is sometimes wanting. 3. The lower or external hæmorrhoidal is almost always a branch of the pudical artery, or that artery which goes to the penis.

HÆMORRHOIDAL VEINS. *Venæ hæmorrhoi-*

dales. These are two. 1. The external, which evacuates itself into the vena iliaca interna.

2. The internal, which conveys its blood into the vena portæ.

HÆMORRHOIDES ORIS. A discharge of blood from the turgid veins of the palate, uvula, and fauces, arising from suppression of the hæmorrhoidal discharge. — *Blancard.*

HÆMORRHOIDES UTERI. Varicose veins in and around the genital organs in women. — *Blancard.*

HÆMORRHOIDES VESICÆ. A varicose state of the veins around the neck of the bladder.

HÆMO'RRHOIS. (From αἷμα, blood, and ῥεω, to flow.) 1. A flow of blood. In this sense the term was generally used by the Greek and Latin writers.

2. The name of a particular disease. See *Piles.*

HÆMO'RRHOUS. The name of a very venomous African serpent mentioned by Pliny. Sprengel thinks it the same with the *Coluber cerastes* of Linnæus.

HÆMOSTA'SIA. (*a*, *æ*. f.; from αἷμα, blood, and ἱστημι, to stand.) A stagnation of blood.

HÆMOSTA'TIC. (*Hæmostaticus*; from αἷμα, blood, and σταω, to stop.) Having the power of stopping an hæmorrhage. See *Styptics.*

HAGER. *Hagian.* An Armenian stone.

HAGIOSPE'RMUM. (From ἁγιος, holy, and σπερμα, seed: so called from its reputed virtues.) An obsolete name of the seed of the *Artemisia santonica.*

HAGIO'XYLUM. (From ἁγιος, holy, and ξυλον, wood: so named because of its medicinal virtues.) Guiacum.

Hair. See *Capillus*, and *Pilus.*

Hairy river weed. See *Conferva rivalis.*

Hake. See *Gadus merluccius.*

HALA'TIUM. (Ἁλατιον; from ἁλς, salt.) A medicine composed of salt and purgatives.

Halberd-shaped. See *Hastatus.*

Halberd-shaped leaf. See *Hastatus.*

HALCHE'MIA. (From ἁλς, salt, and χεω, to pour out.) The art of fusing salts.

Halec. See *Clupea harrengus.*

HALELÆ'UM. (From ἁλς, salt, and ελαιον, oil.) A mixture of salt and oil, used by the ancients to swellings of the joints.

HALICA'CABUM. (From ἁλς, the sea, and κακαβος, night-shade: so called because it grows upon the shores of the sea.) See *Physalis alkekengi.*

HALICES. Yawning after sleep.

HA'LIMUS. (From ἁλιμος, belonging to the sea.) See *Atriplex halimus.*

HALINI'TRUM. (From ἁλς, salt, and νιτρον, nitre.) Nitre, or rock salt.

HA'LITUS. (*us*, *ûs*. m.; from *halo*, to breathe out.) A vapour.

HALLUCINA'TION. (*Hallucinatio*, *onis*. f.; from *hallucinor*, to err.) A genus of mental disease in Good's Nosology. See *Alusia.*

HA'LLUS. (From ἁλλομαι, to leap.) The great toe, from its use in springing from the ground.

HA'LMYRAX. The nitre of Media.

HALMYRO'DES. (From ἁλμυρος, salt.) A term applied to the humours: it means acrimonious. It is also applied to fevers which communicate such an itching sensation as is perceived from handling salt substances.

HA'LO. (*o*, *onis*. m.; from ἁλως, an area, or circle.) See *Areola.*

HA'LOID. (From ἁλς, sea-salt, and ειδος, resemblance.)

A term applied to all those compounds which consist of a metal, on the one hand, and of chlorine, iodine, fluorine, and the radicals of the hydracids in general, excepting sulphur, on the other. The whole series of the metallic chlorides, iodides, and fluorides, such as chloride of sodium, iodide of potassium, and fluor spar, as well as the cyanurets, sulphocyanurets, and ferrocyanurets, are included in the list of *Haloid-salts.* In point of composition they have a striking resemblance to oxides and sulphurets, in connexion with which they have already been described; but, when we compare soda with sea-salt, we cannot fail to be struck with the striking difference of their character: the perfect neutrality of the one, both as to test paper and tendency to combine with other bodies, forming a strong contrast with the causticity, alkalinity, and extensive affinity of the other. The word *haloid* is aptly applied to distinguish the whole of the series, because in constitution they are all similar to sea-salt; and the term *halogenous* is applied to chlorine and those elements by which haloid-salts are generated. Besides the simple haloid-salts, Berzelius distinguishes the three following kinds of combination: — *hydro-haloid-salt*, or combinations of a simple haloid-salt with the hydracid of its radical; *oxy-haloid salts*, or combinations of a metallic oxide with a haloid-salt of the same metal; *double haloid-salts*, consisting of two simple haloid-salts, which contain different metals, but the same non-metallic ingredient, or of two haloid-salts, consisting of the same metal, but having the other ingredients different; or, lastly, of two simple haloid-salts, both the elements of which are wholly different.

HALONI'TRUM. (From ἁλς, salt, and νιτρον, nitre.) A name formerly given to the efflorescence found on the damp walls of places inhabited by men or animals. It is a mixture of the subcarbonate of soda and ammonia.

HALOTE'CHNIA. (From ἁλς, salt, and τεχνη, an art.) A name formerly given to that part of chemistry which treats of salts.

HA'LUX. Improperly written for *Hallus.*

Hamalgama. See *Amalgam.*

HA'MMA. (Ἁμμα, from ἁπτω, to bind, or fit on.) A truss for a hernia.

HAMO'SUS. Hooked. Applied to the bristly pubescence of seeds and plants; as the pericarp of the *Arctium lappa*; the seeds of *Daucus muricatus*, and *Alisma cordifolia.*

HAMPSTEAD. A village near to London, where there is an excellent chalybeate water not inferior to that of Tunbridge-wells in any respect, except being nearer to the metropolis.

HAMULA'RIA. (*Hamularia*, *æ*. f.; from *hamus*, a hook.) A genus of worm described by Rudolphi. Dr. Treutler found two worms of this genus in the bronchial glands of a person who died of phthisis. These animals, *Ha-*

mularia subcompressa, were oblong, round, and a little compressed on both sides, dark brown, studded with black spots, tapering slightly towards the anterior extremity, and a little transparent towards the tail. The two extremities bent up a little after the death of the animal. The head terminated in an obtuse point, and was furnished with two prominent hooks or projections: except these two crotchets, no other traces of organs were perceptible. — *Rhind on Worms.*

HA'MULUS. (*us*, *i.* m.; diminutive of *hamus*, a hook.) A little hook. In *Anatomy*, applied to any hook-like process; as the hamulus of the pterygoid process of the sphenoid bone.

HA'MUS. (*us*, *i.* m.) A hook. A species of pubescence of plants formed of bristles, bent at their point into a hook; as in *Rumex tuberosus*, *Caucalis daucoides*, and *Galium aparine*, &c.

HAND. *Manus.* The hand is composed of the carpus or wrist, metacarpus, and fingers. The *arteries* of the hand are the palmary arch, and the digital arteries. The veins are the digital, the cephalic of the thumb, and the salvatella. The nerves are the external and internal cutaneous.

HANDALA. Colocynth.

Hanging. See *Suspensio.*

HANNAY'S LOTION. *Preventive wash.* A nostrum for preventing venereal infection. It is a solution of potash.

HAPSIS. Ἁψις. 1. The sense of touch.

2. A lesion of any kind. Hippocrates uses the phrase ἁψις φρενων, to signify delirium.

HA'PSUS. An old name for a compress of lint or other material.

HARDE'RI GLA'NDULA. Gland of Harderus. So called after an anatomist of that name, although it was described long before his time. A gland found in ruminant and pachydermatous quadrupeds, and also in birds. It is situated near the inner angle of the eye, and secretes a thick whitish fluid, which is diffused over the eye-ball.

Hardesia. See *Lapis hibernicus.*

Hare. See *Lepus timidus.*

HARE-LIP. *Labium leporinum*; called also, *Lagocheilus*, and *Lagostoma*. A fissure or longitudinal division of one or both lips. Children are frequently born with this kind of malformation, particularly of the upper lip. Sometimes the portions of the lip which ought to be united have a considerable space between them; in other instances they are not much apart. The cleft is occasionally double, there being a little lobe, or small portion of the lip, situated between the two fissures. Every species of the deformity has the same appellation of hare-lip, in consequence of the imagined resemblance which the part has to the upper lip of a hare.

The fissure commonly affects only the lip itself. In many cases, however, it extends along the bones of the palate, even as far as the uvula. Sometimes these bones are totally wanting: sometimes they are only divided by a fissure.

Such a malformation is always peculiarly afflicting. In its least degree, it constantly occasions considerable deformity; and, when it is more marked, it frequently hinders infants from sucking, and makes it indispensable to nourish them by other means. When the lower lip alone is affected, which is more rarely the case, the child can neither retain its saliva, nor learn to speak, except with the greatest impediment. But when the fissure pervades the palate, the patient not only never articulates perfectly, but cannot masticate or swallow, except with great difficulty, on account of the food readily getting up into the nose.

Harengus. See *Clupea harengus.*

HARMA. Ἅρμα. A Greek word for a collyrium.

Harmala. See *Peganum harmala.*

HARMATTAN. A prevailing wind on the coast of Africa, between Cape Verd and Cape Lopez, in the months of December, January, and February. It is a particularly dry wind, from passing over the burning deserts of Africa; so much so, that, in a very short time, the leaves of plants become dry and crisp, and the skin of human beings dry and chapped, the nose and lips sore, the fauces arid, and the perspiration acrid; yet it is not pestilential, but, on the contrary, puts an end to epidemic diseases.

HARMO'NIA. (*a*, *æ.* f.; from αρω, to fit together.) Harmony. A species of synarthrosis, or immovable connexion of bones, in which bones are connected together by means of rough margins, not dentiform: in this manner most of the bones of the face are connected together.

HA'RPAX. *Ha'rpaga.* Amber.

HARROGATE. Harrowgate. The villages of High and Low Harrogate are situate in the centre of the county of York, adjoining the town of Knaresborough. Harrogate possesses at present no less than fourteen wells, which are in greater or less repute. Six of them are sulphureous, five pure chalybeate, one saline chalybeate, and two saline, containing only a trace of iron, and no sulphur. Some years ago the chalybeate waters only were used internally, and the sulphureous confined to external use; but both are now largely employed as an internal medicine. The sulphureous springs contain variable proportions of sulphuretted and carburetted hydrogen gases, carbonic acid, azotic gas, muriates of soda, lime, and magnesia, and bicarbonate of soda. The pure chalybeates, as they are called, contain from one grain to two grains and a half of protoxide of iron, kept in solution by carbonic acid, with an inconsiderable impregnation of earthy salts, and some azotic and oxygen gas. The saline chalybeate, called *Oddy's saline chalybeate*, and Cheltenham spring, is the only one of its kind. A gallon of the water contains the following ingredients, according to the analysis of Dr. A. Hunter: —

Carbonate of iron.....	5·3 grains.
Common salt.....	576·5
Chloride of calcium.....	43·5
Chloride of magnesium.....	9·65
Carbonic acid gas.....	5·75 cubic inches.
Azotic gas.....	7·75

The saline wells, of which there are two, differ considerably. The Crescent old well, as it is called, contains a large quantity of muriate of soda, with a considerable proportion of sulphate of soda, and smaller proportions of muriates of lime and magnesia, with carbonic acid and azotic gases. The other saline spring, called Knaresborough dropping-well, has been long celebrated for its petrifying power. It contains a large quantity of sulphate of lime, with carbonate of lime, sulphate of magnesia, a little carbonate of lime, and carbonic acid, azotic, and oxygen gases.

The virtues of the Harrogate waters are different according to their kind, and may easily be inferred from their compositions. The sulphureous springs enjoy great and deserved reputation in the cure of certain cutaneous diseases: even the most obstinate frequently disappear, and remain absent as long as the patient continues to use the water, although they too frequently return when he ceases to do so.

HART. The male of a five-year-old deer. See *Cervus*.

Hart's tongue. See *Asplenium*.

Hart-wort. See *Laserpitium siler*.

Hart-wort of Marseilles. See *Seseli tortuosum*.

HARTFELL. The name of a place near Moffat, in Scotland. It has a mineral water, which contains iron dissolved by the sulphuric acid, and is much celebrated in scrofulous affections, and cutaneous diseases. It is used no less as an external application, than drank internally. The effects of this water, at first, are some degree of drowsiness, vertigo, and pain in the head, which soon go off, and this may be hastened by a slight purge. It produces generally a flow of urine, and an increase of appetite. It has acquired much reputation also in old and languid ulcers, where the texture of the diseased part is very lax, and the discharge profuse and ill-conditioned.

The dose of this water is more limited than that of most of the mineral springs which are used medicinally. It is of importance in all cases, and especially in delicate and irritable habits, to begin with a very small quantity, for an over-dose is apt to be very soon rejected by the stomach, or to occasion griping and disturbance in the intestinal canal; and it is never as a direct purgative that this water is intended to be employed. Few patients will bear more than an English pint in the course of the day; but this quantity may be long continued. It is often advisable to warm the water for delicate stomachs, and this may be done without occasioning any material change in its properties.

Hartshorn. See *Cornu*.

Hartshorn shavings. See *Cornu*.

Harvest bug. See *Acarus autumnalis*.

HA'STA. (*a*, *æ*. f.) A spear: applied to parts of animals and vegetables, which are supposed to resemble this instrument.

HASTA REGIA. The *Asphodelus luteus*.

HASTA'TUS. Hastate: spear or halberd-shaped. Applied to a triangular leaf, hollowed out at the base and sides, but with spreading lobes; as in *Rumex acetocella*, and *Solanum dulcamara*.

HASTE'LLA. (*a*, *æ*. f.; diminutive of *hasta*.) A splint like a spear, used for fractured limbs.

Hatchet-shaped. See *Dolabriformis*.

HATFIELD'S TINCTURE. A nostrum, consisting of guiac, soap, and rectified spirit of wine.

HAU'STUS. (*us*, *ûs*. m.; from *haurio*, to swallow.) A draught or single dose of a liquid medicine.

HAUTERIVE. A village, a league and a half from Vichy, in the department of Allier, where there are two saline springs, said to be similar to that of the Celestius at Vichy.

HAVERS' GLANDS. Glands in and about the synovial membrane of joints; first described by Havers.

HAWK. A species of the genus *Falco*. See *Falco*.

Hawkweed. See *Hypochæris*.

Hawkweed, greater. See *Sonchus*.

Hawkweed, lesser. See *Hypochæris*.

Hay, camel's. See *Juncus odoratus*.

Hazel-nut. See *Corylus avellana*.

Head. See *Caput*.

HEADACHE. *Cephalagia*. Headache, or pain in the head, as a generic term, has received a variety of trivial names, according as it may be produced by some other disease, or the variety of its cause, or the part of the head that is affected: hence cephalalgia venerea, rheumatica, &c.; cephalalgia nervosa, inflammatoria, &c.; cephalalgia stomachica, intermittens, &c. It is sometimes an obtuse pain, with a sense of heaviness extending over the whole head, attended by a general disquiet and confusion, rather than by acute pain; by a general torpitude of the sensorial power, which disqualifies the person for a continuance of mental exertion. The sight is often dim, the hearing dull, and the memory vacant. This kind of headache is a nervous affection of the brain. It is mostly the result of weakness, or a want of proper supply of that kind of sensorial energy on which the feeling of comfort depends, and is produced by irregular circulation of the blood in the head, mental exertion, and the passions of the mind.

Another kind of headache is usually called hemicrania, because it occupies one half only, or the great part of one half of the head. The vulgar name is megrim. It begins with uneasy feelings, or creepings over a part of the scalp, which increase to an acute and often throbbing pain within the head, and mostly over one eye. The person often describes it like to an opening and shutting of the skull. There is often sickness of the stomach with it. This kind of headache lasts an uncertain time, seldom more than a few hours. It frequently assumes an intermittent type, coming on at a certain time like an ague, and hence it is called an ague in the head. It differs much in the degree of violence, and is either a purely nervous disease, or a bilious one. When the latter, it terminates when the stomach and bowels are relieved, and does not return, is accompanied by vomiting of bile, and is denominated a sick headache.

All ordinary cases of headache depend on one of the following causes: —

1. A weakness or exhaustion of the power of the encephalon.

2. A sympathy with the stomach and chylopoietic viscera.

Their cure consequently is to be effected by nervous tonics when the disease is nervous, and by removing the states of stomach and chylopoietic viscera which excite the sympathetic headache.

Rest is in all cases necessary: cold, and pressure on the head, often give relief; as the application of a napkin wrung out of cold water, sponging the head with iced water, spirituous lotions, bandaging the head, &c.

When the pain appears to be purely nervous, from exhaustion or mental exertion, or other causes of debility, nervous tonics are to be given; as cinchona, cascarilla, calumba, gentian, and the like, and also dilute ethers and wine; and if the pain be considerable, a small dose of opium, or Dover's powder, immediately after a warm pediluvium or fomentation, and a warm bed.

When the headache is periodical, these tonics are to be administered in the same way as against an ague, in the period of ease.

The sympathetic headache requires the removal of the chylopoietic derangement, which is generally best effected by a vomit, and the warm aloetic purges.

Headache is very often indeed a symptomatic affection; so much so that there are very few diseases in which it does not take place. It is a prominent symptom in all fevers and inflammations, and in many nervous diseases, the venereal disease, and rheumatism.

Headed. See *Capitulatus.*

HEALTH. That state of the living body in which all its functions are duly performed.

Hearing. *Auditus.* See *Auris.*

HEART. *Cor.* A hollow muscular viscus, which forms the centre of the circulating system in the higher orders of animals. Some observations on the general mechanism of the heart will be found in the article *Circulation;* and its peculiarities in different classes of animals are noticed in the article *Animal Kingdom.* The human heart is irregularly pyramidal in its shape, and lies between the lungs, enclosed in its proper investing membrane, the *pericardium.*

It is placed so obliquely, that if a line corresponding with its axis were passed through it, at the moment of its pulsation, its direction, taken from base to apex, would be downwards, forwards, and to the left side. The anterior surface of the heart is convex in its general outline; the posterior is flat, and rests on the diaphragm: the lower, or right border, is rather thin, and longer than the upper, which is rounded. The heart's surface is marked on its anterior and posterior aspect by two lines, of which one runs transversely, the other from above downwards; their position indicates the division of the organ into four different compartments, or cavities. The base of the heart (which is comparatively thin and flaccid in its structure) consists of that part which is in immediate connexion with the veins (*pars cordis venosa*), and is divided into two cavities, called auricles, from the fact that each is surmounted by an appendage resembling an ear (*auricula.*) It is separated from the lower or pyramidal part by a deep transverse groove (*sulcus auriculo-ventricularis.*) These circumstances are most distinctly observable when the heart is distended. The portion between the transverse sulcus and the summit is thick and muscular, and connected with the arterial trunks; it consists of two cavities (ventricles), the division between which is indicated by two slight grooves extending from the base to the apex, and lodging the descending branches of the coronary vessels.

When we consider the heart in its physiological relations, we adopt a different mode of division; for we find it to be a double organ, made up of two hearts, one for the pulmonary circulation (cor pulmonale), occupying the right side, and consisting of an auricle and a ventricle; the other for the system at large (cor systemicum), also consisting of two cavities of the same denomination. The pulmonic heart is the agent for the circulation of black blood, the systemic circulates red blood. Now, as no two of these cavities agree in form, or in the arrangement of their components, it becomes necessary to describe each separately.

The *right auricle* rests on the diaphragm, and forms the right and anterior part of the base of the heart. It presents two parts which, though not marked off by any precise line of division, yet differ in size and form. One of these, large and flaccid, occupies the interval between the venæ cavæ, so as to receive directly the blood which they convey, and is hence named *sinus venarum cavarum.* The other projects forwards and inwards, between the right ventricle and the root of the aorta, like an appendage to the general cavity; and so it is sometimes named "auricular appendage," but more frequently *auricula*, from some resemblance to a dog's ear. It is triangular in form, compressed, and slightly dentated at its border. It is thicker and more fleshy than the sinus.

The external surface of the auricle, unattached in the greater part of its extent, is prolonged upwards, and to the left side, into its auricular appendage; inferiorly, it is connected with the right ventricle, internally with the left auricle, and into its two extremities open the venæ cavæ.

In order to examine the interior of the auricle, an incision may be made from the junction of the cavæ across to the auricula, from the middle of which another may be carried upwards into the superior cava. If the lower border of this incision be drawn forwards, the cavæ will be observed to incline inwards at an angle, their conflux being marked by a slight elevation, called *Lower's tubercle* (tuberculum Loweri.) The greater part of the cavity forms a pouch (*sinus*), which is smooth, and but slightly muscular in its structure. The inner surface of the auricula is distinguished from the rest by several fleshy fasciculi, which run transversely upon it, called *musculi pectinati.* The inner side of the auricle is thin and smooth; it corresponds with or is formed by the partition (*septum auricularum*), which separates it from the left auricle. At its lower part, and just above the orifice of the inferior vena cava, is situated an oval depression, (*fossa ovalis, vestigium foraminis ovalis,*)

indicating the original communication between the auricles: it is bounded superiorly by a prominent convex border of a lunated form, its concavity looking downwards, and named *annulus fossæ ovalis*. Though the development of the septum be carried to the full extent, that lamella of it which closes the foramen ovale having extended up to a level with the annulus, we often find its upper border merely in apposition, but not united by adhesion to the corresponding part of the septum, so that an oblique or valvular aperture remains between the auricles; still, during the action of the organ, there is sufficient provision against any communication between these cavities. At the line of union between the inferior cava and the auricle is situated a crescentic fold of the lining membrane, called *valvula Eustachii*. This in the fœtal state is large; in the adult it is comparatively diminutive, and often even perforated by several foramina. One border of the valve rests upon the wall of the auricle, with which it is continuous. Another is free and unattached, being of a crescentic form; its upper extremity blends itself with the inner border of the annulus ovalis, and the inferior with the corresponding part of the orifice of the vena cava inferior. Between this valve (its left side) and the ventricular opening is situated the orifice of the coronary vein, protected by a valve. Several minute foramina may also be observed in different parts of the auricle, resembling the orifices of small veins, and called *foramina Thebesii*. Placed obliquely between the appendix and the inferior cava, we observe the *auriculo-ventricular opening*, of an elliptic form, and about an inch in diameter; round its circumference is attached the base of the tricuspid valve, the rest of which lies in the cavity of the ventricle.

The *right ventricle* (ventriculus pulmonalis) extends from the base of the right auricle to the apex of the heart. Its form is somewhat triangular: to see its interior it will be found convenient to make an angular or V-shaped flap, by dissecting up its anterior wall. When this is done, we observe that the interior surface presents a number of rounded fleshy fasciculi, which are called *columnæ carneæ*, and are divisible into three orders. The first, adherent by both extremities, are free in the rest of their extent; others are but slightly prominent, being attached by their extremities, and also by the greater part of their circumference; the third set form three or four fasciculi, which are directed from the summit towards the base of the ventricle, where they are connected with the borders and apices of the tricuspid valves, through the medium of several tendinous processes, called *chordæ tendineæ*. The base of the ventricle is prolonged upwards; its surface becoming at the same time quite smooth, somewhat in the form of a funnel, where it gives attachment to the pulmonary artery; so that the mouth of this vessel is placed higher up, and to the left of the auricular opening. At its orifice three membranous folds are placed, called *sigmoid valves*. One border of these is attached at the line of union of the ventricle with the artery; the other is free in the cavity of the latter, and presents in its middle a small granule, called *nodulus* or *corpus aurantii*. The *tricuspid valve* is so called from its being divided into three points or processes, formed by the lining membrane of the auricle and ventricle. Each is triangular in its form; their bases, which are continuous and undivided from one another, being attached all round the circumference of the opening, whilst in the rest of their extent they lie within the cavity of the ventricle. One of them rests upon the septum, or corresponds with it; another with the anterior wall of the cavity; whilst the third or larger is inclined obliquely upwards, and, as it were, interposed between the auricular and pulmonary apertures. The free margin of each is a little thickened, and gives attachment to the chordæ tendineæ.

The *left auricle* (sinus pulmonalis) is situated at the posterior part of the base of the heart, where the greater portion of it is concealed by the pulmonary artery and the aorta, which overlap it, the auricula alone being visible, without detaching these vessels, or inverting the position of the heart. When distended, it is of a square form, and into its angles open the pulmonary veins, those of the left lung being very close together. From its upper and left extremity projects the auricula, which is narrower but longer and more tapering than that of the right side. Its margins are more deeply dentated, and present some angular inflections or zigzags. Its point rests on the root of the pulmonary artery. The interior of the left auricula presents musculi pectinati similar to those in the right, but the general cavity of the auricle is smooth. A slight depression may be observed in the septum auricularum, corresponding with the fossa ovalis. In the inferior part of the cavity is situated the *auriculo-ventricular opening*, the circumference of which gives attachment to the mitral valve.

The *left ventricle* (ventriculus aorticus) occupies the left border of the heart, about one-third of its extent appearing on the anterior surface, the rest being placed posteriorly, owing to the obliquity of the septum ventriculorum. Its cavity can be conveniently exposed by making two incisions through its wall, parallel with the septum, and uniting at an angle near the apex. When the flap thus formed is drawn upwards, the great thickness of the walls of the cavity, as compared with those of the right ventricle, is rendered manifest. The columnæ carneæ resemble those of the right side, but are thicker, and directed for the most part from the base to the apex of the heart. Their intersections are exceedingly numerous at the summit of the cavity, and along its posterior wall, but the upper part of the anterior one is comparatively smooth. Two fleshy fasciculi of considerable size, commencing by smaller bundles, one from the anterior, the other from the posterior surface, pass upwards and terminate each in a blunted extremity, from which numerous chordæ tendineæ branch off to be inserted into the edges of the mitral valve. The auriculo-ventricular opening is guarded by a valve, similar in structure to that of the right side, but differing from in presenting but two pointed processes; hence,

it has been termed the *mitral valve* (*valvula mitralis.*) The larger division of it looks towards the aortic opening. To the right side of and before the large opening just noticed, is situated a smaller one, which communicates with the aorta, and is guarded by three valvular folds of the lining membrane, similar in structure and form to those of the pulmonary artery, and also called *sigmoid* or *semi-lunar valves.*

The heart is covered by the serous layer of the pericardium, which is reflected upon it, and lined in its interior by a membrane of apparently similar structure, which not only serves as a coating for its proper substance, but also forms folds or valves at the auriculo-ventricular openings at each side, as well as the semi-lunar valves, where it is prolonged into the aorta and the pulmonary artery. Between the investing and the lining membrane is placed the proper muscular tissue of the organ.

The heart receives its blood by the two coronary arteries; its veins terminate in the right auricle; its nerves come from the cardiac plexus, and appear very small as compared with the bulk and quantity of matter of the organ; a circumstance which was much insisted on in the discussion of the long-litigated question — Do the fibres of the heart possess their susceptibility to impression (irritability) *per se*, or do they derive it from the nerves?

The muscular fibres of which the parietes of the heart are made up, differ not only in their quantity and number in each of its cavities, but also in their mode of arrangement. The smoothness of the heart's surface is obviously owing to the membrane which invests it. Within the cavities of the ventricles, and in the auricular appendages, we can readily see how the muscular fibres are disposed and interlaced, without disturbing the lining membrane; but to expose those on the outer surface, the investing membrane must be taken off. When this is carefully done, it will be found that the fibres of the ventricles run obliquely from above downwards to the left, and backwards, which disposition of them can be demonstrated even to the apex. M. Gerdy has shown that the fibres also form curves, whose convexity is turned forwards towards the apex; for if any given fibre commences at the surface, it will be found to dip in so as to become deeply seated at its termination, and *vice versâ*, by which means the bend of their curves will be turned as above stated. Owing to this disposition, the fibres of one ventricle are not all continued across into the other; many of them are seen to turn inwards at the septum, and mix with its substance. By following the course of these, we can separate the septum into two planes; but the greater part of its substance appears to belong to the left ventricle. The external stratum of fibres extends over the whole surface of the ventricles; within these is another plane (not, however, so extensive, as it does not reach much more than halfway to the apex), whose fibres take a different direction, so as to decussate with those of the outer layer; and, lastly, a third plane at the inner surface of the ventricles runs longitudinally from below upwards to the base, being continuous with the columnæ carneæ; but towards the apex they run in every possible direction, rendering the surface minutely reticulated.

But, it will be asked, have these fibres any common point of departure — an origin, as it is usually called? They will be found to commence at the base of each ventricle, deeply in the groove which separates it from the auricle. The examination of them is facilitated by filling all the cavities with plaster of Paris, and immersing the heart in boiling water for an hour or two; the serous pericardium can then be easily removed, and the muscular fibres traced deeply into the groove, where they will be found attached to a white tendinous, or rather cellulo-fibrous band of fibres. A fasciculus of this sort occupies the grooves at the anterior and posterior aspect, corresponding with the auriculo-ventricular openings; but it does not reach round their circumference; it seldom extends more than half way. The two pair of fasciculi thus disposed are connected with a fibrous structure placed at the aortic aperture, at each side of which are two tendinous points, connected by a transverse band passing round the posterior segment of the aperture. To this band the fibrous fasciculi in the posterior grooves are attached, whilst the anterior pair are connected with the tendinous points. Taken altogether, this structure may be called apparatus tendinosus cordis. M. Gerdy names it "tissu albuginé cardiaque," and Wolff "textus cartilagineus cordis." The muscular fibres of the auricles are thin, and in a manner scattered; most of those in the sinuses are transverse, but posteriorly, at the junction of the venæ cavæ in the right auricle, some run longitudinally; and higher up, at the orifice of the superior cava, they become circular, and seem as if prolonged a little way upon it.

Heart, diseases of the. The heart is subject to a variety of diseases which may be distinguished into *sympathetic*, *inflammatory*, and *organic*.

1. *Sympathetic affections.* These consist in irregularity, increase, or diminution of the heart's action, or painful nervous affections of the heart, arising from various causes not operating immediately on the organ itself. Thus palpitations and syncope are frequently the results of dyspepsia, hysteria, agitation or distress of mind, and other causes which tend to disturb the nervous functions. Neuralgic affections of the heart also are not uncommon.

2. *Inflammatory affections.* Three distinct textures are involved in the structure of the heart, namely, the pericardium, a serofibrous membrane, which forms its outer envelope; the muscular structure of the heart itself; and the endocardium or serous membrane which lines its cavities. Each of these textures is liable to inflammation, which, when seated in the pericardium, is termed *Pericarditis;* when in the membrane lining the cavities of the heart, *Endocarditis;* and when in its muscular substance, *Carditis.*

a. Pericarditis. — This may assume an acute, subacute, or chronic, form. It may proceed from the same remote causes which induce in-

flammation of other serous membranes; or it may be caused by extension of inflammation from the pleura; or it may arise from the metastasis of rheumatism, which is the most frequent cause, especially in young patients. The symptoms of pericarditis are extremely variable and deceptive, and it has been frequently found on dissection to have existed in a severe degree, in cases where it had altogether escaped the attention of the practitioner. Generally speaking, the following are the principal symptoms of acute pericarditis: sharp burning pain in the region of the heart, accompanied by an attack of acute inflammatory fever; the pain shoots to the left scapula and shoulder, and often descends some way down the arm; it is increased by full inspiration and by the movements of the ribs, and also by pressure between the ribs over the apex of the heart, and in the epigastrium; the respiration is hurried and laborious, and there is a sense of constriction in the præcordial region with restlessness and anxiety; the patient cannot lie on the left side, and generally feels least distress when lying on the back; the state of the pulse varies extremely; it is always frequent, but is sometimes full, hard, and vibratory, and at others feeble, irregular, or intermittent; in the advanced stage of the disease the pulse is generally feeble and irregular, though the action of the heart continues violent; there is frequent fainting, and extreme anxiety, restlessness, and misery. The duration of this disease is very various; if not checked, it sometimes proves fatal in two or three days, and at other times is protracted for several weeks. This diversity of symptoms and duration depends on the nature and progress of the organic changes which take place in the course of the inflammation. These changes consist, for the most part, in effusions of lymph or serum, which are more or less copious, and take place more or less rapidly. Thus, if serum be effused in large quantity at an early period, the action of the heart will almost from the first be much oppressed, and the pulse feeble and irregular; if the effusion be more gradual, these symptoms will not occur till a more advanced period: again, if a copious exudation of coagulating lymph take place, and glue the pericardium to the heart, serous effusion will be restrained, the symptoms dependent on it averted, and the duration of the case protracted.

Inflammation of the pericardium does not often extend to the muscular substance of the heart, and when it does so, there seem to be no very well established symptoms by which the fact can be ascertained; this, however, is of little consequence in practice, because the treatment is not influenced by it.

The physical signs of pericarditis are, increased impulse of the heart; bellows sound; and, where there is considerable effusion, a more than usual dulness on percussion in the cardiac region.

When there are partial exudations of lymph on the opposite surfaces of the pericardium, the sound of friction is not uncommon.

The physical signs taken in conjunction with the symptoms, generally speaking, remove all obscurity from the diagnosis of pericarditis.

The symptoms of chronic pericarditis are those of the acute in a less degree, and the accompanying fever is of the hectic kind. The increased impulse of the heart and the bellows sound exist, but are less remarkable than in the acute form; when there is effusion of serum or lymph within the pericardium, the dulness on percussion is the same.

Pericarditis may be considered as almost always a fatal affection, except in those instances of the acute disease in which the inflammation is cut short by vigorous practice, before any organic change has ensued. When pericarditis terminates in adhesion of the pericardium to the heart, the patient frequently remains for some months, or even for several years, free from any symptoms which appear formidable, but this state always, sooner or later, induces enlargement of the heart, generally hypertrophy with dilatation; and when this takes place it goes on very rapidly to a fatal issue.

The signs by which an adhesion of the pericardium to the heart may be recognised, are not always very distinctly marked, nor are some which have been brought forward as particularly diagnostic, sufficiently established to merit much confidence. In a general way, when we find after acute or chronic inflammation of the pericardium, that there is a permanently increased dulness on percussion in the cardiac region, with a degree of dyspnœa and more or less oppression on the chest, we may infer that this lesion has probably taken place.

b. Endocarditis. Inflammation of the lining membrane of the heart assumes an acute, subacute, or chronic form. It frequently arises from the metastasis of rheumatism, and its causes may in general be considered as similar to those of pericarditis. Endocarditis is a disease which has been recognised by pathologists only within the last few years, nor have its symptoms yet been determined with the accuracy that could be wished. In the acute form there is generally no severe pain, but rather a sense of oppression, anxiety, and faintness. There is a very tumultuous action of the heart, and great increase of impulse, frequently accompanied with a tremour or vibration, which, in some instances, amounts to what is called the purring tremour. The pulse varies much; it is generally very rapid and irregular, but does not partake of the force of the heart's action, being usually soft and weak; it is sometimes hard and vibratory, and is then generally more regular. There is usually a bellows sound, which is more distinct in proportion to the strength of the heart's action, and which is rougher, or approaches more to the rasp sound, in proportion to the tumefaction of the valves, and the effusion of lymph on the surface of the lining membrane of the heart.

The more chronic forms of endocarditis are frequently very difficult to distinguish from chronic pericarditis, unless where the latter is attended with copious serous effusion or extensive adhesion, in which case percussion may greatly aid the diagnosis.

On the dissection of those who have died of acute endocarditis, the lining membrane of the

heart presents various appearances, according to the degree and duration of the inflammatory action; increased vascularity, thickening, softening, albuminous exudations, puriform deposits: if the case be of some duration, the depositions of lymph become vascular, and give rise to excrescences, vegetations, organised false membranes, and various adhesions.

Chronic endocarditis gives rise to narrowing of the different orifices of the heart, cartilaginous and osseous induration of the valves, and, as particularly illustrated by M. Andral, to hypertrophy of the ventricles. Inflammation of the lining membrane of the heart may be readily conceived to conduce to the thickening of the parietes of that viscus; first, by direct irritation of the contiguous muscular substance, as we find the muscular coat of the stomach thickened in chronic gastritis; secondly, by stimulating the muscular fibres to increased action, both by the morbid stimulus of the disease, and by the opposition offered by the narrowing of the heart's apertures, just as the muscular coat of the bladder is thickened by a stricture of the urethra.

c. Carditis. General inflammation of the substance of the heart is a rare disease. Induration and softening of the entire muscular substance are, however, sometimes found; and as these occasionally present themselves in cases of pericarditis, and are found to occupy only a superficial portion of the muscular substance contiguous to the pericardium, it is reasonable to infer that they are the result of an extension of inflammation from that membrane, and consequently, that when they occur, independently of pericarditis, they are the result of primary inflammation of the substance of the heart. Dr. Latham has recorded a solitary instance of universal suppuration of the substance of the heart. There appear to be no distinct instances of gangrene of the heart.

Partial carditis is not so rare, but still not common. It terminates in abscess or ulceration, more frequently the latter. Ulcers occupy the external or the internal surface of the heart; but the latter oftener than the former. Ulceration is the most common cause of rupture of the heart, which, however, is a very rare accident.

The treatment of pericarditis, endocarditis, and carditis may be considered under one head, as it is perfectly similar in all. In acute cases it consists, in the first place, in a very bold and early use of the lancet, and a rigid observance of all the particulars of the antiphlogistic regimen. We need be less cautious in the abstraction of blood in this than in any other case of acute inflammation; the very centre of life is attacked, and a fatal event is certain, if the disease be not speedily subdued: still reference must be had to the strength of the patient; if a decided impression have been made by the lancet, cupping and leeches may be sufficient to subdue the remaining inflammatory action. In some cases of debilitated patients, they may, indeed, supersede the use of the lancet altogether, for this is one of the cases of inflammation in which local bleeding has a very powerful effect. The next most important remedy after bloodletting is mercury, which, in this, as in other cases, is a powerful means of preventing effusion, or causing the absorption of such matters as may already have been effused: with this view calomel should be given in the manner best suited to insure its effect on the mouth, namely, in small doses frequently repeated. Antimonial diaphoretics and saline purgatives are also serviceable. Digitalis may be useful in keeping the pulse down, and opium, combined with the calomel, has frequently a very beneficial effect; other narcotics and antispasmodics may also be useful according to circumstances. In the rheumatic and gouty forms of carditis, colchicum is highly esteemed by some practitioners. The use of counter irritants is better adapted to the subacute and chronic states of carditis, than to the acute.

Chronic carditis demands the same treatment as the acute, but in a very moderate degree, small evacuations of blood, general or local, and continued counter irritation by blisters, setons, tartar emetic ointment, &c. are the principal means; mercury is also applicable here on the same principle as in the acute disease. When lymph has been effused within the heart or pericardium, and become organised, the case is beyond the reach of art; and when pericarditis has terminated in serous effusion, if the patient survive any length of time, the case, in effect, becomes one of dropsy of the pericardium, on the treatment of which little need be said, because no treatment is, generally speaking, of any avail.

3. *Organic diseases of the heart.* The most remarkable of these are, *Induration — Softening — Atrophy — Hypertrophy — Dilatation — Morbid growths — Morbid deposits and degenerations — Diseases of the valves and orifices of the heart.*

1. *Induration.* Induration of the muscular substance of the heart is not common. It appears to be always the result of inflammation either extending from the pericardium to the muscular substance, or originating in the latter.

2. *Softening.* A pale and flabby state of the muscular substance of the heart is frequent in leucophlegmatic and dropsical subjects, but this may be considered as indicative of debility rather than of absolute disease. Distinct softening of the heart is like induration, rare, and like it appears to be always the result of inflammatory action.

3. *Atrophy.* Most writers on diseases of the heart, mention cases of diminished size of the organ, but the etiology of the affection appears to be entirely unknown.

4. *Hypertrophy.* Hypertrophy, or morbid increase of the muscular substance of the heart is very common. It is more frequent, and greater in degree, in the left ventricle than in the right. In most cases both ventricles are more or less affected. The auricles also, are occasionally hypertrophied, but always in connexion with diseases of the ventricles or valves. Hypertrophy may occupy the parietes of only one cavity of the heart, or of all. M. Bertin divides hypertrophy into — *a. Simple hypertrophy*, in which the walls of the cavities are merely thickened without any change in the capacity

the cavities; *b. Hypertrophy, with increase of the capacity of the cavities; c. Hypertrophy, with diminution of the capacity of the cavities.*

Hypertrophy may arise from any of those causes by which the substance of muscles in general is augmented; namely, from any of those causes which occasion a permanent increase in the force or frequency of contraction. Hence simple nervous palpitation, if habitual, may occasion hypertrophy; it seldom does so however, to any great extent; inflammation of the pericardium or endocardium, and obstruction of the orifices of the heart, are the common causes of this affection: we have already noticed the manner of their operation, when speaking of endo-carditis. The essential signs of simple hypertrophy are, a full and hard pulse, which is almost always regular, and generally more or less vibratory; dyspnœa; and increased impulse of the heart, with diminished sound. Hypertrophy with diminution of the capacity of the cavities, is indicated by nearly the same signs, except that in some cases it appears to be attended by symptoms of obstructed circulation. Hypertrophy with dilation, presents, as might be expected, the mixed characters of these two states; there is increase both of impulse and of sound, and the symptoms will vary according as the hypertrophy or the dilatation predominates. If we consider the respective relations of the right and left cavities of the heart to the pulmonary and systemic circulation, we shall be prepared to expect a difference in the symptoms of hypertrophy, when situated in the one and in the other. In hypertrophy of the right cavities, the respiration is more embarrassed, the complexion is inclined to livid, and hæmoptysis is more frequent. In hypertrophy of the left cavities, the brain suffers more than the lungs; the carotid arteries pulsate very strongly; there is a remarkable tendency to apoplexy, and other forms of cerebral disease, and the patient is frequently annoyed with pain, drowsiness, or throbbing in the head, noises in the ears, and other disagreeable sensations.

Hypertrophy of the auricles is not accompanied with any diagnostic symptoms; but this is of little consequence, because it is always connected with and dependent on some disease or obstruction of the corresponding ventricle. The stethoscope aids the symptoms, in enabling us to determine which side of the heart is affected with hypertrophy; when the increased impulse is perceived under the bottom of the sternum, we infer that the right ventricle is hypertrophied; when it is increased between the cartilages of the fifth and seventh ribs, on the left side, we infer that the left ventricle is diseased; and when we find increased impulse in both these situations, we conclude that both sides of the heart are affected.

5. Dilatation. Dilatation of the cavities of the heart may take place without any change in the thickness of their parietes; or it may be accompanied with thickening; or it may be accompanied with preternatural thinness of their parietes: hence, we have *Simple dilatation; Dilatation with hypertrophy;* and *Dilatation with attenuation.*

Various causes may occasion temporary distension of the cavities of the heart, but when these causes are removed, the cavities return by their own elasticity to their natural dimensions. Permanent dilatation, therefore, is as distinctly a disease as hypertrophy; and it seems better entitled to rank as a primary disease, in as much as it is oftener found unconnected with inflammation or obstruction. Dilation of the heart indeed seems always to depend on an original or acquired debility of its muscular fibres, because in some instances, where we find it independently of other disease, it can only be attributed to such debility, and in other instances, again, where it is induced by the same exciting causes as hypertrophy, we must presuppose some such debility to account for the occurrence of dilatation, in place of the thickening which would be the natural result of over action were the organ more robust.

a. Dilatation with hypertrophy is a mixed case, combining the symptoms and signs of dilatation with those of hypertrophy. There is one symptom, however, which is considered very diagnostic of this state; namely, turgescence of the external jugular veins, and a pulsation of these veins synchronous with that of the arteries: the rationale of this symptom has not yet been satisfactorily explained.

b. Simple dilatation, as it is called, is in reality a case of dilatation with hypertrophy, in which the dilatation predominates over the hypertrophy; for since the parietes of the heart are extended, without diminution of their thickness, there must have been a real increase of substance.

c. Dilatation with attenuation. This affects the right ventricle rather than the left, but in most cases both ventricles are involved. The auricles also are sometimes affected, most commonly from disease of the auricular valves. In dilation of the cavities of the heart with attenuation, the symptoms are in many respects precisely the reverse of those of hypertrophy. The heart palpitates, but its action is feeble and oppressed; the pulse is soft and weak, though seldom irregular, except in an advanced stage of the disease; the circulation is languid, and the evolution of animal heat deficient; the lungs are oppressed with venous congestion, whence arise dyspnœa, cough, œdema of the lungs, and passive hæmorrhage from the bronchial membrane; effusion takes place within the cavities of the pleura, pericardium, or both; the countenance is of a leaden hue; the functions of the brain are torpid, from insufficient aëration of the blood; the liver is extremely liable to become enlarged, and ascites ensues as a consequence of the obstruction of the portal veins: the prevalence of the dropsical diathesis generally shows itself first in the lower extremities, but is never confined to these; and, when it once shows itself, is certain eventually to invade one or more of the great cavities of the body. The above are the consequences of a considerable degree of dilatation, but minor degress frequently exist for many years without occasioning any formidable symptoms; and slight dilatation of the heart is very common in cases of asthma, and

other diseases which obstruct the pulmonary circulation.

The physical signs of dilatation of the heart with attenuation of its walls, are exactly the reverse of those which indicate hypertrophy. The impulse of the heart is diminished, while its sound is increased and heard over a greater extent of the chest than is natural. We can here only state the physical signs of this and other affections of the heart in a very general manner, referring the reader for more minute information to the elaborate treatises on auscultation, which have appeared of late years in France and in this country — at the same time, cautioning him not to adopt too implicitly some of the minor distinctions pointed out by their authors, and never to trust absolutely to the ear, unless the information thus obtained be corroborated by the symptoms of the case.

The different forms of dilatation of the heart, have been designated by some pathologists under the title of *Aneurism of the heart* — dilatation with hypertrophy being called *Active aneurism*, and dilatation with attenuation, *Passive aneurism*; these, however, are unmeaning terms, and should be banished from pathology.

6. *Morbid growths.* These consist chiefly of fungous growths and excrescences, which spring from the lining membrane of the heart, and acquire various degrees of vascularity and consistence, and present various forms and appearances. The only known cause of these morbid productions is, inflammation of the endocardium, and they are more frequently found springing from that portion of the membrane which covers the valves, in which case the valves themselves are often ossified. It is probably that in some cases the excrescences in question originate from the gradual organisation of portions of lymph effused on the surface of the inflamed membrane; in other cases there seems to be no reason to attribute them to such an origin, and they are probably caused by some unknown perversion of action in the vessels of the membrane itself, like polypi in other parts. They are more frequently met with in the left than in the right cavities of the heart. Morbid growths, of a bony consistence, are occasionally met with, usually attached to the valves, but sometimes springing from other parts of the endocardium.

7. *Morbid depositions and degenerations.* These consist chiefly in the formation of bony matter, and in fatty and greasy degenerations. Ossific deposits are common in the pericardium and under the lining membrane of the heart, in the situation of the valves. They have occasionally also been found in the muscular substance of the heart, large portions of which, in some rare instances, have been found converted into bone. Fat is often deposited, in very large quantities, within the pericardium, and sometimes insinuates itself between the muscular fibres, causing atrophy of the muscular substance. In other cases, small portions of the substance of the heart, generally towards the apex, have been found infiltrated with a greasy matter. It does not appear that these fatty and greasy degenerations are productive of any particular bad effects.

8. *Diseases of the valves and orifices of the heart.* The valves of the heart, consisting of fibrous membrane invested on each side by the serous membrane which lines the cavities of the heart, are like other parts of similar texture, particularly liable to cartilaginous induration and to ossification. It would appear that these changes always commence in the fibrous part, and are consequently situated under the serous membrane. All the valves of the heart are liable to these diseases, but those of the left side are much more so than those of the right. The induration of the valves on the right, also, seldom goes beyond the cartilaginous stage, or at all events not so frequently as on the left side. The mitral valve is more frequently diseased than any other; next to this the semilunar valves of the aorta: disease of the tricuspid valve is not very common, and that of the semilunar valves of the pulmonary artery very rare. Bony degenerations of the valves of the heart appear to be of two very different kinds; in the one a cartilaginous induration becomes gradually converted into an imperfectly organised bone; in the other, a calcareous matter, which possesses no organization, is deposited in a caseous or steatomatous nidus. The former appears to be generally the result of inflammation of the endocardium, or of straining of the valves from over action of the heart; the latter of that ossific diathesis, prevalent in old age, which occasions bony depositions in various parts of the arterial system. Fungous growths — or vegetations, as they are strangely called — are frequently found springing from the serous membrane of the indurated valves.

Disease of the valves, when to any considerable extent, is almost always connected in the relation of cause or effect with hypertrophy or dilatation; the case, therefore, is usually a mixed one, in which the symptoms and signs of hypertrophy or dilatation are complicated with others indicative of obstruction to the free exit of the blood from the cavities of the heart. The symptoms of hypertrophy or of dilatation, are greatly aggravated by the presence of the valvular disease, and to these are superadded intermission or irregularity of the pulse; the bellows, or rasp sound; and, occasionally, the purring tremour. In general, disease of the auriculo-ventricular valves occasions more irregularity of the pulse than that of the semilunar valves; the pulse also is more affected by disease of the valves on the left than on the right side of the heart. The degree of roughness of the sounds which attend the contraction of the heart, depends chiefly on the degree of valvular obstruction; and the sound varies from the softest bellows sound to the roughest rasp sound. The situation in which the sound is heard most distinctly, indicates the particular valve which is diseased.

In the case of the mitral valve, the sound seems nearest when the stethoscope is applied at the left margin of the sternum, between the third and fourth ribs; when the aortic valves are affected, the sound is most distinct about the middle of the sternum (speaking relatively both to its length and breadth); when the tricuspid valve is diseased, the sound is clearest

at a point a little to the right of the mesial line of the sternum, opposite to the space between the third and fourth ribs. The purring tremour is sometimes present and sometimes absent; it is chiefly heard when the action of the heart is increased by a fit of palpitation. It is not by itself at all diagnostic of disease of the valves, because it occurs also in other morbid states of the heart. It is to be observed also, that a single auscultation is by no means sufficient to enable us to form a just opinion as to the presence or absence of disease of the valves, since from causes not easily explained, we may be able to detect no sound one day although it be loud and distinct on another. The above is a very rude, though it is hoped not very incorrect outline of the pathology and semeiography of the organic diseases of the heart: the limits of this Dictionary do not permit us to extend it.

With respect to the treatment of these diseases, the general principles which should guide the practitioner may be stated in few words. When, as most frequently happens, the organic change is consecutive on some other disease, as, for example, hypertrophy on inflammation of the investing or lining membranes of the heart, or passive dilatation on congestion in the lungs, it is our business to remove the cause, if this be possible, before the effects have become serious: again, when we can perceive no manifest cause of such structural changes, we have no immediate means of preventing or arresting them: hence, the *curative* treatment of such diseases resolves itself entirely into that of the affections on which they may be consecutive. With respect to the *paliative* treatment, it consists in the avoidance of all causes which can hurry or disturb the circulation, as too active exercise, strong emotions of the mind, the use of indigestible aliments, or sudden vicissitudes of temperature; the occasional use of blood-letting, when necessary to relieve congestion; of digitalis, to allay increased action of the heart; and of those means calculated to obviate disorders of the digestive organs, which have very great influence in producing an irritable state of the heart. By a judicious observance of these rules, the fatal termination of organic diseases of the heart may often be kept at bay for a long time, and the patient exempted from any very severe suffering.

Heart, displacement of the. *Ectopia cordis.* Various deviations from the natural position of the heart occur, as the consequence of congenital malformation, and of disease or external violence. In cases of original malformation, the heart may be contained in the chest although its position be anormal, or it may be excluded from the chest altogether. Thus, it may be placed in the chest vertically, with its apex upwards or downwards; it may be placed horizontally; it may have its apex turned to the right side instead of the left, or the whole viscus may be situated on the right side of the chest instead of being in the middle of that cavity. Where the heart is excluded altogether from the chest, it is found either in different parts of the abdomen, or in the neck: in the former case the individual has been known to live, and even to enjoy good health; in the latter, life must necessarily cease at, or soon after birth.

Displacement of the heart may occur in consequence of various diseases of the chest, as *hypertrophy with dilation of the heart*, which has a natural tendency to render the position of the heart more horizontal by carrying the apex to the left — *serous effusion in the cavity of the pleura* — *empyema* or *pneumothorax*, which appear to be by far the most frequent morbid causes of displacement of the heart — *aneurism of the aorta* — *tumours* — and *diaphragmatic hernia*. Enlargement of the liver, and emphysema of the lung on one side, have also been stated as causes.

With respect to displacement from violence, it is evident, that such an injury must generally be instantly fatal. Dr. Stokes, however, has recorded an instance in which there is little doubt that this accident took place, and yet the patient survived. (*Ed. Med. & Surg. Journal*, No. 108.)

Heart, malformations of the. The principal malformations of the heart which have been recorded are: 1. That in which there is only one auricle and one ventricle, as in the normal condition of fishes. 2. That in which there are two auricles and one ventricle, as in reptiles. 3. Those in which the septum is wanting between the auricles or ventricles. 4. Those in which one or all of the peculiarities of the fœtal heart remain after birth, as when the foramen ovale or ductus arteriosus remains open. Besides these malformations, in which the heart, though monstrous in relation to the human organism, has a resemblance to the heart of the inferior animals, there are others in which the structure is more irregular and anomalous, as where the aorta rises from the right ventricle and the pulmonary artery from the left; where there are supernumerary ventricles, auricles, or septa; or where the auricle does not communicate with its proper ventricle, but with the other, as the right auricle with the left ventricle.

Heart-shaped. See *Cordatus.*

Heart's ease. See *Viola tricolor.*

Heat. See *Calor*, and *Caloric.*

Heat, absolute. This term is applied to the whole quantity of caloric existing in a body in chemical union.

Heat, animal. See *Animal temperature.*

Heat, free. If the heat which exists in any substance be from any cause forced in some degree to quit that substance, and to combine with those that surround it, then such heat is said to be free, or sensible, until the equilibrium is restored.

Heat, latent. When any body is in equilibrium with the bodies which surround it with respect to its heat, that quantity which it contains is not perceptible by any external sign, or organ of sense, and is termed combined caloric, or latent heat.

Heat, prickly. See *Lichen tropicus.*

Heat, sensible. See *Heat, free.*

Heat, vital. See *Animal temperature.*

Heavy carbonated hydrogen. See *Carburetted hydrogen.*

Heavy inflammable air. See *Carburetted hydrogen.*

HE'BE. (Ἥβη; from ἡβάω, *flores, vigeo.*) The hair which grows upon the pubes; the part on which it grows; or the age when it appears.

HE'CTIC. (*Hecticus*; ἑκτικος; from ἕξις, habit.) Appertaining to the habit or constitution.

Hectic fever. *Febris hectica.* A disease of great perplexity and irregularity. Nothing can more fully prove this than the different characters given of it, and the different places allotted to it by different authors. Sauvages and Sagar introduce it into the list of continued fevers. Linnæus, Chrichton, and Parr, into that of remitting and exacerbating fevers. Boerhaave regards it as of a mixed nature, a continued intermittent. "Febris hectica," says he, "est referenda ad febres continuatas intermittentes." Vogel and Cullen degrade it into a mere symptomatic affection. "As I have never," says the latter, "observed a fever of this kind except when symptomatic, I could not consent to admit it into the list of idiopathic fevers, which alone ought to be enumerated."

Those who have adopted Dr. Cullen's opinion have usually contemplated it as a mere effect of absorbed pus. Dr. Heberden seems to think it dependent upon a local cause; but that irritability in any diseased organ, which cannot be brought into a healthy state, will excite it as effectually as pus introduced into the system.

Galen, on the contrary, John Hunter, and Willan, contend, that hectic may be, and often is, a strictly idiopathic affection. The second of these regards hectic fever as of two sorts, symptomatic and idiopathic. The first he ascribes entirely to local irritability, and opposes the idea that it is ever produced by absorbed pus. His argument is, that if absorbed pus be capable of producing it in one instance, it ought in every instance. He does not think that more pus is absorbed during the existence of hectic fever than when no such fever is present: but, admitting that this should be the case, he would rather ascribe the increased absorption to the hectic constitution, operating upon the abscess or sore, than to the abscess or sore operating upon the constitution; in which case the hectic diathesis is the cause, and the increased absorption is only the effect. So that, even here, he regards the hectic as a primary or constitutional disease.

As a symptomatic affection, however, he refers it to a general irritability of the constitution, produced by sympathy, in consequence of "some incurable local disease of a vital part, or of a common part when of some magnitude;" and which becomes incurable from two causes: firstly, because, though the local irritation is small, the constitution is bad, and does not dispose the parts to a healing state; and secondly, because, though the constitution is good, the local irritation is so considerable that it cannot muster up a sufficiency of remedial energy to subdue it; and hence, while sympathising in the irritable action, falls a prey to its own efforts.

Yet, says he, it is possible for hectic fever to be an original disease of the constitution; for the constitution may fall into the same mode of action, without any local cause whatever, at least that we know of. And in this manner he accounts for its existence as an idiopathic affection. And, in effect, nothing is more common than for hectic fever to exist in patients in which we can trace no local cause whatever: and in all such cases we must either indulge in a gratuitous hypothesis, and throw our suspicion at random upon the lungs, or the liver, or the kidneys, or the heart, or the mesenteric glands, or whatever other organ a few casual symptoms may suggest to the fancy; or we must at least act upon the principle of its being an idiopathic affection, even though we should refuse, in terms, to admit that it is so.

There seems great reason for admitting a hectic diathesis or temperament, the features of which are for the most part strongly marked, and are to be found in a fair skin, blue eyes, yellow hair, lax fibre, and sanguine disposition. And, wherever this exists, it is probable that most of the causes of other fevers, operating upon it, will produce a hectic. And we can hence readily account for the examples brought by different authors of its being excited by diseased actions or affections of the heart, stomach, mesentery, liver, pancreas, lungs, or brain; by a suppression of various exanthems or other eruptions, or of various habitual discharges, natural or morbid; by other fevers; by chronic inflammations or abscesses. It is well known to be a common sequel to the measles, occasionally so to the small-pox, and, in a few instances, to rosalia or scarlet fever. It may be a result of dyspepsia. And it is possible that hectic fever may occasionally spring, like other remittents, from febrile miasm.

The character of the disease is well given by John Hunter in the following words: "Hectic may be said to be a slow mode of dissolution; the general symptoms are those of a low or slow fever, attended with weakness, but more with the action of weakness than real weakness: for, upon the removal of the hectic cause, the action of strength is immediately produced, as well as every natural function, however much it was decreased before. The particular symptoms are debility; a small, quick, and sharp pulse; the blood forsaking the skin; loss of appetite; often rejection of all aliment by the stomach; wasting; a great readiness to be thrown into sweats; sweating spontaneously when in bed; frequently a constitutional purging." — To which he adds, "the water clear." There is, in reality, much difference of opinion upon this last point. Dr. Heberden has observed that the same irregularity which accompanies most other symptoms of the disease attends this also; that the urine is equally clear or turbid in the exacerbations and the intervals: sometimes clear in the first, and turbid in the second; and sometimes turbid in the first and clear in the second: while Dr. Duncan, from long and assiduous attention asserts, that the urine is peculiarly distinguished by a natural furfuraceous separation. Where authorities thus clash, it is not a symptom to be depended upon as a pathognomic.

From the frequent approaches which the hectic makes towards a perfect apyrexy, it is sometimes apt to be confounded with an intermittent; but there is rarely any remission in which the pulse is not at least ten strokes in a minute quicker than it ought to be; and by this it is sufficiently distinguishable, as it is also by the greater irregularity of its different stages, and indeed of all its symptoms.

It is owing to this last feature that sometimes the exacerbation commences with a chilly fit, and sometimes without; and that, when there is a chilly fit, sometimes it is immediately succeeded by heat, but sometimes by perspiration, without any intervening hot fit; while occasionally the cold fit only leads to heat, or even terminates singly without either heat or perspiration. Hence the exacerbations must vary in duration: but even where every stage is present and succeeds in regular order, the duration of the entire exacerbation is almost equally uncertain, insomuch that it is seldom that three exacerbations of equal length recur in succession. The remissions will sometimes extend to ten or twelve days, without a single intervening pyrectic symptom; and sometimes the cold, or the hot fit, or the sweating, will be renewed several times in the same day. Yet, let the perspiration appear whenever it may, the patient is never relieved by it; but is as anxious and restless during its continuance as in the heat or chill.

Dr. Heberden tells us, that he has sometimes seen a hectic attack persons who seemed in tolerable health, in a sudden and violent manner, like a common inflammatory fever; and, like that, in a little time bring them into imminent danger of their lives; after which it as abated, and afforded hopes of recovery. But the hopes have been deceitful: for the hectic has still been fed by some lurking mischief; and, resisting the power of medicine, has gradually undermined the patient's health and destroyed him.

More commonly, however, hectic fever commences slowly and insidiously, and is not suspected for some months; and the only symptoms noticeable are, lassitude upon slight exercise, loss of appetite, and a wasting of the flesh. But if these symptoms be connected with a general increase of pulse, so that the artery beats from ninety to a hundred, or a hundred and twenty strokes in a minute, there will be a real ground for apprehension.

This is one of many diseases in which the art of medicine has hitherto laboured in vain to strike into any direct track of cure. The real cause is commonly involved in great and impenetrable obscurity, and we can do little more than attack single symptoms as they make their appearance.

Where the disease is evidently symptomatic, the case must depend upon curing, or, if incurable, upon removing, when this can be accomplished, the part affected. Where idiopathic, we must combat, as far as we are able, the irritable diathesis; and above all things endeavour to strengthen, without increasing, the action of the machine. The best sedatives, as well as tonics, are acids; and of these the vegetable will usually be found preferable to the mineral, since, on account of their corrosive property, the latter can only be taken in small quantities. They abate the febrile heat, diminish the restlessness, and frequently succeed in checking the night-sweats. And if, as is often the case, the patient be tormented with pains in the limbs or joints, resembling rheumatism, and preventing him from sleeping, we may combine the acids with opium. The bowels must be kept regular by gentle laxatives, and the neutral salts seem to answer this purpose better than most others. It will, however, be convenient to vary them occasionally, and sometimes to exchange them for the senna confection, or some other aperient.

Stimulants rarely answer any good purpose, and in many instances evidently heighten and accelerate the exacerbation. The Peruvian balsam has been given advantageously with nitre; but myrrh is a medicine of fairer promise; and beyond these we can scarcely ever venture to proceed.

The lighter bitters are certainly serviceable in many cases, and may conveniently be employed in combination with the acids; but bark, though tried in numerous instances, and with great perseverance, has not been found successful. Dr. Heberden, however, says that he never saw it do any harm in the hectic fever, and his opinion is confirmed by that of Sir Edward Hulse, after having prescribed it for forty years: yet neither of them ever obtained proofs of any beneficial result.

Sarsaparilla has, in some instances, proved highly serviceable, and many cases of hectic have been cured by it. Every thing depends on having the genuine article. The decoction is the best preparation of it, and next to it the powder. Its use should be persevered in for a considerable time, and with it a vegetable and milk diet.

A light and regular diet, regular hours, and gentle exercise, are coadjutants of great importance. When the disease is dependent upon some local affection, the Bath waters have often afforded relief; but in idiopathic cases, they usually augment the fever, aggravate the patient's sufferings, and hasten his death.

HE'DERA. (*a*, *æ*. f.; from *hæreo*, to stick: because it attaches itself to trees and old walls.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*. The ivy.

Hedera arborea. See *Hedera helix*.

HEDERA HELIX. The ivy; called also, *Hedera arborea*. The leaves of this tree have little or no smell, but a very nauseous taste. Haller informs us, that they are recommended in Germany against the atrophy of children. By the common people of this country they are sometimes applied to running sores, and to keep issues open. The berries were supposed by the ancients to have a purgative and emetic quality; and an extract was made from them by water, called by Quercetanus *extractum purgans*. Later writers have recommended them in small doses as alexipharmic and sudorific: it is said, that in the plague at London, the powder of them was

given in vinegar, or white wine, with good success. It is from the stalk of this tree that a resinous juice, called *Gummi hederæ*, exudes very plentifully in warm climates. It is imported from the East Indies, though it may be collected from trees in this country. It is brought over in hard compact masses, externally of a reddish-brown colour, internally of a bright brownish yellow, with reddish specks or veins. It has a strong, resinous, agreeable smell, and an astringent taste. Though never used in the practice of the present day, it possesses corroborant, astringent, and anti-spasmodic virtues.

Hedera terrestris. See *Glechoma.*

HEDERA'CEÆ. (From *hedera*, the ivy.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of the ivy, and a few other allied genera.

Hedge hyssop. See *Gratiola officinalis.*

Hedge mustard. See *Erysimum.*

Hedge mustard, stinking. See *Erysimum.*

Hedgehog. See *Erinaceus.*

Hedgehog mushroom. See *Hydnum erinaceum.*

HE'DRA. Ἕδρα. 1. A fracture of the cranium with depression. — *Hippocrates.*

2. According to Mahon this word signified also the anus, the alvine excrements, and the bottom of an abscess.

HEDYO'SMOS. Mint.

HEDY'PNOIS. (*oïs, idis.* f.; from ἡδυς, sweet, and πνεω, to breathe.) Sweet-breathing: a name in some writings for the dandelion.

HEDY'SARUM. (*um, i.* n.; from ἡδυς, sweet.) The name of a genus of plants. Class, *Diadelphia;* Order, *Decandria.*

HEDYSARUM ALHAGI. A small shrub which grows in Persia and Mesopotamia. Its leaves become covered during the night with a granular manna or honey dew which is used as food, and has very little laxative quality. The leaves of this plant are said to be purgative.

HELCO'MA. Ulceration.

HELCY'DRION. (Diminutive of ἑλκος, an ulcer.) A little ulcer.

HELCY'STER. (Ἑλκυστηρ; from ἑλκω, to draw.) The crotchet used by obstetricians.

HELE'NIUM. (*um, ii.* n.; so called from *Helene*, an island where it grew.) See *Inula helenium.*

Heleoselinum. See *Elcoselinum.*

Helianthemum. See *Helianthus.*

HELIA'NTHUS. (*us, i.* m.; from ἡλιος, the sun, and ανθος, a flower.) This name originated from the resemblance which its broad golden disk and ray bear to the sun, and is rendered further appropriate by its having the power of constantly presenting its flowers to that luminary.) The name of a genus of plants. Class, *Syngenesia;* Order, *Polygamia frustranea.* The sun-flower.

HELIANTHUS ANNUUS. The systematic name of the *Corona solis*, and *Chimalatus.* The seeds have been made into a nutritious bread. The whole plant, when young, is boiled and eaten in some countries, as being aphrodisiac.

HELIANTHUS TUBEROSUS. Jerusalem artichoke. The root of this plant somewhat resembles the artichoke in flavour. It is not very wholesome, being apt to produce flatulency and dyspepsia.

HELICA'LIS. Appertaining to the helix, or border of the ear.

Helicalis major. See *Helicis major.*

Helicalis minor. See *Helicis minor.*

HE'LICIS MAJOR. A proper muscle of the ear, which depresses the part of the cartilage of the ear into which it is inserted; it lies upon the upper or sharp point of the helix, or outward ring, arising from the upper and acute part of the helix anteriorly, and passing to be inserted into its cartilage a little above the tragus.

HELICIS MINOR. A proper muscle of the ear, which contracts the fissure of the ear: it is situated below the helicis major, upon part of the helix. It arises from the inferior and anterior part of the helix, and is inserted into the crus of the helix, near the fissure in the cartilage opposite to the concha.

HELIOSCO'PIOS. (From ἡλιος, the sun, and σκοπεω, to behold: because it turns to the sun.) See *Helianthus*, and *Heliotropium.*

HE'LIOTROPE. *Heliotropium. Heliotropius lapis.* The blood-stone. A subspecies of rhomboidal quartz. It was formerly in high esteem as an amulet against hæmorrhage, epilepsy, renal calculi, &c.

Heliotro'pii succus. See *Croton.*

HELIOTRO'PIUM. (*um, ii.* n.; from ἡλιος, the sun, and τροπη, a turning or inclination: and so called because it turns its leaves round with the declining sun. Ἡλιοτροπιον τοω μεγα, of Dioscorides. 1. The name of a genus of plants. Class, *Pentandria;* Order, *Monogynia.*

2. The name of a mineral, why so called we know not. See *Heliotrope.*

Heliotropium indicum. See *Convolvulus batatas.*

HELIOTROPIUM MAJUS. This is the *Heliotropium europæum* of Linnæus, which is bitter throughout.

Heliotropium tricoccum. See *Croton.*

HELI'TIS. (From ἡλος, a nail: so called in the Cyprian copper-works, because obtained by hammering copper nails.) A copper-flake.

HE'LIX. (*ix, icis.* m. Ἑλιξ, a spiral line; from ειλω, to turn round.) The external circle or border of the outer ear, that curls inwards.

HELLEBORA'STER. (From ἑλλεβορος, hellebore.) See *Helleborus fœtidus.*

Helleborastrum. See *Helleborus.*

Hellebore. See *Helleborus.*

Hellebore, black. See *Helleborus niger.*

Hellebore, white. See *Veratrum album.*

HELLE'BORUS. (*us, i.* m. Ἑλλεβορος: from ἑλειν 2. aor. inf. of αιρεω, to slay, and βορα, food; because it is poisonous if eaten.) The name of a genus of plants in the Linnæan system. Class, *Polyandria;* Order, *Polygynia.* Hellebore.

Helleborus albus. See *Veratrum album.*

HELLEBORUS FŒTIDUS. Stinking hellebore, or bear's-foot; called also, *Helleboraster.* It is the *Helleborus — caule multifloro folioso, foliis pedatis*, of Linnæus. The leaves of this indigenous plant are recommended by many as

possessing extraordinary anthelmintic powers. The smell of the recent plant is extremely fetid, and the taste is bitter and remarkably acrid, insomuch that, when chewed, it excoriates the mouth and fauces. It commonly operates as a cathartic, sometimes as an emetic, and, in large doses, proves highly deleterious.

HELLEBORUS NIGER. Black hellebore, or Christmas rose; called also, *Melampodium*.

Helleborus — scapo subbiflore subnudo, foliis pedatis, of Linnæus. The root of this exotic plant is the part employed medicinally: its taste, when fresh, is bitterish, and somewhat acrid; it also emits a nauseous acrid smell; but, being long kept, both its sensible qualities and medicinal activity suffer very considerable diminution. The ancients esteemed it as a powerful remedy in maniacal cases. At present it is exhibited principally as an alterative, or, when given in a large dose, as a purgative. It often proves a very powerful emmenagogue in plethoric habits, where steel is ineffectual, or improper. It is also recommended in dropsies, and some cutaneous diseases.

Helmet. See *Galea*.

Helmet-flower. See *Anthora*.

HELMI'NTHAGOGUE. (*Helminthagogus*; from ἑλμινς, a worm, and αγω, to drive out.) Synonymous with anthelmintic. See *Anthel*.

HELMI'NTHIA. (*a*, *æ*. f.; from ἑλμινς, a worm.) The same as *helminthiasis*.

HELMINTHI'ASIS. (*is*, *is*. f. Ἑλμινθιασις; from ἑλμινς, which signifies any species of worm.) A disease in which worms, or the larvæ of worms, are bred in any part of the body.

HELMI'NTHIC. (*Helminthicus*; from ἑλμινς, a worm.) Appertaining to worms.

Helminthoco'rton. See *Fucus helminthocorton*.

HELO'DES. (From ἑλος, a swamp.) A fever, characterised throughout by profuse sweating. The sweating sickness.

HELO'SIS. (From εἱλω, to turn.) An eversion or turning out of the eyelids.

HELVE'LLA. (*a*, *æ*. f. A word used by Cicero, for some sort of plant, supposed to be a fungus.) The name of a genus of plants. Class, *Cryptogamia*; Order, *Fungi*.

HELVELLA ESCULENTA. According to Persoon, this and the mitra are eaten on the Continent for the morel, with which they are confounded.

HE'LXINE. (*e*, *es*. f.; from ἑλκω, to draw: so called because it sticks to whatever it touches.) See *Parietaria*.

HE'MATINE. The colouring principle of logwood. See *Hæmatoxylon campechianum*.

Hematu'ria. See *Hæmaturia*.

HEMERALO'PIA. (*a*, *æ*. f.; from ημερα, the day, and ωψ, the eye.) A defect in the sight, which consists in being able to see in broad daylight, but not in the evening. This disease of the sight is said to be endemic in some parts of France, Russia, Poland, the West Indies, Brazils, and the intertropical regions generally. It proceeds from too great an habitual exposure to light, whence the retina becomes torpid, and requires a strong stimulus to raise it. At noontide, therefore, it is sensible to the impression of objects, but does not clearly discern them in the shade, or towards the close of day. Scarpa says, it is properly nothing but a kind of imperfect periodical amaurosis, most commonly sympathetic with the stomach. Its paroxysms come on towards the evening, and disappear in the morning. At sunset, objects appear to persons affected with this complaint, as if covered with an ash-coloured veil, which gradually changes into a dense cloud, which intervenes between the eyes and surrounding objects. Patients with hemarolopia have the pupil, both in day and night time, more dilated and less moveable than it usually is in healthy eyes. The majority of them, however, have the pupil more or less moveable in the day-time, and always expanded and motionless at night. When brought into a room faintly lighted by a candle, where all the bystanders can see tolerably well, they cannot discern at all, or in a very feeble manner, scarcely any one object; or they only find themselves able to distinguish light from darkness, and at moonlight their sight is still worse. At daybreak, they recover their sight, which continues perfect all the rest of the day till sunset. Tonics and gentle stimulants are the best remedies for hemeralopia; especially cinchona and cascarilla, with the mineral acids. Blisters are useful; and stimulating the ball of the eye with ether, dilute citrine ointment, and also the vapour of camphire.

The derivation and meaning of the term hemeralopia have been much disputed. Some critics are for inserting an α privative between ημερα and ωψ, and others are for deriving the term from ημερα, the day, αλαος, blind, and ωψ, the eye; if either of which be admitted, the meaning becomes exactly opposite to that given above, and the word signifies *day-blindness*. The term ημεραλωψ is not defined by any Greek writer; we must therefore infer its meaning from that of its opposite, νυκταλωψ; but the latter term is differently defined by different Greek authors. For the examination of this point, we therefore refer the reader to the article *Nyctalopia*.

HE'MERALOPS. (*ops*, *opis*. m.; from ημερα, the day, and ωψ, the eye.) One who can see but in the day-time.

HEMEROCA'LLIS. (From ημερα, day, and καλος, beautiful: so called because its flowers open in the day and shut at night.) The name of a genus of plants. Class, *Hexandria*; Order, *Monogynia*. The day-lily.

HEMEROCALLIS FULVA. *Lilium rubrum*, *purpureum*, and *croceum*. The tawny day-lily. The leaves are cooling, and the roots aperient; but they have fallen into disuse.

HEMICERAU'NIOS. (From ημισυς, half, and κεραυνος, a thunder-bolt, because it was forked like a thunder-bolt.) A bandage for the back and breast.— *Galen*.

HEMICRA'NIA. (*a*, *æ*. f.; from ημισυς, half, and κρανιον, the head.) A pain that affects only one side of the head. It is generally nervous or hysterical, sometimes bilious; and, in both cases, sometimes comes at a regular period, like an ague. When it is accompanied by a strong pulsation, like that of a nail piercing the part, it is denominated *clavus*.

HEMIO'BOLON. Half an obolus, or the twelfth part of a drachm.

HEMIO'LION. According to Galen, this means twelve drachms. In another sense, it is the same as *sesquialtera*, the whole of a thing, and as much more; as *sesquiuncia*, an ounce and a half.

HEMIONI'TIS. (From ἡμιονος, a mule: so called because it is supposed to be, as a mule is, sterile.) See *Asplenium hemionitis.*

HEMIO'PSIA. (*a*, *æ*. f.; from ἡμισυς, half, and ωψ, an eye.) A defect of vision, in which a person sees only the half of an object.

HEMIPA'GIA. (From ἡμισυς, half, and παγιος fixed.) A fixed pain on one side of the head. See *Hemicrania.*

HEMIPLE'GIA. (*a*, *æ*. f.; from ἡμισυς, half, and πλησσω, to strike: so called because one side of the body is affected.) See *Paralysis.*

HEMI'PTERA. (From ἡμισυς, half, and πτερον, a wing.) An order of insects having the upper wings half membranous and half coriaceous.

HEMIRHO'MBION. (From ἡμισυς, half, and ρεμβω, to revolve. *Semirhombus.*) An old bandage, which extended half way round the part it was applied to.

HEMISPHERE. (*Hemisphera*, *æ*. f.; half a globe.) The two masses which form the upper part of the brain are called the hemispheres of the brain. See *Encephalos.*

HEMI'TOMON. (From ἡμισυς, half, and τεμνω, to cut.) An old bandage, which was cut halfway down.

HEMITRITÆ'US. (Ἡμιτριταιος, from ἡμισυς, half, and τριταιος, third, or tertian.) The Greek synonyme of *semitertian.* See *Ague.*

Hemlock. See *Conium maculatum.*

Hemlock, water. See *Cicuta virosa.*

Hemlock-dropwort. See *Œnanthe.*

Hemp. See *Cannabis sativa.*

Hemp, water. See *Eupatorium.*

Hemp-agrimony. See *Eupatorium.*

HEMP-SEED CALCULUS. Some varieties of the mulberry calculus have been so called.

Henbane. See *Hyoscyamus.*

HEN-BLINDNESS. Nyctalopia has been so called, because hens are affected with it.

Henna. See *Lawsonia inermis.*

HE'PAR. (*ar*, *atis*. n. Ἡπαρ, the liver.) See *Liver.*

HEPAR ANTIMONII. An oxy-sulphuret of antimony.

HEPAR MARTIALE. A compound of liver of sulphur and oxide of iron.

Hepar sulphuris. See *Sulphuretum.*

HEPAR SULPHURIS VOLATILIS. Boil's fuming liquor. The hydrosulphuret of ammonia.

HEPAR UTERINUM. The placenta.

HEPATA'LGIA. (*a*, *æ*. f.; from ἡπαρ, the liver, and αλγος, pain.) Pain in the liver.

HEPATIC. (*Hepaticus*; from ηπαρ, the liver.) 1. Belonging to the liver.

2. Applied to designate the liver colour. See *Colour.*

Hepatic air. See *Hydrogene, sulphuretted.*

HEPATIC ARTERY. *Arteria hepatica.* The artery which nourishes the substance of the liver. It arises from the cœliac, where it almost touches the point of the *lobulus Spigelii.* Its root is covered by the pancreas; it then turns a little forwards, and passes under the pylorus to the porta of the liver, and runs betwixt the biliary ducts and the vena portæ, where it divides into two large branches, one of which enters the right, and the other the left lobe of the liver. In this place it is enclosed, along with all the other vessels, in the capsule of Glisson.

HEPATIC DUCT. *Ductus hepaticus.* The trunk of the biliary pores. It runs from the sinus of the liver towards the duodenum, and is joined by the cystic duct, to form the ductus communis choledochus. See *Biliary duct.*

HEPATIC FLUX. A form of dysentery accompanied with copious discharge of bilious matter.

HEPATIC VEINS. *Venæ hepaticæ.* From the extremities of the vena portæ, and also from those of the hepatic artery, a number of veins arise, which are called *venæ hepaticæ*, and accompany the branches of the hepatic artery and vena portæ. The branches of the hepatic veins finally unite into two or three large trunks, which recede from the hepatic artery and vena portæ, and terminate in the vena cava ascendens, just below the diaphragm.

Hepatica fontana. See *Marchantia.*

HEPATICA HERBA. (So called because it was thought to be useful in diseases of the liver.) See *Marchantia.*

Hepatica jecoraria. See *Marchantia.*

Hepatica nobilis. See *Anemone.*

Hepatica stellata. See *Marchantia.*

Hepatica terrestris. See *Marchantia.*

Hepatica vulgaris. See *Marchantia.*

HEPATIRRHŒ'A. (*a*, *æ*. f.; from ἡπαρ, the liver, and ῥεω, to flow.) 1. A purging, with bilious evacuations.

2. A diarrhœa, in which portions of flesh, like liver, are voided.

HEPATISATION. (*Hepatisatio*, *onis*. f.; from ἡπαρ, the liver: so called from its appearing like liver.) The conversion of any texture into a substance resembling liver. The term is applied chiefly to the lungs. Hepatisation is generally divided into *red* and *yellow*; the former deriving its colour from the presence of blood, the latter from purulent infiltration. — See *Pneumonia.*

HEPATI'TIS. (*is*, *idis*. f.; from ἡπαρ, the liver.) *Inflammatio hepatis.* An inflammation of the liver. A disease attended with inflammatory fever; tension and pain of the right hypochondrium, often pungent, like that of a pleurisy, but more frequently dull or obtuse; a pain at the clavicle, and at the top of the shoulder of the right side; much uneasiness in lying down on the left side; difficulty of breathing; a dry cough, vomiting, and hiccough.

Besides the causes producing other inflammations, such as the application of cold, external injuries from contusions, blows, &c., this disease may be occasioned by certain passions of the mind, by violent exercise, by intense summer heats, by long-continued intermittent and remittent fevers, and by various solid concretions in the substance of the liver. In warm

climates this viscus is more apt to be affected with inflammation than perhaps any other part of the body, probably from the increased secretion of bile which takes place when the blood is thrown on the internal parts, by an exposure to cold; or from the bile becoming acrid, and thereby exciting an irritation in the part. Hepatitis has generally been considered of two kinds; the one *acute*, the other *chronic*.

The *acute* species of hepatitis comes on with a pain in the right hypochondrium, extending up to the clavicle and shoulder; which is much increased by pressing upon the part, and is accompanied with a cough, oppression of breathing, and difficulty of lying on the left side, together with nausea and sickness, and often with a vomiting of bilious matter. The urine is of a deep saffron colour, and small in quantity: there is loss of appetite, great thirst, and costiveness, with a strong, hard, and frequent pulse; and when the disease has continued for some days, the skin and eyes become tinged of a deep yellow. When the inflammation is in the cellular structure or substance of the liver, it is called, by some, *hepatitis parenchymatosa*; and when the gall-bladder, which is attached to this organ, is the seat of the inflammation, it has been called *hepatitis cystica*.

The *chronic* species is usually accompanied with a morbid complexion, loss of appetite and flesh, costiveness, indigestion, flatulency, pains in the stomach, a yellow tinge of the skin and eyes, clay-coloured stools, high-coloured urine, depositing a red sediment and ropy mucus; an obtuse pain in the region of the liver, extending to the shoulder, and not unfrequently with a considerable degree of asthma.

These symptoms are, however, often so mild and insignificant as to pass almost unnoticed; as large abscesses have been found in the liver upon dissection, which in the person's lifetime had created little or no inconvenience, and which we may presume to have been occasioned by some previous inflammation.

Hepatitis, like other inflammations, may end in resolution, suppuration, gangrene, or scirrhus; its termination in gangrene is a rare occurrence in temperate, but a very frequent one in hot, climates.

In the East and West Indies, and all hot climates, inflammation of the liver is a very fatal disease; but in the temperate parts of Europe, the disease is seldom attended with fatal consequences of an immediate nature.

When suppuration takes place, the patient mostly recovers, unless the strength has been greatly reduced by the remedial process, or the constitution has given way before. Then it often happens that a hectic fever is produced, and the patient sinks without any bursting of the abscess; but when the constitution is good, and the strength is yet to be trusted to, adhesions form between the part where the abscess lies and some neighbouring part, and the pus is discharged by the different outlets with which this part is connected, by coughing, vomiting, purging, or by the abscess breaking outwardly.

On dissection, the liver is often found much enlarged, and hard to the touch; its colour is more of a deep purple than what is natural, and its membranes are more or less affected by inflammation. Dissections, likewise, show that adhesions to the neighbouring parts often take place, and abscesses, containing a considerable quantity of pus, are often found in its substance.

The treatment of this disease is different, in the two forms which it assumes. That of the acute hepatitis only differs from that which is resorted to against all acute inflammation, in the particular way in which mercury is exhibited. As soon, therefore, as the disease is pathognomonically established, the lancet and purgatives are to be resorted to; and, in this climate, as boldly and as frequently as against inflammation of any equally important viscus. A sufficient quantity of blood is to be abstracted rapidly from an athletic, young, and good-constitutioned subject; and its repetition to be directed according to the effect, and the state of the pulse. The bowels are next to be cleared by five grains of the submuriate of mercury, followed by saline purgatives with senna, until the nature of the evacuations shows that it is not likely that any fæcal matter remains in the intestines in a solid form, and that the bile passes off freely. Much depends on attending to this circumstance, and guarding against a tardy movement, or lodgment in the sacculi of the colon. In the East Indies, where this disease is so frequent, and proves fatal to so many, the bowels are mostly loose, from the great secretion of an acrimonious bile; and it is found necessary to arrest in some degree the peristaltic movement of the bowels, by combining opium with the purgatives. In all cases where it becomes doubtful whether the lancet should be again resorted to, cupping and leeches are useful; after which, a large blister should be applied over the affected organ. As soon as the intestinal canal has been cleansed of all the crude fæcal matter, mercury should be administered in such a way as to produce, as soon as possible, its peculiar action on the gums and mouth. In very acute cases, and especially those which exist in the East, where a few days determine whether the patient is to live or die, this is attempted by rubbing mercurial ointment into the legs and thighs, and giving calomel and opium in large doses, and frequently: five grains of the former with half a grain of the latter, or five grains of the compound powder of ipecacuanha, every two, three, or four hours. In this country much smaller doses are given, because the disease does not proceed so rapidly; and James's antimonial powder is administered in the dose of five grains, with one of the submuriate of mercury, every four or six hours. The appearance of a soreness of the gums is always hailed as a precursor of a decline of the disease. In this climate, much good results from effecting and keeping up a perspiration; and, where the urgency of the inflammatory action is not very great, the period between the mercurial diaphoretics may be lengthened, and saline sudorifics given in the intervals. Hepatitis soon shows in what way it will terminate; and if no diminution of the symptoms is affected, death soon

takes place, from the violence of the inflammatory action, or from gangrene. A gradual mitigation of the force of the symptoms indicates its resolution. A shivering, with remission of febrile action, announces the formation of pus: an abscess then forms, and bursts either through the integuments, or into the stomach, colon, lungs, or kidney. As soon as this becomes known, the strength of the patient is no longer to be reduced: the strict antiphlogistic diet before adopted must yield to a more nourishing one, but not a stimulating one; and tonics, especially bitters, as calomba and gentian, or cascarilla, are to supply the place of the former medicines.

Chronic hepatitis requires the same treatment with the acute, but in miniature. General blood-letting is only to be had recourse to when there is acute pain, and there is no reason why blood should not be abstracted; but cupping, and frequently applying leeches, are beneficial. Mercurial alteratives are especially serviceable; Plummer's pill, or the Pilula hydrargyri submuriatis composita of the London Pharmacopœia, or small doses of the blue pill, are to be administered regularly, so as to effect a perceptible action on the gums, and no more. This is to be kept up for a considerable time, unless no benefit results, and the bowels are to be kept open with mild aperients and bitters, such as are recommended against indigestion. The nitric acid was once very well thought of against the chronic hepatitis of hot climates: five drops of the pure nitric acid is to be mixed with three ounces of distilled water, sweetened, and taken three times a day. The nitro-muriatic acid foot-bath has been found beneficial, when used at the same time. Taraxacum was also once a favourite medicine against this disease. Dr. Baillie thought he had seen it decidedly useful. The extract and strong decoctions are given, and often in combination with bicarbonate of soda. The diet is to be nourishing, not heating. Those who are resident in hot climates should move into the European states, which often effects a cure without any medicine.

HEPATOCE'LE. (*e*, *es*. f.; from *ἡπαρ*, the liver, and *κηλη*, a tumour.) A hernia, caused by a portion of the liver protruding through the abdominal parietes.

Hepatogastric omentum. The lesser omentum, which passes from the liver to the stomach.

Hepato'rium. See *Eupatorium*.

Hepatotomia. (From *ἡπαρ*, the liver, and *τεμνω*, to cut.) Dissection of the liver.

Hephæ'stias. (From *Ἡφαιστος*, Vulcan, or fire.) A drying plaster of burnt tiles.

Hepi'alus. (From *ηπιος*, gentle.) A mild quotidian fever.

HEPTA'NDRIA. (*a*, *æ*. f.; from *ἑπτα*, seven, and *ανηρ*, a man, or husband.) The name of a class in the sexual system of plants, consisting of such hermaphrodite flowers as have seven stamens.

Heptapha'rmacum. (*um*, *i*. n.; from *ἑπτα*, seven, and *φαρμακον*, medicine.) A medicine composed of seven ingredients, the principal of which were cerusse, litharge, wax, &c.

Heptaphy'llum. (*um*, *i*. n.; from *ἑπτα*, seven, and *φυλλον*, a leaf: so named because the leaf has seven leaflets.) The tormentil; and, according to others, the alchemilla.

Heptaple'urum. (From *ἑπτα*, seven, and *πλευρα*, a rib: so named from its having seven ribs upon the leaf.) See *Plantago major*.

Heracle'a. (*a*, *æ*. f.; so called from its growing in abundance in Heraclea.) 1. Water horehound. See *Marrubium*.

2. The wild marjoram. See *Origanum vulgare*.

HERACLE'UM. (*um*, *i*. n.; from *Heraclea*, the name of several ancient cities, near some of which, the plant may have grown; or from *Ἡρακλης*, Hercules, the plant having been found or used by that hero.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*.

Heracleum gummiferum. This species was till lately supposed to yield the gum resin called *ammoniacum*, which, however, is now ascertained to be the produce of another plant. See *Dorema ammoniacum*.

Heracleum spondylium. *Branca ursina Germanica*. *Spondylium*. Cow-parsnip. All-heal. *Heracleum—foliolis pinnatifidis, lævibus; floribus uniformibus* of Linnæus. In Siberia it grows extremely high, and appears to have virtues in the cure of dysentery which the plants of this country do not possess.

Heracleus morbus. Epilepsy has been so called either on account of the strength of the disease, or because Hercules was subject to it.

Herb-bennet. See *Geum urbanum*.

Herb-of-grace. See *Gratiola*.

Herb-mastich. See *Thymus mastichina*.

Herb-trinity. See *Anemone hepatica*.

HE'RBA. (*a*, *æ*. f.) A herb. A plant is properly so called which bears its flower and fruit once only, and then with its root wholly perishes. There are two kinds: *annuals*, which perish the same year; and *biennials*, which have their leaves the first year, and their flowers and fruit the second, and then die away.

2. By the term *herba*, Linnæus denominates that portion of every vegetable which arises from the root, and is terminated by the fructification.

Herba alexandrina. See *Smyrnium*.

Herba benedicta. See *Geum*.

Herba britannica. See *Rumex*.

Herba felis. See *Nepeta*.

Herba julia. Milfoil.

Herba melancholifuga. See *Fumaria*.

Herba militaris. See *Achillæa*.

Herba paris. See *Paris*.

Herba patri. See *Primula veris*, and *Crithmum maritimum*.

Herba regia. See *Ocymum*.

Herba sacra. See *Verbena trifoliata*.

Herba sanctæ barbareæ. See *Erysimum*.

Herba trinitatis. See *Anemone hepatica*.

HERBA'CEUS. Herbaceous. Plants are so considered which have succulent stems or stalks, and die down to the root every year.

HERBA'RIUM. *Hortus siccus*. A collection of dried specimens of plants.

Hercules's all-heal. See *Laserpitium chironium*.

HE'RCULES BO'VII. A once famed emetic and cathartic compound, prepared from gold and mercury, dissolved in a distillation of copperas, nitre, and sea-salt.

HERE'DITARY DISEASES. *Morbi hereditarii.* Diseases which are propagated from parents to their offspring, as gout, scrofula, mania, &c.

HERMA'PHRODITE. (*Hermaphroditus;* from Ερμης, Mercury, and Αφροδιτη, Venus: *i. e.* partaking of both sexes.) A term applied adjectively and substantively to an animal possessed of the generative organs, and reproductive power of both sexes. The true hermaphrodite of the ancients was, the man with male organs of generation, and the female stature of body; that is, narrow chest and large pelvis: or the woman with female organs of generation, and the male stature of body, broad chest and narrow pelvis. The term is now loosely applied to any *lusus naturæ*, wherein the parts of generation appear to be a mixture of both sexes. There is no such thing as a true human hermaphrodite; the individuals supposed to be so, are always, either males with some defect of the organs of generation, giving them a resemblance to those of the female, or *vice versâ*.

2. In *Botany*, an hermaphrodite flower is one which contains both the male and female organs, for the production of the fruit, within the same calyx and petals.

HERME'TIC. (*Hermeticus;* from Ερμης, Mercury, who was the father of chemistry.) Appertaining to chemistry, of which art Hermes is said to have been the founder.

HERMETIC MEDICINE. Medicine as practised by the chemical sect, as opposed to the Galenical medicine.

HERMETIC SEAL. The closing the end of a glass vessel while in a state of fusion, according to the usage of chemists.

Hermodactyl. See *Hermodactylus.*

HERMODA'CTYLUS. (Ερμοδακτυλος. This word has been derived from Ερμης, Mercury, and δακτυλος, a finger.) Its real derivation is, however, probably from *Hermus*, a river in Asia, upon whose banks it grows, and δακτυλος, a date, which it resembles. *Hermodactyl. Anima articulorum.* A root much celebrated among the ancients for the cure of gout. There has been much dispute as to the plant to which this root belonged: according to some it was the *colchicum illyricum;* according to others, the *iris tuberosa;* and according to others the *colchicum autumnale.* From its antiarthritic virtues, it is highly probable that it was some species of colchicum.

HERMO'LAOS. Ερμολαος. The name of an astringent collyrium: two kinds of it, a greater and a less, are mentioned by Actius.

HE'RNIA. (*a, æ.* f.; from ἑρνος, a branch: from its protruding out of its place.) *Ecnexis. Ramex.* A rupture. Surgeons understand by the term *hernia*, a tumour formed by the protrusion of some of the viscera of the abdomen out of that cavity into a kind of sac, composed of the portion of peritonæum, which is pushed before them. However, there are certainly some cases which will not be comprehended in this definition; either because the parts are not protruded at all, or have no hernial sac. The places in which these swellings most frequently make their appearance, are the groin, the navel, the labia pudendi, and the upper and fore part of the thigh; they do also occur at every point of the anterior part of the abdomen; and there are several less common instances, in which hernial tumours present themselves at the foramen ovale, in the perinæum, in the vagina, at the ischiatic notch, &c. The parts which, by being thrust forth from the cavity in which they ought naturally to remain, mostly produce hernia, are either a portion of the omentum, or a part of the intestinal canal, or both together. But the stomach, the liver, the spleen, uterus, ovaries, bladders, &c. have been known to form the contents of some hernial tumours. From these two circumstances of situations and contents, are derived all the different appellations by which herniæ are distinguished. If a portion of intestine only forms the contents of the tumour, it is called *enterocele;* if a piece of omentum only, *epiplocele;* and if both intestine and omentum contribute to the formation of a tumour, it is called *entero-epiplocele.* When the contents of a hernia are protruded at the abdominal ring, but only pass as low as the groin, or labium pudendi, the case receives the name of *bubonocele*, or *inguinal hernia;* when the parts descend into the scrotum, it is called an *oscheocele*, or *scrotal hernia.* The *crural*, or *femoral hernia*, is the name given to that which takes place below Poupart's ligament. When the bowels protrude at the navel, the case is named an *exomphalos*, or *umbilical hernia;* and *ventral* is the epithet given to the swelling, when it occurs at any other promiscuous part of the front of the abdomen. The *congenital rupture* is a very particular case, in which the protruded viscera are not covered with a common hernial sac of peritonæum, but are lodged in the cavity of the tunica vaginalis, in contact with the testicle; and, as must be obvious, it is not named, like hernia in general, from its situation or contents, but from the circumstance of its existing from the time of birth.

When the hernial contents lie quietly in the sac, and admit of being readily put back into the abdomen, it is termed a *reducible hernia;* and when they suffer no constriction, yet cannot be put back, owing to adhesions, or their large size in relation to the aperture through which they have to pass, the hernia is termed *irreducible.* An *incarcerated* or *strangulated* hernia, signifies one which not only cannot be reduced, but suffers constriction; so that, if a piece of intestine be protruded, the pressure to which it is subjected stops the passage of its contents onward towards the anus, makes the bowel inflame, and brings on a train of most alarming and often fatal consequences.

The general symptoms of a hernia which is reducible, and free from strangulation, are — an indolent tumour at some point of the parietes of the abdomen; most frequently descending out of the abdominal ring, or from just below Poupart's ligament, or else out of the navel; but occasionally from various other situations.

The swelling mostly originates suddenly, except in the circumstances above related; and it is subject to a change of size, being smaller when the patient lies down upon his back, and larger when he stands up, or draws in his breath. The tumour frequently diminishes when pressed, and grows large again when the pressure is removed. Its size and tension often increase after a meal, or when the patient is flatulent. Patients with hernia are apt to be troubled with colic, constipation, and vomiting, in consequence of the unnatural situation of the bowels. Very often, however, the functions of the viscera seem to suffer little or no interruption.

If the case be an *enterocele*, and the portion of the intestine be small, the tumour is small in proportion; but though small, yet, if the gut be distended with wind, inflamed, or have any degree of stricture made on it, it will be tense, resist the impression of the finger, and give pain upon being handled. On the contrary, if there be no stricture, and the intestine suffers no degree of inflammation, let the prolapsed piece be of what length it may, and the tumour of whatever size, yet the tension will be little, and no pain will attend the handling it: upon the patient's coughing, it will feel as if it was blown into; and, in general, it will be found very easily returnable. A gurgling noise is often made when the bowel is ascending.

If the hernia be an *epiplocele*, or one of the omental kind, the tumour has a more flabby and a more unequal feel; it is in general perfectly indolent, is more compressible, and (if in the scrotum) is more oblong and less round than the swelling occasioned in the same situation by an intestinal hernia; and, if the quantity be large, and the patient an adult, it is, in some measure, distinguishable by its greater weight.

If the case be an *entero-epiplocele*, that is, one consisting of both intestine and omentum, the characteristic marks will be less clear than in either of the simple cases; but the disease may easily be distinguished from every other one, by any body in the habit of making the examination.

Hernia aquosa. See *Hydrocele.*

Hernia carnosa. See *Sarcocele.*

Hernia cerebri. *Encephalocele.* This term has been applied to several different cases. One case is, where there is a congenital defect in the ossification of some part of the cranium; and the subjacent portion of the brain, projecting through the aperture, forms a tumour under the integuments. Another case is, where there is a congenital deficiency of a large portion, both of the cranium and integuments, and the greater part of the brain protrudes; this is a monstrosity which is incompatible with the continuance of life for a longer period than a few days. A third case is, where a tumour connected with the brain rises through the aperture made in the operation of trephining. Concerning the nature of the last-mentioned case, there is difference of opinion among surgical writers; and indeed the tumour seems to be of a different character in different cases, sometimes consisting of the substance of the brain, at others, of a mass of congealed blood, and at others, again, of a fungous mass, which has been supposed to spring from the cerebral substance; it is very likely, however, that fungous tumours of the dura mater may frequently have passed under the name of hernia cerebri.

Hernia congenita. This species of hernia consists in the adhesion of a protruded portion of intestine or omentum to the testicle after its descent into the scrotum. This adhesion takes place while the testicle is yet in the abdomen. Upon its leaving the abdomen, it draws the adhering intestine, or omentum, along with it into the scrotum, where it forms the hernia congenita.

From the term *congenital*, we might suppose that this hernia always existed at the time of birth. The protrusion, however, seldom occurs till after this period, on the operation of the usual exciting causes of hernia in general. The congenital hernia does not usually happen till some months after birth; in some instances not till a later period. Hey relates a case, in which a hernia congenita was first formed in a young man, aged sixteen, whose right testis had, a little while before the attack of the disease, descended into the scrotum. It seems probable that, in cases of hernia congenita, which actually take place when the testicle descends into the scrotum before birth, the event may commonly be referred, as observed above, to the testicle having contracted an adhesion to a piece of intestine, or of the omentum, in its passage to the ring. Wrisberg found one testicle which had not passed the ring, adhering, by means of a few slender filaments, to the omentum, just above this aperture, in an infant that died a few days after birth.

Excepting the impossibility of feeling the testicle in hernia congenita, as we can in most cases of bubonocele, (which criterion Mr. Samuel Cooper, in his Surgical Dictionary, observes Mr. Pott should have mentioned,) the following account is very excellent: — "The appearance of a hernia, in very early infancy, will always make it probable that it is of this kind; but in an adult, there is no reason for supposing his rupture to be of this sort, but his having been afflicted with it from his infancy; there is no external mark, or character, whereby it can be certainly distinguished from the one contained in a common hernial sac; neither would it be of any material use in practice, if there was."

Hernia cruralis. Femoral hernia. The parts composing this kind of hernia are always protruded under Poupart's ligament, and the swelling is situated towards the inner part of the bend of the thigh. The rupture descends on the side of the femoral artery and vein, between these vessels and the os pubis. Females are particularly subject to this kind of rupture, in consequence of the great breadth of their pelvis, while in them the inguinal hernia is rare. It has been computed, that nineteen out of twenty married women, afflicted with hernia, have this kind; but that not one out of an hundred unmarried females, or out of the same

number of men, have this form of the disease. The situation of the tumour makes it liable to be mistaken for an enlarged inguinal gland; and many fatal events are recorded to have happened from the surgeon's ignorance of the existence of the disease. A gland can only become enlarged by the gradual effects of inflammation; the swelling of a crural hernia comes on in a momentary and sudden manner, and, when strangulated, occasions the train of symptoms described in the account of the hernia incarcerata, which symptoms an enlarged gland could never occasion. Such circumstances seem to be sufficiently discriminative: though the feel of the two kinds of swelling is often not in itself enough to make the surgeon decided in his opinion. A femoral hernia may be mistaken for a bubonocele, when the expanded part of the swelling lies over Poupart's ligament. As the taxis and operation for the first case ought to be done differently from those of the latter, the error may lead to very bad consequences. The femoral hernia, however, may always be discriminated, by the neck of the tumour having Poupart's ligament above it. In the bubonocele, the angle of the pubes is behind and below this part of the sac; but in the femoral hernia, it is on the same horizontal level, a little on the inside of it.

Till of late years, the stricture, in cases of femoral hernia, was always supposed to be produced by the lower border of the external oblique muscle, or, as it is termed, Poupart's ligament. A total change of surgical opinion on this subject has, however, latterly taken place, in consequence of the accurate observations first made in 1793, by Gimbernat, surgeon to the king of Spain. In the crural hernia (says he) the aperture through which the parts issue is not formed by two bands (as in the inguinal hernia), but it is a foramen, almost round, proceeding from the internal margin of the crural arch (Poupart's ligament), near its insertion into the branch of the os pubis, between the bone and the iliac vein; so that, in this hernia, the branch of the os pubis is situated more internally than the intestine, and a little behind; the vein externally, and behind; and the internal border of the arch before. Now, it is this border which always forms the strangulation.

Hernia femoralis. See *Hernia cruralis.*

Hernia flatulenta. *Pneumatocele.* Windy rupture; a rupture, in the contents of which there is much gurgling from an accumulation of gas.

Hernia guttalis. Bronchocele.

Hernia gutturis. Bronchocele.

Hernia humoralis. See *Orchitis.*

Hernia incarcerata. Incarcerated hernia. Strangulated hernia, or a hernia with stricture. The symptoms are a swelling in the groin, &c. resisting the impression of the fingers. If the hernia be of the intestinal kind, it is generally painful to the touch, and the pain is increased by coughing, sneezing, or standing upright. These are the very first symptoms, and if they are not relieved, are soon followed by others; viz. a sickness at the stomach, a frequent retching, or inclination to vomit, a stoppage of all discharge per anum, attended with frequent hard pulse, and some degree of fever. These are the first symptoms; and if they are not appeased by the return of the intestine, that is, if the attempts made for this purpose do not succeed, the sickness becomes more troublesome, the vomiting more frequent, the pain more intense, the tension of the belly greater, the fever higher, and a general restlessness comes on which is very terrible to bear. When this is the state of the patient, no time is to be lost; a very little delay is now of the utmost consequence; and if the one single remedy which the disease is now capable of be not administered immediately, it will generally baffle every other attempt. This remedy is the operation whereby the parts engaged in the stricture may be set free. If this be not now performed, the vomiting is soon exchanged for a convulsive hiccough, and a frequent gulping up of bilious matter: the tension of the belly, the restlessness and fever, having been considerably increased for a few hours, the patient suddenly becomes perfectly easy, the belly subsides, the pulse, from having been hard, full, and frequent, becomes low, languid, and generally interrupted; and the skin, especially that of the limbs, cold and moist; the eyes have now a languor and glassiness, a lack-lustre not easy to be described: the tumour of the part disappears, and the skin covering it sometimes changes its natural colour for a livid hue; but whether it keeps or loses its colour, it has an emphysematous feel, a crepitus to the touch, which will easily be conceived by all who have attended to it, but is not easy to convey an idea of by words. This crepitus is the too sure indicator of gangrenous mischief within. In this state, the gut either goes up spontaneously, or is returned with the smallest degree of pressure; a discharge is made by stool, and the patient is generally much pleased at the ease he finds: but this pleasure is of short duration; for the hiccough and the cold sweats, continuing and increasing, with the addition of spasmodic rigors and subsultus tendinum, the tragedy soon finishes.

Hernia inguinalis. *Bubonocele.* Inguinal hernia. The *hernia inguinalis* is so called because it appears in both sexes at the groin. It is one of the divisions of hernia, and includes all those herniæ in which the parts displaced pass out of the abdomen through the ring, that is, the arch formed by the aponeurosis of the musculus obliquus externus in the groin, for the passage of the spermatic vessels in men, and the round ligament in women. The parts displaced that form the hernia, the part into which they fall, the manner of the hernia being produced, and the time it has continued, occasion great differences in this disorder. There are three different parts that may produce a hernia in the groin, viz. one or more of the intestines, the epiploon, and the bladder. That which is formed by one or more of the intestines, was called by the ancients *enterocele.* The intestine which most frequently produces the hernia, is the *ilium,* because, being placed in the iliac region, it is nearer the groin than the rest: but notwithstanding the situation of the other intestines, which seems not to allow of their coming

near the groin, we often find the jejunum, and frequently also a portion of the colon and cæcum, included in the hernia. It must be remembered that the mesentery and mesocolon are membranous substances, capable of extension, which, by little and little, are sometimes so far stretched by the weight of the intestines, as to escape with the ilium in this species of hernia. The hernia made by the epiploon is called *epiplocele;* as that caused by the epiploon and any of the intestines together is called *entero-epiplocele*. The hernia of the bladder is called *cystocele*. Hernia of the bladder is uncommon, and has seldom been known to happen but in conjunction with some of the other viscera. When the parts, having passed through the abdominal rings, descend no lower than the groin, it is called an incomplete hernia; when they fall into the scrotum in men, or into the *labia pudendi* in women, it is then termed complete.

The marks of discrimination between some other diseases and inguinal hernia are these: —

The disorder in which a mistake may possibly be made, are the circocele, bubo, hydrocele, and hernia humoralis, or inflamed testicle.

For an account of the manner of distinguishing circocele from a bubonocele, see *Circocele*.

The circumscribed incompressible hardness, the situation of the tumour, and its being free from all connection with the spermatic process, will sufficiently point out its being a bubo, at least while it is in a recent state; and when it is in any degree suppurated, he must have a very small share of the *tactus eruditus* who cannot feel the difference between matter, and either a piece of intestine or omentum.

The perfect equality of the whole tumour, the freedom and smallness of the spermatic process above it, the power of feeling the spermatic vessels, and the vas deferens in that process; its being void of pain upon being handled, the fluctuation of the water, the gradual formation of the swelling, its having begun below and proceeded upwards, its not being affected by any posture or action of the patient, nor increased by his coughing or sneezing, together with the absolute impossibility of feeling the testicle at the bottom of the scrotum, will always, to an intelligent person, prove the disease to be hydrocele.

Pott, however, allows that there are some exceptions in which the testicle cannot be felt at the bottom of the scrotum, in cases of hernia. In recent bubonoceles, while the hernial sac is thin, has not been long, or very much distended, and the scrotum still preserves a regularity of figure, the testicle may almost always be easily felt at the inferior and posterior part of the tumour. But in old ruptures, which have been long down, in which the quantity of contents is large, the sac considerably thickened, and the scrotum of an irregular figure, the testicle frequently cannot be felt; neither is it in general easily felt in the *congenital hernia*, for obvious reasons.

In the *hernia humoralis*, the pain in the testicle, its enlargement, the hardened state of the epididymis, and the exemption of the spermatic cord from all unnatural fulness, are such marks as cannot easily be mistaken; not to mention the generally preceding gonorrhœa. But if any doubt still remains of the true nature of the disease, the progress of it from above downwards, its different state and size in different postures, particularly lying and standing, together with its descent and ascent, will, if duly attended to, put it out of all doubt that the tumour is a *true hernia*.

When an inguinal hernia does not descend through the abdominal ring, but only into the canal for the spermatic cord, it is covered by the aponeurosis of the external oblique muscle, and the swelling is small and undefined.

Now and then, the testicle does not descend into the scrotum till a late period. The first appearance of this body at the ring, in order to get into its natural situation, might be mistaken for that of a hernia, were the surgeon not to pay attention to the absence of the testicle from the scrotum, and the peculiar sensation occasioned by pressing the swelling.

Hernia intestinalis. *Enterocele*. A rupture caused by the protrusion of a portion of the intestine. See *Hernia inguinalis*.

Hernia ischiatica. A rupture at the ischiatic notch. This is very rare. A case, however, which was strangulated, and undiscovered till after death, is related in Sir A. Cooper's second part of his work on hernia. The disease happened in a young man aged 27. On opening the abdomen, the ilium was found to have descended on the right side of the rectum into the pelvis; and a fold of it was protruded into a small sac, which passed out of the pelvis at the ischiatic notch. The intestine was adherent to the sac at two points: the strangulated part, and about three inches on each side, were very black. The intestines, towards the stomach, were very much distended with air, and here and there had a livid spot on them. A dark spot was even found on the stomach itself, just above the pylorus. The colon was exceedingly contracted, as far as its sigmoid flexure. A small orifice was found in the side of the pelvis, in front of, but a little above the sciatic nerve, and on the fore part of the pyriformis muscle. The sac lay under the gluteus maximus muscle, and its orifice was before the internal iliac artery, below the obturator artery, but above the vein.

Hernia lachrymalis. A swelling of the lachrymal sac from over distension.

Hernia mesenterica. Mesenteric hernia. If one of the layers of the mesentery be torn by a blow, while the other remains in its natural state, the intestines may insinuate themselves into the aperture and form a kind of hernia. The same consequences may result from a natural deficiency in one of these layers. Sir A. Cooper relates a case in which all the small intestines except the duodenum, were thus circumstanced. The symptoms during life were unknown.

Hernia mesocolica. Mesocolic hernia. So named by Sir A. Cooper, when the bowels glide between the layers of the mesocolon. Every surgeon should be aware that the intestines may

be strangulated from the following causes: — 1. Apertures in the omentum, mesentery, or mesocolon, through which the intestine protrudes. 2. Adhesions, leaving an aperture, in which a piece of intestine becomes confined. 3. Membranous bands at the mouths of hernial sacs, which, becoming elongated by the frequent protrusion and return of the viscera, surround the intestine, so as to strangulate it within the abdomen when returned from the sac.

Hernia omentalis. *Epiplocele.* An omental rupture; or a protrusion of the omentum through any of the apertures of the abdomen. Sometimes, according to Sharpe, so large a quantity of the omentum hath fallen into the scrotum, that its weight, drawing the stomach and bowels downwards, hath excited vomiting, inflammation, and symptoms similar to those of the incarcerated hernia.

Hernia oschealis. A scrotal hernia.

Hernia perinealis. Perineal hernia. In men, the parts protrude between the bladder and rectum; in women, between the rectum and vagina. The hernia does not project so as to form an external tumour; and, in men, its existence can only be distinguished by examining from the rectum. In women, it may be detected both from this part and the vagina.

Hernia phrenica. Diaphragmatic, or phrenic hernia. The abdominal viscera are occasionally protruded through the diaphragm, either through some of the natural apertures in this muscle, or deficiencies, or wounds and lacerations in it. The second kind of case is the most frequent. Morgagni furnishes an instance of the first. Two cases related by Dr. Macauley, and two others published by Sir A. Cooper, are instances of the second sort. Another case has been lately recorded by the latter gentleman affording an example of the third kind. Hildanus, Paré, Petit, Schenck, &c. also mention cases of phrenic hernia.

Hernia pudendalis. Pudendal hernia. This is the name assigned by Sir A. Cooper to that which descends between the vagina and ramus ischii, and forms an oblong tumour in the labium, traceable within the pelvis, as far as the os uteri. Sir A. Cooper thinks this case has sometimes been mistaken for a hernia at the foramen ovale.

Hernia scrotalis. *Hernia oschealis. Oscheocele.* Paracelsus calls it *Crepatura.* When the omentum, the intestine, or both, descend into the scrotum, it has these appellations; when the omentum only, it is called *epiplocele.* It is styled a perfect rupture, in contradistinction to a bubonocele, which is the same disorder; but the descent is not so great. The hernia scrotalis is distinguished into the true and false: in the former, the omentum, or intestine, or both, fall into the scrotum; in the latter, an inflammation, or a fluid, causes a tumour in this part, as in hernia humoralis, or hydrocele. Sometimes sebaceous matter is collected in the scrotum; and this hernia is called *steatocele.*

Hernia thyroidealis. *Hernia foraminis ovalis.* Thyroideal hernia. In the anterior and upper part of the obturator ligament there is an opening, through which the obturator artery, vein, and nerve proceed, and through which, occasionally, a piece of omentum, or intestine, is protruded, covered with a part of the peritonæum, which constitutes the hernial sac.

Hernia umbilicalis. Umbilical rupture; which has received, also, the following names: *Exomphalos, Epiploomphalon, Omphalocele,* and *Pneumatomphalos.* The umbilical rupture is so called from its situation, and has, like other herniæ, for its general contents, a portion of intestine, or omentum, or both. In old umbilical ruptures, the quantity of omentum is sometimes very great. Mr. Ranby says, that he found two ells and a half of intestine in one of these, with about a third part of the stomach, all adhering together. Gay and Nourse found the liver in the sac of an umbilical hernia; and Bohnius says that he did also. But whatever are the contents, they are originally contained in the sac formed by the protrusion of the peritonæum.

In recent and small ruptures, this sac is very visible; but in old and large ones it is broken through, at the knot of the navel, by the pressure and weight of the contents, and is not always to be distinguished; which is the reason why it has, by some, been doubted whether this kind of rupture has a hernial sac or not.

Infants are very subject to this disease, in a small degree, from the separation of the funiculus; but, in general, they either get rid of it as they gather strength, or are easily cured by wearing a proper bandage. It is of still more consequence to get this disorder cured in females than in males; that its return, when they are become adult and pregnant, may be prevented as much as possible; for at this time it often happens from the too great distension of the belly, or from unguarded motion, when the parts are upon the stretch.

Dr. Hamilton has met with about two cases annually, for the space of seventeen years, of umbilical hernia, which strictly deserve the name of *congenital* umbilical hernia. The funis ends in a sort of bag, containing some of the viscera, which pass out of the abdomen through an aperture in the situation of the navel. The swelling is not covered with skin, so that the contents of the hernia can be seen through the then distended covering of the cord. The disease is owing to a preternatural deficiency in the abdominal muscles, and the hope of cure must be regulated by the size of the malformation and quantity of viscera protruded.

Hernia uteri. *Hysterocele.* Hernia of the uterus. Instances have occurred of the uterus being thrust through the rings of the muscles; but this is scarcely to be discovered, unless in a pregnant state. It may be occasioned by violent muscular efforts, by blows on the abdomen at the time of gestation, and also by wounds and abscesses of the abdomen, which permit the uterus to dilate the part. Ruysch relates the case of a woman, who becoming pregnant, after an ulcer had been healed in the lower part of the abdomen, the tumid uterus descended into

a dilated sac of the peritonæum in that weakened part, till it hung, with the included fœtus, at her knees. Yet, when her full time was come, the midwife reduced this wonderful hernia, and, in a natural way, she was safely delivered of a son.

Hernia vaginalis. *Elytrocele. Colpocele.* Vaginal hernia. A tumour occurs within the os externum of the vagina. It is elastic, but not painful. When compressed, it readily recedes, but is reproduced by coughing, or even without this, when the pressure is removed. The inconveniences produced are an inability to undergo much exercise or exertion; for every effort of this sort brings on a sense of bearing down. The vaginal hernia protrudes in the space left between the uterus and rectum. This space is bounded below by the peritonæum, which membrane is forced downwards, towards the perinæum; but, being unable to protrude further in that direction, is pushed towards the back part of the vagina. These cases, probably, are always intestinal. Some herniæ protrude at the anterior part of the vagina.

Hernia varicosa. See *Circocele.*

Hernia veneris. *Testiculus venereus.* An old name for a swelled testicle from suppressed gonorrhœa.

Hernia ventosa. See *Pneumatocele.*

Hernia ventralis. A hernia may appear at almost any point of the anterior part of the belly, but is most frequently found between the recti muscles. The portion of intestine, &c. is always contained in a sac made by the protrusion of the peritonæum. Sir A. Cooper imputes its causes to dilatation from congenital deficiencies, lacerations, and wounds of the abdominal muscles, or their tendons. In small ventral herniæ, a second fascia is found beneath the superficial one; but in large ones, the latter is the only one covering the sac.

Hernia ventriculi. *Gastrocele.* A ventral rupture, caused by the stomach protruding through some part of the abdominal parietes. It rarely occurs but at or near the navel.

Hernia vesicalis. *Hernia cystica; Cystocele.* The urinary bladder is liable to be thrust forth from its proper situation, either through the opening in the oblique muscle, like the inguinal hernia, or under Poupart's ligament, in the same manner as the femoral.

This is not a very frequent species of hernia, but does happen, and has as plain and determined a character as any other.

HERNIA'RIA. (*a, æ.* f.; from *hernia*, a rupture: so called from its supposed efficacy in curing ruptures.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*. Rupture-wort.

Herniaria glabra. The systematic name of the rupture-wort. *Herniaria.* This plant, though formerly esteemed as efficacious in the cure of hernias, appears to be destitute, not only of such virtues, but of any other. It has no smell nor taste.

HE'RPES. (*es, is.* m.; ἕρπης; from ἕρπω, to creep: because it spreads and creeps about the skin.) Tetter. A cutaneous disease, known by an assemblage of numerous little vesicles, in clusters, itching very much, and difficult to heal, but terminating in furfuraceous scales. The eruption is preceded, when it is extensive, by considerable constitutional disorder, and is accompanied by a sensation of heat and tingling, sometimes by severe deep-seated pain, in the parts affected. The lymph of the vesicles, which is at first clear and colourless, becomes gradually milky and opake, and ultimately concretes into scabs: but, in some cases, a copious discharge of it takes place, and tedious ulcerations ensue. The disorder is not contagious in any of its forms.

It has been principally confounded with erysipelas, on the one hand, and with eczema, impetigo, and other slowly spreading eruptions, on the other. From erysipelas it may be distinguished by the numerous, small, clustering vesicles, by the natural condition of the surface in the interstices between the clusters, and by the absence of redness and tumefaction before the vesicles appear: and from the chronic eruptions just alluded to, by the purely vesicular form of the cuticular elevations in the commencement, by the regularity of their progress, maturation, and scabbing, and by the limitation of their duration, in general, to a certain number of days.

The various appearances of herpes may be comprehended under the six following heads:

1. *Herpes phlyctænodes.* This species of the eruption is commonly preceded by a slight febrile attack for two or three days. The small transparent vesicles then appear, in irregular clusters, sometimes containing colourless, and sometimes a brownish, lymph; and, for two or three days more, other clusters successively arise, near the former. The eruption has no certain seat: sometimes it commences on the cheeks or forehead, and sometimes on one of the extremities; and occasionally it begins on the neck and breast, and gradually extends over the trunk to the lower extremities, new clusters successively appearing for nearly the space of a week. The included lymph sometimes becomes milky or opake in the course of ten or twelve hours; and, about the fourth day, the inflammation round the vesicles assumes a duller red hue, while the vesicles themselves break, and discharge their fluid, or begin to dry and flatten, and dark or yellowish scabs concrete upon them. These fall off about the eighth or tenth day, leaving a reddened and irritable surface, which slowly regains its healthy appearance. As the successive clusters go through a similar course, the termination of the whole is not complete before the thirteenth or fourteenth day.

The disorder of the constitution is not immediately relieved by the appearance of the eruption, but ceases as the latter proceeds. The heat, itching, and tingling of the skin, which accompany the patches as they successively rise, are sometimes productive of much restlessness and uneasiness, being aggravated especially by external heat, and by the warmth of the bed.

The predisposing and exciting causes are equally obscure. The eruption sometimes occurs in a miliary form, and spreads mo-

extensively over the greater portion of the surface of the body, in young and robust people, who generally refer its origin to cold. But it is liable to appear, in its more partial forms, in those persons who are subject to headaches and other local pains, which are probably connected with derangements of the chylopoietic organs.

The same treatment is requisite for this as for the following species.

2. *Herpes zoster.* This form of the eruption, which is sufficiently known to have obtained a popular appellation, the *shingles*, is very uniform in its appearances, following a course similar to that of small-pox, and the other exanthematic fevers. It is usually preceded, for two or three days, by languor and loss of appetite, rigours, headach, sickness, and a frequent pulse, together with a scalding heat, and tingling in the skin, and shooting pains through the chest and epigastrium. Sometimes, however, the precursory febrile symptoms are slight, and scarcely noticed, and the attention of the patient is first attracted by a sense of heat, itching, and tingling in some part of the trunk, where he finds several red patches, of an irregular form, at a little distance from each other, upon each of which numerous small elevations appear, clustered together. These, if examined minutely, are found to be distinctly vesicular; and, in the course of twenty-four hours, they enlarge to the size of small pearls, and are perfectly transparent, being filled with a limpid fluid. The clusters are of various diameter, from one to two, or even three inches, and are surrounded by a narrow red margin, in consequence of the extension of the inflamed base a little beyond the congregated vesicles. During three or four days, other clusters continue to arise in succession, and with considerable regularity; that is, nearly in a line with the first, extending always towards the spine, at one extremity, and towards the sternum, or linea alba of the abdomen, at the other, most commonly round the waist, like half a sash, but sometimes like a sword-belt, across the shoulder.

While the new clusters are appearing, the vesicles of the first begin to lose their transparency, and on the fourth day acquire a milky or yellowish hue, which is soon followed by a bluish, or livid colour of the bases of the vesicles, and of the contained fluid. They now become somewhat confluent, and flatten or subside, so that the outlines of many of them are nearly obliterated. About this time they are often broken, and, for three or four days, discharge a small quantity of a serous fluid, which at length concretes into thin dark scabs, at first lying loosely over the contained matter, but soon becoming harder, and adhering more firmly, until they fall off about the twelfth or fourteenth day. The surface of the skin is left in a red and tender state; and, where the ulceration and discharge have been considerable, numerous cicatrices or pits are left.

As all the clusters go through a similar series of changes, those which appeared latest arrive at their termination several days later than the first; hence the disease is sometimes protracted to twenty, or even twenty-four days, before the crusts exfoliate.

The febrile symptoms commonly subside when the eruption is completed; but sometimes they continue during the whole course of the disease, probably from the incessant irritation of the itching and smarting connected with it. In many instances, the most distressing part of the complaint is an intense darting pain, not superficial, but deep-seated in the chest, which continues to the latter stages of the disease, and is not easily allayed by anodynes.

Although the *shingles* commonly follow the regular course of fever, eruption, maturation, and decline, within a limited period, like the eruptive fevers, or exanthemata of the nosologists, yet the disorder is not, like the latter, contagious, and may occur more than once in the same individual. The disease, on the whole, is in most cases very slight; and seldom exhibits any untoward symptom, or is followed by much debility: in the majority of cases, it does not confine the patients to the house.

The causes of the *shingles* are not always obvious. Young persons, from the age of twelve to twenty-five, are most frequently the subjects of the disease, although the aged are not altogether exempt from its attacks, and suffer severely from the pains which accompany it. It is most frequent in the summer and autumn, and seems occasionally to arise from exposure to cold, after violent exercise. Sometimes it has appeared critical, when supervening to bowel complaints, or to the chronic pains of the chest remaining after acute pulmonary affections. Like erysipelas, it has been ascribed, by some authors, to paroxysms of anger.

It is unnecessary to speak of the treatment of a disorder, the course of which scarcely requires to be regulated, and cannot be shortened, by medicine. Gentle laxatives and diaphoretics, with occasional anodynes, when the severe deep-seated pains occur, and a light diet, seem to comprise every thing that is requisite in the cure.

In general, no external application to the clustered vesicles is necessary: but, when they are abraded by the friction of the clothes, a glutinous discharge takes place, which occasions the linen to adhere to the affected parts, producing some irritation: under these circumstances, a little simple ointment may be interposed, to obviate that effect. With the view of clearing off the morbid humours, the older practitioners cut away the vesicles, and covered the surface with their unguents, or even irritated it with the nitrico-oxide of mercury, notwithstanding the extreme tenderness of the parts. These pernicious interruptions of the healing process probably gave rise to ulceration, and prolonged the duration of the disorder, and thus contributed to mislead practitioners in their views of the nature of the disease.

3. *Herpes circinatus.* The form of the herpes is vulgarly termed a *ringworm*, and is, in this country, a very slight affection, being unaccompanied with any disorder of the constitution. It appears in small circular patches, in which the vesicles arise only round the circumference: these are small, with moderately red bases, and

contain a transparent fluid, which is discharged in three or four days, when little, prominent, dark scabs form over them. The central area, in each vesicular ring, is at first free from any eruption; but the surface becomes somewhat rough, and of a dull red colour, and throws off an exfoliation, as the vesicular eruption declines, which terminates in about a week, with the falling off of the scabs, leaving the cuticle red for a short time.

The whole disease, however, does not conclude so soon; for there is commonly a succession of the vesicular circles, on the upper parts of the body, as the face and neck, and the arms and shoulders, which have occasionally extended to the lower extremities, protracting the duration of the whole to the end of the second or third week. No inconvenience, however, attends the eruption, except a disagreeable itching and tingling in the patches.

The *herpetic* ringworm is most commonly seen in children, and has been deemed contagious. It has sometimes, indeed, been observed in several children, in one school or family, at the same time: but this was, most probably, to be attributed to the season, or some other common cause; since none of the other species of herpes are communicable by contact. It is scarcely necessary to point out here the difference between this *vesicular* ringworm, and the contagious *pustular* eruption of the scalp and forehead, which bears a similar popular appellation.

The itching and tingling are considerably alleviated by the use of astringent and slightly stimulant applications, and the vesicles are somewhat repressed by the same expedients. It is a popular practice to besmear them with ink: but solutions of the salts of iron, copper, or zinc, or of borax, alum, &c., in a less dirty form, answer the same end.

All the forms of herpes appear to be more severe in warm climates than in our northern latitudes; and the inhabitants of the former are liable to a variety of herpetic ringworm, which is almost unknown here. This variety differs materially from the preceding in its course, and is of much greater duration; for it does not heal with the disappearance of the first vesicles, but its area continually dilates by the extension of the vesicular margin. The vesicles terminate in ulcerations, which are often of a considerable depth; and, while these undergo the healing process, a new circle of vesicles rises beyond them, which passes through a similar course, and is succeeded by another circle exterior to itself: and thus the disease proceeds, often to a great extent, the internal parts of the ring healing as the ulcerous and vesicular circumference expands.

4. *Herpes labialis.* A vesicular eruption upon the edge of the upper and under lip, and at the angle of the mouth, sometimes forming a semicircle, or even completing a circle round the mouth, by the successive rising of the vesicles, is very common, and has been described by the oldest writers. At first, the vesicles contain a transparent lymph, which, in the course of twenty-four hours, becomes turbid, and of a yellowish white colour, and ultimately assumes a puriform appearance. The lips become red, hard, and tumid, as well as sore, stiff, and painful, with a sensation of great heat and smarting, which continues troublesome for three or four days, until the fluid is discharged, and thick dark scabs are formed over the excoriated parts. The swelling then subsides, and in four or five days more the crusts begin to fall off; the whole duration being, as in the other herpetic affections, about ten or twelve days.

This labial herpes occasionally appears as an idiopathic affection, originating from cold, fatigue, &c., and is then preceded, for about three days, by the usual febrile symptoms, shiverings, headach, pains in the limbs and the stomach, with nausea, lassitude, and languor. Under these circumstances, a sort of *herpetic* sore throat is sometimes connected with it; a similar eruption of inflamed vesicles taking place over the tonsils and uvula, and producing considerable pain and difficulty of deglutition. The internal vesicles, being kept in a state of moisture, form slight ulcerations when they break; but these heal about the eighth and ninth days, while the scabs are drying upon the external eruption.

The herpes labialis, however, occurs most frequently in the course of diseases of the viscera, of which it is symptomatic, and often critical; for these diseases are frequently alleviated as soon as it appears. Such an occurrence is most common in bilious fevers, in cholera and dysentery, in peritonitis, and severe catarrhs; but it is not unfrequent in continued malignant fevers, and even in intermittents.

5. *Herpes præputialis.* This local variety of herpes was not noticed by Dr. Willan; but it is particularly worthy of attention, because it occurs in a situation where it is liable to occasion a practical mistake of serious consequence to the patient. The progress of the herpetic clusters, when seated on the prepuce, so closely resembles that of chancre, as described by some authors, that it may be doubted whether it has not been frequently confounded with the latter.

The attention of the patient is attracted to the part by an extreme itching, with some sense of heat; and on examining the prepuce he finds one, or sometimes two red patches, about the size of a silver penny, upon which are clustered five or six minute transparent vesicles, which, from their extreme tenuity, appear of the same red hue as the base on which they stand. In the course of twenty-four or thirty hours, the vesicles enlarge, and become of a milky hue, having lost their transparency; and, on the third day, they are coherent, and assume an almost pustular appearance. If the eruption is seated within that part of the prepuce which is, in many individuals, extended over the glans, so that the vesicles are kept constantly covered and moist (like those that occur in the throat), they commonly break about the fourth or fifth day, and form a small ulceration upon each patch. This discharges a little turbid serum, and has a white base, with a slight elevation at the edges; and by an inaccurate or inexperienced observer it may be readily mistaken for chancre; more especially if any escharotic has

been applied to it, which produces much irritation, as well as a deep-seated hardness beneath the sore, such as is felt in true chancre. If no irritant be applied, the slight ulceration continues till the ninth or tenth day nearly unchanged, and then begins to heal; which process is completed by the twelfth, and the scabs fall off on the thirteenth or fourteenth day.

When the patches occur, however, on the exterior portion of the prepuce, or where that part does not cover the glans, the duration of the eruption is shortened, and ulceration does not actually take place. The contents of the vesicles begin to dry about the sixth day, and soon form a small, hard, acuminated scab, under which, if it be not rubbed off, the part is entirely healed by the ninth or tenth day, when the little indented scab is loosened, and falls out.

This circumstance suggests the propriety of avoiding not only irritative, but even unctuous or moist applications, in the treatment of this variety of herpes. And accordingly it will be found, that, where ulceration occurs within the prepuce, it will proceed with less irritation, and its course will be brought within the period above mentioned, if a little clean dry lint alone be interposed, twice a day, between the prepuce and the glans.

The causes of this eruption on the prepuce are not yet ascertained. Whencesoever it may originate, it is liable to recur in the same individual, and often at intervals of six or eight weeks.

6. *Herpes iris.* This rare and singular morbid appearance, which has not been noticed by medical writers, occurs in small circular patches, each of which is composed of concentric rings, of different colours. Its usual seat is on the back of the hands, or the palms and fingers, sometimes on the instep. Its first appearance is like an efflorescence; but, when it is fully formed, not only the central umbo, but the surrounding rings become distinctly vesicular. The patches are at first small, and gradually attain their full size, which is nearly that of a sixpence, in the course of a week or nine days, at the end of which time the central part is prominent and distended, and the vesicular circles are also turgid with lymph; and, after remaining nearly stationary a couple of days, they gradually decline, and entirely disappear in about a week more. The central vesicle is of a yellowish white colour: the first ring surrounding it is of a dark or brownish red; the second is nearly of the same colour as the centre; and the third, which is narrower than the rest, is of a dark red colour; the fourth, and outer ring, or areola, does not appear until the seventh, eighth, or ninth day, and is of a light red hue, which is gradually lost in the ordinary colour of the skin.

The iris has been observed only in young people, and was not connected with any constitutional disorder, nor could it be traced to any assignable cause. In one or two cases it followed a severe catarrhal affection, accompanied with hoarseness, and also with an eruption of herpes labialis. In others, it had recurred several times in the persons affected, occupying always the same parts, and going through its course in the same periods of time.

No internal medicine is requisite in the treatment of the different species of herpes, except when the constitution is disordered (and then the general antiphlogistic plan must be adopted); for, like the other eruptive diseases, which go through a regular and limited course, they cannot be interrupted or accelerated in their progress by any medicinal expedient; but their termination may be retarded by improper treatment.

Herpes ambulati'vus. A name that has been given to a disease which is, probably, erratic erysipelas.

Herpes depa'scens. An eating or corroding form of herpes.

Herpes esthio'menos. A variety of herpes, where there is great destruction of the skin by ulceration.

Herpes exe'dens. A form of herpes in which there is a rapid spreading of the disease.

Herpes farinosus. This is characterised by its having furfuraceous exfoliations.

Herpes ferus. An erysipelas.

Herpes i'ndicus. A fiery, itchy herpes, peculiar to India.

Herpes milia'ris. Herpes is so called when it begins with an eruption like millet-seeds.

Herpes peri'sceles. The shingles, or *herpes zoster*.

Herpes pustulo'sus. This name has been given to the different forms of acne.

Herpes serpi'go. The ringworm. See *Herpes circinatus*.

Herpes siccus. The dry, mealy tetter.

Herpes zoster. The shingles. See *Herpes*.

HERPETIC. (*Herpeticus*; from *herpes*, a disease of the skin.) Relating to herpes.

Herpetogra'phia. Herpetography. (From ἑρπης, and γραφω, to describe.) The description of herpes.

Herpeto'logy. *Herpetologia.* This term has been applied to the study of herpetic diseases; but it is objectionable, first, because it already exists as a term of zoology applied to the study of reptiles, and, secondly, because in pathology it is quite superfluous.

He'rpeton. (Ἑρπετον. Ἑρπετικον; from ἑρπω, to creep.) A creeping pustule or ulcer. — *Hippocrates.*

Herring. See *Clupea harengus.*

Hesmis. An alchemical name for a weight equal to a quarter of a pound.

HESPERI'DEÆ. Fancifully so named from the gardens of the Hesperides. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of plants which have rigid evergreen leaves, odorous and polyandrous flowers; as the myrtle, clove, &c.

Hespe'ridine. *Hesperidina.* A peculiar crystallizable matter detected in unripe bitter oranges by Lebreton and Brandes.

Hetero'pathy. (*Heteropathi'a*; from ἑτερος, different, and παθος, affection.) That mode of treating diseases in which a morbid state is removed by inducing a different morbid state. It is opposed to *Homœopathy.*

Hetero'poda. (From ἑτερος, different, and

πους, a foot.) The name of an order of gasteropodous mollusca in Cuvier's system.

HEXAGY'NIA. (*a*, *æ*. f.; from ἑξ, six, and γυνη, a woman, or wife.) The name of an order of plants in the sexual system, which, besides the classic character, have six pistils.

HEXA'NDRIA. (*a*, *æ*. f.; from ἑξ, six, and ανηρ, a man, or husband.) The name of a class of plants in the sexual system, consisting of plants with hermaphrodite flowers that are furnished with six stamens of an equal length.

HEXAPE'TALOUS. *Hexapetalus.* Six-petalled.

HEXAPHA'RMACUM. (From ἑξ, six, and φαρμακον, a medicine.) A plaster mentioned by Paulus Ægineta, consisting of six ingredients.

HEXAPHY'LLOUS. *Hexaphyllus.* Six-leaved.

HE'XIS. (Ἑξις; from ἐχω, to have.) A habit or constitution of body.

HI'ANS. Gaping, applied, in *Botany*, to seed-vessels, &c.

Hibernicus lapis. See *Lapis hibernicus.*

HIBI'SCUS. (*us*, *i*. m.; the Latin name of the marsh-mallow: its real derivation is not known.) The name of a genus of plants in the Linnæan system. Class, *Monodelphia*; Order, *Polyandria.*

HIBISCUS ABELMOSCHUS. The systematic name of the plant, the seeds of which are called musk-seed. *Abelmoschus, Granum moschi, Moschus Arabum, Egyptia moschata, Bammia moschata, Alcea, Alcea Indica, Alcea Egyptiaca villosa, Abrette, Abelmosch, and Abelmusk.* The plant is indigenous in Egypt, and in many parts of both the Indies. The seeds have the flavour of musk. The best comes from Martinique. By the Arabians they are esteemed cordial, and are mixed with their coffee, to which they impart their fragrance. In this country they are used by the perfumers.

Hiccup. See *Singultus.*

HYDRO'A. (Ἱδρωα; from ἱδρως, sweat.) Synonymous with *Sudamina.* See *Sudamina.*

HIDRO'NOSOS. (From ἱδρως, sweat, and νοσος, a disease.) The sweating sickness. See *Sudor anglicus.*

HIDROPY'RETUS. (From ἱδρως, sweat, and πυρετος, a fever.) The same.

HIDRO'TICUS. (From ἱδρως, sweat.) Hydrotic, synonymous with *sudorific.*

HIDUS. Flowers of brass. — *Ruland.*

HI'ERA PI'CRA. (From ἱερος, holy, and πικρος, bitter.) Holy bitter. Aloetic powder, made into an electuary with honey. It is now kept in the form of dry powder, prepared by mixing Socotorine aloes, one pound, with three ounces of white canella.

HIERABO'TANE. (From ἱερος, holy, and βοτανη, a herb: so called from its supposed virtues.) See *Verbena trifoliata.*

HIERACA'NTHA. (From ἱεραξ, a hawk, and ανθος, a flower: so named because it seizes passengers as a hawk does its prey.) A sort of thistle.

HIERA'CIUM. (*um*, *ii*. n.; from ἱεραξ, a hawk: so called because hawks feed upon it, or because it was said that hawks applied the juice of it to cleanse their eyes.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order *Polygamia æqualis.* Hawkweed.

Hieracium alpinum. See *Hypochæris.*

Hieracium minus. See *Hypochæris.*

Hieracium montanum. See *Chondrilla.*

HIERACIUM PILOSELLA. The systematic name of the mouse-ear; called also, *Auricula muris, Pylosella, Myosotis*, and *Hieraoulum.* This common plant contains a bitter lactescent juice, which has a slight degree of astringency. The roots are more powerful than the leaves. They are very seldom used in this country.

Hieracium pulcrum. See *Chondrilla.*

Hieraculum. See *Hieracium.*

HIERA'NOSOS. (*us*, *i*. m.; from ἱερος, holy, and νοσος, a disease, *morbus sacer.*) 1. The epilepsy was so called, because it was supposed to be that disease which our Saviour cured in those who were said to be possessed of devils.

2. Chorea has been so called, from the belief that it was induced by the immediate agency of a superior order of beings.

3. Convulsions were formerly so called.

HIERA'TICUM. (Ἱερατικον; from ἱερος, holy.) The epithet of a malagma used in diseases of the stomach and liver, and pains in the bowels.

Highmore, antrum of. See *Antrum Highmorianum.*

HIGUE'RO. The calabash tree. *Crescentia cujete* of Linnæus, the fruit of which is said to be febrifuge.

Hill's balsam of honey. See *Balsam of honey.*

HILL'S ESSENCE OF BARDANA. A solution of guaiac in proof spirit.

HI'LUM. (*um*, *i*. n.) The eye of a seed, or scar or point by which the seed is attached to its seed-vessel or receptacle, and through which alone life and nourishment are conveyed for the perfecting of its internal parts. Consequently all those parts must be intimately connected with the inner surface of this scar, and they are all found to meet there, and to divide or divaricate from that point, more or less immediately. In describing the form or various external portions of any seed, the *hilum* is always to be considered as the base. When the seed is quite ripe, the communication through this channel is interrupted; it separates from the parent plant without injury, a scar being formed on each. Yet the hilum is so far capable of resuming its former nature, that the moisture of the earth is imbibed through it, previous to germination. — *Smith.*

HIMANTO'SIS. (From ἱμας, a thong of leather.) A relaxation of the uvula, when it hangs down like a thong.

HI'MAS. The same.

HIP. 1. The articulation of the thigh with the pelvis. See *Femoris os.*

2. The ripe fruit of the dog-rose. They are chiefly used as a sweetmeat, or as a confection. See *Confectio rosæ caninæ.*

HI'PPACE. (Ἱππακη; from ἱππος, a horse or mare.) The rennet of a colt; also cheese made of mare's milk.

HIPPOCA'MPUS. (*us*, *i*. m. Ἱπποκαμπος; from ἱππος, a horse, and καμπτω, to bend: because its head resembles that of a horse, and its

tail is curved.) A small marine animal. A particular part of the brain is called *hippocampus*, from a fancied resemblance to this animal.

HIPPOCA'STANUM. (*um, i.* n.; from *ἱππος*, a horse, and *καστανον*, a chesnut.) The horse-chesnut. See *Æsculus hippocastanum.*

HI'PPOCRAS. An aromatic wine, formerly much used in England. It is made with twelve pints of Canary, and as much Lisbon, two ounces of cinnamon, half an ounce of canella alba, and a drachm of cloves, of mace, of nutmeg, of ginger, and of galangal or cardamoms. These are to be digested for three days, and the liquor strained: lastly, two pounds and a half of refined sugar are to be added.

Hippocrates' sleeve. See *Manica Hippocratis.*

HIPPOLA'PATHUM. (From *ἱππος*, a horse, and *λαπαθον*, the lapathum: so named from its size.) See *Rumex patientia.*

HIPPOMA'RATHRUM. (From *ἱππος*, a horse, and *μαραθρον*, fennel: so named from its size.) See *Peucedanum silaus.*

HIPPOSELI'NUM. (From *ἱππος*, a horse, and *σελινον*, purslane: so named because it resembles a large kind of purslane.) See *Smyrnium olusatrum.*

HIPPU'RIS. (*is, is.* f.; from *ἱππος*, a horse, and *ουρα*, a tail.) 1. Some herbs are thus named because they resemble a horse's tail.

2. The name of a genus of plants in the Linnæan system. Class, *Monandria;* Order, *Monogynia.* Mare's tail.

HIPPURIS VULGARIS. The systematic name of the horse's or mare's tail. Called also, *Equisetum*, and *Cauda equina.* It possesses astringent qualities, and is frequently used by the common people as tea, in diarrhœas and hæmorrhages. The same virtues are also attributed to the *Equisetum arvense, fluviatile, limosum*, and other species, which are directed indiscriminately by the term *Equisetum.*

HI'PPUS. (*us, i.* m.; from *ἱππος*, a horse: because the eyes of those who labour under this affection are continually twinkling and trembling, as is usual with those who ride on horseback.) A repeated dilatation and alternate constriction of the pupil, arising from a spasmodic affection of the iris.

HIR. (From *χειρ*, the hand.) The palm of the hand. — *Turton.*

HI'RA. (From *hir*, the palm of the hand; because it is usually found empty.) The jejunum. — *Turton.*

HI'RCUS. (*us, i.* m.; *quasi hirtus*, from its shaggy hair.) The goat. See *Capra hircus.*

HIRCUS BEZOARTICUS. The goat which affords the oriental bezoar. See *Bezoar orientale.*

HI'RQUUS. A Latin name for the corner of the eye.

HIRSU'TIES. Hairiness: a species of disease in which hair grows in unusual situations, or in more than usual abundance.

HIRSU'TUS. Hairy: applied very generally, in *Natural History*, to that which is hairy or shaggy; to leaves, petals, seeds, &c. of plants; as the petals of the *Menyanthes trifoliata* and *Asclepias crispa*, and the seeds of the *Scandix trichosperma.*

HI'RTUS. (A contraction of *hirsutus.*) Rough-haired: applied to stems of plants; as that of the *Cerastium alpinum.*

HIRU'DO. (*o, inis.* f.; *quasi haurudo;* from *haurio*, to draw out: so named from its greediness to suck blood.) See *Leech.*

Hirudo medicinalis. See *Leech.*

HIRUNDINA'RIA. (*a, æ.* f.; from *hirundo*, the swallow: so called from the resemblance of its pods to a swallow.) Swallow-wort. See *Lysimachia nummularia*, and *Asclepias vincetoxicum.*

HIRU'NDO. (*o, onis.* f.) The bird called a swallow. It was formerly esteemed medicinal in epilepsy, diseases of the eyes, &c.

HISPI'DULA HERBA. (From *hispidus*, rough: so named from the rough, woolly surface of its stalks.) See *Gnaphalium.*

HI'SPIDUS. Hispid: bristly. Applied to stems, seeds, &c. of plants. The *Borago officinalis* is a good example of the *caulus hispidus:* the seeds of the *Daucus carota* and *Galium boreale.*

HIVES. The popular name, in the north of England and in Scotland, for the *varicella globularis* of Willan.

Hoary. See *Glaucus*, and *Incanus.*

Hog. See *Sus scrofa.*

Hog's fennel. See *Peucedanum.*

Hog's lard. See *Adeps præparata.*

HOLCE. *Ὁλκη.* A Greek weight equal to a drachm.

HO'LCUS. (*us, i.* m.) 1. The name of a genus of plants in the Linnæan system. Class, *Polygamia;* Order, *Monœcia.*

2. The Indian millet-seed, which is said to be nutritive.

HOLCUS SORGUM. Guinea corn.

Holly. See *Ilex aquifolium.*

Holly, knee. See *Ruscus.*

Holly, sea. See *Eryngium.*

Hollyhock. See *Alcea.*

HOLMI'SCUS. (Dim. of *ὁλμος*, a mortar.) 1. A small mortar.

2. The alveolar cavities or sockets of the teeth.

HOLOPHLY'CTIS. (From *ὁλος*, whole, and *φλυκτις*, a pustule.) A little pimple which appears all over the body.

Holo'stes. See *Holosteus.*

Holo'steum. See *Holosteus.*

HOLO'STEUS. (*us, i.* m.; from *ὁλος*, whole, and *οστεον*, a bone.) Glue-bone. See *Osteocolla.*

HOLOTO'NICUS. (From *ὁλος*, whole, and *τεινω*, to stretch.) That form of tetanus has been so called in which the muscles are universally affected.

Holy thistle. See *Centaurea.*

Holybut. See *Pleuronectes hypoglossus.*

Holywell. See *Malvern.*

HO'MA. An anasarcous swelling.

HOMBERG'S PHOSPHORUS. Ignited muriate of lime.

Homberg's pyrophorus. See *Alum.*

Homberg's salt. See *Boracic acid.*

Homoplata. See *Omoplata.*

HOMO. Man. Man, considered as an object of zoology, is a mammiferous animal belong-

ing to the order *Bimana*, or *two-handed*, of which he constitutes the sole genus. Man is distinguished from other animals by a much greater developement of mind; by the use of articulate speech, as a means of communicating ideas; and by moral and religious feelings, which are unknown to the inferior animals. The human species presents great variety of external form, and of moral and intellectual endowment, according to climate, political condition, and various other circumstances, which influence the physical constitution, and advance or retard the progress of civilization. The following table of the different races of mankind, derived chiefly from the researches of M. Desmoulins, is given by M. Magendie.

1. Celto-Scythi-Arabians.	Hair smooth, silky, plentiful; facial angle open; incisor teeth vertical; cheeks not projecting or large; skin and hair varying from black to white, according to the climate. Inhabit all Europe, but less its central polar countries; Asia to the Ganges, and to the sources of the Irtish; the Atlantic region of Africa, Egypt, and Abyssinia.	1. *Celts.* Black hair; primitive inhabitants of Europe to the west of the Rhine and the Alps, to the ocean and its isles. 2. *Scythians.* White hair. Central Europe, Asia to the sources of the Irtish; Mountains of Belur and Himalayah. 3. *Arabians.* Hair always black. Atlantic Africa, and Asia to the south of Caucasus, as far as the Ganges. 4. *Atlantians.* Olecranian *fossa* of the humerus pierced as in the South African; hair black, chesnut, and fair. *Guanches*, an ancient people of the Canaries.
2. Mongols.	Hair smooth, but stiff and thin; beard thin; eye small, raised obliquely backwards; cheeks projecting, incisors vertical; skin yellow, and hair black; colour invariable under all climates; marriage precocious.	Greenland, the polar coasts of Europe and America, under the name of Laplanders, Samoids, Esquimaux, &c.; all Asia to the east of the Ganges, of the mountains of Belur, and the Irtish.
3. Ethiopians.	Hair woolly; cranium compressed; forehead depressed; nose flattened; facial part of the intermaxillary bone and chin obliquely inclined upon one another, as also the incisors; skin and hair black under all climates.	Africa, from the Senegal, the Niger, and the Bahr-el-Azrek, to within a little of the southern tropic. Separated from the Euro-Africans by a chain of high mountains running parallel to the sea-shore from India.
4. Euro-Africans.	Hair woolly; skin black; cranium less compressed than in the Ethiopians; and forehead almost as projecting as in Europeans; incisors vertical; nose little depressed. Commonly designated negroes of Mozambique.	The eastern coast of Africa, upon the Indian ocean.
5. Austro-Africans.	Hair woolly, and the bones of the nose usually in one single scaly plate, as in Makas, and much more flat and broad than in other Africans; olecranium cavity of the humerus perforated by a hole; incisors and chin much more oblique than in Ethiopians. Skin yellow bistre.	Africa, beyond the southern tropic, less the part corresponding to the eastern coast. 1. *Hottentots, Boschiemans, Betjuanas*, &c. 2. *Malegaches*, (aborigines of the island,) on the eastern coast of Madagascar. Hair short and woolly; colour of skin deep copper; orbits wider than in the negro.
6. Malays, or Oceanians.	Cranium conformable to that of Europeans; cheeks a little larger; teeth quite alike; hair smooth and black; skin olive or brown, in the same climate where the Arab Indian is as black as the negro. The shores of Indian China, all the Asiatic Archipelago, and Oceanica to Madagascar.	1. *Carolinians*, or natives of New Philippine Islands (Lat. 7°. N. Long. 145°. E.). Form regularly beautiful; shape more full and elevated than the middle of Europe; character mild; quick apprehension. 2. *Dayaks* and *Beadjus* of Borneo, and several of the *Harraforas* of the Moluccas. The whitest of the Malays. 3. *Javanese, Sumatrians, Timorians*, and *Malays* of the rest of the Indian Archipelago. Lips generally large, nose flat, cheeks projecting; shape smaller than the middle of Europe. Character perfidious and ferocious.

		4. *Polynesians*, properly so called. Generally, tall like the Carolinians, but with visage of Javanese, Sumatrians, &c. 5. *Hovas* of Madagascar. Inhabiting the zone between the eastern shore and the mountains; ordinary size five feet ten inches; colour bright olive; orbits large and square; chin a long transverse oval; nose almost European.
7. Papoos.	Almost negro; hair black, half woolly, very tough, naturally curling; beard black and thin; physiognomy between the black and the Malay; but with teeth somewhat prominent; nasal opening wider still than in the natives of Guinea.	Inhabit the little islands around New Guinea, Waigioo, and New Guinea.
8. Oceanian Negroes.	Colour quite black, cranium compressed and depressed; hair short, very woolly, and curled; nose flat to the root, and very broad; lips thick; facial angle very acute; on the whole, closely approaching the negroes of Guinea. New Guinea, Archipelago *del Esperitu Santò*, or New Hebrides, Andaman isles, Formosa.	Have peopled, or people still, the north of the western Oceanica, some small archipelagos of Polynesia, a great part of the Indian Archipelago, and some countries of Indian China, and the adjacent islands. 1. *Moys*, or *Moyes*, of the mountains of Cochinchina; *Samang*, *Dayak*, &c. of the mountains of Malacca; peopling also the interior of Formosa, the Archipelago of Andaman, and anciently the south of the Isle of Niphon, according to the *Japanese history*. 2. The interior of Borneo, and of some of the Philippine Islands; the interior of the Celebes, and some of the Molucca; anciently the anterior of the isle of Java, according to *Japanese history*. 3. They people exclusively in Australasia, New Caledonia, the Archipelago *del Esperitu Santò*, or New Hebrides, and Van Dieman's land, where they have a length and meagerness of limb disproportioned to the body, as in the *semno-pithecas*, in the genus Guenon. 4. The *Vinzimbars* of the mountains of Madagascar, an island of which the animal population is equally related to the system of organization of Oceanica.
9. Australians.	Hair smooth, black; beard and hair thin; limbs slender, and of a length disproportionate to the body; teeth vertical, nose very broad; forehead depressed and compressed.	New Holland.
10. Columbians.	Head elongated; nose long, projecting, and strongly aquiline; forehead compressed and flattened; considerable height of the jaws; red copper colour in all climates; hair black, never becoming grey; beard thin; forehead more depressed than with the Mongols; nubility precocious; imagination lively and strong; moral character energetic. These characters belong chiefly to the people of North America, and the table-lands of the Cordilleras, as far as Cumana.	*Tchutkis*, of the north-eastern extremity of Asia. The Columbians occupy the whole of North America, all the table-lands and declivities of the Cordilleras, from Chili to Cumana, and the Caribean Archipelago included.

11. Americans.	Head general spherical; forehead broad, but depressed, as in the Mongols; superciliary arches projecting outwards; cheeks prominent; nose flat and depressed at the root; hair long, thick, rigid, and straight; skin neither black, nor yellow, nor copper-coloured; lips very thick; understanding generally obtuse, and moral character extremely debased.	1. *Omaguas, Guaranis, Coroados, Puris, Atures, Ottomacs,* &c. Prominent belly, breast hairy, beard plentiful; size under the medium of the Spaniards; skin of a very dark, dirty, bistre colour; mind indolent, improvident; head of a volume disproportionate to the body, flattened at the top, sunk between the shoulders; all South America, to the south of the Amazon and Orinoco rivers, to the east of the Andes, and of La Plata. The *Guaranis* and *Coroados* are without beard, and without hair upon the breast. 2. *Botocudes.* Skin clear brown, sometimes almost white. *Guiacas* of a very small size; skin almost white; dwelling near the sources of the Orinoco, under the equator. 3. *Mbayas, Charruas,* &c. skin of a brown and all but black colour, without a shade of red; forehead and physiognomy open; nose narrow, depressed at the root; eyes small and confined; teeth vertical; hair long, black, rigid; feet and hands small in proportion, and better made than in the Spaniards; inhabit Paraguay. 4. The *Puelches* and the *Tchuellets,* or *Patagonians,* on the south of La Plata, as far as the straits of Magellan. Size above 5 feet 11½ inches English; hair long; constitution void of any analogy to that of the preceding species.

HOMŒO'PATHY. (*Homœopathi'a*; from *ὁμοιος*, similar, and *παθος*, affection.) A new medical doctrine, promulgated some years since by Dr. Samuel Hahnemann, of Leipsig. According to this doctrine every medicine has a specific power of causing alterations in the healthy system, by which a certain diseased state is set up; but, when a medicine is given to a person already labouring under that disease which the medicine has a natural tendency to produce, the effect will be to resolve the disease, because two similar diseased actions cannot go on simultaneously in the same part. With this view, medicines are given in doses sufficient to excite an action somewhat more powerful than than that of the disease; and the doses which are found to answer this purpose are what are called *infinitesimal* doses, that is, doses which appear to practitioners in general most ridiculously small, as the millionth or quadrillionth part of a grain. In too large doses, medicines homœopathically administered would be productive of the worst results.

It is a principle with Hahnemann that only one medicine is to be administered at a time, and that the medicinal substances employed must be perfectly pure. The homœopathists in general now give doses larger than those recommended by Hahnemann, but still so small that they cannot, on the ordinary principles of medicine, be supposed to have any appreciable effect; they pay great attention, however, to regimen. With respect to the homœopathic theory of the operation of medicines, all that can be said is, that it is a mere whim, unsupported either by reason or by facts. With respect to the practice, it evidently amounts to doing nothing but regulating the diet and habits of the patient. Now, all judicious practitioners have long been agreed, that there are many cases which are best treated in the manner above mentioned; and in which medicine, meaning thereby the administration of drugs, would do more harm than good: hence we need be at no loss to account for the occasional success of homœopathic practice, without admitting that there is any truth in homœopathic principles.

Homo'tonos. (*Ὁμοτονος*; from *ὁμος*, equal, and *τονος*, tone.) A Greek term applied to fevers. It is synonymous with *acmasticos;* which see.

Honey. See *Mel.*

Honey-cup. See *Nectarium.*

Honeysuckle. See *Lonicera.*

Honeycomb-like. See *Favosus.*

Hooded. See *Cucullatus.*

Hoof-shaped. See *Ungulatus.*

Hooping-cough. See *Pertussis.*

Hop. See *Humulus lupulus.*

Hoplochri'sma. (From *ὁπλον*, a weapon, and *χρισμα*, a salve.) A salve which was believed to cure wounds by sympathy; that is, by anointing the instrument with which the wound was made. See *Unguentum armarium.*

Ho'rdein. A peculiar substance found by Proust in barley. It is allied to starch, but is thought to differ from it sufficiently to constitute a peculiar substance.

HORDE'OLUM. (*um, i.* n.; diminutive of *hordeum*, barley.) A little tumour on the eyelids, resembling a barley-corn: vernacularly called a stye. Scarpa remarks, the stye is strictly only a little boil, which projects from the edge of the eyelids, mostly near the great angle of

the eye. This little tumour, like the furunculus, is of a dark red colour, much inflamed, and a great deal more painful than might be expected, considering its small size. The latter circumstance is partly owing to the vehemence of the inflammation producing the stye, and partly to the exquisite sensibility and tension of the skin which covers the edge of the eyelids. On this account, the hordeolum very often excites fever and restlessness in delicate, irritable constitutions; it suppurates slowly and imperfectly; and, when suppurated, has no tendency to burst.

The stye, like other furunculous inflammations, forms an exception to the general rule, that the best mode in which inflammatory swellings can end is resolution; for, whenever a furunculous inflammation extends so deeply as to destroy any of the cellular substance, the little tumour can never be resolved, or only imperfectly so. This event, indeed, would rather be hurtful, since there would still remain behind a greater or smaller portion of dead cellular membrane, which, sooner or later, might bring on a renewal of the stye, in the same place as before, or else become converted into a hard indolent body, deforming the edge of the eyelid.

HO'RDEUM. (*um, i.* n.) 1. The name of a genus of plants in the Linnæan system. Class, *Triandria*; Order, *Digynia*. Barley.

2. The pharmacopœial name of the common barley. See *Hordeum vulgare*.

Hordeum causticum. See *Cevadilla*.

Hordeum distichon. See *Hordeum vulgare*.

Hordeum perlatum. See *Hordeum vulgare*.

HORDEUM VULGARE. The systematic name of the common barley. The seed called barley is obtained from several species of *hordeum*, but principally from the *vulgare*, or common or Scotch barley, and the *distichon* or *hordeum gallicum vel mundatum*, or French barley, of Linnæus. It is extremely nutritious and mucilaginous, and in common use as a drink, when boiled, in all inflammatory diseases and affections of the chest, especially where there is cough or irritation about the fauces. A decoction of barley with gum is considered a useful diluent and demulcent in dysury and strangury; the gum mixing with the urine, sheaths the urinary canal from the acrimony of the urine. Amongst the ancients, decoctions of barley, *κριθη*, were the principal medicine, as well as aliment, in acute diseases. Barley is freed from its husks in mills, and in this state called Scotch and French barley. In Holland, they rub barley into small round grains, somewhat like pearls, which is therefore called *pearl barley*, or *hordeum perlatum*.

Horehound. See *Marrubium*.

HORIZONTAL. *Horizontalis*. Applied to leaves, roots, &c. which spread in the greatest possible degree; as the leaves of *Gentiana campestris*, and roots of the *Anemone nemorosa*.

HORMINUM. (*um, i.* n.; from *ὁρμαω*, to incite: named from its supposed qualities of provoking venery.) See *Salvia sclarea*.

HORN. *Cornu*. 1. An animal substance composed of coagulated albumen, with a little gelatine, and about a half per cent. of phosphate of lime. The horns of the buck and hart are of a different nature, being intermediate between bone and horn. See *Cornu*.

2. A horn or spur. See *Calcar*.

Horn-pock. See *Variola*.

Horn-shaped. See *Cornutus*.

HORRIPILA'TION. (*Horripilatio, onis.* f.; from *horror*, and *pilus*, a hair.) A shuddering or sense of creeping in different parts of the body.

Horse-chesnut. See *Æsculus hippocastanum*.

Horse-radish. See *Cochlearia armoracia*.

Horse-tail. See *Hippuris vulgaris*.

HO'RTUS. (*us, i.* m.; from *orior*, to rise; as being the place where vegetables grow up.) 1. A garden.

2. The genitals of a woman, as being the repository of the human semen.

HORTUS SICCUS. A collection of dried plants, kept in paper or books.

HOSPITAL GANGRENE. A peculiar form of gangrene, which sometimes prevails in hospitals. See *Mortification*.

Hound's-tongue. See *Cynoglossum*.

HOUSE-LEEK. (So called because it grows on the roofs of houses.) See *Sempervivum tectorum*.

HUME'CTANT. (*Humectans*; from *humecto*, to make moist.) Synonymous with *diluent*.

HU'MERAL. *Humeralis*. Belonging to the humerus or arm.

HUMERAL ARTERY. *Arteria humeralis*. Brachial artery. The axillary artery, having passed the tendon of the great pectoral muscle, changes its name to the brachial or humeral artery, which name it retains in its course down the arm to the bend, where it divides into the radial and ulnar arteries. In this course it gives off several muscular branches, three of which only deserve attention: 1. The *arteria profunda superior*, which goes round the back of the arm to the exterior muscle, and is often named the upper muscular artery. 2. Another like it, called *arteria profunda inferior*, or the lower muscular artery. 3. *Ramus anastomoticus major*, which anastomoses round the elbow with the branches of the ulnar artery.

Humeralis musculus. See *Deltoides*.

HU'MERUS. (*us, i.* m.; from *ὠμος*, the shoulder.) 1. The arm, as composed of hard and soft parts, from the shoulder to the fore-arm.

2. The shoulder.

3. The bone of the arm, *os humeri*, or *os brachii*. A long cylindrical bone, situated between the scapula and fore-arm. Its upper extremity is formed, somewhat laterally and internally, into a large, round, and smooth head, which is admitted into the glenoid cavity of the scapula. Around the basis of this head is observed a circular fossa, deepest anteriorly and externally, which forms what is called the neck of the bone, and from the edge of which arises the capsular ligament, which is further strengthened by a strong membraneous expansion, extending to the upper edge of the glenoid cavity, and to the coracoid process of the scapula;

and likewise, by the tendinous expansions of the muscles, inserted into the head of the humerus. The capsular ligament is sometimes torn in luxation, and becomes an obstacle to the easy reduction of the bone. The articulating surface of the head is covered by a cartilage which is thick in its middle part, and thin towards its edges; by which means it is more convex in the recent subject than in the skeleton. This upper extremity, besides the round smooth head, affords two other smaller protuberances. One of these, which is the largest of the two, is of an irregular oblong shape, and is placed at the back of the head of the bone, from which it is separated by a kind of groove, that makes a part of the neck. This tuberosity is divided, at its upper part, into three surfaces: the first of these, which is the smallest and uppermost, serves for the insertion of the supraspinatus muscle; the second, or middlemost, for the insertion of the infraspinatus; and the third, which is the lowest and hindmost, for the insertion of the teres minor. The other smaller tuberosity is situated anteriorly, between the larger one and the head of the humerus, and serves for the insertion of the subscapularis muscle. Between these two tuberosities there is a deep groove for lodging the tendinous head of the biceps brachii; the capsular ligament of the joint affording here a prolongation, thinner than the capsule itself, which covers and accompanies this muscle to its fleshy portion, where it gradually disappears in the adjacent cellular membrane. Immediately below its neck the os humeri begins to assume a cylindrical shape, so that here the body of the bone may be said to commence. At its upper part is observed a continuation of the groove for the biceps, which extends downwards, about the fourth part of the length of the bone, in an oblique direction. The edges of this groove are continuations of the greater and lesser tuberosities, and serve for the attachment of the pectoralis, latissimus dorsi, and teres major muscles. The groove itself is lined with a glistening substance like cartilage, but which seems to be nothing more than the remains of tendinous fibres. A little lower down, towards the external and anterior side of the middle of the bone, it is seen rising into a rough ridge for the insertion of the deltoid muscle. On each side of this ridge the bone is smooth and flat, for the lodgment of the brachialis internus muscle; and behind the middle part of the outermost side of the ridge is a channel, for the transmission of vessels into the substance of the bone. A little lower down, and near the inner side of the ridge, there is sometimes seen such another channel, which is intended for the same purpose. The os humeri, at its lower extremity, becomes gradually broader and flatter, so as to have this end nearly of a triangular shape. The bone, thus expanded, affords two surfaces, of which the anterior one is the broadest, and somewhat convex, and the posterior one narrower and smoother. The bone terminates in four large processes, the two outermost of which are called *condyles*, though not designed for the articulation of the bone. These condyles, which are placed at some distance from each other, on each side of the bone, are rough and irregular protuberances, formed for the insertion of muscles and ligaments, and differ from each other in size and shape. The external condyle, when the arm is in the most natural position, is found to be placed somewhat forwarder than the other. The internal condyle is longer, and more protuberant, than the external. From each of these processes, a ridge is continued upwards, at the side of the bone. In the interval between the two condyles are placed the two articulating processes, contiguous to each other, and covered with cartilage. One of these, which is the smallest, is formed into a small, obtuse, smooth head, on which the radius plays. This little head is placed near the external condyle, as a part of which it has been sometimes described. The other, and larger process, is composed of two lateral protuberances and a middle cavity, all of which are smooth and covered with cartilage. From the manner in which the ulna moves upon this process, it has the name of *trochlea*, or pulley. The sides of this pulley are unequal: that which is towards the little head is the highest of the two; the other, which is contiguous to the external condyle, is more slanting, being situated obliquely from within outwards, so that when the fore-arm is fully extended it does not form a straight line with the os humeri; and, for the same reason, when we bend the elbow, the hand comes not to the shoulder, as it might be expected to do, but to the fore-part of the breast. There is a cavity at the root of these processes, on each of the two surfaces of the bone. The cavity on the anterior surface is divided by a ridge into two, the external of which receives the end of the radius, and the internal one lodges the coronoid process of the ulna in the flexions of the fore-arm. The cavity on the posterior surface, at the basis of the pulley, is much larger, and lodges the olecranon when the arm is extended. The internal structure of the os humeri is similar to that of other long bones. In new-born infants, both the ends of the bone are cartilaginous, and the large head, with the two tubercles above, and the condyles, with the two articulating processes below, become epiphyses before they are entirely united to the rest of the bone.

HU'MILIS. (From *humi*, on the ground: so named, because it turns the eye downwards, and is expressive of humility.) A name of the inferior straight muscle of the eye. See *Rectus inferior oculi*.

HU'MOR. (*or, oris.* m.; *ab humo*, from the ground: because moisture springs from the earth.) Humour, a general name for any fluid of the body except the blood.

Humor vitreus. The vitreous humour of the eye, so called from its glassy appearance. See *Oculus*.

HUMORAL PATHOLOGY. That pathology which attributed all diseases to disordered states of the fluids, without taking the solids into consideration. It originated with the Greeks, and was universally prevalent till the beginning of last century. We appear now to have run into the opposite extreme, and not

to pay sufficient attention to the state of the fluids in disease.

Humoric. This name is given by M. Piorry to the sound produced by percussion on the stomach, when it is distended with air and liquid.

Humour. See *Humor.*

Humour, aqueous. See *Aqueous humour.*

Humour, vitreous. See *Humor vitreus.*

Humours, cardinal. See *Cardinal humours.*

Humours of the eye. See *Oculus.*

HU'MULIN. The narcotic principle of the hop. See *Humulus.*

HU'MULUS. (*us, i.* m.; from *humus*, the ground: so named because, without factitious support, it creeps along the ground.) The name of a genus of plants in the Linnæan system. Class, *Diœcia;* Order, *Pentandria.* The hop.

Humulus lu'pulus. The systematic name of the hop plant: called also *Lupulus*, and *Convolvulus perennis.* The hop is the floral leaf or bractea of this plant: it is dried and used in various kinds of strong beer. Hops have a bitter taste, less ungrateful than most of the other strong bitters, accompanied with some degree of warmth and aromatic flavour, and are highly intoxicating. The hop-flower exhales a considerable quantity of its narcotic power in drying; hence those who sleep in the hop-houses are with difficulty roused from their slumber. A pillow stuffed with these flowers is said, in some instances, to have induced sleep when other remedies had failed. The young sprouts, called hop-tops, if plucked when only a foot above the ground, and boiled, are eaten like asparagus, and are a wholesome delicacy. The scales of the hop secrete a yellow powder, which is easily separable by means of a fine sieve. According to the experiments of Dr. Ives, of New York, this substance is the active principle of the hop, and is accordingly named *Lupulin.*

HUNGER. *Fames.* The want of solid aliments is characterised by a peculiar sensation in the region of the stomach, called hunger, and by a general feebleness, more or less marked. This feeling is generally renewed after the stomach has been for some time empty: it is variable in its intensity and its nature in different individuals, and even in the same individual. In some its violence is excessive; in others it is scarcely felt: some never feel it, and eat only because the hour of repast is come. Many persons perceive a drawing, a pressure more or less painful in the epigastric region, accompanied by yawnings, and a particular noise, produced by the gases contained in the stomach, which becomes contracted. When this want is not satisfied it increases, and may become a severe pain: the same takes place with the sensation of weakness and general fatigue, which is felt, and which may increase, so as to render the motions difficult, or even impossible.

Authors distinguish in hunger local and general phenomena. This distinction is good in itself, and may be useful for study: but have not mere gratuitous suppositions been described as local or general phenomena of hunger, the existence of which was rendered probable by this theory? This point of physiology is one of those in which the want of direct experiment is the most strongly felt. The pressure and contraction of the stomach are considered amongst the local phenomena of hunger. "The sides of that viscus," it is said, "become thicker: it changes its form and situation, and draws the duodenum a little towards it; its cavity contains saliva mixed with air, mucosities, bile, which has regurgitated in consequence of the dragging of the duodenum; the quantity of these humours increases in the stomach in proportion as hunger is of longer continuation. The cystic bile does not flow into the duodenum; it collects in the gall-bladder, and becomes abundant and black according to the continuance of abstinence. A change takes place in the order of the circulation of the digestive organs: the stomach receives less blood, perhaps on account of the flexion of these vessels, which is then greater; perhaps by the compression of the nerves, in consequence of this confinement, the influence of which upon the circulation will then be diminished. On the other hand, the liver, the spleen, the epiploon, receive more, and perform the office of *diverticula:* the liver and the spleen, because they are less supported when the stomach is empty, and then present a more easy access to the blood; and the epiploon, because the vessels are then less *flexuous,*" &c. The most of these data are mere conjectures, and nearly devoid of proof. After twenty-four, forty-eight, and even sixty hours of complete abstinence, Dr. Magendie says, he never saw the contraction and pressure of the stomach of which some authors speak; this organ has always presented to him very considerable dimensions, particularly in its splenic extremity: it was only after the fourth and fifth day that it appeared to return upon itself, to diminish much in size, and slightly in position: even these effects are not strongly marked, unless fasting has been very strictly observed.

Bichât thinks that the pressure sustained by the empty stomach is equal to that which it supports when distended by aliments, since, says he, the sides of the abdomen are compressed in proportion as the volume of the stomach diminishes. The contrary of this may be easily proved by putting one or two fingers into the abdominal cavity, after having made an incision in its sides: it will then be easily seen that the pressure sustained by the viscera is, in a certain degree, in direct proportion to the distension of the stomach: if the stomach is full, the finger will be stronger pressed, and the viscera will press outward to escape through the opening; if it is empty the pressure will be very trifling, and the viscera will have little tendency to pass out from the abdominal cavity. It must be understood, that in this experiment the pressure exerted by the abdominal muscles, when they are relaxed, ought not to be confounded with that which they exert when contracted with force. Also, when the stomach is empty, all the reservoirs contained in the abdomen are more easily distended by the matters which remain some time in them. Perhaps this is the principal reason why bile then accumulates in the gall-

bladder. With regard to the presence of bile in the stomach, that some persons regard as the cause of hunger: unless in certain sickly cases, bile does not enter it, though it continues to flow into the small intestine.

The quantity of mucus that the cavity of the stomach presents is so much greater in proportion to the prolongation of fasting.

Relatively to the quantity of blood which goes to the stomach when empty, in proportion to the volume of its vessels, and the mode of circulation which then exists, the general opinion is, that it receives less of this fluid than when it is full of aliments; but, far from being in this respect in opposition with the other abdominal organs, this disposition appears to be common to all the organs contained in the abdomen.

To the general phænomena of hunger is ascribed a weakness and diminution of the action of all the organs: the circulation and the respiration become slow, the heat of the body lowers, the secretions diminish, the whole of the functions are exerted with more difficulty. The absorption alone is said to become more active, but nothing is strictly demonstrated in this respect.

Hunger, appetite itself, which is only its first degree, ought to be distinguished from that feeling which induces us to prefer one sort of food to another, from that which causes us, during a repast, to choose one dish rather than another, &c.

These feelings are very different from real hunger, which expresses the true wants of the economy; they, in a great measure, depend on civilisation, on habits, and certain ideas relative to the properties of aliments. Some of them are in unison with the season and climate, and then they are equally legitimate as hunger itself; such is that which inclines us to a vegetable regimen in hot countries, or during the heats of summer.

Certain circumstances render hunger more intense, and cause it to return at nearer intervals: such as a cold and dry air, winter, spring, cold baths, dry frictions upon the skin, exercise on horseback, walking, bodily fatigue, and generally all the causes that put the action of the organs in play, and accelerate the nutritive process with which hunger is essentially connected. Some substances, being introduced into the stomach, excite a feeling like hunger, but which ought not to be confounded with it.

There are causes which diminish the intensity of hunger, and which prolong the periods at which it habitually manifests itself: amongst this number are the inhabiting of hot countries and humid places, rest of the body and mind, depressing passions, and, indeed, all the circumstances that interrupt the action of the organs, and diminish the activity of nutrition. There are also substances which, being brought into the digestive canals, prevent hunger, or cause it to cease; as opium, hot drinks, &c.

With respect to the cause of hunger, it has been, by turns, attributed to the providence of the vital principle, to the frictions of the sides of the stomach against each other, to the dragging of the liver upon the diaphragm, to the action of bile upon the stomach, to the acrimony and acidity of the gastric juice, to fatigue of the contracted fibres of the stomach, to compression of the nerves of this viscus, &c. &c.

Hunger arises, like all other internal sensations, from the action of the nervous system; it has no other seat than this system itself, and no other causes than the general laws of organisation. What very well proves the truth of this assertion is, that it sometimes continues though the stomach is filled with food; that it cannot be produced, though the stomach has been sometime empty; lastly, that it is so subject to habit as to cease spontaneously after the habitual hour of repast is over. This is true not only of the feeling which takes place in the region of the stomach, but also of the general weakness that accompanies it, and which, consequently, cannot be considered as real, at least in the first instant in which it is manifested.

Hurtsickle. (So called because it is troublesome to cut down, and sometimes notches the sickle.) See *Centaurea cyanus.*

Husk. See *Gluma.*

Husson's Eau médicinale. See *Eau médicinale.*

HY'ACINTH. *Hyacinthus.* A gem much prized by jewellers. It is a subspecies of pyramidal zircon. It was formerly esteemed in medicine as an antispasmodic and cordial.

HYACI'NTHUS. (*us, i.* m.; said by the poets to be named from the friend of Apollo, who was turned into this flower.) The name of a genus of plants. Class, *Hexandria;* Order, *Monogynia.*

Hyacinthus mu'scari. *Muscari.* The systematic name of the musk-grape flower, which, according to Ray, possesses emetic and diuretic qualities.

Hyacinthus non scriptus. See *Scilla nutans.*

HY'ALOID. (*Hyaloides;* from ὑαλος, glass, and εἰδος, likeness.) Transparent, like glass.

Hyaloid membrane. The capsule of the vitreous humour. See *Oculus.*

HYBERNA'CULUM. (*um, i.* n.) This is defined by Linnæus to be a part of the plant which protects the embryo herb from external injuries. It is an organic body which sprouts from the surface of different parts of a plant, enclosing the rudiments of the new shoot, and which is capable of evolving a new individual perfectly similar to the parent. This is a modification of the definition of Gærtner.

Hybo'ma. Ὑβωμα. A gibbosity of the spine.

HY'BRID. (*Hybrida, æ.* m.; from ὑβρις, an injury: because its nature is tainted.) The offspring of two animals or plants of a different species. Neither the hybrid animal, nor hybrid plants, propagate their species.

HYDA'RTHRUS. (*us, i.* m.; from ὑδωρ, water, and αρθρον, a joint.) This disease, called also *hydarthron,* and *hydarthros,* by the Greeks, and *spina ventosa* by the Arabian physicians, is by us termed, from its colour, a white swelling. In this country it is a very common and an extremely intractable and fatal disease. The varieties of white swelling are very numerous, and might usefully receive particular appellations

Systematic writers have generally been content with a distinction into two kinds, viz. *rheumatic* and *scrophulous*. The last species of the disease they also distinguish into such tumours as primarily affect the bones, and the ligaments and soft parts; and into other cases, in which the ligaments and soft parts become diseased before there is any morbid affection of the bones.

These divisions, Mr. Samuel Cooper, in his Treatise on the Diseases of the Joints, proves to be not sufficiently comprehensive; and the propriety of using the term *rheumatic* he thinks to be very questionable.

The knee, ankle, wrist, and elbow are the joints most subject to white swellings. As the name of the disease implies, the skin is not at all altered in colour. In some instances the swelling yields, in a certain degree, to pressure; but it never pits, and is almost always sufficiently firm to make an uninformed examiner believe that the bones contribute to the tumour. The pain is sometimes vehement from the very first; in other instances, there is hardly the least pain in the beginning of the disease. In the majority of scrophulous white swellings, let the pain be trivial or violent, it is particularly situated in one part of the joint, viz., either *the centre of the articulation*, or the *head of the tibia*, supposing the knee affected. Sometimes the pain continues without interruption; sometimes there are intermissions; and in other instances the pain recurs at regular times, so as to have been called, by some writers, periodical. Almost all authors describe the patient as suffering more uneasiness in the diseased part when he is warm, and particularly when he is in this condition in bed.

At the commencement of the disease, in the majority of instances, the swelling is very inconsiderable, or there is even no visible enlargement whatever. In the little depressions, naturally situated on each side of the patella, a fulness first shows itself, and gradually spreads all over the affected joint.

The patient, unable to bear the weight of his body on the disordered joint, in consequence of the great increase of pain thus created, gets into the habit of only touching the ground with his toes: and the knee being generally kept a little bent in this manner, soon loses the capacity of becoming extended again. When white swellings have lasted a while, the knee is almost always found in a permanent state of flexion. In scrophulous cases of this kind, pain constantly precedes any appearance of swelling; but the interval between the two symptoms differs very much in different subjects.

The morbid joint, in the course of time, acquires a vast magnitude. Still the integuments retain their natural colour, and remain unaffected. The enlargement of the articulation, however, always seems greater than it really is, in consequence of the emaciation of the limb both above and below the disease.

An appearance of blue distended veins, and a shining smoothness, are the only alterations to be noticed in the skin covering the enlarged joint. The shining smoothness seems attributable to the distention which obliterates the natural furrows and wrinkles of the cutis. When the joint is thus swollen, the integuments cannot be pinched up into a fold, as they could in the state of health, and even in the beginning of the disease.

As the distemper of the articulation advances, collections of matter form about the part, and at length burst. The ulcerated openings sometimes heal up; but such abscesses are generally followed by other collections, which pursue the same course. In some cases, these abscesses form a few months after the first affection of the joint; on other occasions, several years elapse, and no suppuration of this kind makes its appearance.

Such terrible local mischief must necessarily produce constitutional disturbance. The patient's health becomes gradually impaired; he loses both his appetite and natural rest and sleep; his pulse is small and frequent; and obstinate debilitating diarrhœa and profuse nocturnal sweats ensue. Such complaints are sooner or later followed by dissolution, unless the constitution be relieved in time, either by the amendment or removal of the diseased part. In different patients, however, the course of the disease, and its effects upon the system, vary very much in relation to the rapidity with which they occur.

Rheumatic white swellings are very distinct diseases from the *scrophulous distemper* of large joints. In the first, the pain is said never to occur without being attended with swelling. Scrophulous white swellings, on the other hand, are always preceded by a pain, which is particularly confined to one point of the articulation. In rheumatic cases, the pain is more general, and diffused over the whole joint.

With respect to the particular causes of all such white swellings as come within the class of rheumatic ones, little is known. External irritation, either by exposure to damp or cold, or by the application of violence, is often concerned in bringing on the disease; but very frequently no cause of this kind can be assigned for the complaint. As for scrophulous white swellings, there can be no doubt that they are under the influence of a particular kind of constitution, termed a *scrophulous* or *strumous* habit. In this sort of temperament, every cause capable of exciting inflammation, or any morbid and irritable state of a large joint, may bring such disorders as may end in the severe disease of which we are now speaking.

In a man of a sound constitution, an irritation of the kind alluded to might only induce common healthy inflammation of the affected joint.

In scrophulous habits, it also seems probable that the irritation of a joint is much more easily produced than in the other constitutions; and no one can doubt that, when once excited in scrophulous habits, it is much more dangerous and difficult of removal than in other patients.

HYDA'TID. (*Hydatis, idis.* f.; from ὑδωρ, water.) 1. The name of a genus of entozoary animals, which are characterised by being formed of a membrane containing a water-like fluid. See *Entozoa*.

2. A tumour or vesicle, consisting of a membrane distended with a water-like fluid.

HY'DERUS. (Ὑδερος; from ὑδωρ, water.) In a general sense, the Greek writers use this word for *dropsy*. Galen uses the phrase λευκοφλεγματιας ὑδερος for *anasarca*; and, according to the editors of Castelli, ὑδερος προς αμιδα, *hydrops ad matulam*, signifies *diabetes*.

HY'DNUM. (*um, i.* n.) A genus of the Order *Fungi*; Class, *Cryptogamia*. Some of the species of this genus of mushrooms are eaten on the Continent; all the dark-coloured, with spots on their underscarf, are to be suspected as poisonous. The species occasionally used are the following: —

1. *Hydnum crinaceum*. The hedgehog mushroom.
2. *Hydnum coralloides*.
3. *Hydnum caput Medusæ*, *Fungo istrice*, and two other undetermined analogous species; but not the *Caput Medusæ* of Paulet, which is poisonous.
4. *Hydnum repandum*. The *chevrette*.
5. *Hydnum auriscalpium*. *Brouquichons*, which is said to be excellent.

HY'DRAGOGUE. (*Hydragogus*; from ὑδωρ, water, and αγω, to drive out.) A medicine is so termed, which possesses the property of increasing the secretions or excretions of the body, so as to cause the removal of water from any of its cavities. The term is chiefly applied to catharties which have this effect, as jalap, gamboge, &c.

HYDRARGYRA'TUS. Of or belonging to mercury.

HYDRA'RGYRI ACETAS. Acetate of mercury: called also *Mercurius acetatus*, and *Pilulæ Keyseri*. By this preparation of mercury, the celebrated Keyser acquired an immense fortune in curing the venereal disease. The dose is from three to five grains. Notwithstanding the encomium given to it by some, it does not appear to be so efficacious as some other preparations of mercury.

HYDRA'RGYRI AMMIO'NIO-CHLO'RIDUM. *Hydrargyrum præcipitatum album. Calx hydrargyri alba.* Take of bichloride of mercury, six ounces; solution of ammonia, eight fluid ounces. Dissolve the bichloride of mercury in the water, by the aid of heat, and add to this, when cold, the solution of ammonia, frequently stirring the mixture. Wash the precipitated powder till it become tasteless, and then dry it. The product of this process is an insoluble submuriate of mercury and ammonia. It is only used externally, in ointments for some cutaneous affections.

HYDRA'RGYRI BICHLO'RIDUM. *Oxymurias hydrargyri. Hydrargyrus muriatus. Murias hydrargyri corrosivus. Mercurius sublimatus corrosivus. Mercurius corrosivus albus.* Oxymuriate of mercury. Bichloride of mercury. Take of mercury, two pounds; sulphuric acid, three pounds; chloride of sodium, a pound and a half. Boil the mercury with the sulphuric acid in a proper vessel until the sulphate of mercury shall be left dry. Rub this, when it is cold, with the chloride of sodium in an earthenware mortar; then sublime with a heat gradually increased. An extremely acrid and violently poisonous preparation.

Given internally, in small doses, it possesses antisyphilitic and alterative virtues, and is of great use in some chronic and cutaneous affections, especially lepra. Externally, applied in form of lotion, it facilitates the healing of venereal sores, and cures the itch. In gargles for venereal ulcers in the throat, the oxymuriate of mercury gr. iii. or iv., barley decoction ℔ j., honey of roses ʒ ij., proves very serviceable; also in cases of tetters, from gr. v. to gr. x. in water ℔ j.; and for films and ulcerations of the cornea, gr. j. to water ʒ iv.

Mr. Pearson remarks, that, "when the sublimate is given to cure the primary symptoms of syphilis, it will sometimes succeed; more especially when it produces a considerable degree of soreness of the gums, and the common specific effects of mercury in the animal system. But it will often fail in removing even a recent chancre; and where that symptom has vanished, during the administration of corrosive sublimate, I have known," says he, "a three months' course of that medicine fail of securing the patient from a constitutional affection. The result of my observation is, that simple mercury, calomel, or calcined mercury, are preparations more to be confided in for the cure of primary symptoms than corrosive sublimate. The latter will often check the progress of secondary symptoms very conveniently; and I think it is peculiarly efficacious in relieving venereal pains, in healing ulcers of the throat, and in promoting the desquamation of eruptions. Yet, even in these cases, it never confers permanent benefit; for new symptoms will appear during the use of it; and on many occasions it will fail of affording the least advantage to the patient from first to last. I do sometimes, indeed, employ this preparation in venereal cases; but it is either at the beginning of a mercurial course, to bring the constitution under the influence of mercury at an early period, or during a course of inunction, with the intention of increasing the action of simple mercury. I sometimes also prescribe it after the conclusion of a course of friction, to support the mercurial influence in the habit, in order to guard against the danger of a relapse. But on no occasion whatever is it safe to confide in this preparation singly and uncombined for the cure of any truly venereal symptoms.

The bichloride of mercury may be given in a liquid form, or made into pills with bread crumb. The dose is from an eighth to a fourth of a grain twice a day.

A solution of it is ordered in the Pharmacopœia, termed *Liquor hydrargyri bichloridi*, which is made by dissolving bichloride of mercury and hydrochlorate of ammonia, of each ten grains, in a pint of distilled water.

This solution is directed in order to facilitate the administration of divisions of the grain of this active medicine. Half an ounce of it contains one fourth of a grain of the salt. The dose is from one drachm to half an ounce.

HYDRA'RGYRI BICYA'NIDUM. Bicyanide of mercury. Take of percyanide of iron, eight

ounces; binoxide of mercury, ten ounces; distilled water, four pints: boil them together for half an hour, and strain. Evaporate the liquor that crystals may form. Wash what remains frequently with boiling distilled water, and again evaporate the mixed liquors that crystals may form.

Bicyanide of mercury may also be prepared by adding as much binoxide of mercury as will exactly saturate it, to hydrocyanic acid distilled from ferrocyanide of potassium with diluted sulphuric acid.

In the first of these processes, the cyanogen quits the iron and unites with the mercury, while the oxygen, leaving the mercury, unites with the iron. In the second process, the oxygen of the binoxide unites with the hydrogen of the hydrocyanic acid, and the cyanogen combines with the mercury. The bicyanide of mercury is used for the preparation of hydrocyanic acid. See *Hydrocyanic acid.*

Hydrargyri biniodidum. Biniodide of mercury. Take of mercury, an ounce; iodine, ten drachms; alkohol as much as may be sufficient. Rub the mercury and iodine together, adding the alkohol gradually, until the globules disappear. Dry the powder with a gentle heat, and keep it in a well-stopped vessel.

The biniodide of mercury is of a red colour, approaching to scarlet; it is easily fusible, and sublimes in rhombic scales, which are yellow at first, but become red on cooling. It is insoluble in water. It is soluble in some acids, and in heated alkohol.

This salt consists of two equivalents of iodine, and one of mercury.

It has been used in scrofulous and syphilitic affections, in doses of gr. ss. to gr. j. It has also been applied as an ointment.

Hydrargyri bino'xydum. *Oxydrum hydrargyri rubrum. Hydrargyrus calcinatus.* Binoxide of mercury. Red oxide of mercury. Take of bichloride of mercury four ounces, solution of potash twenty-eight fluid ounces, distilled water six pints. Dissolve the bichloride in the water, strain, and add the solution of potash. Pour off the liquor, wash the precipitate till nothing alkaline can be perceived, and dry it with a gentle heat. This preparation of mercury is given with great advantage in the cure of syphilis. Its action, however, is such, when given alone, on the bowels, as to require the addition of opium, which totally prevents it. It is also given in conjunction with opium and camphire, as a diaphoretic, in chronic pains and diseases of long continuance. It is given as an alterative and diaphoretic, in chronic pains and diseases of long continuance. It is given as an alterative and diaphoretic from gr. ss. to ij. every night, joined with camphire and opium, each gr. one fourth or one half. It is violently emetic and cathartic in the dose of gr. iv. to gr. v.

Hydrargyri chlo'ridum. *Hydrargyri submurias. Calomelas. Mercurius dulcis sublimatus. Sublimatum dulce.* Calomel. Take of mercury, four pounds; sulphuric acid, three pounds; chloride of sodium, one pound and a half; distilled water as much as may be sufficient. Boil two pounds of the mercury with the sulphuric acid in a proper vessel, until the sulphate of mercury is dry; when this is cold, triturate it with two pounds of mercury, in an earthen mortar, that they may be perfectly mixed. Then add the chloride of sodium, and rub them together until all globules disappear; afterwards sublime. Reduce the sublimed matter to a very fine powder, and wash it carefully with boiling distilled water, and dry it.

Calomel is the most extensively useful of all the preparations of mercury, and its virtues are too well known to require any particular description here. As a purgative, it has a power of correcting morbid states of the abdominal secretions which is not possessed by any other medicine of that class. As a mercurial, it is applicable in a larger number of cases than, perhaps, any other. Its operation is variously modified by combination with opium, antimony, purgatives, &c. The dose is from one grain to twenty, according to the intention with which it is given.

Hydrargyri iodi'dum. Take of mercury, an ounce; iodine, five drachms; alkohol as much as may be sufficient. Rub the mercury and iodine together, until the globules disappear. Dry the powder immediately, with a gentle heat, without the access of light, and keep it in a well-stopped vessel.

The iodide of mercury is a greenish yellow powder. It is insoluble in water. It is decomposed by exposure to light or heat, being resolved into mercury and biniodide; when quickly heated, however, it sublimes nearly or quite unchanged.

Iodide of mercury is composed of one equivalent of iodine, and one equivalent of mercury.

It has been given internally in scrophulous cases, in the dose of from gr. j. to gr. iij.; but it is chiefly employed in the form of ointment.

Hydrargyri nitrico-oxydum. *Nitrico-oxydum hydrargyri. Hydrargyrus nitratus ruber. Mercurius corrosivus ruber. Mercurius præcipitatus corrosivus.* Nitric oxide of mercury. Red precipitate. Take of purified mercury, by weight, three pounds; of nitric acid, by weight, a pound and a half; of distilled water two pints. Mix in a proper vessel, and apply a gentle heat, until the mercury be dissolved. Evaporate the liquor, and pulverise what remains. Put this into another shallow vessel, then apply a moderate heat, and raise the fire gradually, until red vapour shall cease to rise. This preparation is very extensively employed by surgeons as a stimulant and escharotic; but its extraordinary activity does not allow of its being given internally. Finely levigated, and mixed with common cerates, it is an excellent application to indolent ulcers, especially those which remain after burns and scalds, and those in which the granulations are indolent and flabby. It is also an excellent caustic application to chancres.

Hydrargyri oxydum. *Oxydum hydrargyri cinereum. Oxydum hydrargyri nigrum.* The gray or black oxide of mercury. It has received several names: *Æthiops per se; Pulvis mercurialis cinereus; Mercurius cinereus; Turpethum nigrum; Mercurius præcipitatus niger.* Take

of chloride of mercury, an ounce; lime-water, a gallon. Mix them and agitate frequently. Set the mixture aside, and when the oxide has subsided, pour off the liquor. Lastly, wash the precipitate till it be perfectly free from lime, and dry it in the air wrapped in bibulous paper The dose is from gr. ij. to x. There are four other preparations of this oxide in high estimation: —

One made by rubbing mercury with mucilage of gum arabic. Plenk, of Vienna, has written a treatise on the superior efficacy of this medicine. It is very troublesome to make; and does not appear to possess more virtues than some other mercurial preparations. Another made by triturating equal parts of sugar and mercury together. The third, composed of honey or liquorice and purified mercury. The fourth is the blue mercurial ointment. These preparations possess anthelmintic, antisyphilitic, alterative, sialagogue, and deobstruent virtues, and are used in the cure of worms, syphilis, amenorrhœa, diseases of the skin, chronic diseases, obstructions of the viscera, &c.

Hydrargyri oxydum cinereum. See *Hydrargyri oxydum.*

Hydrargyri oxydum nigrum. See *Hydrargyri oxydum.*

Hydrargyri submurias. See *Hydrargyri chloridum.*

Hydrargyri sulphas. See *Hydrargyrum vitriolatum.*

Hydrargyri sulphuretum nigrum. *Hydrargyrus cum sulphure.* Æthiop's mineral. Take of purified mercury, sublimed sulphur, each a pound, by weight. This preparation is called *Hydrargyri sulphuretum cum sulphure* in the last London Pharmacopœia of 1836. Rub them together, till the metallic globules disappear. Some suppose that the mercury is oxidised in this process, but that is not confirmed by the best experiments. The mercury, by this admixture of the sulphur, is deprived of its salivating power, and may be administered with safety to all ages and constitutions, as an anthelmintic and alterative.

Hydrargyri sulphuretum rubrum. Red sulphuret of mercury. *Hydrargyrus sulphuratus ruber. Minium purum. Minium Græcorum. Magnes epilepsiæ. Alzemafor. Amnion. Azamar.* Vitruvius calls it *anthrax.* A red mineral substance composed of mercury combined with sulphur. It is either native or factitious.

1. The *native* is an ore of quicksilver moderately compact, and of an elegant striated red colour. It is found in the duchy of Deuxponts, in the Palatine, in Spain, South America, &c. It is called native vermilion, and cinnabar in flowers.

2. The *factitious* is thus prepared: — "Take of mercury, two pounds; sulphur, five ounces. Having melted the sulphur over the fire, mix in the mercury, and as soon as the mass begins to swell, remove the vessel from the fire, and cover it with considerable force to prevent inflammation; then rub the mass into powder, and sublime." This preparation is called *Hydrargyri bisulphuretum* in the London Pharmacopœia of 1836. It is esteemed a mild mercurial alterative, and given to children in small doses. Hoffmann greatly recommends it as a sedative and antispasmodic. Others deny that cinnabar, taken internally, has any medicinal quality; and their opinion is grounded on the insolubility of it in any menstruum. In surgery its chief and almost only use is in the administration of quicksilver by fumigation. Thus employed it has proved extremely serviceable in venereal cases. Ulcers and excrescences about the pudendum and anus in women are particularly benefited by it; and in these cases it is most conveniently applied by placing a red-hot heater at the bottom of a night stool-pan, and, after sprinkling on it a few grains of the red sulphuret of quicksilver, placing the patient on the stool. To fumigate ulcers in the throat, it is necessary to receive the fumes on the part affected, through the tube of a funnel. By enclosing the patient naked in a box, it has, on some occasions, been contrived to fumigate the whole body at once, and in this way the specific operation of the quicksilver has been very rapidly produced.

This mode of curing the lues venerea is spoken of as confirmed, in a treatise by Sabonette, and by trials made in Bartholomew's hospital.

Mr. Pearson, from his experiments on mercurial fumigation, concludes, that where checking the progress of the disease suddenly is an object of great moment, and where the body is covered with ulcers or large and numerous eruptions, and in general to ulcers, fungi, and excrescences, the vapour of mercury is an application of great efficacy and utility; but that it is apt to induce a ptyalism rapidly, and great consequent debility, and that for the purpose of securing the constitution against a relapse, as great a quantity of mercury must be introduced into the system, by inunction, as if no fumigation had been employed.

HYDRARGY'RIA. (*a, æ.* f.; so called because produced by hydrargyrus.) A name, in some writings, of the erythematous redness which mercury sometimes produces. See *Eczema.*

HYDRA'RGYRUM. (*um, i.* n. Ὑδραργυρος; from ὑδωρ, water, and αργυρος, silver: so named, from its having a resemblance to fluid silver.) *Hydrargyrus.* Quicksilver. A metal of great importance in the arts, and the compounds of which are very extensively used in medicine. See *Mercury.*

Hydrargyrum acetatum. See *Hydrargyri acetas.*

Hydrargyrum cum creta. Mercury with chalk. *Mercurius alkalizatus.* Take of purified mercury, by weight, three ounces; prepared chalk, five ounces. Rub them together, until the metallic globules disappear. This preparation is milder than any other mercurial except the sulphuret, and does not so easily act upon the bowels; it is therefore used largely by many practitioners, and possesses alterative properties in cutaneous and venereal complaints, in obstructions of the viscera, or of the prostate gland, given in the dose of ℈ss. to ʒss., two or three times a day.

HYDRARGYRUM PHOSPHORATUM. This remedy has been observed to heal inveterate venereal ulcers in a very short time, nay, in the course of a very few days, particularly those about the pudenda. In venereal inflammations of the eyes, chancres, rheumatisms, and chronic eruptions, it has proved of eminent service. Upon the whole, if used with necessary precaution, and in the hands of a judicious practitioner, it is a medicine mild and gentle in its operation. The cases in which it deserves the preference over other mercurial preparations are these: in an inveterate stage of syphilis, particularly in persons of torpid insensible fibres; in cases of exostosis, as well as obstructions in the lymphatic system; in chronic complaints of the skin. The following is the formula. ℞ Hydrargyri phosphorati, gr. iv. Corticis cinnamomi in pulverem triti, gr. xiv. Sacchari purif. ʒ ss. Misce. The whole to be divided into eight equal parts, one of which is to be taken every morning and evening, unless salivation takes place, when it ought to be discontinued. Some patients, however, will bear from one to two grains of the phosphate of quicksilver, without inconvenience.

Hydrargyrum præcipitatum album. See *Hydrargyri ammonio-chloridum.*

HYDRARGYRUM PRÆCIPITATUM CINEREUM. This preparation is an oxide of mercury, nearly the same with the *hydrargyri oxydum* of the London Pharmacopœia. It is used as an alterative in cases of pains arising from an admixture of rheumatism with syphilis. It may be substituted for the hydrargyrus sulphuratus ruber, in fumigating ozæna, and venereal ulcerated sore throat, on account of its not yielding any vapour offensive to the patient.

HYDRARGYRUM PURIFICATUM. Purified mercury. *Argentum vivum purificatum.* Take of mercury, by weight, six pounds; iron filings, a pound. Rub them together, and distil the mercury from an iron retort, by the application of heat to it. Purified quicksilver is sometimes administered in its metallic state, in doses of an ounce or more, in constipation of the bowels.

Hydrargyrum vitriolatum. See *Subsulphas hydrargyri flavus.*

HY′DRATE. A compound in which water is chemically combined with some other substance. Thus, when water is poured upon quicklime, the water disappears, and the properties of the lime are modified; the slaked lime which results is a *hydrate of lime.*

HY′DRATED. Chemically combined with water.

HYDRELÆ′UM. (*um, i.* n.; from ὑδωρ, water, and ελαιον, oil.) A mixture of oil and water.

HYDRE′NTEROCE′LE. (*e, es.* f.; from ὑδωρ, water, εντερον, an intestine, and κηλη, a tumour.) A hydrocele, or dropsy of the scrotum, attended with an intestinal hernia.

HYDRI′ODATE. *Hydriodas.* A compound of the hydriodic acid with a salifiable base.

HY′DRIO′DIC ACID. *Acidum hydriodicum.* If four parts of iodine be mixed with one of phosphorus, in a small glass retort, applying a gentle heat, and adding a few drops of water from time to time, a gas comes over, which must be received in the mercurial bath. This is hydriodic acid in a gaseous form.

An aqueous hydriodic acid can easily be obtained, very economically, by passing sulphuretted hydrogen gas through a mixture of water and iodine in a Woolf's bottle. On heating the liquid obtained, the excess of sulphur flies off, and leaves liquid hydriodic acid. Hydriodic acid may also be formed by passing hydrogen over iodine at an elevated temperature.

The compounds of hydriodic acid with the salifiable bases are called hydriodates, and may be easily formed, either by direct combination, or by acting on the basis in water with iodine.

None of these salts have yet been applied to any medical purpose, except the hydriodates of potash, soda, and zinc, which are used as external applications to scrophulous tumours.

Hydriodate of potash. See *Potassæ hydriodas.*

Hydriodate of soda. See *Sodæ hydriodas.*

HYDRO′A. (*a, æ.* f.; from ὑδωρ, water.) A watery pustule.

HY′DROBRO′MATE. A salt formed by the hydrobromic acid with a base.

HY′DROBRO′MIC ACID. *Acidum hydrobromicum.* An acid composed of equal volumes of hydrogen and bromine. This may be obtained from bromine, water, and phosphorus by a process similar to that from which the hydriodic acid results. The constitution of hydrobromic acid, and its compounds, are analogous to those of the hydrochloric and hydriodic acids.

HY′DROCHLO′RIC ACID. (*Acidum hydrochloricum;* so named from its being a compound of chlorine and hydrogen.) This acid is a compound of equal volumes of chlorine and hydrogen. The following is the process for obtaining it given in the London Pharmacopœia. Take of dried chloride of sodium, two pounds; sulphuric acid, twenty ounces; distilled water, twenty-four fluid ounces. Add the sulphuric acid, previously mixed with twelve fluid ounces of water, to the chloride of sodium in a glass retort. Pour the remainder of the water into a receiver; then, having fitted the retort to it, let the acid distil over into this water by the heat of a sand bath gradually increased. The specific gravity of this acid is stated at 1·10.

When received in glass jars over dry mercury, it is invisible, and possesses all the mechanical properties of air. Its odour is pungent and peculiar; its taste acid and corrosive. The specific gravity of muriatic acid gas, compared with atmospheric air, is 1·269. If an inflamed taper be immersed in it, it is instantly extinguished. It is destructive of animal life; but the irritation produced by it on the epiglottis scarcely permits its descent into the lungs. It is merely changed in bulk by alterations of temperature; it experiences no change of state. Water at the temperature of 40° Fahr. dissolves about 480 times its volume of hydrochloric acid gas, forming liquid acid of specific gravity 1·210.

When potassium, tin, or zinc is heated in contact with this gas over mercury, one half of the volume disappears, and the remainder is pure hydrogen. On examining the solid re-

sidue, it is found to be a metallic chloride. Hence, muriatic acid gas consists of chlorine and hydrogen, united in equal volumes. This view of its nature was originally given by Scheele, though obscured by terms derived from the vague and visionary hypothesis of phlogiston. The French school afterwards introduced the belief that muriatic acid gas was a compound of an unknown radical and water; and that chlorine consisted of this radical and oxygen. Sir H. Davy has proved, by decisive experiments, that, in the present state of our knowledge, chlorine must be regarded as a simple substance, and muriatic acid gas as a compound of it with hydrogen. See *Chlorine*.

In the old process for obtaining muriatic acid, common salt was previously decrepitated, then ground with dried clay, and kneaded or wrought with water to a moderately stiff consistence, after which it was divided into balls of the size of a pigeon's egg: these balls, being previously well dried, were put into a retort, so as to fill the vessel two thirds full; distillation being then proceeded upon, the muriatic acid came over when the heat was raised to ignition. In this process eight or ten parts of clay to one of salt are to be used. The retort must be of stoneware well coated, and the furnace must be of that kind called reverberatory.

It was formerly thought that the salt was merely divided in this operation by the clay, and on this account more readily gave out its acid; but there can be little doubt that the effect is produced by the silicious earth, which abounds in large proportions in all natural clays, and detains the alkali of the salt by combining with it.

Sir H. Davy first gave the just explanation of this decomposition. Common salt is a compound of sodium and chlorine. The sodium may be conceived to combine with the oxygen of the water in the earth, and with the earth itself, to form a vitreous compound; and the chlorine to unite with the hydrogen of the water, forming muriatic acid gas. "It is also easy," adds he, "according to these new ideas, to explain the decomposition of salt by moistened litharge, the theory of which has so much perplexed the most acute chemists. It may be conceived to be an instance of compound affinity: the chlorine is attracted by the lead, and the sodium combines with the oxygen of the litharge, and with water, to form hydrate of soda, which gradually attracts carbonic acid from the air. When common salt is decomposed by oil of vitriol, it was usual to explain the phenomenon by saying, that the acid, by its superior affinity, aided by heat, expelled the gas, and united to the soda. But, as neither muriatic acid nor soda exists in common salt, we must now modify the explanation, by saying that the water of the oil of vitriol is first decomposed, its oxygen unites to the sodium to form soda, which is seized on by the sulphuric acid, while the chlorine combines with the hydrogen of the water, and exhales in the form of muriatic acid gas."

100 parts of dry sea-salt are capable of yielding 62 parts by weight of muriatic acid gas.

The English manufacturers use iron stills for this distillation, with earthen heads: for the purpose of philosophical chemistry, glass should be used.

The muriatic acid of commerce has a straw colour; but this is owing to accidental impurity; for it does not obtain in the acid produced by the impregnation of water with the aëriform acid.

The substances which were formerly regarded as salts of muriatic acid are now considered as *chlorides* of metallic bases, which become muriates or hydrochlorates only when dissolved in water. Combined with nitric acid, it forms the nitro-muriatic acid, or *aqua regia*.

Hydrochloric acid possesses tonic powers. In typhoid fevers, although employed on the Continent with success, it has not proved so beneficial in this country; and, when freely used, it is apt to determine to the bowels. Externally, the muriatic acid has been applied in the form of a bath, to the feet, in gout. When combined with the nitric acid, and diluted with water, it forms the nitro-muriatic bath much celebrated in diseases of the liver and other cases. See *Balneum*.

Hydro-fluoric acid. *Acidum hydrofluoricum*. So called, because it is supposed to be a compound of hydrogen, manna, and fluorine.

This acid was made known by Scheele: the process for procuring it pure was first suggested by Mr. Knight; and its properties were examined by Gay Lussac and Thenard in 1810. When finely powdered *fluoride of calcium*, or *fluor spar* as it is usually called, (carefully selected for its purity,) is distilled with twice its weight of sulphuric acid, a highly volatile and corrosive liquid, which is *hydro-fluoric acid*, is obtained; it acts powerfully on glass and most of the metals: the retort employed in the experiment may be of lead, with a tube and receiver of pure silver; the receiver must be immersed in a mixture of ice and salt. The product is best preserved in a silver bottle, with a well-fitted stopper of the same material. When pure, it is clear and colourless, is very volatile, and smokes when exposed to air: at temperatures above 60° it flies off in vapour. Its specific gravity is 1·0609; but by the gradual addition of a certain proportion of water it acquires a considerable increase of density, the mixture having a specific gravity of 1·25. Its attraction for water exceeds that of sulphuric acid; and when dropped into water it excites a hissing noise, and great heat is evolved. Its vapour is dangerously pungent and irritating, and the liquid acid eminently active upon organic substances; a minute drop of it upon the skin produces a painful sore, and in larger quantities dangerous and malignant ulceration: hence the vessels containing it require to be handled with great caution. Its most characteristic property is the energy with which it acts upon glass: its vapours soon destroy the polish and transparency of all neighbouring glass vessels, and when dropped upon glass, great heat and effervescence are produced, and dense fumes evolved consisting of *fluo-silicic acid*. Diluted with about six parts of water, the acid may be used for *etching upon glass*, which it very effectually accomplishes in a few minutes.

The nature of this powerful and peculiar acid is as yet imperfectly understood, its basis, *fluorine*, not having been obtained in an insulated form. All analogy, however, leads us to regard it as a compound of fluorine and hydrogen. In the voltaic circuit, hydrogen is evolved from it at the negative pole, and the positive platinum wire corroded and converted into a brown compound, probably of fluorine and platinum. Many of the metals also decompose it with the evolution of hydrogen; and peculiar compounds result, *fluorides*, consisting of the metal in combination with fluorine. The action of potassium upon this acid is very energetic; it is attended by explosion, by the liberation of hydrogen, and by the formation of a peculiar soluble saline compound, which is considered as a *fluoride of potassium*.

The hydro-fluoric acid is probably a compound analogous to the other hydracids; that is, constituted of one atom of hydrogen and one of fluorine. This view of its nature, as opposed to its containing oxygen, was first suggested by Ampère, and Davy, and is adopted by Berzelius. "If this acid," he says, "be a hydracid, as we we assume it to be, it will consist of 94·95 fluorine, and 5·05 hydrogen; if, on the other hand, it be a hydrated oxyacid, it consists of 54·34 acid and 45·66 water." Upon the whole, the analogies in favour of the former opinion are too strong to be rejected. — *Brande*.

Hydro-sulphuric acid. *Acidum hydrosulphuricum*. The aqueous solution of sulphuretted hydrogen is so called by Gay Lussac. See *Hydrogen*.

Hydro-sulphurous acid. *Acidum hydrosulphurosum*. When three volumes of sulphuretted hydrogen gas and two of sulphurous acid gas, both dry, are mixed together over mercury, they are condensed into a solid orange yellow body, which Dr. Thompson calls hydro-sulphurous acid.

Hydrocarbonate. See *Carburetted hydrogen*.

Hydroca'rdia. (*a*, *æ*. f.; from ὑδωρ, water, and καρδια, the heart.) *Hydrocordis*. *Hydrops pericardii*. Dropsy of the pericardium. Dropsy of the heart. See *Hydropericardium*.

HY'DROCE'LE. (*e*. *es*, f.; from ὑδωρ, water, and κηλη, a tumour.) The term *hydrocele*, used in a literal sense, means any tumour produced by water; but surgeons have always confined it to those which possess either the membranes of the scrotum, or the coats of the testicle and its vessels. The first of these, viz. that which has its seat in the membranes of the scrotum, *anasarca integumentorum*, is common to the whole bag, and to all the cellular substance which loosely envelopes both the testes. It is, strictly speaking, only a symptom of a disease, in which the whole habit is most frequently more or less concerned, and very seldom affects the part only. The latter, or that which occupies the coats immediately investing the testicle and its vessels, hydrocele tunicæ vaginalis, is absolutely local, very seldom affects the common membrane of the scrotum, generally attacks one side only, and is frequently found in persons who are perfectly free from all other complaints.

The anasarca integumentorum retains the impression of the finger. The vaginal hydrocele has an undulating feel.

The hydrocele of the tunica vaginalis testis is a morbid accumulation of the water separated on the internal surface of the tunica vaginalis, to moisten or lubricate the testicle.

From its first appearance, it seldom disappears or diminishes, but generally continues to increase, sometimes rapidly, at others more slowly. In some it grows to a painful degree of distension in a few months: in others, it continues many years with little disturbance. As it enlarges it becomes more tense, and is sometimes transparent; so that if a candle is held on the opposite side, a degree of light is perceived through the whole tumour; but the only certain distinction is the fluctuation, which is not found when the disease is a hernia of the omentum or intestines, or an inflammatory or a scirrhous tumour of the testicle.

Hydrocele cystata. Encysted hydrocele of the spermatic cord resembles the common hydrocele; but the tumour does not extend to the testicle, which may be felt below or behind it, while in the hydrocele of the vaginal coat, when large, the testicle cannot be discovered. In this disease, also, the penis is not buried in the tumour. Sometimes the fluid is contained in two distinct cells; and this is discovered by little contractions in it. It is distinguished from the anasarcous hydrocele by a sensible fluctuation, and the want of the inelastic pitting; from hernia, by its beginning below, from its not receding in an horizontal position, and not enlarging by coughing and sneezing.

Hydrocele funiculi spermatici, or hydrocele of the spermatic cord. Anasarcous hydrocele of the spermatic cord sometimes accompanies ascites, and at other times it is found to be confined to the cellular substance in or about the spermatic cord. The causes of this disease may be obstructions in the lymphatics, leading from the part, in consequence of scirrhous affections of the abdominal viscera, or the pressure of a truss applied for the cure of hernia.

When the affection is connected with anasarca in other parts, it is then so evident as to require no particular description. When it is local, it is attended with a colourless tumour in the course of the spermatic cord, soft and inelastic to the touch, and unaccompanied with fluctuation. In an erect position of the body, it is of an oblong figure; but when the body is recumbent, it is flatter, and somewhat round. Generally it is no longer than the part of the cord which lies in the groin; though sometimes it extends as far as the testicle, and even stretches the scrotum to an uncommon size. By pressure, a great part of the swelling can always be made to recede into the abdomen. It instantly, however, returns to its former situation, on the pressure being withdrawn.

Hydrocele peritonæi. The common dropsy of the belly, or ascites.

Hydrocele spinalis. A watery swelling on the vertebræ. See *Hydrorachis*.

HYDROCE'PHALUS. (*us*, *i*. m.; from ὑδωρ, water, and κεφαλη, the head.) *Hydro-*

cephalum. *Hydrencephalus*. Dropsy of the brain. Dropsy of the head. It is distinguished by authors into *external* and *internal*; into *hydrocephalus membranarum* and *ventriculorum*; into acute and chronic. Dr. Cullen places the acute form, which has dilated pupils, and symptoms of pressure on the brain, amongst his comatose diseases, as a species of apoplexy, and calls it *Apoplexia hydrocephalica*; and the chronic form amongst the intumescentiæ.

Pain in the head, particularly across the brow, stupor, dilatation of the pupils, nausea, vomiting, preternatural slowness of the pulse, and convulsions, are the pathognomic symptoms of this disease, which have been laid down by the generality of writers.

The effusion of serous fluid, which gives name to this disease, is one of the many symptoms which accompany it. It has been stated, in treating of dropsy, and of the more remarkable divisions of dropsical maladies, that it was necessary to consider the primary and intrinsic causes, as well as the result of preternatural action, and this precaution is above all proper in speaking of hydrocephalus; for here much doubt has always existed as to its nosological arrangement. Pathologists, who have had in view chronic hydrocephalus, with dilatation of the sutures of the cranium, and who have traced this condition to a cachectic or scrofulous diathesis, have classed hydrocephalus with dropsy; but it is more common, with systematic writers on medicine, to regard the effusion as an occasional and secondary matter, and to consider the true disease as altogether an inflammation of the brain and membranes. The last-mentioned explanation of the disease is supported by the most approved teachers, and claims the first attention.

Acute hydrocephalus, in its early stages, is characterised by the symptoms of inflammation of the brain. The head is hot, the face flushed, the eyes dull, and without expression. The arteries of the temples and neck pulsate strongly. The child, for this is chiefly an infantile malady, is restless and fretful, evidently suffering pain, while both the countenance and the gestures refer to the head as its seat. There is pyrexia more or less intense, the pulse is accelerated, the skin hot and dry, and the tongue covered with a white fur. The appetite is lost, and sometimes there is vomiting. The bowels are generally costive.

Although there are occasional instances of hydrocephalus occurring at the age of twelve and fourteen, it is, as has been already remarked, chiefly prevalent among children, and in these from the second to the sixth year. This circumstance, with others, makes the *diagnosis* difficult and important. Dr. Abercrombie remarks, that minute attention to the correspondence of the symptoms is of more consequence than any particular symptom. Thus, the peculiar oppression which accompanies a high degree of fever is not an unfavourable symptom; but the same degree of oppression, occurring without fever, or with a very slight fever, would denote a head affection of much danger: a degree of headach and delirium, accompanying a high fever, would only be symptomatic; but, accompanying slight fever, would indicate a dangerous affection of the brain.

Dr. Gregory, in speaking of the diagnosis of hydrocephalus, mentions, as the disease with which it is most commonly confounded, common or typhus fever; and says, the "only manner of guarding against this source of fallacy is by bearing in mind that idiopathic fever is not common in young subjects, and that hydrocephalus is. Unless the evidence, therefore, be very unequivocal (as where the disease can be *distinctly* traced to contagion), the symptoms should always be attributed to hydrocephalus, and not to typhus."

"The second source of difficulty in the diagnosis arises from the *early* symptoms of hydrocephalus, being in every respect the same with those which accompany abdominal irritation; but chiefly from the important pathological principle, that several abdominal diseases, particularly those of children, are liable, in their progress, to affect the brain and nervous system, and to produce symptoms resembling those of the *latter* stages of hydrocephalus. The exact nature of these abdominal affections has been a frequent subject of dispute. By some it is supposed, that derangements in the *hepatic* system have a strong tendency to produce hydrocephalic symptoms; but I do not believe that the liver is more, if even so much, concerned in this, than the stomach and intestinal tract. A mere functional disturbance of these organs gives rise to remitting fever, headach, and vomiting. The presence of worms creates a degree of irritation that in the most striking manner counterfeits hydrocephalus. But, of all the states of abdominal disease which are liable to be mistaken for it, by far the most important is inflammation and ulceration of the mucous coat of the small intestines, particularly the ileum. In its latter stages, I have seen this disease attended in children with coma, dilated pupil, and screaming, constituting a secondary affection of the brain and nervous system.

"With reference to the diagnosis of hydrocephalus, it may further be observed that, in children, the latter stages of what appears to be pneumonia are sometimes attended with coma and screams: the early symptoms, that is to say, having been difficult breathing, a hard pulse, and cough. These cases are extremely deceiving. On dissection, the thoracic viscera often appear healthy, while the ventricles of the brain are perhaps loaded with serum."

Dr. Marshall Hall, in a pamphlet entitled "On a Morbid Affection of Infancy," has quoted, in addition to his own doctrine, the opinions of Dr. Abercrombie, Dr. Good, and others, on the subject of the diagnosis of hydrocephalus, and the importance of considering and treating differently a disorder which resembles it in many respects.

Dr. Abercrombie observes: "In the last stage of diseases of exhaustion, patients frequently fall into a state resembling coma a considerable time before death, and while the pulse can still be felt distinctly. I have many times

seen children lie for a day or two in this kind of stupor, and recover under the use of wine and nourishment. It is often scarcely to be distinguished from the coma which accompanies diseases of the brain. It attacks them after some continuance of exhausting diseases, such as tedious or neglected diarrhœa; and the patients lie in a state of insensibility, the pupils dilated, the eyes open and insensible to light, the face pale, and the pulse feeble. It may continue for a day or two, and terminate favourably, or it may prove fatal. This affection seems to correspond with the apoplexia ex inanitione of the older writers. It differs from syncope, in coming on gradually, and in continuing a considerable time, perhaps a day or two; and it is not, like syncope, induced by sudden and temporary causes, but by causes of gradual exhaustion going on for a considerable time. It differs from mere exhaustion, in the complete abolition of sense and motion, while the pulse can be felt distinctly, and is, in some cases, of tolerable strength. I have seen in adults the same affection, though it is perhaps more uncommon than in children." Again: "The state of infants which I have referred to is a state of pure coma, scarcely distinguishable at first sight from the perfect stupor of the last stage of hydrocephalus, the child lying with the eyes open, or half open, the pupils dilated, the face pale. It is difficult to describe distinctly the appearance, but it is one which conveys the impression of coma rather than of sinking; and I remember, the first time I met with this affection, the circumstance which arrested my attention, and led me to suppose that the disease was not hydrocephalus, and the state somewhat different from coma, was finding, on further inquiry, that it came on after diarrhœa, and not with any symptoms indicating an affection of the head. The child recovered under the use of wine and nourishment.

Dr. Good writes: "I am anxious to call the attention of medical men to a disorder of children, which I find invariably attributed to, and treated as, congestion or inflammation of the brain, but which I am convinced often depends on, or is connected with, the opposite state of circulation. It is chiefly indicated by heaviness of head and drowsiness: the age of the little patients whom I have seen in this state has been from a few months to two or three years; they have been rather small of their age, and of delicate health, or they have been exposed to debilitating causes. The physician finds the child lying on its nurse's lap, unable or unwilling to raise its head, half asleep, one moment opening its eyes, and the next closing them again with a remarkable expression of languor. The tongue is slightly white, the skin is not hot, at times the nurse remarks that it is colder than natural; in some cases there is at times a slight and transient flush; the bowels I have always seen already disturbed by purgatives, so that I can scarcely say what they are when left to themselves: thus, the state which I am describing is marked by heaviness of the head and drowsiness, without any signs of pain; great languor, and a total absence of all active febrile symptoms. The cases which I have seen have been invariably attributed to congestion of the brain; and the remedies employed have been leeches and cold lotion to the head, and purgatives, especially calomel. Under this treatment they have gradually become worse: the languor has increased, the deficiency of heat has become greater and more permanent, the pulse quicker and weaker, and at the end of a few days or a week, or sometimes longer, the little patients have died with symptoms apparently of exhaustion. In two cases, however, I have seen, during the last few hours, symptoms of oppressed brain, as coma and stertorous breathing, and dilated and motionless pupil."

But, to return to the subject of genuine hydrocephalus, and describe its progress and termination.

Dr. Clutterbuck says, "Inflammation of the membranes of the brain, like others, is often slight in degree, and terminates quickly in health. If it be long-continued, though slight, it often ends in serous accumulation, which is known or suspected by the marks of oppressed brain that take place. The pulse then loses its frequency, and often becomes preternaturally slow; the pupils are dilated; there is torpor of the bowels, and, indeed, throughout the whole system. The inflammation now frequently declines, or subsides altogether, the heat of head and of skin disappearing, and the tongue becoming clean. More frequently, however, the continuance of the febrile symptoms shows the continuance of the inflammation, but in very different degrees. If the child is very young, so that the bones are not firmly united, the head gradually enlarges in its dimensions, and becomes misshapen in its figure, and that so obviously and variously as not to require being described. The extent to which the enlargement goes is very various. Sooner or later, it generally stops by the bones uniting, the head remaining afterwards through life preternaturally large. In this case a quantity of fluid remains, without seeming (in many instances at least) to interfere with the proper exercise of the *sensorial functions*, or even with the general health, except that the body is commonly stunted in its growth. Such subjects are always liable to repeated returns of inflammation in the brain or its membranes, and which, sooner or later, in many cases prove fatal. The *ventricles* are always, I believe, the principal seat of the serous accumulation, and they become enlarged and distended in consequence. In most cases, though not all, there is fluid found between the *dura mater* and the *arachnoid* membrane, and, in this case, it makes its way to the basis of the brain, and down the spinal canal. The enlargement of the ventricles appears to take place from a kind of evolution of the brain, without any material injury to the structure, if we may judge from the perfect way in which the functions are sometimes carried on in these cases. The cerebral substance, in extreme cases of this sort, becomes so attenuated by the expansion, as hardly to equal a line in thickness; which has led to the mistake of supposing that, in such cases, the brain had wholly disappeared.

Such is the progress, in the milder forms, of

membranous inflammation of the brain. On many occasions the disease assumes a more active character, and soon spreads to the substance of the brain, as is known by the great disturbance of functions that ensues. Then it is that the restlessness becomes extreme, irritability both of mind and body is excessive, the expression of the countenance is altered, and especially that of the eyes, which are often directed irregularly, with the pupils unequally dilated. The eyelids remain half open, if the child sleeps; there is often delirium, as far as this can be observed in infants; the muscles of the hands and feet are in a state of contraction, and, frequently, general convulsions take place. The fur on the tongue becomes thicker, and of a darker colour; somnolency or stupor follows, and death ensues. The disease often proves fatal, in two or three days, and, in very young infants, sometimes at the very commencement of the inflammation, and then commonly with convulsions. Sometimes the disease is protracted to two or three weeks before it proves fatal, depending chiefly upon the age of the patient. If the disease is thus protracted, it wears at first merely the appearance of ordinary fever, which indeed it is. As the disease advances, the brain begins to be *oppressed*, partly from some degree of serous accumulation, partly from the arterial excitement and consequent distension, so that there is a mixture of the symptoms of *inflamed* with those of *oppressed* brain. In many instances, towards the end, a *paralytic state* of one side of the body is observed, while the limbs on the opposite side, perhaps, are convulsed.

"It is not, therefore," he says, "the mere presence of a certain quantity of fluid in the brain that gives rise to the symptoms of hydrocephalus; and, on the other hand, we have seen a disease go through all the usual symptoms of hydrocephalus, and terminate fatally, without any effusion. The fair conclusion from these facts appears to be, that the prominent symptoms in these cases are not the result of the effusion, but of that disease of the brain of which the effusion is one of the *terminations*. From a variety of facts adduced, there seems little reason to doubt that this disease is of an inflammatory nature; and therefore it follows, that our practice ought to be directed principally to subduing the inflammation at its earliest period, and preventing it from passing into *ramollissement*, which we have seen to be a fatal termination of the disease, even though of small extent and without effusion. This termination, I think, we have every reason to consider as the result most to be dreaded in this class of the inflammatory diseases of the brain; for, in regard to the mere effusion, were the parts otherwise in a healthy state, there does not seem to be any very satisfactory reasons for considering it as a hopeless affection. In other words, I mean to submit, that we have no good reasons for doubting the possibility of serous fluid being *absorbed from the ventricles of the brain*. We are warranted in this supposition, both by the analogy of other serous cavities, and by what we actually see take place in the brain itself. In the other serous cavities, we have every reason to believe that there is constantly going on an absorption of the old fluid, and a deposition of new fluid in its place; and we see them, in a state of disease, relieve themselves by an increased absorption from an excess of fluid that has been deposited. Upon the whole, we have sufficient ground for the following conclusions: —

"1. That, in the ordinary cases of hydrocephalus, the coma and other symptoms attending it are not to be considered as the direct effect of the effusion, but of that morbid condition of the brain of which the effusion is the consequence.

"2. That we have no certain mark which we can rely upon as indicating the presence of effusion in the brain. Slowness of pulse, followed by frequency, squinting, double vision, dilated pupil, paralytic symptoms, and perfect coma, we have seen exist *without any effusion*.

"3. That all these symptoms may exist in connection with a state of the brain which is active, or simply inflammatory. While the disease is the subject of active treatment, adopted with decision at an early period, we have a prospect of arresting its progress in a considerable proportion of cases. The ground of prognosis in particular cases depends, perhaps, in a great measure, upon the activity of the symptoms. The more they approach to the character of active inflammation, our prospect of cutting them short will be greater; and the more they partake of the low scrofulous inflammation, it will be the less. In all of them, the period for active practice is short, the irremediable mischief being probably done at an early period of the disease. These principles bear immediately upon the question. Has hydrocephalus been cured? There is no doubt that many cases have recovered, which exhibited all the usual symptoms of it. Such cases have, by some, been confidently brought forward as examples of hydrocephalus cured; while others have only considered them as remarkable from their singular resemblance to that disease. If the principles now referred to be admitted, we shall see reason to believe that we have no certain rule by which we can decide upon the presence of effusion in the brain; but that all the symptoms usually attending it exist in connection with an inflammatory condition of the brain, which, if allowed to go on, would probably lead to effusion; but which, if treated with *decision in its early stage*, may, in a certain proportion of cases, be treated with success. Whether the fluid can be absorbed, or the disease cured after effusion has taken place, must remain a matter of conjecture, but, from the facts which have been adduced, we have every reason to believe, that, in the ordinary cases of this disease, the *removal of the fluid, if it did take place, would in no respect improve the situation of the patient*, because there would still remain that deep-seated disease of the central parts of the brain which accompanies the effusion in so large a proportion of cases, and which, we have seen, may be fatal without any effusion, yet with all the usual symptoms of hydrocephalus. Hydrocephalus is, then, originally an inflammatory affection, chiefly seated in the substance of the central

parts of the brain: that it generally terminates by *ramollissement* of these parts, combined with serous effusion in the ventricles; and that it may be fatal by the *ramollissement* alone, even of small extent, but with all the symptoms which are commonly considered as characteristic of hydrocephalus."

With regard to the prognosis of hydrocephalus authors have differed. Dr. Abercrombie considers that the ground on which we may expect a cure depends, in a great measure, upon the activity of the symptoms. The more they approach the character of active inflammation, the greater the prospect of cutting them short; and the more they partake of the character of low scrofulous inflammation, the less it will be. The disease must be admitted, in accordance with general testimony, to be always alarming, and not less so, from the obscurity which so commonly accompanies it. In every instance, too, the period for active practice is short.

An accumulation of water in the ventricles of the brain, is one of the most common appearances to be observed on dissection. In different cases, this is accumulated in greater or less quantities. It sometimes amounts to a few ounces. When the quantity of water is considerable, the fornix is raised at its anterior extremity, in consequence of its accumulation, and an immediate opening of communication is thereby formed between the lateral ventricles. The water is of a purer colour and more limpid than what is found in the dropsy of the thorax, or abdomen. It appears, however, to be generally of the same nature with the water that is accumulated in these cavities. In some instances, the water in hydrocephalus contains a very small proportion of coagulable matter, and in others it is entirely free from it.

When the water is accumulated to a very large quantity in the ventricles, the substance of the brain appears to be a sort of pulpy bag, containing a fluid.

The remedial means indicated in cases of acute hydrocephalus, are of the kind usually employed in membraneous inflammation. Blood should be freely drawn by the lancet or by leeches. The treatment must be prompt and active, to give a tolerable chance of success: and the blood should be abstracted either from the temporal artery or jugular vein, proportioning the quantity and repetition to the state of the system. Cold applications to the head are useful. The head must be shaved, and the evaporating lotion applied constantly by rags all over the head; the best is, two ounces of the spirit of sulphuric æther, four ounces of distilled vinegar, and twelve of water, made cold by ice: the evaporation is promoted, and the coldness consequently kept steady, by passing cold air over the head. Purgatives, frequently repeated at the commencement of the attack, are necessary. The pulvis scammonii cum calomelane is an excellent medicine of this class; and the elaterium, which acts by vomiting and purging, has been given with success in cachectic habits, and with a loose cohesion of the flesh, or what is called a leucophlegmatic state of the constitution. Digitalis has been a good deal used, but with very opposite testimony as to its utility. Mercury, in its various forms, and administered in different ways, has enjoyed a high character, but is not without its opponents. The submuriate has been occasionally of decided use, given in the dose of two grains every four hours to children from one to three years of age, and more in proportion to the periods of life. Mercurial ointment rubbed into the extremities has been resorted to with the same view, namely, that of producing a ptyalism under which the inflammatory action has been arrested, and effused fluid absorbed. Blisters, and counter irritants should never be applied previously to depletion, or while there is a high degree of excitement; for under such circumstances they tend to aggravate the disease. Dr. Mills has occasionally used the antimonial ointment as an application to the vertex with benefit, and especially in cases which have supervened to repelled scabies of the hairy scalp.

Chronic hydrocephalus is a very different disease, both in its character and progress, from the acute form which has been described. It is frequently congenital; or, at least, there is a predisposition to it running through families, and developed sooner or later in the different individuals. It is connected with rachitis and scrofula; and is plainly a disease of cachexy and debility. It is this circumstance, doubtless, which has led to the confusion which is found to exist among authorities: the name hydrocephalus implying some connection with dropsical effusion, while the symptoms of active inflammation, which mark the acute disease, place that form among the pyrexial maladies.

Dropsy of the head, like that of every other organ, may proceed from a relaxed condition of the secernents of the brain, a torpitude of its absorbents, or from both.

With the deficiency of tone there is also not unfrequently some deficiency of structure or substance; and it is in consequence of this that the fluid, when morbidly secreted or collected in one part, spreads without resistance to another. A deficiency of structure or substance is sometimes found in the brain itself, and sometimes in the cranium. Generally speaking, there is some deficiency of bony earth; and the bones of the cranium have occasionally been so thin as to be pellucid, and transmit the light of a candle.

This chronic disease is always dangerous, and there is much difficulty in determining its extent, and the degree of cerebral disorganisation which may accompany it. Where, however, it is limited to a weak condition of the excernents of the brain, and medicines are speedily and steadily exhibited, there is a probability of its being removed; but where, on the contrary, no favourable impression can be made on the organ, the general frame partakes by degrees of the debility, the vital powers flag, the limbs become emaciated, and death ensues at an uncertain period; or the patient survives, a miserable spectacle to the world, and a burden to the family perhaps for years. Post mortem examinations of these enlargements of the head have not only found the skull very much enlarged in

size, and altered in its shape,—and it appears exceeding large in proportion to the face,—but on removing the scalp, the bones are found to be very thin, and there are frequently broad spots of membrane in the bone. These appearances are observed where the disease has been of some years' continuance. In some cases, where the quantity of water collected is not great, the substance of the brain has appeared to be indurated, and in others softened. Collections also of a viscid tenacious matter have been discovered in cysts, upon its external surface; tumours have also been found attached to its substance, and in many instances a conversion of a great part of the substance of the cerebrum or cerebellum into hæmatomatous, metanomatous, scrofulous, and other structures.

HYDROCO'TYLE. (*e, es.* f.; from ὑδωρ, water, and κοτυλη, the cotula.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*.

Hydrocotyle vulgaris. Marsh penny wort. This plant has been esteemed for its detersive and vulnerary properties, but is now disused.

HY'DROCYA'NIC ACID. *Acidum hydrocyanicum*. An acid so called from its being a compound of hydrogen and cyanogen. It is also called *Prussic acid* because it was first discovered in Prussian blue.

Prussic acid was discovered by Scheele in 1780; but this chemist obtained it mixed with a variable quantity of water: M. Gay-Lussac first made us acquainted with it in a pure state.

At an ordinary temperature, it is liquid, transparent, and colourless; its taste is at first cool, but soon becomes acrid and irritating: it reddens slightly the tincture of turnsol. Its odour is powerful, and may be deleterious; it is only supportable when diluted with a certain quantity of air, and then resembles the smell of bitter almonds.

Hydrocyanic acid is very volatile: it boils at 26° 5 under a pressure of 0^m, 76, and at 10° sustains a column of mercury of 0^m, 38. It is, however, easily congealed, and this takes place at 50° of cold; when also a few drops are poured upon paper, a part evaporates so rapidly as to produce a degree of cold sufficient to crystallise the remainder. It is the only liquid which possesses this property. Prussic acid is little soluble in water; hence when agitated with ten or twelve times its volume of this fluid, it collects again on the surface like oils and ethers. Alcohol readily dissolves it. When left to itself in a closed vessel, it is sometimes decomposed in less than an hour: it can rarely be preserved for more than a fortnight. According to M. Gay-Lussac, hydrocyanic acid consists of

Carbon	44·27
Azote	52·08
Hydrogen	3·65

Or, of one volume of vaprous carbon, one of azote, and one of hydrogen, condensed into two volumes; or, again, of one volume of cyanogen, and one of uncondensed hydrogen.

In order to obtain hydrocyanic acid, the crystallised deuto-cyanuret of mercury is reduced to powder, and treated with two thirds of its weight of fuming hydrochloric acid. The apparatus to be used consists of a small tubulated retort, to which is adapted a tube of sufficient length, bent to a right angle at one of its extremities; this is placed in a very narrow bottle, or, what is better, in a test tube, surrounded with ice and salt. The horizontal part of the tube, which is adapted to the retort, should contain some fragments of carbonate of lime, succeeded by others of chloruret of calcium. The apparatus being thus adjusted, and placed on a small furnace, the deuto-chloruret of mercury and the hydrochloric acid are to be introduced into the retort through the tube. A gentle heat is then applied, and the decomposition of the deuto-cyanuret of mercury proceeds; the hydrocyanic acid resulting from the action of the hydrochloric acid on the deuto-cyanuret, passes through the tube, and condenses in the test tube, having been deprived, by its contact with the carbonate of lime and chloruret of calcium, of all the water and hydrochloric acid which may have been volatilised along with it.

Vauquelin has proposed to obtain hydrocyanic acid by decomposing cyanuret of mercury with sulphuretted hydrogen. The apparatus differs little from the last. We substitute for the retort a globe containing a mixture of sulphuret of iron and diluted sulphuric acid. The cyanuret of mercury is placed in the horizontal tube already described, and near the end adapted to the globe; beyond this are placed fragments of carbonate of lead and chloruret of calcium, the one to absorb the small quantity of sulphuretted hydrogen that may not have been decomposed by the cyanuret of mercury, the other to absorb the water which the hydrocyanic acid may have brought along with it. This preparation is almost always impure, and contains sulphuretted hydrogen, because a portion of this gas eludes the carbonate of lead intended to absorb it.

If, in the preparation of hydrocyanic acid, according to Gay-Lussac's method, too much hydrochloric acid is added, M. Pelouse states that by the addition of 3 atoms of water, the composition becomes precisely that of formiate of ammonia, and that therefore a great quantity of the latter, and very little prussic acid is formed.

If one drop of pure prussic acid be introduced into the fauces of the strongest dog, he falls dead after one or two convulsive respirations. A few particles applied to the eye produce similar effects almost as suddenly. One drop of the acid diluted with several of alcohol, and injected into the jugular vein, kill the animal as rapidly as if it were struck by lightning. In animals thus poisoned, scarcely any trace of irritability is discoverable in the muscles a few moments after death.

In the Transactions of the Medical Society of Copenhagen, (vol. ii. 1821,) there is a memoir by Dr. Viborg, in which he states that he has given prussic acid to animals, in very large doses, without causing death. It is evident that the acid he employed must have been prepared by Scheele's process, or some other which yields

the acid very impure. To obtain uniform results, which may be compared with each other, the same process should always be adhered to, and we recommend that of Gay-Lussac or Vauquelin.

Prussic acid, when pure, produces the same effects on man as on animals. Even its vapour should be cautiously avoided, since when respired, it occasions acute pains in the chest, and a feeling of oppression which does not subside for some hours. Properly diluted, its action in disease is to allay morbid irritability in certain organs. Given at too short intervals, though in a proper dose, it has been known to produce headach and vertigo, which passed off in a few minutes.

Prussic acid, properly diluted, is employed with success in all cases of morbid irritability of the pulmonary organs. It is advantageously used in nervous and chronic coughs, asthma, and hooping cough, as also in the palliative treatment of phthisis; in the early stage of the latter disease there is reason to believe that it may effect a cure. In England it has been administered with success in hectic cough, sympathetic of some other affection, and also in dyspepsia. Dr. Elliotson has often prescribed it, both in hospital and private practice, prepared according to Vauquelin's process. He has reported more than forty cases of dyspepsia, with or without vomiting, accompanied with considerable pain of the epigastrium, and pyrosis, which were cured by the use of the medicinal prussic acid. He also cites a case of painter's colic, in which Dr. Prout administered the acid with instantaneous benefit. Dr. Elliotson has prescribed it in many affections of the chest, and has almost always found it relieve the harassing cough. Applied externally in lotions, in different diseases of the skin, it has afforded no very marked results in the hands of Dr. Elliotson. Dr. Thomson, however, alleges that he has used it with constant success against the itching and smarting so annoying in these affections, and that he has cured with it several species of cutaneous disease, and especially *acne rosacea*.

M. Jacob Bouchenel has published a very interesting paper on prussic acid as a remedy in chronic pulmonary catarrh, of which he gives four successful cases. He observes that this medicine in small doses produces no more inconvenience than a common linctus; that its use is not proper in the acute stage; and that its success is always most certain when antiphlogistic measures have been previously adopted. He has also employed prussic acid in a case of phthisis, but only with momentary relief of the cough; and doubts whether prussic acid has ever really cured confirmed phthisis. M. Magendie maintains, that he has cured with this medicine individuals who had every symptom of phthisis in the first degree, and even those in a more advanced stage.

In Italy the medicinal hydrocyanic acid has been used to allay morbid irritability of the uterus, even in cases of cancer, and to diminish the activity of the heart in all sthenic diseases.

Professor Brera extols its effects in pneumonia, and recommends it also in rheumatism and as an anthelmintic. Since the professor has employed it in diseases of the heart, Dr. Macleod has tried it in similar cases, and found it allay nervous palpitations, especially those caused by a deranged state of the digestive functions; he has also used it as a palliative in some cases of aneurism of the heart. He never exceeded 28 drops in the twenty-four hours, and has not seen any accident result from the administration of the medicine.

Dr. Frisch, of Nyborg, has relieved intolerable pains occasioned by cancer of the breast, and which had resisted all the antispasmodics, by washing the ulcerated surface with diluted prussic acid. He has likewise found benefit from this medicine in several cases of phthisis, one of which was cured.

Prussic acid, prepared as Scheele directs, is not sufficiently uniform, on account of the latitude which his process allows to the operator. Prepared according to Vauquelin's method, it retains a portion of sulphuretted hydrogen. It is, therefore, better to use the acid afforded by Gay-Lussac's process duly diluted. M. Magendie mixes it with six times its volume, or 8·5 times its weight of distilled water. This mixture he calls *medicinal prussic acid*.

The medicinal prussic acid may also be made by diluting the hydrocyanic acid with six times its volume of alcohol; it thus preserves its active properties better, and evaporates much less quickly than when mixed with water. — *Magendie*. A diluted hydrocyanic acid, adapted to medicinal purposes, has been introduced by the London College of Physicians into their recent pharmacopœia. See *Acidum Hydrocyanicum Dilutum*, in the Supplement.

HYDROCY'STIS. (*is, idis.* f.; from *υδωρ*, water, and *κυστις*, a vesicle.) An encysted dropsy.

HYDRO'GARON. *Υδρογαρον*. A mixture of garum and water. See *Garum*. Aëtius speaks of a purging hydrogaron.

HY'DROGEN. (*Hydrogenium, ii.* n.; from *υδωρ*, water, and *γενναω*, to produce: because, with oxygen, it produces water.) The base of inflammable air: a substance not perceptible to the senses in a separate state; but the existence of which is not at all the less certain. Though it cannot be exhibited experimentally uncombined, it can be pursued while it passes out of one combination into another. It cannot, indeed, be arrested on its passage; but it is sure to be discovered, if the proper chemical means be used, when it presents itself in a new compound.

Hydrogen, as its name expresses, is one of the constituent elements of water, from which it can alone be procured. It is plentifully distributed in nature, and acts a very considerable part in the processes of the animal and vegetable economy. It is one of the ingredients in the varieties of bitumen, oils, fat, ardent spirit, æther, and, in fact, all the proximate, component parts of animal and vegetable bodies. It forms a constituent part of all animal and vegetable acids. It is one of the constituents of ammonia, and of various other compound gases.

It possesses so great an affinity for caloric, that

it can only exist separately in the state of gas; it is, consequently, impossible to procure it in the concrete or liquid state, independent of combination.

Solid hydrogen, therefore, united to caloric and light, forms *hydrogen gas.*

This gas, formerly called inflammable air, was discovered by Cavendish, in the year 1768, or, rather, he first obtained it in a state of purity, and ascertained its more important properties, though it had been noticed long before. The famous philosophical candle attests the antiquity of this discovery.

Hydrogen gas possesses all the mechanical properties of atmospheric air. It is the lightest substance whose weight we are able to estimate: when in its purest state, and free from moisture, it is about fourteen times lighter than atmospheric air. It is not fitted for respiration; animals, when obliged to breathe in it, die almost instantaneously. It is decomposed by living vegetables, and its basis becomes one of the constituents of oil, resin, &c. It is inflammable, and burns rapidly when kindled, *in contact with atmospheric air or oxygen gas,* by means of the electric spark, or by an inflamed body; and burns, when pure, with a yellowish lambent flame; but all burning substances are immediately extinguished when immersed in it. It is, therefore, incapable of supporting combustion. It is not injurious to growing vegetables. It is unabsorbable by most substances: water absorbs it very sparingly. The sole product of the combustion of hydrogen gas is water. This fluid consists of two volumes of hydrogen and one of oxygen, or eight parts by weight of oxygen and one of hydrogen. If five volumes of atmospheric air be mixed with two of hydrogen, and a lighted taper applied, or an electric spark sent through the mixture, an explosion takes place, three parts of the gaseous mixture disappear, and water is deposited on the inside of the vessel. If two volumes of hydrogen, and one of oxygen be detonated in a similar manner, the whole is instantly converted into water.

A ready method of obtaining hydrogen consists in subjecting water to the action of a substance which is capable of decomposing this fluid.

1. For this purpose, let sulphuric acid, previously diluted with four or five times its weight of water, be poured on iron filings, or bits of zinc, in a small retort or gas-bottle, called a pneumatic flask, or proof: as soon as the diluted acid comes in contact with the metal, a violent effervescence takes place, and hydrogen gas escapes without external heat being applied. It may be collected in the usual manner over water, taking care to let a certain portion escape on account of the atmospheric air contained in the disengaging vessels.

The production of hydrogen gas in the above way is owing to the decomposition of water. The iron or zinc, when in contact with this fluid, in conjunction with sulphuric acid, has a greater affinity to oxygen than the hydrogen has; the oxygen, therefore, unites to it, and forms an oxide of that metal, which is instantly attacked and dissolved by the acid; the other constituent part of the water, the hydrogen, is set free, which, by uniting with caloric, assumes the form of hydrogen gas. The oxygen is, therefore, the bond of union between the metal and the acid.

The hissing noise, or effervescence, observable during the process, is owing to the rapid motion excited in the mixture by means of the great number of air-bubbles quickly disengaged, and breaking at the surface of the fluid.

We see, also, in this case, that *two* substances exert an attraction, and are even capable of decomposing jointly a *third,* which neither of them is able to do singly; viz., if we present sulphuric acid alone, or iron or zinc alone, to water, they cannot detach the oxygen from the hydrogen of that fluid; but if both are applied, a decomposition is instantly effected. This experiment, therefore, proves that the agency of chemical affinity between two or more bodies may lie dormant, until it is called into action by the interposition of another body, which frequently exerts no energy upon any of them in a separate state. Instances of this kind were formerly called *disposing affinities.*

2. Iron, in a red heat, has also the property of decomposing water, by dislodging the oxygen from its combination with hydrogen, in the following manner: —

Let a gun-barrel having its touch-hole screwed up, pass through a furnace, or large crucible perforated for that purpose, taking care to incline the barrel at the narrowest part; adjust to its upper extremity a retort charged with water, and let the other extremity terminate in a tube introduced under a receiver in the pneumatic trough. When the apparatus is thus disposed, and well luted, bring the gun barrel to a red heat, and when thoroughly red-hot, make the water in the retort boil; the vapour, when passing through the red hot-tube, will yield hydrogen gas abundantly. In this experiment, the oxygen of the water combines with the iron at a red-heat, so as to convert it into an oxide, and the caloric applied combines with the hydrogen of the water, and forms hydrogen gas. It is, therefore, the result of a double affinity, that of the oxygen of the water for the metal, and that of its hydrogen for caloric.

The more caloric is employed in the experiment of decomposing water by means of iron, &c. the sooner is the water decomposed.

Hydrogen combines with a variety of substances forming important products. With oxygen it forms *water;* with nitrogen *ammonia;* with chlorine, *hydrochloric acid;* with sulphur, *sulphuretted hydrogen;* with carbon, *carburetted hydrogen;* with phosphorus, *phosphuretted hydrogen;* with cyanogen, *hydrocyanic acid;* with iodine *hydriodic acid;* with arsenic, *arseniuretted hydrogen;* with tellurium, *telluretted hydrogen;* with potassium, *potassuretted hydrogen;* with selenum, *seleniuretted hydrogen.* For an account of these substances, see their respective titles.

Besides the ordinary compound of hydrogen and oxygen which forms water, another or a *binoxide of hydrogen* was discovered by Thenard in 1818. The following account of this

interesting substance is taken from Dr. Turner's Elements of Chemistry.

Before describing the mode of preparing this compound, it must be observed that there are two oxides of barium; and that when the peroxide of that metal is put into water containing free muriatic acid, oxygen gas is set at liberty, and the peroxide is converted into protoxide of barium or baryta, which combines with the acid. When this process is conducted with the necessary precautions, the oxygen which is set free, instead of escaping in the form of gas, unites with the hydrogen of the water, and brings it to a maximum of oxidation. For a full detail of all the minutiæ of the process, the reader may consult the original memoir of Thenard: the general directions are the following: — To six or seven ounces of water add so much pure concentrated muriatic acid as is sufficient to dissolve 230 grains of baryta; and after having placed the mixed fluids in a glass vessel surrounded with ice, add in successive portions 185 grains of peroxide of barium reduced to powder, and stir with a glass rod after each addition. When the solution, which takes place without effervescence, is complete, sulphuric acid is added in sufficient quantity for precipitating the whole of the baryta in the form of an insoluble sulphate; in order that the muriatic acid, which had been combined with that earth, may be completely separated from it. Another portion of peroxide of barium, amounting to 185 grains, is then put into the liquid; the free muriatic acid instantly acts upon it, and, as soon as it is dissolved, the baryta is again converted into sulphate by the addition of sulphuric acid. The solution is then filtered, in order to separate the insoluble sulphate of baryta; and fresh quantities of peroxide of barium are added in succession, till about three ounces have been employed. The liquid then contains from twenty-five to thirty times its volume of oxygen gas. The muriatic acid, which has served to decompose the peroxide of barium during the whole process, is now removed by the cautious addition of sulphate of silver, and the sulphuric acid afterwards separated by solid baryta.

Peroxide of hydrogen, as thus prepared, is still diluted with a considerable quantity of water. To separate the latter, the mixed liquids are placed, with a vessel of strong sulphuric acid, under the exhausted receiver of an air-pump. As the water evaporates, the density of the residue increases, till at last it acquires the specific gravity of 1·452. The concentration cannot be pushed further; for, if kept under the receiver after reaching this point, the peroxide itself gradually but slowly volatilises without change.

Peroxide of hydrogen, of specific gravity 1·452, is a colourless transparent liquid without odour. It whitens the surface of the skin when applied to it, causes a prickling sensation, and even destroys its texture if the application is long continued. It acts in a similar manner on the tongue; in addition to which it thickens the saliva, and tastes like certain metallic solutions. Brought into contact with litmus and turmeric paper, it gradually destroys their colour and makes them white. It is slowly volatilised *in vacuo*, a fact which shows that its vapour is much less elastic than that of water. It preserves its liquid form at all degrees of cold to which it has hitherto been exposed. At the temperature of 59° F. it is decomposed, being converted into water and oxygen gas. For this reason it ought to be preserved in glass tubes surrounded with ice.

The most remarkable property of peroxide of hydrogen is its facility of decomposition. Diffused daylight does not seem to exert any influence over it, and even the direct solar rays act upon it tardily. It effervesces from escape of oxygen at 59° F., and the sudden application of a higher temperature, as of 212° F., gives rise to such rapid evolution of gas as to cause an explosion. Water, apparently by combining with the peroxide, renders it more permanent; but no degree of dilution can enable it to bear the heat of boiling water, at which temperature it is entirely decomposed. All the metals, except iron, tin, antimony, and tellurium, have a tendency to decompose the peroxide of hydrogen, converting it into oxygen and water. A state of minute mechanical division is essential for producing rapid decomposition. If the metal is in mass and the peroxide diluted with water, the action is slow. The metals which have a strong affinity for oxygen are oxidized at the same time, such as potassium, sodium, arsenic, molybdenum, manganese, zinc, tungsten, and chromium; while others, such as gold, silver, platinum, irridium, osmium, rhodium, palladium, and mercury, retain the metallic state.

Peroxide of hydrogen is decomposed at common temperatures by many of the metallic oxides. That some protoxides should have this effect, would be anticipated in consequence of their tendency to pass into a higher state of oxidation. The protoxide of iron, manganese, tin, cobalt, and others, act on this principle, and are really converted into peroxides. The peroxide of barium, strontium, and calcium may likewise be formed by the action of peroxide of hydrogen on baryta, strontia, and lime. But it is a singular fact, and I am not aware that any satisfactory explanation of it has been given, that some oxides decompose peroxide of hydrogen without passing into a higher degree of oxidation. The peroxide of silver, lead, mercury, gold, platinum, manganese, and cobalt, possess this property in the greatest perfection, acting on peroxide of hydrogen, when concentrated, with surprising energy. The decomposition is complete and instantaneous; oxygen gas is evolved so rapidly as to produce a kind of explosion, and such intense temperature is excited, that the glass tube in which the experiment is conducted becomes red-hot. The reaction is very great even when the peroxide of hydrogen is diluted with water. Oxide of silver occasions very perceptible effervescence when put into water which contains only 1–50th of its bulk of oxygen. All the metallic oxides, which are decomposed by a red heat, such as those of gold, platinum, silver, and mercury, are reduced to the metallic state when they act

upon peroxide of hydrogen. This effect cannot be altogether ascribed to caloric disengaged during the action: for oxide of silver suffers reduction when put into a very dilute solution of the peroxide, although the decomposition is not then attended by an appreciable rise of temperature.

While the tendency of metals and metallic oxides is to decompose the peroxide of hydrogen, acids have the property of rendering it more stable. In proof of this, let a portion of that liquid, somewhat diluted with water, be heated till it begins to effervesce from the escape of oxygen gas; let some strong acid, as the nitric, sulphuric, or muriatic, be then dropped into it, and the effervescence will cease on the instant. When a little finely divided gold is put into a weak solution of peroxide of hydrogen, containing only 10, 20, or 30 times its bulk of oxygen, brisk effervescence ensues; but on letting one drop of sulphuric acid fall into it, effervescence ceases instantly; it is reproduced by the addition of potash, and is again arrested by adding a second portion of acid. The only acids that do not possess this property are those that have a low degree of acidity, as carbonic and boracic acids; or those which suffer a chemical change when mixed with peroxide of hydrogen, such as hydriodic and sulphurous acids, and sulphuretted hydrogen. Acids appear to increase the stability of the peroxide in the same way as water does, namely, by combining chemically with it. Several compounds of this kind were formed by Thenard, before he was aware of the existence of the peroxide of hydrogen. They were made by dissolving peroxide of barium in some dilute acid, such as the nitric, and then precipitating the baryta by sulphuric acid. As nitric acid was supposed, under these circumstances, to combine with an additional quantity of oxygen, Thenard applied the term oxygenized nitric acid to the resulting compound, and described several other new acids under a similar title. But the subsequent discovery of peroxide of hydrogen put the nature of the oxygenized acids in a clearer light; for their properties are easily explicable on the supposition that they are composed, not of acids and oxygen gas, but of acids united with peroxide of hydrogen.

Peroxide of hydrogen was analysed by diluting a known weight of it with water, and then decomposing it by boiling the solution. According to two careful analyses, conducted on this principle, 864 parts of the peroxide are composed of 466 of water, and 398 of oxygen gas. The 466 of water contain 414 of oxygen, whence it may be inferred that peroxide of hydrogen contains twice as much oxygen as water. A small deficiency of oxygen in this experiment was to be expected, owing to the difficulty of obtaining peroxide of hydrogen perfectly free from water. The peroxide consists, therefore, of hydrogen 1, or one equivalent, and oxygen 16, or two equivalents.

Very curious phenomena are found to result from the action of hydrogen on some of the metals. M. Dobereiner found, that a jet of hydrogen gas, playing upon a piece of spongy platina, or the powder of that metal, in contact with atmospheric air, causes its immediate ignition. The same action takes place with spongy palladium. Iridium grows hot without inflaming, and water is generated. Cobalt and nickel give similar results.

Hydrogen, carburetted. See *Carburetted hydrogen.*

Hydrogen, percarburetted. See *Carburetted hydrogen.*

Hydrogen, subcarburetted. See *Carburetted hydrogen.*

Hydrogen, phosphuretted. See *Phosphorus.*

Hydrogen, subphosphuretted. See *Phosphorus.*

Hydrogen gas, heavy, carbonated. See *Carburetted hydrogen.*

Hydrogen gas, light, carbonated. See *Carburetted hydrogen.*

HYDRO'GURET. A compound of hydrogen with a simple inflammable body or a metal. The substances called hydrogurets are now generally designated by other names: thus *Hydroguret of carbon* is called *Carburetted hydrogen*, &c.

HYDROLA'PATHUM. (*um*, *i.* n.; from ὑδωρ, water, and λαπαθον, the dock.) See *Rumex hydrolapathum.*

HY'DROMEL. (*Hydromeli*, indeclinable; from ὑδωρ, water, and μελι, honey.) Water impregnated with honey: called also, *Mulsum; Aqua mulsa; Melicratum; Braggat.* Hydromel, after it is fermented, is called vinous hydromel, or mead.

HYDRO'METER. (*Hydrometrum*, *i.* n.; from ὑδωρ, water, and μετρον, a measure.) The name of an instrument for determining the specific gravity, and thereby the strength, of alkoholic liquids. It is also called *Areometer*, from αραιος, light, and μετρον, a measure — a measure of levity, because the more alkohol the fluid contains the smaller will be its specific gravity.

HYDROME'TRA. (*a*, *æ.* f.; from ὑδωρ, water, and μητρα, the womb.) *Hydrops uteri.* Dropsy of the womb. It produces a swelling in the hypogastric region, slowly and gradually increasing, resembling the figure of the uterus, yielding to or fluctuating on pressure, without ischury or pregnancy. Sauvages enumerates seven species. It must be considered as a very rare disease, and one that can with difficulty be ascertained.

HYDRO'MPHALUM. (*um*, *i.* n.; from ὑδωρ, water, and ομφαλος, the navel.) A tumour at the navel containing water. This may arise from mere distention in cases of ascites, or from an umbilical hernia, the sac of which contains serum.

HY'DROMYRI'NGA. (From ὑδωρ, water, and *myringa* or *myrinx*, a barbarous Latin name of the *membrana tympani.*) Dropsy of the tympanum.

HYDRO'NOSOS. (From ὑδωρ, water, and νοσος, a disease.) Watery disease: applied to the sweating-sickness. See *Sudor anglicanus.*

HYDRO-OXYDE. Synonymous with *Hydrate.*

HYDROPEDE'SIS. (From ὑδωρ, water, and πηδαω, to break out.) A violent sweating.

HY′DROPERICA′RDIUM. (*um, i.* n.; from ὑδωρ, water, and περικαρδιον, the pericardium.) *Hydropericardia.* Dropsy of the pericardium. This occurs as a consequence of inflammation of the pericardium, and as an accompaniment of hydrothorax. It is indicated by orthopnœa, palpitation, and irregular action of the heart, preternatural dulness of sound on percussion in the cardiac region, and a sound of fluctuation. It is generally connected with organic disease of the heart, and is always incurable.

HYDROPHO′BIA. (*a, æ.* f.; from υδωρ, water, and φοβεω, to fear: so called on account of the dread of water which accompanies the disease.) *Rabies canina. Cynanthropia. Cynolyssa.* Canine madness. This disease is considered by all pathologists as the consequence of a morbid poison, introduced into the system by the bite of a rabid animal. The general features of the disorder correspond perfectly with such a notion; but it is not to be overlooked that a strong analogy exists between hydrophobia and tetanus, and that the former might, with no inconsiderable claim to pathological accuracy, be viewed as a kind of tetanic affection, supervening upon wounds of a particular character. The points of analogy between these diseases will be found in the character and course of the symptoms; but previously it is necessary to notice an important *distinction* that exists between them. Idiopathic tetanus is both a frequent and a very fatal disease. Idiopathic or spontaneous hydrophobia has *never* been known to occur in the human subject, — never at least under such circumstances as to remove all suspicion of preceding local injury.

Hydrophobia has certainly existed from a very early period of the world. The first allusion to it is to be found in the writings of Aristotle; but it is to Cælius Aurelianus that we are indebted for the original description of the symptoms and progress of the disease. From his time unceasing attention has been paid to every phenomenon which it presents, and nothing is wanting, which observation can supply, to perfect our knowledge of it. Like tetanus, however, its cure has hitherto equally evaded the suggestions of pathology, and the blind attempts of empiricism. The investigation of the disease, therefore, must be conducted with a view to elucidate its peculiarities and pathological affinities, without any prospect of practical advantage.

Origin. — From the most distant times inquiries have been directed to ascertain what animals are capable of originating, receiving, and propagating, hydrophobia, and what is the precise mode of its communication from animals to man. The opinions of authors on these subjects have been mixed up with many idle tales; but the following may be taken as a summary of the best established results to which their researches have led. The disease almost always commences among animals of the canine race. It is questionable how far it ever originates even in those of the cat kind. To them, however, it is readily *propagated*, and they possess, equally with dogs, the power of transmitting it to man, and to every species of quadruped. It is a matter of doubt whether birds are susceptible of the disease. Herbivorous animals appear incapable of communicating it, and this is even still better ascertained with regard to man. Innumerable attempts have been made to propagate the disease by inoculating animals with the saliva of persons labouring under hydrophobia, but they have always failed.

Of the causes of this peculiar distemper in dogs nothing certain is known. That it originates *spontaneously* in them is now the general opinion; but it is equally well ascertained that among them it chiefly spreads by inoculation. In respect to the mode of its communication from animals to man, the facts in proof of the reality of a peculiar infectious principle are too numerous to admit of dispute. It is universally allowed that the poison cannot operate on the sound skin. In many instances the wound has been so slight as to escape notice; but it may be stated, as an invariable law, that, for the hydrophobic virus to take effect, it must be applied to an abraded, wounded, or ulcerated surface.

A question has arisen whether the infectious principle resides in the salivary secretion, or in the mucus of the trachea and bronchia. Some have conjectured that it is more or less diffused through all the solids and fluids of the rabid animal. This latter suggestion may at once be set aside; but the former opens a curious subject of inquiry. The appearances of inflammation so common about the pharynx, render it by no means improbable that the mucous secretion of that part may undergo a change, by which it is enabled to propagate the disease.

There is some difficulty in ascertaining how it happens that, of a number of persons bitten by a rabid animal, a certain proportion only are subsequently attacked by hydrophobia. The influence of prophylactic measures may be altogether excluded, and differences of constitutional disposition can hardly be trusted to. The circumstance is probably referable to the ineffectual application of the poison in the cases that escape. This conjecture is rendered the more probable by the acknowledged fact of bites upon the face and hands being always more dangerous than where the tooth had previously passed through cloth or leather.

Hydrophobia, as it affects dogs and other animals, exhibits a very different train of symptoms from that which is observed when man is the subject of the disease. For the former the reader is referred to a very ingenious paper by Mr. Meynell. The phenomena of hydrophobia in man are described as follows by Dr. G. Gregory, partly from his own observation, and partly from the very admirable memoir on hydrophobia, published by Dr. John Hunter, in the Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge, vol. i. art. 17.

Incubation of the virus. — The interval between the bite and the development of hydrophobic symptoms (in other words, the *period of incubation* of the virus), is subject to considerable variation. Among the *genuine* cases which

I have seen recorded, the shortest period was twenty-one days, and the longest nine months. From thirty to sixty days usually elapse. Forty days, or six weeks, may be stated as the average; after which time the chances of escape are greatly increased. It is a curious circumstance that, during all this time, there is no local irritation observable in the bitten part, nor any derangement of general health, nor perceptible change in the constitution, provided the person bitten be not under the influence of fear.

Symptoms. — For two or three days previous to the coming on of the more unequivocal symptoms of the disease, the patient often complains of chilliness, some degree of headach, languor and lassitude, low spirits, and restlessness. Frequently also a sense of coldness and numbness is experienced in the bitten part, occasionally amounting to actual pain. This, in some instances, extends up the limb, and it has been observed to follow the course of the nerves rather than that of the absorbents. The freedom of the lymphatic glands from disease, indeed, has often been noticed, and adduced as an argument that the disorder does not depend on the absorption of any virus.

The second or *confirmed* stage of hydrophobia commences with that symptom which gives name to the disease — the horror of liquids. The distressing sense of suffocation, and the violent spasmodic agitation of the whole body, brought on by the sight of liquids, or the attempt to drink, is unquestionably the most remarkable symptom of the disorder. By degrees the disposition to spasm increases so much upon the patient, that not merely the sight of water, but the least exertion of speaking or moving, the slightest noise, or the entrance of a stranger into the room, brings it on. Extreme irritability and sensibility of the whole frame are apparent indeed in every action of the patient, and constitute the unvarying feature of the complaint.

It has been erroneously imagined from the very general use of the term *canine madness*, that delirium is one of its usual symptoms. In a large proportion of hydrophobic cases the mind has continued perfectly clear up to the last moment. In others, where delirium did occur, it was not until a late period of the disease. But though the patient is sensible, he is in the highest degree timid and *nervous*. As the disease advances, the mind is more and more filled with dreadful fears and apprehensions. Excessive anxiety is apparent in the countenance. Almost immediately after the disorder distinctly manifests itself, the respiration is hurried and *gasping*, and the patient commonly complains of an oppression about the præcordia. The pulse is seldom much affected till towards the latter periods of its course, when it becomes small, irregular, feeble, and rapid. Blood has frequently been drawn from the arm; but it does not appear ever to have exhibited any inflammatory crust.

The secretions about the mouth are always very much affected. The saliva is usually viscid, and increased in quantity. The patient complains of a parched mouth and thirst, on which account he continually calls out for drink, which yet no persuasions can induce him to look at, much less to swallow. A frothy saliva is frequently ejected, to the great terror of bystanders; but it arises merely from the patient's inability to swallow.

Hydrophobia is not characterised by any great degree of debility: instances have occurred of persons running a considerable distance, and making great muscular exertion, within a few hours of their death. The degree of bodily weakness which has been observed in particular cases is, perhaps, as much attributable to the remedies employed, as to the natural effects of the disorder. Its duration varies from two to five days, reckoning from the invasion of the *pathognomonic* symptom. The average does not appear to exceed forty hours. The *immediate* cause of death has never been very accurately ascertained, either in the case of tetanus or hydrophobia. Some patients die in a convulsion fit; the greater number sink under the excessive exhaustion of nervous power.

Prognosis and morbid appearances. — The prognosis in hydrophobia may be discussed in a very few words. There does not appear to be, in the records of medicine, a single unequivocal instance of recovery from this disease. A variety of supposed cures may indeed be found. The second volume of the Transactions of the London College of Physicians contains two; but the slightest reflection will convince the reader, that neither in origin, symptoms, nor progress did they substantiate their claim to the character of hydrophobia. It must be viewed, therefore, as the only known disease which has hitherto uniformly resisted the efforts both of nature and of art.

This melancholy fact cannot be imputed to any neglect on the part of the cultivators of morbid anatomy; on the contrary, the appearances on dissection, in those who die of hydrophobia, have been recorded with a degree of minuteness which, favourably as it speaks for their zeal, is a proof at the same time how little aid their labours are calculated to afford to the mere *practitioner* in physic. The usual appearances are, turgescence of vessels (by some called marks of inflammation) about the pharynx, and about the cardiac orifice of the stomach. Sir Astley Cooper, in the course of a minute examination of several dogs who died rabid, found effusion of blood into the cellular membrane connecting the mucous and muscular coats of that organ. No morbid appearance has ever been traced in the brain; and though the spinal marrow has been carefully examined, no important lesion has been detected there. These facts, however, are not decisive against the theory which attributes hydrophobia to a disordered condition of the brain and spinal column; because, from the rapid course of the disease, time is not given for those alterations of structure which are so commonly the results of disordered function. — *Gregory.*

Treatment. — No cure has hitherto been found for this horrible disease when established. The plans which have been said to have been successful in a few cases, have entirely failed in

all others; nor is there, as before observed, a single well-authenticated case on record of recovery from real hydrophobia.

If medical aid can be obtained at the time of the bite, or very soon after, the efficacious means of preventing the absorption of the poison is by removing or destroying the bitten part. This has been done in various ways: the lacerated part has been *amputated* or *dissected* out; in other instances the *actual* and *potential cautery* have been applied. Iron heated nearly to whiteness was used by the ancients. Pure potash, formerly called lapis infernalis, was proposed as a less terrific process. Of these three modes of operating, the potential cautery is the least to be depended on. Of the other two, it is of little consequence which is selected: either will prove sufficiently efficacious alone, if employed early enough, that is, before absorption has taken place; and extensively enough to extirpate or destroy every portion of the bitten part. It has also been strongly recommended to apply a ligature above the bitten part, sufficiently tight to prevent the absorbents from imbibing the virus. But this does not appear likely to answer; for, if the poison be received into the absorbents, it will be carried into the circulation in a circuitous way, if arrested in the regular course.

When the constitutional disease has actually shown itself, the curative processes which have been resorted to are all reducible to one of the four following: —

1. That of stimulating and supporting the vital power, under the severe conflict to which it is exposed.

2. That of suddenly exhausting the system, under the conviction that the disease is inflammatory.

3. That of opposing the poison by certain antidotes.

4. That of considering the disease as highly nervous and spasmodic.

To carry the first intention into effect, volatile alkali, warm and pungent aromatics, with bark, have been resorted to. The confectio aromatica, confectio opii, most of the carbonates of ammonia, essential oils, and cajeput oil, with camphire, were amongst the leading cordials, and the different preparations of cinchona, with or without them.

The means resorted to with a view of suddenly debilitating and exhausting the system, upon the opinion of the disease being inflammatory, are bleeding and purgatives. The former has been said to have cured two cases, very lately, in the East Indies; in consequence of which, though formerly abandoned from its inutility, the bleeding has lately been revived, and carried to the extent of fainting, by large and rapid depletions; and the operation has been repeated almost as long as the powers of life would allow. Under this plan, some cases are loosely recorded as being successful in the last hundred years. There is great reason, therefore, to doubt the efficacy of this practice, which would have been very generally instituted, had it been efficacious. The purgative plan consists in the exhibition of those medicines which have a drastic effect, especially colocynth, camboge, aloes, and the submuriate of mercury: these have been administered in large doses, or such as kept up a continued purgation. Another powerful means of endeavouring to fulfil the same indication is submersion in cold water Celsus appears to have been the first who resorted to it with a view of taking off the spasm of hydrophobia, and quenching the thirst that accompanies it: — "Miserrimum genus morbi; in quo simul æger et siti et aquæ metu cruciatur: quo oppressis in angusto spes est." In this almost hopeless state, the only remedy, he observes, is to throw the patient instantly, and without warning, into a fish-pond, alternately, if he has no knowledge of swimming, plunging him under the water, that he may drink; then raising his head, or forcing him under if he can swim, and keeping him below till he is filled with water, so that the thirst and water dread may be extinguished at the same time. But there is, he further observes, another danger, lest the body of the patient, exhausted and worn out by the submersion, as well as by the disease, be thrown into convulsions: to prevent which, as soon as he is taken out of the pond he is to be put into warm oil. In subsequent times, practitioners have proceeded in a bolder way, regardless of convulsions, and have persevered, at all hazards, in reducing the living power to its last ebb, believing, that the nearer they suffocated the patient, without actually killing him, the greater their chance of success. Van Helmont used to keep the patient submersed while the *Miserere* was chaunted.

With a view of fulfilling the third intention, a vast variety of substances have been put in requisition. The Ophiorrhiza mungos stands the first in this class of antidotes. It has long been supposed to be a specific for the bite of the rattle-snake; and, in India and Ceylon, it is used in the present day as an antidote against the bite of a mad dog. Acids and alkalies were supposed to operate in the same way. The muriatic acid, the sulphuric, and the acetic, were formerly selected. Of the alkalies, the carbonates of ammonia, and the eau de luce, have been largely used, both internally and externally. Mercury, from its being a specific in syphilis, and more especially from its specific action on the salivary organs, the supposed immediate outlet of the poison of rabies, has had a strong claim to general attention, and has been very extensively tried, in various forms, and acquired a high degree of reputation. The grand object with mercurials is to excite a speedy salivation, and maintain it so long as there is supposed to be any danger; and especially where the administration had been delayed till the paroxysm had shown itself. In some few cases this practice is said to have effected a cure; but, like all the others, it has failed in most. As diuretics were supposed to possess a strong alexipharmic power, they have not been without their votaries. Cantharides, and one or two species of scarabei, have been given internally, and applied also externally. The ash-coloured liverwort, or lichen caninus of Linnæus, was once a very popular remedy against canine madness. It was given

in powder, with an equal quantity of black pepper, a drachm and a half of the two forming a dose for an adult, which was taken for four mornings fasting, in half a pint of warm cow's milk: the patient, however, was first to lose nine ounces of blood, and afterwards to be dipped in cold water, for a month together, early in the morning.

The fourth intention regards the highly nervous and spasmodic condition of the system, to allay which antispasmodics and sedatives have been resorted to. Practitioners have universally considered this as the most likely way of subduing the disease; and hence the whole catalogue of antispasmodics and sedatives have been extensively employed: and, indeed, the benefit occasionally derived from volatile alkali, camphire, and cold bathing, must be referred to their antispasmodic virtues. The more direct medicines, however, of this class, are opium, æther, musk, belladonna, nux vomica, hyosciamus, nitrate of silver, and ammoniated copper, oil of amber, and arsenic. Opium alone, and in combination with musk, have been chiefly depended on; but in neither way have the effects been found more beneficial than other means. When the patient can swallow, it is to be administered in full doses; and, if the constriction of the throat prevents the patient swallowing, two grains of opium, dissolved in an ounce of any bland fluid, may be thrown into the rectum, and kept there, every two or three hours. The French practitioners injected a gummy solution of opium into the veins. Two grains of the extract were in this manner thrown in, and the patient was in some degree tranquillised for an hour or two; the dose was doubled towards the evening of the same day. It was repeated at intervals, and at length increased to eight grains at a dose. The relief it afforded, however, was never more than temporary, and he expired on the fifth day from the incursion. Mosch has been said to be a specific antidote in hydrophobia, by Gmelin: but, though given in ample doses in this country, its exhibition has not been followed by any such result as to justify its being depended on. The combination of musk and opium has been very generally tried; and also æther, camphire, oil of amber, &c. at the same time; and such varied compounds, though they certainly bid fair, as the most powerful antispasmodics, failed as generally as other medicines. Musk and cinnabar was supposed to be peculiarly efficacious. The famous powder employed by the natives of Tonquin, and introduced into this country by Mr. Cobb, consisted of sixteen grains of musk, and forty-eight grains of cinnabar, mixed in a gill of arrack. This, taken as a dose, is said to have thrown the patient into a sound sleep and perspiration in the course of two or three hours; and where it did not, the dose was repeated till such effect was produced. Arsenical preparations, and prussic acid, have, under the direction of the most skilful practitioners, had a fair trial, and in every instance been unsuccessful. Besides the remedies already mentioned, there are two or three others. The Ormskirk medicine, so called from the place where its inventor lived, was supposed — for he could not be prevailed on to publish his secret — to consist of powder of chalk, half an ounce; Armenian bole, three drachms; alum, ten grains; powder of elecampane-root, one drachm; oil of anise, six drops. The single dose, thus compounded, is to be taken every morning, for six times, in a glass of water, with a small proportion of fresh milk. The Alisma plantago, or madwort plantain, has for some years been a popular remedy against canine madness, and is depended on in the present day in Russia, where they give the root, reduced to a powder, and spread over bread and butter. Two or three doses are said to be sufficient in the worst cases. In the second number of the Hamburgh Medical Repository, quite a new remedy is mentioned, viz. that of introducing rabid blood into the system. Dr. Ritchmeister of Finland, has collected a number of striking cases, and various authorities, in proof of the blood of a rabid animal, when drunk, being a specific against the canine hydrophobia, even when the symptoms are the most strongly marked. The rabid wolf-dog, or other quadruped, is for this purpose killed, and its blood drawn off and collected as a drink. Chlorine is the last remedy we have to notice, which Brugnatelli o. Pavia, contends has specific powers over this disease; but they are denied by an equally distinguished professor.

Hydrophosphorous acid. See *Phosphorous acid.*

HY'DROPHTHA'LMIA. (*a*, *æ.* f.; from *ὑδωρ*, water, and *οφθαλμος*, the eye.) *Hydrophthalmium.* There are two diseases different in their nature and consequences, thus termed. The one is a mere anasarcous, or œdematous swelling of the eyelid. The other, the true hydrophthalmia, is a swelling of the bulb of the eye, from a morbid increase of the vitreous or aqueous humours.

Hydrophthalmium. See *Hydrophthalmia.*

HY'DROPHTHO'RIC ACID. (*Hydrophthoricus*; from *ὑδωρ*, water, and *phthorum*, a name of fluorine, from *φθορα*, corruption, on account of its supposed corroding power.) Ampère's name for the base of the fluoric acid, called by Davy *fluorine.* See *Hydro-fluoric acid.*

HY'DROPHYSOCE'LE. (*e*, *es.* f.; from *ὑδωρ*, water, *φυση*, *flatus*, and *κηλη*, a tumour.) A name given to a hernia, the sac of which contains fluid and air.

HYDRO'PIC. (*Hydropicus*; from *ὑδρωψ*, the dropsy.) Relating to dropsy. As an *hydropic patient*, or an *hydropic medicine.*

HYDRO'PIPER. (*er*, *eris.* n.; from *ὑδωρ*, water, and *πεπερι*, pepper: so called from its biting the tongue like pepper, and growing in marshy places.) See *Polygonum hydropiper.*

HY'DROPNEUMA'TIC TROUGH. This name has been given to the apparatus generally called the *pneumatic trough.* See *Apparatus, pneumatic.*

HY'DROPNEUMO'NIA. (From *ὑδωρ*, water, and *πνευμων*, the lung.) Serous infiltration of the lungs.

HY'DROPNEUMOSA'RCA. (*a*, *æ.* f.; from *ὑδωρ*, water, *πνευμα*, wind, and *σαρξ*, flesh.) A tumour containing air with liquid and solid matter.

HYDRO'POI'DES. (From ὕδρωψ, a dropsy, and εἶδος, likeness.) Serous or watery: formerly applied to watery excrements.

HY'DROPS. (*ops, opis.* m.; from ὕδωρ, water.) Dropsy. A preternatural collection of serous or watery fluid in the cellular substance, or different cavities of the body. It receives different appellations, according to the particular situation of the fluid. When it is diffused through the cellular membrane, either generally or partially, it is called *anasarca.* When it is deposited in the cavity of the cranium it is called *hydrocephalus;* when in the chest, *hydrothorax;* when in the abdomen, *ascites;* in the uterus, *hydrometra;* and, within the scrotum, *hydrocele.*

Dropsy is a consequence of so many and such various morbid conditions, that much difficulty has always existed in giving just and general views of its nature. The older and more popular theory regarded debility as its universal cause, and made divisions according merely to the different seats of the fluid collected; as anasarca, hydrocephalus, hydrothorax, &c. Later, the attention of chemists and physicians was drawn to the analysis of the urine discharged during the disease, and of the fluid itself, when it could be procured; and upon the differences thus traced was founded the diagnosis, and the practice of this school of *water doctors.* In the present day, the investigation of the morbid anatomy of disease has led pathologists to explain dropsy, by declaring the existence, in all cases, of some obstacle to the circulation in the blood vessels or lymphatics, or of some inflammation of a secreting surface. But perhaps, as in other instances, the nature of this disease may be, in any given case, best illustrated by a consideration of its history in relation to all the various circumstances which may explain it, but without bestowing an exclusive reliance upon any isolated facts: since, although something is to be learned from each view which is taken, it cannot be asserted that there is any one condition, or symptom, or organic defect so peculiar and so constantly present as to be esteemed essential and necessary to its production. Thus, the diffused dropsy, succeeding to profuse hæmorrhage, and to mercurial salivation, and occurring so commonly as a sequel to chronic wasting diseases, may be probably attributed to a profuse exhalation on the part of the secernents or terminal vessels, which open their mouths too widely, and suffer the serum or other aqueous fluid to escape with too much freedom; or it may proceed from a torpid and inactive condition of the correspondent absorbents occasioning too small a removal of this fluid; or by each of these diseased conditions of both sets of vessels operating at the same time: to which double deviation from healthy action has been applied the name of hydropic diathesis. But the debility, which may be truly called characteristic here, cannot be supposed to exist in the sudden effusions from the membrane enveloping the testicle or the heart, from the tunics of the brain, or of the eye. Dr. Blackall has lately revived and insisted on the method of distinguishing the different varieties of dropsy by attending to the chemical qualities of the urine and effused fluid; and this study of consequences promised a very convenient solution of the difficulties generally found in tracing the causes and character of a disease which shows itself under such different combinations of morbid conditions: but, upon a perusal of the cases where this plan has been pursued, there will not be found so great a constancy in the connexion of their chemical qualities with the morbid phenomena co-existing as to afford a sure basis for classification and practice. Again, the divisions founded upon anatomical observations, which are, in many cases, the only true ones, are rendered less satisfactory by the consideration that the same morbid conditions are often found to exist not conjoined with a dropsical state; and that, where this is present, we are called upon to allow of some general hydropic tendency or cachexy which has been superadded to the structural derangement, as, otherwise, we cannot fully account for this consequence not occurring whenever the imputed causes showt hemselves. Thus, obstructions to the circulation, as aneurisms and ossified valves, exist sometimes for years without producing anasarca; inflammation of the peritonæum, though, in the first instance, causing an effusion of serum, does not necessarily lay the foundation of ascites. And we must, in general, admit the influence of modifying circumstances, even in cases where the occasional cause, be this mechanical obstruction or inflammation, is clearly shown; for neither in kind nor degree is the dropsical effusion always in accordance with the existence of organic mischief.

With regard to the treatment of dropsy, it is evident that it must be extremely various according to circumstances, and can only be conducted with any prospect of success when founded on an accurate knowledge of the cause of the disease. Thus we have acute inflammatory forms of dropsy, which require depletion, sometimes to a great extent, and which admit of a rapid and perfect cure by vigorous practice. We have dropsy as a sequel of exanthematous diseases, arising apparently in some cases from a loss of balance between the secernent and absorbent functions, and in others from subacute inflammatory action, and to be treated accordingly by moderate depletion, or by tonics, or a combination of the two. We have dropsy arising from an insidious affection of the brain, the nature of which is little understood, and over which medicine has little control. We have dropsy as a symptom of organic disease of the thoracic or abdominal viscera, in which the indication is merely to drain off the serum by diuretics and hydragogues, when it accumulates beyond a certain point, a cure being out of the question, because the disease on which the dropsy depends is incurable. Lastly, we have dropsy as a symptom of a broken up constitution, and a general failure of the powers of life; a state in which nature cannot be expected to do much, and art can do next to nothing. See *Anasarca, Ascites, Hydrocephalus, Hydrothorax,* &c.

Hydrops abdominis. Dropsy of the belly. See *Ascites*.

Hydrops ad matulam. Diabetes.

Hydrops articuli. A swelling of a joint is so called, when produced by a serous or lymphatic effusion into the joint or surrounding cellular structure.

Hydrops cysticus. *Hydrops saccatus.* A dropsy enclosed in a bag, or cyst. See *Ascites*.

Hydrops genu. An accumulation of fluid within the capsular ligament of the knee.

Hydrops medullæ spinalis. See *Hydrorachis.*

Hydrops oculi. Dropsy of the eye. See *Hydrophthalmia.*

Hydrops ovarii. Dropsy of the ovarium. See *Ovarium.*

Hydrops pectoris. See *Hydrothorax.*

Hydrops pericardii. See *Hydropericardium.*

Hydrops pu'lmonum. Serous infiltration of the lungs.

Hydrops saccatus. See *Hydrops cysticus.*

Hydrops sacci lachrymalis. Distension of the lachrymal sac from obstruction of the nasal duct.

Hydrops scroti. See *Hydrocele.*

Hydrops siccus. Tympanites has been absurdly so called.

Hydrops uteri. See *Hydrometra.*

Hydropy'retus. (From ὑδωρ, water, and πυρετος, fever.) The sweating sickness.

HYDRO'RACHIS. (From ὑδωρ, water, and ραχις, the spine.) *Hydrops medullæ spinalis. Hydrocele spinalis.* Dropsy of the spine. There are two varieties of this disease, the one consisting in serous effusion within the spinal canal, unattended with any malformation of the bones; the other is the case also called *spina bifida*, in which there is an incomplete state of some of the vertebræ, and the membranes of the spinal cord distended with serum, protrude and form a tumour under the skin. For the former the reader is referred to the article *Spinal Cord, Diseases of the.* The latter, which may be considered rather as a malformation than a disease, is not of uncommon occurrence. See *Spina bifida.*

Hydrorachitis. See *Hydrorachis.*

Hy'droro'satum. A drink made of water, honey, and the juice of roses.

Hy'drorrhœ'a. (From ὑδωρ, water, and ῥεω, to flow.) Gräefe gives this name to the first stage of Egyptian ophthalmia, in which there is a profuse flow of tears.

Hy'drosa'ccharum. (*um, i.* n.; from ὑδωρ, water, and σακχαρον, sugar.) Water sweetened with sugar.

HY'DROSA'RCA. (*a, æ.* f.; from ὑδωρ, water, and σαρξ, the flesh.) 1. Synonymous with *anasarca.*

2. Applied by M. A. Severinus to a tumour containing serosity and fleshy matter.

Hy'drosarcoce'le. (*e, es.* f.; from ὑδωρ, water, σαρξ, flesh, and κηλη, a tumour.) Sarcocele, with an effusion of water into the cellular membrane.

Hy'drosele'nic acid. *Acidum hydroselenicum.* (So called because it is a compound of hydrogen and selenium.) Seleniuretted hydrogen. The best process which we can employ for procuring this acid consists in treating the seleniuret of potassium with the liquid muriatic acid. The acid gas evolved must be collected over mercury. This gas is colourless. It has a smell resembling that of sulphuretted hydrogen. It is exceedingly acrid, and instantly inflames the eyes, and destroys for the moment the sense of smell: it produces these effects even when in the smallest quantity. It is highly deleterious. It is more soluble in water than sulphuretted hydrogen.

Hy'droseli'num. (*um, i.* n.; from ὑδωρ, water, and σελινον, purslane.) A species of purslane growing in marshy places.

Hy'drosta'tica. An order of the class *Acalepha*, which have buoyant air vessels.

HYDROSTA'TICS. *Hydrostatica.* (From ὑδωρ, water, and στατικη, the science which treats of weights.) That branch of physics which treats of the weight, pressure, and equilibrium of liquids.

Hydro'steon. (From ὑδωρ, water, and οστεον, a bone.) Van Wy gives this name to a deposition of serum in the extremities of the long bones, which sometimes accompanies dropsy of the joints.

Hydrosu'lphate. *Hydrosulphas.* A salt formed by the hydrosulphuric acid with a base.

HY'DROSU'LPHURET. *Hydrosulphuretum.* A compound of sulphuretted hydrogen with a base. See *Sulphur.*

Hydrosulphure'tum stibii luteum. See *Antimonii sulphuretum præcipitatum.*

Hydrosulphure'tum sti'bii rubrum. *Kermes mineralis.* A hydrosulphuret of antimony formerly in high estimation as an expectorant, sudorific, and antispasmodic, in difficult respiration, rheumatism, diseases of the skin and glands.

Hy'drosulphu'ric acid. The gas commonly called sulphuretted hydrogen is so named by some chemists.

Hy'drotheio'nic acid. (From ὑδωρ, water, and θειον, sulphur.) Sulphuretted hydrogen has been so called.

HYDROTHO'RAX. (*ax, acis.* f.; from ὑδωρ, water, and θωραξ, the chest.) *Hydrops thoracis. Hydrops pectoris.* Dropsy of the chest. Difficulty of breathing, particularly when in an horizontal posture; sudden startings from sleep, with anxiety, and palpitations of the heart; cough, paleness of the visage, anasarcous swellings of the lower extremities, thirst, and a scarcity of urine, are the characteristic symptoms of hydrothorax; but the one which is more decisive than all the rest, is a fluctuation of water being perceived in the chest, either by the patient himself or his medical attendant, on certain motions of the body.

It is doubtful if hydrothorax be ever an idiopathic disease. In those cases in which it has appeared to be so, it has probable been the result of chronic pleuritis.

The causes which give rise to it are pretty much the same with those which are productive of the other species of dropsy. See *Hydrops.* In some cases, it exists without any other kind of dropsical affection being present; but it

prevails very often as a part of more universal dropsy.

It frequently takes place to a considerable degree before it becomes very perceptible; and its presence is not readily known, the symptoms, like those of hydrocephalus, not being always very distinct. In some instances, the water is collected in both sacs of the pleura; but, at other times, it is only in one. Sometimes it is lodged in the pericardium alone; but, for the most part, it only appears there when, at the same time, a collection is present in one or both cavities of the thorax. Sometimes the water is effused in the cellular texture of the lungs, as well as in the cavity of the thorax. In a few cases, the water that is collected is enveloped in small cysts of a membranous nature, known by the name of hydatids, which seem to float in the cavity; but more frequently they are connected with, and attached to, particular parts of the internal surface of the pleura. Cases of this kind, however, do not come under the head of ordinary hydrothorax.

Hydrothorax often comes on with a sense of uneasiness at the lower end of the sternum, accompanied by a difficulty of breathing which is much increased by any exertion, and which is always most considerable during night, when the body is in an horizontal posture. Along with these symptoms there is a cough, which is at first dry, but which, after a time, is attended with an expectoration of thin mucus. There is likewise a paleness of the complexion, and an anasarcous swelling of the feet and legs, together with a considerable degree of thirst, and a diminished flow of urine. Under these appearances, we have just grounds to suspect that there is a collection of water in the chest; but if the fluctuation can be perceived, there can then remain no doubt as to the reality of its presence.

During the progress of the disease, it is no uncommon thing for the patient to feel a numbness, or degree of palsy, in one or both arms, and to be more than ordinarily sensible to cold. With regard to the pulse, it is usually quick at first, but, towards the end, becomes irregular and intermitting.

Our prognostic in hydrothorax must, in general, be unfavourable, as it has seldom been cured, and, in many cases, will hardly admit even of alleviation, the difficulty of breathing continuing to increase, until the action of the lungs is at last entirely overpowered by the quantity of water deposited in the chest. In some cases, the event is suddenly fatal; but, in others, it is preceded, for a few days previous to death, by a spitting of blood.

Dissections of this disease show that, in some cases, the water is either collected in one side of the thorax, or that there are hydatids formed in some particular part of it; but they more frequently discover water in both sides of the chest, accompanied by a collection in the cellular texture and principal cavities of the body. The fluid is usually of a yellowish colour; possesses properties similar to serum, and, with respect to its quantity, varies very much, being from a few ounces to several quarts. According to the quantity, so are the lungs compressed by it; and, where it is very considerable, they are usually found much reduced in size. Organic diseases of the heart, lungs, or their great vessels are the most frequent of the causes to which hydrothorax may be traced; but scirrhus of some of the abdominal viscera, especially the liver, is also frequently the source of the dropsical affection.

The treatment of this disease must be conducted on the same general plan as that of anasarca. Emetics, however, are hazardous, and purgatives do not afford so much benefit; but the bowels must be kept regular, and other evacuating remedies may be employed in conjunction with tonics. Squill has been chiefly resorted to, as being expectorant as well as diuretic; but its power is usually not great, unless it be carried so far as to cause nausea, which cannot usually be borne to any extent. Digitalis is more to be relied upon; but it will be better to conjoin them, adding, perhaps, some form of mercury, and employing at the same time other diuretics, as the supertartrate or acetate of potash, juniper berries, &c. Where febrile symptoms attend, diaphoretics will probably be especially serviceable, as the pulvis ipecacuanhæ compositus, or antimonials, in small doses; which last may also promote expectoration. Blisters to the chest will be proper in many cases, particularly should there be any pain or other mark of inflammatory action. Myrrh seems to answer better than most other tonics, as more decidedly promoting expectoration; or the nitric acid may be given, increasing the secretion of urine, as well as supporting the strength. The inhalation of oxygen gas is stated to have been in some instances singularly beneficial. Where the fluid is collected in either of the sacs of the pleura, the operation of paracentesis of the thorax may afford relief under urgent symptoms, and, perhaps, contribute to the recovery of the patient.

Hydro'tic. (From *ὑδωρ.*) Synonymous with *hydragogue.*

Hydro'tis. (From *ὑδωρ*, water, and *ως*, the ear.) Dropsy of the ear.

Hy'droxa'nthic acid. *Acidum hydroxanthicum.* The acid may be obtained by pouring a mixture of four parts of sulphuric acid, and three of water, on hydroxanthate of potash, and, in a few seconds, adding abundance of water. See *Sulphuret of carbon.* The acid collects at the bottom of the water as a transparent slightly coloured oil. It must be quickly washed with water until free from sulphuric acid. This acid reddens litmus paper powerfully. Its taste is acid and astringent. It was discovered by Zeise of Copenhagen, who has since considered it as an oxy-acid, and called it *xanthic.*

Hydroxure. See *Hydrate.*

HY'DRURET. (*Hydruretum*, *i.* n.) A compound of hydrogen with a metal.

Hygi'dion. *Ὑγιδιον.* The name of a collyrium mentioned by Paul of Ægina.

HYGIE'A. (*a*, *æ.* f. *Ὑγιεια*, health, or the goddess of health.) This name was given to a plaster mentioned by Aëtius, which was in high

repute against malignant ulcers, and a number of other diseases.

HYGIE'NE. (*e, es.* f.; from *ὑγιαινω*, to be well.) *Hygiesis.* Health. Modern physicians have applied this term to that part of *therapeia* which treats of the diet and nonnaturals of the sick.

HYGIE'NIC. Relating to hygiene.

Hygiesis. See *Hygiene.*

HY'GRA. (From *ὑγρος*, moist.) A plaster of a moist consistence.

HYGREMPLA'STRUM. (From *ὑγρος*, moist, and *εμπλαστρον*, a plaster.) A plaster of a moist consistence.

HY'GROBLEPHA'RICUS. (From *ὑγρος*, humid, and *βλεφαρον*, the eyelid.) Applied to the excretory ducts of the lachrymal gland.

HY'GROCIRSOCE'LE. (*e, es.* f.; from *ὑγρος*, moist, *κιρσος*, a varix, and *κηλη*, a tumour.) Circocele, with dropsy of the scrotum.

HYGROCOLLY'RIUM. (From *ὑγρος*, liquid, and *κολλυριον*, a collyrium.) A collyrium composed of liquids.

HYGRO'LOGY. (*Hygrologia, æ.* f.; from *ὑγρος*, humid or liquid, and *λογος*, a discourse.) The doctrine of the fluids.

HYGRO'MA. (*a, atis.* n. *Ὑγρωμα*; from *ὑγρος*, liquid.) A tumour, the contents of which are serum, a fluid like lymph, matter resembling chocolate grounds, or some other morbid humour, but not pus.

HYGRO'METER. (*Hygrometrum, i.* n.; from *ὑγρος*, moist, and *μετρον*, a measure.) Hydrometer. An instrument for measuring the degrees of moisture in the atmosphere. See *Atmosphere.*

HY'GROME'TRIC. Relating to hygrometry.

HYGRO'METRY. The art of ascertaining the degree of moisture of the atmosphere.

HYGRO'MYRUM. (From *ὑγρος*, moist, and *μυρον*, a liquid ointment.) An ointment of a liquid consistence.

Hygrophobia. See *Hydrophobia.*

Hygrophthalmic. See *Hygroblepharic.*

HY'GROSCOPE. (From *ὑγρος*, humid, and *σκοπεω*, to explore.) Synonymous with *hygrometer.* See *Atmosphere.*

HYGROSCOPIC. Synonymous with *hygrometric.*

HYGROSCOPY. Synonymous with *hygrometry.*

HY'GRUS. (From *ὑγρος*, humid.) Humid: applied formerly to liquid plasters.

HY'LE. (*Ὑλη*, matter.) The materia medica, the materia alimentaria, and also the philosopher's stone, have been so called.

HY'MEN. (*en, inis.* m.; from *Hymen*, the god of marriage, because this membrane is supposed to be entire before marriage or copulation.) The hymen is a thin membrane, of a semilunar or circular form, placed at the entrance of the vagina, which it partly closes. It has a very different appearance in different women, but it is generally found in virgins, and is ruptured in the first coition. The presence of the hymen has been very erroneously esteemed the test of virginity: in many females it is naturally wanting; and where it is originally present, it may be destroyed by many causes besides copulation. The remnants of the hymen are called the carunculæ myrtiformes. The hymen is peculiar to the human species. There are two circumstances relating to the hymen which require medical assistance. It is sometimes of such a strong ligamentous texture that it cannot be ruptured, and prevents the connexion between the sexes. It is also sometimes imperforated, wholly closing the entrance into the vagina, and preventing any discharge from the uterus; but both these cases are rare. If the hymen be of an unnaturally firm texture, but perforated, though perhaps with a very small opening, the inconveniences thence arising will not be discovered before the time of marriage, when they may be removed by a crucial incision made through it, taking care not to injure the adjoining parts.

HYMENÆ'A. (*a, æ.* f.; from *Hymen*, the god of marriage: because, as Linnæus informs us, its younger leaves cohere together in pairs, throughout the night.) The name of a genus of plants. Class, *Decandria*; Order, *Monogynia.*

HYMENÆA COURBARIL. The systematic name of the tree which has been said to afford the resin called *gum anime*, which is now fallen into disuse. Some say that the true gum anime is the produce of *H. Martiana.*

HYME'NIUM. (*um, ii.* n.; from *ὑμην*, a membrane.) The dilated exposed membrane of gymnocarpous mushrooms, in which the seed is placed. See *Gymnocarpi.*

HYMENO'DES. (From *ὑμην*, a membrane, and *ειδος*, likeness.) An old term for such urine as is found to be full of little films and pellicles. Hippocrates applies it also to the menstrual discharges when mixed with a tough viscid phlegm.

HYMENOP'TERA. (From *ὑμην*, a membrane, and *πτερον*, a wing.) An order of insects which have membranaceous wings.

HY'O-CHO'NDRO-GLO'SSUS. (From *ὑοειδες*, *χονδρος*, a cartilage, and *γλωσσα*, the tongue.) The hyo-glossus muscle is so named by Dumas.

HYO-EPIGLOTTIC LIGAMENT. A band of cellular membrane which passes from the posterior part of the body of the os hyoides to the base of the epiglottis.

HYO-GLO'SSUS. *Cerato-glossus*, of Douglas and Cowper. *Basio-cerato-chondroglossus*, of Albinus. A muscle situated at the sides between the os hyoides and the tongue. It arises from the basis, but chiefly from the corner of the os hyoides, running laterally and forwards to the tongue, which it pulls inwards and downwards.

HYOI'DES. (From the Greek letter *υ*, and *ειδος*, likeness.) Hyoid, or like the Greek letter upsilon.

HYOIDES OS. This bone, which is situated between the root of the tongue and the larynx, derives its name from its supposed resemblance to the Greek letter *υ*, and is, by some writers, described along with the parts contained in the mouth. Ruysch has seen the ligaments of the bone so completely ossified, that the os hyoides

was joined to the temporal bones by anchy'losis. In describing this bone, it may be distinguished into its body, horns, and appendices. The body is the middle and broadest part of the bone, so placed that it may be easily felt with the finger in the fore-part of the throat. Its fore-part, which is placed towards the tongue, is irregularly convex, and its inner surface, which is turned towards the larynx, is unequally concave. The *cornua*, or horns, which are flat, and a little bent, are considerably longer than the body of the bone, and may be said to form the sides of the *v*. These horns are thickest near the body of the bone. At the extremity of each is observed a round tubercle, from which a ligament passes to the thyroid cartilage. The appendices, or lesser horns, *cornua minora*, as they are called by some writers, are two small processes, which, in their size and shape, are somewhat like a grain of wheat. They rise up from the articulations of the cornua, with the body of the bone, and are sometimes connected with the styloid process on each side, by means of a ligament. It is not unusual to find small portions of bone in these ligaments; and Ruysch, as we have already observed, has seen them completely ossified. In the fœtus, almost the whole of the bone is in a cartilaginous state, excepting a small point of a bone in the middle of its body, and in each of its horns. The appendices do not begin to appear till after birth, and usually remain cartilaginous many years. The os hyoides serves to support the tongue, and affords attachment to a variety of muscles, some of which perform the motions of the tongue, while others act on the larynx and fauces.

Hyoides primus. The sterno-hyoid muscle has been so named.

Hyoides quartus. The omo-hyoideus muscle.

HY'OPHARYNGE'US. (From ὑοειδες, the hyoid bone, and φαρυγξ, the pharynx.) The name of a muscle, so called from its origin in the os hyoides, and its insertion in the pharynx.

Hyophtha'lmus. (*us*, *i.* m.; from ὑς, a swine, and οφθαλμος, an eye: so named from the supposed resemblance of its flower to a hog's eye.) Hog's-eye plant. Most probably the *Buphthalmum spinosum* of Linnæus.

HYOSCIA'MIA. (*a*, *æ.* f.; so called because obtained from hyoscyamus.) A vegetable alkali, extracted from henbane. See *Hyoscyamus niger*.

HYOSCY'AMUS. (*us*, *i.* m.; from ὑς, a swine, and κυαμος, a bean: so named because hogs eat it as a medicine, or it may be because the plant is hairy and bristly, like a swine.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*.

2. The pharmacopœial name of the henbane. See *Hyoscyamus niger*.

Hyoscyamus albus. This plant, a native of the south of Europe, possesses similar virtues to the hyoscyamus niger.

Hyoscyamus luteus. A species of tobacco, the *Nicotiana rustica* of Linnæus.

Hyoscyamus niger. The systematic name of common or black henbane; called also, *Faba suilla*, *Apollinaris altercum*, *Agone*, and *Altercangenon*. *Hyoscyamus — foliis amplexicaulibus sinuatis, floribus sessilibus*, of Linnæus. The leaves of this plant, when recent, have a slightly fetid smell, and a mucilaginous taste; when dried, they lose both taste and smell, and part also of their narcotic power. The root possesses the same qualities as the leaves, and even in a more eminent degree. Henbane resembles opium in its action more than any other narcotic dose. In a moderate dose it increases at first the strength of the pulse, and occasions some sense of heat, which are followed by diminished sensibility and motion; in some cases by thirst, sickness, stupor, and dimness of vision. In a larger quantity it occasions profound sleep, hard pulse, and sometimes fierce delirium, ending in coma, or convulsions, with a remarkable dilatation of the pupil, distortion of the countenance, a weak tremulous pulse, and eruption of petechiæ. On dissection, gangrenous spots have been found on the internal surface of the stomach. Its baneful effects are best counteracted by a powerful emetic, and by drinking largely of the vegetable acids.

Henbane has been used in various spasmodic and painful diseases; as in epilepsy, hysteria, palpitation, headach, paralysis, mania, and scirrhus. It is sometimes employed as a substitute for opium, where the latter, from idiosyncrasy, occasions any disagreeable symptom. The henbane is free from the constipating quality of the opium, and sometimes has rather a laxative effect.

Henbane is an excellent narcotic when given in a sufficient dose. It is frequently given in too small doses. The extract generally produces a full effect in the dose of five grains, but this quantity may be much increased by degrees. The proper dose of the tincture is two drachms and upwards. The powder of the dried leaves is given in doses of from three to ten grains; but it is of uncertain strength, and therefore less eligible than the extract and tincture, both of which are officinal in the three British pharmacopœias.

M. Brandes has extracted a new alkali from this plant, which he calls *hyosciamia*. It crystallises in long prisms, and, when neutralised by sulphuric or nitric acid, forms characteristic salts.

Hy'opharynge'us. The middle constrictor muscle of the pharynx has been so named by some anatomists, from its origin and insertion.

Hy'othyroide'us. (From ὑοειδες, the hyoid bone, and θυροειδης, the thyroid cartilage.) A muscle named from its origin in the hyoid bone, and insertion in the thyroid cartilage.

Hypa'cticus. (Υπακτικος; from ὑπαγω, *subduco*.) Purgative.

Hypalei'ptrum. (From ὑπαλειφω, to spread upon.) A spatula for spreading ointments with.

Hype'latus. (Υπηλατος; from ὑπελαυνω, *subigo*.) Purgative.

Hyperacu'sis. (From ὑπερ and ακουσις, the sense of hearing.) Morbid exaltation of the

sense of hearing. A common symptom in irritable states of the brain.

HYPERÆ'MIA. (From ὑπερ, and αἱμα, blood.) The name given by Andral to congestion of blood in a part, from whatever cause.

HYPERÆSTHE'SIS. (From ὑπερ, and αισθανομαι, to feel.) Morbid increase of sensibility.

HYPERA'PHIA. (From ὑπερ, and αφη, the touch.) Morbid exaltation of the sense of touch.

HYPERBOREAN. Northern. The name given by naturalists to a particular race of mankind. See *Homo*.

HYPERCA'RBONATE. The salts now called *bi-carbonates* have formerly been named *hyper-carbonates*.

HY'PERCATHA'RSIS. (*is, is.* f.; from ὑπερ, *supra*, over or above, and καθαιρω, to purge.) *Hyperinesis. Hyperinos.* An excessive purging from medicines.

HYPERCORYPHO'SIS. (From ὑπερ, above, and κορυφη, the vertex.) A prominence or protuberance. Hippocrates calls the lobes of the liver and lungs *Hypercoryphoses*.

HYPE'RCRISIS. (*is, is.* f. Ὑπερκρισις; from ὑπερ, over or above, and κρινω, to separate.) A critical excretion above measure; as when a fever terminates in a looseness, the humours may flow off faster than the strength can bear, and therefore it is to be checked.

HYPERE'MESIS. (*is, is.* f.; from ὑπερ, in excess, and εμεω, to vomit.) An excessive evacuation by vomiting.

HY'PEREPHIDRO'SIS. (*is, is.* f.; from ὑπερ, above, and εφιδρωσις, excessive sweating.) Immoderate sweating.

HYPERHIDRO'SIS. The same as *hyperephidrosis*.

HYPE'RICUM. (*um, i.* n.; from ὑπερ, over, and εικων, an image or spectre: so named because it was thought to have power over and to drive away evil spirits.) 1. The name of a genus of plants in the Linnæan system. Class, *Polyadelphia*; Order, *Polyandria*. St. John's wort.

2. The pharmacopœial name of the common St. John's wort. See *Hypericum perfoliatum*.

HYPERICUM ANDROSÆMUM. Tutsan or All-heal, Park-leaves, and St. Peter's wort. This plant is the *androsemum* of the shops, which was formerly used internally as a mild purgative, and externally the fresh leaves were applied to heal ulcers. It is now deservedly fallen into disuse.

HYPERICUM BACCIFERUM. *Caa-opia. Arbuncula gummiferæ Braziliensis.* A juice exudes from the wounded bark of this plant, in the Brazils, which, in a dry state, resembles gamboge, but is rather darker.

HYPERICUM CORIS. *Coris lutea. Coris legitima cretica.* Bastard St. John's wort. The seeds are diuretic, emmenagogue, and antispasmodic.

HYPERICUM PERFOLIATUM. The systematic name of the St. John's wort; called also, *Fuga dæmonum*, and *Androsæmum*. *Hypericum perforatum — floribus trigynis, caule ancipiti, foliis obtusis pellucido-punctatis*, of Linnæus. This indigenous plant was greatly esteemed by the ancients, internally in a great variety of diseases, and externally as an anodyne and discutient, but is now very rarely used. The flowers were formerly in our pharmacopœia, on account of the great proportion of resinous oily matter, in which the medical efficacy of the plant is supposed to reside, but are now omitted.

HYPERICUM SAXATILE. *Hypericoides.* The seeds are said to be diuretic and antispasmodic; but have fallen into disuse.

Hyperine'sis. See *Hypercatharsis.*

Hyperi'nos. See *Hypercatharsis.*

HYPERI'NUS. (From ὑπερ, in excess, and ινεω, to evacuate.) Applied to one excessively purged.

HYPERO'A. (From ὑπερ, above, and ωον, the top of a house.) The palate.

HYPEROI'TIS. Inflammation of the palate.

HY'PEROPHARYNGE'US. (From ὑπερ, above, and φαρυγξ, the pharynx.) A muscle named from its situation above the pharynx.

HYPEROSTO'SIS. (*is, is.* m.; from ὑπερ, upon, and οστεον, a bone.) See *Exostosis.*

HYPEROXYMU'RIATE. A compound of the hyperoxymuriatic acid with a base. Such salts are now called *chlorates*.

HYPERSARCO'MA. (*a, atis.* n.; from ὑπερ, in excess, and σαρξ, flesh.) *Hypersarcosis.* A fleshy excrescence.

Hypersarco'sis. See *Hypersarcoma.*

HYPE'RTROPHY. (*Hypertrophi'a, æ.* f.; from ὑπερ, above, and τροφη, nutrition. A morbid increase of any organ, without change in the nature of its substance, arising from an excessive nutrition.

Hypertrophy of the heart. See *Heart, diseases of the.*

HYPNO'BATES. (Ὑπνοβατης; from ὑπνος, sleep, and βαινω, to go.) One who walks in his sleep.

HYPNOLO'GIA. (*a, æ.* f.; from ὑπνος, sleep, and λογος, a discourse.) That part of hygiene which relates to the due regulation of sleeping and waking.

HYPNO'TIC. (*Hypnoticus*; from ὑπνος, sleep.) Somniferous; conducive to sleep. Medicines of this kind belong chiefly to the order of narcotics.

HYPO-SULPHITE. A sulphuretted sulphite.

HYPOÆ'MA. (*a, atis.* n.; from ὑπο, under, and αἱμα, blood: because the blood is under the cornea.) An effusion of red blood into the chambers of the eye. It is an ill-formed term.

HYPOCATHA'RSIS. (From ὑπο, under, and καθαιρω, to purge.) A slight purging; or the insufficient operation of a purgative.

HYPOCAU'STUM. (*um, i.* n.; from ὑπο, under, and καιω, to burn.) A stove. The subterranean apartment which contained the stoves for heating the ancient baths was also called *hypocaustum*. See *Balneum.*

HY'POCERCHNA'LEON. (Ὑποκερχναλεον; from ὑπο, and κερχνος, hoarseness.) A roughness in the windpipe: hoarseness.

HYPOCHÆ'RIS. (*is, idis.* f.; from ὑπο, and χοιρος, a hog.) Swine-weed. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua*.

HYPOCHÆRIS MACULATA. Broad-leaved Hungarian hawkweed; called also, *Hieracium alpinum*, *Pannonica*, *Costa herba*, *Costa pulmonaria*, *Pilocella major*, *Dens leonis*, and *Pulmonaria lutea*. This plant grows on high chalky soils, flowers in June, and is much esteemed by foreign practitioners in those pulmonary complaints for which the Iceland liverwort has been administered.

HYPOCHÆRIS MINIMA. *Hieracium minus*. This plant grows in pasture-grounds, and flowers in June and July. It is not now used.

HYPOCHEO'MENOS. (From ὑποχεω, to suffuse.) One who labours under a cataract.

HYPOCHLORO'SIS. (From ὑπο, and χλωρωσις, the green-sickness.) A slight degree of chlorosis.

HYPOCHO'NDRIAC. (*Hypochondriacus*; from ὑπο, under, and χονδρος, a cartilage.) 1. Belonging to the hypochondria.

2. A person affected with lowness of spirits. See *Hypochondriasis*.

HYPOCHONDRIAC REGION. *Regio hypochondriaca*. The spaces in the abdomen that are under the cartilages of the false ribs on each side of the epigastrium. See *Abdomen*.

HY'POCHONDRI'ASIS. (*is, is.* m.; from υποχονδριακος, one who is hipped.) Hypochondriacism. Vapours, lowness of spirits; called also, *Morbus hypochondriacus*, *Affectio hypochondriaca*, and *Passio hypochondriaca*.

This disease bears so near a resemblance to several of the varieties of genuine melancholy as to be often distinguishable from them with great difficulty; and the more so as it is no uncommon thing for hypochondriacism to terminate in melancholy, or for melancholy to be combined with hypochondriacism. Both may be the result of a predisposing constitution, or may be primarily induced by accidental causes where no such constitution exists; and the predisposition and the accidental causes of the one may become those of the other: for the temperament commonly known by the name of melancholic, and characterised by a lean and dry corporeal texture, small and rigid muscles, a sallow skin, brownish-yellow complexion, little relieved by redness of any kind, deep black and coarse hair, eyes sunk in hollow sockets, large prominent veins, especially in the hands and arms, with a tendency to solitude and private musing, is a common precursor of both. And, in like manner, a sedentary life of any kind, and especially severe study protracted to a late hour in the night, and rarely relieved by social intercourse, exercise, or nugatory amusements, a debauched and dissolute habit, or excesses in eating and drinking, may become causes of either of these maladies, from accessory circumstances that cannot be traced out even where the predisposing temperament does not seem to exist. But, even in those whose health is much deranged, true melancholy seldom arises, except mental causes of grief and distress join themselves to the corporeal ones: and this constitutes one of the characters which distinguishes true melancholy from hypochondriacism. The former may be said to be always excited by mental causes, and consists in various phenomena of grief, despondency, and despair; whereas the latter most commonly arises from corporeal causes, and its mental phenomena consist of erroneous ideas entertained about the patient's own make or body.

The corporeal causes are usually a diseased condition of one or more of the digestive organs. It is also not unfrequently a result of the sudden cessation of some periodical or other habitual discharge, as that of an issue, or of a hæmorrhoidal flux, a chronic ulcer, or some external eruption.

The melancholy man seldom lives long, and his disorder often commences in the meridian of life. He frequently terminates his days by violence, or at the utmost never attains old age. The hypochondriac seldom becomes affected till after the meridian of life, and very generally continues to the stage of longevity.

The common corporeal symptoms are a troublesome flatulency in the stomach or bowels, acrid eructations, costiveness, a copious discharge of pale urine, spasmodic pains in the head and other parts of the body, giddiness, dimness of sight, palpitations, general sleeplessness, and an utter inability of fixing the attention upon any subject of importance, or engaging in any thing that demands vigour or courage. The mental feelings, and peculiar trains of ideas that haunt the imagination and overwhelm the judgment, exhibit an infinite diversity, and lay a foundation for the three following varieties: — vapours, weariness of life, misanthropy, or spleen.

In the *first*, or low spirits, the patient is tormented with a visionary or exaggerated sense of pains, or some concealed disease; a whimsical dislike of particular persons, places, or things; or groundless apprehensions of personal danger or poverty.

Greding gives an account of a medical practitioner who applied to him for assistance, under an impression that his stomach was filled with frogs, which had been successively spawning ever since he had bathed, when a boy, in a pool in which he had perceived a few tadpoles. He had spent his life in trying to expel this imaginary evil, and had travelled to numerous places to consult the first physicians of the day upon his obstinate malady. It was in vain to attempt convincing him that the gurglings he heard were from extricated and erratic wind. He argued himself, says Greding, into a great passion in my presence, and asked me if I did not hear the frogs croak.

The whims that are sometimes seriously entertained under this variety of the disease are so truly ludicrous, that "to be grave exceeds all power of face." One thinks himself a giant, another a dwarf; one is as heavy as lead, another as light as a feather. Marcellus Donatus makes mention of a baker of Ferrara who thought himself a lump of butter, and durst not sit in the sun or come near the fire for fear of being melted. They are all extremely timid, and their fears are exercised upon trifles, or are altogether groundless. Some suspect their nearest and dearest friends of designing to poison them: others dare not be alone in the

dark, lest they should be attacked by ghosts or hobgoblins. They dare not go over a bridge, or near a pool, rock, or steep hill, lest they should be tempted to hang, drown, or precipitate themselves: and, if they come to a place where a robbery or a murder has been committed, they instantly fear they are suspected. Trincavellius had a patient that for three years together could not be persuaded but that he had killed a man, and at length sunk into a confirmed melancholy, and made away with himself for fear of the gallows.

It is a melancholy reflection that the wisest and best of mankind are as open to this affliction as the weakest, and perhaps more so. Pascal himself was at one time so hallucinated with hypochondriacism as to believe that he was always on the verge of an abyss, into which he was in danger of falling; and, under the influence of this terror, he would never sit down till a chair was placed on that side of him on which he thought he saw it, and thus proved the floor to be substantial.

Under the *second variety* we meet with a totally distinct set of morbid feelings and ideas; for the patient is here oppressed with a general listlessness and disgust, an irksomeness and weariness of life, often without any specific reason whatever. Those who, having been actively engaged in the heyday and meridian of life, have retired upon their fortunes with a view of enjoying them in quiet, but who unhappily find themselves fitted for any thing rather than for quiet, are the subjects of this form of hypochondriacism, especially if they have no taste for reading, reflection, or domestic tranquillity, and are too proud to return to the bustle of the world, and the excitement of nicely-balanced speculations. There is here a want of the habitual stimulus to a secretion of sensorial power; in consequence of which the individual sinks into a state of low spirits, and becomes unhappy. A like issue frequently follows upon a life devoted to all the pursuits of sensual gratification, in the course of which the individual has exhausted his stock of enjoyments, and worn out his powers of body and mind before he has reached little more than the midway of his existence. Every thing now palls upon his senses, and he has neither taste nor energy to engage in more rational pursuits.

Burton has well described the state of mind of many that are tormented with this most wretched malady; but still more so those affected with the *third variety*, which is strikingly accompanied with peevishness, general malevolence, and an abhorrence of mankind. "They are soon tired with all things: they will now tarry, now begone; now in bed they will rise, now up, then go to bed; now pleased, and then again displeased; now they like, by-and-by dislike all, weary of all; *sequitur nunc vivendi, nunc moriendi cupido*, saith Aurelianus: discontented, disquieted: upon every light occasion or no occasion, abject; often tempted to make away with themselves; they cannot die, they will not live: they complain, weep, lament, and think they lead a most miserable life: never was any man so bad. Every poor man they see is most fortunate in respect of them: every beggar that comes to the door is happier than they are: jealousy and suspicion are common symptoms in the misanthropic variety. They are testy, pettish, peevish, distrustful, apt to mistake, and ready to snarl upon every occasion, and without any cause, with their dearest friends. If they speak in jest, the hypochondriac takes it in good earnest; if the smallest ceremony be accidentally omitted, he is wounded to the quick. Every tale, discourse, whisper, or gesture he applies to himself; or, if the conversation be openly addressed to him, he is ready to misconstrue every word; and cannot endure that any man should look steadfastly at him, laugh, point the finger, cough, or sneeze. Every question or movement works upon him, and is misinterpreted, and makes him alternately turn pale and red, and even sweat, with distrust, fear, or anger."

As in this species the body is more affected than in any other division of mental alienation, more may often be accomplished by medicine; though we must by no means be inattentive to moral discipline. The skin is very frequently cold and without a free secretion, and hence, general friction with rubefacients and the warmer diaphoretics have often been found serviceable. The digestive organs are almost always torpid, and several of them, especially the stomach and liver, secrete their respective fluids not only in too small a quantity, but of an unhealthy quality, so as to be too viscid, too dilute, or morbidly stimulant. Some kind of acrimony, indeed, is almost always found in the stomach, and particularly that of acidity. And hence aperients, carminatives, and particularly the tonic plan which is recommended for dyspepsia, are manifestly called for, and will often be found serviceable.

Congestions, from weakness of vascular action in one or more of the abdominal viscera, are a frequent result of the present complaint, and not unfrequently a primary cause: and hence we may see why the bleeding piles should be serviceable in so many instances as to obtain from Alberti the name of *medicina hypochondriacorum*, and why leeches repeatedly applied to the anus should often have a like beneficial effect. This is of the greatest importance where the disease has been preceded by a periodical flow of blood from the hæmorrhoidal veins; and should point out to us the necessity of renewing any other discharge or external irritation to which the system may have been accustomed.

It is very doubtful whether opium be admissible, though it is strongly recommended by some respectable writers, and readily had recourse to by hypochondriacs themselves, to relieve their distressful sensations. Cullen asserts peremptorily, that he has always found a frequent use of opiates pernicious in hypochondriasis. It has often, in such cases, been exchanged for other sedatives, but rarely with any decided advantage.

Exercise of all kinds should be encouraged in every modification of the disease, but especially exercise on horseback, though it is seldom in the first and third variety we can succeed in getting a patient to try it. The diet should be

governed by the principles laid down for treating indigestion.

In the *moral management*, assiduous kindness and consoling conversation produce a deeper effect than they seem to do. Loquacity is always hurtful; but a talent for cheerful discourse, intermixed with interesting and amusing anecdotes, frequently draws away the patient's attention from himself, and becomes a most useful palliative. In the variety in which he is perpetually haunted with a feeling of some dreadful disease, which exists nowhere but in his own fancy, the hallucination, when we possess his confidence, should be removed by a candid statement of the fact, and, if necessary, friendly expostulation: but, the moment we find the prepossession is too strong to be removed by argument, it is better to humour the conceit, and to pretend to prescribe for it. It is sometimes necessary, indeed, — for the hypochondriac is often possessed of great cunning, — to drop all pretensions whatever, and to put him in good earnest upon a course of medicines for a disease we know he is as free from as ourselves. Thus, a firm belief that he has an inveterate itch is a common delusion with a patient of this kind, and it will be often found impossible to persuade him that he is cured till his whole body has been repeatedly rubbed over with sulphur or hellebore ointment.

In the second variety, or tædium vitæ, where the time seems to hang intolerably heavy on the patient's hands, from his having, in a mistaken search after happiness, relinquished a life of constant excitement and activity for the fancied delights of rural retirement and quiet, the best and most radical cure would be a return to the situation that has been so unfortunately abandoned: but, if this cannot be accomplished, the patient must be put into a train of pursuits of some other kind. If he be fond of the sports of the country, he should weary himself in the daytime with hunting or shooting, or even horse-racing, rather than be hypochondriacal from idleness; and spend his evenings in the bustle of dinner-parties or cards. And, if he have capacity for higher and more useful occupations, let him plunge headlong into the public concerns of the parish and its neighbourhood, become a member of its select vestries, a trustee of the highways, or a magistrate of the district. The habit of excitement must for some time be maintained, though it be afterwards let down by degrees; and the intermediate steps are of no great importance, so far as they answer their purpose. We are not at present arguing the case upon a principle of ethics or of religion, but merely upon a principle of moral medicine. Yet persons of the above description have been broken in by degrees to a love of domestic quiet, for which they were by no means fitted when they first entered upon it, and who, with a love of domestic quiet, have settled also, as a soberer stage of life has advanced, and reflection has gained ground upon them, into a love of strict moral order, and the higher duties of a conscientious Christian, to which at one time they seemed as little disposed.

HYPOCHO'NDRIUM. (*um, ii.* n.; from *ὑπο*, under, and *χονδρος*, a cartilage.) That part of the body on each side which lies under the cartilages of the false ribs.

HYPO'CHYMA. (*a, æ.* f.; *Ὑποχυμα*, from *ὑποχεω*, to suffuse.) A cataract.

HYPO'CHYSIS. (*is, is.* f.) The same as *Hypochyma*.

HYPOCI'STIS. (*is, is.* m.; from *ὑπο*, under, and *κιστος*, the cistus.) See *Asarum hypocistis*, and *Cytinus hypocistis*.

HYPOCLE'PTICUM. (From *ὑπο*, under, and *κλεπτω*, to steal.) A chemical vessel for separating liquors, particularly the essential oil of any vegetable from the water; and named because it steals, as it were, the water from the oil.

HYPOCOE'LON. (From *ὑπο*, under, and *κοιλον*, a cavity.) The part under the orbit of the eye.

HYPOCOPHO'SIS. A slight degree of deafness.

HYPOCRA'NIUM. (From *ὑπο*, under, and *κρανιον*, the skull.) A collection of pus between the skull and the dura mater has been so called.

HYPOCRATE'RIFORM. (*Hypocrateriformis*; from *υπο*, *χρατηρ*, a cup, goblet, or salver, and *forma*, likeness.) Salver-shaped: applied to leaves so shaped; as those of the *Primula*.

HYPODEI'RIS. According to Rufus Ephesius, the extremity of the fore-part of the neck.

HYPODE'RMIS. *Hypoderis.* (From *ὑπο*, under, and *δερμα*, the skin.) The skin over the clitoris, which covers it like a prepuce.

HYPO'GALA. (*a, æ.* f.; from *ὑπο*, under, and *γαλα*, milk: because it is a milk-like effusion, under the cornea.) A collection of white humour, like milk, in the chambers of the eye. There are two species of this disease: the one takes place, it is said, from a deposition of the milk, as is sometimes observed in women who suckle; the other from the depression and rupture of a soft cataract.

HYPOGA'STRIC. (*Hypogastricus*; from *ὑπο*, under, and *γαστηρ*, the stomach.) Belonging to the hypogastrium.

Hypogastric artery. See *Iliac artery.*

HYPOGASTRIC PLEXUS. A plexus of nerves, formed by the inferior mesenteric plexus with the sacral on the sides and back part of the rectum and lower and back part of the bladder.

HYPOGASTRIC REGION. *Regio hypogastrica.* See *Hypogastrium.*

HYPOGA'STRIUM. (*um, ii.* n.; from *ὑπο*, under, and *γαστηρ*, the stomach.) The part of the abdomen that reaches from above the pubes to within three fingers' breadth of the navel.

HY'POGA'STROCE'LE. (*e, es.* f.; from *ὑπογαστριον*, the hypogastrium, and *κηλη*, a tumour.) A hernia in the hypogastrium.

Hypoglossal. See *Hypoglossus.*

HYPOGLO'SSUS. (From *ὑπο*, under, and *γλωσσα*, the tongue.) Hypoglossal. The lingual nerves are called also, *nervi hypoglossi, hypoglossal nerves.*

HYPOGLO'TTIS. (*is, idis.* f.; *Ὑπογλωττις*; from *ὑπο*, under, and *γλωττα*, the tongue.) The under part of the tongue: applied, also, to a lozenge to be kept under the tongue until dissolved.

HYPOGLU'TIS. (From ὑπο, under, and γλουτος, the nates.) The fleshy part under the nates, towards the thigh.

HYPO'MIA. (From ὑπο, under, and ωμος, the shoulder.) The part subjacent to the shoulder.

Hyponitrous acid. See *Nitrogen.*

HYPO'NOMOS. (From ὑπονομος, a subterraneous place.) A deep phagedænic ulcer or fistulous ulcer.

HYPOPE'DIUM. (From ὑπο, under, and πους, the foot.) A cataplasm for the sole of the foot.

HYPO'PHASIS. (From ὑποφαινομαι, to appear a little.) *Hypophasia.* That state of the eye in which the eyelids are half open, and only the white of the eye is seen.

HYPO'PHORA. (From ὑποφερομαι, to be carried or conveyed underneath.) A deep fistulous ulcer.

HYPOPHOSPHORIC ACID. This name has been given to an acid which M. Dulong has shown to be merely a combination of the *phosphoric* and *phosphorous* acids.

HYPOPHOSPHOROUS ACID. Pour water on the phosphuret of barytes, and wait till all the phosphuretted hydrogen be disengaged. Add cautiously to the filtered liquid dilute sulphuric acid, till the barytes be all precipitated in the state of sulphate. The supernatant liquid is hypophosphorous acid, which should be passed through a filter. It is a powerful deoxidising agent. It unites with the alkalis and alkaline earths, and all its salts are soluble in water.

HYPOPHTHA'LMION. (*um*, *i.* n.; from ὑπο, under, and οφθαλμος, the eye.) The part under the eye which is subject to swell in a cachexy or dropsy.

HYPO'PYUM. (*um*, *ii.* n.; from ὑπο, under, and πυον, pus: because the pus is under the cornea.) *Hypopion. Piosis. Abscessus oculi.* An accumulation of a fluid like pus, which takes place in the anterior chamber of the aqueous humour, and frequently, also, in the posterior one, in consequence of severe acute ophthalmy, particularly the internal species. This viscid matter of the hypopyum is commonly called pus: but Scarpa contends that it is only coagulating lymph. The symptoms portending an extravasation of coagulable lymph in the eye, or an hypopyum, are the same as those which occur in the highest stage of violent acute ophthalmy, viz. prodigious tumefaction of the eyelids; the same swelling and redness as in chemosis; burning heat and pain in the eye; pains in the eyebrow and nape of the neck; fever, restlessness, aversion to the faintest light, and a contracted state of the pupil.

HYPORI'NION. (*um*, *i.* n.; from ὑπο, under, and ρις, the nose.) The part of the upper lip below the nostrils; also the hair which grows on that part.

HYPOSA'RCA. (From ὑπο, under, and σαρξ, flesh.) *Hyposarcidios.* A collection of fluid or air in the cellular membrane.

HYPOSPA'DIA. (From ὑποσπαω, to draw under.) That malformation of the urethra, in which it terminates under the glans penis. The word ὑποσπαδιαιος, is used by Galen to designate an individual who is the subject of this malformation; and from this word the *hypospadia* is derived.

HYPOSPATHI'SMUS. (From ὑπο, under, and σπαθη, a spatula.) A surgical operation, which consisted in making three incisions in the forehead down to the pericranium, letting the blood flow, and then passing a spatula between the soft parts and the pericranium. It is described by Paulus Ægineta, Lib. vi. c. 6.

HYPOSPHA'GMA. (From ὑπο, under, and σφαζω, to kill.) *Aposphagma.* A rupture of the veins in the tunica adnata of the eye, chiefly from external injury. — *Paulus Ægineta.*

HYPOSTA'PHYLE. (From ὑπο, and σταφυλη the uvula.) Relaxation of the uvula.

HYPO'STASIS. (Ὑποστασις; from ὑφιστημι, to subside.) A sediment from the urine.

HYPOSULPHUROUS ACID. An acid detected by Sir J. Herschel, of which little is yet known.

HYPOSULPHU'RIC ACID. An acid discovered by Welter and Gay Lussac. It is formed by passing a current of sulphurous acid gas through water containing peroxide of manganese in fine powder. It is inodorous, and, unlike the sulphuric acid, forms soluble salts with baryta, strontia, lime, and oxide of lead.

HYPO'THENAR. (*ar*, *eros.* n.; from υπο, under, and θεναρ, the palm of the hand.) 1. A muscle which runs on the inside of the hand.

2. That part of the hand which is opposite to the palm.

HYPO'THETON. (*um*, *i.* n.; from ὑπο, under, and τιθημι, to put.) A suppository, or medicine introduced into the rectum, to procure stools.

HYPOZO'MA. (From ὑποζωννυμι, to bind round. The diaphragm.

HYPSIGLO'SSUS. (From ὑψιλοειδες, the hyoid bone, and γλωσσα, the tongue.) A muscle named from its origin in the os hyoides, and its insertion in the tongue.

HYPSILOID. (*Hypsiloides.* From ὑψιλον, the Greek letter, and ειδος, resemblance.) 1. The *os hyoides.*

2. The hyoglossus muscle.

HYPU'LUS. (From ὑπο, under, and ουλη, a cicatrix.) An ulcer unsoundly healed, under the cicatrix of which there is sanies.

Hyssop. See *Hyssopus.*

Hyssop, hedge. See *Gratiola.*

HYSSOPI'TES. (From ὑσσωπος, hyssop.) Wine impregnated with hyssop.

HYSSO'PUS. (*us*, *i.* m. Ὑσσωπος; from *Azob*, Hebrew.) 1. The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Gymnospermia.* Hyssop.

2. The pharmacopœial name of the common hyssop. See *Hyssopus officinalis.*

HYSSOPUS CAPITATUS. Wild thyme.

HYSSOPUS OFFICINALIS. The systematic name of the common hyssop. *Hyssopus — spicis secundis, foliis lanceolatis,* of Linnæus. This exotic plant is esteemed as an aromatic and stimulant, but is chiefly employed as a pectoral, and has long been thought useful in humoral asthmas, coughs, and catarrhal affections; for this purpose, an infusion of the leaves, sweetened with honey or sugar, is recommended to be drunk as tea.

HY'STERA. (*a*, *æ*. f.; from *ὑστερος*, behind: so called because it is placed behind the other parts.) The womb. See *Uterus*.

HYSTERA'LGIA. (*a*. *æ*. f.; from *ὑστερα*, the womb, and *αλγος*, pain. Pain in the womb from any cause; but the term has been used particularly to designate spasmodic pain after childbirth.

HYSTE'RIA. (*a*, *æ*. f.; from *ὑστερα*, the womb, from which the disease was supposed to arise.) *Passio hysterica*. Hysterics.

This complaint appears under such various shapes, imitates so many other diseases, and is attended with such a variety of symptoms, which denote the animal and vital functions to be considerably disordered, that it is difficult to give a just character or definition of it; and it is only by taking an assemblage of all its appearances, that we can convey a proper idea of it to others. The disease attacks in paroxysms, or fits. These are sometimes preceded by dejection of spirits, anxiety of mind, effusion of tears, difficulty of breathing, sickness at the stomach, and palpitations at the heart; but it more usually happens that a pain is felt on the left side, about the flexure of the colon, with a sense of distension, advancing upwards, till it gets into the stomach, and, removing from thence into the throat, it occasions, by its pressure, a sensation as if a ball was lodged there, which by authors has been called *globus hystericus*. The disease having arrived at this height, the patient appears to be threatened with suffocation, becomes faint, and is affected with stupor and insensibility; whilst, at the same time, the trunk of the body is turned to and fro, the limbs are variously agitated; wild and irregular actions take place in alternate fits of laughter, crying, and screaming; incoherent expressions are uttered, a temporary delirium prevails, and a frothy saliva is discharged from the mouth. The spasms at length abating, a quantity of wind is evacuated upwards, with frequent sighing and sobbing, and the woman recovers the exercise of sense and motion, with or without recollection of what has taken place during the fit; feeling, however, a severe pain in her head, and a soreness over her whole body. In some cases, there is little or no convulsive motion, and the person lies seemingly in a state of profound sleep, without either sense or motion. Hiccough is a symptom which likewise attends, in some instances, on hysteria; and now and then it happens that a fit of hysteria consists of this alone. In some cases of this nature it has been known to continue for two or three days, during which it frequently seems as if it would suffocate the patient, and proceeds, gradually weakening her, till it either goes off, or else occasions death by suffocation: but this last is extremely rare. Besides hiccough, other slight spasmodic affections sometimes wholly form a fit of hysteria, which, perhaps, continue for a day or two, and then either go off of themselves, or are removed by the aid of medicine. In some cases, the patient is attacked with violent pain in the back, which extends from the spine to the sternum, and at length becomes fixed upon the region of the stomach, being evidently of a spasmodic nature, and often pevailing in so high a degree as to cause clammy sweats, a pale cadaverous look, coldness of the extremities, and a pulse hardly perceptible. The Cullenian species are —

1. *Hysteria chlorotica*, from a retention of the menses.
2. *Hysteria à leucorrhœa*, from a fluor albus.
3. *Hysteria à menorrhagia*, from an immoderate flow of the menses.
4. *Hysteria libidinosa*, from sensual desires.

Hysteric affections occur more frequently in the single state of life than in the married; and usually between the age of puberty and that of thirty-five years; and they make their attack oftener about the period of menstruation than at any other. They occur, though rarely, in men as well as in women.

They are readily excited, in those who are subject to them, by passions of the mind, and by every considerable emotion, especially when brought on by surprise: hence, sudden joy, grief, fear, &c., are very apt to occasion them. They have also been known to arise from imitation and sympathy.

Women of a delicate habit, and whose nervous system is extremely sensible, are those who are most subject to hysteric affections; and the habit which predisposes to their attacks is acquired by inactivity and a sedentary life, grief, anxiety of mind, a suppression or obstruction of the menstrual flux, excessive evacuations, and a constant use of a low diet, or of crude unwholesome food.

Hysteria differs from hypochondriasis in the following particulars, and, by paying attention to them, may always readily be distinguished from it: — Hysteria attacks the sanguine and plethoric; comes on soon after the age of puberty; makes its onset suddenly and violently, so as to deprive the patient of all sense and voluntary motion; is accompanied with a sensation of a ball rising upwards in the throat, so as to threaten suffocation; is attended usually with much spasmodic affection; is more apt to terminate in epilepsy than in any other disease; and, on dissection, its morbid appearances are confined principally to the uterus and ovaria.

The reverse happens in hypochondriasis. It attacks the melancholic; seldom occurs till after the age of thirty-five; comes on gradually; is a tedious disease, and difficult to cure; exerts its pernicious effects on the membraneous canal of the intestines, as well by spasms as wind; is more apt to terminate in melancholy, or a low fever, than in any other disease; and, on dissection, exhibits its morbid effects principally on the liver, spleen, and pancreas, which are often found in a diseased state.

Another very material difference might be pointed out betwixt these two diseases, which is, that hysteria is much relieved by advancing in age, whereas hypochondriasis usually becomes aggravated.

The two diseases have often been confounded together; but, from considering the foregoing circumstances, it appears that a proper line of distinction should be drawn between them.

The hysteric passion likewise differs from a

syncope, as in this there is an entire cessation of the pulse, a contracted face, and a ghastly countenance: whereas in the uterine disorder there is often something of a colour, and the face is more expanded; there is, likewise, a pulse, though languid; and this state may continue some days, which never happens in a syncope.

It differs from apoplexy in the general absence of coma, and stertorous respiration, and in the state of the pulse, which, in hysteria, is generally natural, and never presents any characteristic disorder as in apoplexy.

It differs from epilepsy in the minor degree of insensibility, and in its general physiognomy; although it must be confessed that hysteria, in its more intense forms, is often with difficulty distinguished from epilepsy, and indeed appears to pass into it.

However dreadful and alarming an hysteric fit may appear, still it is seldom accompanied with danger, and the disease never terminates fatally, unless it changes into epilepsy, or that the patient is in a very weak reduced state.

The indications in this disease are, 1. To lessen the violence of the fits. 2. To prevent their return by obviating the several causes. Where the attack is slight, it may be as well to leave it, in a great measure, to have its course. But, where the paroxysm is severe, and the disease of no long standing, occurring in a young plethoric female, as is most frequent, and especially from suppression of the menses, a moderate abstraction of blood should be made, and will often afford speedy relief. If this step do not appear advisable, and the disorder be rather connected with the state of the primæ viæ, an emetic may check its progress, if the patient can be got to swallow during a remission of the convulsions. At other times, the application of cold water to the skin, more or less extensively; strong and disagreeable odours, as hartshorn, burnt feathers, &c.; rubbing the temples with ether; antispasmodics, particularly opium, by the mouth or in glyster; the pediluvium, &c. may be resorted to, according to the state of the patient. During the intervals, we must endeavour to remove any observable predisposition: in the plethoric, by a spare diet, exercise, and occasional purgatives; in those who are weakly, and rather deficient in blood, by proper nourishment, with chalybeates, and other tonic medicines. The state of the uterine function must be particularly attended to, as well as that of the primæ viæ: those cathartics are to be preferred which are not apt to occasion flatulence, nor particularly irritate the rectum, unless where the menses are interrupted, when the aloetic preparations may claim a preference; and the perspirations should be maintained by warm clothing, particularly to the feet, with the prudent use of the cold bath. The mind ought also to be occupied by agreeable and useful pursuits, and regular hours will tend materially to the restoration of the general health.

HYSTERI'TIS. (*is, idis.* f.; from ὑστερα, the womb.) *Metritis.* Inflammation of the womb. This disease is characterised by fever, heat, tension, tumour, and pain in the region of the womb; pain in the os uteri when touched, and vomiting.

In natural labours, as well as those of a laborious sort, many causes of injury to the uterus, and the peritonæum which covers it, will be applied. The long continued action of the uterus on the body of the child, and the great pressure made by its head on the soft parts, will further add to the chance of injury. Besides these, an improper application of instruments, or an officiousness of the midwife in hurrying the labour, may have contributed to the violence. To these causes may be added exposure to cold, by taking the woman too early out of bed after delivery, and thereby throwing the circulating fluids upon the internal parts, putting a stop to a secretion of milk, or occasioning a suppression of the lochia.

An inflammation of the womb is sometimes perfectly distinct, but is more frequently communicated to the peritonæum, Fallopian tubes, and ovaria; and, having once begun, the natural functions of the organ become much disturbed, which greatly adds to the disease. It is oftener met with in women of a robust and plethoric habit than in those of lax fibres and a delicate constitution, particularly where they have indulged freely in food of a heating nature, and in the use of spirituous liquors. It never prevails as an epidemic, like puerperal fever, for which it has, probably, often been mistaken; and to this we may, with some reason, ascribe the difference in the mode of treatment which has taken place among physicians.

An inflammation of the uterus shows itself usually about the second or third day after delivery, with a painful sensation of the bottom of the belly, which gradually increases in violence, without any kind of intermission. On examining externally, the uterus appears much increased in size, is hard to the feel, and, on making a pressure upon it, the patient experiences great soreness and pain. Soon afterwards there ensues an increase of heat over the whole of the body, with pains in the head and back, extending into the groins, rigors, considerable thirst, nausea, and vomiting. The tongue is white and dry, the secretion of milk is usually much interrupted, the lochia are greatly diminished, the urine is high-coloured and scanty, the body is costive, and the pulse hard, full, and frequent.

These are the symptoms which usually present themselves when the inflammation does not run very high, and is perfectly distinct; but when it is so extensive as to affect the peritonæum, those of irritation succeed, and soon destroy the patient.

Uterine inflammation is always attended with much danger, particularly where the symptoms run high, and the proper means for removing them have not been timely adopted. In such cases, it may terminate in suppuration, scirrhus, or gangrene.

Frequent rigors, succeeded by flushings of the face, quickness and weakness of the pulse, great depression of strength, delirium, and the sudden cessation of pain and soreness in the region of the abdomen, denote a fatal termination. On

the contrary, the ensuing of a gentle diarrhœa, the lochial discharge returning in due quantity and quality, the secretion of milk recommencing, and the uterus becoming gradually softer and less tender to the touch, with an abatement of heat and thirst, prognosticate a favourable issue.

When shiverings attack the patient, after several days' continuance of the symptoms, but little relief can be afforded by medicine, the event being generally fatal. In this case, the woman emaciates and loses her strength, becomes hectic, and sinks under colliquative sweating, or purging.

Upon opening the bodies of women who have died of this disease, and where it existed in a simple state, little or no extravasated fluid is usually to be met with in the cavity of the abdomen. In some instances, the peritonæal surfaces have been discovered free from the disease; whilst, in others, that portion which covers the uterus and posterior part of the bladder has been found partially inflamed. The inflammation has been observed, in some cases, to extend to the ovaria and Fallopian tubes, which, when cut open, are often loaded with blood. The uterus itself usually appears of a firm substance, but is larger than in its natural state, and, when cut into, a quantity of pus is often found. Gangrene is seldom, if ever, to be met with.

Hysteroce'le. (*e, es.* f.; from *ὑστερα*, the womb, and *κηλη*, a tumour.) See *Hernia uteri.*

Hy'sterocystoce'le. (From *ὑστερα*, the womb, *κυστις*, the bladder, and *κηλη*, a tumour.) Hernia of the uterus with displacement of the bladder.

Hysteroma'nia. From *ὑστερα*, the womb, and *μανια*, madness.) Furor uterinus. See *Nymphomania.*

Hy'steron. (From *ὑστερος*, afterwards: so named because it comes immediately after the fœtus.) The placenta.

Hystero'physa. (*a, æ.* f.; from *ὑστερα*, the womb, and *φυσα*, flatus.) A distension of the womb, from a collection of air in its cavity.

Hy'sterotomato'cia. (From *ὑστερα*, the womb, *τεμνω*, to cut, and *τοκος*, parturition.) The extraction of the child by the Cæsarian operation.

Hysteroto'mus. (From *ὑστερα*, the womb, and *τεμνω*, to cut.) A kind of *bistouri caché*, which has been used to divide the neck of the womb.

HYSTERO'TOMY. (*Hysterotomia, æ.* f.; from *ὑστερα*, the womb, and *τεμνω*, to cut.) See *Cæsarian operation.*

Hysteropto'sis. (*is, is.* f.; from *ὑστερα*, the womb, and *πιπτω*, to fall.) A falling down of the womb. See *Prolapsus uteri.*

HYSTRICI'ASIS. (From *ὑστριξ*, a hedgehog, or porcupine.) A disease of the hairs, in which they stand erect, like porcupine quills. An account of this rare disease is to be found in the *Philosophical Transactions*, No. 424.

Hy'stricis lapis. See *Bezoar hystricis.*

Hystri'tis. See *Hysteritis.*

I.

IA'TRALEI'PTES. (*Ιατραλειπτης*; from *ιατρος*, a physician, and *αλειφω*, to anoint.) The Greek name for a physician who cured diseases by *inunction*, friction, and other external remedies. There was a sect of *Ιατραλειπται*, of which Prodicus, a disciple of Esculapius, was the founder.

IA'TROCHY'MIA. The doctrine or practice of the Iatrochymists. See *Iatrochymicus.*

IA'TROCHY'MICUS. (*us, i.* m.; from *ιατρος*, a physician, and *χυμια*, chemistry.) *Chymiater.* The physicians of the chemical school of which Paracelsus was the head were called *Iatro-chymici.*

Ia'troli'ptice. (From *ιατρος*, a physician, and *αλειφω*, to anoint.) The method of curing diseases by unction.

IA'TRO-MATHEMA'TICUS. (From *ιατρος*, a physician, and *μαθεματικος*, a mathematician.) An Iatro-mathematician, or mathematical physician. The Iatro-mathematicians were a sect of which Borelli may be considered as the chief. They attempted to explain the actions of the living body, and the operation of remedies, on mechanical principles. The Iatro-mathematical school owed its modern origin to the atomic philosophy of Descartes; but the principle of a mechanical system of medicine is of high antiquity: the *pores* and *atoms* of Asclepiades constitute him a true Iatro-mathematician. The mathematical doctrine was supported by many distinguished physicians, as Bellini, Baglivi, J. Bernoulli, Keill, the Robinsons, Wintringham, Mead, and Pitcairn. It was, perhaps, notwithstanding, the most absurd of all the doctrines that have had any extensive influence on medicine.

Iatro'phic acid. The active principle of the seed of the croton tiglium, which is now called *crotonic acid*, was at first named *Iatrophic acid* by Pelletier and Caventou, from their erroneously supposing the seeds to be those of the *Iatropha curcas.*

IBE'RIS. (*is, idis.* f.; so named from

Iberia, the place of its natural growth.) 1. The name of a genus of plants in the Linnæan system. Class, *Tetradynamia*; Order, *Siliculosa*.

2. The pharmacopœial name of the *Sciatica cresses*. See *Lipidium iberis*.

Ibirace. See *Guaiacum*.

IBI'XUMA. (From ἰβισκος, the mallow, and ἰξος, glue: so named from its glutinous or soapy qualities.) The herb soap-wort, *Saponaria officinalis*.

ICE. *Glacies*. Water made solid by the application of cold. It is frequently applied to the head in cases of inflammation of the brain, and used by surgeons to resolve external inflammations, to stop hæmorrhages, and constringe relaxed parts.

Iceland moss. See *Cetraria Islandica*, in the Supplement.

Iceland moss. See *Cetraria*, in the Supplement.

ICE'SIUM EMPLA'STRUM. A plaster, the name of which ought to be written Hicesium, the Greek being ἱκεσια, or ἱκεσιος. It was composed of litharge, oil, vinegar, verdigris, euphorbium, myrrh, &c., and was in high repute as an application to scrofulous tumours, abscesses, gout, &c.

I'CHOR. (*or, oris*, m. Ιχωρ.) A thin, aqueous, and acrid discharge.

I'CHOROUS. Of the nature of ichor.

I'CHTHYA. (*a, æ*. f. Ιχθυα, a fish-hook; from ἰχθυς, a fish.) 1. The skin of the *Squatina*, or monk-fish.

2. The name of an instrument like a fish-hook for extracting the fœtus.

Ichthy'asis. See *Ichthyosis*.

ICHTHYOCO'LLA. (*a, æ*, f.; from ἰχθυς, a fish, and κολλα, glue.) *Colla piscium*. Isinglass. Fish-glue. This substance is almost wholly gelatine; 100 grains of good dry isinglass containing rather more than 98 of matter soluble in water.

Isinglass is made from the air-bladder or sound of the *acipenser huso* and other species of sturgeon. It may be obtained also from many other fish. Jackson informs us that the sounds of cod afford this substance; and that the lakes of America abound with fish from which the very finest sort may be obtained.

Isinglass receives its different shapes in the following manner:—The sounds are taken from the fish while sweet and fresh, slit open, washed from their slimy *sordes*, divested of a very thin membrane which envelopes the sound, and then exposed to stiffen a little in the air. In this state, they are formed into rolls about the thickness of a finger, and in length according to the intended size of the staple; a thin membrane is generally selected for the centre of the roll, round which the rest are folded alternately, and about half an inch of each extremity of the roll is turned inwards.

Isinglass is best made in the summer, as frost gives it a disagreeable colour, deprives it of weight, and impairs its gelatinous principle.

Isinglass, boiled in milk, forms a mild nutritious jelly, and is thus sometimes employed medicinally. This, when flavoured by the art of the cook, is the *blanc-mangé* of our tables. A solution of isinglass in water, with a very small proportion of some balsam, spread on black silk, is the court-plaster of the shops.

ICHTHYO'PHAGUS. (*us, i*. m.; from ἰχθυς, a fish, and φαγω, to eat.) A fish-eater. One who lives on fish without any other animal diet. Some savage tribes live almost exclusively on fish, and were therefore named by the ancients Ichthyophagi.

ICHTHYOPHAGIA. (Same etymon.) An exclusive addiction to a diet of fish.

ICHTHYO'SIS. (*is, is*. f.; from ἰχθυς, a fish: on account of the resemblance of the scales to those of a fish.) The fish-skin disease. It is characterised by a thickened, hard, rough, and, in some cases, almost horny texture of the integuments of the body, with some tendency to scaliness, but without the deciduous exfoliations, the distinct and partial patches, or the constitutional disorder, which belong to Lepra and Psoriasis.

1. *Ichthyosis simplex*. In its commencement this disease exhibits merely a thickened, harsh, and discoloured state of the cuticle, which appears, at a little distance, as if it were soiled with mud. When further advanced, the thickness, hardness, and roughness become much greater, and of a warty character, and the colour is nearly black. The roughness, which is so great as to give a similar sensation to the finger passed over it as a file, or the roughest shagreen, is occasioned by innumerable rugged points, into which the surface is divided. These hard papillæ, or prominences, differ somewhat in their form and arrangement in different parts of the body, as well as in different stages of the complaint. Some of them appear to be of uniform thickness from their roots upwards; while others have a short narrow neck, and broad irregular tops. The former occur where the skin, when healthy, is soft and thin; the latter, where it is coarser; as about the olecranon and patella, and thence along the outside of the arms and thighs. On some parts of the extremities, however, especially about the ankles, and sometimes on the trunk of the body, these scaly excrescences are flat and large, and occasionally imbricated, like the scales of carp. In other cases, they have appeared separate, being intersected by whitish furrows.

This unsightly disease appears in large continuous patches, which sometimes cover the greater part of the body, except the flexures of the joints, the inner and upper part of the thighs, and the furrow along the spine. The face is seldom severely affected; but the mammæ, in females, are sometimes encased in this rugged cuticle. There is also an extremely dry and unperspirable condition of the whole skin, and a thickened brittle state of the cuticle in the palms of the hands and soles of the feet. The disease often commences in childhood, and even in early infancy.

This affection has been found to be very little under the control of medicine: stimulating ointments and plasters have been industriously applied, with no material effect; and the disorder has been known to continue for several

years, with occasional variations. Dr. Willan trusted to the following palliation by external management: — "When a portion of the hard scaly coating is removed," he says, "it is not soon produced again. The easiest mode of removing the scales is to pick them off carefully with the nails from any part of the body, while it is immersed in hot water. The layer of cuticle which remains after this operation is harsh and dry; and the skin did not, in the cases I have noted, recover its usual texture and softness: but the formation of the scales was prevented by a frequent use of the warm bath, with moderate friction."

The skin is occasionally cleared of this harsh eruption by bathing in the sulphureous waters, and rubbing it with a flannel or rough cloth, after it had been softened by the bath; but the cuticle underneath does not recover its usual condition, but remains bright and shining, and the eruption recurs. The only good effect from internal medicine has been from the use of pitch, which has occasioned the rough cuticle to crack and fall off, without the aid of external means, and left a sound skin underneath. This medicine, made into pills with flour, or any farinaceous powder, may be taken to a great extent, not only without injury, but with advantage to the general health; and affords one of the most effectual means of controlling the languid circulation, and the inert and arid condition of the skin. Upon the same principle, the arsenical solution would probably be beneficial in ichthyosis.

2. *Ichthyosis cornea.* Several cases of a rigid and horny state of the integuments, sometimes partial, but sometimes extending nearly over the whole body, have been recorded by authors; and occasionally such a condition of the cuticle has been accompanied with the actual production of excrescences of a horny texture. These, however, are rare occurrences.

The ordinary formation of horny excrescences in the human body, of which many examples have been described, from the time of the Arabians downwards, is, however, unconnected with any general rigidity of the cuticle. These excrescences have been improperly called horns; for they are purely of cuticular growth, having no connection with the bones or other parts beneath, and consisting of a laminated callous substance, contorted and irregular in form, and not unlike isinglass in appearance and texture. They originate from two or three different diseased conditions of the cuticle; as from warts, encysted tumours, steatomata, &c. Morgagni has mentioned the growth of a horn on the sinciput of an old man, the basis of which was a wart; and other authors have noticed the same fact. In the most numerous instances, however, they have arisen from the cavity of encysted tumours, of very slow growth, which were lodged under the cuticle of the scalp, or over the spine, after the discharge of their contained fluid. In one case, a horn of this sort was the result of inflammation and discharge from a small steatomatous tumour of many years' continuance. Nearly the whole of these examples have occurred in women of advanced age.

If these excrescences are sawed or broken off, they invariably resprout. Excision, with the complete destruction of the cyst, or morbid secreting surface, is the only effectual remedy, when they have appeared, and a preventive during the growth of the primary tumour.

ICOSA'NDRIA. (*a*, *æ*. f.; from εικοσι, twenty, and ανηρ, a man, or husband.) The name of a class of plants in the sexual system of Linnæus, consisting of those which have hermaphrodite flowers furnished with twenty or more stamina that are inserted into the inner side of the calyx, or petals, or both. By this last circumstance is this class distinguished from *Polyandria.*

ICTERI'TIA. (*a*, *æ*. f.; from *icterus*, the jaundice.) 1. The same as *Icterus.*

2. Erysipelas has been called *Icteritia rubra.*

Icteritia rubra. See *Icteritia.*

I'CTERUS. (*us*, *i*. m.; named from its likeness to the plumage of the golden thrush, of which Pliny relates, that if a jaundiced person looks on one, the bird dies, and the patient recovers.) The jaundice. This disease has received a variety of names, as *Morbus arcuatus*, or *arquatus*, *Aurigo*, *Morbus regius*, *Morbus luteolus*, &c. It is characterised by yellowness of the skin and eyes, first observable in the tunica albuginea; the fæces are white, and the urine of a deep colour, from an admixture of bile.

Jaundice mostly comes on with languor, inactivity, loathing of food, disturbed sleep at night, acidities of the stomach and bowels, frequent sense of nausea. As it advances in its progress, the skin and eyes become of a deep yellow: there is a bitter taste in the mouth, with frequent nausea and vomiting; the urine is very high coloured; the stools are of a grey or clayey appearance; and a dull obtuse pain is felt in the right hypochondrium, which is much increased by pressure.

The remote and exciting causes of jaundice are many. It takes place most usually in consequence of an interrupted excretion of bile, from an obstruction in the ductus communis choledochus, which occasions its absorption into the blood-vessels. The causes producing this, are thick or inspissated bile; biliary calculi in the gall-bladder and its ducts; spasmodic constriction of the ducts themselves; the pressure made by a pregnant uterus; or an enlargement of the abdominal viscera, from tumours, &c.

The proximate cause of jundice, is the presence of bile in the blood, which transmits it to the vessels which carry only the serous part, and hence gives the yellow colour to the skin, the intensity of which varies according to the quantity in the circulating blood, and the degree of concentration. When the colour is very intense, and the disease is protracted, it occasionally causes a green or olive hue, and the disease is called *green jaundice*; when the quality is more concentrated still, and the disease of long duration, it gives a darker colour, and then it is termed the *black jaundice.* Most instances of green and black jaundice are connected with diseased structure of the liver.

From the remote or exciting causes, jaun-

dice has been distinguished into the following species: —

1. *Icterus infantum.* Jaundice of infants, or yellow-green. It affects children at or soon after their birth, and usually continues for some days. It has generally been supposed to arise from the meconium, impacted in the intestines, preventing the flow of bile into them. The effects produced by it, are languor, indolence, a yellow tinge of the skin, and a tendency to sleep. It is mostly a mild disease, and soon gives way to small and repeated doses of castor oil. If this does not remove it, a grain of the submuriate of mercury may be given with the oil, or an emetic, which generally emulges the common cholidic duct of some tenacious bile that wanted to be expelled.

2. *Icterus gravidarum.* Jaundice of pregnant women. This takes place, now and then, about the seventh or eighth month of pregnancy, and is caused by pressure of the uterus on the bile ducts. It seldom proceeds to a total obstruction of the bile, which passes occasionally as the position of the female is changed. Gentle aperients, and lying on the left side, are the best means of meeting it. After delivery it vanishes.

3. *Icterus biliosus,* or *cholæus.* This species, which is very common, is produced by a thick inspissated bile, plugging up the mouth of the ductus communis choledochus. It comes on very insidiously; is not attended by any pain, and soon gives way to proper treatment.

A vomit at the commencement is often beneficial in removing the bile, which comes away sometimes by the mouth, but more frequently by the bowels; very tenacious, like birdlime, high coloured, and even black. Though an emetic is occasionally thus serviceable, it is not always so; and even when so, further medical treatment is required, or the disease returns, for it depends mostly on a morbid secretion, more usually than on too rapid an absorption of the finer parts of the bile. Mercury, in small doses, is required with the regular administration of saline aperients: the pilula hydrargyri, in the dose of two, three, or five grains every night, and a brisk purgative every other morning. If the jaundice have not vanished, the common black dose of senna and salts; but if the bile be flowing in its natural course, though vitiated, small doses of Epsom salts, in the compound infusion of roses, or the Cheltenham waters, will be best calculated to meet the object. This species of jaundice is occasionally very protracted, and requires not only that the condition of the bile be corrected, but also that the energy of the liver be increased, which is, in mere chronic forms, in a state of debility. Plummer's pills should be occasionally given, with a course of mild bitters, as taraxacum, colomba, gentian, &c., with saline aperients.

4. *Icterus calculosus* or *chololithicus.* Gall-stone jaundice. This is caused by a gall-stone, formed in the gall bladder, getting out of the bladder into the cystic or common choledic duct, and there stopping the bile in its course into the bowels. It has the common symptoms of jaundice; but, in addition to these, there is violent pain at the pit of the stomach, darting between the shoulders. It is an extraordinary thing that, with this, the pulse is not affected; and this not affecting the pulse, is considered as the leading pathognomonic symptom. The pain, in some, is extremely acute, ceasing for a short time, and then returning again; in others there is only a slight uneasiness felt about the region of the liver; but its particular seat is the gall-duct, just where it enters the duodenum. The calculi are of various sizes and composition. See *Gall-stone.*

The treatment of this species consists in allaying the pain by opiates, in doses proportioned to the degree of pain. If it be very severe, from 50 to 100 drops of laudanum should be administered in camphire-jalap, and repeated according to circumstances. Fomentations to the painful parts are serviceable, and, above all, a warm bath. The bowels are to be kept open by castor oil, and irritability of stomach allayed by carbonic acid gas, from a saline draught, or hypercarbonated soda water. However tardy the passage of the gall-stone, such means are to be continued.

5. *Icterus spasmodicus.* Spasmodic jaundice. This is, of all, by far the most common species. It is generally caused by violent mental emotions, and particularly by sudden and great fear: but cold to the lower extremities, acrimonious and indigestible food, pips of oranges, and the round worm, will also cause it. It is ushered in by a sense of fulness of the stomach, nausea, and languor; a violent pain at the pit of the stomach soon succeeds, and sometimes sickness; occasionally an incessant vomiting, and an utter impossibility of retaining either food or medicine. The pain increases, and extends towards the right shoulder, or spreads round the loins. The epigastric region is mostly distended, and pressure gives pain. The bowels are costive, and moved with difficulty. The urine soon becomes of a deep blood-like colour. The surface of the body is soon of a yellow colour, and this is preceded by an obvious yellowness of the sclerotic membrane of the eye. A wet-nurse often has the disease without the milk being coloured: but if the obstruction be not removed in a fortnight or thereabout, the milk has a little yellowish hue.

It is no unusual thing for jaundice, supposed to be produced by spasmodic contraction of the gall-duct, to become a chronic disease; the pain, in these cases, ceases with the other distressing symptoms, and little inconvenience results.

Spasmodic jaundice is to be treated by opiates and relaxants. Opium is to be administered in doses proportioned to the extent of pain; and fomentations and warm bath are to be resorted to occasionally. A blister to the pit of the stomach is often successful in relaxing the spasm. Great good results, when the stomach will bear it, from the compound powder of ipecacuanha, in regular and small doses, and the use of warm pediluvium at bed-time.

6. *Icterus hepaticus.* Hepatic jaundice. This embraces all instances of jaundice that are produced by organic diseases of the liver, gal

bladder, pancreas, or any other viscus, and by tumours in the vicinity, as aneurism, enlarged glands, or adventitious structures, which, by pressure on, or by encompassing the, gall-ducts, or by destroying them, cause jaundice. Hepatic jaundice is mostly accompanied by a dull and sometimes a severe pain; and it is a chronic disease for the most part, and attended by itching and defœdations of the skin, anasarcous swellings of the legs, and frequently ascites.

Being always symptomatic of some organic disease, the remedies must be such as those diseases require.

The prognosis in jaundice. — In infants, immediately after birth, and during pregnancy, little or no danger is to be apprehended; if, however, the sleepiness prevent the infant taking the breast for two or three days, there will be no chance of its living. The spasmodic species seldom proves fatal under proper management; but if fever should supervene, and run high, danger is present, and proportioned to the violence of its symptoms. Delirium is always a bad symptom, and the harbinger of a fatal termination.

The regimen in jaundice. — The diet must be accommodated to the state of the stomach, as well as that of the system. When there is retching, sickness, and vomiting, no food will be proper; and if, from length of time, it is called for, farinaceous slops in small quantities, as arrow-root, sago, tapioca, with very dilute brandy, unless its use is interdicted by an inflammatory state of the system. Raw eggs are much resorted to.

In the chronic forms, the strength is to be kept up by a generous diet and cheerful company, moderate exercise, and especially riding on horseback.

Particular medicines in the cure of jaundice. — There are few diseases that have to boast of a greater number of specifics, and no specifics so little worthy of the name.

The *curcuma*, *chelidonium majus*, *polytrichum commune*, highly as they were praised a century ago, are now forgotten.

The *millepedes*, which were swallowed a hundred or two daily, are, very properly, never thought of.

The seeds of common hemp, or *cannabis sativa*, boiled in milk, or made into an emulsion, are esteemed by German physicians, but never used in this country.

Dandelion, or the *leontodon taraxacum*, is much esteemed in this country by many, and thought little of by others. The best way of administering it, is to make a strong decoction of the whole plant; and where it cannot be had, the extract will do, if well prepared.

The *mineral alkalis* and *soap* are universally resorted to. The best way of giving them is to combine them with rhubarb, or colocynth, or aloes; thus: R. Saponis duri, sodæ carbonatis exsiccatæ, āā gr. vj.; extracti colocynthidis compositi, gr. ij.; mucilaginis acaciæ crassioris, q. s.: fiant pilulæ tres, ter in die capiendie. Soda may be taken at the same time in the common beverage. Half an ounce of Castile soap, dissolved in a quarter of a pint of warm milk, and taken every morning, is as good a formula as any: but Castile soap may be formed into five-grain pills, and four or six taken three or four times a day. Many have supposed the alkalies and soap possessed the power of dissolving biliary calculi. This is much to be questioned, even if they came in contact with them. Their beneficial operation is by supplying the chyme with a substitute for the bile, especially when aloes or colocynth are given with them.

The *Bath waters*, used internally and externally. These were much resorted to until very ately. By their warmth they are likely to be beneficial in chronic cases, especially where relaxants are wanting.

The *Cheltenham waters*. These are excellent, and much resorted to in all chronic cases.

The *chlorine bath*, better known by the name of Dr. Scott's nitro-muriatic acid bath. It is very surprising how the use of these baths will emulge the gorged ducts, and attenuate the viscid bile.

Mercury. Of all the medicines given in the cure of jaundice, there is none so beneficial as the oxides and submuriate of mercury when spasmodic irritation is removed. They should be given in alterative doses, and great care should be taken not to produce salivation, which is unnecessary, by keeping the bowels open.

The *bitter stomachics*. Gentian, calumba, and quassia are much esteemed, and especially when given with saline aperients.

The *mineral acids*, especially the nitric. In long continued jaundices, the causes of which are obscure, if attended by much dyspepsy, and all chronic cases of jaundice, are attended by more or less of indigestion, nitric acid should be tried. I have known it often very serviceable. An infusion of roses, calumba, quassia, and aurantium, may be acidulated with it, and a dose given three times a day. The sulphuric acid is the next best, and the muriatic the last.

Icterus albus. The white jaundice. See *Chlorosis*.

Icterus niger. Black jaundice. See *Icterus*.

Icterus viridis. Green jaundice. See *Icterus*.

I'CTUS. (*us*, *ûs*. and *ti*. m.; from *ico*, to strike.) 1. A stroke or blow.

2. The pulsation of an artery.

3. The sting of a bee or other insect.

Ictus solis. A stroke of the sun. See *Coup de Soleil*.

IDEO'LOGY. (*Ideologia*, *æ*. f.; from ἰδεα, a thought, and λογος, a discourse.) The doctrine of ideas. The philosophy of the mind. See *Mens*.

Idiocrasia. See *Idiosyncrasy*.

Idiocy. See *Amentia*.

IDIOPA'THIC. (*Idiopathicus*; from ἰδιος, peculiar, and παθος, an affection.) A disease which is primary, and not symptomatic of, or consecutive upon, any other disease, is styled *idiopathic*. The term is opposed to *symptomatic* or *sympathetic*.

IDIOSY'NCRACY. (*Idiosyncrasia*, *æ*. f.;

from ἰδιος, peculiar, συν, with, and κρασις, a temperament.) A peculiarity of constitution, in which a person is affected by certain agents, which, if applied to the generality of persons, would produce no effect: thus some people faint at the sight of blood; others have violent inflammation induced on the skin by substances that have usually no such effect; others again, suffer from asthma if exposed to the odour of ipecacuan.

Idiotism. See *Amentia.*

Idiotro'pia. (From ἰδιος, peculiar, and τρεπω, to turn.) The same as *Idiosyncrasia.*

Ie'semum. Jessamine. See *Jasminum.*

Igasu'ric acid. *Ascidum Igasuricum.* Pelletier and Caventou, in their experiments on the *faba Sancti Ignatii*, and *nux vomica*, having observed that these substances contained a new vegetable base, called strychnine, in combination with an acid, sought to separate the latter, in order to determine its nature. It appeared to them to be new, and they called it igasuric acid, from the Malay name for the *faba Sancti Ignatii.* This bean, according to the chemists above named, is composed of igasurate of strychnia, a little wax, a concrete oil, a yellow colouring matter, gum starch, bassorine, and vegetable fibre.

IGNA'TIA. (*a, æ.* f.; so named by Linnæus, because the seeds are known in the Materia Medica, by the name of Saint Ignatius's beans.) The name of a genus of plants. Class, *Pentandria;* Order, *Monogynia.*

Ignatia amara. The systematic name of the plant which affords St. Ignatius's bean, called *Faba indica*, *Faba Sancta Ignatii*, and *Faba febrifuga.* These beans are of a roundish figure, very irregular and uneven, about the size of an ordinary nutmeg, semitransparent, and of a hard, horny texture. They have a very bitter taste, and no considerable smell. They are said to be used in the Phillippine islands in all diseases, acting as an emetic purgative. Infusions are given in the cure of intermittents, &c. It is from this bean that the igasurate of strichnia is obtained. See *Igasuric acid.*

Ignatii faba. See *Ignatia amara.*

Ignatius's bean. See *Ignatia.*

I'GNIS. (*is, is.* m.) Fire. 1. The evolution of heat and light which attends combustion. There have been several theories proposed respecting fire, but no one as yet is fully established. See *Caloric*, and *Light.*

2. Val Helmont, Paracelsus, and other alchemists, applied this term to what they considered as universal solvents.

3. In *Medicine*, the older writers used it to express the heat, redness, acrimony, and erosive power of a disease.

Ignis actualis. The actual cautery.

Ignis calidus. A gangrene; or a violent inflammation, just about to degenerate into gangrene, were formerly so called by some.

Ignis columellæ. Erysipelas has been so called.

Ignis fatuus. A luminous appearance or flame, frequently seen in the night in different country places, and called in England *Jack with a lantern*, or *Will with the wisp.* It seems to be mostly occasioned by the extrication of phosphorus from rotting leaves and other vegetable matters. It is probable, that the motionless ignes fatui of Italy, which are seen nightly on the same spot, are produced by the slow combustion of sulphur, emitted through clefts and apertures in the soil of that volcanic country.

Ignis frigidus. A gangrene was so called, because when mortification takes place the part loses its natural heat.

Ignis gehennæ. The fire of hell. The universal solvent was so called by the alchemists.

Ignis persicus. 1. Erysipelas.

2. A carbuncle.

Ignis potentialis. The potential cautery. See *Cautery.*

Ignis rotæ. Fire for fusion. It is when a vessel which contains some matter for fusion is surrounded with red-hot coals.

Ignis sacer. See *Sacer.*

Ignis sancti antonii. See *Erysipelas.*

Ignis sapientum. Heat of horse-dung. — *Ruland.*

Ignis sylvaticus. The wild-fire rash. See *Strophulus volaticus.*

Ignis volagrius. The same.

Ignis volaticus. The same. See *Strophulus volaticus.*

Ignition. (From *ignis*, fire.) The act of catching fire, or the state of a burning substance. See *Combustion.*

Ikan radix. A somewhat oval, oblong, compressed root, brought from China. It is extremely rare, and would appear to be the root of some of the orchis tribe.

I'laphis. A name in Myrepsus for the burdock. See *Arctium lappa.*

I'LEAC PASSION. (*Passio iliaca.* Ειλεος, ιλεος, is described as a kind of a colic, the seat of which is the intestinum ileum.) This disease is also called *Volvulus*, *Miserere mei*, *Convolvulus*, *Chordapsus*, and *Tormentum.* It consists of severe griping pain, vomiting of a fæcal matter, and costiveness, accompanied by retraction and spasms of the abdominal muscles.

The griping pain is very severe: the person at first vomits bilious fluid, which soon smells like fæces, and at length becomes perfectly stercoraceous, from the peristaltic motion of the bowels being inverted through their whole course; so that, after a time, injections thrown into the rectum will pass along the whole tract of the intestines into the stomach, and escape through the mouth by vomiting. In some cases the skin becomes yellow. Ileus arises from many causes, and is generally symptomatic of other diseases. 1. The most common cause is strangulated hernia; and so frequent an attendant is it on ruptures, that the conviction of no such a thing existing should in every instance be carefully ascertained by practitioners. Many cases of women have been dissected, in which the surgeon had decided that there was no strangulation, where a small portion of the gut was found confined, and had killed the patient.

2. Another frequent cause is an *intus-susception*, or a retention of a part of the bowel within another. Dr. Good, who considers an

inflammatory state as productive of ileus, gives an excellent explanation of how this happens. The dissection of persons, he observes, who have died of the stercoraceous or inflammatory colic, has shown, in some cases, that one portion of the affected intestine, constringed and lessened in its diameter, has fallen into another portion, and thus produced an involution or introsusception. The fact is not difficult to be accounted for, and it will readily explain the great torture which is often suffered under this grievous malady. In every case in which the intestinal tube is weakened, there is a very copious extrication of air, producing, in many instances, a palpable distension of the parietes of the abdomen. In ileus there is also, in conjunction with this, a strong inversion of the peristaltic action, operating from the rectum to the stomach, and forcing back whatever recrement or other materials are co-acervated in any part of the intestines. These, by intermixing with the elastic vapour of the intestinal tube, become very voluminous, and distend it to its utmost range, wherever distension can be accomplished. Then if, as is generally the case, a violent spasmadic constriction exists in one or more parts, the distensive force just mentioned, cannot expel the contents, and the two powers are thus brought into immediate contact; and while the gut is rigidly contracted above, it is widened almost to bursting below; and, during the struggle which ensues, the contracted or collapsed part is forced into the other, and thus an intus-susception takes place. In some cases, though very seldom, it happens, that in the midst of this spasmodic commotion, portions of the bowels have become twisted into nooses and knots, in which the portion, forming an encircling cord or bridle, has been drawn so tight as to produce strangulation. In most cases of the ileac passion, there is a mixture of immediate causes; and though there may be intus-susception, which is not common, there is also always inverted peristaltic motion, more or less of spasmodic contraction, and inflammation of the peritoneal covering.

Acrid, cold, and indigestible esculents, cold beverages on a heated stomach, taking cold in the feet when disposed to intestinal derangements, unalimentary substances swallowed by mistake, as metallic money, pieces of glass, plum, cherry, or other fruit stones, worms, calculous or other balls congested in the intestines and obstructing the regular movement, as scybala, gall-stones, intestinal calculi, are mentioned as having produced ileus: and, as a symptomatic affection, it is common in herniæ, tumours, cancerous or otherwise, and stricture. It has also supervened gout and rheumatism.

The medical treatment consists in removing the exciting causes, if possible, by carminative aperients, fomentations, and glysters; and if, at the commencement, there are evidences of an inflammatory state, blood should be abstracted freely from the arm, and by leeches on the abdomen.

The griping and spasmodic pain, and a restoration of the intestines from a state of inverted action to their proper peristaltic motion, which is sure to remove their constipation, are the points to which attention is to be directed. Dry and humid fomentations, and warm baths, and warm and copious glysters, afford a rational chance of success. The last should be rendered emollient by an admixture of oil, and aperient by the addition of infusions of senna, or decoction of colocynth, so that both intentions of cure should be carried forward at the same time. In combination with these, opium, and various other narcotics, may be tried: thus,

℞. Infus. sennæ compositi, Oj.
Olei olivæ, f. ℥iv.
Tincturæ opii, f. ℥ij. Misce. Or,
℞. Extracti colocynthidis compositi, ℥ij.
Tincturæ hyoscyami, f. ℥iij.
Infusi anthemidis, Oj. Misce. Or,
℞. Olei ricini, f. ℥ij.
Decocti avenæ tenuioris, f. ℥vj.
Tincturæ hyoscyami, f. ℥iij. Misce.

One or other of these should be tried occasionally about every six hours, and attention should be given to prevent them immediately returning.

Sir John Pringle speaks highly in favour of a decoction of poppies, which should be thrown up in large quantities, and have been found to succeed, not only in quieting the spasmodic pains, but in obtaining evacuations, after other injections, purgatives by the mouth, fomentations, and opiates, have been tried without effect. To render this kind of injection more active, where it is desirable, two drachms of the extract of poppies may be dissolved in a quart of a strong decoction of the capsules, or heads.

Purgatives, combined with antispasmodics, should also be administered by the mouth: though the vomiting is sometimes so incessant, that little or nothing can be got to remain on it, and vast quantities of vitiated and varied secretions are poured out. Calomel is decidedly the most likely to answer, in doses of about two, three, or four grains. It occupies the smallest space, and, in the form of pill, has the fairest chance of being retained. A saline draught, in the act of effervescing, may be given occasionally. Many practitioners are in the habit of combining opium with the submuriate, which, nevertheless, has a tendency to retard its action; but as the opium may mitigate the spasm, and diminish the pain, it will commonly be found a useful adjunct. Calomel is, in my opinion, more to be depended on than any other aperient; but as it is slow in its operation, it is well to give the solutions of the common saline aperients in an effervescing state, at intermediate periods.

Dr. Cullen, on the advice of De Haën, recommends a continued stream of warm water, thrown forcibly and with a proper syringe into the rectum, so that it may play upon the constricted portion of the intestine, and declares that he has found this remedy to be one of the most powerful and effectual.

When the ordinary means, and particularly those of warm injections, and warm bath, fail, some practitioners have been courageous enough to try cold applications, both internally and externally. Sir George Baker tells us that a

physician of credit informed him, he had once prescribed the cold bath with success. Citois affirms that, in several species of colic, this was his constant practice, and even in the midst of winter; and calls upon all his fellow-citizens to attest that most of his patients, thus treated, had been restored to health: the propriety of the practice is, however, very much to be questioned.

Ileaca passio. See *Ileac passion.*

I'LECH. *Ylech.* By this word, Paracelsus seems to mean a first principle.

ILEI'TS. Inflammation of the *Ileum.* See *Inflammation of the stomach and intestines.*

ILEO-CŒCAL VALVE. *Valvula ileo cæculis.* The valve situated at junction of the *ileum* and *cæcum.* See *Intestine.*

ILEO-COLIC ARTERY. *Arteria ileo-colica.* A branch of the superior mesenteric artery, distributed to the *ileum* and commencement of the *colon.*

ILEO-LUMBAR ARTERY. *Arteria ileo-lumbalis.* A branch of the internal iliac artery, distributed to the psoæ and iliacus internus muscles.

I'LEUM. (*um, i.* n.; from ειλεω, to turn about; from its convolutions.) *Ileum intestinum.* The last portion of the small intestines, about fifteen hands' breadth in length, which terminates at the valve of the cæcum. See *Intestine.*

ILEUS. (*us, i.* m.) See *Ileac passion.*

I'LEX. (*ex, icis.* f.; the name of a genus of plants in the Linnæan system. Class, *Tetrandria;* Order, *Tetragynia.*) The holly.

ILEX AQUIFOLIUM. The systematic name of the common holly: called also, *Agria, Agrifolium,* and *Aquifolium.* The leaves of this plant, *Ilex —foliis ovatis acutis spinosis,* of Linnæus, have been known to cure intermittent fevers; and an infusion of the leaves, drank as tea, is said to be a preventative against the gout.

ILEX CASSINE. *Cassina. Apalachine gallis.* This tree grows in Carolina; the leaves resemble those of senna, blackish when dried, with a bitter taste, and aromatic smell. They are considered as stomachic and stimulant. They are sometimes used as expectorants; and when fresh are emetic.

I'LIA. (The plural of *Ile,* ειλη.) 1. The flanks, or that part in which are enclosed the small intestines.

2. The small intestines.

I'LIAC. (*Iliacus;* from *ilia,* the flanks.) Belonging, situated near to, or connected with, parts about the flanks.

ILIAC ARTERIES. *Arteriæ iliacæ.* The arteries so called are formed by the bifurcation of the aorta, near the last lumbar vertebra. They are divided into *internal* and *external.* The *internal iliac,* also called the *hypogastric artery,* is distributed in the fœtus into six, and in the adult into five branches, which are divided about the pelvis; viz. the little iliac, the gluteal, the ischiatic, the pudical, and the obturatory; and in the fœtus, the umbilical. The *external iliac* proceeds out of the pelvis through Poupart's ligament, to form the femoral artery.

ILIAC REGION. The side of the abdomen, between the ribs and the hips.

Ili'acus. See *Iliac.*

ILIACUS INTERNUS. *Iliacus,* of Winslow. A thick, broad, and radiated muscle, which is situated in the pelvis, upon the inner surface of the ilium. It arises fleshy from the inner lip of the ilium, from most of the hollow part, and likewise from the edge of that bone, between its anterior superior spinous process and the acetabulum. It joins with the psoas magnus, where it begins to become tendinous, and passing under the ligamentum Fallopii, is inserted in common with that muscle. The tendon of this muscle has been seen distinct from that of the psoas, and, in some subjects, it has been found divided into two portions. The iliacus internus serves to assist the psoas magnus in bending the thigh, and in bringing it directly forwards.

ILI'ADUS. *Iliadum. Ileidos. Iliaster.* Terms applied by Paracelsus to the first matter of all things, consisting, according to him, of mercury, salt, and sulphur. He also used these terms in a variety of other acceptations, which the curious reader may find detailed in Castelli's Lexicon. Ed. Lipsiæ, 1713.

ILI'NGOS. (Ιλιγγος; from ιλιγξ, a vortex.) Vertigo, with temporary abolition of sight. See *Scotodynia.*

I'LIUM OS. (*Ilium, i.* n.; from *ilia,* the small intestines: so named because it supports the ilia.) The haunch-bone. The superior portion of the os innominatum, which, in the fœtus, is a distinct bone. See *Innominatum os.*

ILLE'CEBRA. (*a, æ.* f.; enticement; why so called we know not.) See *Sedum acre.*

ILLI'CIUM. (*um, ii.* n.; *ab illiciendo,* denoting an enticing plant, from its being very fragrant and aromatic.) The name of a genus of plants in the Linnæan system. Class, *Polyandria;* Order, *Polygynia.*

ILLICIUM ANI'SATUM. The systematic name of the yellow-flowered aniseed tree: the seeds of which are called the star aniseed. *Anisum stellatum, Anisum sinense,* and also *Semen badian.* They are used with the same views as those of the *Pimpinella anisum.* The same tree is supposed to furnish the aromatic bark, called *cortex anisi stellati,* or *cortex lavola.*

ILLINCTUS. The same as *Linctus.*

ILLI'TIO. (*o, onis.* f.; from *illino,* to anoint.) The process of anointing.

ILLO'SIS. (*is, is.* f.: from ιλλος, the eye.) A distortion of the eyes.

ILLUTAME'NTUM. Any substance used in illutation. See *Illutatio.*

ILLUTA'TIO. (*o, onis.* f.; from *in,* and *lutum,* mud.) Illutation: a besmearing any part of the body with mud, and renewing it as it grows dry, with a view of heating, drying, and discussing. It was chiefly done with the mud found at the bottom of mineral springs; but various artificial illutamenta were also used.

I'LLYS. (From ιλλος, the eye.) A person who squints, or who has distorted eyes.

I'LYS. (From ιλυς, mud.) 1. The fæces of wine. An obsolete term.

2. The sediment in stools, which resembles fæces of wine.

3. The sediment in urine, when it resembles the same.

Imagination. See *Mens.*

IMBECI'LITAS OCULORUM. Celsus speaks of the *Nyctalopia* by this name.

IMBER'BIS. Beardless. Applied generally in natural history.

IMBIBI'TION. (*Imbibitio, onis.* f.; from *imbibo*, to receive into.) The absorption of a liquid into the pores of a solid. M. Magendie considers imbibition as a property universal throughout the organic tissues, with the exception of the epidermis; and regards it in these, as in inorganic bodies, as referrible merely to capillary attraction.

IMBRICA'TUS. Imbricate: tiled; like tiles upon a house. Applied to leaves; as those of the *Euphorbia paralia.*

IMME'RSUS. Immersed: plunged under water. In *Botany*, this term is applied to leaves which are naturally under the water, and are different from those which naturally float. See *Leaf.* It is remarked by Linnæus, that aquatic plants have their lower, and mountainous ones their upper, leaves most divided, by which they better resist the action of the stream in one case, and of the wind in the other.

2. In *Anatomy*, this term has been applied by Bartholine, and some other anatomists, to the *Subscapularis* muscle, because it is hidden or sunk.

IMPASTA'TIO. (From *Pasta*, a paste.) The formation of a paste.

IMPA'TIENS. (*ens, entis.* f.; from *in*, not, and *patior*, to suffer: because its leaves recede from the hand with a crackling noise, as impatient of the touch, or from the great elasticity of the sutures of its seed vessel, which is completely impatient of the touch, curling up with the greatest velocity, and scattering round the seeds, the instant any extraneous body comes in contact with it.) The name of a genus of plants. Class, *Pentandria*; Order, *Monogynia.*

IMPATIENS BALSA'MINA. This plant has been considered vulnerary and diuretic, but is not now in use.

IMPATIENS NOLI ME TANGERE. This species is believed to possess diuretic virtues.

IMPERATO'RIA. (*a, æ.* f.; from *impero*, to overcome: so named because its leaves extend and overwhelm the lesser herbs which grow near it.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.*

2. The pharmacopœial name of the master-wort. See *Imperatoria ostruthium.*

IMPERATORIA OSTRU'THIUM. The systematic name of the master-wort. Called also *Magistrantia.* The roots of this plant are imported from the Alps and Pyrenees, notwithstanding it is indigenous to this island: they have a fragrant smell, and a bitterish pungent taste. The plant, as its name imports, was formerly thought to be of singular efficacy; and its great success, it is said, caused it to be distinguished by the name of *divinum remedium.* At present it is considered merely as an aromatic, and consequently is superseded by many of that class which possess superior qualities.

IMPERFECT. *Imperfectus.* Applied to such flowers as want either anther or pistil, or both.

IMPERFORATION. (*Imperforatio, onis*; f.) The preternatural occlusion of any part which is usually pervious; thus *imperforation of the vagina*, of the rectum, &c.

IMPETI'GINES. (The plural of *impetigo*; from *impeto*, to infest.) An order in the class *Cachexiæ* of Cullen, the genera of which are characterised by cachexia deforming the external parts of the body with tumours, eruptions, &c.

IMPETI'GO. (*o, onis.* f.) A disease of the skin, called the humid or running tetter. It is characterised by the appearance of the small psydracious pustules. It is not accompanied by fever, not contagious, nor communicable by inoculation. It chiefly occurs on the extremities, and under the following forms: —

1. The *impetigo figurata* is the most common variety of the moist tetter. It appears in circumscribed patches, of various figures and magnitude, which are usually smaller and more circular on the upper, and larger, oval, and irregular on the lower extremities. The patches consist at first of clusters of the yellow psydracious pustules, set close together, and surrounded by a slight inflammatory border; the whole being somewhat raised, but the pustules not very prominent or acuminated. In a few days the pustules break, and discharge their fluid; the surface becomes red and excoriated, shining as if it were stretched, but exhibiting numerous minute pores, from which a considerable ichorous discharge is poured out, accompanied with much troublesome itching, heat, and smarting. The discharge soon concretes partially into thin yellowish or greenish scabs; but still continues to ooze from under the scab which it forms. In the course of three or four weeks, as the quantity of the discharge diminishes, the scabs dry and fall off, leaving the surface of the cuticle red, rough, and somewhat thickened, and at the same time extremely brittle, and liable to crack and to be excoriated; so that the ichorous discharge and scabbing are easily reproduced, and the disease is often thus much prolonged in its duration. Occasionally fresh crops of the psydracious pustules re-appear, as at the commencement; and the whole course of the eruption is repeated.

When the impetigo figurata is beginning to heal, the patches undergo a process somewhat similar to that which takes place in the lepra vulgaris. The amendment commences at the centre of the patch, which first subsides, leaving the border elevated: at length this also disappears; but the cuticle, which was the seat of the patch, remains for some weeks red, shining, and tender.

But though this is the most usual and regular, it is by no means the uniform progress of impetigo: for this eruption, like scabies and eczema, varies so much in its phænomena, as almost to bid defiance to arrangement. Sometimes the patches enlarge by the formation of successive pustular margins; an exterior circle of pustules arising, while the preceding border

is drying, to be followed by others which go through the same course, until the patch attains a considerable extent. The area, in the mean time, becomes dry and rough, with a scaly or scabby incrustation in its centre. This impetiginous *ringworm* bears a considerable resemblance to the herpes circinatus, which spreads by a succession of *vesicular* borders. A severe form of this tetter occurs in hot climates, according to the testimony of physicians who have prastised there. Sometimes the papulæ of the lichen agrius become pustular, or are intermixed with psydracia, and the disease assumes all the characters of impetigo.

But the affinity of impetigo with the vesicular diseases is manifested by a common variety of it, in the upper extremities, in which the psydracious pustules are intermixed with transparent vesicles, resembling the pustules in size and form. Where this intermixture occurs, the disease is much more troublesome, from the extreme irritation, itching, smarting, and heat, which accompany it; and much more tedious and difficult of cure. It takes place chiefly on the hand, about the knuckles and sides of the fingers, or on the wrist; and the space between the metacarpal bones of the forefinger and thumb is usually the seat of one of the blotches. The vesicles are slower in their progress than the psydracia: they remain many days transparent, but not much elevated, the cuticle over them being thick in that situation. When they break, an acrid ichor is discharged, which produces inflamed points where it touches the cuticle, and these become vesicles or psydracia. Each vesicle, thus broken is not disposed to heal; but the cuticle round its base now becomes inflamed and raised, and discharges a thin ichor when in any degree irritated. The vesicles appear, in slow succession, at a little distance from each other, and from the pustules; and at length an irregular blotch is produced, of a red, chopped, and thickened cuticle, interspersed with the rising eruptions, little humid ulcers, and chops or fissures. The sense of burning and intense itching, accompanying especially the first rise of the vesicles, is extremely distressing, and is much aggravated by the irritation of almost every application that is resorted to.

2. The *impetigo sparsa* differs from the preceding rather in the *form*, than in the nature and progress of the eruption: for, with the exception of the indeterminate distribution of the pustules, which are not congregated in circumscribed clusters, but dispersed without any regular order along the extremities, and sometimes about the neck and shoulders, the foregoing description is applicable to both species of the disorder. The impetigo sparsa more frequently occurs in the lower extremities, than the former; and is, in that situation, more troublesome and obstinate. In elderly people, especially of debilitated habits, the excoriations are liable to pass into deep, irregular ulcers, surrounded by a purplish colour, and often accompanied with œdema.

These two forms of impetigo are not always traced to any obvious exciting cause: but they are frequently preceded by some derangement of the digestive organs, languor, and headach. A predisposition to the disease appears to be connected with the sanguine temperament, with a thin soft skin, and a relaxed and bloated habit of body; or with the sanguineo-melancholic temperament, a spare form, and a thin but harsh skin. Certain seasons appear to have great influence on the disease, in those who are predisposed to it. The accession of the eruption has been ascribed to violent exercise, intemperance, cold, and sudden depressing passions, especially fear and grief.

Local tetters are produced by the action of particular irritants on the cuticle, which soon disappear when the source of irritation is withdrawn. The affection of the hands and fingers, in those who work among sugar, which is called the grocer's itch, is of this nature; and similar eruptions are produced on the hands of bricklayers, by the acrid stimulus of lime. It is worthy of remark, that both the grocer's and the bricklayer's itch is, in some individuals, a pustular, and in others a vesicular, eruption, referable to the eczema; but in neither case contagious, as the popular appellation might lead us to suppose.

Local pustular patches are also the result of the application of the tartrate of antimony to the skin by friction, and in some cases of the application of blisters, and other stimulating plasters. These pustules are liable to extend considerably beyond the blistered or stimulated part, and sometimes continue to arise in succession for a fortnight or more; and many of them often assume the form of phlyzacia, or of large, protuberant pustules, with a hard, elevated, and inflamed base. Some of these even acquire the size of small boils, and suppurate deeply and slowly, with great pain, and considerable restlessness and feverish heat in the night.

The impetigo figurata and sparsa are sometimes confounded with two contagious diseases, of the pustular order, porrigo and scabies. The appellation of *ringworm*, which is popularly given to the oval or circular patches of the first, has partly contributed to occasion this mistake. They differ, however, from the contagious circles of porrigo, inasmuch as they seldom affect children, occur principally on the extremities, and do not continue to discharge a purulent and glutinous, but, after the first eruption, an ichorous, humour; nor do they form the thick, soft, and copious scabs of porrigo—not to mention the absence of contagion.

The prevalence of transparent vesicles in the patches of impetigo may mislead an incautious or inexperienced observer into a suspicion that the disease is scabies: but the copious exudation of ichor, the rough, reddened, and fissured cuticle, the magnitude and slow progress of the vesicles, and the heat and smarting which accompany the itching, in this form of impetigo, will serve in general to determine the diagnosis. In the strictly purulent form of scabies, the pustules about the hands arise to a much greater magnitude and elevation than the psydracia; they are filled with a thick yellow pus, and are more considerably inflamed round their base.

In the incipient state of these two forms of

mpetigo, it is useful to administer sulphur internally, in such quantities as not to induce purging; and, if there is much irritability or inflammation of the cuticle, a portion of nitre or crystals of tartar may be advantageously combined with it. The impetigo sparsa commonly yields to these medicines, if diligent ablution with tepid water be at the same time employed. But when the disease is of long standing, it requires a treatment somewhat similar to that recommended for inveterate psoriasis; namely, the diet drinks, decoctions of sarsaparilla and cinchona, with the fixed alkalis and antimonials. The mercurial alteratives, however, in this affection, are of essential assistance to this plan of cure; such as small doses of cinnabar, the hydrargyrus cum cretâ, or Plummer's pill.

The external applications adapted to these forms of impetigo, especially to the figured species, are the mild desiccative unguents; for, in the majority of cases, the irritable surface of the tetter will not bear stimulants with impunity. When the discharge is considerable, the ointments prepared with the oxide of zinc alone, or united with saturnine ointment, or with the white precipitated oxide of mercury, are the most efficacious in allaying the inflammatory condition of the excoriated surface, and in reducing the quantity of the discharge. When there is less of this irritability and exudation, the ointment of the nitrate of mercury, much diluted, as with five or six parts of simple ointment, will be beneficial. From the too active employment of this unguent, and still more of the nitrico-oxide of mercury, by practitioners unacquainted with the character of the disorder, a great aggravation of the eruption and of the sufferings of the patient, is sometimes occasioned.

In some instances, indeed, the skin, under this impetiginous affection is peculiarly sensible to the stimulus of mercury, whether employed internally or externally. But the most irritable of all the varieties of impetigo are those in which vesicles abound; in some of which the zinc and saturnine applications, and even simple cold, occasion an aggravation of the symptoms. In these cases, it is particularly necessary to keep the parts covered, with a view to avoid the effects of friction from the clothes, as well as of heat and of cold; to wash the surface daily with some emollient fluid, such as milk and water, or an infusion of bran; to interdict the use of soap; and to besmear the part with cream, or an emulsion of almonds. A lotion prepared of boiling mallow, digitalis, and poppy-heads, has been found serviceable, where the parts were very painful.

In the drier and less irritable forms of the impetigo, the use of the waters of Harrowgate is the most effectual remedy, and likewise the best preventive of its returns; under the same circumstances, the warm sea-water bath, followed by a course of bathing in the open sea, is productive of great benefit.

3. *Impetigo erysipelatodes.* This form of the disease, in its commencement, presents nearly the ordinary appearances of erysipelas; namely, redness and puffy swelling of the upper part of the face, with œdema of the eyelids; and is accompanied with slight febrile symptoms for the space of two or three days. But, on a minute examination, the surface, instead of the smooth polish of erysipelas, is found to exhibit a slight inequality, as if it were obscurely papulated; and in a day or two the true character of the disease is manifested by the eruption of numerous psydracious pustules over the inflamed and tumid skin, instead of the large irregular bullæ of erysipelas. These pustules first appear below the eyes, but soon cover the greater part of the face, and sometimes extend to the neck and breast: they are accompanied with a distressing sense of heat, smarting, and itching. When they break, they discharge a hot and acrid fluid, which adds to the irritation and excoriation of the surface. In this painful condition the face remains for ten days or a fortnight, when the discharge begins to diminish, and to concrete into thin yellowish scabs. But, on the interstices between the scabs, fresh pustules arise at intervals, with renewed heat and pain, and subsequently discharge, ulcerate, and form scabs like the former. The disease continues thus severe and troublesome for an uncertain period, from one to two or three months, and ultimately leaves the cuticle in the same dry, red, and brittle state which remains after the other forms of impetigo. The constitution is scarcely disturbed during the progress of this disease, and is much less disordered in the outset than in erysipelas.

In the commencement of the disease, purgative medicines, with the antiphlogistic regimen, afford great alleviation to the symptoms; but when the copious exudation and scabbing take place, the cinchona, in considerable doses, alone, or with the sarsaparilla, or mineral acids, is administered with the greatest benefit. The same local treatment is requisite as in the other forms of the eruption; viz. tepid ablution, with emollient liquids; the application of the mildest ointments; and the use of sea-bathing, or of the sulphureous waters, in its decline.

4. *Impetigo scabida.* In this more rare and severe form of the disease, one or more of the limbs becomes encased in a thick, yellowish, scabby crust, not unlike the bark of a tree, which is accompanied with a disagreeable heat and itching, and renders the motion of the affected limbs difficult and painful. This crust is the result of the concretion of an acrimonious humour, which is discharged in great abundance from numerous psydracious pustules, as they successively form, break, and ulcerate over the surface of the limb. The concretion commences about the third or fourth week, when the discharge begins to abate, and invests the whole of the arm from the elbow to the wrist, or the leg from the knee to the ankle. After some time longer, the scabby coating is divided by large cracks or fissures, from which a thin ichor exudes, and concretes into additional layers of scabs. If any portion of the scab be removed, the excoriated surface pours out its fluid again, and fills up the space with a new concretion. In the lower extremities, the disease is most severe and obstinate, is ultimately conjoined

with anasarca, and often produces severe ulceration. The incrustation sometimes extends to the fingers and toes, and destroys the nails; and, as in other similar instances, the new ones are thick, notched, and irregular.

This species requires the same internal medicines which have been recommended for the inveterate forms of the preceding varieties, especially the sulphureous waters. The chief peculiarity of its treatment consists in clearing the surface of its incrustation, and correcting the morbid action of the superficial vessels. The thick scab can only be softened and gradually removed by perseverance in the application of the steam of warm water to it, for a short time, daily. Those parts of the surface, which are thus cleared, must be covered with soft linen, or oiled silk, after tepid ablution, twice a day; and some of the unguentum zinci, or a much diluted ointment of nitrate of mercury, with common cerate, containing a fourth or fifth part of the mercurial, must be interposed.

5. The *impetigo rodens* is a rare but intractable species of the disease, probably of a cancerous nature, in which the cellular membrane is affected, as well as the skin, and seems to shrink away, as the ulceration and discharge go on. The disorder commences with a cluster of pustules, sometimes intermixed with vesicles, which soon break, and discharge, for a long period of time, an acrid humour, from open pores or from under scabs; and the skin and cellular texture are slowly, but deeply and extensively, corroded, with extreme irritation and pain, which are only to be alleviated by large doses of opium. The disease commonly begins on the side of the chest or trunk of the body, and gradually extends itself.

IMPETUM FACIENS. The name given by Boerhaave to the vital energy. The expression is a translation of the word ἐνορμοῦν used by Hippocrates; and Boerhaave published a book on the subject, intitled *Impetum faciens Hippocrati dictum*. The word, however, by which Hippocrates seems most generally to have designated the vital energy or principle, is φυσις — *nature*. See *Life*.

I'MPIA HERBA. (Said to be so called because it grows only on barren ground.) See *Gnaphalium*.

IMPLICA'TUS. Implicate. Celsus, Scribonius, and some others, call those parts of physic so, which have a necessary dependance on one another; but the term has been more significantly applied, by Bellini, to fevers, where two at a time afflict a person, either of the same kind, as in the case of a double tertian; or of different kinds, as in the case called a *semitertian*, which is a mixture of a tertian and a quotidian.

IMPLU'VIUM. (From *impluo*, to shower upon.) 1. The shower bath.

2. An embrocation.

IMPOSTHUMA. *Imposthume*. A term corrupted from *apostema*. An abscess.

Imposthume. See *Imposthuma*.

Impo'tency. See *Sterility*.

IMPREGNA'TION. *Impregnatio*. See *Conception*, and *Generation*.

INANI'TION. (*Inanitio, onis*. f.; from *inanio*, to empty.) The absence of nutrition from want of food. Starvation.

INCANTA'TION. (*Incantatio, onis*. f.; from *incanto*, to enchant.) A way of curing diseases by charms, much practised in ancient times, and adopted also by Paracelsus, Van Helmont, and other enthusiasts among the moderns.

INCA'NUS. Hoary. Applied to stems and leaves which are covered with a kind of scaly mealiness; as that of the *Artemisia absinthium*, and *Atriplex portutacoides*. See *Glaucus*.

INCE'NDIUM. (From *incendo*, to burn.) *Incensio*. A burning fever or inflammation. Synonymous with *phlogosis*.

INCERNI'CULUM. (From *incerno*, to sift. 1. A strainer, or sieve.

2. A name for the pelvis of the kidney, from its office as a strainer.

INCIDE'NTIA. (From *incido*, to cut.) A name given to medicines which were supposed to promote the discharge of phlegm, by cutting it as it were, and destroying its viscidity. The term is now obsolete.

INCINERA'TION. (*Incineratio*; from *incinero*, to reduce to ashes.) The reduction of any substance to ashes by combustion.

INCISI'VUS. Relating to the incisor teeth. A term applied to certain parts situated near the incisor teeth.

Incisivum foramen. See *Foramen incisivum*.

Incisivus inferior. See *Levator labii inferioris*.

Incisivus lateralis. See *Levator labii superioris alæque nasi*.

Incisivus medius. See *Depressor labii superioris alæque nasi*.

INCI'SOR. (*or, oris*. m.; from *incido*, to cut, from its use in cutting the food.) The four front teeth of both jaws are called *incisores*, because they cut the food. See *Teeth*.

INCISO'RIUM. (*um, i*. n.; from *incido*, to cut.) A table whereon a patient is laid for an operation.

INCISORIUM FORAMEN. The same as the *foramen incisivum*.

INCI'SUS. (From *incido*, to cut.) Cut; snipped: applied, in *Botany*, synonymously with *dissectus*, to leaves; as those of the *Geranium dissectum*.

INCOMPATIBLE. Substances which cannot with propriety be prescribed together in the same formula, on account of their having a chemical action on each other, are said to be *incompatible*.

INCOMPLE'TUS. Incomplete: applied to flowers, such as want either the cup or the blossom: the tulip, for example, wants the cup.

INCONTINE'NTIA. (*a, æ*. f.; from *in*, and *contineo*, to contain.) Incontinence. Inability to retain the natural evacuations. Thus we say, incontinence of urine, &c.

INCRA'SSANS. (From *incrasso*, to make thick.) Formerly applied to medicines supposed to have the property of thickening the fluids. *Incrassantia medicamenta*.

INCREME'NTUM. Increase: growth. See *Nutritio*.

I'NCUBUS. (*us, i*. m.; from *incubo*, to

lie upon: because the patient fancies that something lies upon his chest.) The nightmare. See *Ephialtes.*

INCU'RVUS. Curved inwards: applied to leaves. See *Inflexus.*

I'NCUS. (*us, udis.* f.; a smith's anvil.) The largest of the bones of the tympanum, so named from its shape. See *Auris.*

Indented. See *Sinuatus.*

I'NDEX. (*ex, icis.* c. g.; from *indico*, to point out: because it is generally used for that purpose.) The fore-finger.

Indian arrow-root. See *Maranta.*

Indian cress. See *Tropæolum majus.*

Indian date-plum. See *Diospyros lotus.*

Indian fig. See *Cactus opuntia.*

Indian leaf. See *Malabathrum.*

Indian pink. See *Spigelia.*

Indian rubber. See *Caoutchouc.*

Indian wheat. See *Zea mays.*

INDIA'NA RADIX. Ipecacuanha.

I'NDICA CAMO'TES. The potatoe.

I'NDICANT. (*Indicans;* from *indico*, to show.) Relating to an indication. See *Indication.*

INDICATING DAYS. *Dies indicantes.* Critical days.

INDICA'TION. (*Indicatio, onis.* f.; from *indico*, to show.) In medical language, an indication is that which demonstrates what ought to be done. It is threefold: *preservative*, which relates to the preservation of health; *curative*, which relates to the cure of a present disease; and *vital*, which respects the powers and reasons of diet. The scope from which indications are taken, or determined, is comprehended in this distich: —

—— *Ars, ætas, regio, complexio, virtus,*
Mos et symptoma, repletio, tempus, et usus.

INDICA'TOR. (*or, oris.* m.; from *indico*, to point: so named from its office of extending the index, or fore-finger.) An extensor muscle of the fore-finger, situated chiefly on the lower and posterior part of the fore-arm. *Extensor indicis*, of Cowper. *Extensor secundii internodii indicis proprius, vulgo indicator*, of Douglas. It arises, by an acute fleshy beginning, from the middle of the posterior part of the ulna; its tendon passes under the same ligament with the extensor digitorum communis, with part of which it is inserted into the posterior part of the fore-finger.

INDICUM LIGNUM. Logwood.

INDICUS MORBUS. The venereal disease. Because it was supposed to have been caught from the North American Indians by the followers of Columbus, and by them imported into Europe.

INDI'GENOUS. (*Indigenus; ab indu, i. e. in et geno, i. e. gigno*, to beget.) Applied to things which are peculiar to any country, as animals, plants, or diseases.

Indigestion. See *Dyspepsia.*

I'NDIGO. A blue colouring matter extracted from the *Indigofera tinctoria.* Anil, or the indigo plant.

INDIGO'FERA. (From *indigo*, and *fero*, to bear.) The name of a genus of plants. Class, *Diadelphia;* Order, *Decandria.*

INDIGOFERA TINCTORIA. *Indigofera anil.* The systematic name of the plant which affords indigo.

INDU'RANS. (From *induro*, to harden.) Applied to medicines which were supposed to condense the animal fibres — *Medicamenta indurantia.*

INDU'SIUM. (*um, ii.* n.; from *induco*, to cover or draw over.) A shirt or under garment. 1. A name of the amnios, from its covering the fœtus like a shirt.

2. The name given by most botanists to the involucrum, or thin membraneous covering of the fructification of ferns.

Its varieties are,

1. *Inducium planum*, flat; as in the genus *Polypodium.*

2. *Pellatum*, connected with the seed by a filament or stalk; as in *Aspidium filix mas.*

3. *Corniculatum*, round and hollow; as in *Equisetum.*

INEQUA'LIS. Unequal. Applied to a leaf when the two halves are unequal in dimensions, and the base end parallel; as in *Eucalyptus resinifera.*

INE'RMIS. (From *in*, priv. and *arma.*) Unarmed: opposed, in designating leaves, to *spinous.*

Infection. See *Contagion.*

I'NFERUS. Inferior. Much used in *Botany:* thus, a blossom is said to be *beneath* when it includes the germen, and is attached to the part immediately below it; as the blossom of sage, borage, &c. A germen is *beneath* when it is placed below the attachment of the blossom, and therefore not included within it; as in *Lonicera, Ribes, Cratægus*, &c.

INFIBULA'TIO. (From *infibulo*, to button together.) 1. An impediment to the retraction of the prepuce.

2. Synonymous with *ancteriasmus.*

INFLAMMABLE. (*Inflammabilis;* from *inflammo*, to burn.) Chemists distinguish by this term such bodies as inflame with facility. See *Combustion.*

Inflammable air. See *Hydrogen gas.*

Inflammable air, heavy. See *Carburetted hydrogen.*

INFLAMMATION. (*Inflammatio, onis;* f. from *inflammo*, to set on fire.) Inflammation is a state which may in general be said to be characterised by *pain, swelling, heat*, and *madness.* Of these the first, although often the most urgent, is, in fact, the least constant symptom. It is much felt in external inflammations, and in those which affect the outer coverings of the different viscera, but is little felt in some cases of inflammation of the internal membranes, and of the substance of viscera (perhaps because the parts affected in those cases have fewer nerves of common sensation); and is often excited only by occasional impressions made on the affected parts. The increased temperature, in all probability exists in every case of inflammation; but it seldom amounts to more than a few degrees; it is of course often concealed from the observer; and, as the sensibility to heat is less general over the body than the susceptibility of common sensation, the heat of

inflammation is less generally felt by the patient than the pain.

The swelling and redness, although very various in degree, in form, shade of colour, &c., in different cases, and often concealed from view, likewise exist, more or less, in every case of inflammation; and depend, in the first instance, not on any extravasations, but on the distension of the small vessels of the part, and on the passage of the colouring matter of the blood into vessels which had before hardly, if at all, admitted it.

But in order that inflammation may be clearly distinguished from all other states of any living texture, it is necessary to add to these four characters two other distinctive marks: 1st, That the affection should remain fixed in the part for at least some hours; — and, 2dly, That unless the affection be speedily and artificially arrested in its course, more or less of *extravasation* should show itself from the vessels of the part, first, of the serous part of the blood only, but afterwards of a more glutinous fluid, or even of the solid matters, — constituting the different inflammatory effusions to be presently considered. This last character, drawn from the local effects, rather than the symptoms, of inflammation, is the only sure mark of distinction between this state and mere congestion of blood, already considered.

These are the characters which appear, on careful consideration of the phenomena of inflammation in all parts of the body, and after exclusion of all individual and local peculiarities, to be the most uniformly present, and therefore the most essential parts of its history, in its earliest stages. But in many individual cases, these are in a great measure concealed from view; and, in order both to secure the recognition of this condition of individual parts, and also to understand the manner in which it gradually deranges the living action of other parts, and endangers life, it is necessary to observe minutely and generalise the *effects* which are found by experience to result from it, — *first*, in the condition of the system at large; *secondly*, in the *functions* of individual organs, — either those that take on the diseased action themselves, or those most closely connected with them.

I. The effects of local inflammation on the system at large, may be ranked under two heads, 1. The inflammatory fever, and, 2. The inflammatory state of the blood; both of which very generally attend inflammation of any considerable extent and intensity, and in many cases, bear a tolerably uniform proportion to its amount.

Of the combination and succession of symptoms which constitute the state called fever, it is generally allowed that the most uniform and characteristic are (as stated in Cullen's definition of Pyrexiæ) a sense of coldness and debility, succeeded by increased heat of skin, and increased frequency of pulse, and by a general derangement of the other functions, of which continued debility of the voluntary muscles is an important part.

The general derangement of functions, during the febrile state, may be thus arranged.

1. During the first, or cold stage (which is almost always observed, and always very important to be marked, as fixing the date of the febrile attack,) there is very generally, for a short time, besides the increased frequency of pulse, more or less of depression or debility of the heart's action, and afterwards an increase of the force, and sharpness or quickness of its pulsations, as well as of their frequency, to which change, and the concomitant rise of temperature, the term *Febrile Reaction* is properly applied. In the decline (whether temporary or permanent) of the febrile state, the usual change is in the pulsations becoming softer, or taking place more slowly, as well as becoming less frequent; but there may be many variations in the pulse in the course of fever, before that improvement takes place.

2. The functions of secretion, exhalation, and nutrition, in all parts of the body, are more or less diminished during the febrile state; as appears from the surface being more parched, or any sweat being temporary, and ineffectual in cooling the surface; from the mouth and tongue being clammy, or dry, with the feeling of thirst; from the appetite being deficient, and digestion imperfect; from the bowels being costive (unless there be a special affection of their mucous membrane;) from the urine, sometimes limpid and abundant in the cold stage, soon becoming high coloured, and often turbid and acrid; from the morbid secretion of ulcers, and the morbid exudation of eruptions on the surface, usually abating or disappearing; and from the general wasting of the body.

3. The respiration is often somewhat irregular, and attended with a sense of anxiety in the cold stage of fever, and becomes always somewhat more frequent than natural, when the febrile reaction is established; and the heat of the surface becomes greater than natural at the same time, although by no means in exact proportion to the strength and frequency of the pulse.

4. The functions of the nervous system are very often and variously affected during the febrile state. 1. The *sensations* are generally somewhat blunted in the first stage, when the febrile depression is most strongly marked, and often morbidly increased, at least partially, when the reaction is established. Pains of the back and limbs, and more especially of the head, are also natural accompaniments of the earlier stages of fever, independently of any inflammation in the parts pained. 2. There is, in general, disinclination to voluntary muscular exertion, and *debility* on attempting it, so important as to be introduced into the general definition of fever; but there is occasionally, during the febrile state, especially when the more active kind of delirium is present, an excitement and transient morbid energy of voluntary action, even when the circulation has become feeble; and there is more frequently, during some part of the febrile state, irregular and involuntary action of the voluntary muscles, tremors, subsultus tendinum, or even convulsions. 3. There is always, during fever, more or less affection of the *mental faculties;* at first a degree of

torpor, which is often succeeded, when the reaction is established, by a morbid rapidity, and more generally by a morbid energy, of the different mental acts composing the train of thought, with a peculiar difficulty of exerting the power of voluntary attention, from which there naturally results some confusion of thought, and often such hallucination as characterises delirium; and this febrile condition of the mental faculties often blends itself with, or passes gradually into coma.

It is chiefly by greater or less predominance of different parts of the combination of symptoms now sketched, that the species of varieties of fever are distinguished from each other; and that called *Inflammatory Fever*, which most commonly attends inflammation, is especially denoted by the following circumstances:—1. That the febrile reaction of the vascular system is stronger, and more enduring; 2. That there is less derangement of the secretions; and, 3. That there is less disorder of the nervous system, — than in those fevers which cannot be so distinctly ascribed to local inflammation as their cause. On the other hand, when the vascular reaction is feebler, or less permanent, the derangement of the secretions more obvious, and the nervous system earlier and more decidedly affected, and especially if that affection shows itself by depression, and tendency to stupor, rather than by more active delirium, the form of fever is said to be *typhoid*.

Several other circumstances, in regard to the fever which accompanies inflammation, demand notice.

1. Although the febrile symptoms are generally regarded as the effects of the local inflammation, and accordingly, are generally posterior to some part of the local symptoms in date, yet there are instances, — not only in the case of specific inflammations attending febrile exanthemata (of which the whole pathology is different,) — but of simply inflammatory diseases, pneumonia, cynanche tonsillaris, mastodynia, &c. where the febrile attack precedes any local symptoms; and perhaps may contribute to excite them. And there are other cases, particularly in irritable constitutions, where the febrile symptoms last for a time (*e. g.* a few days,) after the local symptoms of inflammation have subsided, and where these do not recur.

2. Although intense and extensive inflammation is usually attended with high fever, and *vice versâ*, yet the proportion is by no means uniform. The degree of febrile symptoms, attending a given extent of inflammation, is generally increased by youth, plethoric habit, and sanguine temperaments, and lessened by the reverse of these. In some, even vigorous constitutions, the degree of fever excited by active inflammation is slight; and there are some organs, as the tonsils, the inflammation of which is frequently attended with a degree of fever quite disproportioned to their size, or importance in the system.

3. Although the febrile symptoms attending the earlier stage of the inflammation have generally the character of inflammatory fever, as above distinguished, yet deviations from this type of fever are frequently seen, and may be referred to two heads, as they depend either *first*, on the peculiarity of the part affected, or *secondly*, on the action of some other cause influencing the system simultaneously with the inflammation itself.

Of the modification of the fever of inflammation by the part affected, the most important instance is in the case of inflammation of the stomach and intestines; where the fever is characterised by an early and often very rapid depression of the heart's action, strongly resembling, and evidently illustrated by, the effect on the heart's action of violent injuries of the abdomen, which is familiar to all surgeons. An effect somewhat similar results from active inflammation of the kidneys, uterus, bladder, and larger joints.

The modification of the fever of inflammation by the action of a concurrent cause affecting the system, is remarkably seen, 1. In the case of inflammation from an injury which has given a violent shock or concussion; 2. In the case of inflammation occurring in a constitution in which the nervous system has been habitually influenced by peculiar stimuli, such as alkohol taken in excess; 3. In the case of inflammation attended with the introduction of peculiar animal poisons into the system.

In all these cases, the fever attending inflammation shows a less forcible and less enduring reaction, and is attended with more derangement, both of the secretions and of the functions of the nervous system, than is usual; and therefore assumes, more or less exactly, the form to which the term *typhoid* is applied.

The state of the blood which usually attends inflammation, of considerable intensity, is that in which it shows the buffy coat, *i. e.* in which a separation, more or less complete, of the fibrin from the colouring matter of the crassamentum takes place spontaneously during coagulation.

It is stated in the article *Sanguis*, that this separation does not depend on the circumstance of slow coagulation of the blood and consequent subsidence of the colouring matter, but that there appears to be in this state a repulsion between the particles of the fibrin and the red matter; causing them to separate from each other before the fibrin has become solid, or in films so thin, that they separate laterally instead of vertically. This repulsion may or may not coexist with a strong aggregation of the particles of the fibrin among themselves; but in most cases of violent inflammation there is both the complete separation and the strong aggregation; the effect of which is a buffy coat, both thick and strong, *i. e.* contracted.

A thin buffy coat, implying imperfect separation of the fibrin from the colouring matter, usually attends cases of slight or very partial inflammation only. A thick, but loose, flabby buffy coat, implying more separation from the colouring matter, but weak aggregation of the particles of fibrin among themselves, is generally observed where another cause of disease of the system (*e. g.* contagious fever) coexists with local inflammation. It appears from the observations of Gendrin, that the proportion of

albumen in the serum of sizy blood, and especially in that part of the serum which is entangled in the buffy coat itself, is much greater than in the serum of healthy blood.

The buffy coat is seen on the blood in some persons, chiefly of a plethoric habit, without inflammatory disease existing in them, and is often found in the blood of pregnant women; but in these cases it is seldom thick or very firm. The formation of the buffy coat, though not dependent on slow coagulation, is of course facilitated by that circumstance; and when coagulation is much hastened, a complete separation of the parts of the crassamentum cannot take place. Hence blood which is drawn in a small stream, or spread over a flat surface, as its coagulation takes place quickly, is not apt to show the buffy coat; and this is probably also the reason why blood drawn from weakened or fainting persons, which is more serous, and coagulates more quickly than most venous blood, seldom shows the buffy coat; and why the last drawn blood in a bleeding on account of inflammation, is usually the least sizy.

In a few cases the last drawn blood is the most sizy, and that especially when the pulse, previously depressed, becomes fuller and stronger by reason of the bleeding; probably because the capillary circulation becoming more free, and more serum being admitted there, the blood in the large veins then becomes less serous, and the coagulation takes place more slowly.

Inflammation, even when violent, generally lasts for a day or two, before it causes the blood to show the buffy coat. It is not yet ascertained whether the blood in the veins leading from an inflamed part, becomes sizy sooner than that in other veins of the body; but microscopical observations on the changes which take place in the blood in the capillary vessels of an inflamed part render this supposition probable.

II. The concurrence of the symptoms already considered is generally sufficient to indicate the existence of inflammation, even when seated in internal parts; but there are almost always more local symptoms, indicating a peculiar derangement of the function of some particular organ, which enables us more decidedly to fix on the seat of the inflammation. These local symptoms are such as denote *alteration of the function*, either of the part that is inflamed, or of an adjoining part, or of a part connected with it in function, or by known sympathies, although not adjacent.

1. When any internal part is inflamed, its own functions are in general perceptibly, though somewhat variously altered. Thus inflammation of the heart and large arteries causes generally preternatural, and sometimes irregular impulse of the heart, inflammation of the lungs causes dyspnœa, and soon alters the sound produced by the air entering the lungs; inflammation of the serous or synovial membranes causes increase and alteration of the serum naturally effused into these cavities, which often becomes obvious to the observer; inflammation of the mucous membrane of the air-passages or bowels, leads to increased and altered secretions there, and consequent *profluvia*; inflammation of the serous, or perhaps more especially of the muscular coat of the bowels, causes costiveness; inflammation of the kidneys alters the composition of the urine, that of the bladder renders its excretion difficult and painful; inflammation of the brain leads generally to derangement of some part of its functions, to palsy, spasm, delirium, or coma; inflammation of the eye or ear augments the sensibility to light or sound, while inflammation of the lining membrane of the nose blunts the sensibility to smells; inflammation of muscles or their coverings, or of motor nerves, greatly impedes or wholly prevents the motion of the parts they are destined to move.

But there are many cases of important, at least apparent, exception to this rule, especially in the case of those internal viscera, the whole of which is not required for the outward manifestation of their functions. Thus a portion of the liver may be inflamed, without the flow of bile being perceptibly altered; and experience shows, that portions of the lungs, and of the brain, may be inflamed, without the usual alterations of the functions of these parts being observed.

2. Alteration of the functions of parts adjoining those that are actually inflamed, is seen in the painful and difficult deglutition caused by inflamed parotids, tonsils, or larynx, in the painful and difficult descent of the diaphragm, when the peritoneum or liver is inflamed, &c.

3. When inflammation of the liver causes pain of the right shoulder, inflammation of the bladder pain at the point of the urethra, inflammation of the spinal cord, pain stretching round the abdomen, or inflammation of the hip-joint pain at the knee, we have examples of the phenomenon considered formerly under the name of sympathetic sensation: and when inflammation of the brain, liver, stomach, bowels (especially their serous coat), kidneys or bladder, causes vomiting, the diaphragm and abdominal muscles take on a sympathetic action; the sensations which excite them to the act of vomiting being excitable by irritation of all these parts. Again, when inflammation of the mucous membrane of the trachea or bronchia causes violent and painful cough, when that of the colon or rectum causes painful and ineffectual tenesmus, or that of the mucous coat of the bladder causes strangury, the actions excited are only an excessive degree of those sympathetic actions of various and sometimes distant muscles, which the natural sensations of these parts excite, for useful and important purposes. And in all these cases, the sympathetic phenomena, when coexistent with other symptoms of inflammation, are an important indication of its seat. — *Alison.*

Inflammation either subsides, leaving the affected part in a healthy state, or it terminates in one of several ways, involving more or less serious lesion of the part.

Whatever opinion may be formed regarding the *precise* condition of the blood-vessels in inflammation, it is obvious, from the general tenour of the phenomena now described, that they are loaded with an unusual proportion of blood. This is, for all practical purposes, the

essence of inflammation; of such increased quantity of blood the vessels must be *relieved*, before they can be restored to their natural healthy condition and mode of action. The terminations of inflammation therefore consist for the most part of the several modifications of *effusion*.

1. *Resolution.* — When an inflamed part gradually regains its healthy state without any derangement of its structure, or any *sensible* effusion from its vessels, the disease is said to terminate by *resolution*. This is invariably the object of the physician; but the surgeon may have cause to regret it, because he occasionally excites inflammation with a view of profiting by some of its subsequent stages. Resolution may happen, first, without medical aid, when the inflammation is very slight; but far more frequently it takes place when, secondly, the requisite *unloading* of the vessels has been effected by *local* or *general* blood-letting, or, in milder cases, by local cold and purging. It is a most fortunate provision of nature that such relief may be afforded by emptying vessels at a distance from the actual seat of disease. Were it not for this, every case of acute inflammation of the lungs would prove fatal. We judge of the tendency to resolution by the *gradual* giving way of the symptoms of inflammation, particularly by the diminution of pain, and by the pulse becoming *soft*.

2. *Increased secretion.* — The second termination of inflammation is an increase of the natural secretions of the part. In membranes which have an external outlet, such as the several mucous membranes, this is almost equivalent to resolution. In the shut cavities, as those of the pleura, pericardium, and peritonæum, such a termination of inflammation is more to be dreaded; but in many cases the fluid thus effused is gradually absorbed, and health ultimately restored.

3. *Hæmorrhage, dropsy, and effusion of coagulable lymph.* — The third mode by which inflammation terminates is *effusion* from the vessels of the part, either of blood or of its principal constituent parts, serum, and fibrine. The mucous membrane of the bowels, when inflamed, frequently relieves itself by a discharge of pure blood. In some cases the *serum* of the blood is effused, as in hydrocephalus and inflammation of the tunica vaginalis testis. In other cases the *coagulating lymph* of the blood is effused, forming adhesions, as in pleurisy and peritonitis. A peculiar gelatinous fluid is thrown out in rheumatism, and a saline matter in gout. The consequences of these effusions vary according to the violence of the inflammation, and the situation and structure of the part affected. Adhesions from pleuritic inflammation are productive of little or no inconvenience; occurring in peritonæal inflammation, they sometimes lead to incurable marasmus or ileus. The effusion of serum from inflamed vessels forms a part, and a very important part, of the general pathology of *dropsy* (as explained in various parts of this work). When effusion takes place in the substance of the solid viscera, they become hardened, or *hepatised*, and are rendered more or less unfit for the due performance of their functions.

4. *Suppuration.* — The fourth termination of inflammation is the effusion of a new product of the blood, called *pus*, a bland fluid, of the colour and consistence of cream. When this is poured out into some cavity formed during the process of inflammation, an *abscess* is said to exist; when the purulent matter forms upon an exposed surface, *ulceration* is said to be established. This subject opens an extensive field of inquiry, in which the labours of John Hunter have been successfully exerted. He pointed out the remarkable analogy which subsists between pus and a secreted fluid, an ulcerating and a secreting surface. The symptoms by which we judge of suppuration having taken place in an internal organ are the following: — A change from the lancinating to the throbbing pain. A sensation of weight or fulness in the inflamed part. The pulse continuing frequent, but becoming soft and full. The occurrence of rigors and of night sweats, — in other words, the development of *hectic fever*. See *Abscess*.

5. *Destruction of the inflamed part.* — In the most aggravated cases of acute inflammation the part dies. This most formidable of all its terminations may be either gradual and partial, or complete. Partial destruction is called sloughing, or phagedenic ulceration; total destruction, sphacelus, gangrene, or mortification. Such a result may happen in three ways: — 1. From the excessive violence of the first stage of inflammation, rendering it impossible for the vessels to restore themselves by any kind or degree of effusion. But as the tendency to gangrene often shows itself early, and without any particular violence of the first stage, it must be ascribed, *secondly*, to a *septic* tendency in the disease itself, as in the case of plague. The malignity of that contagion so overpowers the nervous system, that the vessels of the inflamed part are unable to resist the shock of the disease and the part itself dies. 3. The disposition to gangrene is, in many instances, independent both of the *nature* and of the *violence* of the inflammation, and is referable simply to the weakness of the patient's habit, which is unable to oppose resistance, even to a mild attack. The occurrence of gangrene is marked by — 1. The sudden cessation of pain. 2. A sinking and irregular pulse. 3. A change in the expression of countenance, from that of febrile excitement to exhaustion. 4. Delirium. 5. Cold sweats. See *Mortification*.

It remains to be stated, that several of these terminations of inflammation may be going on at the same time. Thus a mucous membrane may throw out a *muco-purulent* fluid. Flakes of coagulable lymph may float in the serum which an inflamed peritonæum has thrown out. Some portions of the cellular membrane may suppurate whilst others mortify. — *Gregory*.

The phenomena and terminations of inflammation are greatly influenced by the texture in which it occurs — a truth of the utmost importance in pathology, and which was first distinctly apprehended by Dr. Carmichael Smyth. Since his time the study of general anatomy has afforded it a more extensive application. The following are the varieties of inflammation,

according to texture, which are most distinctly known.

1. *Inflammation of the skin.* — The effects of inflammation on this part of the body are very various: such as the formation of rashes, as in scarlatina, roseola, &c.; pustules, as in small-pox, porrigo, &c.; vesicles, as in chicken-pox, herpes, &c.; papulæ, as in measles, lichen, &c.; scales, as in lepra; ulceration with loss of substance; and also gangrene.

2. *Inflammation of mucous membranes.* — This is characterised by swelling and dryness; effusion of mucus, or of matter of a puriform character — a mixture of the two, appropriately termed muco-purulent; of a serous fluid, and coagulable lymph. These different products of inflammation are sometimes colourless, at others yellow, and sometimes red like currant jelly. The mucous membranes are likewise liable to softening, thickening, passive hæmorrhage, ulceration, contraction, sloughing, and tubercular formation.

Some of these effects are common to the mucous lining of the air passages, alimentary canal, and urinary passages, as for instance, copious exudations of mucus, softening, thickening, and passive hæmorrhage. Others are not so; tubercular formation, for instance, is more frequently met with in the alimentary canal. Ulceration is sometimes found in the air tubes, but more frequently in the stomach and bowels, particularly the latter, rarely in the bladder. Some parts of the mucous membrane of the same canal are more liable to inflammation and ulceration than others; for instance, the termination of the ilium and the colon. Inflammation is more liable to terminate in the exudation of coagulable lymph in some parts than others; it is seen most frequently in the windpipe and rectum, although other parts are not altogether exempt.

Considerable vascularity is not alone a certain proof of inflammation having existed in the mucous membranes before death, because it may be found only in depending parts of the canals; and congestions of this membrane may be occasioned by diseases of the heart and lungs, and by any other cause which obstructs the circulation of the blood.

3. *Inflammation of the cellular membrane.* — This terminates in effusion of blood, of lymph, of serum, of pus; — in induration and gangrene. Inflammation in this tissue is generally termed phlegmonous, and although the cellular membrane is so extensive and loose in its texture, the disease tends to circumscribe itself by a sanatory process, and the effused matter to make its way to the surface of the body. Occasionally, though rarely, the inflammation has a tendency, from the first, to spread very extensively, from peculiar circumstances, which have never been satisfactorily explained. This is termed "diffuse cellular inflammation." Sometimes the death of a small portion of the cellular membrane takes place; then the affection is called carbuncle.

4. *Inflammation of fibrous membranes.* — Fibrous membrane is the tissue which is generally supposed to be affected in gout and rheumatism; the chief peculiarities are said to be, that it never terminates in suppuration, ulceration, or gangrene, and that the functions of the brain are rarely disturbed during the course of the disease. It is said to terminate sometimes by effusion of a gelatinous nature, or deposition of calcareous matter. This subject ought to be held as being open to future investigation; it is by no means proved that the inflammation which attends gout or rheumatism is situated in such a texture. All the phenomena and the terminations of these diseases, tend to confirm a suspicion, that it is seated in the extremities of nerves, more particularly when we reflect upon the sudden metastases. At all events, it is rather strange that so many authors should make the assertion, that inflammation of fibrous membranes *never* terminates in suppuration and ulceration. What do they call the periosteum? But this question is too intricate and extensive, and some may think, too surgical, to be investigated in this work.

5. *Inflammation of serous membranes.* In a state of health serous membranes show few red vessels, and their surfaces exhale a thin serous fluid, which is just sufficient to bedew them. When inflamed, red vessels are seen during life, an effusion takes place either of serum or lymph or of both. Sometimes the effusion is limpid, or turbid like whey: at other times it looks like pus, and occasionally it is greenish, or resembles lees of wine; often large masses of coagulable lymph are discovered glueing the parts together. Adhesions between the different viscera of the thorax and of the abdomen seem to be effected by means of intervening portions of lymph, which subsequently become organised. The quantity of the effused matter is sometimes small, amounting only to a few ounces, at others there are several pounds.

A bloody effusion is sometimes found, more particularly in the abdomen. Ecchymosis not unfrequently takes place when the inflammatory action is very violent. There can be no doubt that tubercles form *occasionally* under a sub-acute and chronic inflammation of this class of membranes, more particularly in the peritoneum, *pleura pulmonalis*, and arachnoid coat. Emphysema also occurs in the cellular tissue immediately under the peritoneum. It has been proved by experiment, that the peritoneum, however vascular under acute inflammation during life, loses its red appearance even during the act of death. In chronic inflammation, it is sometimes found very red in colour, and thickened in texture.

Ulceration is also to be considered as an occasional, although rare, effect of inflammation in serous membranes.

Gangrene is one of the rarest results of inflammation of serous membranes, and it is to be doubted whether it ever occurs when the diseased action is confined to this tissue.

6. *Inflammation of the solid viscera.* The first circumstance generally perceived is the presence of an unusual quantity of blood in the affected organ. The first change in the structure of the viscus is softening. Hardening is owing, in general, to chronic inflammation. Generally speaking suppuration is not a frequent

result of inflammation in the substance of the viscera. Abscesses of the liver, however, are very common.

7. *Inflammation affecting glands.* This has an aptitude to terminate speedily in suppuration. Sometimes, however, they suppurate very slowly, and occasionally induration takes place. — *Mackintosh.*

The terminations of inflammation in different textures are stated more at large under the respective heads of inflammation of particular organs in different parts of this dictionary.

With respect to the predisposing causes of inflammation, and the state of system which renders an individual most obnoxious to it, there has been considerable difference of opinion.

Dr. Cullen states, that the inflammatory diathesis chiefly prevails in systems of the greatest vigour. A full habit of body, a plethoric state of vessels, and *tension of fibre*, are the terms usually employed to express the state of the system, when predisposed to acute inflammation. In such habits we often meet with genuine inflammatory diseases; but the student must bear in mind that this is neither the only state of body in which they occur, nor is it even the most common. He will find, that when the constitution is *below par*, when it has been weakened by previous diseases, by low living, by anxiety of mind, or excessive bodily fatigue, continued for a long period of time, inflammation of the most acute kind is often excited, which runs as rapid a course, and is attended with symptoms as violent, as inflammation occurring in persons full of blood, and of the most robust habit.

The state of *weakness* then, of *irritability*, and of *atony*, is at least as favourable to the development of inflammation as that of *plethora* and *tension*. The intermediate state is that which affords the surest preservative against the attack, not only of inflammatory, but of every other description of disorder. To that kind of inflammation which occurs in robust habits, the term *entonic* has been applied; *atonic* to that which takes place in a reduced state of the system. As expressive of a pathological principle, these terms are not objectionable; but in *practice* the several kinds of inflammation are to be treated on the same principles. It is with reference to prognosis, and the extent to which measures of depletion are to be pushed, that the study of the predisposition to inflammation is principally useful.

Inflammation sometimes arises in the human frame unexpectedly, and from causes wholly unknown; but at other times we can define its exciting causes with considerable certainty. Among the most important of the acknowledged causes of internal inflammation, will be found the following: — Mechanical and chemical irritants; — Cold; — Acrimony of the blood and humours; — Morbid poison; — Contagion; and Metastasis.

1. *Mechanical and chemical irritants.* — The phrenitis of infants has been traced to blows and falls; gastritis to poison; enteritis to the presence of hardened fæces; nephritis to calculus in the kidney; ophthalmia to dust and sand; erysipelas to leech-bites, or the distension of the skin from dropsy.

2. *Cold.* — This is the most important of all the exciting causes of internal inflammation. There is scarcely any form of it which does not occasionally owe its origin to cold; and many inflammatory affections, as rheumatism and pleurisy, have no other cause of the smallest practical importance. The period of time that elapses between the application of cold and the occurrence of inflammatory symptoms is subject to great variety. In the case of sore throat, it often follows in the course of a few hours. In that of acute rheumatism, a week, or even a fortnight, has been known to elapse. Sudden atmospheric changes, whether from heat to cold, or from cold to heat, are the frequent sources of internal as well as external inflammation. The change from great cold to great heat appears to be the most prejudicial. The vessels are thereby distended to a dangerous extent. It is thus that chilblains are formed; and many of the severest cases of pneumonia arise in this way. Several circumstances concur to augment the danger of *catching cold*, the principal of which are violent exercise, and insufficient clothing.

3. *Acrimony of the fluids.* — Some forms of inflammation, which, to a superficial observer, might appear to arise without any assignable cause, have their origin in a peculiar state of body, the nature of which is not always understood, but which the older physicians supposed to consist in some acrid state of the fluids or humours. This is well exemplified in the phenomena of gout, and in the inflammation of absorbent glands occurring in scrofulous children on the approach of winter. The most striking illustration of this principle, however, is to be found in the frequent occurrence of thoracic and abdominal inflammation during the progress of typhoid and malignant fevers, implicating the fluids of the body. Several forms of chronic cutaneous inflammation appear to have their origin in an acrid or unhealthy state of the blood. This has been called the *scorbutic acrimony.*

4. *Morbid poison.* — The existence of a morbid poison in the system is a frequent occasion of internal inflammation. This principle was illustrated in the phenomena of the plague, small-pox, measles, and the other exanthemata. It is equally exemplified in those of secondary syphilis, where inflammation of the fauces, iris, and joints is obviously attributable to such a source. The bite of the rattlesnake excites a peculiar kind of inflammation in the cellular membrane. Anatomists frequently suffer from the absorption of matter formed in the course of disease, especially of *acute* disease, such as peritonitis. In irritable habits this induces not merely inflammation of the glands and cellular membrane, but also of internal structures, often of the most acute and dangerous kind. Closely allied to this is the important but well-ascertained fact of the origin of many inflammatory affections from *contagion*. Two species of Cynanche are contagious (parotidæa and maligna). There is a contagious form of Ophthalmia. Erysipelas is contagious under certain

circumstances. So, in all probability, is Dysentery. There is reason to suspect that one of the forms of peritoneal inflammation (the peritonitis puerperarum) is occasionally propagated in the same way.

5. *Metastasis.* — The last cause of internal inflammation which it will be necessary to notice is *metastasis*, or the translation of inflammation from one organ or structure to another. This is a very curious but obscure point in pathology. It is exemplified in the ophthalmia which succeeds gonorrhœa; in the inflammation of the testicle which succeeds the mumps; in the inflammation of the pericardium which succeeds rheumatism; in the inflammation of the brain which succeeds erysipelas of the face. In what manner the metastasis is effected has never yet been developed. It appears, however, that something may be referred to *sympathy from similarity of structure*, for in most cases of metastasis it will be found that the structures primarily and secondarily affected have an affinity to each other. — *Gregory.*

The theory of inflammation has occupied a number of ingenious reasoners in all ages, but it still remains immersed in the deepest obscurity.

The following extract from Dr. Bostock's physiology contains a full statement of the opinions that have been held, and a candid and judicious estimate of their merits.

"It is generally agreed that the capillaries are the immediate seat of the inflammatory action, and that when any change occurs in the large vessels, it is to be attributed to a secondary or consequential operation, originating from the affection of the minute arteries. All the four symptoms mentioned above, redness, heat, pain, and swelling, may be attributed to one primary cause, an increase in the size of the minute vessels, by which they are enabled to admit of more than the ordinary quantity of blood to be received into them; but a great diversity of opinion has prevailed concerning the mode in which the blood is conveyed or retained there, or concerning what has been termed the proximate cause of inflammation.

After the vital power of the vessels had been established by Stahl and his disciples, the phenomena of local inflammation were referred to this action; and, as all the natural operations of the arterial system seemed to be augmented during this state, so it followed, almost as an obvious consequence, that inflammation essentially consists in increased action of the capillaries. For a clear and candid statement of the opinions which have been entertained upon the state of the blood-vessels in inflammation, I may refer the reader to Dr. Thomson's Lectures on Inflammation, p. 71—75; and Hastings's Treatise on the Mucous Membrane of the Lungs, p. 67. et seq. A strong objection to this supposition was, however, quickly perceived, that the effect of the vital action of the vessels is contraction, while, as we observed above, the very essence of inflammation consists in an increase of the capacity of the vessels. But the ingenuity of the physiologists was not baffled by this difficulty; various means were invented to accommodate the theory to the facts, depending upon the presence of some obstacle which the blood was conceived to meet with in its passage through the vessels, which, at the same time, was not incompatible with their increased diameter. Boerhaave attributed the obstruction to a change in the texture of the blood itself, by which it became more thick and viscid, acquiring, what he called, a state of lentor, and to this lentor he added the further hypothesis, that the increased action of the arteries forces the larger particles of the blood into vessels, which, in their natural condition, are too small to receive them. This constitutes the *error loci* of the mathematical physiologists, and by the lentor and *error loci* were the phenomena of local inflammation explained by Boerhaave and his numerous disciples, until this, like most of their other speculations, was assailed by the powerful genius of Cullen. In place of the mechanical doctrine of Boerhaave, Cullen substituted his favourite hypothesis of spasm; for he admitted the increased action of the vessels in local inflammation, while he was aware that, without some counteracting circumstance, this increased action would produce effects totally inconsistent with the actual phenomena. Haller was quite aware that an increased action of the arteries must have a tendency to diminish their capacity, and employed this consideration as an argument against the muscularity of the capillaries. We shall, however, find, upon due reflection, that the spasm of Cullen is equally unfounded, and perhaps even less intelligible, than the lentor and *error loci* of the Boerhaavians; and, accordingly, his explanation has been generally regarded as incomplete; yet since his time no regular attempt has been made to reconcile the increased action of the vessels with their enlarged diameters.

In this dilemma, a totally different view of the question has been taken, according to which, local inflammation is to be attributed to a diminished action of the capillaries. This hypothesis, which appears to have been originally proposed by Vacca, an Italian physiologist, about the middle of the last century, was first brought forwards in a clear and consistent form by Mr. Allen, who, for some years, lectured in Edinburgh on the animal economy: it was adopted by Dr. Wilson Philip, who performed a series of experiments in support of it, and has been since embraced by Dr. Parr, Dr. Thomson, and Dr. Hastings (On the Mucous Membrane, p. 71. et seq.). Dr. Thomson and Dr. Hastings likewise supported the hypothesis by numerous experiments. Although Philip, Thomson, and Hastings agree in the main point, that inflammation essentially consists in diminished action of the capillary arteries, they differ respecting the actual state of the vessels. Dr. Philip supposed that the constant effect of inflammation is to dilate the vessels, and to diminish the velocity of their contents. (Treatise on Febrile Diseases, v. iii. p. 15. et seq.; also Preface to 4th ed. p. vii.; and Med. Chir. Trans. v. xii. p. 407.) Dr. Thomson concludes that the velocity is sometimes increased and sometimes diminished (Lect. on Inflammation, p. 89); while Dr. Hastings adopts the opinion

of Dr. Philip, that, in the proper inflammatory state, the velocity of the fluids is always retarded. (On the Mucous Membrane, p. 91. et alibi.) It may be worth noticing, that the article "Inflammation," in the Dict. des Scien. Méd. t. xxiv. p. 525. et seq. written by Boyer in 1818, contains no account of either the hypothesis or experiments of the English physiologists: inflammation is referred, according to the old doctrine, to the increase of vital action.

According to Mr. Allen's hypothesis, the redness, heat, pain, and tumour are to be ascribed to the increased quantity of blood which the vessels contain in consequence of their relaxed state; the symptoms, therefore, which had been usually attributed to excessive action he ascribes to this partial stagnation of the fluids, together with a kind of struggle between the loss of power in the part, and the unusual stimulus to which it is thus subjected. Although this doctrine of the proximate cause of inflammation may, at first view, seem to counteract our established notions upon the subject, yet it will, I think, be found upon examination to be more consistent in all its parts, and to accord better with the various phenomena both of pathology and of physiology, than any of the speculations which had preceded it, derived from the principle of increased action combined with obstruction. And, indeed, if we take into account that the exact seat of the inflammatory action is not visible to the eye, and that, according to the hypothesis of Dr. Hastings, the state of active inflammation consists in an increased action of the larger arteries, while the capillaries are in their natural state, it will approximate this hypothesis, at least as to all pathological and practical consequences, pretty nearly to the old doctrine. But I must add, that I think we are not arrived at that degree of knowledge on the subject, which will enable us to form a decisive opinion respecting it. Waiving, therefore, the regular discussion of the hypothesis, I shall conclude by a few observations which may be of some use to those who are inclined to investigate the proximate cause of inflammation with more minuteness.

The theory of inflammation has been lately discussed, in an ample and luminous manner, by Mr. James Earle, in a series of essays in the successive numbers of the Medical Gazette. He conceives that the essence of inflammation consists in obstruction of the minute vessels, and that its greater or less degree of activity depends principally upon the relation between the degree of obstruction and consequent dilatation, and the compulsive force of the blood. He does not admit of the proper contractility of the capillaries; and, therefore, refers all the actual force of the circulation to the action of the heart. On this, as well as on some minor points, I must dissent from the doctrine of Mr. Earle; but I must recommend the attentive perusal of his essays to those who are interested in the progress of physiological science, as containing much valuable information on the various topics on which he treats. Dr. Alison takes a totally different view of the subject; he ascribes the effect to a vital action in the fluids, not in the vessels or in any of the solids.

Although we may conceive that the phenomena of inflammation are as readily explicable upon the hypothesis of diminished as of increased contractility of the capillaries, yet it appears to me that both the exciting causes of this affection, and the treatment, coincide more with the idea of excessive than of defective action. All those circumstances which we are usually in the habit of considering as stimulants excite inflammation; and where the same effect is brought about by sedatives, or by agents of a more doubtful operation, still we can generally perceive the existence of what has been termed reaction, which is the immediate precursor of the change in the state of the circulation. In the same way the remedies for inflammation appear to me more adapted to remove or relieve an excess than a defect of vital energy, as for this purpose, except under peculiar circumstances, we always apply either direct or indirect sedatives, and find stimulants to be as injurious as the others are beneficial. From these considerations I am induced to recur to the former idea of increased action being the proximate cause of inflammation, or, at least, as being essential to it, and to inquire whether there be no correct method of combining a state of increased action with distention of the vessels. This, it is obvious, must be accomplished by obstruction in some form or other, either arising from the nature of the fluid, or from the difficulty with which it leaves the vessels after it has entered into them. Now, although we may agree with Cullen that Boerhaave adduced no sufficient proof of the existence of his lentor and *error loci*, yet it does not follow that no alteration in the condition of the blood exists. May we not conceive, that by the inflammatory action the proportion of fibrin is increased, or that the fibrin already present acquires a greater tendency to coagulate? That the solid contents generally of the blood are augmented, either by an increased quantity being thrown into the vessels, or a portion of the more fluid part being removed? May not some new arrangement take place with respect to the globules, so that they may coalesce or be more strongly attracted together? Or, without having recourse to any speculations of this kind, may we not conceive it possible that, if the minute arteries are contracting more vigorously than ordinary, their relaxation will be proportionably great, so as to allow of the different parts of the blood, as the fibrin and the globules, to be admitted into vessels which are generally impervious to them, and which, when once entered, from the *vis à tergo* on the one hand, and from the decreasing diameter of the vessels as they divide into small branches on the other, are forcibly detained, and produce all those symptoms which seem to originate from mechanical obstruction? These considerations are thrown out rather to show what may be conceived as a possible occurrence, than from the idea of our possessing any evidence of their actual existence. They may, however, show that we have not a sufficiently intimate acquaintance with the sub-

ject to enable us to decide peremptorily respecting the proximate cause of inflammation."

The treatment of inflammation may be distinguished into two general divisions; — the employment of remedies adapted to the removal or mitigation of the local affection, and the administration of remedies adapted to the removal or extinction of the general symptoms. Though, in consequence of the intensity of the latter class of complaints bearing a very accurate proportion to the severity of the local inflammation, the remedial measures calculated to remove or assuage the latter are also well suited to the mitigation of the former, and in many cases the febrile disorder subsides as the local disease is controlled; yet it is proper to observe some distinction both in specifying and in describing the employment of individual remedies of each class. In the management of inflammation, in short, the physician should always direct his attention to the nature and tendency of the local affection, and should observe assiduously the state of the inflamed organ, and its changes under the use of remedies; but he should also not neglect the general febrile symptoms, and should arrange his therapeutic measures accordingly.

It has been already shown that inflammation in every texture has a tendency to the formation of new products, and the destruction, more or less extensive, of the tissue in which it takes place. In certain favourable circumstances, indeed, of constitution and vigorous organic properties, or under the seasonable use of various agents, it is possible for the inflammatory action to be resolved; and the chief duty of the rational physician is to know the circumstances under which this is most likely to take place, and by all means to prevent the formation of new products, and the destruction of the tissue.

Though we possess no direct means of accomplishing these objects, it is always practicable to effect them more or less perfectly by the use of indirect measures. As inflammation depends on the concurrence of remote exciting causes and predisposition with proximate causes, the only direct curative method is, by putting a stop to their operation, to counteract, if not to subdue, their effects. When the adoption of these measures is inadequate to check the new orgasm, as all the morbid products are prepared from the blood, by diminishing the quantity of that fluid generally, and diminishing the proportion contained in the vessels of the inflamed tissue, resolution is more readily effected than if the vessels be left to themselves. Though it is impractible to restore their tone and energy to the capillary vessels of an inflamed part, it is possible, by diminishing the mass of their contents, to give them less to do, and to place their exhausted powers more upon a level with the duty which they have to perform. It is hence necessary, in all cases of inflammation, to employ more or less freely those measures which act on the sanguiferous system.

The first and most effectual of these is blood-letting, general and local. The first is indicated when the local inflammation is accompanied with great and evident fever, when the patient is young, robust, and vigorous, when the disease is in its commencement or fully established — not when it is declining, when the inflammation is seated in an organ essential to life, and when, consequently, it is liable, if allowed to proceed, to injure irreparably the structure of the part.

In order to be efficient in controlling inflammation, full bleeding should be carried to the extent of making a great and evident impression on the vascular system, especially as indicated by the change in the number and beats of the pulse, by the appearance of the countenance, by the relief afforded to the urgent symptoms of the disease, especially the pain, and by the amelioration effected in the functions of the affected organ. If these objects be not attained by one blood-letting of considerable amount, it is requisite to repeat the evacuation; and in some instances of visceral inflammation, the extent to which the evacuation requires thus to be carried, both in amount and by repetition, is very great. It may be from 60 to 100 ounces in adults. Blood-letting in this manner operates at once on the local affection, and on the general disorder.

In most instances of inflammation seated in any important organ, with evident symptoms of symptomatic fever, one, two, or three large blood-lettings from the system will be adequate to subdue the disease. In some instances, however, in which the symptomatic fever is either not violent in proportion to the local affection, or is already subdued by general evacuation, or in which it is inexpedient to carry general evacuation farther, it becomes necessary to draw blood from the vessels of the inflamed part, or from the nearest accessible region, to it, for instance, from the temples, scalp, frontal or occipital regions, in inflammation of the brain, or its membranes; from the surface of the chest, sides, or the inter-scapular region, in inflammation of the lungs, or their bronchial membrane; and from the surface of the belly, in the case of inflammatory symptoms in the peritoneum, or any of the organs invested by that membrane. These local evacuations, which may be accomplished either by the application of leeches, or by scarifying and cupping, or by numerous minute punctures, not only tend to unload directly the vessels of the part, and, by thus relieving them of part of their contents, enable them to propel the residual mass more easily, but, by thus diminishing directly, swelling, and abating distension, tend materially to relieve painful sensations, heat, and other symptoms, and thereby tend to alleviate sometimes the signs of general disorder.

The curative effects of local blood-letting are most clearly evinced in inflammation of the eyes, of the throat, of the articulations, and their constituent tissues, of the breast of the female, and the *testis* of the male, and in the inflammatory swelling, pain, and redness attending attacks of rheumatism, gout, and rheumatic gout; because in these instances, the blood, which is most conveniently drawn by leeches, can be taken from vessels very closely connected with those of the affected organ.

Upon the same principle, in inflammation of the mucous surfaces, it is desirable, by applying leeches to these surfaces, if accessible, to draw

blood immediately from them. Thus, in inflammation of the eye, it is common to scarify the *conjunctiva*, and occasionally to apply leeches immediately upon it; and in inflammation of the rectum and vagina, Dr. Craigie has directed the application of leeches to the mucous surfaces of these cavities with great benefit.

Evacuation of blood by means of the cupping-glass is a more precise method of depletion, and is suited to affections of the lungs, of the joints, and of the *fasciæ*, and the nervous trunks.

Of local bleeding, by means of numerous punctures or incisions, for the removal of inflammation, the most favourable examples are seen in diffuse inflammation of the cellular membrane and skin, in whitloe, in inflammation of the *fasciæ* (*Sparganitis*), and in the erysipelatous inflammation attacking the lower extremities of seamen. The practice of drawing blood, indeed, from the vessels of inflamed parts by means of incisions is suited to almost every species of inflammation affecting the exterior tissues of the body. It is found by far the most effectual remedy in general inflammation of gun-shot wounds, and other contused wounds; it might occasionally be used with advantage in controlling inflammation of the articular tissues; and it has been proposed by Dr. Prichard as to the scalp, in order to mitigate the intensity and arrest the progress of cerebro-meningeal inflammation.

With the means now mentioned, it is necessary to conjoin the use of various auxiliary local remedies, which are conceived to operate in abating the intensity of the inflammatory process. These are various; but it is at present convenient to enumerate them in the order of relaxants or emollients, refrigerants or sedatives, and revellents or counter-irritants.

The administration of relaxants is found to be useful in the early stage of many inflammatory affections, in abating some of the painful sensations with which the process is attended. The most effectual, and perhaps that to which all remedies of this kind are referable, is warmth applied in the humid or dry form, more or less directly, to the affected part. Of this description are fomentations by warm water, either pure or medicated, fomentations by means of watery vapour, and fomentations by means of poultices. The whole of these agents operate on the general principle of diminishing tension, relaxing the rigidity of parts almost mechanically, and favouring, by the least painful means, the tendency to one or other of the natural terminations. The vapour of warm water is often very effectual in relieving the sense of soreness, rawness, and dryness of several of the mucous surfaces when inflamed. The best rule in the employment of this agent is to make the temperature agreeable to the feelings of the patient. Inflammation in the eyes, the testicle, or any other gland, is often thus most readily treated.

Various applications of a refrigerant or sedative character are employed in certain forms of inflammation with much advantage. Of most of these the essential principle is cold, in whatever mode applied, whether by means of cold water, ice, snow, saline solutions, as sal-ammoniac or common salt, or the metallic astringent solutions, as sugar of lead, white vitriol, &c. Their employment is chiefly indicated in the case of inflammations seated on the surface, and unconnected with disorder of the lungs, heart, stomach, or liver, or intestines,—after and along with suitable evacuation, and when the sense of heat is very great, and evidently contributes much to the sufferings of the patient. Cold applied to the shaven scalp is a powerful means of abating inflammation or congestion of the brain or its membranes. It is very effectual in abating the scorching heat and pain of erysipelatous inflammation; and it often is beneficial in alleviating the burning heat and swelling of gout. The application of cold is contra-indicated in inflammatory affections of the throat, windpipe, lungs, heart, stomach, and intestines. In affections of the glandular system it is injurious at the commencement, but favourable at the termination.

The use of the metallic astringent salts is principally indicated in inflammations of the mucous surfaces without much congestion of the vessels, and in abrasions of the skin.

Sedative and narcotic substances are not unfrequently employed as local applications in the treatment of various inflammatory affections. Of this kind are watery solutions of opium, decoction of poppy heads, decoction or infusion of hemlock, bitter-sweet, henbane, deadly nightshade, and similar narcotic substances. It is extremely doubtful whether the application of such means is accordant with correct physiological principles; for, as inflammation is certainly not primarily an affection either of the inherent properties, or of the nervous system of the tissues, it is difficult to perceive in what manner narcotics can operate efficiently. By diminishing sensibility, they may alleviate pain, or prevent it from being felt very acutely; but they cannot operate on the process of inflammation itself. At the close of the disease, however, and after suitable evacuation, they may be useful in abating tenderness or morbid sensibility. In general, they are applied along with cold; but the decoction of poppy capsules is a convenient mode of applying a warm sedative in cases of inflammation of parts on the surface of the body.

Revellent or counter-irritant agents, or those which, by irritating or inflaming a sound surface, diminish the inflammation of a diseased organ, are very beneficial under certain conditions and restrictions. Considered according to their physiological effects in the treatment of inflammation, they are either rubefacient, or such as cause erythematous redness,—vesicating, or such as cause erysipelatous inflammation,—vesiculating, or such as bring out vesicles,—pustulo-facient, or such as cause pustular inflammation,—and cauterising, or such as produce death, more or less complete, of the surface.

For effecting the first purpose, the application of sinapisms, friction by the ammoniated oil, or turpentine, are the most usual means. Vesication is most usually induced by the ointment of the blistering fly, but may be effected by the sudden application of boiling water or steam. Vesicular inflammation is excited by friction

with croton oil; pustular inflammation is induced by tartar-emetic ointment; and death of the surface may be occasioned by any of the mineral acids, caustic potass, butter of antimony (the chloride), or the hot iron.

Erythematous counter-irritation is chiefly useful in rheumatism and rheumatic or neuralgic pains. Vesication is most generally practised in all instances of deep-seated inflammation of internal organs over the corresponding surface of the skin. The principal condition regarding its employment is, that in cases of inflammation with acute fever, it ought not to be put in practice without previous blood-letting, or until the symptoms of general fever, and the urgent pain of the part, have been abated by these and similar evacuant measures. A species of imperfect vesication, induced by nitrate of silver, is sometimes beneficial as a counter-irritant; but it is most effectual as a check to spreading inflammation, and as a means of inducing a new action. The counter-irritant effect of friction with croton-oil, or tartar-emetic ointment, is chiefly suited to moderate the violence of chronic inflammation, seated either in the thoracic or abdominal viscera. Caustics, actual and potential, or those agents which destroy part of the integuments, and are hence followed by a long-continued ulcerative inflammation, are, perhaps, still more effectual in counteracting the progress, and moderating the intensity, of chronic inflammation of the thoracic viscera, of the cuticular tissues, and of the bones. Setons and issues act nearly in the same manner. The whole of these remedies, which operate more or less upon the principle of transferring morbid action from one tissue or set of tissues to another, are chiefly indicated in the treatment of inflammatory action, which has either been chronic from the commencement, or which, after being acute, has become chronic.

Such is a general view of the principal remedies to be employed in the treatment of the local affections in inflammation.

The management of the symptomatic fever of inflammation is to be conducted upon the general principles already explained in considering the treatment of simple continued fever, and may be briefly designated under the general name of the antiphlogistic treatment. These consist, together with blood-letting, of low diet, the use of diluents, purgatives, emetics in nauseating or diaphoretic doses, especially tartar-emetic and other antimonials, mercurials in alterative doses, especially calomel combined with opium, and such sedative medicines as foxglove and lead. The particular circumstances requiring the use of each of these remedial agents, or two or more combined, will be fully considered under the head of particular inflammatory diseases.

It is requisite, nevertheless, here to mention, that, in the treatment either of the symptomatic fever of inflammation, or the still more general affection of the system denominated the *phlogistic diathesis*, the principal object is, to employ that system of dietetic rules named the antiphlogistic regimen. As these symptoms acquire much of their intensity from the general fulness of the vascular system, and as this is always closely connected with the quantity and quality of articles employed as food and drink, it becomes necessary to regulate both in such a manner, as to abate, diminish, and obviate that congestion or plethora which the vascular system thus acquires, and in this manner to counteract the irritation thus induced.

The most effectual mode of accomplishing these purposes, is to withdraw entirely all animal diet, and every sort of food or drink containing animal matter, and all malt or fermented liquors, and to restrict the patient rigidly to the use of aqueous diluents, the vegetable ptisans, and such small quantities of farinaceous food, and the saccharine fruits, as may be sufficient to sustain life, without stimulating in any degree the heart or arteries. The employment of cathartic medicines is also requisite to remove morbid secretion, to prevent accumulation, and remove all irritation from the mucous membrane of the alimentary canal. If, under these means, the symptoms of general phlogistic disposition do not appear to abate, the appropriate remedy is tartar-emetic in divided doses, or digitalis, given so as to produce some degree of giddiness, faintness, and complete loss of appetite. — *Craigie.*

Emetic tartar, in very large doses, has been employed of late years in the treatment of several inflammatory diseases, especially in inflammation of the lungs; and some are of opinion that it possesses a specific power, since it has been observed to act beneficially without producing any sensible effect. In general, however, it is a most depressing agent; and, even admitting it to possess all the efficacy which its advocates claim for it, it may fairly be doubted whether, in most cases, a severe hypercathasis, and keeping the patient in a state approaching to syncope for a length of time, may not leave more permanent debility than a reasonable abstraction of blood.

In scrofulous inflammation, or inflammation dependent on the strumous *diathesis*, and in chronic and asthenic inflammation generally, it has been supposed that this proscription of animal diet and fermented liquors is neither requisite nor beneficial; and many practitioners have represented that they have beneficially recommended these articles, sometimes in moderate quantities, sometimes rather liberally. That there may be cases of asthenic and strumous inflammation, in which the use of animal food and wine or malt liquor may seem to be beneficial, is not impossible. But it must be remembered that the recovery of such cases, or the subsidence of the inflammatory symptoms, does not prove the safety or beneficial influence of the practice. In short, it is the general result of accurate observation and long experience, that even in strumous and chronic inflammation it is beneficial to regulate the diet, to diminish the allowance of animal food, if not to withdraw it, and to restrict the patient to diet consisting chiefly of milk, grain, and similar unstimulating articles.

When inflammation has proceeded to suppuration, it is generally advantageous to augment the allowance of food, and in some instances to allow a proportion of wine or malt liquor.

For the local management of the effects of inflammation, we refer to the treatises on surgery.

In the treatment of the phlogistic diathesis and chronic inflammation, much attention to clothing and exercise is also requisite. As in these states of the system the vessels of the skin are not only less energetic than usual, but liable to have their circulation and secretions readily deranged by exposure to cold or atmospheric vicissitudes, it is of the utmost consequence to prevent the operation of these agents, or to counteract their effects. This is to be done, in the *first* place, by means of flannel clothing, or clothing at least of woollen materials; in the *second* place, by frequent frictions of the surface, so as to promote the circulation; and, *thirdly*, by exercise, either active, to as great an extent as the strength of the patient will endure, or, if this be impracticable, by means of passive exercise or gestation.

Cold bathing, which is occasionally recommended, is always unsafe, and should never be allowed unless under the superintendence of the medical adviser. Warm or tepid bathing is much more beneficial; but even this must be practised with due attention to its effects. — *Craigie.*

Inflammation of the stomach. See *Inflammation of the stomach and intestines.*

Inflammation of the stomach and intestines. This may attack the peritoneal or the mucous coat, and in either case may involve the muscular structure. See *Peritonitis.* The mucous membrane of the *stomach* is liable to inflammation from a variety of causes, but the principal are excess in the use of ardent spirits, and poison.

The idiopathic gastritis mucosa of drunkards is characterised by pain at the epigastrium, vomiting, even of the mildest ingesta, low fever, and that trembling hand which never fails to accompany diseases of alkoholic origin. When in its utmost intensity the vessels of the mucous membrane often give way, and a burst of hæmorrhage succeeds.

The *cure* of this disease can be effected only by that most difficult of all things, a reformation in the habits of a drunkard. Its relief may be obtained by leeches to the epigastrium, followed by a blister, and the internal administration of some mild mucilage, such as the mistura amygdalæ, holding in solution five grains of nitre, which may be repeated three times a day.

The second source of gastritis mucosa is poison. It has been supposed that the immediate cause of death by arsenic is inflammation of the stomach; but Sir Benjamin Brodie has shown the incorrectness of this as a general proposition. Occasionally, after a certain interval, inflammation of the mucous membrane of the stomach does come on in consequence of arsenic, and the case published by Dr. Roget may be brought forward as an instance; but even there, the symptoms of high nervous irritation predominated greatly over those of local inflammation. Dr. Baillie states that, on dissection of those who die from the effects of arsenic, an intense degree of redness appears in the inner membrane of the stomach. Portions of it are sometimes destroyed, and occasionally a thin layer of coagulable lymph is thrown out. Such appearances, however, cannot be relied on as unequivocal proofs of poisoning by arsenic; but the further prosecution of this subject is especially in the province of the medical jurist.

Inflammation of the mucous membrane of the small intestines occurs in *adults*, both as an idiopathic affection, and as symptomatic of other diseases, — in an *acute* as well as chronic form. The symptoms by which it is characterised are not always very distinct; and hence it is that the disease, though by no means uncommon, has hitherto remained without any appropriate designation from nosological writers. It was by some authors called the intestinal catarrh. Mucous enteritis appears to be its legitimate denomination. Dr. Pemberton was the first author who treated of it as a distinct disease.

Symptoms. — Mucous enteritis is attended with a diffused soreness over the whole abdomen, rather than with pain. This is sometimes increased on pressure, but never to the extent that prevails on peritoneal inflammation. There is no considerable tension in the belly. The pulse is quick, with thirst, *languor*, and considerable febrile oppression. By these symptoms we distinguish *inflammation* of the mucous membrane of the bowels, from that state of *irritation* of the membrane, which exists in common cases of diarrhœa; but it must never be forgotten, that the two states of disease are closely allied, and, in fact, run into each other by insensible degrees. The tongue in mucous enteritis is *red and smooth*, and eruptions take place about the lips. Vomiting is frequently noticed, with loss of appetite, indigestion, and irregularity in the alvine evacuations. Diarrhœa is almost uniformly present; the stools are slimy, and tinged with blood. In severe cases, pure blood is occasionally passed in considerable quantity. An increased secretion of mucus from the intestines constitutes one of the principal features of the disease. It must be confessed, however, that in the appearance of the

evacuations there is considerable diversity. In some instances, inflammation exists to a considerable extent, while the motions differ but slightly from those of common diarrhœa. Nothing, perhaps, more strikingly distinguishes this complaint than that degree of morbid irritability of the whole intestinal canal, by which food, even of the lightest kind, or a little cold water, taken into the stomach, stimulates the rectum to immediate contraction.

Prognosis. — The disease is always tedious, but not commonly fatal. It occasionally proves so, with or without supervening peritoneal inflammation, or it passes into a chronic state, in which the patient at length sinks exhausted. The chronic form of the affection is marked by pain of the abdomen, diarrhœa alternating with costiveness, increasing weakness and emaciation, hectic fever, and a tongue preternaturally red, or aphthous. It is certainly a curious circumstance, that the appetite, in this state of disease, often continues good.

Morbid anatomy. — The appearances, on dissection, vary with the degree of violence in the inflammatory action, or, what amounts nearly to the same thing, with the period of disease at which death takes place. Sometimes we observe only an increased redness of the whole membrane; at other times, irregular patches of inflammation may be traced, elevated sensibly above the sound parts. The lower end of the ileum has been long observed to be the most common situation of these morbid appearances. Ulcers are frequently met with there, of an oval shape, having elevated ridges. Sometimes a considerable extent of the inner membrane of the intestine is seen completely stripped from the muscular coat, or hanging attached to it in tattered shreds. In a few cases the ulceration perforates the peritoneal coat, and a portion of the contents of the intestine passes into the general cavity of the abdomen, producing inflammation that speedily proves fatal. Mucous inflammation of the intestines sometimes, although rarely, advances to mortification.

Causes. — The causes of this affection of the internal membrane of the bowels are not very well understood. A disposition seems to be given to it by irregular habits of life. The state of the atmosphere has probably at times some share in producing it, for it will be seen occasionally to prevail with almost epidemic frequency. It is sometimes observed to occur in its idiopathic form from accidental exposure to cold and moisture, and one attack certainly favours a recurrence of the complaint. Mucous enteritis, however, is far more commonly a symptomatic than an idiopathic affection. It appears in the progress of continued fever, especially the low nervous or typhoid fever, scarlet fever, consumption, and all diseases attended with hectic; and it is one of the many sequelæ of measles. It would seem, indeed, as if inflammation and ulceration of this structure readily took place, whenever the system was in the state either of very high or very long protracted inflammatory excitement.

Treatment. — If the disease, when idiopathic, comes under treatment in an early stage, great advantage will be derived from taking away ten or twelve ounces of blood from the arm. This will very often be found to give an immediate check to its advance. At a later period, leeches to the abdomen prove an excellent substitute, and they may be repeated according to the urgency of the symptoms. Active purgatives of all kinds are carefully to be avoided, such as extr. colocynthidis compos. jalap, scammony, and senna. The secretions of the bowels, being very vitiated, must not remain pent up in the body, but their evacuation must be entrusted to the mildest means — two spoonfuls of castor oil, eight grains of rhubarb, or two drachms of manna.

When diarrhœa and irritable bowels constitute (as they generally do) the leading features of the complaint, the remedies to be relied on are demulcents and anodynes. Some practitioners have great confidence in the hydr. cum creta, believing that the mercury may contribute something to the relief of the inflamed membrane. Starch injections, with laudanum, are useful where the tenesmus is troublesome; but sometimes the mechanical irritation which enemata produce more than counterbalances their good effects. Fomentations to the bowels are always serviceable, and the warm bath is an excellent resource. Particular attention should be paid to the diet of the patient, which should be of the lightest kind. Even broths should be strictly prohibited in the early periods of the disease.

Such are the general principles which guide the physician in the management of this severe disease. The choice of remedies may be left in a great degree to his own discretion.

Where the stomach is irritable, and rejects fluid medicines, the acetate of morphia may be administered in the form of pill.

When the feverish symptoms subside, and diarrhœa lessens, the tone of the bowels may be supported, and a healthier action induced, by some gentle tonic.

When the disease has assumed a chronic form, with extensive ulceration, the treatment is very precarious. Astringents and bitters, with laudanum, are indispensable with the view of checking the diarrhœa, but the astringent tinctures should carefully be avoided. Dr. Gregory thinks the compound infusion of catechu less irritating than any of those to which he has given trial. The decoction of logwood, or of pomegranate, with a due proportion of laudanum, are also valuable remedies. A pill, consisting of one grain of calomel with three of the extr. hyoscyami, may be administered at night with considerable advantage. Change of air may be advised, and a milk diet. — *Gregory.*

Inflammation of the large intestine gives rise to those symptoms which constitute what is generally called *dysentery.* See *Dysentery.*

Inflammation of the testicle. See *Orchitis.*

Inflammation of the tunica arachnoides. See *Encephalitis.*

Inflammation of the urethra. See *Urethritis.*

Inflammation of the uterus. See *Hysteritis.*

Inflammation of a vein. See *Phlebitis.*

INFLAMMATORY. (*Inflammatorius;*

from *inflammatio.*) Of the nature of inflammation.

Inflammatory crust. The buffy coat of the blood. See *Sanguis* and *Inflammation.*

Inflammatory fever. See *Febris.*

Infla'tio. (*o, onis.* f.; from *inflo*, to puff up.) In *Pathology*, a windy swelling. See *Pneumatosis.*

INFLA'TUS. Inflated: applied, in *Botany*, to parts which are distended like a blown bladder; as *legumen inflatum*, seen in *Astragalus vesicarius;* and the distended and hollow perianths of the *Cucubalus behen*, and *Physalis alkekengi*, in fruit.

INFLE'XUS. Curved, or bent inwards; synonymous to *incurvus;* applied to leaves, petals, &c.; as the petals of the *Pimpinella* and *Chærophyllum.*

INFLORE'SCENCE. (*Inflorescentia, æ.* f.; from *inflouresco*, to flower, or blossom.) A term used by Linnæus to express the particular manner in which flowers are situated upon a a plant: denominated by preceding writers, *modus florendi*, or manner of flowering.

It is divided into *simple*, when solitary, and *compound*, when many flowers are placed together in one place.

The first affords the following distinctions: —

1. The *Pedunculate*, furnished with a stalk; as in *Gratiola* and *Vinca.*
2. *Sessile*, adhering to the plant without a flower-stalk; as in *Daphne mezereum*, and *Zinia pauciflora.*
3. *Cauline*, when on the stem.
4. *Rameal*, when on the branch.
5. *Terminal*, when on the apex of the stem, or branch; as *Paris quadrifolia* and *Chrysanthemum leucanthemum.*
6. *Axillary*, in the axilla; as in *Convallaria multiflora.*
7. *Foliar*, on the surface of the leaf; as in *Phyllanthus.*
8. *Radical*, on the root; as *Carlina acaulis, Crocus*, and *Colchicum.*
9. *Latitant*, concealed in a fleshy receptacle; as in *Ficus carica.*

Again, it is said to be, —

1. *Alternate;* as in *Polyanthus tuberosa.*
2. *Opposite;* as in *Passiflora hirsuta.*
3. *Unilateral*, hanging all to one side; as *Erica herbacea*, and *Silene amœna.*
4. *Solitary;* as in *Campanula speculum* and *Carduus tuberosus.*

The second, or compound inflorescence, has the following kinds: —

1. The *Verticellus*, or whorl.
2. The *Capitulum*, or tuft.
3. The *Spica*, or spike.
4. The *Racemus*, or cluster.
5. The *Corymbus*, or corymb.
6. The *Umbella*, or umbel.
7. The *Cyma*, or cyme.
8. The *Fasciculus*, or fascicle.
9. The *Panicula*, or panicle.
10. The *Thyrsus*, or bunch.
11. The *Spadix*, or sheath.
12. The *Omentum*, or catkin.

INFLUE'NZA. (*a, æ,* f. The Italian word for influence.) Epidemic catarrh is so named, because it was supposed to be produced by a peculiar influence of the stars. See *Catarrhus.*

Infra-orbitary foramen. *Foramen infra orbitarium.* A foramen in the superior maxillary bone, immediately below the orbit. It gives egress to the infra-orbitary twig of the second branch of the fifth pair of nerves, and to a small twig of the internal maxillary artery.

Infrascapula'ris. (From *infra*, beneath, and *scapula*, the shoulder-blade.) A muscle named from its position beneath the scapula. See *Subscapularis.*

INFRASPINA'TUS. (From *infra*, beneath, and *spina*, the spine.) A muscle of the humerus, situated on the scapula. It arises fleshy, from all that part of the dorsum scapulæ which is below its spine; and from the spine itself, as far as the cervix scapulæ. The fibres run obliquely towards a tendon in the middle of a muscle, which runs forwards, and adheres to the capsular ligament. It is inserted, by a flat thick tendon, into the upper and outer part of the large protuberance on the head of the os humeri. Its use is to roll the os humeri outwards, to assist in raising and supporting it when raised, and to pull the ligament from between the bones. This muscle and the supraspinatus are covered by an aponeurosis, which extends between the costæ, and edges of the spine of the scapula, and gives rise to many of the muscular fibres.

INFUNDIBULIFORM. *Infundibuliformis.* Funnel-shaped: applied, 1. in *Botany*, to plants, when the blossom consists of one petal, the lower part of which is tubular, the upper part conical; as in *Primula, Cynoglossum*, &c.

2. In *Anatomy*, to the circular ligament of the atlas, and to a fascia connected with the anatomy of hernia. See *Fascia.*

INFUNDI'BULUM. (*um,'i.* n.; a funnel: from *infundo*, to pour in.) 1. A canal that proceeds from the lower and anterior part of the third ventricle of the brain, to the pituitary gland. See *Encephalos.*

2. The beginnings of the excretory duct of the kidney, or cavities into which the urine is first received, from the secretory cryptæ, are called *infundibula.* See *Kidney.*

INFUSO'RIA. Infusory animals. A class of the animal kingdom, comprehending those animalcules which are found in infusions of organic substances, and in stagnant waters. See *Animal kingdom.*

INFU'SUM. (*i.* n.; and *infusio, onis.* f.: from *infundo*, to pour in.) An infusion. A preparation made by pouring water, of any required degree of temperature, on such substances as have a loose texture, as thin bark, wood, in shavings or small pieces, leaves, flowers, &c., and suffering it to stand a certain time. The process itself, as well as the liquor resulting from it, is called *infusion.* The following are among the most approved infusions.

Infusum anthemidis. Infusion of camomile. Take of camomile flowers, five drachms;

boiling distilled water, a pint. Macerate for ten minutes, in a lightly covered vessel, and strain. For its virtues, see *Anthemis nobilis*.

Infusum armoraciæ compositum. Compound infusion of horseradish. Take of fresh horseradish root sliced, mustard seeds bruised, of each one ounce; boiling distilled water, a pint. Macerate for two hours, in a lightly covered vessel, and strain; then add compound spirit of horseradish, a fluid ounce. See *Cochlearia armoracia*.

Infusum aurantii compositum. Compound infusion of orange-peel. Take of orange-peel, dried, half an ounce; lemon-peel, fresh, two drachms; cloves, bruised, a drachm; boiling distilled water, a pint. Macerate for a quarter of an hour, in a lightly covered vessel, and strain. See *Citrus aurantium*.

Infusum calumbæ. Infusion of calumba. Take of calumba root, sliced, five drachms; boiling distilled water, a pint. Macerate for two hours, in a lightly covered vessel, and strain. See *Calumba*.

Infusum caryophylli. Infusion of cloves. Take of cloves, bruised, three drachms; boiling distilled water, a pint. Macerate for two hours, in a lightly covered vessel, and strain. See *Eugenia caryophyllata*.

Infusum cascarillæ. Infusion of cascarilla. Take of cascarilla bark, bruised, an ounce and a half; boiling distilled water, a pint. Macerate for two hours, in a lightly covered vessel, and strain. See *Croton cascarilla*.

Infusum catechu compositum. Compound infusion of catechu. Take of extract of catechu, ground, six drachms; cinnamon bark, bruised, half a drachm; boiling distilled water, a pint. Macerate for an hour, in a lightly covered vessel, and strain. See *Acacia catechu*.

Infusum cinchonæ. Infusion of cinchona. Take of lance-leaved cinchona bark, bruised, an ounce; boiling distilled water, a pint. Macerate for two hours, in a lightly covered vessel, and strain. See *Cinchona*.

Infusum cusparie. Infusion of cusparia. Take of cusparia bark, bruised, five drachms; boiling distilled water, a pint. Macerate for two hours, in a lightly covered vessel, and strain. See *Cusparia febrifuga*.

Infusum digitalis. Infusion of fox-glove. Take of purple fox-glove leaves, dried, a drachm; boiling distilled water, a pint. Macerate for four hours, in a covered vessel, and strain; then add spirit of cinnamon, half a fluid ounce. See *Digitalis purpurea*.

Infusum diosmæ. Take of the leaves of diosma, an ounce; boiling distilled water, a pint. Macerate for four hours, in a lightly covered vessel, and strain. This infusion has been introduced into the London pharmacopœia of 1836. See *Diosma*.

Infusum gentianæ compositum. Compound infusion of gentian. Take of gentian root, sliced, orange-peel, dried, of each two drachms; lemon-peel, fresh, four drachms; boiling distilled water, a pint. Macerate for an hour, in a lightly covered vessel, and strain. See *Gentiana lutea*.

Infusum lini. Infusion of linseed. Take of linseed, bruised, an ounce; liquorice root, sliced, half an ounce; boiling water, two pints. Macerate for two hours, near the fire, in a covered vessel, and strain. See *Linum usitatissimum*.

Infusum Krameriæ. Take of the root of Krameria an ounce; boiling distilled water a pint. Macerate for four hours, in a lightly covered vessel, and strain. This infusion has been lately introduced into the London pharmacopœia.

Infusum lupuli. Take of hops, six drachms; boiling distilled water, a pint. Macerate for four hours, in a lightly covered vessel, and strain. See *Humulus lupulus*.

Infusum pareiræ. Take of the root of pareira, six drachms; boiling distilled water, a pint. Macerate for two hours, in a lightly covered vessel, and strain. This infusion is recently introduced into the London pharmacopœia. See *Cissampelos pareira*.

Infusum quassiæ. Infusion of quassia. Take of quassia wood, two scruples; boiling distilled water, a pint. Macerate for two hours, in a lightly covered vessel, and strain. See *Quassia amara*.

Infusum rhei. Infusion of rhubarb. Take of rhubarb root, sliced, three drachms; boiling distilled water, a pint. Macerate for two hours, in a lightly covered vessel, and strain. See *Rheum*.

Infusum rosæ compositum. Take of the petals of red rose, dried, three drachms; boiling water, a pint; dilute sulphuric acid, a fluid drachm and a half; sugar, six drachms. Pour the water upon the petals of the rose, in a glass vessel; then add the acid, and macerate for six hours. Lastly, strain the infusion, and add the sugar to it. See *Rosa gallica*.

Infusum scoparii. Take of fresh broom tops, an ounce; boiling distilled water, a pint. Macerate for two hours, in a lightly covered vessel, and strain. See *Cytisus scoparius*, in the Supplement.

Infusum sennæ compositum. Infusion of senna. Take of senna leaves, fifteen drachms; ginger root, sliced, four scruples; boiling water, a pint. Macerate for an hour, in a lightly covered vessel, and strain. See *Cassia senna*.

Infusum serpentariæ. Infusion of Virginian snake-root. Take of serpentaria, half an ounce; boiling distilled water, a pint. Macerate for four hours, in a lightly covered vessel, and strain. See *Aristolochia serpentaria*.

Infusum simaru'bæ. Infusion of simarouba. Take of simarouba bark, bruised, half a drachm; boiling water, half a pint. Macerate for two hours, in a covered vessel, and strain. See *Quassia simarouba*.

Infusum tabaci. Infusion of tobacco. Take of tobacco leaves, a drachm; boiling water, a pint. Macerate for an hour, in a covered vessel, and strain. See *Nicotiana*.

Infusum valerianæ. Take of valerian, half an ounce; boiling distilled water, a pint. Macerate for two hours, in a lightly covered vessel, and strain. See *Valeriana officinalis*.

INGE'STA. (*Ingestus* from *ingero*, to

throw in.) A term applied to the aliments taken into the body, as opposed to *egesta*, the matters excreted.

INGLU'VIES. (*es, ei.* f.) 1. Gluttony. 2. The craw, crop, or gorge of a bird.

INGRAVIDATION. (From *in*, and *gravidus*, big with young.) The same as pregnancy.

I'NGUEN. (*en, inis.* n.) The groin. The lower and lateral part of the abdomen, above the thigh.

I'NGUINAL. (*Inguinalis;* from *inguen*, the groin.) Appertaining to the groin.

INGUINAL ARTERY. The external iliac in the groin.

Inguinal hernia. See *Hernia.*

Inguinal ligament. See *Poupart's ligament.*

INHALATION. The drawing in of fumes or vapours along with the breath. The inhalation of the vapour of warm water is very serviceable in some cases of inflammation of the mucous membrane of the air passages and throat. The steam may be rendered anodyne by the addition of henbane seeds, poppy-heads, ether, or opium; or gently stimulant by vinegar, &c. Tar vapour is of great service in chronic bronchitis, in which disease iodine and chlorine have also lately been found useful. See the *Supplement.*

INHUMA'TION. (*Inhumatio, onis.* f.; from *inhumo*, to put into the ground.) 1. The placing of a patient in an earth bath. See *Balneum.*

2. Some chemists have fancied thus to call that kind of digestion which is performed by burying the materials in dung, or in the earth.

I'NION. Ινιον. The occiput. — *Rufus ephesius.*

INJACULA'TIO. (From *injaculor*, to shoot into.) So Helmont calls a disorder which consists of a violent spasmodic pain in the stomach and an immobility of the body.

INJE'CTION. (*Injectio, onis.* f.; from *injicio*, to cast into.) 1. A medicated liquor to be thrown into a natural or preternatural cavity of the body by means of a syringe. Those injections which are thrown into the rectum are called *enemata.*

2. A liquid thrown into the vessels of the dead body to display them more distinctly. Anatomists use injections of various colours and compositions.

3. In pathology, the presence of an increased quantity of blood in the vessels of a part is sometimes called injection of the vessels.

Ink, sympathetic. See *Sympathetic ink.*

INNERVA'TION. The vital process by which a part is supplied with nervous energy.

INNOMINA'TUS. (From *in*, priv. and *nomen*, a name.) Some parts of the body are so called: thus, the pelvic bones which in the young subject are three in number, to which names are given, become one in the adult, which is without a name. An artery from the arch of the aorta, and the fifth pair of nerves, have also had this unmeaning designation applied to them.

INNOMINATA ARTERIA. The first branch given off by the arch of the aorta. It soon divides into the right carotid and right subclavian arteries.

INNOMINATI NERVI. The fifth pair of nerves. See *Nervous system.*

INNOMINATUM OS. (So called, because the three bones of which it is originally formed grow together, and form one complete bone, which is thus left nameless.) A large irregular bone, situated at the side of the pelvis. It is divided into three portions, viz. the iliac, ischiatic, and pubic, which are usually described as three distinct bones.

The *os ilium*, or haunch-bone, is of a very irregular shape. The lower part of it is thick and narrow; its superior portion is broad and thin, terminating in a ridge, called the *spine* of the ilium, and more commonly known by the name of the *haunch.* The spine rises up like an arch, being turned somewhat outward, and from this appearance, the upper part of the pelvis, when viewed together, has not been improperly compared to the wings of a phæton. This spine, in the recent subject, appears as if tipped with cartilage; but this appearance is nothing more than the tendinous fibres of the muscles that are inserted into it. Externally, this bone is unequally prominent, and hollowed for the attachment of muscles; and internally, at its broadest fore part, it is smooth and concave. At its lower part, there is a considerable ridge on its inner surface. This ridge, which extends from the os sacrum, and corresponds with a similar prominence, both on that bone and the ischium, forms, with the inner part of the ossa pubis, what is called the brim of the pelvis. The whole of the internal surface, behind this ridge, is very unequal. The os ilium has likewise a smaller surface posteriorly, by which it is articulated to the sides of the os sacrum. This surface has, by some, been compared to the human ear; and, by others, to the head of a bird; but neither of these comparisons seem to convey any just idea of its form or appearance. Its upper part is rough and porous; lower down it is more solid. It is firmly united to the os sacrum by a cartilaginous substance, and likewise by very strong ligamentous fibres, which are extended to that bone from the whole circumference of this irregular surface. The spine of this bone, which is originally an epiphysis, has two considerable tuberosities, one anteriorly, and the other posteriorly, which is the largest of the two. The ends of this spine too, from their projecting more than the parts of the bone below them, are called spinal processes. Before the anterior spinal process, the spine is hollowed, where part of the sartorius muscle is placed; and below the posterior spinal process there is a very large niche in the bone, which, in the recent subject, has a strong ligament stretched over its lower part, from the os sacrum to the sharp-pointed process of the ischium; so that a great hole is formed, through which pass the great sciatic nerve, and the posterior crural vessels, under the pyriform muscle, part of which is likewise lodged in this hole. The lowest, thickest, and narrowest part of the ilium, in conjunction with the other two portions of each os innominatum, helps to form the acetabulum for the os femoris.

The *os ischium*, or hip-bone, which is the

lowest of the three portions of each os innominatum, is of a very irregular figure, and usually divided into its body, tuberosity, and ramus. The body externally forms the inferior portion of the acetabulum, and sends a sharp-pointed process backward, called the spine of the ischium. This is the process to which the ligament is attached, which was just now described as forming a great foramen for the passage of the sciatic nerve. The tuberosity is large and irregular, and is placed at the inferior part of the bone, giving origin to several muscles. In the recent subject, it seems covered with a cartilaginout crust; but this appearance, as in the spine of the ilium, is nothing more than the tendinous fibres of the muscles that are inserted into it. The tuberosity, which is the lowest portion of the trunk, supports us when we sit. Between the spine and the tuberosity is observed a sinuosity, covered with a cartilaginous crust, which serves as a pulley, on which the obturator muscle plays. From the tuberosity, the bone, becoming narrower and thinner, forms the ramus, or branch, which, passing forwards and upwards, makes, with the ramus of the os pubis, a large hole, of an oval shape, the *foramen magnum ischii*, which affords, through its whole circumference, attachment to muscles. This foramen is more particularly noticed in describing the os pubis.

The *os pubis*, or share-bone, which is the smallest of the three portions of the os innominatum, is placed at the upper and fore part of the pelvis, where the two ossa pubis meet, and are united to each other by means of a very strong cartilage, which constitutes what is called the *symphisis pubis*. Each os pubis may be divided into its body, angle, and ramus. The body, which is the outer part, is joined to the os ilium. The angle comes forward to form the symphysis, and the ramus is a thin apophysis, which, uniting with the ramus of the ischium, forms the *foramen magnum ischii*, or *thyroideum*, as it has been sometimes called, from its resemblance to a door or shield. This foramen is somewhat wider above than below, and its greatest diameter is from above downwards, and obliquely from within outwards. In the recent subject, it is almost completly completely closed by a strong fibrous membrane, called the *obturator* ligament. Upwards and outwards, where we observe a niche in the bone, the fibres of this ligament are separated, to allow a passage to the posterior crural nerve, an artery and vein. The great uses of this foramen seem to be to lighten the bones of the pelvis, and to afford a convenient lodgment to the obturator muscles. The three bones now described as constituting the os innominatum on each side, all concur to form the great *acetabulum*, or cotyloid cavity, which receives the head of the thigh-bone; the os ilium and os ischium making each about two fifths, and the os pubis one fifth, of the cavity. This acetabulum, which is of considerable depth, is of a spherical shape. Its brims are high, and, in the recent subject, it is tipped with cartilage. These brims, however, are higher above and externally than they are internally, and below, where we observe a niche in the bone (namely, the ischium), across which is stretched a ligament, forming a hole for the transmission of blood-vessels and nerves to the cavity of the joint. The cartilage which lines the acetabulum is thickest at its circumference, and thinner within, where a little hole is to be observed, in which is placed the apparatus that serves to lubricate the joint, and facilitate its motions. We are likewise able to discover the impression made by the internal ligament of the os femoris, which, by being attached both to this cavity, and to the head of the os femoris, helps to secure the latter in the acetabulum. The bones of the pelvis serve to support the spine and upper parts of the body, to lodge the intestines, urinary bladder, and other viscera, and likewise to unite the trunk to the lower extremities. But, besides these uses, they are destined, in the female subject, for other important purposes; and the accoucheur finds, in the study of these bones, the foundation of all midwifery knowledge. Several eminent writers are of opinion that, in difficult parturition, all the bones of the pelvis undergo a certain degree of separation. It has been observed, likewise, that the cartilage uniting the ossa pubis is thicker, and of a more spongy texture, in women than in men, and therefore more likely to swell and enlarge during pregnancy. That many instances of a partial separation of these bones, during labour, have happened, there can be no doubt; such a separation, however, ought by no means to be considered as an uniform and salutary work of nature, as some writers seem to think, but as the effect of disease. But there is another circumstance, in regard to this part of osteology, which is well worthy of attention; and this is, the different capacities of the pelvis in the male and female subject. It has been observed, that the os sacrum is shorter and broader in women than in men; the ossa ilia are also found more expanded: whence it happens, that in women the centre of gravity does not fall so directly on the upper part of the thigh as in men, and this seems to be the reason why, in general, they step with less firmness, and move their hips forward in walking. From these circumstances, also, the brim of the female pelvis is nearly of an oval shape, being considerably wider from side to side, than from the symphisis pubis to the os sacrum; whereas, in men, it is rounder, and every where of less diameter. The inferior opening of the pelvis is likewise proportionably larger in the female subject, the ossa ischia being more separated from each other, and the foramen ischii larger, so that where the os ischium and os pubis are united together, they form a greater circle: the os sacrum is also more hollowed, though shorter, and the os coccygis more loosely connected, and, therefore, capable of a greater degree of motion than in men.

INOCULA'TION.) (*Inoculatio, onis.* f.) The insertion of a poison into any part of the body. It was first practised by physicians with that of the small-pox, because we had learned from experience, that by so doing we generally procured fewer pustules, and a much milder disease than when the small-pox was taken in a natural way. Although the advantages were evident,

yet objections were raised against inoculation, on the notion that it exposed the person to some risk, when he might have passed through life without ever taking the disease naturally; but it is obvious that he was exposed to much greater danger, from the intercourse which he must have with his fellow-creatures, by taking the disorder in a natural way. It has been adduced, that a person is liable to take the small-pox a second time, when produced at first by artificial means; but such instances are very rare, and appear to relate as much to the natural as to the inoculated disease. We may conjecture that, in most of those cases, the matter used was not variolous, but that of some other eruptive disorder, such as the chicken-pox, which has often been mistaken for the small-pox. However, since the discovery of the preventive power of the cow-pock, small-pox inoculation has been rapidly falling into disuse. See *Cow-pox*.

To illustrate the benefits arising from inoculation, it has been calculated that a third of the adults die who take the disease in a natural way, and about one seventh of the children; whereas of those who are inoculated, and are properly treated afterwards, the proportion is probably not greater than one in five or six hundred.

Inoculation is generally thought to have been introduced into Britain from Turkey, by Lady Mary Wortley Montague, about the year 1721, whose son had been inoculated at Constantinople, during her residence there, and whose infant daughter was the first that underwent the operation in this country. It appears, however, to have been well known before this period both in the south of Wales and Highlands of Scotland. Mungo Park, in his travels into the interior of Africa, found that inoculation had been long practised by the Negroes on the Guinea coast; and nearly in the same manner, and at the same time of life, as in Europe. It is not clearly ascertained where inoculation really originated. It has been ascribed to the Circassians, who employed it as the means of preserving the beauty of their women. It appears more probable that accident first suggested the expedient among different nations, to whom the small-pox had long been known, independently of any intercourse with each other; and what adds to the probability of this conjecture is, that in most places where inoculation can be traced back, for a considerable length of time, it seems to have been practised chiefly by old women, before it was adopted by regular practitioners.

Many physicians held inoculation in the greatest contempt at first, from its supposed origin; others, again, discredited the fact of its utility; while others, on the testimony of the success in distant countries, believed in the advantages it afforded, but still did not think themselves warranted to recommend it to the families they attended; and it was not until the experiment of it had been made on six criminals (all of whom recovered from the disease and regained their liberty), that it was practised, in the the year 1726, on the royal family, and afterwards very generally adopted.

To insure success from inoculation, the following precautions should strictly be attended to: —

1. That the person should be of a good habit of body, and free from any disease, apparent or latent, in order that he may not have the disease and a bad constitution, or perhaps another disorder, to struggle with at the same time.

2. To enjoin a temperate diet and proper regimen; and, where the body is plethoric, or gross, to make use of gentle purges, together with mercurial and antimonial medicines.

3. That the age of the person be as little advanced as possible, but not younger, if it can be avoided, than four months.

4. To choose a cool season of the year, and to avoid external heat, either by exposure to the sun, sitting by fires, or in warm chambers, or by going too warmly clothed, or being too much in bed.

5. To take the matter from a young subject, who has the small-pox in a favourable way, and who is otherwise healthy, and free from disease; and, when fresh matter can be procured, to give it the preference.

Where matter of a benign kind cannot be procured, and the patient is evidently in danger of the casual small-pox, we should not, however, hesitate a moment to inoculate from any kind of matter that can be procured; as what has been taken in malignant kinds of small-pox has been found to produce a very mild disease. The mildness or malignity of the disease appears, therefore, to depend little, or not at all, on the inoculating matter. Variolous matter, as well as the vaccine, by being kept for a length of time, particularly in a warm place, is apt, however, to undergo decomposition by putrefaction; and then another kind of contagious material has been produced.

In inoculating, the operator is to make a moderate-sized puncture or scratch in the arm of the person, rubbing that part of the lancet which is besmeared with matter repeatedly over it, by way of insuring the absorption; and, in order to prevent the matter being wiped off, the shirt-sleeve ought not to be pulled down until the part is dry.

A singular circumstance attending inoculation is, that when this fails in producing the disease, the inoculated part nevertheless sometimes inflames and suppurates, as in cases where the complaint is about to follow; and the matter produced in those cases is as fit for inoculation as that taken from a person actually labouring under the disease. The same happens very frequently in inoculation for the cow-pox.

If, on the fourth or fifth day after the operation, no redness or inflammation is apparent on the edge of the wound, we ought then to inoculate in the other arm, in the same manner as before; or, for greater certainty, we may do it in both.

Some constitutions are incapable of having the disease in any form. Others do not receive the disease at one time, however freely exposed to its contagion, even though repeatedly inoculated, and yet receive it afterwards by merely approaching those labouring under it.

On the coming on of the febrile symptoms,

which is generally on the seventh day in the inoculated small-pox, the patient is not to be suffered to lie a-bed, but should be kept cool, and partake freely of antiseptic cooling drinks. See *Variola*.

INOSCULA'TION. (*Inosculatio, onis.* f.; from *in*, and *osculum*, a little mouth.) *Anastomosis.* The union of the extremities of vessels.

INSA'NIA. (*a, æ.* f.; from *in*, not, and *sanus*, sound.) Insanity, or deranged intellect. See *Mania*.

INSANITY. *Insanitas.* Madness. No author has yet succeeded in giving a satisfactory definition of the state of insanity, as opposed to that of sound mind; yet every body knows the practical difference between being mad and being in one's senses; the definition, therefore, is not of much importance, and, instead of attempting one, we shall proceed to give an outline of the different forms of mental disease. Dr. Prichard, in his admirable work on insanity, to which we are much indebted in the present article, includes its several varieties under the four following heads: —

1. *Moral insanity*, or madness consisting in a morbid perversion of the natural feelings, affections, inclinations, temper, habits, moral dispositions, and natural impulses, without any remarkable disorder or defect of the intellect, or knowing and reasoning faculties, and particularly without any insane illusion or hallucination.

The three following modifications of the disease may be termed *Intellectual insanity*, in contradistinction to the preceding form. They are severally: —

2. *Monomania*, or partial insanity, in which the understanding is partially disordered or under the influence of some particular illusion, referring to one subject, and involving one train of ideas, while the intellectual powers appear, when exercised on other subjects, to be in a great measure unimpaired.

3. *Mania*, or raving madness, in which the understanding is generally deranged; the reasoning faculty, if not lost, is confused and disturbed in its exercise; the mind is in a state of morbid excitement, and the individual talks absurdly on every subject to which his thoughts are momentarily directed.

4. *Incoherence*, or dementia. By some persons it may be thought scarcely correct to term this a form of insanity, as it has been generally considered as a result and sequel of that disease. In some instances, however, mental derangement has nearly this character from the commencement, or at least assumes it at a very early period. We are therefore justified in stating it, after Pinel, to be a fourth and distinct form of madness. It is thus characterised by that justly celebrated writer: "Rapid succession or uninterrupted alternation of insulated ideas, and evanescent and unconnected emotions; continually repeated acts of extravagance; complete forgetfulness of every previous state; diminished sensibility to external impressions; abolition of the faculty of judgment; perpetual activity."

We may, then, describe insanity as a chronic disease, manifested by deviations from the healthy and natural state of the mind, such deviations consisting either in a *moral perversion*, or a disorder of the feelings, affections, and habits of the individual, or in *intellectual derangement*, which last is sometimes partial, namely, in *monomania*, affecting the understanding only in particular trains of thought; or general, and accompanied with excitement, namely, in *mania*, or *raving madness*; or, lastly, confounding or destroying the connexions or associations of ideas, and producing a state of *incoherence*.

Each of these forms demands separate notice.

I. *Moral insanity.* — This form of mental derangement has been described as consisting in a morbid perversion of the feelings, affections, and active powers, without any illusion or erroneous conviction impressed upon the understanding; it sometimes coexists with an apparently unimpaired state of the intellectual faculties.

There are many individuals living at large, and not entirely separated from society, who are affected in a certain degree with this modification of insanity. They are reputed persons of a singular, wayward, and eccentric character. An attentive observer will often recognise something remarkable in their manners and habits, which may lead him to entertain doubts as to their entire sanity; and circumstances are sometimes discovered, on inquiry, which add strength to his suspicion. In many instances, it has been found that an hereditary tendency to madness has existed in the family, or that several relatives of the person affected have laboured under other diseases of the brain. The individual himself has been discovered to have suffered, in a former period of life, an attack of madness of a decided character. His temper and dispositions are found to have undergone a change; to be not what they were previously to a certain time: he has become an altered man, and the difference has, perhaps, been noted from the period when he sustained some reverse of fortune, which deeply affected him, or the loss of some beloved relative. In other instances, an alteration in the character of the individual has ensued immediately on some severe shock which his bodily constitution has undergone. This has been either a disorder affecting the head, a slight attack of paralysis, a fit of epilepsy, or some febrile or inflammatory disorder, which has produced a perceptible change in the habitual state of the constitution. In some cases, the alteration in temper and habits has been gradual and imperceptible, and it seems only to have consisted in an exaltation and increase of peculiarities, which were always more or less natural and habitual.

In a state like that above described, many persons have continued for years to be a source of apprehension and solicitude to their friends and relatives. The latter, in many instances, cannot bring themselves to admit the real nature of the case. The individual follows the bent of his inclinations; he is continually engaging in new pursuits, and soon relinquish-

ing them, without any other inducement than mere caprice and fickleness. At length the total perversion of his affections, the dislike, and perhaps even enmity, manifested towards his dearest friends, excite greater alarm. When it happens that the head of a family labours under this ambiguous modification of insanity, it is sometimes thought necessary, from prudential motives, and to prevent absolute ruin from thoughtless and absurd extravagance, or from the results of wild projects and speculations, in the pursuit of which the individual has always a plausible reason to offer for his conduct, to make some attempt with a view to take the management of his affairs out of his hands. The laws have made inadequate provision for such contingencies, and the endeavour is often unsuccessful. If the matter is brought before a jury, and the individual gives pertinent replies to the questions that are put to him, and displays no particular mental illusion, a feature which is commonly looked upon as essential to madness, it is most probable that the suit will be rejected.

Persons labouring under this disorder are capable of reasoning or supporting an argument upon any subject within their sphere of knowledge that may be presented to them; and they often display great ingenuity in giving reasons for the eccentricities of their conduct, and in accounting for and justifying the state of moral feeling under which they appear to exist. In one sense, indeed, their intellectual faculties may be termed unsound; they think and act under the influence of strongly excited feelings, and persons accounted sane are, under such circumstances, proverbially liable to error both in judgment and conduct.

Esquirol and Georget both recognise the same form of disease, and the former considers moral perversion as constant and essential in every species of madness. The affirmation of Esquirol is, however, much too general, as instances are not wanting in which patients, labouring under mental alienation, have exhibited an amiable moral disposition, and an undisturbed flow of the natural affections. The ordinary connexion between insanity and moral depravity is nevertheless striking; indeed, the latter is sometimes the earliest indication of the former. It is justly remarked by Dr. Haslam, that young persons who exhibit an uncontrollable disposition to vice, notwithstanding the influence of excellent moral precept and example, frequently become deranged in their intellect as they advance in life. It is equally true, that when insanity is hereditary in a family, one member of it may be absolutely deranged, while another, with unimpaired intellect, shall exhibit a frantic violence in his passions, or an inveterate immorality in his habits.

There is a form of mental derangement peculiar to old age, which constitutes a variety of moral insanity.

This disordered state makes its appearaace in old men who have never before been insane or suspected of any tendency to mental derangement. It consists, like other forms of moral insanity, in a morbid excitement of passions and a remarkable perversion of the temper and propensities. The whole moral character of the person is changed. 'The pious,' says Dr. Burrows, 'become impious, the content and happy discontented and miserable, the prudent and economical imprudent and ridiculously profuse, the liberal penurious, the sober drunken.' In some elderly persons, impulses which had long been effete become, of a sudden, excited, and a strong tendency to vicious habits is displayed. 'In fact, the reverence which age and the conduct suited to it always command is converted into shame and pity at the perversion of those moral and social qualities which, perhaps, have hitherto adorned the patient's declining days.' This description coincides accurately with the character of moral insanity. There are instances, though rare, of the appearance of hallucinative madness in old persons, but the case we have now described is of a different character, and consists in a disordered condition of the moral or active powers alone.

II. *Monomania.* — This is the form of insanity formerly termed *melancholia*, which term is frequently inapplicable, since the hallucination under which the patient labours is sometimes quite the reverse of gloomy. The term *monomania*, first suggested by M. Esquirol, is of more general applicability, and expresses the characteristic feature of the affection.

"This form of insanity," says Dr. Prichard, "is characterised by some particular illusion or erroneous conviction impressed upon the understanding, and giving rise to a partial aberration of judgment. The individual affected is rendered incapable of thinking correctly on subjects connected with the particular illusion, while in other respects he betrays no palpable disorder of mind."

"The notion, however, which many persons entertain as to the nature of this disease, is far from being correct in its full extent. It is supposed that the mind of the monomaniac is perfectly sound when its faculties are exercised on any subject unconnected with a particular impression, which in itself constitutes the entire disease. Cases are indeed on record, which, if faithfully related, fully come up to this description. In general, the real character of monomania is very different. The individual affected is, under ordinary circumstances, calm, and exhibits no symptom of that perturbation and constant excitement which are observed in raving madness. But, on careful inquiry, it will be found that his mind is in many respects in different condition from that of perfect health. The habits and disposition have, perhaps, been long, in a greater or less degree, in the state which characterises moral insanity. If we advert to the order and connexion of morbid phenomena, we often learn that on a settled and habitual melancholy, or on a morose and sullen misanthropy, long growing and indulged, or on some other disordered and perverted state of the feelings and affections, a particular illusion has more recently supervened. An indi-

vidual of melancholic temperament, who has long been under the influence of circumstances calculated to impair his health, and call into play the morbid tendencies of his constitution, sustains some unexpected misfortune, or is subjected to causes of anxiety; he becomes dejected in spirits, desponds, broods over his feelings till all the prospects of life appear to him dark and comfortless. His inclinations are now so altered that no motive has sufficient influence over him to rouse him to voluntary and cheerful exertion. During this period, if questioned as to the causes of his mental dejection, he will probably assign no particular reason for it. At length, his gloom and despondency becoming more and more intense, his imagination fixes upon some particular circumstance of a distressing nature, and this becomes afterwards the focus round which the feelings which harass him concentrate themselves. This circumstance is often some real, occasionally some trifling, act of delinquency, for which the individual expresses the strongest, and perhaps disproportionate, self-condemnation. In other instances, an unreal phantom suggests itself, in harmony with the prevalent tone of the feelings, which at first haunts the mind as possible, and is at length admitted as reality. Other individuals begin by indulging morose and unfriendly sentiments towards all their acquaintance, magnifying in imagination every trifling neglect into a grievous contumely. They fancy, at length, that they find in some casual occurrence glaring proofs of premeditated designs to ruin them and expose them to the contempt and derision of society. The disease, in these cases, has its real commencement long before the period when the particular illusion, which is only an accessary symptom, is discovered, and even before it became impressed on the imagination; but it is not until that impression has taken place, that the case assumes the proper character of monomania."

It may be observed, that the illusion of the monomaniac usually bears a close relation to his former habits of thought; and that monomania generally supervenes on some disordered state of the moral feelings. In reasoning on insanity, much instruction may be derived from an attentive observation of what passes in our own minds; for the mind of a maniac is composed of the same materials as that of a sane person — but their equilibrium is lost.

Now, it must have occurred to every man who has been much occupied with moral reflections, to dwell so long on some one point on which his feelings were deeply interested, that his judgment has begun to lose its ascendancy, and he has felt the necessity of receding from the subject as one which his mind was no longer equal to grapple with, and of allowing his faculties to recover their wonted elasticity amid the diversions and occupations of ordinary life. Had he continued to indulge in such contemplations, insanity might have been the result.

Supposing a sane state of mind, there would appear to be this difference in the effect of too long continued attention to subjects of a purely intellectual, and to those of a moral, character: in the former instance, the mind becomes simply fatigued, and cannot get any further in the inquiry; in the latter there is a tendency to illusion, and the object is magnified or distorted: hence many men go mad of love or religion, for one who takes his start from mathematics or chemistry.

As the illusions of monomania are connected with the peculiar impressions which have been predominant in the mind of the individual, so they must necessarily partake largely of the genius of the age and country in which he lives — its politics — its philosophy — and its superstitions. Thus the Greeks were hunted by furies, the Jews possessed by demons, the Europeans of unenlightened ages bound by the spells of witches, and the men of later times mystified by the dreams of religious or political fanaticism, or tormented by the horrors of ideal pecuniary embarrassment.

It is not always easy to draw the line between hypochondriasis and monomania, since the illusions of the latter state sometimes have reference to bodily ailments.

A great number and variety of cases coming under the same head, of monomania associated with fear and despondency, are instances in which the apprehensions of the individual are concentrated on his bodily feelings, or relate to some diseased or preternatural state in which he conceives himself to exist. In the first stage this disease is hypochondriasis; the patient dwells constantly on some trifling ailments, which he magnifies in apprehension, broods over, and on account of which he makes himself miserable. In this form, hypochondriasis constitutes a variety of moral insanity, and a hundred cases of this description are to be found for one which actually makes the transition into erroneous belief. When this change has taken place, the disorder is accounted a decided one of insanity; as when a man fancies that his head has grown larger than his body, that his legs are made of glass, that he has a wolf or a fish in his stomach. The absurd ideas which the diseased imagination frames, in order to account for trifling bodily suffering, are as numerous as they are strange and surprising. Dr. Prichard mentions a lunatic who laboured apparently under neuralgic pains. He fancied that the physician, to whose care he was confided, had the power of torturing him by electricity, and that invisible wires were spread through every part of the house, as conductors of the fluid, which was used at night as the instrument of cruel and tyrannical persecution. Many a flatulent hypochondriac has fancied the existence of a goblin or demon in his stomach; and the association between his internal feelings and the idea by which it was accounted for, has become so firm, that nothing in future has been capable of changing it.

III. *Mania.* — It is not necessary to be diffuse on the phenomena of mania. The utter subversion of the intellectual and moral powers, which constitutes this affection, defies classification; all the faculties are over excited without any permanent object on which to exercise themselves. Dr. Prichard gives, as a general

illustration of this form of disease in its greatest intensity, an abstract of the description by Chiaruggi, which is cited with high commendation by Professor Heinroth.

"Among the phenomena of the first stage of this disease, we are at first struck by impetuous, audacious, shameless habits, a bold menacing aspect; the natural evacuations are deficient; the skin becomes of a slaty colour; the forehead contracted; the eyebrows drawn up; the hair bristled; the breathing hurried. The countenance begins to glow; the eyes become fiery and sparkling; the looks are wandering, and scarcely ever fixed; the eyelids are by turns drawn widely open, and closely shut; the eyeballs are prominent, as if pushed forward out of the orbits. With this wild and menacing appearance is combined a patient endurance of hunger, and a remarkable insensibility of cold. If sleep visits the patient at all, it is short, unquiet, and easily disturbed. In the second stage, anger, violence, and the loss of reason, manifest themselves in their greatest intensity; shrieking, roaring, raging, abusive expressions and conduct towards the dearest friends and the nearest relations, who are now looked upon as the bitterest enemies. The patient tears his clothes to tatters, destroys, breaks in pieces whatever comes in his way. A striking and characteristic circumstance is the propensity to go quite naked. Whoever touches the patient is abused or struck by him. Strange confused ideas, absurd prejudices, occupy the mind. Stillness soon follows, or a murmuring sound, as if the patient were alone: on the other hand, when he is alone, talking and gesticulating as if he were in company. If such individuals are confined and tied during the height of their paroxysms, for their own security or that of others, nothing can be compared to the truly satanical expression which their countenances display. In this state they throw hastily away, with cries and shrieks, all the food presented to them, except fluids, which thirst compels them to receive. When, after some days, hunger begins to be felt, they swallow every thing with brutal greediness; they even devour, as it has often been observed, their own excrements, which, black and offensive, escape from them in great quantity, or smear with them clothes, beds, and walls. Notwithstanding his constant exertion of mind and body, the muscular strength of the patient seems daily to increase; he is able to break the strongest bonds, and even chains; his limbs seem to acquire a remarkable nimbleness and pliability, and a singular aptitude of performing movements and actions which appear almost supernatural. Chiaruggi saw a woman, who, clothed in a strait-waistcoat, and laced down in her bed like a child in a cradle, drew out her limbs from this double confinement with the greatest nimbleness and pliancy. Bold, however, and impudent as such patients are, yet they are, according to common observation, although not without exceptions, easily daunted by a strong threatening voice, by the sight of stocks, by close though harmless restraint. After their violence has expended itself, they become still, gloomy, appear to be reflecting or brooding over something; but they break out again, before it can be anticipated, into a new storm of rage. At length comes on the *third stage*. A real cessation of violent paroxysms now ensues, exhaustion, sleep, though unquiet, disturbed by fearful dreams. The pulse is small, the aspect of the whole body squalid, the countenance pallid and meager. The patient is obdurately silent, or sings and laughs in a strange manner, or chatters with incessant volubility. These uncertain intervals, which often put on the appearance of fatuity, are frequently interrupted by new but short renewals of violence. Memory for the most part remains unimpaired through all the stages, and during the highest intensity of the disease the senses appear to acquire an unusual degree of acuteness and susceptibility. A patient who had recovered described to Chiaruggi all the scenes of his wild reverie and long-continued mental perturbation. It has often been observed that maniacal patients of this description are never attacked by any epidemic, and are seldom affected by any contagious malady. According to Mead and many others, even consumptive disorders, dropsies, and other chronic maladies, have disappeared on the accession of violent insanity. When patients are not freed from the disease after a succession of attacks, which come on like so many paroxysms of fever, one or the other of the following events ensues: either the powers of mind are exhausted to that degree that the disease subsides into a permanent fatuity; or this appearance of fatuity is only a space of calmness interposed between relapses of violent madness, which now and then break out, like the eruptions of a volcano, after a long period of repose; or the patient falls into a state of melancholy, or of complete mental confusion; or, finally, his madness becomes chronical, and he scarcely recovers from this condition, in which sense and understanding appear to be lost in incoherence. Chiaruggi saw a woman who had sat during twenty-five years on a stone floor, in a fearfully demented state, beating the ground with her chains without ceasing by day or by night."

It is often observed that violent mania soon arrives at a kind of imperfect crisis, the intensity of the symptoms abates, and the disease passes into a chronic state. M. Esquirol thinks that this change generally, or, at least, frequently, takes place within a month from the first accession of an acute attack.

The ultimate tendency of insanity is to produce a state of mental decay or *dementia*. The transition to this, however, is gradual, consisting of a stage of protracted mental derangement, in which the majority of patients in lunatic asylums are found to exist for years, and which sometimes continues during life, without ever terminating in complete dementia. This state is a combination of mania, or monomania, and dementia, in which the symptoms of these different forms of insanity are not distinctly marked, but in some measure blend and pass into each other.

The symptoms belonging to one form of madness are often confounded with those of

another, and from the combination there results, as it has been remarked by a writer of extensive observation and research, an assemblage of phenomena which bears little or no similitude to the description found in books, and commonly entertained.

Some writers have maintained that, in all cases of insanity, there are successive periods of monomania, mania, and dementia; but such an opinion must have been formed from very limited observation, and is certainly incorrect.

IV. *Dementia.* — This is a state in which imperfectly defined and unconnected ideas chase each other rapidly through the mind; the powers of continued attention and reflexion are lost, and even the perceptive faculty at length becomes indistinct. Dr. Prichard describes the phenomena of dementia as referable to four distinct stages: —

1. That of *impaired memory*, which obtains especially with regard to recent events.

2. That of *irrationality* — a total loss of reasoning power, arising from the absence of voluntary control over the thoughts.

3. That of *incomprehension*, in which the patient cannot understand any thing that is said to him.

4. That of *inappetency, or loss of instinct and volition*, in which the individual loses even his animal instincts, and does not obey the calls of nature.

He observes, that dementia approaches most gradually when it occurs as the accompaniment of old age, and that its several degrees are most distinctly recognised in such instances.

Such are the forms to one or other of which, or to a mixture of several, every case of insanity may be referred. We have now to notice certain morbid conditions, which occur as complications of insanity, and materially influence the prognosis and the treatment.

General paralysis. — There is a peculiar modification of paralysis which often accompanies the advanced stages of insanity, and especially those cases which are passing, or have already degenerated into dementia. M. Esquirol was the first writer who directed the attention of physicians to this morbid state, and pointed out the incurable nature of insanity complicated with paralysis.

This form of paralysis is much more frequent in men than in women. Of 109 insane paralytic patients, who came under the care of M. Esquirol, at Charenton, during three years, 95 were males. The same author made similar observations at the Bicêtre, and the fact has been corroborated by Dr. Foville, chief physician to the asylum at St. Yon, near Rouen. Of 334 lunatics at that institution, 31 were paralytic, and of these 22 were men. At Charenton, M. Esquirol has found the proportion of paralytics still greater, forming no less than one sixth of the whole number of patients; of 609 cases of insanity, 109 were also paralytic. The proportion of male to female cases is immense: thus of 366 male lunatics, 95 were paralytic; of 253 females, only 14.

M. Calmeil has marked three degrees in the general paralysis of the insane. The first degree is characterised merely by an impediment in the motions of the tongue, which renders the articulation imperfect, the patient drawling and stammering, like an intoxicated person; the tongue, however, can be naturally protruded, and the muscles of the mouth and face preserve their usual position. In the second degree the defect of articulation is greater, and the patient is incapable of uttering a word distinctly. The limbs are now affected with paralysis; the patient rises from his chair with difficulty, by fixing his hands upon its arms, and when he attempts to walk, his gait is tottering. When in the recumbent posture, he moves all his limbs with freedom. The upper extremities are less affected than the lower, yet in some instances the arms are impeded in their movements, and raised to the head with difficulty. The chin has a tendency to fall upon the chest, from the relaxation of the muscles of the neck, and the trunk is ill poised upon the pelvis, from the impaired action of its muscles. The senses in general are much obtunded; the patient however still continues to feel, see, hear, and smell. The excretions escape without notice, whether from paralysis of the sphincters, or the inattention of the patient — more probably the latter. Patients affected with this degree of paralysis are generally in an advanced stage of dementia. In the third degree, the patient is nearly reduced to a state of vegetation. Articulation is almost or entirely lost. The patient cannot stand, and at last loses all power of moving the lower extremities; the hand and arms are less completely paralysed. Frequently no trace of intelligence remains; the patient waits till food is put into his mouth; he is insensible to the calls of nature; and though he still retains the senses of sight and taste, and perceives strong odours, he pays no attention to surrounding objects. In the first and second stages, just described, the functions of organic life are nearly in a healthy state; the circulation is natural, sleep undisturbed, excretion is duly performed, and the flesh remains firm and plump. In the third stage, however, digestion is impaired, and the frame becomes emaciated. At length the integuments slough on those parts most subjected to pressure, œdema of the most depending parts supervenes, and hectic fever closes the scene. Death seldom occurs as the simple consequence of the cerebral disease, the abdominal or thoracic viscera being generally affected.

Dissection has proved that this species of paralysis is almost uniformly connected with chronic inflammation of the substance of the brain, especially near its surface. The observations of M. Calmeil on this subject will be presently alluded to. From numerous observations of MM. Calmeil, Esquirol, and others it results that this kind of paralysis commences in some instances, a long time after the accession of insanity, in others simultaneously with it, while in a few it precedes it. M. Calmeil states that, at Charenton, the paralysis generally supervened soon after the commencement of insanity. A few cases have occurred to M. Esquirol, in which patients seized with genera

paralysis have retained perfect vigour of intellect for some time, but have subsequently fallen into a state of mental derangement. The mean duration of the paralysis of the insane is stated by Calmeil at thirteen months; and he confirms the observation of Esquirol, that few patients survive longer than three years. The disorder is generally progressive, though a few individuals have suddenly recovered so far as to be able to walk several miles a day, and to resume, for a time, their ordinary occupations. The prognosis, however, is, on the whole, most unfavourable. M. Royer Collard, during twenty years' experience in a very large establishment, did not witness a single recovery. Esquirol and Calmeil agree in considering the malady as generally incurable; the former, however, has seen three, and the latter two, instances of recovery.

Diseases of the brain. — The disturbed state of the brain in insanity has reference rather to its operations as the organ of the mind, than to its general functions as a part of the corporeal frame. Many lunatics have remained in asylums for thirty, forty, or fifty years; nor are cases of unusual longevity wanting among the insane. Still, however, the brain is in a morbid state, and hence very liable to inflammation and congestion, with their ordinary results, as apoplexy, palsy, and convulsive affections, to which the insane are much more liable than other persons.

Diseases of the thoracic and abdominal viscera. — Many insane patients die of diseases of the abdominal and thoracic viscera. Such complications of insanity are too frequent to be regarded as accidental, although it may puzzle pathologists to account for them. We should be much disposed to regard defective innervation as a frequent cause of their occurrence; it being established, by the experiments of Dr. Wilson Philip, that the abstraction of the nervous energy from a part gives rise to disordered action of its minute vessels. The coexistence of phthisis with insanity is so frequent as to have been made the subject of particular observation. M. Esquirol states that phthisis often precedes or accompanies the invasion of melancholia. The patient loses his strength, and becomes emaciated; he has slow fever, sometimes accompanied with cough and diarrhœa, while the symptoms of insanity are rather increased than diminished, and continue until death. On dissection, the lungs are found to be tuberculated, or affected with melanosis. Dr. Greding found that 40 out of 100 maniacs, and 20 out of 24 melancholics, laboured under phthisis: according to the same writer, 76 out of 100 maniacs, and 20 out of 24 melancholic patients, had effusion in one or both cavities of the pleura.

Diseases of the heart are not uncommon. M. Foville found some organic change in the heart or great vessels in five out of six of all the bodies of lunatics which he examined after death, during three years: the most frequent morbid state was hypertrophy. Dr. Prichard concurs in the opinion of M. Foville, that these lesions are more frequently results of the continued violence done to the thoracic organs by the agitation, efforts, and cries of the patient, than predisposing causes of cerebral disease.

Diseases of the intestinal canal are frequent among the immediate causes of death. A protracted state of obstinate constipation is at length succeeded by, or alternates with, diarrhœa, which terminates in fatal dysentery. On examination after death, the intestines are found loaded with indurated matter, or empty and pale, with discoloured patches, abrasions, ulcerations, or gangrenous spots in the mucous coat.

Cachectic diseases. — In the advanced stage of insanity, cachectic disorders are prevalent; as scaly or papular eruptions, scorbutic affections of the gums, furunculi, and a disposition to sloughing in different parts of the body. These are accompanied by diarrhœa and griping pains, and the patient dies in a state of extreme emaciation.

Such are the more important of those causes of death which seem to have some peculiar relation to the state of insanity. There are some others to which, though they may be considered as accidental, the physical condition of insane patients renders them particularly obnoxious. Among these are pulmonary catarrh and typhoid fever: cephalic fevers are, as might be expected, peculiarly fatal to lunatics. The diagnosis of accidental diseases in the insane is attended with much difficulty, since they have a great tendency to make unfounded complaints, and either conceal or are insensible to the presence of real disease. Patients should therefore be carefully watched; and altered habits, and the expression of dejection and suffering in the countenance of a lunatic, should lead to an immediate examination of his physical state, as they probably indicate the approach of some serious malady.

The prognosis of insanity is greatly influenced by a variety of circumstances. Under judicious treatment a large proportion of cases recover. In many instances the recovery is complete and permanent; in others, and perhaps the majority, the disease is curable only to a certain point, and the patient retains such a susceptibility to it, that, although he may be perfectly rational, a studious avoidance of all sources of mental inquietude is necessary to keep him so; and, even when all tendency to insanity appears to have passed away, the fact of its having once existed affords ground for fearing its recurrence; an observation which is true with reference to all the diseases of the nervous system.

The termination of mania in dementia has already been noticed. The circumstances which chiefly influence our prognosis in insanity are the following: —

1. *The complication of insanity with other cerebral disorders.* — The most unfavourable complication is that of general paralysis; if this affection be present, even in the slightest degree, the case must generally be considered hopeless. Epilepsy is also a very unfavourable complication; it is much less so, however, in those cases where the fits occur only at periods of high maniacal excitement, as the effects of a

transient cause, than in those where violent mania appears as the sequel or occasional interlude of inveterate epilepsy, which latter case is a very desperate one.

2. *The form of the disease.* — This is of great importance with reference to the event. The following comparative statement of recoveries among the patients at Charenton is given by M. Esquirol.

Mania . .	115	cases out of	226
Monomania	91	. . .	289
Dementia .	3	. . .	99
	209		614

In the total number of cases are included 109 paralytics, 19 epileptics, and 4 idiots; so that the number of curable cases may be considered as reduced to 487, of which number more than two fifths were restored. "It is remarkable," observes Dr. Prichard, "that the greater sanability of maniacs, in comparison with monomaniacs, had place only in males. From this it would appear that monomania is comparatively a more curable disease in females than in men."

3. *The period of the disease.* — This is a very important consideration; the chance of recovery being much greater when the case comes early under treatment. In the practice of Dr. Willis, nine out of ten are stated to have recovered when placed under his care within three months after the first attack. Under similar circumstances, Dr. Finch treated successfully 61 cases out of 69. Dr. Burrows cured 221 out of 242 recent cases; and the practice of the Retreat, near York, affords a proportion of at least seven recoveries out of eight recent cases.

A table of recoveries at the Gloucester Lunatic Asylum is given on the authority of Mr. Hitch, the resident medical officer, which affords similar results, and contains some examples of restoration to reason after so long a duration of insanity, as to show that we ought never absolutely to despair.

Age. — M. Esquirol has found that the most favourable age for recovery is between the twentieth and thirtieth year, and that few are cured after the age of fifty. From the table of recoveries at Charenton, it appears that the greatest number of cures were in patients from twenty-five to thirty, and from thirty to thirty-five years of age. The proportion of recoveries diminishes progressively from the forty-fifth year onwards. The diminution is more abrupt in women, and more uniform in men. Cases occurring before the twentieth year are most numerous in males. In men the disease most frequently makes its invasion from twenty to twenty-five, and from twenty-five to thirty; in women between twenty-five and thirty. The experience of Charenton shows that advanced age does not preclude hope, twenty men having recovered after their fiftieth year; in which number are included four out of twelve lunatics who were more than seventy years old.

5. *Sex.* — Insanity has generally been observed to be more curable in women than in men.

6. *Season*, and the *circumstances of the constitution*, are alluded to by our author as modifying the prognosis; these, however, we need not dilate upon.

The general proportion of recoveries, in cases of all kinds, is very differently estimated by different writers. The experience of Dr. Burrows affords 240 cures in an aggregate of 296 cases of various descriptions — 221 in 242 recent cases, 19 in 64 old cases — giving an average of 81 in 100 cases of all sorts, and 91 in 100 recent cases.

Dr. Jacobi ascribes the large proportion of recoveries in England to the practice, which he believes to obtain in this country, of discharging patients from the asylums too soon after apparent restoration. In this gentleman's establishment at Sieburg, in Westphalia, 40 out of 100 cases were dismissed completely cured, and 6 with alleviation of symptoms. Dr. Prichard justly remarks, that Jacobi is certainly mistaken in supposing that patients are dismissed too early from lunatic asylums in England. "It is plainly not the interest of those who conduct private establishments to err on this side; and, in most of the public hospitals in this country, the proportion of recoveries is by no means so great as to require such an explanation."

M. Esquirol has for many years been engaged in extensive researches into the statistics of lunatic asylums. In the Dict. des Sciences Méd. he gives the following table of recoveries, taken from the reports of the French establishments: —

Fr. Lunatic Asylums.	Dates.	Admis.	Rec.
Charenton, from Nov. 22.	1798 to 1800, 22 July,	97...	33
	1803	499...	161
Salpêtrière ...	from 1801 to 1805 ...	1002...	407
— ...	from 1804 to 1813 ...	2005...	1218
— ...	from 1806 to 1807 ...	531...	286
— ...	from 1812 to 1814 ...	891...	413
In M. Esquirol's private establ.	from 1801 to 1813 ...	335...	173
	Totals	5360	2691

In a still larger calculation, contained in the Mem. Acad. Roy. Med., 4968 cures are reported out of 12,592 cases, treated at the Salpêtrière and Bicêtre. A more recent report of the same eminent observer, referring to the practice of Charenton in 1826–28, gives a proportion of recoveries amounting to one third of cases of all descriptions; and an official report, made at Paris in 1825, of the state of lunatic hospitals for the three preceding years, affords nearly a corresponding result; the recoveries being 34 in 100, including cases deemed curable and incurable. Esquirol has collected the following statements from English lunatic hospitals: —

English Lunatic Asylums.	Dates.	Admis.	Reco.
In Bethlem Hospital,	from 1784 to 1794 ...	8874 ...	2557
— —	in 1813 ...	422 ...	204
In St. Luke's	from 1751 to 1801 ...	6458 ...	2811
In York Asylum		599 ...	286
In the Retreat near York,	from 1801 to 1814 ...	163 ...	60
	Totals	16516	5918

From these calculations it appears that the proportion of cures formerly obtained in English lunatic asylums was, in some instances, less than that which is reported from the celebrated hospitals in France. This is the more remarkable when we take into our account the peculiar

regulations of the great lunatic establishments of London. The hospitals of Bethlem and St. Luke impose certain exclusions, elsewhere unknown. They reject all patients who have been more than twelve months insane; those affected by paralysis, however slight, and by epilepsy or convulsive fits; idiots, the aged and infirm; those discharged uncured from other hospitals: there are, likewise, other exclusions besides those above mentioned; and all persons who have not recovered at the expiration of one year are dismissed. Yet, on comparing the reports of these hospitals with those of other institutions, the regulations of which are less favourable to a high proportion of cures, and where no selection or exclusion exists, we do not find, as Dr. Burrows remarks, the relative number of recoveries to be so great as might be expected. It is indeed surprising to observe that the reports of Bethlem Hospital, of a century and a half ago, give a greater proportion of cures than those of many years preceding 1817, when an improvement took place in the arrangements of that establishment. Dr. Burrows remarks, on the authority of Stow, who derived his information from Dr. Tyson, physician to Bethlem Hospital, that from 1684 to 1703, 1294 patients were admitted, of whom 890 were cured, which is a proportion of two in three. But from 1784 to 1794, 1664 patients were admitted, of whom 574, or rather more than one in three, recovered.

So great a difference could not be accounted for by any presumed inferiority of skill in the practitioners, or of arrangement in the institutions of this country; nor is there any reason to believe that any such inferiority existed. Since the removal of Bethlem Hospital to a new site the average of recoveries has greatly increased. From a table drawn up by Mr. Lawrence for Dr. Prichard, it appears that, out of 2060 cases, admitted between 1819 and 1833, 1124, or considerably more than one half, were cured. The report of the Stafford Asylum, from 1818 to 1828, gives about 43 cures in every 100 cases; that of Wakefield County Asylum, from 1819 to 1826, about 42 in 100. A report of the Lancaster County Asylum, obtained by Dr. Pritchard through Dr. Whalley, states a proportion of recoveries amounting to about 40 in 100 of the total number of cases (1750) from 1817 to 1832. A report from the Gloucester Asylum, drawn up by Mr. Hitch, and referring to the years 1823–32, gives a very favourable list of recoveries, — 234 out of 516 cases; without taking into account a considerable number of recoveries which afterwards took place among those dismissed as relieved and on trial. In this establishment there is no selection of cases, lunatics of all descriptions being freely admitted. Dr. Prichard concludes a very ample and excellent view of this important subject with a table obtained from Mr. Tuke of York, from which it appears that, out of 334 patients, admitted into the Retreat in that city, from 1812 to 1833, 168 have recovered, 50 have died, 37 have derived no benefit and been removed, 10 have left the asylum in an improved state, and 69 remain.

The chief predisposing causes of insanity are hereditary predisposition, which is by far the most influential, the melancholic temperament, and diseases or injuries of the brain. Many other causes, however, both moral and physical, might be enumerated as predisposing to one or other form of insanity. Our limits will not allow us to enter into these subjects; nor do they, indeed, admit of much elucidation in the present state of our knowledge.

The chief exciting causes of insanity are injuries and diseases of the brain, intoxication, insolation, excess in venery, intestinal irritation, and morbid conditions of the uterine system. In this country, it is well known that a large proportion of the cases found in the public asylums have been brought thither by dram-drinking.

Some very interesting tables, illustrative of the comparative influence of different causes in the production of insanity, are given by Dr. Pritchard.

The morbid anatomy of the brain in cases of insanity has occupied the attention of many careful observers; but their researches have as yet thrown very little light on the pathology of the disease. The following are the most important of the observations which have been made.

Greding has recorded the following facts: —

1. In the *cranium*. — "Experience has proved," as he says, "that the skulls of almost all insane persons have a natural shape." Of sixteen cases only of the whole number examined, viz. nearly 220, the forehead was contracted, the temples compressed, and the occiput large and expanded. In a few the head was elongated and compressed at the temples. Some had a head almost round, or of a square shape: these were epileptic idiots. Two had small heads, quite circular: these were epileptic madmen. Of 216 cases, including those of madmen, idiots, and epileptics, the skull was unusually thick in 167: this fact was observed in 78 out of 100 cases of raving madness, and in 22 among 30 of idiotism. In many cases the cranium was remarkably thin. Holes were observed in the inner table in 115 out of 216 cases: in other instances bony projections from the inner surface.

2. *Membranes*. — Dura mater firmly adherent to the skull in 107 out of 216 cases; in a few instances of a blueish black colour, thickened and partially ossified. Pia mater thickened and opaque more or less in 86 out of 100 cases of mania; beset with small spongy bodies in 92 out of 100: these bodies were often united to the surface of the brain, and were, in some instances, the seats of ossific deposits.

3. *Brain*. — Cerebral substance softer than usual in 118 out of 216 cases: soft and pulpy in 51 cases of mania out of 100, as likewise in 19 out of 24 cases of melancholia, in 8 out of 20 epileptics, and in 16 out of 30 idiots. Those maniacs who had the cerebrum softened had the cerebellum still more soft and pulpy.

4. *Effusions*. — Between the dura and pia mater in 120 out of 216 cases; in 58 out of 100 maniacs. Between the pia mater and the surface of the brain in 28 among 100 maniacs. Lateral ventricles in 29 very full of serum, in

23 ready to burst; in 10 among 24 melancholics astonishingly distended. Third ventricle quite full in 57 of 100 maniacs, and in 16 of 24 melancholics. Fourth ventricle ready to burst in 80 out of 100 maniacs, and quite empty in only 3: completely distended in every one of 24 melancholics.

Other appearances. — Plexus choroides in a nearly healthy state in only 16 out of 216 cases, thickened and full of hydatids in 96 out of 100 maniacs. Lateral ventricles either larger or smaller than natural in many cases. Softness of parts of the brain, as of the tubercula quadrigemina in some cases.

Haslam has given the histories of 37 cases of madness, with the appearances discovered on dissection. In not one of these cases were the brain and its membranes free from morbid appearances. In almost all, either the membranes bore marks of former inflammation, or their vessels were distended with blood. There was effusion of serum between the membranes in 16 cases, and in the lateral ventricles in 18. The consistence of the brain was firmer than natural in 9 cases, softer in 7, and not perceptibly altered in 20. The cranium was thicker than usual in 3 cases, and thinner in 3. In several cases a peculiar looseness of the scalp was observed.

Georget has noticed the following appearances: —

Irregular conformations of the cranium, the prominences of which are developed irregularly, those of the right side being generally larger than those of the left; some skulls having the lateral diameter of equal extent with the antero-posterior, and the cavities of the base irregular in extent; some skulls, one in twenty, thickened partially or generally; more frequently the bones hard, white, without diploë, resembling ivory; some very light. Dura mater rarely changed; sometimes adherent to the skull, thickened, containing deposits of bone. Arachnoid displaying in places additional laminæ of a red or grey colour; sometimes thickened but smooth. Pia mater injected; or thickened and infiltrated with serum, giving at first the appearance of a gelatinous deposit. Volume of the brain sometimes less than the cavity of the cranium seems to require. Some brains very hard, cut with difficulty; the white substance glutinous, elastic, and suffering distension; more frequently the brain is soft, the grey matter being pale and yellowish, and the white substance discoloured, of a dirty white, the colour and consistence of these portions almost confounded. The convolutions separated by serosity, and the pia mater thickened. Interior cavities of the brain appearing in some instances very large, in others small, often filled with a serous fluid remarkably clear and limpid; plexus choroides exsangueous, containing hydatiform vesicles. Partial softenings of the brain; erosions, ulcerations of the surface of the ventricles. Cerebellum generally softer than the cerebrum; sometimes partially softened. Mesocephalon, medulla oblongata, and medulla spinalis, rarely displaying morbid changes of structure.

Bayle, after extensive observations at Charenton, comes to the conclusion that the proximate cause of insanity is seated, not in the substance of the brain, but in its membranes, from the inflammation of which effusions follow, producing the symptoms of different degrees of compression of the brain, corresponding accurately with those of insanity in its progressive stages. With respect to M. Bayle's *nouvelle doctrine*, it may be remarked, that his anatomical observations differ from those of all other inquirers, and that his pathological views seem to be somewhat at variance with facts. The progressive symptoms of insanity are not those of gradually increasing compression of the brain: if they were so, a case of chronic hydrocephalus would be one of insanity; instead of which, it is well known that children affected with the former are usually particularly acute and intelligent.

Calmeil, labouring in the same field as the last-mentioned writer, has made his observations exclusively on the *general paralysis* of the insane; and most of the phenomena noticed by him agree with those which other morbid anatomists have found in connexion with mental derangement, whether complicated with paralysis or not.

The consistence of the white substance is generally natural, except that, in a few instances, it is harder than usual in the convolutions. The grey substance contiguous to the pia mater is softened, and reduced to a pulp, to the depth of a quarter or half a line; it is separated into laminæ, of which the external adheres to the pia mater, and the colour of the cortical substance undergoes a peculiar change. All these phenomena are referred by M. Calmeil to inflammation of the cortical substance, which he considers as the proximate cause of the general paralysis of the insane.

M. Foville has still more recently investigated the brain in cases of insanity. In many leading particulars his observations agree with those of M. Calmeil; but certain appearances, which the latter regards as confined to general paralysis, are connected by Foville with mental derangement. M. Foville has remarked, in the cortical and medullary substances of the brain, various changes of consistence, colour, and nutrition. In the most acute cases of mania the cortical substance has presented an intensely red colour, approaching to that of erysipelas. Among the chronic changes in this substance the most frequent is an increased firmness and density of its surface, extending to no great depth, but constituting a distinct lamina, smooth externally, and internally irregular, which, when torn off, leaves the subjacent surface red, soft, and mammillated. The colour of this superficial lamina is considerably paler than natural. M. Foville has noticed morbid appearances somewhat similar to those just described, in the brains of wild animals which have died in a state of confinement. Among the appearances observed in the medullary substance, one of the most remarkable is an almost fibro-cartilaginous hardness, usually accompanied with a splendid white colour: the colour is not uniformly white, being sometimes yellowish or grey. This indu-

ration is conjectured, by M. Foville, to arise from a matting together of the cerebral fibres by adhesive inflammation. According to this writer, the fibrous mass of the hemispheres is formed by the superposition of several distinct layers of substance, connected by a very fine cellular tissue: these planes, which are easily separable in the healthy state, become inseparable in the induration of the brain accompanying madness. M. Foville found these morbid adhesions in all the cases of general paralysis which he examined, except two.

We must not omit to mention that this anatomist thinks he has traced some morbid alterations of the *nerves*, in connexion with hallucination of the senses: in a female lunatic, who had been tormented by optical illusions, the optic nerves were found hard and semitransparent through a great part of their thickness.

The two principal inferences drawn by M. Foville from his researches are, 1. That morbid changes in the cortical substance are directly connected with mental derangement. 2. That morbid changes in the white substance are directly connected with disorder of voluntary motion. The uniform detection of disease in the cortical substance, in cases of general paralysis, induced M. Calmeil to ascribe the loss of muscular power to such disease; M. Foville, however, contends that this conclusion cannot be legitimately derived from the facts, since, in all his cases, although the cortical substance was diseased, there was also induration, serous infiltration, or softening in the white substance, and, in most instances, adhesion of the principal medullary planes to each other.

Such are the principal observations which have been made in the morbid anatomy of insanity.

Notwithstanding the labour and ingenuity that have been devoted to the subject, nothing is yet known of the real proximate cause of insanity; there is, however, one point connected with its pathology which admits of discussion: namely, whether insanity be a disease of the *mind* or of the body. It appears, however, not a little extraordinary that there should be two opinions on this subject among men accustomed to think, since the notion of disease of the *mind* is utterly incompatible with either of the possible views of our intellectual constitution. If, according to the doctrine of the materialist, thought is a mere function of the brain, as the biliary secretion is a function of the liver, insanity is merely a disordered state of this function — the soul, as an abstract thinking principle, being out of the question; if, again, there be in man an independent and immaterial thinking principle, of which we, for our own part, have no doubt, it is absurd to talk of this principle being diseased, except as a metaphor, since disease means deranged action in a material organism — at least, this is the only signification we can attach to the term. The notion that the soul or immaterial thinking principle is actually diseased in insanity, though generally abandoned in this country as entirely unphilosophical, has several eminent advocates in Germany, who build their opinion on the unsatisfactory results of anatomical investigations, and the acknowledged influence of moral causes in the production of mental alienation. Professor Heinroth, who adopts this doctrine in its fullest extent, has deduced from it a conclusion as monstrous in morals as it is false in fact — namely, that *moral depravity* is the essential cause of madness! Heinroth has been fully answered by Jacobi, who refers to many examples of insanity occurring in the most pious and excellent individuals, and cites in particular the case of Madame Lavater, the wife of the celebrated physiognomist, a lady remarkable for her amiable character, who, at an advanced period of life, became insane, and continued for a long time in a state of the deepest melancholy. She recovered her reason, however, some months before her death, and evinced all the excellent dispositions which were natural to her.

The treatment of insanity resolves itself into *medical* and *moral*. With respect to the former the general principle which should guide our practice is simple. Of the actual physical state which constitutes insanity we are entirely ignorant: we cannot, therefore, at present hope to strike off the root of the disease; we know, however, that certain morbid conditions of the brain and other organs accompany its progress, and exercise an important influence on the event of the case; to these, therefore, the resources of medicine should be directed, according to the general principles of the science — always keeping in view, however, that we are not dealing with ordinary idiopathic affections, but with the accompaniments of a peculiar and usually a protracted malady. Although medical treatment has great influence in many cases, the moral treatment is, on the whole, the more important, since by means of this we have the more direct control over the mental disorder. The moral treatment of insanity is a subject of great extent, and one into which it would be out of character to enter in a work like the present.

INSE'CTA. (From *inseco*, to cut into, on account of the deep fissures by which one part of their body is divided from another.) Insects. A class of articulated animals. See *Animal kingdom*.

INSE'SSUS. *Insessio*. (From *insideo*, to sit upon.) A hot-bath, simple or medicated, over which the patient sits.

INSIDIOUS. *Insidiosus*. Pathologists give this name to diseases which do not at first appear so formidable as they are, and which are apt to elude the attention of the practitioner.

INSIPIE'NTIA. (From *in*, not, and *sapientia*, wisdom.) Synonymous with *dementia*.

INSOLA'TIO. (*o, onis*. f.; from *in*, and *sol*, the sun.) Insolation. Exposure to the direct rays of the sun. This is a frequent source of disease. Chemists subject bodies to insolation with a view to certain changes in their constitution; the colour of bodies is particularly affected by this process: bleaching affords a familiar illustration.

INSPIRA'TION. (*Inspiratio, onis*, f.; from *in*, and *spiro*, to breathe.) In physiology, the act of drawing the air into the lungs. See *Respiration*.

INSTINCT. (*Instinctus, ûs*. m.) That power of living bodies by which they spontaneously assume those modes of action which are

necessary for the preservation of the individual, or the perpetuation of the species, independently of any intelligence.

Insulation. Applied in electricity to the state of a body surrounded by non-conductors. See *Electricity*.

I'NTEGER. Entire. Applied to leaves, perianths, petals, &c.: *folium integrum*, means an undivided leaf; and it is said of the simple leaves, as those of the orchises and grasses. It is opposed to cloven, gashed, indented, &c.; but it does not signify that it is not serrated or scolloped. When, however, a leaf is said to be very entire (see *Integerrimus*), it is not even scalloped or serrated. The female flower of the oak affords an example of the *perianthium integrum*; and the petals of the *Nigella arvensis* and *Silene quinque-vulnera* are described as *petala integra*.

INTEGE'RRIMUS. Most perfect or entire. Applied to leaves, the margin of which has no teeth, notches, or incisions. It regards solely the margin; whereas the *folium integrum* respects the whole shape, and has nothing to do with the margin.

Intellect. See *Mens*.

INTERCO'STAL. (*Intercostalis*; from *inter*, between, and *costa*, a rib.) A name given to muscles, vessels, &c. which are between the ribs.

Intercostal arteries. *Arteriæ intercostales*. The arteries which run between the ribs. The superior intercostal artery is a branch of the subclavian. The other intercostal arteries are given off from the aorta.

Intercostal muscles. *Intercostales externi et interni*. Between the ribs on each side are eleven double rows of muscles: these are the *intercostales externi* and *interni*. Galen has very properly observed, that they decussate each other like the strokes of the letter X. The *intercostales externi* arise from the lower edge of each superior rib, and, running obliquely downwards and forwards, are inserted into the upper edge of each inferior rib, so as to occupy the intervals of the ribs, from as far back as the spine to their cartilages; but from their cartilages to the sternum there is only a thin aponeurosis covering the internal intercostales. The *intercostales interni* arise and are inserted in the same manner as the external. They begin at the sternum, and extend as far as the angles of the ribs, their fibres running obliquely backwards. These fibres are spread over a considerable part of the inner surface of the ribs, so as to be longer than those of the external intercostales. Some of the posterior portions of the internal intercostals pass over one rib, and are inserted into the rib below. Verheyen first described these portions as separate muscles, under the name of *infracostales*. Winslow has adopted the same name. Cowper, and after him Douglas, calls them *costarum depressores proprii*. These distinctions, however, are altogether superfluous, as they are evidently nothing more than appendages of the intercostals. The number of these portions varies in different subjects. Most commonly there are only four, the first of which runs from the second rib to the fourth, the second from the third rib to the fifth, the third from the fourth rib to the sixth, and the fourth from the fifth rib to the seventh. The internal intercostals of the two inferior false ribs are frequently so thin as to be with difficulty separated from the external; and, in some subjects, one or both of them seem to be altogether wanting.

Intercostal nerve. *Nervus intercostalis*. Great intercostal nerve. Sympathetic nerve. The great intercostal nerve arises in the cavity of the cranium, from a branch of the sixth and one of the fifth pair, uniting into one trunk, which passes out of the cranium through the carotid canal, and descends by the sides of the bodies of the vertebræ of the neck, thorax, loins, and os sacrum: in its course, it receives the small accessory branches from all the thirty pair of spinal nerves. In the neck, it gives off three cervical ganglions, the upper, middle, and lower; from which the cardiac and pulmonary nerves arise. In the thorax, it gives off the splanchnic or anterior intercostal, which perforates the diaphragm, and forms the semilunar ganglions, from which nerves pass to all the abdominal viscera. They also form in the abdomen ten peculiar plexuses, distinguished by the name of the viscus to which they belong, as the cœliac, splenic, hepatic, superior, middle, and lower mesenteric, two renal, and two spermatic plexuses. The posterior intercostal nerve is dispersed in accessory branches about the pelvis and ischiatic nerve. Many opinions have been entertained with respect to the functions of this nerve, or, rather, system of nerves. Some regard it as the great centre of the organic life, as the cerebro-spinal system is that of the animal life; others regard it as associating the functions of all the other parts of the nervous system; others again deny it either of these offices; and M. Magendie questions whether the great sympathetic be a nerve at all.

Intercostal veins. These accompany the intercostal arteries, and empty their blood into the vena azygos.

INTERCU'RRENT. *Intercurrens*. Diseases which occur sporadically during the prevalence of epidemic or endemic diseases have been termed *intercurrent diseases* — *morbi intercurrentes*.

Inte'rcus aqua. A dropsy between the skin and the flesh. See *Anasarca*.

INTERDE'NTIUM. (*um*, *i*. n.; from *inter*, between, and *dens*, a tooth.) The intervals between teeth of the same order.

Interdigi'tium. (*um*, *i*. n.; from *inter*, between, and *digitus*, a toe, or finger.) As corns or warts between the toes or fingers.

Interfæmi'neum. (From *inter*, between, and *femur*, the thigh.) The space between the anus and pudendum. See *Perineum*.

Intergastrum. A barbarous term applied by Paracelsus to the decussation of the optic nerves.

Interlu'nius. (From *inter*, between, and *luna*, the moon: because it was supposed to affect those who were born in the wane of the moon.) An old epithet of epilepsy. — *Morbus interlunius*.

INTERMITTENT. (*Intermittens*; from *intermitto*, to discontinue.) An intermittent

disease is one which ceases and returns again at regular or uncertain periods, as agues, &c.

Intermittent fever. See *Ague.*

INTERNO'DIS. The space between the joints: applied to a flower-stalk or pedunculus when it proceeds from the intermediate part of a branch between two leaves; as in *Ehretia internodis.*

INTERNU'NTII DIES. (From *internuncio*, to go between.) Applied in the doctrine of critical days synonymously with *dies indices.*

INTERO'SSEI MANUS. These are small muscles situated between the metacarpal bones, and extending from the bones of the carpus to the fingers. They are divided into *internal* and *external*; the former are to be seen only on the palm of the hand, but the latter are conspicuous both on the palm and back of the hand. The *interossei interni* are three in number. The first, which Albinus names *posterior indicis*, arises, tendinous and fleshy, from the basis and inner part of the metacarpal bone of the fore-finger, and likewise from the upper part of that which supports the middle finger. Its tendon passes over the articulation of this part of these bones with the fore-finger, and, uniting with the tendinous expansion that is sent off from the extensor digitorum communis, is inserted into the posterior convex surface of the first phalanx of that finger. The second and third, to which Albinus gives the names of *prior annularis* and *interosseous auricularis*, arise, in the same manner, from the basis of the outsides of the metacarpal bones that sustain the ring-finger and the little finger, and are inserted into the outside of the tendinous expansion of the extensor digitorum communis that covers each of those fingers. These three muscles draw the fingers into which they are inserted towards the thumb. The *interossei externi* are four in number; for among these is included the small muscle that is situated on the outside of the metacarpal bone that supports the fore-finger. Douglas calls it *extensor tertii internodii indicis*, and Winslow, *semi interosseus indicis.* Albinus, who describes it among the interossei, gives it the name of *prior indicis.* This first interosseus externus arises by two tendinous and fleshy portions. One of these springs from the upper half of the inner side of the first bone of the thumb, and the other from the ligaments that unite the os trapezoides to the metacarpal bone of the fore-finger, and likewise from all the outside of this latter bone. These two portions unite as they descend, and terminate in a tendon which is inserted into the outside of that part of the tendinous expansion from the extensor digitorum communis that is spread over the posterior convex surface of the fore-finger. The second, to which Albinus gives the name of *prior medii*, is not quite so thick as the last-described muscle. It arises by two heads; one of which springs from the inner side of the metacarpal bone of the fore-finger, chiefly towards its convex surface, and the other arises from the adjacent ligaments, and from the whole outer side of the metacarpal bone that sustains the middle finger. These two portions unite as they descend, and terminate in a tendon, which is inserted, in the same manner as the preceding muscle, into the outside of the tendinous expansion that covers the posterior part of the middle finger. The third belongs likewise to the middle finger, and is therefore named *posterior medii* by Albinus. It arises, like the last-described muscle, by two origins, which spring from the roots of the metacarpal bones of the ring and middle fingers, and from the adjacent ligaments, and is inserted into the inside of the same tendinous expansion as the preceding muscle. The fourth, to which Albinus gives the name of *posterior annularis*, differs from the two last only in its situation, which is between the metacarpal bones of the ring and little fingers. It is inserted into the inside of the tendinous expansion of the extensor digitorum communis, that covers the posterior part of the ring finger. All these four muscles serve to extend the fingers into which they are inserted, and likewise to draw them inwards, towards the thumb, except the third, or *posterii medii*, which, from its situation and insertion, is calculated to pull the middle finger outwards.

INTEROSSEI PEDIS. These small muscles, in their situation between the metatarsal bones, resemble the interossei of the hand, and, like them, are divided into *internal* and *external.* The *interossei pedis interni* are three in number. They arise, tendinous and fleshy, from the basis and inside of the metatarsal bones of the middle, the third, and the little toes, in the same manner as those of the hand, and they each terminate in a tendon that runs to the inside of the first joint of these toes, and from thence to their upper surface, where it loses itself in the tendinous expansion that is sent off from the extensors. Each of these three muscles serves to draw the toe into which it is inserted towards the great toe. The *interossei externi* are four in number. The first arises, tendinous and fleshy, from the outside of the root of the metatarsal bone of the great toe, from the os cuneiforme internum, and from the root of the inside of the metatarsal bone of the fore-toe. Its tendon is inserted into the inside of the tendinous expansion that covers the back part of the toes. The second is placed, in a similar manner, between the metatarsal bones of the fore and middle toes, and is inserted into the outside of the tendinous expansion on the back part of the fore-toe. The third and fourth are placed between the two next metatarsal bones, and are inserted into the outside of the middle and third toes. The first of these muscles draws the fore-toe inwards towards the great toe. The three others pull the toes, into which they are inserted, outwards. They all assist in extending the toes.

INTERO'SSEOUS. (*Interosseus*; from *inter*, between, and *os*, a bone.) Between bones: applied to muscles, ligaments, &c. which are situated between bones.

INTERPELLA'TUS. (From *interpello*, to interrupt.) A term applied by Paracelsus to a disease attended with irrregular or uncertain paroxysms.

INTERPOLA'TI DIES. (From *interpolo*, to renew.) Paracelsus uses this phrase synonymously with intercalary days.

INTERRU'PTUS. Interrupted; broken in its regular form: applied to spikes, leaves, &c.; as the spike of the *Betonica officinalis*. A stem is sometimes interrupted by the intervention of leaves, or smaller sets of flowers.

INTERSCAPU'LIUM. (*um, i.* n.; from *inter*, between, and *scapula*, the shoulder-blade.) 1.[1] The spine of the scapula. — *Bartholin.*

2. The fossa on each side of the spine of the scapula. — *Vander Linden.*

INTERSE'PTUM. (*um, i.* n.; from *inter*, between, and *septum*, an inclosure.) The uvula, or the septum narium.

INTERSPINA'LIS. (From *inter*, between, and *spina*, the spine.) Muscles, nerves, &c. are so named which are situated between the processes of the spine.

INTERSPINALES. The portions of muscle between the spinous processes of the neck, back, and loins, distinguished by the names of *interspinales colli, dorsi, et lumborum*. Those which connect the processes of the back and loins are rather small tendons than muscles: they draw these processes nearer to each other.

INTERSTI'TIAL. (From *intersto*, to stand between.) Applied to a substance which is situated in the interstices of an organ, or to an action which takes place in those interstices. As *interstitial matter* — *interstitial absorption*, *&c.*

I'NTERTRANSVERSA'LES. Four distinct small bundles of muscular fibres which fill up the spaces between the transverse processes of the vertebræ of the loins, and serve to draw them towards each other.

INTERTRI'GO. (*o, inis.* f.; from *inter*, between, and *tero*, to rub.) An excoriation, or galling of the skin, about the anus, groins, axilla, or other parts of the body, attended with inflammation and moisture. It is most commonly produced by the irritation of the urine, or from riding; in infants it often arises without any external cause. It is relieved by the liquor plumbi acetatis dilutus, ointment of flowers of zinc, powdered starch, and the compound sarcocolla powder.

INTERVE'RTEBRAL. Situated between the vertebræ.

Intervertebral cartilages. See *Vertebræ.*

Intestinal canal. See *Intestine.*

INTE'STINE. (*Intestinum, i.* n.; from *intus*, within.) The convoluted membranous tube that extends from the stomach to the anus, receives the ingested food, retains it a certain time, mixes with it the bile and pancreatic juice, propels the chyle into the lacteals, and covers the fæces with mucus, is so called. The intestines are situated in the cavity of the abdomen, and are divided into the small and large, which have, besides their size, other circumstances of distinction. The whole length of the intestinal tube in the human subject is about six times that of the body. The small intestine comprises about the upper four fifths of the tube, and the large intestine the remaining fifth.

The *small* intestines are supplied internally with folds, called *valvulæ conniventes*, and have no bands on their external surface. The *large* intestines have no folds internally; are supplied externally with three strong muscular bands, which run parallel upon the surface, and give the intestines a saccated appearance; they have also small fatty appendages, called *appendiculæ epiploicæ*.

The first portion of the intestinal tube, for about the extent of twelve fingers' breadth, is called the *duodenum*: it lies in the epigastric region, makes three turnings, and, between the first and second flexure, receives, by a common opening, the pancreatic duct and the ductus communis choledochus. It is in this portion of the intestines that chylification is chiefly performed. The remaining portion of the small intestines is distinguished by an imaginary division into the jejunum and ileum.

The *jejunum*, which commences where the duodenum ends, is situated in the umbilical region, and is mostly found empty: hence its name. It is every where covered with red vessels, and, about an hour and a half after a meal, with distended lacteals.

The *ileum* occupies the hypogastric region and the pelvis; is of a more pallid colour than the former, and terminates by a transverse opening into the large intestines, which is called the *valve of the ileum, valve of the cæcum, or the valve of Tulpius.*

The beginning of the large intestines is firmly tied down in the right iliac region, and, for the extent of about four fingers' breadth, is called the *cæcum*, having adhering to it a worm-like process, called the *processus cæci vermiformis*, or *appendicula cæci vermiformis.* The great intestine then commences *colon*, ascends towards the liver, passes across the abdomen, under the stomach, to the left side, where it is contorted like the letter *S*, and descends to the pelvis: hence it is divided in this course into the *ascending portion*, the *transverse arch*, and the *sigmoid flexure.* When it has reached the pelvis it is called the *rectum*, whence it proceeds, in a straight line, to the anus.

The intestinal canal is composed of three membranes or coats; a *common* one from the peritonæum, a *muscular coat*, and a *mucous* or *villous coat*, the villi being formed of the fine terminations of arteries and nerves, and the origins of lacteals and lymphatics. The mucous coat is perforated by the ducts of numerous simple glands or follicles, by which it is supplied with mucus. These glands are solitary or in clusters. The former are named *Brunner's glands*, and are most numerous in the duodenum, though they exist throughout the tube; the latter are named *Peyer's glands*, which are found in the jejunum and ileum, but most numerously in the ileum. The intestines are connected with the spine by the mesentery; the duodenum has also a peculiar connecting cellular substance, as have, likewise, the colon and rectum, by means of which the duodenum is firmly accreted to the back, the colon to the kidneys, and the rectum to the os coccygis, and, in women, to the vagina. The remaining portion of the tube floats in the cavity of the abdomen. The arteries of this canal are branches of the *superior* and *inferior mesenteric*, and the *duodenal.* The veins evacuate their blood into the vena portæ.

The nerves are branches of the eighth pair and intercostals. The *lacteal vessels*, which originate principally from the jejunum, proceed to the glands, in the mesentery.

INTESTI'NA. The name given by Cuvier to worms inhabiting the bodies of other animals. See *Animal Kingdom*.

INTOXICATION. (*Intoxicatio*; from *in*, and *toxicum*, a poison.) The effect of an alkoholic liquor taken in excess.

I'NTRAFOLIA'CEOUS. *Intrafoliaceus.* Within the leaves: applied to stipulæ which are above the footstalk, and internal with respect to the leaf; as in *Ficus carica*, and *Morus nigra*.

I'NTROSUSCE'PTION. *Introsusceptio.* (From *intro*, within, and *suscipio*, to receive.) *Intus-susceptio. Invaginatio. Volvulus.* When one portion of intestine slips within another the accident is called *introsusception*. It takes place more frequently near the termination of the ilium than in any other situation. See *Ileac Passion*.

I'NTUS-SUSCE'PTION. (*Intus-susceptio*; from *intus*, within, and *suscipio*, to receive. 1. Synonymous with *introsusception*.

2. Nutrition. The interstitial deposition of particles, by which the existence of living bodies is sustained and their waste supplied.

I'NTYBUS. (*us*, *i.* m.; from *in*, and *tubus*, a tube: so named from the hollowness of its stalk.) See *Cichorium endivia*.

I'NULA. (*a*, *æ.* f.; contracted or corrupted from *helenium*, ἕλενιον, fabled to have sprung from the tears of Helen.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua*.

2. The herb elecampane. See *Inula helenium*.

Inula, common. See *Inula helenium*.

INULA CRITHMOIDES. *Caaponga* of the Brazilians; called also, *Trifolia spica*, and *Crithmum marinum non spinosum*. The leaves and young stalks of this plant are pickled for the use of the table; they are gently diuretic.

INULA DYSENTERICA. The systematic name of the lessor inula, or flea-bane; called likewise, *Conyza media*, *Arnica Suedensis*, *Arnica spuria*, and *Conyza*. *Inula — amplexicaulibus, cordato oblongis; caule villoso, paniculato; squamis calycinis, setaceis*, of Linnæus. This indigenous plant was once considered as possessing great anti-dysenteric virtues. The whole herb is to the taste acrid, and, at the same time, rather aromatic. It is now fallen into disuse.

INULA HELENIUM. The systematic name of the common inula, or elecampane, called *Enula campana*, and *Helenium*. *Inula — foliis amplexicaulibus ovatis rugosis subtus tomentosis, calycum squamis ovatis*, of Linnæus. This plant, though a native of Britain, is seldom met with in its wild state, but mostly cultivated. The root, which is the part employed medicinally, in its recent state has a weaker and less grateful smell than when thoroughly dried, and kept for a length of time, by which it is greatly improved; its odour then approaching to that of Florentine orris root. It was formerly in high estimation in dyspepsia, pulmonary affections, and uterine obstructions, but is now fallen into disuse. From the root of this plant Rose first extracted the peculiar vegetable principle called *inulin*. Funke has since given the following as the analysis of elecampane root: — A crystallisable volatile oil; inulin; extractive; acetic acid; a crystallisable resin; gluten; a fibrous matter. See *Inulin*.

I'NULIN. In examining the *Inula helenium*, or *Elecampane*, Rose imagined he discovered a new vegetable product, to which the name of *Inulin* has been given. It is white and pulverulent, like starch. When thrown on red-hot coals, it melts, diffusing a white smoke, with the smell of burning sugar. It yields, on distillation in a retort, all the products furnished by gum. It dissolves readily in hot water; and precipitates almost entirely on cooling, in the form of a white powder; but, before falling down, it gives the liquid a mucilaginous consistence. It precipitates quickly on the addition of alkohol. It is obtained by boiling the root of this plant in four times its weight of water, and leaving the liquid in repose.

INU'STION. (From *in*, and *uro*, to burn.) The operation of a cautery.

INVERECU'NDUM OS. (From *in*, not, and *verecundus*, modest.) An obsolete name of the frontal bone, from its being regarded as the seat of impudence.

INVERMINA'TION. (*Inverminatio*; from *in*, and *vermis* a worm.) Certain diseased states of the intestinal canal give rise to the formation or evolution of entozoary animals, or worms as they are called, the principal varieties of which have been already noticed in the article *entozoa*. Under the present title of *invermination* we shall consider the morbid states occasioned by the presence of these animals.

Worms often inhabit the human intestines without producing any inconvenience. Ascarides have, in many instances, infested the alvine channel for twenty or thirty years without any serious evil, and, for the greater part of the time, been known only to exist there from their being seen in the expelled fæces. When, however, the canal becomes irritated by them, a number of symptoms arise, both locally and in distant parts, so that they may be arranged into primary and secondary; and the latter are either symptomatic or sympathetic.

1. *Primary symptoms* are those which exist in the part where the worms are, and, consequently, are local: these occasion griping pains, more particularly about the navel; the presence of worms eliminated with or without the fæces; fœtid breath; acrid eructations; slimy stools; and inflammation of the bowels.

2. The *secondary symptoms* are, occasional sickness and vomiting, variable and voracious appetite, wasting away of the body, heat and itching about the anus, and a vast number of sympathetic affections; for the most remote parts of the system have been known to afford symptoms from this very frequent source of irritation; the stomach and bowels, when that irritation is caused by worms: there are not merely symptoms, such as headach, vertigo, disturbed dreams, grinding of the teeth during sleep, picking of the nose, tenesmus, paleness of the coun-

tenance, dizziness, &c.; but also the formation of a regular disease, as verminous colic, a remittent fever, a state that stimulates hydrocephalus, convulsion fits, chorea Sancti Viti, peripneumonia, and even hæmorrhages.

The treatment of verminous symptoms and diseases consists in getting rid of the worms, by destroying them, or driving them from the body, and by strengthening the system generally, particularly the alvine canal. Both these intentions may sometimes be pursued simultaneously. A decided vermifuge process is, however, yet a desideratum in medical practice; because worms lie for the most part so low in the bowels, and are so completely involved in viscid mucus, or other slime, that even oil of turpentine, tobacco infusion, and mercurials, which readily enough destroy them out of the body, seldom go directly home to them when within it; and because, also, most of the medicines which are likely to produce this effect have a tendency to weaken the stomach and bowels, and thus render them a fitter habitation for worms.

The bowels should always be kept loose, by which the slime in which the worms burrow is continually passing out of the intestines.

If this bed, that so much favours the generation as well as the growth of the worms, does not pass of by mild aperients, more active ones should be given; for it is necessary to remove it as much as possible, in order to give the anthelmintic medicines a better chance of acting upon the worms.

The list of vermifuges is almost interminable. They may conveniently be divided into two classes: —

1. Those that dislodge and drive away intestinal worms by some mechanical or other external action; as all drastic purges, all oleaginous vermifuges; as oil of olives, beech nuts, castor, and turpentine, sulphur, petroleum, sea salt, tin filings, crude quicksilver, Plenck's grey mucilage of it, the lunar pill of Boerhaave, and the down of the pods of cowhage.

2. Those that destroy them by killing them before they are expelled; as the male fern, hellebore, fœtid hellebore, cavadilla, tansy, savine, rue, dittany, tobacco, worm-seed, the bark of the bulgewater tree, and of the cabbage tree, the spigelias, and Indian scabiosa. Many of these are hardly worth noticing.

The First Class.

The vermifuges, which are *simply purgative*, even the most active and drastic, seem to have little other effect than that of clearing away the slime in which most of the worms are enveloped, and thus exposing their naked and tender bodies to the action of other and more direct anthelmintics. Even aloes and colocynth, which unite a bitter principle to a cathartic power, are now well known to be incapable of poisoning them. They are, nevertheless, very useful, and especially with children, whose bowels are very much loaded with mucus.

Little or no dependence can be placed on the oily vermifuges, except the *terebinthinate*: these have been found highly serviceable. The vermicular ascarides rarely resist the oil of turpentine, when given in a dose sufficiently large to reach the rectum, or when injected into the rectum, and they have been discharged in great abundance. The best injections are these: —

℞. Terebinthinæ venetæ, saponis mollis, singulorum, ℥ ss.; aquæ puræ, f. ℥ viij.; misce pro enemate.

℞. Olei terebinthinæ rectificati, f. ℥ j.; decocti avenæ tenuioris, f. ℥ viij.: misce pro enemate.

These are for adults; and one or other may be administered every or every other day, with directions to retain them as long as possible.

The rectified oil of turpentine is given, in the dose of from half a drachm to a tea-spoonful, to a child ten years old, and from half an ounce to an ounce to an adult, in any convenient vehicle, as milk, gruel, peppermint, or any distilled water, once or twice a week, according as may be found necessary. Much larger doses have been found necessary, and more frequently repeated, when the stomach and bowels have been accustomed to spirituous liquors. In delicate and weak habits the above dose will sit uneasy on the stomach, and very much disquiet the system. In most cases it produces a slight vertigo, which soon passes by; and in some it acts like a glass of strong spirit, and produces a state very like to intoxication. These effects require always a diminution of the dose when repeated. There are several other terebinthinate preparations which have been in vogue as vermifuges, and which have been supposed to agree better with some stomachs; as the *Hungarian balsam*, and *oleum templinum*. Less valuable are some empyreumatic oils; as the *petroleum*, and animal oil from horns.

Sulphur: the *sulphureous* Harrogate *waters*. These act in the same way as, but are much less efficacious remedies than, oil of turpentine.

Tin filings. On what the anthelmintic virtues of these depend is yet undetermined: most probably their operation is mechanical. They have been given principally against the tape-worm, but seldom with benefit. The dose is from one scruple to two drachms or more in syrup.

Crude quicksilver most probably proves a vermifuge in the same way; though its oxides, the gray mucilage of Plenck, and the lunar pill of Boerhaave, have, perhaps, some peculiar property which kills the worms.

Cowhage, the *Dolichos pruriens* of Linnæus, is, of all those means which act mechanically on worms, the most powerful. It is the prickly and pungent down of the pod, which is scraped off, and mixed with any syrup. It is a common remedy, and an excellent one, in the West Indies, but seldom administered in this country.

The Second Class.

Almost all the vermifuges of this class possess great pungency and bitterness; and it is the former principle, and not the bitterness, which is the active part.

The *semen santonici*, or worm-seed. These are the produce of the *Artemisia santonica* of Linnæus, and are said to be a very good vermifuge in hot climates: those, however, which are found in our shops do not maintain tha

character. Of nearly the same efficacy is the *Juniperus sabina*, the *Tanacetum vulgare*, the *Origanum dictamnus*, and *Chænopodium anthelminticum*, now almost forgotten as vermifuges.

Assafœtida was once esteemed a powerful destroyer of worms; and it is probable that, near its native place, this juice may be more efficacious than in this country, where its anthelmintic powers are not believed.

Hellebore, helleboraster, and the cevadilla, a species of veratrum, are all drastic purgatives and pungent bitters. Although formerly esteemed, they are never thought of in this country as vermifuges.

Tobacco, like the last, is so powerful in its operation as never to be selected.

Gamboge is believed to possess some specific power in addition to its purgative; for it is generally given with calomel and scammony to expel tape-worms.

Besides these, there are some anthelmintics which are supposed to possess a specific power: viz.

The *Areca oleracea*, or cabbage-tree palm. The bark of the shoots of this is made into an infusion, decoction, syrup, and powder. It has a mucilaginous and sweetish taste, and an agreeable smell. In a large dose it vomits and purges violently, but does not remove worms from operating in this way, but in small doses which sit easy upon the stomach; from which it would appear that the anthelmintic power is a specific one.

The *Andira inermis*, or cabbage tree. This is very similar to the former, and is employed in the same way.

The *Aspidium filix mas*, or male fern. This is much esteemed in the cure of tape-worm. Madam Noufer's mode of expelling the tape-worm, which seldom failed, is detailed under the article *Aspidium*.

The *Spigelia anthelmia*, and *Marylandica*, or Indian pinks, or worm grasses. These are acrid narcotics, and, though esteemed in their native places, are seldom given in this country.

The *Fucus helminthocorton*, or Corsican worm weed. This at one time got into great repute as a vermifuge, but has now fallen into neglect.

Mare's-milk. This has been given in Germany with great alleged success in expelling tape-worm. The dose is half a pint night and morning. No reliance is placed on this remedy in England.

A great variety of medicines have been at different times in vogue as vermifuges, which have now lost all reputation. These are noticed under their respective heads.

INVE'RSIO. Inversion. The turning of any thing inside out, or the state of any thing turned inside out.

Inversion of the uterus. See *Uterus, inversion of*.

INVOLUCE'LLUM. A partial involucrum. See *Involucrum*.

INVOLU'CRUM. (*um*, *i.* n.; from *in*, and *volvo*, to wrap up: because parts are inclosed by it.) A wrapper. I. In *Anatomy*.

1. A name of the pericardium.
2. A membrane which covers any part.

II. In *Botany*, a leafy calyx, remote from the flower: applied particularly to umbelliferous plants. From the part of the umbel in which it is placed, the involucrum is called,

1. *Universal*, being at the base of the whole umbel; as in *Coriandrum sativum*, *Scandix cerefolium*, and *Cornus mascula*.
2. *Partial*, called *involucellum*, at the bottom of each umbellula, or partial stalk of the umbel; as in *Daucus carota*.
3. *Dimidiate*, surrounding the middle of the stalk at the base of the umbel; as in *Æthusa cynapium*.

From the number of the involucre leaves,

4. *Monophyllous*; as in *Coriander* and *Hermas*.
5. *Triphyllous*; as in *Bupleurum junceum*.
6. *Polyphyllous*; as in *Bunium bulbocastanum*, and *Sium*.
7. *Pinnatifid*; as in *Daucus carota*, and *Sium angustifolium*.
8. *Reflex*, turned back; as in *Selinum monnieri*.

Solitary flowers rarely have an involucrum; yet it is found in the anemones.

INVOLU'TUS. Involute: rolled inwards. Applied to leaves, petals, &c., when their margins are turned inward; as in the leaves of *Pinguicula*, and petals of *Anethum*, *Pastinaca*, and *Bupleurum*.

I'ODATE. (*Iodas*, *atis*. f.) A compound of the iodic acid with a base.

Io'DES. (Ιωδες; from ιος, verdigris.) Æruginous; of the colour of verdigris. Applied by Hippocrates to green bilious matters ejected by vomiting — εμετοι ιωδεες.

IO'DIC ACID. *Acidum iodicum*. Oxiodic acid. A compound of iodine and oxygen. When iodine is brought into contact with protoxide of chlorine, the chlorine of the protoxide combines with one portion of the iodine, and its oxygen with another, whence a chloride of iodine and iodic acid result. The chloride, which is volatile, is driven off by heat, and the iodic acid remains. It is white and semi-transparent, of a strong acid and astringent taste, and destitute of smell. It forms salts, called *iodates*.

I'ODIDE. *Iode*. *Ioduret*. A compound of iodine with a simple body. Several of the iodides have been lately introduced into medicine.

Iodide of arsenic. This is strongly poisonous, and has only been used externally in some cases of herpes, in the form of a pomade, made with gr. iij. of the iodide to ℥j. of lard.

Iodide of barium. This has only been used externally to scrofulous swellings. An ointment may be made with gr. iv. of the iodide to ℥j. of lard.

Iodide of iron. See *Ferri iodidum*.

Iodide of sulphur. This has been employed by M. Biett in some tuberculous affections of the skin. An ointment is made, 5 parts of the iodide to 96 of lard, or 8 parts of iodide to 144 of lard.

Iodide of zinc. Dr. Ure recommends this

as a powerful external remedy for scrofulous tumours. The proportion for an ointment is a drachm of the iodide to an ounce of lard. Some prefer the iodide of zinc to the hydriodate of potash in such cases.

Iodi'na. See *Iodine.*

I'ODINE. (*Iodium, ii.* n. ; from ιωδες, violet coloured.) *Iodinium.* A simple body, accidentally discovered, in 1812, by De Courtois, a manufacturer of saltpetre at Paris. In his processes for procuring soda from the ashes of sea-weeds he found the metallic vessels much corroded; and, in searching for the cause of the corrosion, he made this important discovery.

Iodine derived its first illustration from Clement and Desormes, in their memoir, read at a meeting of the Institute.

In 1813 Sir H. Davy happened to be on a visit to Paris, receiving, amid the political convulsions of France, the tranquil homage due to his genius. "When Clement showed iodine to me," says Sir H. Davy, "he believed that the hydriodic acid was muriatic acid; and Gay Lussac, after his early experiments, made originally with Clement, formed the same opinion, and *maintained* it, when I *first* stated to him my belief that it was a new and peculiar acid, and that iodine was a substance analogous, in its chemical relations, to chlorine."

Iodine has been found in various marine productions: as Fucus cartilagineus, membranaceous, filamentosus, rubens, nodosus, serratus, siliquosus, palmatus, filum, digitatus, saccharinus, vesiculosus: the Ulva umbilicalis, pavonia, and linza; Spongia, Gorgonia, Doris, Venus, Ostrea, &c.

Iodine has been lately ascertained to exist in the mineral kingdom by M. Vauquelin, who found it in a Mexican mineral labelled *virgin silver in serpentine.* It was contained in this mineral in the proportion of 18·5 parts in 100.

It is from the incinerated sea-weed, or kelp, that iodine in quantities is to be obtained. Dr. Wollaston first communicated a precise formula for extracting it. Dissolve the soluble part of kelp in water. Concentrate the liquid by evaporation, and separate all the crystals that can be obtained. Pour the remaining liquid into a clean vessel, and mix with it an excess of sulphuric acid. Boil this liquid for some time. Sulphur is precipitated, and muriatic acid driven off. Decant off the clear liquid, and strain it through wool. Put it into a small flask, and mix it with as much black oxide of manganese as we used before of sulphuric acid. Apply to the top of the flask a glass tube, shut at one end. Then heat the mixture in the flask. The iodine sublimes into the glass tube. None can be obtained from sea-water.

Iodine is a solid, of a greyish-black colour and metallic lustre. It is often in scales similar to those of micaceous iron ore, sometimes in rhomboidal plates, very large and very brilliant. Its fracture is lamellated, and it is soft and friable to the touch. Its taste is very acrid, though it be very sparingly soluble in water. It gives a deep brown stain to the skin, which soon vanishes by evaporation. In odour, and power of destroying vegetable colours, it resembles very dilute aqueous chlorine. It dissolves in 7000 parts of water. The solution is of an orange-yellow colour, and in small quantity tinges raw starch of a purple hue.

It melts at 227° F., and is volatilised, under the common pressure of the atmosphere, at the temperature of 350°. The vapour is of a rich violet colour. It evaporates pretty quickly at ordinary temperatures. Boiling water aids its sublimation, as is shown in the above process of extraction.

Iodine forms with sulphur a feeble compound, of a greyish-black colour, radiated like sulphuret of antimony. When it is distilled with water iodine separates.

Iodine and phosphorus combine with great rapidity at common temperatures, producing heat without light. From the presence of a little moisture small quantities of hydriodic acid gas are exhaled.

Oxygen expels iodine from both sulphur and phosphorus.

Oxygen unites with iodine, forming iodic acid. See *Iodic acid.*

Hydrogen, whether dry or moist, does not seem to have any action on iodine at ordinary temperatures; but, if we expose a mixture of hydrogen and iodine to a red heat in a tube, they unite together, and hydriodic acid is produced. See *Hydriodic acid.*

Charcoal has no action upon iodine, either at a high or low temperature. Several of the common metals, on the contrary, as zinc, iron, tin, mercury, attack it readily, even at a low temperature, provided they be in a divided state.

The compound of iodine and zinc, or iodide of zinc, is white.

Iron is acted on by iodine in the same way as zinc; and a brown iodide results, which is fusible at a red heat.

The iodide of tin is very fusible.

Antimony presents, with iodine, the same phenomena as tin.

The iodides of lead, copper, bismuth, silver, and mercury are insoluble in water, while the iodides of the very oxidisable metals are soluble in that liquid.

There are two iodides of mercury; the one yellow, the other red; both are fusible and volatile, the yellow or prot-iodide contains one half less iodine than the deut-iodide. The latter, when crystallised, is of a bright crimson colour. See *Hydrargyri iodidum.*

From all the above recited facts it is concluded that iodine is a simple body. In its specific gravity, lustre, and magnitude of its prime equivalent, it resembles the metals; but, in all its chemical agencies, it is analogous to oxygen and chlorine.

Iodine exerts a very powerful action on the animal economy. In an overdose it is a violent poison. Orfila swallowed 6 grains, and was immediately affected with heat, constriction of the throat, nausea, eructation, salivation, and cardialgia. In ten minutes he had copious bilious vomitings, and slight colic pains. Hi

pulse rose from 70 to about 90 beats in the minute. By swallowing large quantities of mucilage, and by emollient clysters, he recovered, and felt nothing next day but slight fatigue. About 70 or 80 grains proved a fatal dose to dogs. They usually died on the fourth or fifth day.

Iodine, properly administered, is a medicine of great efficacy. Its most obvious action is that of stimulating the capillary circulation throughout the system, and increasing the activity of the absorbents. Hence it is particularly adapted to scrofulous and other chronic enlargements of the glands, and to enlargements of the abdominal viscera. It has been regarded as a specific in scrofula, but on very insufficient grounds, since its general action above alluded to is quite sufficient to explain its beneficial effects in many strumous affections. It has been found useful as an emmenagogue; and it frequently produces good effects in syphilis, acting apparently in a manner somewhat analogous to mercury. It has been used with various success in schirrus, chronic enlargements of the joints, periostitis, chronic hydrocephalus, and many other cases. It is used internally and externally in the form of tincture and ointment. See *Tinctura iodinii* and *Unguentum iodinii*. It is less frequently given alone, however, than in combination with the hydriodate of potash, which renders it more easily soluble in water. The common dose of iodine is from gr. ¼ to gr. i. twice or thrice a day.

Iodo-nitric acid. See *Iodo-sulphuric acid.*

Iodo-phosphoric acid. See *Iodo-sulphuric acid.*

I'ODOSULPHU'RIC ACID. *Acidum iodosulphuricum.* When sulphuric acid is poured, drop by drop, into a concentrated and hot aqueous solution of iodic acid, there immediately results a precipitate of iodosulphuric acid, possessed of peculiar properties. Analogous acids are produced by the action of the nitric and phosphoric acids on iodine. These acids act powerfully on the metals, and dissolve gold and platina.

I'ODOUS ACID. *Acidum iodosum.* The acid obtained by distilling equal parts of chlorate of potash and iodine.

IO'NTHUS. (*us, i.* m. Ιονθος.) 1. The down on the face which precedes the beard.

2. A small tubercle on the face; a variety of acne. See *Acne.* Various derivations have been given of this word, as from ανθος, a flower, in allusion to the age of the subject; from ονθος, dung, because the pimple defiles the face, —a very improbable derivation given by Blancard; others have derived it, as improbably, from ιον, a violet, and ανθος, a flower; the *Etymologicon Magnum* derives it απο τοῦ εις τα ανω ιεναι την τριχα ὡς ανθος βλασταvουσαν.

IO'TACI'SMUS. (*us, i.* m.; from ιωτα, the Greek letter ι.) A defect in the organs of speech, which renders a person incapable of pronouncing the letter *J* or *G* soft.

IPECACUA'NHA. (*a, æ.* f.) Ipecacuan. According to Decandolle, the term ipecacuanha, in South America, implies generally *vomiting root*; and, therefore, it is applied to the roots of very different species of plants. The plant, however, which we have described from Professor Brotero's description, published in the sixth volume of the Linnæan Transactions, and the Psycotria *emetica*, which Mutis says yields the Peruvian grey ipecacuan, are the plants that yield the varieties of the root brought to this country. The title of ipecacuan is generally given to the roots of the following plants, besides those mentioned in South America: Viola *parviflora*, V. *Ipecacuanha*, V. *Calceolaria*, Cynanchum *Ipecacuanha*, C. *tomentosum*, and Asclepias *currassavica*; and sometimes to Euphorbia *Ipecacuanha*, Dorstenia *Brasiliensis*, and D. *arifolia*. In St. Domingo several species of Ruellia, which provoke vomiting, are named false ipecacuan. *Nouveau Dictionnaire d'Histoire Naturelle*, art. *Ipecacuanha*. Dr. A. T. Thomson has found very little of the white ipecacuan in any of the specimens of the ipecacuan of the shops which he has examined. Both the grey and the brown varieties of the root are brought to this country, packed in bales, from Rio Janeiro. Both are in short, wrinkled, variously bent and contorted pieces, which break with a resinous fracture. The grey is about the thickness of a small quill, full of knots and deep circular fissures, that nearly reach down to a white woody vascular cord that runs through the heart of each piece; the external part is compact, brittle, and looks smooth; the brown is smaller, more wrinkled, of a blackish brown colour on the outside, and white within: the white is woody, and has no wrinkles.

In choosing ipecacuanha, the larger roots, which are compact, and break with a resinous fracture, having a whitish grey, somewhat semi-transparent appearance in the inside of the cortical part, with a pale straw-coloured medullary fibre, are to be preferred.

It is impossible to ascertain at what period the effects of this root were first known in America, where the Indians used it as an emetic before their connexion with Europeans: but although Piso described its uses fully, in his Natural History of Brazil, so early as 1618, and brought the root to Europe, yet it was scarcely used by Europeans before the year 1700. It was carried to France by a French physician, of the name of Le Gras, in 1672; but it did not attract general notice until it was, a third time, introduced by a French merchant, of the name of Grenier, who brought 150 lbs. of it from Spain in 1686, with which trials were made at the Hotel Dieu. Helvetius first made known its use in dysentery, and was rewarded by Louis XIV. with 1000*l.* sterling for the discovery.

The entire root is inodorous, but the powder has a faint disagreeable odour. The taste is bitter, subacrid, and extremely nauseous. Water at 212° takes up rather more than eight parts in twenty of ipecacuan, but decoction destroys the emetic power of the root: alkohol takes up four parts, and proof spirit six and a half; and the alkoholic is more emetic than the aqueous solution. Various analyses of ipecacuanha have been made in order to detect its emetic principle, but the most satisfactory is that of MM. Magendie and Pelletier. After digesting the powdered root in double its weight of ether, in

order to separate any fatty matter, the remainder was treated with four times its weight of highly rectified alkohol, until it ceased to become coloured even when aided by heat. These tinctures, after being allowed to cool, and to deposit some flakes of wax which were separated by filtration, were then evaporated to dryness, and the residue redissolved in water: acetate of lead being added to the watery infusion, a precipitate formed, which, when edulcorated and diffused through water, was exposed to a current of sulphuretted hydrogen gas to separate the lead; after which the liquid, being filtered and evaporated to dryness, afforded a substance of a peculiar nature, which they termed *Emetine*, and on which it was experimentally demonstrated that the emetic properties of the root depend. *Emetine*, when pure, is of a reddish brown colour, solid, and pulverulent, nearly inodorous, and has a slightly bitter, acrid, but not nauseous taste. When exposed to a heat stronger than that of boiling water, it is decomposed, furnishing water, carbonic acid, some oil, and acetic acid, charcoal being left. It is little soluble in water, and does not deliquesce in a moist atmosphere. It is soluble in alkohol, but not in ether. To detail the action of other chemical agents on this body it is here unnecessary; the results are sufficient to characterise it as a substance *sui generis*. Besides emetine, ipecacuanha has been found, by the experiments of the above chemists, to contain oil, wax, gum, starch, and lignin.

The medicinal value of ipecacuanha depends, undoubtedly, on the quantity of emetine it contains; and this varies in the three varieties of the root found in the shops. MM. Magendie and Pelletier obtained 16 parts of it in 100 of the cortical part of brown ipecacuanha, the root of the psycotria *emetica* of Mutis; 14 in 100 of the gray ipecacuanha, the root of the callicocca *ipecacuanha*; and 5 only in 100 of the white ipecacuanha, the root of the viola *emetica*. The woody pith even of the brown variety contains very little emetine, and hence it should be separated in reducing the root to the form of powder.

Experiments made with emetine on animals prove that it is emetic and purgative, in doses of half a grain, and exerts a specific action on the lungs and mucous membrane of the intestinal canal, and has also narcotic properties: that it may be employed instead of ipecacuanha in every case in which this medicine is useful, the dose being more easily regulated, and the effects more certain. When taken in an overdose its action can be instantly paralysed by decoction of galls. These experiments are at variance with those of Dr. Irvine, which led him to conclude that the watery solution of ipecacuan is more emetic than the alcoholic, the reverse being found to be the case.

The powder of ipecacuanha is apt to become inert by keeping; and therefore it should be preserved in small phials, well corked, and not exposed to the light. Long-continued boiling also renders it inert.

Ipecacuanha, when administered in large doses, is emetic; in smaller ones diaphoretic and expectorant; and in still smaller doses it acts as a stomachic, stimulating and giving energy to the digestive organs. As an emetic it is mild, safe, and certain in its operation; but it is a mistake that, when given in larger doses than are necessary, it does not operate more violently, but only in a shorter space of time. It does not act so quickly as many other emetic substances; but it evacuates, completely, the contents of the stomach, and does not so much weaken it as antimonial emetics. It is given at the commencement of continued fevers, the progress of which is sometimes cut short by its operation; and it is, also, frequently found to stop the paroxysm of an intermittent, when given immediately before the accession of the cold stage. At the commencement of inflammation of the pharynx, larynx, and trachea, when the inflammation does not run very high, in cynanche tonsillaris, purulent ophthalmy, abscess, and every case in which it is necessary to evacuate the stomach, or to increase the energy of the absorbent system by full vomiting, ipecacuan has been found useful. As an emetic, however, it is contraindicated when there is any reason for suspecting inflammation of the encephalon, passive hæmorrhage, or hernia; and in the advanced stage of typhus fevers, when the pulse is feeble, and the strength much diminished; but in these instances all emetics are hurtful. In doses sufficient to excite nausea, without producing vomiting, ipecacuan is given with excellent effects in dysentery and obstinate diarrhœa; in which cases its efficacy seems to arise in a great degree from the nausea, which is kept up by the repetition of the small doses, diminishing the arterial excitement, and determining to the surface; and partly, also, as Cullen supposed, from its producing a steady determination of the peristaltic motion of the intestines downwards. Perhaps, also, to these first-mentioned effects of the nausea may be attributed much of the benefit which results from the use of ipecacuan in spasmodic asthma, dyspnœa, pertussis, and epilepsy. In the first of these diseases its emetic power is taken advantage of to relieve the paroxysm, after which it is given in repeated small doses to prevent its return. In nauseating doses, also, owing to the nausea lessening the force of the circulation, it has been employed with the best success in uterine and pulmonary hæmorrhages. As a sudorific, it is used in acute rheumatism, arthritic affections, dropsy, and other diseases in which sweating is necessary. It is generally given, in these cases, in combination with opium and neutral salts, according to the mode introduced by Dover (see *Pulvis ipecacuanhæ compositus*). But we have found it in combination with opium alone, in a larger proportion, more efficacious, particularly in rheumatism. Its expectorant powers have been found exceedingly useful in catarrhal affections, pneumonia after bleeding, and in the early stage of phthisis, in which its diaphoretic effect is also beneficial.

The emetic operation of ipecacuan is quickened by combining it with tartarised antimony: and, on the contrary, it is counteracted by opium, by vegetable infusions containing tannin,

and by vegetable acids. Opium, however, is rendered less narcotic when combined with ipecacuan, although its power of allaying pain is not diminished, while the sudorific effect of the ipecacuan is much augmented by the combination. We do not, however, agree in opinion with those who think, that it is to be relied upon as an antidote against the deleterious effects of opium; its emetic effect being too slow, and checked by the opium. The infusion of nutgalls is the only certain and powerful antidote for an overdose of ipecacuan, instantly rendering it inert. Idiosyncracy occasions some persons to be affected with the most distressing sensation of suffocation, by the effluvia of this root.

Ipecacuan is exhibited in substance, and in aqueous and vinous infusions: and, on the continent, a syrup of it is used for children. The dose of the powder to produce full vomiting, is from grs. xv. to ℈ss.; and of the aqueous infusion, which is made by macerating for an hour ℈ij. of the powdered root in f ℥vj. of boiling water, and filtering, f ℥j. or f ℥jss. may be given every half hour till it excite vomiting. The emetic effect is continued, and rendered easier to the patient, by drinking, in the intervals of vomiting, large draughts of tepid water. For producing the other effects of ipecacuan, it is given in doses of one, two, or three grains, generally in the form of pills, and repeated every four or five hours: but although its sudorific effect, when begun, is aided and kept up by the use of warms fluids, yet these must not be drank soon after the dose has been taken.

Officinal preparations. *Pulvis ipecacuanhæ compositus*, L. D. *Vinum ipecacuanhæ*, L. E. D. — *A. T. Thomson.*

IPOMŒ'A. (*a*, *æ*. f.; so called by Linnæus from ἰψ, which he unaccountably mistakes for the convolvulus plant, whereas it means a creeping sort of worm that infests and corrodes vines, and *ὁμοιος*, like. By this appellation he evidently intended to express the close resemblance of *Ipomœa* to the genus *convolvulus*, with which it agrees in habit altogether.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*.

IPOMŒA QUA'MOCLIT. *Batata peregrina*. The cathartic potatoe. If about two ounces of the root are eaten at bed-time, they gently open the bowels by morning.

IQUETA'IA. The inhabitants of the Brazils give this name to the *Scrofularia aquatica*, which is there celebrated as a corrector of the ill flavour of senna.

IRACU'NDUS. (From *ira*, anger: so called because it contributes to the expression of anger.) The abductor muscle of the eye.

IRI'DIUM. (*um*, *ii*. n.; so called from *iris*, the rainbow, on account of the variety of colours exhibited by its salts.) A metal found with another called osmium, in the black powder left after dissolving platinum. See *Platinum*.

I'RIS. (*is*, *idis*. f.; a rainbow: so called because of the variety of its colours.) I. In *Anatomy*, the septum between the anterior and posterior chambers of the eye, which is perforated in the middle by the pupil. See *Oculus*.

II. In *Botany*. 1. The *flower-de-luce*, from the resemblance of its flowers to the rainbow.

2. The name of a genus of plants in the Linnæan system. Class, *Triandria*; Order, *Monogynia*.

IRIS FLORENTINA. Florentine iris, or orris. The root of this plant, *Iris — corollis barbatis, caule foliis altiore subbifloro, floribus sessilibus*, of Linnæus, which is indigenous to Italy, in its recent state is extremely acrid, and, when chewed, excites a pungent heat in the mouth, that continues several hours: on being dried, this acrimony is almost wholly dissipated; the taste is slightly bitter, and the smell agreeable, and approaching to that of violets. The fresh root is cathartic, and for this purpose has been employed in dropsies. It is now chiefly used in its dried state, and ranked as a pectoral and expectorant, and hence has a place in the *trochisci amyli* of the pharmacopœias.

Iris, florentine. See *Iris florentina*.

IRIS GERMANICA. The systematic name of the common iris, or orris, or flower-de-luce. *Iris nostra*. The fresh roots of this plant, *Iris — corollis barbatis, caule foliis altiori multifloro, floribus inferioribus pedunculatis*, of Linnæus, have a strong disagreeable smell, and an acrid, nauseous taste. They are powerfully cathartic, and are given in dropsical diseases, where such remedies are indicated.

Iris nostra. See *Iris germanica*.

Iris palustris. See *Iris pseudacorus*.

IRIS PSEUDA'CORUS. The systematic name of the yellow water-flag: called also, *Iris palustris; Gladiolus luteus; Acorus adulterinus*, and *Acorus vulgaris*. This indigenous plant, *Iris — imberbis, foliis ensiformibus, petalis alternis, stigmatibus minoribus*, is common in marshes, and on the banks of rivers. It formerly had a place in the London pharmacopœia, under the name of *Gladiolus luteus*. The root is without smell, but has an acrid styptic taste, and its juice, on being snuffed up the nostrils, produces a burning heat in the nose and mouth, accompanied by a copious discharge from these organs: hence it is recommended both as an errhine and sialagogue. Given internally, when perfectly dry, it possesses considerable astringent power. The expressed juice is said to be an useful application to serpiginous eruptions and scrofulous tumours.

Irish slate. See *Lapis hybernicus*.

IRI'TIS. (*is*, *idis*. f.; from *iris*, the name of a membrane of the eye. The more proper term is *Iriditis*.) Inflammation of the iris: it produces the symptoms of deep-seated or internal inflammation of the eye. See *Ophthalmitis*.

IRON. *Ferrum*. Of all the metals, there is none which is so copiously and so variously dispersed through nature as iron. In animals, in vegetables, and in all parts of the mineral kingdom, we detect its presence. Mineralogists are not agreed with respect to the existence of native iron, though immense masses of it have been discovered, which could not have been the products of art; but there is much in favour of

the notion that these specimens have been extracted by subterraneous fire. A mass of native iron, of 1600 pounds weight, was found by Pallas, on the river Denisei, in Siberia; and another mass of 300 pounds was found in Paraguay, of which specimens have been distributed every where.

There are a vast variety of iron ores: they may, however, be all arranged under the following genera; namely, sulphurets, carburets, oxides, and salts of iron. The sulphurets of iron form the ores called *pyrites*, of which there are many varieties. Iron in a state of carburet forms *plumbago*. Its combination with oxygen is very abundant, and forms the loadstone, the specular ores, and bloodstones. It is found combined with the carbonic, arsenic, &c. &c.

Properties of iron. — Iron is distinguished from every other metal by its magnetical properties. It is attracted by the magnet, and acquires, under various conditions, the property of attracting other iron. Pure iron is of a whitish grey, or rather bluish colour, very slightly livid; but when polished, it has a great deal of brilliancy. Its texture is either fibrous, fine-grained, or in dense plates. Its specific gravity varies from 7·6 to 7·8. It is the hardest and most elastic of all the metals. It is extremely ductile, and may therefore be drawn into wire as fine as a human hair; it is also more tenacious than any other metal, and yields with facility to pressure. It is extremely infusible, and when not in contact with the fuel, it cannot be melted by the heat which any furnace can excite: it is, however, softened by heat, still preserving its ductility; and when thus softened, different pieces may be united: this constitutes the valuable property of *welding*. It is very dilatable by heat, It is the only metal which takes fire by the collision of flint. Heated in contact with air it becomes oxidised. If intensely and briskly heated, it takes fire with scintillation, and becomes a black oxide. It combines with carbon, and forms what is called *steel*. It combines with phosphorus in a direct and an indirect manner, and unites with sulphur readily by fusion. It decomposes water in the cold slowly, but rapidly when ignited. It decomposes most of the metallic oxides. All acids act upon iron. Very concentrated sulphuric acid has little or no effect upon it, but when diluted it oxidises it rapidly. The nitric acid oxidises it with great vehemence. Muriate of ammonia is decomposed by it. Nitrate of potass detonates very vigorously with it. Iron is likewise dissolved by alkaline sulphurets. It is capable of combining with a number of metals. It does not unite with lead or bismuth, and very feebly with mercury. It detonates by percussion with the oxygenated muriates.

Method of obtaining iron. — The general process by which iron is extracted from its ores, is first to roast them by a strong heat, to expel the sulphur, carbonic acid, and other mineralisers which can be separated by heat. The remaining ore, being reduced to small pieces, is mixed with charcoal, or coke; and is then exposed to an intense heat, in a close furnace, excited by bellows; the oxygen then combines with the carbon, forming carbonic acid gas during the process, and the oxide is reduced to its metallic state.

The metal thus obtained, and called smelted, pig, or cast iron, is far from being pure, always retaining a considerable quantity of carbon and oxygen, as well as several heterogeneous ingredients. According as one or other of these predominates, the property of the metal differs. Where the oxygen is present in a large proportion, the colour of the iron is whitish grey; it is extremely brittle, and its fracture exhibits an appearance of crystallisation: where the carbon exceeds, it is of a dark grey, inclining to blue, or black, and is less brittle. The former is the *white*, the latter the *black crude iron of commerce*. The *grey* is intermediate to both.

To obtain the iron *more pure*, or to free it from the carbon with which it is combined in this state, it must be refined by subjecting it to the operations of melting and forging By the former, in which the metal is kept in fusion for some time, and constantly kneaded and stirred, the carbon and oxygen it contains are partly combined, and the produced carbonic acid gas is expelled: the metal at length becomes viscid and stiff: it is then subjected to the action of a very large hammer, or to the more equal, but less forcible pressure of large rollers, by which the remaining oxide of iron, and other impurities, not consumed by the fusion, are pressed out. The iron is now no longer granular nor crystallised in its texture; it is fibrous, soft, ductile, malleable, and totally infusible. It is termed forged, wrought, or bar iron, and is the metal in a purer state, though far from being absolutely pure.

The compounds of iron are the following: —

I. *Oxides;* of which the existence of two only is well established.

1. *Protoxide.* — This is the base of the native carbonate of iron, and of the sulphate. Its existence was inferred some years ago by Gay Lussac; but it has not yet been obtained in an insulated form. Its salts, particularly when in solution, absorb oxygen from the atmosphere with great rapidity. This protoxide is always formed when metallic iron is put into diluted sulphuric or muriatic acid; and its composition may be determined by collecting and measuring the hydrogen gas which is simultaneously evolved. The composition of this oxide has not been precisely determined. It is composed of eight parts of oxygen united with 27·16 parts of iron according to Berzelius, with 27·8 according to Stromeyer, and with 28·3 according to Gay Lussac.

Protoxide of iron is precipitated from its salts as a white hydrate by pure alkalis, as a white carbonate by alkaline carbonates, and as a white ferrocyanate by ferrocyanate of potash. The two former precipitates when exposed to the air, become first green and then red, and the latter first green and then blue. Infusion of gall produces no change of colour. Sulphuretted hydrogen does not act if the protoxide is united with any of the stronger acids; but alkaline

hydrosulphurets cause a black precipitate of protosulphuret of iron.

2. *Peroxide.* — The peroxide or red oxide is a natural product, known to mineralogists under the name of *red hæmatite*. It may be artificially procured by dissolving iron in nitro-muriatic acid, and adding an alkali. The hydrate of the red oxide subsides, which is of a brownish red colour, and identical in composition with the mineral called *brown hæmatite*. It consists of 40 parts or one equivalent of the peroxide, and 9 parts or one equivalent of water.

Peroxide of iron combines with most of the acids, forming salts, the greater number of which are red. Its presence may be detected by very decisive tests. The pure alkalis precipitate it as a hydrate. Alkaline carbonates have a similar effect, peroxide of iron not forming a permanent salt with carbonic acid. With ferrocyanate of potash it forms Prussian blue. See *Prussian blue*. Sulphocyanate of potash forms with it a deep blood-red, and infusion of galls a black colour. Sulphuretted hydrogen converts the peroxide into protoxide of iron, with deposition of sulphur. Peroxide of iron is not magnetic.

The researches of several chemists, such as Gay Lussac, Berzelius, Bucholz, and Thomson, leave no doubt that the oxygen contained in the blue and red oxides of iron, is in the ratio of one to one and a half. Consequently, the peroxide consists of 28 parts or one equivalent of iron, and 12 parts or an equivalent and a half of oxygen; and its equivalent is 40: hence it is properly a *sesquioxide*.

The *black oxide*, which was long regarded as a protoxide, is now found to be a mixture in variable proportions of the two oxides above described.

II. *Chlorides* of iron; of which there are two.

1. The *protochloride* may be procured by heating to redness, in a glass tube with a very small orifice, the residue which is obtained by evaporating to dryness the green muriate of iron. It is a fixed substance, requiring a red heat for its fusion. It has a greyish variegated colour, a metallic splendour, and a lamellar texture.

2. The *deutochloride* may be formed by the combustion of iron wire in chlorine gas, or by gently heating the green muriate in a glass tube. It is of a light yellowish brown colour, and crystallises in small plates which have an irridescent appearance.

III. For the *iodide* of iron, see *Ferri iodure-tum*.

IV. *Sulphurets* of iron; of which, according to Porrett, there are four, though only two are usually described, his protosulphuret and persulphuret.

V. *Carburets* of iron. These compounds form steel, and probably cast iron, though the latter contains also some other ingredients. Black lead, at least when artificially prepared, is also a carburet of iron. See *Plumbago*.

VI. Iron unites also with *phosphorus* and with *bromine*.

VII. *Salts* of iron. These are noticed under their respective heads.

Medical virtues. — The general medicinal properties of iron, and the several preparations of it, are to constringe the fibres, to quicken the circulation, to promote the different secretions in the remoter parts, and at the same time to repress inordinate discharges into the intestinal tube. By the use of chalybeates, the pulse is very sensibly raised, the colour of the face, though before pale, changes to a florid red; the alvine, urinary, and cuticular excretions are increased.

When given improperly, or to excess, iron produces headach, anxiety, heats the body, and often causes hæmorrhages, or even vomiting, pains in the stomach, spasms, and pains of the bowels.

Iron is given in most cases of debility and relaxation; in passive hæmorrhages; in dyspepsia, hysteria, and chlorosis; in most of the cachexiæ; and it has been recommended by some as a specific in cancer. Where either a preternatural discharge, or suppression of natural secretions, proceeds from a languor or sluggishness of the fluids, and weakness of the solids, this metal, by increasing the motion of the former and the strength of the latter, will suppress the flux, or remove the suppression; but where the circulation is already too quick, the solids too tense and rigid, where there is any stricture, or spasmodic contraction of the vessels, iron, and all the preparations of it, will aggravate both diseases. Iron probably has no action on the body when taken into the stomach, unless it be oxidised; but during its oxidisement hydrogen gas is evolved, and accordingly we find that fœtid eructations and black fæces are considered as proofs of the medicines having taken effect. It can only be exhibited internally in the state of filings, which may be given in doses from five to twenty grains. Iron wire is to be preferred for pharmaceutical preparations, both because it is the most convenient form, and because it is the purest iron.

The medicinal preparations of iron now in use are. —

1. The sesquioxide. See *Ferri sesquioxidum*.
2. The sulphate. See *Ferri sulphas*.
3. Tartarised iron. See *Ferri potassio-tartras*.
4. The solution of alkaline iron. See *Ferri alkalini liquor*.
5. The tincture of the acetate of iron. See *Tinctura ferri acetatis*.
6. The tincture of the muriate of iron. See *Tinctura ferri sesquichloridi*.
7. The tincture of ammoniated iron. See *Tinctura ferri ammoniochloridi*.
8. Steel wine. See *Vinum ferri*.
9. Ammoniated iron. See *Ferri ammonio-chloridum*.
10. The red oxide. See *Oxidum ferri rubrum*.
11. The black oxide. See *Oxydum ferri nigrum*.

IRRITABI'LITY. (*Irritabilitas, atis.* f.; from *irrito*, to provoke.) *Vis insita*, of Haller. *Vis vitalis*, of Gærtner. *Oscillation*, of Boerhaave. *Tonic power*, of Stahl. *Muscular power*, of Bell. *Inherent power*, of Cullen.

The contractility of muscular fibres, or a property *peculiar* to muscles, by which they contract upon the application of certain stimuli, without a consciousness of action. This power may be seen in the tremulous contraction of muscles when lacerated, or when entirely separated from the body in operations. Even when the body is dead to all appearance, and the nervous power is gone, this contractile power remains till the organisation yields, and begins to be dissolved. It is by this inherent power that a cut muscle contracts and leaves a gap, that a cut artery shrinks and grows stiff after death. This irritability of muscles is so far independent of nerves, and so little connected with feeling, which is the province of the nerves, that upon stimulating any muscle by touching it with caustic, or irritating it with a sharp point, or driving the electric spark though it, or exciting with the metallic conductors, as those of silver or zinc, the muscle instantly contracts, although the nerve of that muscle be tied; although the nerve be cut so as to separate the muscle entirely from all connection with the system; although the muscle be separated from the body; although the creature upon which the experiment is performed may have lost all sense of feeling, and have been long apparently dead. Thus, a muscle cut from the limb, trembles and palpitates a long time after; the heart, separated from the body, contracts when irritated; the bowels, when torn from the body, continue their peristaltic motion, so as to roll upon the table, ceasing to answer to stimuli only when they become stiff and cold; and too often, in the human body, the vis insita loses the exciting power of the nerves, and then palsy ensues; or, losing all governance of the nerves, the vis insita, acting without the regulating power, causes partial or general convulsions. Even in vegetables, as in the sensitive plant, this contractile power lives. Thence comes the distinction between the irritability of muscles and the sensibility of nerves: for the *irritability* of muscles survives the animal, as when it is active after death; survives the life of the part, or the feelings of the whole system, as in universal palsy, where the vital motions continue entire and perfect, and where the muscles, though not obedient to the will, are subject to irregular and violent actions; and it survives the connection with the rest of the system, as when animals very tenacious of life are cut into parts: but *sensibility*, the property of the nerves, gives the various modifications of sense, as vision, hearing, and the rest; gives also the general sense of pleasure or pain, and makes the system, according to its various conditions, feel vigorous and healthy, or weary and low. And thus the eye feels, and the skin feels; but their appointed stimuli produce no emotions in these parts; they are sensible, but not irritable. The heart, the intestines, the urinary bladder, and all the muscles of voluntary motion, answer to stimuli with a quick and forcible contraction; and yet they hardly feel the stimuli by which these contractions are produced, or, at least, they do not convey that feeling to the brain. There is no consciousness of present stimulus in those parts which are called into action by the impulse of the nerves, and at the command of the will: so that muscular parts have all the irritability of the system, with but little feeling, and that little owing to the nerves which enter into their substance; while nerves have all the sensibility of the system, but no motion.

The discovery of this singular property belongs to our countryman Glisson; but Baron Haller must be considered as the first who clearly pointed out its existence, and proved it to be the cause of muscular motion.

The laws of irritability, according to Dr. Chrichton, are,—1. After every action in an irritable part, a state of rest, or cessation from motion, must take place before the irritable part can be again incited to action. If, by an act of volition, we throw any of our muscles into action, that action can only be continued for a certain space of time; the muscle becomes relaxed, notwithstanding all our endeavours to the contrary, and remains a certain time in that relaxed state, before it can be again thrown into action. 2. Each irritable part has a certain portion or quantity of the principle of irritability which is natural to it, part of which it loses by action, or from the application of stimuli. 3. By a a process wholly unknown to us, it regains this lost quantity, during its repose, or state of rest. In order to express the different quantities of irritability in any part, we say that it is either more or less redundant, or more or less defective. It becomes redundant in a part when the stimuli which are calculated to act on that part are withdrawn or withheld for a certain length of time, because then no action can take place; while, on the other hand, the application of stimuli causes it to be exhausted, or to be deficient, not only by exciting action, but by some secret influence, the nature of which has not yet been detected; for it is a circumstance extremely deserving of attention, that an irritable part, or body, may be suddenly deprived of its irritability by powerful stimuli, and yet no apparent muscular or vascular action takes place at the time. A certain quantity of spirits taken at once into the stomach, kills almost as instantaneously as lightning does; the same thing may be observed of some poisons, as opium, distilled laurel-water, the juice of the cerbera ahovai, &c. 4. Each irritable part has stimuli which are peculiar to it, and which are intended to support its natural action: thus, blood, which is the stimulus proper to the heart and arteries, if, by any accident, it gets into the stomach, produces sickness or vomiting. If the gall, which is the natural stimulus to the ducts of the liver, the gall-bladder, and the intestines, is by any accident effused into the cavity of the peritonæum, it excites too great action of the vessels of that part, and induces inflammation. The urine does not irritate the tender fabric of the kidneys, ureters, or bladder, except in such a degree as to preserve their healthy action; but if it be effused into the cellular membrane, it brings on such a violent action of the vessels of these parts as to produce gangrene. Such stimuli are called *habitual* stimuli of parts. 5. Each irritable part

differs from the rest in regard to the quantity of irritability which it possesses. This law explains to us the reason of the great diversity which we observe in the action of various irritable parts; thus the muscles of voluntary motion can remain a long time in a state of action, and if it be continued as long as possible, another considerable portion of time is required before they regain the irritability they lost; but the heart and arteries have a more short and sudden action, and their state of rest is equally so. The circular muscles of the intestines have also a quick action and short rest. The urinary bladder does not fully regain the irritability it loses during its contraction for a considerable space of time, the vessels which separate and throw out the menstral discharge, act, in general, for three or four days, and do not regain the irritability they lose for a lunar month. 6. All stimuli produce action in proportion to their irritating powers. As a person approaches his hand to the fire, the action of all the vessels in the skin is increased, and it glows with heat; if the hand be approached still nearer, the action is increased to such an unusual degree as to occasion redness and pain; and if it be continued too long, real inflammation takes place; but if this heat be continued, the part at last loses its irritability, and a sphacelus or gangrene ensues. 7. The action of every stimulus is an inverse ratio to the frequency of its application. A small quantity of spirits taken into the stomach, increases the action of its muscular coat, and also of its various vessels, so that digestion is thereby facilitated. If the same quantity, however, be taken frequently, it loses its effect. In order to produce the same effect as at first, a larger quantity is necessary; and hence the origin of dram-drinking. 8. The more the irritability of a part is accumulated, the more that part is disposed to be acted upon. It is on this account that the activity of all animals, while in perfect health, is much livelier in the morning than at any other part of the day; for, during the night, the irritability of the whole frame, and especially that of the muscles destined for labour, viz. the muscles for voluntary action, is re-accumulated. The same law explains why digestion goes on more rapidly the first hour after food is swallowed than at any other time; and it also accounts for the great danger that accrues to a famished person upon first taking in food. 9. If the stimuli which keep up the action of any irritable body be withdrawn for too great a length of time, that process on which the formation of the principle depends is gradually diminished, and at last entirely destroyed. When the irritability of the system is too quickly exhausted by heat, as happens in some warm climates, the application of cold invigorates the frame, because cold is a mere diminution of the overplus of that stimulus which was causing the rapid consumption of the principle. Under such, or similar circumstances, therefore, cold is a tonic remedy; but if, in a climate naturally cold, a person were to go into a cold bath, and not soon return into a warmer atmosphere, it would destroy life, just in the same manner as many poor people who have no comfortable dwellings, are often destroyed from being too long exposed to the cold in winter. Upon the first application of cold, the irritability is accumulated, and the vascular system therefore is exposed to great action; but, after a certain time, all action is so much diminished, that the process, whatever it be, on which the formation of the irritable principle depends, is entirely lost.

IRRITATION. *Irritatio.* The action of a stimulus on a part endowed with irritability, or the state of a part the irritability of which is excited by a stimulus. The term is applied to the action both of natural and morbid stimuli, but more frequently the latter. It is very often incorrectly used; thus physiologists speak of exciting irritation in a nerve, whereas irritability is conceived to reside only in the *muscular fibre.*

I'SATIS. (*is, is.* f. Ισατις of Dioscorides, and *Isatis*, of Pliny; the derivation of which is unknown.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia;* Order, *Siliquosa.*

Isatis tinctoria. *Glastum.* The systematic name of the plant used for dyeing, called woad. It is said to be astringent.

I'sca. Ισκα. A sort of fungous excrescence growing on the oak and hazel. The ancients used it as the moderns use the moxa. — *Paulus Ægineta.*

ISCHÆ'MON. (*on, onis.* m.; from ισχω, to restrain, and αἱμα, blood.) Any medicine which restrains bleeding.

ISCHIA'DIC. *Ischiatic.* Appertaining to the ischium.

Ischiadic artery. A branch of the internal iliac, which passes out at the ischiadic foramen, between the puriform and gemelli muscles, in company with the great sciatic nerve. It is distributed within the pelvis to the rectum and the internal obturator, puriform, coccygeal, and levator ani muscles; after its passage out of the pelvis, it is distributed chiefly to the rotator muscles of the thigh. It sends a twig down on the surface of the sciatic nerve.

Ischiadic foramen. See *Innominatum os.*

Ischiadic notch. See *Innominatum os.*

Ischiatic. See *Ischiadic.*

Ischiatic nerve. See *Sacro-sciatic nerve.*

ISCHI'AGRA. (*a, æ.* f.; from ισχιον, the haunch, and αγρα, a seizure.) This name has been given to hip gout, and also to neuralgia of the sacro-sciatic nerve. See *Sciatica.*

I'SCHIAS. (*as, adis.* f. Ισχιας; from ισχιον, the hip.) The hip gout. A rheumatic affection of the hip-joint. See *Rheumatismus.*

Ischiatoce'le. See *Ischiocele.*

I'schio-caverno'sus. Chaussier's name for the *Erector penis.*

ISCHIOCE'LE. (*e, es.* f.; from ισχιον, the hip, and κηλη, a tumour.) A hernia at the ischiadic foramen. See *Hernia.*

Ischio-clitoreana arteria. The branch of the internal pudic, which furnishes the two arteries of the clitoris.

Ischio-clitorianus. The nerve of the clitoris — a branch of the pudic.

Ischio-clitoride'us. The *Erector clitoridis.* — *Dumas.*

Ischio-coccyge'us. The muscle more generally called *coccygeus.*

Ischio-femoralis. Chaussier's name for the *Adductor magnus femoris.*

Ischio-femoro-peroneus. The *biceps femoris.* — *Chaussier.*

Ischio-perinea'lis. The *transversus perinei muscle.* — *Chaussier.*

Ischio-popliti-tibial. The *semi-membranosus* muscle. — *Chaussier.*

Ischio-prætibialis. The *semi-tendinous* muscle. — *Chaussier.*

Ischio-prosta'ticus. A name given by some anatomists to the muscular fibres, otherwise called *Transversus perinei alter.*

Ischio-pubi-femoralis. The *Adductor magnus femoris.* — *Dumas.*

Ischio-pubi-prostaticus. The *Transversus perinæi.* — *Dumas.*

Ischio-trochanteria'ni. The gemelli muscles. — *Chaussier.*

I'SCHIUM. (*um, i.* n.; from *ισχις*, the loin: so named because it is near the loin.) A bone of the pelvis of the fœtus, and a part of the os innominatum of the adult. See *Innominatum os.*

Ischnopho'nia. (*a, æ.* f.; from *ισχνος*, slender, and *φωνη*, the voice.) A tenuity or shrillness of the voice.

Ischure'ticus. (From *ισχουρια*, a suppression of the urine.) Having the power of relieving a suppression of the urine.

ISCHU'RIA. (*a, æ.* f.; from *ισχω*, to restrain, and *ουρον*, the urine.) A retention of urine. When there is a frequent desire of making water, attended with much difficulty in voiding it, the complaint is called a dysury; and when there is a total retention of urine, it is known by the name of an ischury. Both ischuria and dysuria are distinguished into acute, when arising in consequence of inflammation; and chronic, when proceeding from any other cause, such as calculus, &c.

The causes which give rise to these diseases, are an inflammation of the urethra, occasioned either by venereal sores, or by a use of acrid injections, tumour or ulcer of the prostate gland, inflammation of the bladder or kidneys, considerable enlargements of the hæmorrhoidal veins, a lodgment of indurated fæces in the rectum, spasm at the neck of the bladder, the absorption of cantharides applied externally, or taken internally, and excess in drinking either spirituous or vinous liquors; but particles of gravel sticking at the neck of the bladder, or lodging in the urethra, and thereby producing irritation, prove the most frequent cause. Gouty matter falling on the neck of the bladder, will sometimes occasion these complaints.

There are four species of ischuria: —

1. *Ischuria renalis,* coming after a disease of the kidneys, with a troublesome sense of weight or pain in that part.

2. *Ischuria ureterica,* after a disease of the kidneys, with a sense of pain or uneasiness in the course of the ureters.

3. *Ischuria vesicalis,* marked by a frequent desire to make water, with a swelling of the hypogastrium, and pain at the neck of the bladder.

4. *Ischuria urethralis,* marked by a frequent desire to make water, with a swelling of the hypogastrium, and pain of some part of the urethra.

In dysury there is a frequent inclination to make water, attended with a smarting pain, heat, and difficulty in voiding it, together with a sense of fulness in the region of the bladder. The symptoms often vary, however, according to the cause which has given rise to it. If it proceed from a calculus in the kidney or ureter, besides the affections mentioned, it will be accompanied with nausea, vomiting, and acute pains in the loins and regions of the ureter and kidney of the side affected. When a stone in the bladder, or gravel in the urethra, is the cause, an acute pain will be felt at the end of the penis, particularly on voiding the last drops of urine, and the stream of water will either be divided into two, or be discharged in a twisted manner, not unlike a corkscrew. If a scirrhus of the prostate gland has occasioned the suppression or difficulty of urine, a hard indolent tumour, unattended with any acute pain, may readily be felt in the perinæum, or by introducing the finger in ano.

Dysury is seldom attended with much danger, unless, by neglect, it should terminate in a total obstruction. Ischury may always be regarded as a dangerous complaint, when it continues for any length of time, from the great distension and often consequent inflammation which ensue. In those cases where neither a bougie nor a catheter can be introduced, the event, in all probability, will be fatal, as few patients will submit to the only other means of drawing off the urine before a considerable degree of inflammation and tendency to gangrene have taken place.

Isinglass. See *Ichthyocolla.*

ISO'CHRONOS. (From *ισος*, equal, and *χρονος*, time.) Isochronous. Applied to two or more actions which are performed in an equal length of time; thus the pulsations of the arteries throughout the body are isochronous, or very nearly so.

Iso'crates. (From *ισος*, equal, and *κερανυμι*, to mix.) Wine mixed with an equal quantity of water.

Iso'dromus. (From *ισος*, equal, and *δρομος*, a course.) The same as *Isochronos.*

ISOME'RIC. (From *ισος*, equal, and *μερος*, a part.) 1. In *Chemistry;* Berzelius applies this term to compounds which consist of the same components united in the same ratio, and yet differ in their chemical properties. Thus *olefiant gas* and *quadru-carburetted hydrogen gas,* are each composed of six parts by weight of *carbon,* and one of *hydrogen,* or one atom of carbon to one of hydrogen; they are, nevertheless, very distinct substances, and endowed with distinct properties. There is some reason to believe that there are two kinds of isomeric compounds — those in which the constituents are the same and combined in the same ratio, but the equivalents of the substances are different; and those in which the constituents are

the same, and the ratio of their combination the same, and the equivalents of the resulting substance the same. Thus, in the instance above cited, the olefiant gas and the quadru-carburetted hydrogen, each consist of carbon and hydrogen united in the same proportion; but their equivalents are different, for the density of a volume of the former is to that of a volume of the latter as 1 to 2, and their equivalent numbers are respectively 14 and 28. Again, the *cyanic* and *fulminic* acids are thought to consist of *cyanogen* and *oxygen* in the same proportions, and their equivalent numbers are considered the same. The composition of the fulminic acid, however, is still somewhat doubtful; and, on the whole, the existence of the second kind of isomeric compound here mentioned, cannot be considered as fairly established. For the probable explanation of the nature of isomeric compounds, see art. *Carburetted hydrogen, sub fine.*

2. In *Botany;* regular flowers have been called *Isomeric.*

ISO'MERISM. (From ισος, equal, and μερισμος, a portioning out.) The state of an isomeric compound. See *Isomeric.*

Isosta'thmos. Ισοσταθμος. A medicine for a cough used by the Greeks.

Issue. See *Fonticulus.*

I'STHMION. (From ισθμος, a narrow piece of land between two seas.) The fauces, or passage between the mouth and gullet.

Isthmus vieussenii. The ridge surrounding the remains of the foramen ovale, in the right auricle of the human heart.

Itch. See *Scabies.*

Itch, baker's. See *Psoriasis.*

Itch, grocer's. See *Psoriasis.*

Itch, bricklayer's. See *Psoriasis.*

Itinera'rium. (From *iter*, a way.) The catheter; also a staff used in cutting for the stone.

I'va frute'scens. A corymbiferous plant, which produces the Mexican quinquina, celebrated in its native country as a febrifuge.

Iva pecanga. See *Smilax sarsaparilla.*

IVORY. The tusk of the elephant. It is an intermediate substance between bone and horn. The dust is occasionally boiled to form jelly, instead of isinglass, for which it is a bad substitute. In 100 parts there are 24 gelatine, 64 phosphate of lime, and 0·1 carbonate of lime.

Ivy. See *Hedera.*

Ivy, ground. See *Glecoma hederacea.*

Ivy-gum. See *Hedera helix.*

I'XIA. (*a, æ.* f.; from ιξος, glue.) 1. A name of the *Carlina gummifera*, from its viscous juice.

2. The name of a genus of plants. Class, *Triandria;* Order, *Monogynia.*

Ixia. Ιξια. A varix.

Ixine. See *Atractylis gummifera.*

J.

JACE'A. (*a, æ.* f.) 1. A name given to several herbs, among others to the pansy.

2. The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia frustranea.*

Jaceranta tinga. See *Acorus calamus.*

Jacinthus. See *Hyacinthus.*

Jack-by-the hedge. See *Erysimum alliaria.*

JACOBÆ'A. (*a, æ.* f.; named because it was dedicated to St. James, or because it was directed to be gathered about the feast of that saint.) See *Senecio Jacobæa.*

JACTITATION. *Jactitatio.* The constant tossing arising from restlessness in acute diseases.

Jalap. See *Jalapa.*

JALA'PA. (*a, æ.* f.; from *Chalapa*, or *Xalapa*, in New Spain, whence it is brought.) Jalap. See *Convolvulus jalapa.*

Jalapium. See *Convolvulus jalapa.*

Jalapa alba. White jalap. See *Convolvulus mecoacan.*

Jaleyrac. A village of Auvergne, where there is a mineral spring containing carbonates of soda and lime.

Jamaica bark. See *Cinchona caribæa.*

Jamaica pepper. See *Myrtus pimenta.*

Ja'mblichi sales. A preparation with sal-ammoniac, some aromatic ingredients, &c., so called from Jamblichus, the inventor.

James's analeptic pills. These are made of equal parts of James's powder, ammoniacum, and the aloes and myrrh pill beat up with tincture of castor.

James's powder. An antimonial medicine, much used in this country. The inventor, a man of great skill, and a regularly bred physician, the author of a Medical Dictionary, called it his *fever powder*, and was so successful in his practice with it, that it obtained very great reputation, which it still in some measure retains. Probably, the success of Dr. James was in great measure owing to his free use of the bark, which he always gave as largely as the stomach would bear, as soon as he had completely evacuated the primæ viæ by the use of his antimonial preparation, with which at first he used to combine some mercurial. His specification, lodged in Chancery, is as follows: "Take antimony, calcine it with a continued

protracted heat, in a flat, unglazed earthen vessel, adding to it from time to time a sufficient quantity of any animal oil and salt, well dephlegmated; then boil it in melted nitre for a considerable time, and separate the powder from the nitre by dissolving it in water." The real recipe has been concealed, and a false one published in its stead. See also *Antimonialis pulvis.*

JA'NITOR. (*or, oris.* m. A door keeper; from *janua*, a gate.) The pylorus, from its being at the entrance of the intestine.

JANUA EMPLASTRUM. A plaster described by Lemery. Betony was a principal ingredient in it.

JANUARII CATAPLASMA. A cataplasm invented by Januarius, and described by Marcellus Empiricus. It was used in diseases of the spleen.

JANITRIX. (Fem. of *Janitor*, a door keeper.) The *vena portæ.*

Japan earth. See *Acacia catechu.*

JAPO'NICA TERRA. (So called from Japan, the place it came from.) See *Acacia catechu.*

JASMINEÆ. A natural family of plants, of which the genus jasminum is the type.

JA'SMINUM. (*um, i.* n.; from the Arabic *jasmen.*) 1. The name of a genus of plants in the Linnæan system. Class, *Diandria;* Order, *Monogynia.*

2. The pharmacopœial name of the jessamine. See *Jasminum officinale.*

JASMINUM OFFICINALE. The systematic name of the jessamine-tree. The flowers of this beautiful plant have a very fragrant smell, and a bitter taste. They afford, by distillation, an essential oil, which has been used as a liniment in paralysis and rheumatism.

JASPACHA'TES. An ancient name of Jaspar agate, which was anciently used in hepatic diseases, dropsies, &c.

JASPER. *Jaspis.* A sub-species of rhomboidal quartz. It was formerly used as an amulet against hæmorrhage, &c.

JA'TROPHA. (*a, æ.* f.; from ιαομαι, to heal, and τρεφω, to nourish.) The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Monadelphia.* The purging nut or physic nut. The plants of this genus grow in South America and the West Indies.

JATROPHA CURCAS. The systematic name of a plant, the seeds of which resemble the castor-oil seeds, and which is also called, *Aipima coxera, Aipicoca, Ricinus major, Ricinoides, Pineus purgans, Pinhones indici, Faba cathartica, Nux cathartica, Nux Americana,* and *Nux barbadensis.* The seed or nut is oblong and black, the produce of the *Jatropha — foliis cordatis angulatis,* of Linnæus. It affords a quantity of oil, which is given, in many places, as the castor-oil is in this country, to which it is very nearly allied. The seeds of the *Jatropha multifida* are of an oval and triangular shape, of a pale brown colour, are called purging-nuts, and give out a similar oil.

JATROPHA ELASTICA. The juice of this plant affords an elastic gum. See *Caoutchouc.*

JATROPHA MANIHOT. This is the plant which affords the Cassada root; called also, *Cassada, Cacavi, Cassave, Cassava, Pain de Madagascar, Ricinus minor, Maniot, Yucca, Manibar, Aipi, Aipima coxera, Aipipoca,* and *Janipha.* The leaves are boiled, and eaten as we do spinach. The root abounds with a milky juice, and every part, when raw, is a strong poison. It is remarkable that the poisonous quality is destroyed by heat: hence the juice is boiled with meat, pepper, &c., into a wholesome soup, and what remains after expressing the juice, is formed into cakes or meal.

Cassada roots yield a great quantity of starch, called tapioca, exported in little lumps by the Brazilians, and now well-known to us as a diet for sick and weakly persons.

Jaundice. See *Icterus.*

JECORA'RIA. (From *jecur*, the liver: so named from its supposed efficacy in diseases of the liver.) 1. The name of a plant. See *Marchantia polymorpha.*

2. An epithet of the basilic vein, because it was usually opened in diseases of the liver.

JECTIGA'TIO. A name given by Van Helmont to a species of epilepsy.

JE'CUR. (*ur, oris,* or *jecinoris.* neut.) The liver. See *Liver.*

JECUR UTERINUM. The placenta has been thus called, from a supposed similitude of its office with that of the liver.

JEJU'NUM. (*um, i.* n.; from *jejunus*, hungry or empty.) *Jejunum intestinum.* The second portion of the small intestines, so called because it is generally found empty in the dead body. See *Intestine.*

Jelly. See *Gelatine.*

Jerusalem cowslips. See *Pulmonaria.*

Jerusalem oak. See *Chenopodium botrys.*

Jerusalem sage. See *Pulmonaria officinalis.*

Jessamine. See *Jasminum.*

JESUITA'NUS CORTEX. (From *jesuita*, a jesuit.) A name of the Peruvian bark, because it was first introduced into Europe by Cardinal de Lugo, a jesuit. See *Cinchona.*

Jesuiticus cortex. See *Cinchona.*

Jesuit's bark. See *Cinchona.*

JESUIT'S DROPS. *Balsamum polychrestum. Elixir venereum.* Composed of guiac, peruvian balsam, and sarsaparilla.

Jew's ears. See *Peziza auricula.*

Jew's pitch. See *Bitumen judaicum.*

Joint. See *Articulus,*

Jointed. See *Articulatus.*

Jointed leaf. See *Articulatus.*

JUDÆI COMPOSITIO. An application consisting of lime, nitre, and urine, recommended by Celsus against gangrene.

JUDÆI EMPLASTRUM. The name of two plasters, one recommended by Celsus for a broken head, and the other by Aëtius as a detergent and incarnative.

Judaicus lapis. See *Lapis judaicus.*

JUDICATO'RII DIES. Critical days. See *Critical days.*

JUGA'LIS. (From *jugum*, a yoke.) Jugal: appertaining to the cheek or os jugale.

JUGALE OS. (So called from its resemblance; or because it is articulated to the bone of the upper jaw, like a yoke.) *Os malæ. Os zygomaticum.* The cheek-bone. The ossa malarum

are the prominent square bones which form the upper part of the cheeks. They are situated close under the eyes, and make part of the orbit. Each of these bones has three surfaces to be considered. One of these is exterior and somewhat convex. The second is superior and concave, serving to form the lower and lateral parts of the orbit. The third, which is posterior, is very unequal and concave, for the lodgment of the lower part of the temporal muscle. Each of these bones may be described as having four processes, formed by their four angles. Two of these may be called *orbitar* processes. The superior one is connected with the orbitar process of the os frontis; and the inferior one with the malar process of the maxillary bone. The third is connected with the temporal process of the sphenoid bone; and the fourth forms a bony arch, by its connection with the zygomatic process of the temporal bone. In infants, these bones are entire and completely ossified.

JUGALIS SUTURA. The *sagittal* suture, and also the *zygomatic* suture, has been so called.

JUGAME'NTUM. The cheek-bone.

JU'GLANS. (*ans, andis.* f.; *quasi Jovis glans*, Jupiter's nut, from its excellence.) 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Polyandria.* The walnut tree.

2. The pharmacopœial name of the walnut. See *Juglans regia.*

JUGLANS REGIA. The systematic name of the walnut tree. The tree which bears the walnut is the *Juglans —foliolis ovalibus glabris subserratis subæqualibus*, of Linnæus. It is a native of Persia, but cultivated in this country. The unripe fruit, which has an astringent bitterish taste, and has been long employed as a pickle, is the part which was directed for medicinal use by the London College, on acconut of its anthelmintic virtues. An extract of the green fruit is the most convenient preparation, as it may be kept for a sufficient length of time, and made agreeable to the stomach of the patient, by mixing it with cinnamon-water.

The *putamen*, or green rind of the walnut, has been celebrated as a powerful anti-venereal remedy, for more than a century and a half; and Petrus Borellus has given directions for a decoction not unlike that which is commonly called the Lisbon diet-drink, in which the walnut, with its green bark, forms a principal ingredient. Ramazzini, whose works were published early in the present century, has likewise informed us that, in his time, the green rind of the walnut was esteemed a good anti-venereal remedy in England. This part of the walnut has been much used in decoctions during the last fifty years, both in the green and dried state: it has been greatly recommended by writers on the Continent, as well as by those of our own country; and is, without doubt, a very useful addition to the decoction of the woods. Pearson has employed it during many years, in those cases where pains in the limbs and indurations of the membranes have remained after the venereal disease has been cured by mercury; and he informs us, that he has seldom directed it without manifest advantage.

Brambilla and Girtanner also contend for the anti-venereal virtues of the green bark of the walnut: but the result of Pearson's experience will not permit him to add his testimony to theirs. "I have given it," says he, "in as large doses as the stomach could retain, and for as long a time as the strength of the patients, and the nature of their complaints, would permit; but I have uniformly observed, that if they who take it be not previously cured of *lues venerea*, the peculiar symptoms will appear, and proceed in their usual course, in defiance of the powers of this medicine. The *Decoctum Lusitanicum* may be given with great advantage in many of those cutaneous diseases which are attended with aridity of the skin; and I have had some opportunities of observing, that when the putamen of the walnut has been omitted, either intentionally or by accident, the same good effects have not followed the taking of the decoction, as when it contained this ingredient."

JU'GULAR. (*Jugularis;* from *jugulum*, the throat.) Belonging to the throat.

JUGULAR VEINS. The veins so called run from the head down the sides of the neck, and are divided, from their situation, into external and internal. The *external*, or *superficial jugular vein*, receives the blood from the frontal, angular, temporal, auricular, sublingual, or ranine, and occipital veins. The *internal*, or *deep-seated jugular vein*, receives the blood from the lateral sinuses of the dura mater, the laryngeal and pharyngeal veins. Both jugulars unite, and form, with the subclavian vein, the superior vena cava, which terminates in the superior part of the right auricle of the heart.

JU'GULUM. (*um, i.* n.; from *jugum*, a yoke: because the yoke is fastened to this part.) The throat, or anterior part of the neck.

JUJUBA. (An Arabic word.) Jujube. See *Rhamnus zizyphus.*

Jujube. See *Rhamnus zizyphus.*

JU'LEP. (*Julapium. Julepus;* from *julab*, Arabic.) Those forms of medicine which are now called mixtures, were formerly called juleps, as *camphor julep*, the *mistura camphoræ.*

July-flower. See *Dianthus.*

JUMNISUM. Yeast. — *Ruland.*

JUMBLE BEADS. The seeds of the *Abrus precatorius.*

JU'NCUS. (*us, i.* m. An old Latin word, *à jungendo*, say the etymologists, from the use of the plants which bear this name in joining or binding things together.) The name of a genus of plants in the Linnæan system. Class, *Hexandria;* Order, *Monogynia.*

Jungus odoratus. See *Andropogon.*

Juniper. See *Juniperus communis.*

Juniper gum. See *Juniperus communis.*

JUNIPERUM VINUM. Wine impregnated with the flavour of juniper berries.

JUNI'PERUS. (*us, i.* f.; from *juvenis*, young, and *pario*, to bring forth: so called because it produces its young berries while the old ones are ripening.) 1. The name of a genus of plants. Class, *Diœcia;* Order, *Monodelphia.*

2. The pharmacopœial name of the common juniper. See *Juniperus communis.*

Juniperus communis. The systematic name of the juniper-tree. *Juniperus — foliis ternis patentibus mucronatis, baccis longioribus*, of Linnæus. Both the tops and berries of this indigenous plant have entered our pharmacopœias; the latter are usually preferred, and are brought chiefly from Holland and Italy. Of their efficacy as a stomachic, carminative, diaphoretic, and diuretic, there are several relations by physicians of great authority; and medical writers have also spoken of the utility of the juniper in nephritic cases, uterine obstructions, scorbutic affections, and some cutaneous diseases. Our pharmacopœias direct the essential oil, and a spirituous distillation of the berries, to be kept in the shops. From this tree is also obtained a concrete resin, which has been called sandarach, or gum-juniper. It exudes in white tears, more transparent than mastich. It is almost totally soluble in alkohol, with which it forms a white varnish that dries speedily. Reduced to powder it is called *pounce*, which prevents ink from sinking into paper from which the exterior coating of size has been scraped away.

Juniperus lycia. This, according to some, is the plant which yields the *olibanum* or frankincense, but the true plant is now generally believed to be the *Boswellia serrata.* Frankincense has received different appellations, according to its different appearances: the single tears are called simply *Olibanum*, or *thus;* when two are joined together, *thus masculum;* and when two are very large, *thus femininum;* if several adhere to the bark, *thus corticosum;* the fine powder which rubs off from the tears, *mica thuris;* and the coarser, *manna thuris.* The gum-resin that is so called, is the juice of the *Juniperus — foliis ternis undique imbricatis ovatis obtusis*, and is brought from Turkey and the East Indies; but that which comes from India is less esteemed. It is said to ooze spontaneously from the bark of the tree, appearing in drops, or tears, of a pale yellowish, and sometimes of a reddish colour. Olibanum has a moderately strong and not very agreeable smell, and a bitterish, somewhat pungent taste: in chewing, it sticks to the teeth, becomes white, and renders the saliva milky. Laid on a red-hot iron, it readily catches flame, and burns with a strong diffusive and not unpleasant smell. On trituration with water, the greatest part dissolves into a milky liquor, which, on standing, deposits a portion of resinous matter. The gummy and resinous parts are nearly in equal proportions; and though rectified spirit dissolves less of the olibanum than water, it extracts nearly all its active matter. In ancient times, olibanum seems to have been in great repute in affections of the head and breast, coughs, hæmoptysis, and in various fluxes, both uterine and intestinal; it was also much employed externally. Recourse is now seldom had to this medicine, which is superseded by myrrh, and other articles of the resinous kind. It is, however, esteemed by many as an astringent; and, though not in general use, is considered as a valuable medicine in fluor albus, and debilities of the stomach and intestines: applied externally in the form of plaster, it is said to be corroborant, &c., and with this intention it forms the basis of the *emplastrum thuris.*

Juniperus sabina. The systematic name of the common or barren savin-tree; called also, *Sabina, Savina, Sabina sterilis*, and *Brathu. Juniperus — foliis oppositis erectis decurrentibus, oppositionibus pyxidatis*, of Linnæus. Savin is a native of the south of Europe and the Levant; it has long been cultivated in our gardens, and from producing male and female flowers on separate plants, it was formerly distinguished into the barren and berry-bearing savin. The leaves and tops of this plant have a moderately strong smell of the disagreeable kind, and a hot, bitterish, acrid taste. They give out great part of their active matter to watery liquors, and the whole to rectified spirit. Distilled with water, they yield a large quantity of essential oil. Decoctions of the leaves, freed from the volatile principle by inspissation to the consistence of an extract, retain a considerable share of their pungency and warmth along with their bitterness, and have some degree of smell, but not resembling that of the plant itself. On inspissating the spirituous tincture, there remains an extract consisting of two distinct substances, of which one is yellow, unctuous, or oily, bitterish, and very pungent; the other black, resinous, less pungent, and subastringent. Savin is a powerful and active medicine, and has been long reputed one of the most efficacious in the materia medica, for producing a determination to the uterus, and thereby proving emmenagogue; it heats and stimulates the whole system very considerably, and is said to promote the fluid secretions. The power which this plant possesses (observes Dr. Woodville) in opening uterine obstructions, is considered to be so great, that we are told it has been frequently employed, and with too much success, for purposes the most infamous and unnatural. It seems probable, however, that its effects in this way have been somewhat overrated, as it is found very frequently to fail as an emmenagogue, though this, in some measure, may be ascribed to the smallness of the dose in which it has been usually prescribed by physicians; for Dr. Cullen observes, "savin is a very acrid and heating substance, and I have been often, on account of these qualities, prevented from employing it in the quantity necessary to render it emmenagogue. I must own, however, that it shows a more powerful determination to the uterus than any other plant I have employed; but I have been frequently disappointed in this, and its heating qualities always require a great deal of caution." Dr. Home appears to have had very great success with this medicine, for in five cases of amenorrhœa, which occurred at the Royal Infirmary at Edinburgh, four were cured by the sabina, which he gave in powder from a scruple to a drachm twice a day. He says it is well suited to the debile, but improper in plethoric habits, and therefore orders repeated bleedings before its exhibition. Country people give the juice from the leaves and young tops of savin mixed with milk to their children, in

order to destroy the worms: it generally operates by stool, and brings them away with it. The leaves, cut small, and given to horses, mixed with their corn, destroy the bots. Externally, savin is recommended as an escharotic to foul ulcers, syphilitic warts, &c. A strong decoction of the plant in lard and wax forms an useful ointment to keep up a constant discharge from blisters, &c. See *Ceratum sabinæ.*

JUNO. An alchemical name of atmospheric air.

JU'PITER. The ancient chemical name of tin, because supposed to be under the government of that planet.

JURISPRUDENCE, MEDICAL. Synonymous with *forensic medicine.*

JUS. (*s, uris.* n.) The Latin for broth or potage.

JU'SCULUM. (*um, i.* n.) The same.

JUSQUIA'MUS. Corrupted from *hyoscyamus.*

JUSSA. Gypsum. — *Ruland.*

JUSTI'CIA. (*a, æ.* f.; so named in honour of Mr. Justice, who published the British Gardener's Director.) The name of a genus of plants. Class, *Diandria;* Order, *Monogynia.*

JUSTICIA ADHATODA. A plant of Ceylon, supposed by the natives to have the power of expelling the dead fœtus.

JUVA'NTIA. Those means, whether dietetic, regiminal, or medicinal, which do good to sick people, as opposed to *Lædentia,* or those things which do them harm.

Juventus. See *Age.*

JUXTANGI'NA. (From *juxta,* near, and *angina,* a quinsy.) Inflammation of the muscles of the pharynx.

JUZAM. The Arabic name of the tubercular elephantiasis, or *Elephantiasis Græcorum.* See *Elephantiasis.*

K.

KAATH. See *Acacia catechu.*

KÆMPFE'RIA. (*a, æ.* f.; named after Kæmpfer, the Westphalian naturalist.) The name of a genus of plants. Class, *Monandria;* Order, *Monogynia.*

KÆMPFERIA GALA'NGA. The plant which affords the greater galangal root. It is aromatic, and has the mixed flavour of pepper and ginger.

KÆMPFERIA ROTUNDA. The systematic name of the plant which affords the officinal zedoary. *Zedoaria. Kæmpferia — foliis lanceolatis petiolatis,* of Linnæus. The roots of this plant are brought to us in long pieces, *zedoaria longa,* about the thickness of the little finger, two or three inches in length, bent, rough, and angular; or in roundish pieces, *zedoaria rotunda,* about an inch in diameter, of an ash colour on the outside, and white within. They have an agreeable camphoraceous smell, and a bitterish aromatic taste. Though formerly much esteemed against rheumatic affections, they are at present thought to possess little medicinal power, and are very seldom used.

Kajeputi oleum. See *Melaleuca.*

KA'LI. (An Arabian word: indeclinable.) The vegetable alkali. See *Potash.*

Kali acetatum. See *Potassæ acetas.*

Kali aeratum. See *Potassæ carbonas.*

Kali arsenicatum. See *Potassæ arsenias,* and *Arsenic.*

Kali citratum. See *Potassæ citras.*

Kali præparatum. See *Potassæ subcarbonas.*

Kali purum. See *Potassæ fusa.*

Kali sulphuratum. See *Sulphuretum potassæ.*

Kali tartarizatum. See *Potassæ tartras.*

Kali vitriolatum. See *Potassæ sulphas.*

Keel. See *Carina.*

Keeled. See *Carinatus.*

Keiri. See *Cheiranthus cheiri.*

KELP. Incinerated sea-weed. See *Barilla.*

KENOSPU'DIA. (Κενοσπουδια; from κενος, empty, and σπουδη, a study.) A Greek word for what is commonly called *a brown study.* Swediaur uses it to express *somnambulism.* When Latinised it should be written *Cenospudia.*

KERATONY'XIS. (From κερας, a horn, and νυσσω, to puncture.) A term used in Germany to designate an operation for cataract, in which the needle is passed through the cornea. (See *Cataract.*) The word should be written *ceratonyxis;* but the term is a bad one, and does not express the meaning intended, as it really signifies nothing but the puncturing of a horn.

KE'RMES. (*Kermes. Kermer,* Arabian.) *Granum tinctorium. Coccus baphica.* Round reddish grains, about the size of peas, found in Spain, Italy, and the south of France, adhering to the branches of the scarlet oak. They are the nidus of a minute red animalcule, called *Coccus quercus illicis.* The *Confectio alkermes,* now obsolete, was prepared with these, which were supposed to possess corroborant and astringent virtues.

KERMES MINERAL. *Kermes mineralis.* A hydro-sulphuretted oxide of antimony, so termed from its resemblance in colour to the insect of that name. See *Antimonii sulphuretum.* It was formerly much esteemed as a deobstruent and alterative. The dose is from 1 to 4 grains. It is now fallen out of use.

Kernel wort. See *Scrofularia.*

Ke'rva. See *Ricinus communis.*

KETCHUP. The prepared liquor of the mushroom, made by sprinkling salt on that vegetable, and collecting the fluid which escapes.

KEYSER'S PILLS. A once celebrated mercurial medicine, the method of preparing which

was purchased by the French government, and has since been published by Richard. The hydrargyrus acetatus is considered as an adequate substitute for the more elaborate form of Keyser. Richard concludes his account of Keyser's pills with observing, that he considers it to be, without exception, the most effectual remedy for the venereal disease hitherto discovered. But further trials of this remedy do not justify the sanguine accounts of its properties; though it may sometimes succeed when some of the other mercurial preparations have failed.

Kibes. A name for chilblains.

Kid. See *Capra hircus.*

KIDNEY. (*Ren, enis.* m.) An abdominal viscus, shaped like a kidney-bean, that secretes the urine. There are two kidneys, which are glandular bodies of a pale red colour, situated in the upper and back part of the abdomen, in the lumbar region. They are placed one on each side of the spine, extending from the eleventh pair of ribs to near the crista of the ossa ilia, and rest upon the diaphragm, large psoæ, quadrati lumborum, and transversales abdominis. The right kidney is situated at the under and back part of the large lobe of the liver, behind the colon, and is commonly a very little lower than the left, being supposed to be affected by the great lobe of the liver. The left kidney is placed at the under and back part of the spleen, and behind the left portions of the stomach, pancreas, and colon. The kidney is between four and five inches in length, but considerably less from the outer to the inner side, and less still from before backwards. It is rounded anteriorly, flattened posteriorly, convex and uniform at its outer margin, and has a deep depression or sinus towards the vertebræ, surrounded with unequal edges, where the renal vessels and nerves enter. It is a little broader behind than before, and a little broader and more curved above than below; from which circumstances, but more particularly from the disposition of the vessels, to be afterwards mentioned, it is easy to distinguish the right from the left kidney when taken out of the body. The right kidney is connected to the liver and duodenum, the left to the spleen, and both to the muscles on which they are placed, and to the renal glands and colon, by cellular substance, and by the peritoneum; which last, reflected from the liver and spleen to the kidneys, have by some been called the *ligaments* of the *kidneys.* They are also connected to the aorta and vena cava by their blood-vessels, and to the bladder of urine by the ureters. — They accompany the motions of the liver and spleen in the different states of respiration. Each kidney is surrounded by loose cellular substance, which commonly contains a considerable quantity of fat, from which it is termed *tunica adiposa.* The *tunica adiposa* covers not only the kidney, but the large vessels, and defends them from the pressure of the surrounding viscera. Under the tunica adiposa, there is a *membrane* composed of the original proper coat and cellular substance incorporated, which adheres closely to the kidney, and is reflected over the edges of the sinus, to be joined to the pelvis and large vessels. The surface of the kidney is commonly smooth and uniform, though sometimes it is irregular, in consequence of the lobes which originally form it not being completely incorporated. It consists of an outer part called *cortical,* and an inner termed *medullary.* The *cortical substance,* termed also *secerning,* surrounds the kidney, and is about a fourth or third part of an inch in thickness: it likewise sends in partitions, which separate the medullary parts from each other. The *medullary,* termed also *tubular* or *uriniferous substance,* is more compact and of a paler colour than the former, and is divided into a number of distinct columns, each of which terminates in a projection called *papilla,* vel *processus mammillaris.* The *papillæ* are merely the continuation of the uriniferous part, though frequently considered as a third division of the substance of the kidney. Each kidney has one, and sometimes more *arteries,* of great proportional size, which run transversely from the aorta, and a *vein* still larger than the artery, which terminates in the cava: they enter at the sinus of the kidney, and are included in cellular substance, which accompanies them throughout their course. The right renal artery is longer than the left, in consequence of the vena cava, behind which it passes, being placed upon the right side of the aorta. The artery, as it approaches the kidney, is divided into branches, which are afterwards minutely distributed through the cortical substance, forming arches and anastomoses; but these are found to be much less frequent than are commonly described; for a fine injection thrown into a branch of the artery, fills only the ramifications belonging to that branch. The small branches, after turning and winding in various directions, pass partly towards the surface of the kidney, where they form irregular *stars,* some of which supply the proper membrane. Others turn inwards in a waving direction, and form *corpuscles,* or *acini,* disposed after the manner of *clusters of small berries,* which can only be seen distinctly by the assistance of glasses, after a minute injection. The *corpuscles* were considered by Dr. Nichols as the globular terminations of blood-vessels, and termed by him *Globuli arteriarum termini;* but these globuli were afterwards observed by Mr. Hewson, and others, to consist of small vessels intimately intermixed. A fine injection thrown into the artery sometimes appears to fill the uriniferous tubes, and thereby to imitate the secretion of urine; but this experiment is more readily performed on some of the brute creation, as the horse, where the structure of the kidney seems to be more simple than in man. The *veins* returning from the extremities of the arteries, unite in the cortical substance of the kidney. The branches of the renal vein are much larger than those of the artery; they communicate freely, especially on the surface of the kidney, but correspond with them in their course. They form a large trunk on each side, which lies anterior to the corresponding artery, and runs transversely to the cava; the left, which is the longer of the two, passing across the fore part of the aorta. The *lymphatics* of the kidney run from without

inwards, and terminate in the lumbar glands, and afterwards in the thoracic duct. The superficial lymphatics are so small as seldom to be seen, excepting in the diseased state of this organ. The *nerves* are from the semilunar ganglion, formed by the great sympathetic and eighth pair. They compose a plexus which surrounds the blood-vessels, and accompanies them in the kidney. From the minute extremities of the renal artery, in the corpuscles situated in the cortical substance, the *uriniferous tubes* arise. They are mixed with some extremely small blood-vessels, and constitute the medullary substance of the kidney. By degrees they unite into larger tubes, which run in a radiated manner, the direction being from the outer edge or circumference, towards the sinus or inner part of the kidney. The radiated tubes, becoming still larger in their passage, terminate in the *papillæ*, which are of a compressed conical form, and at a little distance from each other. The *papillæ* are twelve or more in each kidney, the number varying according to that of the original lobes of which the kidney is composed, and likewise from some of the papillæ being occasionally incorporated with each other. Upon the points of the papillæ are the terminations of the uriniferous tubes — large enough to be distinguished by the naked eye —through which the urine distils from the substance of the kidney. Round the root of each papilla, a membranous tube arises, termed *infundibulum* or *calix*, which receives the urine from the papilla. The *infundibula* are commonly the same in number with the papillæ; the number, however, varying in different subjects, two or more of the papillæ sometimes opening into the same infundibulum. The infundibula join into two or three large trunks, at the sinus of the kidney, which afterwards form a dilatation of considerable size, of the shape of an inverted cone, and termed *pelvis* of the kidney. The *pelvis* is placed between the principal branches of the renal artery and vein, partly within, but the greater part of it without the body of the kidney, and contracts into a long tube, about the size of a goose-quill, called *ureter*.

Kidney, inflammation of. See *Nephritis.*

Kidney-shaped. See *Reniformis.*

Ki'dria terrestris. Barbadoes tar.

Kikekunemalo. A pure resin, very similar to copal, but of a more beautiful whiteness and transparency. It is brought from America, where it is said to be used medicinally, in the cure of hysteria, tetanus, &c. It forms the most beautiful of all varnishes.

Ki'ki. (*Kike*, Arabic.) See *Ricinus.*

Kina kina. See *Cinchona.*

KINATE. *Kinas.* A compound of the kinic acid, with a salifiable base.

Kincough. See *Pertussis.*

King's evil. See *Scrofula.*

King's yellow. See *Arsenic.*

KINIC ACID. (*Acidum kinicum*; from *kina*, a name of cinchona.) A peculiar acid found in all the species of the genus cinchona, and therefore called also cinchonic acid. Let a watery extract from hot infusions of the bark powder be made. Alkohol removes the resinous bark of this extract, and leaves a viscid residue, of a brown colour, which has hardly any bitter taste, and which consists of kinate of lime and a mucilaginous matter. This residue is dissolved in water, the liquor is filtered, and left to spontaneous evaporation in a warm place. It becomes thick like syrup, and then deposits by degrees crystalline plates, sometimes hexaedral, sometimes rhomboidal, sometimes square, and always coloured slightly of a reddish brown. These plates of kinate of lime must be purified by a second crystallisation. They are then dissolved in ten or twelve times their weight of water, and very dilute aqueous oxalic acid is poured into the solution, till no more precipitate is formed. By filtration, the oxalate of lime is separated, and the kinic acid, being concentrated by spontaneous evaporation, yields regular crystals. It is decomposed by heat. While it forms a soluble salt with lime, it does not precipitate lead or silver from their solutions. These are characters sufficiently distinctive. The kinates are scarcely known; that of lime constitutes seven per cent. of *cinchona*.

Kinki'na. See *Cinchona.*

KI'NO. (An Indian word.) *Gummi gambiense. Gummi rubrum adstringens gambiense.* A medicinal substance of which there are several varieties, supposed to be the produce of different trees. The *African kino*, which is the best, but seldom to be found genuine in the shops, is thought to be the produce of the *Pterocarpus erinaceus*; the *Botany Bay kino* of the *Eucalyptus resinifera*; the *East India* or *Amboyna kino* of the *Nauclea Gambir*. Besides these, there is said to be a *Jamaica kino*, the produce of the *Cocoloba uvivera*; but there is no such substance now to be found in our shops. The greater part of the kino at present used, is brought from the East Indies. The chemical composition of kino varies considerably in the different kinds; but the predominant principles in all are tannin and extractive matter. According to Vauquelin, it contains no gallic acid. Solution of pure potash or ammonia dissolves it, and there is no precipitate on the addition of water. It is stated, however, by Dr. A. T. Thomson, that these alkalis completely destroy the astringency of the kino. The best menstruum for kino is dilated alkohol. The medicinal virtues of kino are very similar, though inferior in power to those of catechu; and hence it is generally supplanted by the latter medicine. The dose of kino in substance is from ten grains to half a drachm. The officinal preparations are *Pulvis kino compositus*, L. D. *Tinctura kino*, L. E. D. *Electuarium catechu compositum*, E. D.

Ki'otome. *Kio'tomus.* (From κιων, a column, and τεμνω, to cut.) The name of an instrument devised by Desault, for dividing pseudo-membranous bands in the rectum and bladder. This, like all other similar words, should be spelled with *c* instead of *k*.

Kirchwasser. A liqueur distilled in Switzerland from the Machaleb cherry.

Kirkland's neutral cerate. This is prepared by melting ℥viij. of lead plaster, with

℥ iv. of olive oil, stirring in ℥ iv. of prepared chalk; adding to the mixture, when sufficiently cooled, ℥ iv. of acetic acid, and ʒ iij. of sugar of lead in powder; and lastly, stirring the whole till it is nearly cold.

Knee-holly. See *Ruscus.*

Knee-jointed. See *Geniculatus.*

Knee-pan. See *Patella.*

KNOX'S POWDER. This consists of eight parts of common salt, and three of chloride of lime. By dissolving an ounce of it in a tumbler of water, a solution is obtained similar to Labarraque's disinfecting fluid.

KOLTO. (A Polonese word.) The plica polonica, or plaited hair.

KOUMIS. A vinous liquid which the Tartars make by fermenting mares' milk. Something similar is prepared in the Orkneys and Shetland.

Krameria. See *Crameria.*

KRAME'RIC ACID. An acid found by Peschier in the rhatany root. See *Crameria triandra.*

KYMIA. A cucurbit — *Ruland.*

KYMIT. Sublimed cinnabar. — *Ruland.*

Kynanche. See *Cynanche.*

L.

LABARRAQUE'S disinfecting *fluid.* See *Calcis chloridum.*

LABDANUM FACTITIUM. A mixture of yellow wax, hog's lard, and ivory black.

La'bdanum. See *Ladanum.*

LABE'LLUM. (*um, i,* n.; a diminutive of *labrum.*) A little lip. Applied, in *Botany,* to the barba, or inferior lip of ringent and personate plants. See *Corolla.*

LABIA'TÆ. A natural family of plants which have labiate corollæ See *Labiatus.* They are all more or less aromatic.

LABIA'TUS. Labiate: lipped; having lips. Applied in Botany to corollæ, as those of mint, sage, rosemary, &c.

LA'BIUM. (*um, i.* n.; απο του λαβειν.) 1. In *Anatomy,* the lip of animals.

2. In *Botany,* applied to corols of plants, which are termed *unilabiate, bilabiate,* &c.; and from their position in certain flowers, *superior, inferior,* &c.

Labium leporinum. See *Hare-lip.*

LABIUM PUNDENDI. The parts forming the orifice of the female vagina exterior to the nymphæ, are called *labia pudendi.*

LABORATO'RIUM. (*um, i,* n.; from *laboro,* to labour.) A laboratory. A place properly fitted up for the performance of chemical operations.

Labour. See *Parturitio.*

Labour, premature. See *Abortion.*

LA'BYRINTH. (*Labyrinthus, i,* m. Λάβυρινθος.) In *Anatomy,* that part of the internal ear which is behind the cavity of the tympanum; it is constituted by the cochlea vestibulum, and semicircular canals. See *Auris.*

LAC. (*Lac, tis.* n.) 1. Milk. See *Milk.*

2. The name of a peculiar substance deposited by an insect on certain trees. See *Coccus.*

Lac ammoniaci. See *Mistura ammoniaci.*

Lac amygdalæ. See *Mistura amygdalæ.*

Lac asininum. See *Milk, asses.*

Lac assafœtidæ. See *Mistura assafœtidæ.*

Lac bubulum. See *Milk, cows.*

Lac capræ. See *Milk, goats.*

Lac caprinum. See *Milk, goats.*

Lac equinum. See *Milk, mares.*

Lac humanum. See *Milk, human.*

Lac pressum. The curd of milk.

Lac sulphuris. See *Sulphur præcipitatum.*

Lac vaccinum. See *Milk, cows.*

Lac villum. See *Milk, ewes.*

Lacca. See *Coccus lacca.*

LA'CCIC ACID. *Acidum laccicum.* A peculiar acid, of a wine yellow colour, obtained from stick-lac.

LA'CERUS. Rugged.

LA'CHRYMA. (*a, æ.* f. Δάκρυμα, a tear.) A tear. See *Tear.*

Lachryma abiegna. See *Terebinthina argentoratensis.*

LA'CHRYMAL. *Lachrymalis.* Of or belonging to the tears, or parts near where they are secreted; as lachrymal bone, duct, gland, &c.

LACHRYMAL APPARATUS. The parts which secrete and conduct the tears. These consist of the lachrymal gland which secretes the tears; of the puncta lachrymalia, and ducts, into which the tears pass from the eye and the eye-lids; of the lachrymal sac, which receives the tears from the lachrymal ducts; of the nasal duct, which conveys the tears from the sac downwards into the nose.

The lachrymal gland is situated within the orbit, at its upper and outer part, beneath the fossa in the orbitar plate of the frontal bone. It is about the size of a small almond, and it will be readily discovered, either by dividing the integuments of the upper eyelid, and then dissecting towards the cavity of the orbit, between the upper tarsus and the supra-orbitary ridge, or by dividing the conjunctiva uniting the upper tarsus to the eye, and then drawing the eye a little forwards. The gland is of a yellowish white colour, of an oval and flattened figure, and is connected with the surrounding parts by loose cellular tissue. It is composed of numerous small portions united by cellular tissue. Its excretory ducts are so small in the human subject that they are not easily discovered. Their

number is from six to eight. They leave the gland along its front edge, and descending between the tarsal ligament and the conjunctiva, perforate the latter towards the temporal side of the eye, and near the ciliary edge of the upper lid.

The *puncta lacrymalia* are two small orifices situated at the edges of the eye-lids, just within their ciliary margins, and towards the inner side of the eye. Each punctum is situated in the centre of a small eminence, and the two openings are opposite to each other, so that they meet when the eye is shut.

From the puncta lacrymalia, two small ducts are continued through the eye-lids to the lacrymal sac. The superior duct proceeds from the punctum, first a little upwards, and then turning inwards at an acute angle, is continued obliquely downwards and inwards close to the ciliary border of the upper lid, and immediately beneath the conjunctiva lining it. The inferior duct first descends, and then turning inwards at an acute angle, is continued obliquely upwards and inwards, and close to the ciliary border of the lower lid. In the latter part of their course, the two ducts following the direction of the edges of the lids, gradually approach each other, and then proceeding transversely behind the tendon of the orbicularis palpebrarum, terminate in the external part of the lacrymal sac. The two ducts may terminate in the sac by distinct orifices, or they may unite into a common duct just before they reach the sac.

The *lachrymal sac* is lodged in the groove formed by the os unguis, and by the nasal process of the superior maxillary bone. Above, it is closed and has a rounded form. Below it contracts, and is here continued into the nasal duct. The tendon of the orbicularis palpebrarum crosses the front of the sac transversely, at about one-fourth from the upper end. The sac is formed by the union of a fibrous with a mucous membrane. The fibrous membrane is expanded over the external side of the sac, and adheres to the margins of the groove in the bones lodging it.

The *nasal duct*, continued from the lower end of the lacrymal sac, descends obliquely backwards through the canal formed by the os unguis, by the superior maxillary and inferior spongy bones. It terminates in the nose on the outside of the inferior spongy bone, and at about one-third from its front extremity, by a small slit-like opening. The orifice is overhung by the spongy bone, so as to be concealed from view, until a part of the bone has been taken away. The nasal duct is formed only by the mucous membrane, which is continuous above, with the lining of the sac; below, with the pituitary membrane of the nose; and externally, is adherent to the periosteum of the bone surrounding it. The nasal sac and lacrymal sac are together about an inch and a quarter in length. — *Stanley.*

Lachrymal bone. See *Unguis os.*

LACHRYMAL DUCT. *Ductus lachrymalis.* The excretory duct of the lachrymal gland. See *Lachrymal apparatus.*

LACHRYMAL GLAND. *Glandula lachrymalis.* A glomerate gland situated above the external angle of the orbit in a depression of the frontal bone. Its use is to secrete the tears. See *Lachrymal apparatus.*

LACHRYMAL NERVE. (*Nervus lachrymalis.*) A branch of the ophthalmic nerve. See *Nervus system* and *Lachrymal apparatus.*

LACI'NIA. The segment of a fringed leaf or petal.

LACINIA'TUS. (From *Lacinia*, a fringe.) Laciniate: jagged, fringe like; cut into numerous irregular portions: applied to leaves, petals, &c.; as the leaves of the *Ranunculus parviflorus*, and *Geranium columbinum*, the petals of the *Reseda*. See *Erosus*

LACO'NICUM. (Because they were much used by the people of Laconia.) A stove or sweating-room.

LACQUER. A solution of lac in alkohol.

LA'CTATE. (*Lactas, atis.* f.; so named from its acid base.) A compound, formed by the union of the lactic acid with a base.

LACTA'TION. (*Lactatio, onis.* f.; from *lacteo*, to suckle.) The suckling of a child or other young animal.

LA'CTEAL. (*Lacteus*; from *lac*, milk: because the fluid they absorb looks like milk.)

1. In *Anatomy*, this term is applied to the absorbents of the mesentery, *vasa lactea*, which originate in the small intestines, and convey the chyle from thence to the thoracic duct. They are very tender and transparent vessels, possessed of an infinite number of valves, which, when distended with chyle, a milky or lacteal fluid, give them a knotty appearance. They arise from the internal surface of the villous coat of the small intestine, perforate the other coats, and form a kind of network, whilst the greater number unite one with another between the muscular and external coats. Thence they proceed between the laminæ of the mesentery to the conglobate glands. In their course they constitute the greater part of the glands through which they pass, being distributed through them several times, and curled in various directions. The lacteals having passed these glands, go to others, and at length seek those nearest the mesentery. From these glands, which are only four or five, or perhaps more, the lacteals pass out and ascend with the mesenteric artery, and unite with the lymphatics of the lower extremities, and those of the abdominal viscera, and then form a common trunk, the *thoracic duct*, which, in some subjects, is dilated at its origin, forming the *receptacalum chyli.* See *Nutrition.*

2. Milky.

3. Applied to designate a milk-white colour. See *Colour.*

LACTE'SCENS. (From *lac*, milk.) Lactescent: milky; abounding with milk, or a milk-like fluid. Applied to plants which have the sap of a white colour.

LACTIC ACID. Acid of milk. By evaporating sour whey to one eighth, filtering, precipitating with lime-water, and separating the lime by oxalic acid, Scheele obtained an aqueous solution of what he supposed to be a peculiar acid, which has accordingly been termed the *lactic.* Purified, it has a brown-yellow colour, and a sharp sour taste, which is much weakened by

diluting it with water. It is without smell in the cold, but emits, when heated, a sharp sour odour.

LACTICA. The name given by the Arabic writers to typhous fever.

LACTU'CA. (*a*, *æ*. f.; from *lac*, milk: named from the milky juice which exudes upon its being wounded.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia æqualis*. The lettuce.

2. The pharmacopœial name of the garden-lettuce, the *Lactuca sativa*.

Lactuca graveolens. See *Lactuca virosa*.

LACTUCA SATIVA. The systematic name of the lettuce. *Eunuchium*. It is esteemed as a wholesome aperient bitter anodyne, easy of digestion, but affording no nutriment. Lettuces appear to agree better with hot, bilious, melancholic temperaments, than the phlegmatic. The seeds possess a quantity of oily substance, which, triturated with water, forms an emulsion esteemed by some in ardor urinæ, and some diseases of the urinary passages. Lettuce was famous for the cure of the Emperor Augustus, and formed the opiate of Galen in his old age; a proof that, in the warmer climates, it must acquire an exaltation of its virtues above what is met with in this country.

LACTUCA SCARI'OLA. *Lactuca sylvestris*. *Scariola*. *Scariola gallorum*. This species possesses a stronger degree of bitterness than the *Lactua sativa*, and is said to be more aperient and laxative. It is nearly similar, in virtue as in taste, to endive unblanched.

Lactuca sylvestris. See *Lactuca scariola*.

LACTUCA VIROSA. The systematic name of the opium, or strong-scented lettuce. *Lactuca graveolens*. *Lactuca — foliis horizontalibus carino aculeatis dentatis*, of Linnæus. A common plant in our hedges and ditches. It has a strong ungrateful smell, resembling that of opium, and a bitterish acrid taste: it abounds with a milky juice, in which its sensible qualities seem to reside, and which appears to have been noticed by Dioscorides, who describes the odour and taste of the juice as nearly agreeing with that of the white poppy. Its effects are also said, according to Haller, to be powerfully narcotic. Dr. Collin, at Vienna, first brought the lactuca virosa into medical repute; and its character has induced the Edinburgh College of Physicians to insert it in their catalogue of the materia medica. More than twenty-four cases of dropsy are said, by Collin, to have been successfully treated by employing an extract prepared from the expressed juice of this plant, which is stated not only to be powerfully diuretic, but, by attenuating the viscid humours, to promote all the secretions, and to remove visceral obstructions. In the more simple cases, proceeding from debility, the extract, in doses of eighteen to thirty grains a day, proved sufficient to accomplish a cure; but when the disease was inveterate, and accompanied with visceral obstructions, the quantity of extract was increased to three drachms; nor did larger doses, though they excited nausea, ever produce any other bad effect; and the patients continued so strong under the use of this remedy, that it was seldom necessary to employ any tonic medicines. Though Dr. Collin began his experiments with the lactuca at the Pazman hospital, at the time he was trying the arnica, 1771, yet very few physicians, even at Vienna, have since adopted the use of this plant. Plenciz, indeed, has published a solitary instance of its efficacy, while Quarin informs us that he never experienced any good effect from its use; alleging, that those who were desirous of supporting its character, mixed it with a quantity of extractum scillæ. It is hardly ever used in this country.

LACTUCE'LLA. (*a*, *æ*. f.; a diminutive of *lactuca*, the lettuce: so named from its milky juice.) The sow-thistle. The *Sonchus arvensis*.

LACTUCI'MINA. The thrush.

LACTU'MEN. (From *lac*, milk: so named from the white colour of the pustules.) *Crusta lactea*. Milk-scab. See *Porrigo larvalis*.

LACU'NA. (*a*, *æ*. f.; from *lacus*, a channel.) 1. In *Anatomy*, the mouth or opening of the excretory duct of a muciparous gland, as those of the urethra, and other parts.

2. In *Botany*, the opening of a glandiform body; a puncture like an opening on surfaces of stems or leaves.

LACUNOSUS. Dotted; pitted. Applied to a leaf when the surface lies in hollows between the veins.

LA'DANUM. (*um*, *i*, n.; from *ladon*, Arab.) See *Cistus creticus*.

Ladies' bedstraw. See *Galium*.

Ladies' mantle. See *Alchemilla*.

Ladies' smock. See *Cardamine*.

LÆTIFICA'NTIA. (From *lætifico*, to make glad.) Medicines intended to dispel melancholy and raise the spirits, were formerly so called.

LÆ'VIS. Smooth and even; level. Applied, in *Anatomy*, *Pathology*, and *Natural History*, to membranes, bones, &c.; and is opposed to all roughness and inequality whatever. See *Even*.

LÆVITAS INTESTINORUM. An old name of the lientery. See *Diarrhœa*.

LAGOCHEI'LUS. (*us*, *i*. m.; from λαγωος, a hare, and χειλος, a lip.) Hare-lip.

LAGOPHTHA'LMIA. (*a*, *æ*. f.; from λαγωος, a hare, and οφθαλμος, an eye: because it is believed that hares sleep with their eyes open.) *Lagophthalmos*. The hare's eye. A disease in which the eye cannot be shut. It is either connate or symptomatic of paralysis, or some disease causing a protrusion or enlargement of the eye.

LAGORO'DIUM. (*um*, *ii*. n.; from λαγωος, a hare, and πους, a foot: so called because it has narrow hairy leaves, like the foot of a hare.) The herb hare's-foot trefoil; the *Plantago media* of Linnæus.

LAGO'PUS. (*us*, *i*. m.; from λαγωος, a hare, and πους, a foot.) Hare's foot. Applied, in *Botany*, to several plants, from the resemblance of the flower or leaves; in *Zoology*, to the fox and some species of dog; and, in *Ornithology*, to the grouse genus.

LAGOPUS ALPINUS. The ptarmigan. This is more rare than the grouse, and esteemed as a great delicacy.

Lagopus scoticus. The grouse. The flesh of this bird, when in season and tender, is much esteemed, and is easy of digestion.

Lago'stoma. (*a, atis.* n.; from λαγωος, a hare, and στομα, the mouth: so called because the upper lip is divided in the middle like that of a hare.) See *Hare-lip.*

Lakeweed. See *Polygonum.*

Lalla'tio. That species of vicious pronunciation in which the letter *l* is rendered unduly liquid, or substituted for an *r*. The Greeks denominated it *lambdacismus*, from the letter λ, *lambda*. See *Psellismus.*

Lalo. See *Adansonia digitata.*

Lamac. Gum-arabic.

Lamb. See *Ovis aries.*

Lambdaci'smus. A defect in speech, which consists in an inability to pronounce certain consonants; or that stammering or difficulty of speech when the letter *l* is pronounced too liquid, and often in the place of *r*. See *Psellismus lallans.*

Lambdoidal suture. *Sutura lambdoidalis.* The suture that unites the occipital bone to the two parietal bones. So called because it has somewhat the shape of the Greek letter Λ.

Lambiti'vum. (*um, i.* n.; from *lambo*, to lick up.) A linctus or medicine to be licked up.

LAME'LLA. (*a, æ.* f.; diminutive of *lamina*, a plate of metal.) 1. A thin plate of any substance.

2. The parallel gill or plate in the inferior surface of the agaric family of plants.

LA'MINA. (*a, æ.* f.; from ελαω, to beat off.) A layer or plate. 1. In *Anatomy*, a thin plate or layer of any organic substance, as a *lamina of bone*, &c.

2. In *Surgery*, a name formerly given to several instruments, on account of their shape.

3. In *Botany*, the border of the corol of a polypetalous flower, which is distinguished into, *unguis*, the claw, and *lamina*, the border.

Lamina spiralis. The plate of bone which winds spirally round the modiolus of the cochlea. See *Auris.*

LAMINABI'LITY. *Laminabilitas.* A property possessed by some bodies of being extended in dimensions by a gradually applied pressure. See *Ductility.*

LAMINATED. Composed of thin laminæ that lie close and flat one upon an other. Applied in *Natural History, Anatomy*, &c.

LA'MIUM. (*um, ii.* n.; from the name of a mountain of Ionia, where it grew; or from *lama*, a ditch, because it usually grows about ditches and neglected places.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia*. The nettle.

Lamium album. *Urtica mortica. Archangelica. Galeobdolon. Stachys fœtida. Urtica urens magna fœtidissima.* Dead nettle. White archangel nettle. Uterine hæmorrhages and fluor albus are said to have been relieved by infusions of this plant, from the sensible qualities of which very little medicinal efficacy can be expected.

Lamp-black. See *Charcoal.*

Lampern. See *Petromyzon branchialis.*

Lampic acid. *Acidum lampicum.* A compound obtained by Mr. Daniel by placing a lamp filled with ether, and trimmed with a coil of red-hot platina wire, under the head of an alembic. The vapour which rose was condensed in the alembic, and received in a phial applied to its beak. Mr. Daniel at first thought this to be a peculiar acid, to which he gave the singular name of *lampic*, from the lamp concerned in the experiment; but he afterwards found that this substance consists of acetic acid, combined with a compound of carbon and hydrogen, differing both from alkohol and from ether.

Lamprey. See *Petromyzon marinus.*

Lampsana. See *Lapsana.*

LA'NA. (*a, æ.* f.) Wool. In *Botany*, a species of hairy pubescence, consisting of white, long, somewhat crisp hair, like wool. It is applied to stems, leaves, seeds, &c.

Lana philosophica. The snowy flakes of white oxide of zinc, which rise and float in the air from the combustion of that metal.

LANA'TUS. Woolly: applied to the stems, leaves, seed, &c. of plants. The *Verbascum thapsus*, is a good example of the *caulis lanatus*; the *Stachys lanata* of the woolly leaf; and the *Gossypium* of the seed.

LANCEOLA'TUS. Lanceolate: lance or spear-shaped. Applied to leaves, petals, seeds, &c., of a narrow oblong form, tapering towards each end; as the *leaves* in *Plantago lanceolata*, and *petals* of *Narcissus minor*, and *seeds* of the *Fraxinus.*

LANCE'TTA. (*a, æ.* f.; diminutive of *lancea*, a spear.) A lancet. An instrument used for bleeding and other purposes.

LANU'GO. (*o, inis.* f.) Soft wool or down.

Lao'nica cura'tio. An old method of curing the gout, by evacuating the morbid matter by topical applications.

Lapa'cticus. (Λαπακτικος; from λαπαζω, to evacuate.) Purgative. — *Galen.*

La'para. (*a, æ.* f.; Λαπαρα; from λαπαζω, to empty: so named from its concave and empty appearance.) The flank.

Laparoce'le. (*e, es.* f.; from λαπαρα, the flank, and κηλη, a rupture.) A rupture through the side of the belly.

La'pathum. (*um, i.* n.; from λαπαζω, to evacuate: so named because it purges gently.) The dock. See *Rumex.*

Lapathum acetosum. See *Rumex.*

Lapathum acutum. See *Rumex acutus.*

Lapathum aquaticum. See *Rumex.*

LAPIDEUS. Stony: applied very generally in all departments of science.

Lapides cancrorum. See *Cancer.*

Lapidi'llum. *Lapidillus.* A scoop for removing fragments of stone from the bladder.

Lapilli cancrorum. See *Cancer.*

Lapillous. Stony.

Lapis ageratus. See *Ageratus.*

Lapis bezoar. See *Bezoar.*

Lapis cæruleus. See *Lapis lazuli.*

Lapis calaminaris. See *Calamine.*

Lapis calcareus. Carbonate of lime.

Lapis cyanus. See *Lapis lazuli.*

Lapis divinus. *Lapis ophthalmicus.* The preparation originally known under this name, was a compound of vitriol, nitre, alum, and camphor, and was recommended by Woolhus. It has since been modified. Beer's lapis ophthalmicus consists of equal parts of subacetate of copper, nitre, and alum, melted together. It is used to form collyria.

Lapis hæmatites. See *Hæmatites.*

Lapis hibernicus. Irish slate; called also, *Tegula hibernica*, *Ardesia hibernica*, and *Hardesia.* A kind of slate, or very hard stone, found in different parts of Ireland, in a mass of a bluish black colour, which stains the hands. When dried and powdered, it is pale, or of a whitish blue, and, by keeping, grows black. In the fire it yields a sulphureous gas, and acquires a pale red colour, with additional hardness. It is occasionally powdered by the common people, and taken in spruce beer, against inward bruises.

Lapis hystricis. See *Bezoar hystricis.*

Lapis infernalis. See *Potassa fusa.*

Lapis la'zuli. *Lapis cyanus. Lapis cæruleus.* Azure stone. According to the analysis of Klaproth, it consists of silica, alumina, carbonate, and sulphate of lime, oxide of iron, and water. Guyton Morveau, however, regards it as a blue sulphuret of iron, mechanically blended with pyrites, potash, baryta, and other substances. It was formerly exhibited as a purgative and emetic, and given in epilepsy.

Lapis lydius. Lydian stone. A variety of flinty slate, sometimes used as a touchstone to try the purity of gold and silver.

Lapis malacensis. See *Bezoar.*

Lapis medicamentosus. This name has been given to two compounds, the one consisting of white vitriol, sal ammoniac, cerusse, Armenian bole, and vinegar; the latter of iron filings, mastiche, saffron, aloes, myrrh, &c. The former is the one most commonly known by the name, and was used as an application to ulcers.

Lapis ophthalmicus. See *Lapis divinus.*

Lapis philosophorum. The philosopher's stone. A wonderful substance, the discovery of which was the chief object of the alchemists. It was imagined to have the power of transforming all the baser metals into gold, and of curing all diseases. The appellation of *stone* is a fanciful one, as it does not appear from the writings of the alchemists, that the great arcanum was of a lapideous nature. The greater part of the processes given by the adepts for its preparation, are utterly unintelligible. All the instances on record of the apparent transmutation of metals by this mysterious agent, savour strongly of imposture, and the existence of any such substance as the philosopher's stone, is now generally disbelieved.

Lapis porcinus. See *Bezoar hystricis.*

Lapis simiæ. See *Bezoar simiæ.*

LA'PPA. (*a*, *æ*. f.; απο του λαβειν, from its seizing the garments of passengers.) A bur or clit-bur. See *Arctium lappa.*

Lappa major. See *Arctium lappa.*

LA'PSANA. (*a*, *æ*. f. Λαψανη; from *Lampsacus*, the town near which it flourished: or from λαπαζω, to evacuate; because it was said to relax the bowels.) The name of a genus of plants. Class, *Syngenesia*; Order, *Polygamia æqualis.*

Lapsana communis. *Lampsana. Napium. Papillaris herba.* Dock-cresses. Nipple-wort. This plant is a lactescent bitter, and nearly similar in virtues to the chicory, dandelion, and endive. It has been employed chiefly for external purposes, against wounds, and excoriations of the nipple, whence the name of nipple-wort and papillaris.

La'queus gu'tturis. A malignant inflammation of the tonsils, in which the patient appears as if he were suffocated with a noose.

La'rbason. Antimony. — *Pliny.*

Larch. See *Pinus larix.*

LARD. Hog's fat melted down. See *Adeps suilla.*

Lark. See *Alauda.*

LARVA'LIS. (From *larva*, a particular state of insects.) Larval: pertaining to a larva, and applied also to a disease of the skin. See *Porrigo larvalis.*

LARYNGEAL. *Laryngæ'us.* Appertaining to the larynx.

Laryngeal arteries. Branches of the thyroid arteries distributed to the larynx. The superior thyroid artery is called laryngeal by some anatomists.

Laryngeal nerves. These are the *superior laryngeal nerve*, given off from the pneumogastric in the upper part of the neck, and the *inferior laryngeal*, more frequently called the recurrent of the par vagum, which is given off from the pneumogastric within the thorax. See *Nervous system.*

LARYNGI'SMUS. (*us*, *i*. m.; from *larynx*, the windpipe.) A genus of disease formed by Dr. Mason Good, to include the affection commonly called spasmodic croup, which he, in common with many other writers, regards as depending essentially on spasm of the muscles, which close the larynx, and consequently as entirely distinct from the inflammatory croup. This learned writer observes, that while the general symptoms of the *Laryngismus stridulus* make a near approach to those of croup, the suddenness of its attack, and the absence of inflammation, and the peculiar secretion, form strong pathognomic distinctions between them.

There are instances, indeed, in which genuine croup has also commenced abruptly, but these are very rare; for it has usually the precursive symptoms of a slight cough and hoarseness for a day, and sometimes two days, as though the patient were labouring under a catarrh. In croup also, the inflammation, when it has once taken effect, becomes a permanent cause of excitement, and the anxiety and struggle for breath continue with little if any abatement till the inflammation is subdued. In the disease before us, the spasm suddenly subsides in a short time, though it may perhaps return in an hour, or half an hour, or even a few minutes; and in the interval the patient enjoys perfect ease, though the voice is rendered hoarse from the previous straining. Croup is, moreover, an exclusive disease of children; stridulous spasm of the larynx is sometimes found in adults.

Those who have been dissatisfied with the name of spasmodic asthma, have, however, treated of it under the name of spasmodic croup, but merely because they have not known how else to distinguish it: for almost every one who has thus noticed it, has acknowledged that it is a different disease, and demands a different plan of cure.

The exciting causes are not always clear: cold and teething are the most common. It appears most frequently in relaxed and irritable habits, where, in truth, we should soonest expect a display of spasmodic action. As there is mostly some degree of cough, and always a secretion of a small portion of viscid mucus, and a croaking voice, there is indeed great reason for supposing some degree of local irritation; and on this account Dr. Good has placed it among the diseases of the respiratory function, in preference to arranging among purely nervous affections. It is possible, however, that some of these symptoms may be the result of the spasmodic struggle itself.

An active and speedy plan of treatment is imperiously demanded. Yet an antimonial emetic generally effects a cure as soon as it begins to operate, if employed early: but the diaphoresis which it excites should be maintained for some hours, by keeping the child in bed, and the use of diluents; which will be the most effectual means of preventing a return of the spasm. The bowels should always be excited by a purgative of calomel. And if the emetic do not prove sufficient, or the stricture should be renewed, laudanum should be exhibited according to the age of the patient, and a blister be applied to the throat. But bleeding, which is indispensable in croup, should here be avoided, as it will only add to the irritability. Millar, Parr, and various other writers, have regarded this affection as a form of asthma, and have strongly recommended the fetid antispasmodics, as assafœtida, both by the mouth and injections; but Dr. Good did not find them successful.

Generally speaking, after the action of the emetic, the child falls into a deep and quiet sleep, and awakes with few remains of the complaint. Yet if the spasm be not attacked at once, suffocation may soon follow. Those who have once laboured under it are more susceptible of it than before; and the younger branches of some families seem much more predisposed to it than those of others.

It is right to state, that several practical writers of high authority, deny the existence of *laryngismus stridulus* as being distinct from croup.

The late Dr. Hugh Ley, in an able monograph on *Laryngismus stridulus*, has introduced an entirely new pathology of this disease. He regards it as arising from pressure on the nerves of respiration, in consequence of enlargement of the thoracic or cervical absorbent glands; and instead of referring the constriction of the glottis to spasm of the muscles which close that orifice, he refers it to loss of power in the muscles which open it. The tendency of dentition and inflamed and ulcerated states of the scalp, producing *laryngismus stridulus*, is explained by Dr. Ley, from their well known influence in causing enlargement of the lymphatic glands. This view of the subject throws no light on the exciting cause of any individual paroxysm; but those which have preceded it, are not more satisfactory in this respect. Dr. Ley has argued the point with much ingenuity, supported by great knowledge of the subject; but it does not seem likely that his pathology of this disease will be generally adopted.

LARYNGI'TIS. (*is, idis.* f.; from *larynx*, the part affected.) An inflammation of the larynx; that is, of the membrane which lines the larynx, or the cellular tissue connecting it to the parts beneath. It mostly forms a part of croup, or more extended inflammation of the air passages, having all its characters; but occasionally the inflammation is confined to the larynx. The disease makes its approach with the common symptoms of inflammatory fever; the voice immediately becomes hoarse and indistinct, the breathing laborious, with a painful sense of constriction in the throat. The fauces are red and inflamed, swollen and turgid; the face and eyes partake of the swelling, as in cases of threatened strangulation. The symptomatic fever is strong; the heat great; the pulse frequent and hard; there is great difficulty in swallowing, and great distress is caused by it. An examination of the throat, externally, makes us acquainted with its seat: the larynx is very painful to the touch; and a little pressure here, like an attempt to swallow, is productive of spasms, threatening the patient with instant death from suffocation, and causing him to pant for air. This disease attacks adults. It is distinguished from croup by a perpetual and voluntary hawking, rather than a forcible and involuntary cough, as though to clear the passage by expectoration. It is also distinguished from it by the nature of the expuition, which is a viscid mucus rather than a coagulable and membrane-like exudation. The two diseases differ also in their proximate causes. Laryngitis consists in a suppurative inflammation of the membrane of the larynx, and the cellular tissue which connects it to the parts beneath; while croup or bronchitis is a peculiar inflammation of the trachea, and perhaps larynx, extending through the bronchia, and exciting on their internal surface a concrete membrane-like material. Laryngitis, as now described, is an extremely acute disease, and destroys by suffocation in a few hours, or a day or two, unless promptly and actively opposed, and even when the attempt to cure is so conducted under the most experienced practitioners. It killed the celebrated Dr. Pitcairn in a short time. In Dr. Hooper's museum was the larynx of a soldier; under the membrane which covers the thyroid cartilage, and lines the larynx, is an abscess the size of a hazel-nut, which closed the passage. He was under arms at six of the evening, and dead the following night.

In the treatment of this disease, the most active remedies are to be promptly used; — blood-letting, generally and locally, and blistering, are to be immediately flown to; and

blood must be taken from the arm, *usque ad deliquium*, and repeated as the judgment and experience of the practitioner may justify and direct. The submuriate of mercury, in full doses, should be followed by strong infusions of senna with salts whilst the patient can swallow.

If, notwithstanding the judicious enforcement of these means, the symptoms are still urgent, tracheotomy must be performed, and iced lotions kept about the larynx.

Laryngitis often exists in a chronic form. This is a disease that affords a very different state of things: the voice is hoarse, the swallowing always a little painful, and pressure on the larynx gives pain. It is common to coachmen, and those who drink drams. It requires demulcent gargles, mercurial alteratives, leeches, and blistering, with great attention to diet and the interdiction of spirits.

LARYNGO'PHONY. (*Laryngophonia*; from λαρυγξ, the larynx, and φωνη, the voice.) The sound of the voice as heard through the stethoscope applied over the larynx.

LARYNGO'TOMY. (*Laryngotomia*, *æ.* f.; from λαρυγξ, the larynx, and τεμνω, to cut.) See *Bronchotomy*.

LA'RYNX. (*x*, *gis.* f.; Λαρυγξ.) A cartilaginous cavity, situated behind the tongue, in the anterior part of the fauces, and lined with an exquisitely sensible mucous membrane. It is composed of the *annular* or *cricoid* cartilage, the *scutiform* or *thyroid*, the *epiglottis*, and two *arytænoid* cartilages. The superior opening of the larynx is called the *glottis*. The *laryngeal arteries* are branches of the external carotids. The *laryngeal veins* evacuate their blood into the external jugulars. The nerves of the larynx are from the eighth pair. The use of the larynx is to constitute the organ of voice, and to serve also for respiration.

LA'SER. (*er*, *eris.* n.; said to be a Cyrenian word.) The herb laser-wort, or assafœtida.

LASERPI'TIUM. (*um*, *ii.* n.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*.

LASERPITIUM CHIRONIUM. *Panax*. Hercules' all-heal, or wound-wort. The seeds and roots of this plant are warm, and similar in flavour and quality to those of the parsnip. The roots and stalks have a much stronger smell, which resembles that of opoponax; and Boerhaave relates that, on wounding the plant in the summer, he obtained a yellow juice, which, being inspissated a little in the sun, agreed perfectly in both respects with that exotic gum resin.

LASERPITIUM LATIFOLIUM. The systematic name of the white gentian. *Gentiana alba*. The root of this plant, *Laserpitium — foliis cordatis, inciso-serratis*, of Linnæus, possesses stomachic, corroborant, and deobstruent virtues. It is seldom used.

LASERPITIUM SILER. The systematic name of the heart-wort, or sermountain. *Seseli. Siler montanum*. The seeds and roots of this plant, which grows in the southern parts of Europe, are directed as officinals. They have an agreeable smell, and a warm, glowing, aromatic taste; and though neglected in this country, do not appear to be deservedly so.

LASSITU'DO. (*o*, *onis.* f.) Lassitude. A feeling of weakness and debility, independent of fatigue.

Latent heat. See *Heat, latent*.

LATENT PERIOD. Certain diseases lurk in the system for a longer or shorter period, before their presence is manifested by any symptoms; this period is called their *latent period*. Thus we speak of the latent period of small-pox, of measles, &c., meaning thereby the time that elapses from the moment of infection, to the accession of the symptoms.

LA'TERAL. (*Lateralis*; from *latus*, the side.) Situated on the side of anything.

LATERAL FLOWER. That which grows on the side of the stem; as in *Erica vagans*.

LATERAL OPERATION. The name given to one mode of cutting for the stone, because the prostate gland and neck of the bladder are divided laterally. See *Lithotomy*.

Lateral sinus. See *Sinus*.

LATERALIS MORBUS. Pleurisy.

LATERI'TIOUS. (*Lateritius*, made of brick; from *later*, a brick.) A term applied to a sediment resembling brickdust occasionally deposited in the urine.

LA'THYRIS. (From λαθω, to forget; because it was thought to affect the memory.) A name given by some authors to a species of tithymal or spurge, commonly known by the name of *Tithymalus latifolius*, the broad-leaved spurge, and called by some also *Cataputia*.

LA'THYRUS. (*us*, *i.* m.; a name adopted from Theophrastus, whose λαθυρος appears evidently to be like ours, something of the pea or vetch kind, though it is impossible precisely to determine what.) The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria*. The vetch.

LATI'BULUM. (From *lateo*, to lie hid.) The fomes, or hidden matter of infectious diseases.

LA'TICA. The epithet given by some writers to a quotidian fever, in which the paroxysms are very long, and the febrile symptoms but slightly developed. It is the *Amphemerina latica* of Sauvages. Some say it is called *latica* from *latens*. (!)

Latissimus colli. See *Platysma myoides*.

LATISSIMUS DORSI. *Aniscalptor*, of Cowper. A muscle of the humerus, situated on the posterior part of the trunk. It is a very broad, thin, and, for the most part, fleshy muscle, which is placed immediately under the skin, except where it is covered by the lower extremity of the trapezius. It arises tendinous from the posterior half of the upper edge of the spine of the os ilium, from the spinous processes of the os sacrum and lumbar vertebræ, and from five or six, and sometimes from seven, and even eight, of the lowermost ones of the back; also tendinous and fleshy from the upper edges and external surface of the four inferior false ribs, near their cartilages, by as many distinct slips. From these different origins the fibres of the muscle run in different directions: those

from the ilium and false ribs run almost perpendicularly upwards; those from the sacrum and lumbar vertebræ, obliquely upwards and forwards; and those from the vertebræ of the back, transversely outwards and forwards, over the inferior angle of the scapula, where they receive a small thin bundle of fleshy fibres, which arise tendinous from that angle, and are inserted with the rest of the muscle, by a strong, flat, and thin tendon, of about two inches in length, into the fore part of the posterior edge of the groove observed between the two tuberosities of the os humeri, for lodging the tendon of the long head of the biceps. In dissection, therefore, this muscle ought not to be followed to its insertion, till some of the other muscles of the os humeri have been first raised. Its use is to pull the os humeri downwards and backwards, and to turn it upon its axis. Riolanus, from its use on certain occasions, gave it the name of *ani tersor*. When we raise ourselves upon our hands, as in rising from off an arm-chair, we may easily perceive the contraction of this muscle. A *bursa mucosa* is found between the tendon of this muscle and the os humeri, into which it is inserted.

Lattice-leaf. See *Canaliculatus.*

Lattice-work. See *Cancellatus.*

LAU'DANUM. (*um*, *i.* n.; said to be from *laus*, praise, on account of its valuable properties.) See *Tinctura opii.*

Laudanum abbatis Rousseau. See *Rousseau's drops.*

Laurel. See *Laurus.*

Laurel, cherry. See *Prunus laurocerasus.*

Laurel, spurge. See *Daphne laureola.*

LAURENT, SAINT. A place five leagues from Joyeuse in France, where there is a thermal spring of the temperature of 127° Fahr.

LAURE'OLA. (*a*, *æ.* f.; diminutive of *laurus*, the laurel: named from its resemblance to the laurel.) See *Daphne laureola.*

LAU'ROCE'RASUS. (From *laurus*, the laurel, and *cerasus*, the cherry-tree: so called because it has leaves like the laurel.) See *Prunus laurocerasus.*

LAURO'SIS. (So called from Mount Laurus, where there were silver mines.) The spodium of silver.

LAU'RUS. (*us*, *i.* and *ús.* f.; from *laus*, praise: because it was usual to crown the heads of eminent men with branches of it.) 1. The name of a genus of plants in the Linnæan system. Class, *Enneandria*; Order, *Monogynia.* The laurel.

2. The pharmacopœial name of the sweet-bay. See *Laurus nobilis.*

LAURUS CAMPHORA. This is one of the trees which produce camphor. See *Camphora.*

LAURUS CASSIA. Wild cinnamon-tree; Malabar cinnamon-tree, or cassia lignea tree. Cassia lignea is the bark of this tree, *Laurus — foliis triplinerviis lanceolatis*, of Linnæus. The leaves are called *folia malabathri*, in the shops. The bark, called also, *Cassia lignea*, *Canella malabarica*, *Cassia lignea malabarica*, *Xylocassia*, *Canella malabarica et javensis*, *Karva*, *Canella cubana*, *Arbor judaica*, *Cassia canella*, *Canellifera malabarica*, *Cinnamomum malabaricum*, *Calihacha canella*, abounds with the flavour of cinnamon, for which it may be substituted, but in much larger doses, as it is considerably weaker.

LAURUS CINNAMO'MUM. The systematic name of the cinnamon tree. This tree affords the true cinnamon, *cinnamomum*, which is its inner bark. Jacquin describes the tree thus: *Laurus cinnamomum — foliis trinerviis ovato-oblongis; nervis versus apicem evanescentibus.* Cinnamon bark is one of the most grateful of the aromatics; of a fragrant smell, and a moderately pungent, glowing, but not fiery taste, accompanied with considerable sweetness, and some degree of astringency. It is one of the best cordial, carminative, and restorative spices we are in possession of, and is generally mixed with the diet of the sick. The essential oil, on account of its high price, is seldom used: a tincture, and a simple and spirituous water, are kept in the shops. The watery infusion of cinnamon is given with advantage to relieve nausea and check vomiting. The cassia flowers of the shops are the flowers of this tree.

LAURUS CULILA'WAN. The systematic name of the plant, the bark of which is called *cortex culilawan* in the shops. *Cortex caryophylloides.* *Laurus — foliis triplinervis oppositis*, of Linnæus. This bark very much resembles cinnamon in appearance and properties.

LAURUS NOBILIS. The systematic name of the sweet bay tree. *Laurus — foliis venosis lanceolatis perennantibus, floribus quadrifidis*, of Linnæus. This tree is a native of Italy, but cultivated in our gardens and shrubberies as a handsome evergreen. The leaves and berries possess the same medicinal qualities, both having a sweet fragrant smell, and an aromatic astringent taste. The laurus of honorary memory, the distinguished favourite of Apollo, may be naturally supposed to have had no inconsiderable fame as a medicine; but its pharmaceutical uses are so limited in the practice of the present day, that this dignified plant is now rarely employed, except in the way of enema, or as an external application: thus the leaves are directed in the *decoctum pro fomento*, and the berries in the *emplastrum cumini.*

LAURUS PERSEA. This species of laurel affords the *Avigato pear*, which, when ripe, melts in the mouth like marrow, which it greatly resembles in flavour. It is supposed to be the most nutritious of all the tropical fruits, and grows in vast abundance in the West Indies and New Spain. The unripe fruit have but little taste; yet, being very salubrious, are often eaten with salt and pepper. The sailors, when they arrive at the Havannah, and those parts, purchase them in great quantities; and, chopping them into small pieces, with green capsicums, and a little salt, regale themselves heartily with them. They are esteemed, also, for their antidysenteric qualities, and are prepared in a variety of ways for the tables of the rich.

LAURUS PICHU'RIM. This is one of the plants which produce the Pechurim bean, called also Brazilian, and Carthagena bean. The bean is of an oblong-oval shape, heavy, of a brown

colour, and a musky odour. It is aromatic and carminative, but is now little used.

Laurus sa'ssafras. The systematic name of the sassafras tree. *Sassafras. Cornus mas odorata. Lignum pavanum. Anhuiba.* The wood of this tree, *Laurus — foliis trilobis integrisque*, of Linnæus, is imported from North America, in long straight pieces, very light, and of a spongy texture, and covered with a rough, fungous bark. It has a fragrant smell, and a sweetish, aromatic sub-acrid taste; the root, wood, and bark, agree in their medicinal qualities, and are all mentioned in the pharmacopœias; but the bark is the most fragrant, and thought to be more efficacious than the woody part; and the branches are preferred to the large pieces. The medical character of this drug was formerly held in great estimation, and publications were professedly written on the subject. It is now, however, thought to be of little importance, and seldom used but in conjunction with other medicines, as a corrector of the fluids. It is an ingredient in the *decoctum sarsaparillæ compositum*, or *decoctum lignorum;* but the only officinal preparation of it is the essential oil, which is carminative and stimulant, and which may be given in the dose of two drops to ten.

Lautissima vina. Wines strongly impregnated with myrrh, were formerly so called.

Lavandula. See *Lavendula.*

Lavender. See *Lavendula.*

Lavender, French. See *Lavendula stœchas.*

LAVE'NDULA. (*a, æ.* f.; from *lavo*, to wash: so called, because, on account of its fragrancy, it was used in baths.) 1. The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Gymnospermia.* Lavender.

2. The pharmacopœial name of the common lavender. See *Lavendula spica.*

Lavendula spica. The systematic name of the common lavender. *Nardus italica. Lavendula — foliis sessilibus lanceolata-linearibus margine revolutis, spica interrupta nuda*, of Linnæus. A native of the southern parts of Europe, but cultivated in our gardens on account of the fragrance of its flowers. Their taste is bitter, warm, and somewhat pungent; the leaves are weaker and less grateful. The essential oil, obtained by distillation, is of a bright yellow colour, of a very pungent taste, and possesses, if carefully distilled, the fragrance of the lavender in perfection. Lavender has been long recommended in nervous debilities, and various affections proceeding from a want of energy in the animal functions. An essential oil, a simple spirit, and a compound tincture, are officinal.

Lavendula stœchas. The systematic name of the French lavender. *Stœchas. Stœchas arabica. Spica hortulana. Stucadore.* This plant is much less grateful in smell and flavour than the common lavender, to which it is allied in its properties.

La'ver. (From *lava*, to wash: so named because it is found in brooks, where it is constantly washed by the stream.) 1. The brook-lime.

2. The English name of a species of ulva, which is eaten as a delicacy.

Laver, shield. See *Ulva lactuca.*

LAVIPE'DIUM. (*um, ii.* n.; from *lavo*, to wash, and *pes*, the foot.) A bath for the feet.

LAWSO'NIA. (*a, æ.* f.; named after Mr. Lawson, who published an excellent account of his voyage to Carolina, containing much information concerning the plants of that country.) The name of a genus of plants in the Linnæan system. Class, *Octandria;* Order, *Monogynia.*

Lawsonia inermis. The systematic name of the true alkanna: called also, *Alkanna vera*, and *Alkanna orientalis.* An oriental plant; the *Lawsonia — ramis inermibus*, of Linnæus; principally employed, in its native place, as a dye. The root is the officinal part, which, however, is rarely met with in the shops. It possesses astringent properties, and may be used as a substitute for the *anchusa.*

LA'XATIVE. (*Laxativus;* from *laxo*, to loosen.) Gently purgative. See *Cathartic.*

LAXA'TOR. (*or, oris.* m.; from *laxo*, to loosen: so called from its office to relax.) A name applied to muscles, &c., the office of which is to relax parts into which they are inserted.

Laxator tympani. *Externus mallei*, of Albinus. *Anterior mallei*, of Winslow. *Obliquus auris*, of Douglas. *Externus auris vel laxator internus*, of Cowper. A muscle of the internal ear, that draws the malleus obliquely forwards towards its origin; consequently, the membrana tympani is made less concave, or is relaxed.

Laxator tympani minor. A very small muscle of the ear, described as rising from the upper part of the meatus auditorius externus, and inserted into the inferior part of the handle of the malleus. Most anatomists deny its existence.

LA'XUS. Lax: loose. 1. In *Physiology* and *Pathology*, applied to the state of the animal fibre.

2. In *Botany*, diffused: in opposition to crowded or compact; as in the stem of the *Bunias cakile*, or sea-rocket, the stem of which is described as *caulis laxus.*

LAZZARETTO. (Italian.) A solitary building attached to most foreign sea-ports, for the performance of quarantine.

LEAD. *Plumbum.* A metal found in considerable quantity in many parts of the earth, in different states, seldom, if at all, in the metallic state. It is found in that of oxide, *red lead ore*, mixed with a portion of iron, clay, and other earths. The colour of this ore is aurora red, resembling red arsenic. It is found in small lumps, of an indeterminate figure, and also crystallised in four-sided rhomboidal prisms.

Combined with carbonic acid, it forms the *sparry lead ore*, so called because it has the texture and crystallisation of certain spars. There are a great many varieties of this kind. It is found also united with sulphuric, phosphoric, arsenic, molybdic, and chromic acids. Lastly, lead is found mineralised by sulphur,

forming what is called *galena (sulphuret of lead)*, which is by far its most abundant ore. This ore, which is very common, is found both in masses and crystals. The primitive form of its crystals is a cube. Its colour is of a bluish-lead grey. It has a considerable metallic lustre; its texture is foliated; it stains the fingers, and often feels greasy. It contains, in general, a minute quantity of silver.

Properties. — Lead is of a bluish white colour, and very brilliant when fresh cut. It is malleable. It soon tarnishes with the atmosphere. It may easily be cut with a knife, and stains the fingers bluish grey when rubbed. It fuses at 612° Fahr., and renders other more refractory metals fusible. It becomes vitrified in a strong and continued heat, and vitrifies various other metals. It is the least elastic of all the metals. It is very laminable, but it possesses very little ductility. Its specific gravity is about 11·4. It crystallises by cooling in small octahedra. When fused in contact with air, its surface first becomes yellow, and then red. It unites by fusion with phosphorus and sulphur. The greater part of the acids act upon it. The sulphuric acid requires the assistance of a boiling heat. Nitric acid is decomposed by it. Muriatic acid acts very weakly on it. Acetic acid dissolves it. Fluoric acid attacks it by heat, and slightly in the cold. It combines with other metals, but few of its alloys are applied to any use. When combined with mercury, it forms a crystallisable alloy which becomes fluid when triturated with that of bismuth.

Method of obtaining Lead. — In order to obtain lead in a great way, the ore is picked from among the extraneous matter with which it was naturally mixed. It is then pulverised and washed. It is next roasted in a reverberatory furnace, in which it is to be agitated, in order to bring the whole in contact with the air. When the external parts begin to soften, or assume the form of a paste, it is covered with charcoal, the mixture is stirred, and the heat increased gradually: the lead then runs on all sides, and is collected at the bottom of the furnace, which is perforated so as to permit the metal to flow into a receptacle defended by a lining of charcoal.

There are three, and probably four oxides of lead, of which the protoxide only is a salifiable base: —

1. The powder precipitated by potash from the solution of the nitrate of lead, being dried, forms the yellow *protoxide*, commonly called *massicot*. When somewhat vitrified, it constitutes *litharge*, and combined with carbonic acid, *white lead*, or *cerusse*. The protoxide of lead consists of one equivalent of the metal, and one of oxygen.

2. When massicot has been exposed for about 48 hours to the flame of a reverberatory furnace, it becomes red lead, or *minium*. This is generally regarded as a sesquioxide; but according to M. Dumas, it varies in its composition.

3. If upon 100 parts of red lead we digest nitric acid of the sp. gr. 1·26, 92·5 parts will be dissolved, but 7·5 of a dark brown powder will remain insoluble. This is the *peroxide* of lead, consisting of one equivalent of lead, and two of oxygen.

4. If oxalate of lead be subjected to a dull red heat in a retort, carbonic oxide and carbonic acid are evolved, and a dark grey powder remains. This, according to Dulong and Boussingault, is a definite suboxide consisting of two equivalents of lead, and one of oxygen. According to Berzelius, the grey powder that forms on lead after long exposure to the air, is of the same nature. This suboxide of lead is resolved by acids into the protoxide and metallic lead.

Lead combined with chlorine forms a semi-transparent greyish white mass, somewhat like horn, whence the old name of *plumbum corneum*, or horn lead. A formula for its preparation is now given in the London pharmacopœias.

The *iodide* is easily formed by heating the two constituents. It is now introduced into the London pharmacopœia. See *Plumbi iodidum*.

Lead combines also with *bromine* and with *fluorine*.

The salts of lead have the protoxide for their base, and are distinguishable by the following general characters: —

1. The salts, which dissolve in water, usually give colourless solutions, which have an astringent sweetish taste.

2. Placed on charcoal they all yield, by the blow-pipe, a button of lead.

3. Ferroprussiate of potash occasions in their solutions a white precipitate.

4. Hydrosulphuret of potash, a black precipitate.

5. Sulphuretted hydrogen a black precipitate.

6. Gallic acid, and infusion of galls, a white precipitate.

7. A plate of zinc a white precipitate, or metallic lead.

Most of the acids act upon lead.

The sulphuret, sulphate, carbonate, phosphate, arseniate, and chromate of lead are found native.

Oils dissolve the oxide of lead, and become thick and consistent; in which state they are used as the basis of plasters.

Sulphur readily dissolves lead.

The *phosphoric acid*, exposed to heat, combines with the metal.

Litharge, fused with common salt, decomposes it: the lead unites with the muriatic acid, and forms a yellow compound, used as a pigment.

Lead unites with most of the *metals*.

The oxides of lead are poisonous, and the salts have been till lately considered so; but the experiments of Dr. A. T. Thomson have rendered it probable that the carbonate is the only really poisonous salt of this metal. See *Plumbi acetas*. The symptoms of lead poison are those which constitute the disease called *Colica pictonum*. See *Colica* and *Poisons*.

The preparations of lead used in medicine are, —

1. The subcarbonate. See *Plumbi subcarbonas*.

2. The red oxide. See *Minium*.

3. The semivitreous oxide. See *Lithargyrum.*

4. The acetate. See *Plumbi acetas.*

5. The solution of the acetate. See *Plumbi diacetatis liquor.*

6. The dilute solution of the acetate. See *Plumbi diacetatis liquor dilutus.*

7. The *Iodide.* See *Plumbi iodidum.*

Lead, red. See *Minium.*

Lead, white. See *Plumbi subcarbonas.*

LEAF. *Folium.* A laminar expansion of a plant, generally of a green colour.

It is difficult, however, to define this universal and important organ of vegetables.

Leaves are, for the most part, remarkable for their expanded form; their colour is almost universally green, their internal substance pulpy and vascular, sometimes very succulent, and their upper and under surfaces differ commonly in hue, as well as in kind or degree of roughness. They are considered as the respiratory organs of plants.

In discriminating the species of plants, a knowledge of the various forms of leaves is of the utmost importance. Botanists, therefore, have paid particular attention to their names, which are derived either from their origin, distribution, situation, direction, insertion, form, base, point, margin, surface, distribution of its vessels, nerves, expansion, substance, duration, composition, &c.

A leaf consists of a thin and expanded part, which in common language is named the *leaf, folium*, and a stalk, called the *petiolus* or petiole. The surface of a leaf, *superficies* or *pagina*, is distinguished into the upper part, or face, and the under part, or back of the leaf. The *base*, or *origin* of a leaf, is that part next the stem or branch; the *apex* is the termination of the leaf; the *margin*, or edge, the circumference; the disk, *discum*, is the middle part of the surfaces within the margin.

From their *origin*, we have the following terms: —

1. *Seminal; folia seminalia*, which are the first leaves of the majority of plants, proceeding from seeds that bave more than one seed-lobe: they are seen in *Raphanus sativus*, and *Cannabis sativa.*

2. *Radical*, which spring directly from the root; as in *Leontodon taraxacum*, and *Viola odorata.*

3. *Cauline*, or stem-leaf. The *Valeriana phu* has its radical leaves undivided, and the cauline leaves pinnate.

4. *Ramial*, or branch-leaf, which are only described when they differ from those of the stem. The *Sison ammi* has its radical leaves linear; its cauline, setous; and its branch leaves, tripinnate.

5. *Axillary*, when seated on joints or axillæ; as in *Parthenium integrifolium.*

6. *Floral*, when next the flower, and like the other leaves; as in *Lonicera caprifolium.*

From their *distribution* on the stem and branches, leaves are named, —

7. *Alternate*, when not in pairs, and are given off in various directions, one after another; as in *Malva rotundifolia.*

8. *Opposite*, when they appear directly on opposite sides of the stem, in pairs; as in *Lamium album*, and *Urtica dioica.*

9. *Two-ranked; folia disticha*, which implies that they spread in two directions, and yet are not regularly opposite at their insertion; as in *Cupressus disticha, Taxus baccata, Pinus picea*, and *Lonicera symphoricarpos.*

10. *Bifarial*, that is, two-ranked, but given off from the side only of the branch; as in *Carpinus betulus*, and *Fagus sylvatica.*

11. *Unilateral*, looking to one side only; as in *Convallaria multiflora.*

12. *Scattered*, irregular, or without any order; as in *Reseda luteola*, and *Sedum reflexum.*

13. *Decussate*, crossing each other in pairs, cross-like; as in *Euphorbia lathyris*, and *Crassula tetragona.*

14. *Imbricate*, like tiles upon a house; as in *Cupressus sempervirens*, and *Aloë spiralis.*

15. *Fasciculate*, or tufted, when several spring from the same point; as in *Pinus larix*, and *Berberis vulgaris.*

16. *Stellate*, star-like, whorled; several leaves growing in a circle round the stem, without any reference to the precise number; as in *Rubia tinctorum, Lilium martagon, Asperula odorata.* In large natural genera it is necessary to mention the number; as in *Galium.*

17. *Remote*, when at an unusual distance from each other.

18. *Clustered;* crowded together, as in *Antirrhinum linaria*, and *Trientalis europea.*

19. *Binal*, when there are only two on a plant; as in *Galanthus nivalis, Scilla bifolia*, and *Convallaria magalis.*

20. *Ternal*, three together; as in *Verbena triphylla.*

21. *Quaternal, Quinal*, &c., when four, five, or more are situated together; as in various species of *Erica.*

From their determinate *direction*, leaves are distinguished into, —

22. *Close-pressed; adpressa*, when their upper surface is close to the stem; as in *Thlaspi campestre*, and *Xeranthemum sesamoides.*

23. *Erect*, when nearly perpendicular, or forming a very acute angle with the stem; as in *Juncus articulatus*, and *Bryum ventricosum.*

24. *Spreading*, forming a moderately acute angle with the stem; as in *Atriplex portulacoides, Nerium oleander*, and *Veronica beccabunga.*

25. *Horizontal*, spreading in the greatest possible degree; as in *Gentiana campestris*, and *Pelargonium patulum.*

26. *Ascending*, rising gently, so as to be somewhat arched; as in *Geranium nitifolium.*

27. *Recurved*, reflected, curved backward; as in *Erica retorta*, and *Bryum pellucidum.*

28. *Reclined*, depending, hanging downward towards the earth; as in *Cichorium intybus*, and *Leonurus cardiaca.*

29. *Olique*, twisted, so that one part is vertical, the other horizontal; as *Allium obliquum*, and *Fritillaria obliqua.*

30. *Adverse*, the upper surface turned to the meridian, not the sky; as in *Lactuca scariola*.

31. *Resupinate*, or reversed, when the upper surface is turned downward; as in *Alstroemeria pelegrina*, and *Stæbe prostrata*.

32. *Revolute*, having a spiral apex; as *Dianthus carthusianorum*, and *barbatus*.

33. *Rooting*, sending rootlets into the earth; as *Asplenium rhizophylla*.

34. *Floating* on the surface of the water; as in *Potamogeton natans*, and *Nymphæa alba*.

35. *Submersed*, demersed, immersed under water; as *Hottonia palustris*, and *Ranunculus aquatilis*.

From their *insertion* into, —

36. *Petiolate*, leaves on footstalks; as *Prunus cerasus*, and *Verbascum nigrum*.

37. *Sessile*, without footstalk, lying immediately on the stem; as in *Saponaria officinalis*, and *Pinguicula vulgaris*.

38. *Adnate*, the upper surface adhering a little way to the branch; as in *Xeranthemum vestitum*.

39. *Decurrent*, when a lamellar part of the leaf runs down the stem, or branch; as in *Carduus spinosus*, and *Verbascum thapsus*.

40. *Connate*, when two opposite leaves embrace, and are united at their bases; as in *Cerastium perfoliatum*, and *Dipsacus laciniatum*.

41. *Connato-perfoliate*, when the union is in the whole, or nearly the whole breadth of the leaves, so as to give the two leaves the appearance of being united into but one leaf; as in *Eupatorium perfoliatum*, and *Lonicera dioica*. Connate leaves are, in some instances, united by a membrane, which, stretching from the margins of the opposed leaves, near the base, forms a kind of pitcher around the stem, in which the rain is retained; as in *Dipsacus fullonum*.

42. *Embracing*, clasping the stem with their bases; as in *Carduus marianus*, and *Papaver somniferum*.

43. *Vaginate*, sheathing the stem at their bases; as in *Canna indica*, and *Polygonum bistorta*.

44. *Peltate*, when the footstalk is inserted not into the basis, but into the disk of the leaf; as in *Drosera peltata*, and *Tropæolum majus*.

45. *Perfoliate*, when the stem runs through the leaf; as in *Bupleurum rotundifolium*, and *Uvularia perfoliata*.

46. *Articulate*, one leaf growing out of the apex of another; as *Cactus opuntia*, and *Cactus ficus indica*.

From the *base* of the leaf, it is called, —

47. *Cordate*, heart-shaped or ovate, hollowed out at the base; as in *Arctium lappa*, and *Tamus communis*.

48. *Arrow-shaped*, triangular, hollowed out very much at the base; as *Rumex acetosa*, and *Sagittaria sagittifolia*.

49. *Hastate*, halbert-shaped, triangular, hollowed out at the base and sides, but with spreading lobes; as in *Arum maculatum*, and *Rumex acetosella*.

50. *Reniform*, kidney-shaped, a short, broad, roundish leaf, the base of which is hollowed out; as *Asarum europeum*, and *Glecoma hederacea*.

51. *Auricled*, furnished at its base with a pair of leaflets, properly distinct, but occasionally joined with it; as in *Citrus aurantium*.

Linnæus uses the term *appendiculatum*, which is correct.

52. *Unequal*, the basis larger on one side than the other; as in *Tilia europea*, and *Piper tuberculatum*.

The form of the *apex* of a leaf gives rise to the following names: —

53. *Acute*, sharp, ending in an acute angle, which is common to a great number of plants; example in *Linum angustifolium*, and *Campanula trachelium*.

54. *Acuminate*, pointed, having a taper, or awl-shawled point; as *Arundo phragmitis*, and *Syringa vulgaris*.

55. *Cuspidate*, or *mucronate*, sharp-pointed, tipped with a rigid spine; as in the thistles, and *Ficus religiosa*.

56. *Obtuse*, blunt, terminating in a segment of a circle; as *Rumex obtusifolius*, and *Hypericum quadrangulum*.

57. *Retuse*, ending in a broad shallow notch; as in *Ervum ervilia*, and *Rumex digynus*.

58. *Præmorse*, jagged pointed, as if bitten off; very blunt, with various irregular notches; as in *Hibiscus præmorsus*, and Swartz's genus *Aëride*.

59. *Truncate*, an abrupt leaf, with the extremity cut off, as it were, by a transverse line; as in *Liriodendrum tulipifera*.

60. *Dedalous*, with a broad, incised, and crisp apex; as in *Asplenium scolopendrum*.

61. *Emarginate*, nicked, having a small notch at the summit; as *Hydrocotile vulgaris*, and *Euphorbia tuberosa*.

62. *Summit-cut*, — *folia apice incisa*; as in *Glinko biloba*.

63. *Cirrhose*, tipped with a tendril; as in *Lathyrus articulatus*, and *Gloriosa superba*.

64. *Tridentate*, three-toothed; an obtuse point, beset with three teeth; as in *Buchera æthiopica*, and *Genista tridentata*.

65. *Ascidiate*, or pitcher-leaf, a cylindrical tube, filled with water; as in *Nepenthes distillatoria*, and *Saracenia*.

The terms derived from the *margin* of the leaf, are, —

66. *Entire*, not divided; as in *Tragopogon pratense*, and *Porrifolium*.

67. *Very entire*, *integerrima*, the margin void of irregularity; as *Citrus aurantium*.

68. *Undulate*, when the disk near the margin is waved obtusely up and down; as in *Panicum hirtellum*, and *Reseda lutea*.

69. *Crenate*, notched, when the teeth are rounded, and not directed towards either end of the leaf; as in *Betonica officinalis*, and *Scutellaria galericulata*.

70. *Doubly crenate*, the greater teeth notched with smaller ones; as in *Salvia sclara*, and *Ranunculus auricomus*.

71. *Serrate*, when the teeth are sharp, and resemble those of a saw, pointing towards the extremity of the leaf; as in *Sedum telephium*.

72. *Acutely serrate;* as in *Thymus acinos.*

73. *Obtusely serrate;* as in *Ballota nigra.*

74. *Doubly serrate,* having a series of smaller serratures intermixed with the larger; as in *Rubus fruticosus,* and *Campanula trachelium.*

75. *Dentate,* toothed, beset with projecting, horizontal, rather distant teeth of its own substance; as the lower leaves of the *Centaurea cyanus,* and *Campanula trachelium.*

76. *Jagged,* irregularly cut or notched, especially when otherwise also divided; as in *Salvia ægyptica,* and *Senecio squalidus.*

77. *Cartilaginous-edged,* hard, and hoary; as in *Saxifraga callosa,* and *Yucca gloriosa.*

78. *Prickle-edged,* beset with prickles; as in *Carduus lanceolatus,* and *Ilex aquifolium.*

79. *Fringed,* bordered with soft parallel hairs; as in *Sempervivum tectorum,* and *Galium cruciatum.*

From the *openings* or *sinuses* in the margin,—

80. *Sinuated,* cut as it were into rounded or wide openings; as in *Quercus robur,* and *Alcea rosea.*

81. *Repand,* wavy, bordered with numerous angles and segments of circles, alternately; as in *Menyanthes nymphoides,* and *Erysimum alliaria.*

82. *Pinnatifid,* cut transversely into several oblong parallel segments; as in *Centaurea calcitrapa,* and *Scabiosa arvensis.*

83. *Bipinnatifid,* doubly pinnatifid; as in *Papaver argemone.*

84. *Lyrate,* lyre-shaped, cut into several transverse segments, gradually larger towards the extremity of the leaf, which is rounded; as in *Geum urbanum,* and *Erysimum barbarea.*

85. *Panduriform,* fiddle-shaped, oblong, broad at the two extremities, and contracted in the middle; as in *Rumex pulcher,* and *Convolvulus panduratus.*

86. *Runcinate,* lion-toothed, cut into several transverse, acute segments, pointing backwards; as in *Leontodon taraxacum,* and *Erysimum officinale.*

87. *Laciniate,* cut into numerous irregular portions; as in *Ranunculus parviflorus,* and *Geranium columbinum,* and *Cotyledon laciniata.*

88. *Squarrose,* the margin beset with a rough fringe; as in *Centaurea calcitrapa,* and *Carduus marianus.*

89. *Partite,* deeply divided nearly to the basis; as in *Helleborus viridis.*

Bipartite, tripartite, and *multipartite,* according to the number of the divisions.

90. *Trifid,* divided into three; as in *Bidens tripartita.*

91. *Quinquifid,* divided into five; as in *Geranium maculatum.*

92. *Multifid,* the margin of round leaves cut from the apex almost to the base, without leaving any great intermediate sinuses; as in *Aconitum napellus,* and *Cucumis colocynthis.*

From the *angles* in the margin of the leaf,—

93. *Rounded,* the margin not having any angle.

94. *Angulate,* the margin having acute angles.

a. *Triangular;* as in *Chenopodium bonus henricus,* and *Atriplex hortensis.*

b. *Quinqueangular;* as in *Geranium peltatum.*

c. *Septangular;* as in *Hibiscus abelmoschus.*

95. *Rhomboid, trapeziform* or approaching to a square; as in *Chenopodium vulvaria,* and *Trapa natans.*

96. *Quadrangular,* with four angles; as in *Liriodendrum tulipifera.*

97. *Deltoid,* trowel-shaped, having three angles, of which the terminal one is much further from the base than the lateral ones; as in *Mesembryanthemum deltoideum,* and *Populus nigra.*

98. *Lobate,* when the margins of deep segments are rounded, hence:

a. *Two-lobed;* as in *Bauhinia porrecta.*

b. *Three-lobed;* as in *Anemone hepatica.*

c. *Five-lobed;* as in *Humulus lupulus,* and *Acer pseudo-platanus.*

99. *Palmate,* cut into several oblong nearly equal segments, about halfway, or rather more, towards the base, leaving an entire space, like the palm of the hand; as in *Passiflora cærulea,* and *Alcea ficifolia.*

From the *figure of the circumference,* are derived the following names:—

100. *Orbiculate,* circular, the length and breadth of which are equal, and the circumference in an even circular line; as in *Cotyledon orbiculata,* and *Hydrocotile vulgaris.*

101. *Subrotund,* roundish; as in *Pyrola,* and *Malva rotundifolia.*

102. *Oblong,* three or four times longer than broad; as in *Musa sapientum,* and *Elæagnus orientalis.*

103. *Ovate,* of the shape of an egg, cut lengthwise, the base being rounded, and broader than the extremity; as in *Origanum vulgare,* and *Inula helenium.*

104. *Obovate,* of the same figure, with the broader end uppermost; as in *Primula veris,* and *Samulus valerandi.*

104. *Oval,* ovate, but each end has the same roundness; as in *Rhus catinus,* and *Mammea americana.*

105. *Elliptical,* oval, the longitudinal diameter being greater than the transverse.

106. *Parabolic,* oblong, the summit narrow and round; as in *Marrubium pseudo-dictamnus.*

107. *Cuneiform,* wedge-shaped, broad and abrupt at the summit, and tapering down to the base; as *Saxifraga cuneifolia,* and *Iberis semperflorens.*

108. *Spatulate,* of a roundish figure, tapering to an oblong base; as in *Cotyledon spurea* and *Cucubalus otites.*

109. *Lanceolate,* of a narrow oblong form, tapering towards each end; as in *Plantago lanceolata.*

113. *Linear,* narrow, with parallel sides; as in *Senecio linifolius.*

111. *Capillary,* long, fine, and flexible, resembling a hair; as in *Anethum fœniculum,* and *Graveolens.*

112. *Setaceous,* bristly; as in *Asparagus officinalis,* and *Scirpus setaceus.*

113. *Acerose,* needle-shaped, linear and evergreen, generally acute and rigid; as in *Pinus sylvestris,* and *Juniperis communis.*

From the difference of the *surface* of leaves,—

114. *Glabrous*, smooth, without roughness; as the leaves of most plants.

115. *Nitid*, smooth and shining; as in *Laurus nobilis*, and *Canna indica*.

116. *Lucid*, as if covered with a varnish; as in *Angelica lucida*, and *Royena lucida*.

117. *Viscid*, covered with a clammy juice; as in *Senecio viscosus*, and *Erygeron viscosum*.

118. *Naked*, without bristles or hairs; as the leaves of many plants.

119. *Scabrous*, or *asperous*, with little roughness visible as well as tangible; as in *Morus nigra*, and *Humulus lupulus*.

120. *Punctate*, dotted, perforated with little holes; as in *Hypericum perforatum*.

121. *Pertuse*, bored, naturally having large perforations; as in *Dracontium pertusum*.

122. *Maculate*, spotted; as in *Orchis maculata*, and *Pulmonaria officinalis*.

123. *Coloured*, being of any other than a green colour; as in *Amaranthus tricolor*, and *Atriplex hortensis rubra*.

124. *Hoary*, having a whitish mealy surface; as in *Populus alba*.

125. *Lineate*, having superficial lines; as in *Scirpus maritimus*.

126. *Striate*, marked with coloured lines; as in *Phalaris arundinacea*.

127. *Sulcate*, furrowed, having broad and deep furrows; as in *Digitalis ferruginea*.

128. *Rugose*, rugged; as in *Salvia sclara*.

129. *Bullate*, blistered, a greater degree of the last; as in *Brassica oleracea*.

130. *Papulous*, or *vesiculous*, covered with hollow vesicles; as in *Mesembryanthemum crystallinum*.

131. *Papillose*, or *varicose*, covered with solid wart-like tubercles; as in *Aloë margaritifera*.

132. *Glandular*, covered with small glandiform bodies; as in *Salix alba*, and *Prunus padus*.

From the *distribution of the vessels on the surface* of the leaf.

Nerves are white elevated chords, which originate from the base of the leaf.

A *rib* is the middle nerve, thick, and extending from the basis to the apex of the leaf.

Veins are anastomosing vessels which are given off from the costa or rib.

The greater clusters of vessels are generally called *nervi* or *costæ*, nerves or ribs, and the smaller *venæ*, whether they are branched or reticulate, simple or otherwise.

133. A *nervous* or *ribbed* leaf is where they extend in simple lines from the base to the point; as in the *Convallariæ*, and *Helianthus annuus*. The *Laurus camphora* is an example of a trinerve; the *Smilax tetragona* has five nerves; the *Dioscorea septemloba*, seven.

134. When a pair of large ribs branch off from the main one above the base, and run in a straight line towards the apex, as in *Helianthus tuberosus*, the leaf is said to be *triple nerved*.

135. When two go from the base and four from the costa in a straight line, it is termed *folium quintuplinervum*.

136. *Venous*, veiny, when the vessels by which the leaf is nourished are branched, subdivided, and more or less prominent, forming a network over either or both its surfaces; as in *Clusia venosa*, and *Verbascum lychnitis*.

137. *Avenial*, or veinless, when without veins; as in *Clusia alba*, and *Rosea*.

138. *Enervous*, ribless, when no nerve is given off from the base; as in *Asperula levigata*.

The terms from the *expansion* of the leaves are, —

139. *Flat*, as most leaves are.

140. *Concave*, hollow, depressed in the middle; as in *Saxifraga stolonifera*.

141. *Convex*, the reverse of the former; as in *Ocymum basilicum majus*.

142. *Canaliculate*, channelled, having a longitudinal furrow; as in *Plantago maritima*.

143. *Cucullate*, hooded, when the edges meet in the lower parts, and expand in the upper; as in *Geranium cucullatum*, and that curious genus *Saracenia*.

144. *Plicate*, plaited, when the disk of the leaf, especially towards the margin, is acutely folded up and down; as in the *Malvus*, and *Alchemilla vulgaris*.

145. *Undulate*, waved, when the disk near the margin is waved obtusely up and down; as in *Reseda lutea*, and *Ixia undulata*.

146. *Crisp*, curled, when the border of the leaf becomes more expanded than the disk, so as to grow elegantly, curled, and twisted; as in *Malva crispa*.

From the *internal substance*, —

147. *Membranaceous*, when there is scarcely any pulp between the external membranes of the leaf; as in *Citrus aurantium*, and the leaves of many plants.

148. *Thick*, the membranes being rather more than usually firm; as in *Sedum telephium*.

149. *Carneous*, fleshy, of a thick substance, as in all those called succulent plants; as *Crassula lactea*, and *Sempervivum tectorum*.

150. *Pulpy*, very thick, and of the consistence of a plum; as in *Mesembryanthemum verruculatum*.

151. *Tubular*, hollow within; as in *Allium cepa*. The leaf of the *Lobelia dortmanna* is very peculiar, in consisting of a double tube.

152. *Compact*, not hollow.

153. *Rigid*, easily broken on being bent; as in *Stapelia*.

The thick leaves, *folia crassa*, afford the following distinctions: —

154. *Gibbous*, swelling on one side, or both, from excessive abundance of pulp; as in *Crassula cotyledon*, and *Aloë retusa*.

155. *Round*, cylindrical; as in *Allium schœnoprasum*, and *Salsola sativa*.

156. *Subulate*, awl-shaped, tapering from a thickish base to a point; as in *Allium ascalonicum*, and *Narcissus jonquilla*.

157. *Compressed*, flattened laterally; as in *Cacalia ficoides*.

158. *Depressed*, flattened vertically; as in *Crassula tetragona*.

159. *Triquetral*, thick and triangular; as in *Butomus umbellatus*.

160. *Tetragonal*, quadrangular and awl-shaped; as in *Gladiolus tristis*.

161. *Lingulate*, tongue-shaped, a thick oblong blunt figure, and a little convex on its

inferior surface; as in *Mesembryanthemum linguiforme.*

162. *Ancipital*, two-edged; as in *Typha latifolia.*

163. *Ensiform*, sword-shaped, two edges tapering to a point, slightly convex on both surfaces, neither of which can properly be called upper or under, as in *Iris germanica*, and *Gladiolus communis.*

164. *Carinate*, keeled, when the bark is longitudinally prominent; as in *Allium carinatum*, and *Narcissus biflorus.*

165. *Acinaciform*, cimeter-shaped, compressed with one thick and straight edge, the other thin and curved; as in *Mesembryanthemum acinaciforme.*

166. *Dolabriform*, hatchet-shaped, compressed with a very prominent dilated keel, and a cylindrical base; as in *Mesembryanthemum dolabriforme.*

167. *Uncinate*, hooked, flat above, compressed at its sides, and turned back at the apex, forming a hook.

When the shape of membranaceous leaves is *imperfect*, the particle *sub* is attached, as *sub*-sessile, *sub*-ovate, *sub*-pilous, &c.

When the shape is *reversed*, by the prefixing the preposition *ob*, as *ob*-cordate, when the point is inserted into the petiole, *ob*-ovate, &c.

From the *coadunation*, leaves are designated by prefixing the prominent shape, as *lanceolato-ovate;* as in *Nicotiana tabacum:* and ovato-lanceolate, lanceolate, but swelling out in the middle; as in *Saponaria officinalis.*

From their *duration*, leaves are termed, —

168. *Deciduous*, falling off at the approach of winter, as in most European trees and shrubs.

169. *Caducous*, falling off in the middle of summer.

170. *Perennial*, green the whole year, and falling off as the new ones appear.

171. *Persistent*, lasting many years, and always green; as in *Pinus*, and *Taxus.*

All the foregoing terms belong to *simple leaves*, or those which have one leaf only on the petiole or footstalk.

The following regard *compound leaves*, or such as consist of two or any greater number of *foliola*, or leaflets, connected by a common footstalk: —

172. *Digitate*, fingered, when several leaflets proceed from the summit of a common footstalk; as in *Trifolium pratense.*

173. *Pinnate*, when several leaflets proceed laterally from one footstalk, instead of being supported at the top; as in *Acacia pseudacacia.*

A digitate leaf is called after its *mode of digitation*, —

174. *Conjugate*, or yoked, when there is one pair of leaflets, or *pinnæ;* as in *Zygophyllum fabago.*

175. *Binate*, when the pair of leaflets unite somewhat at their base; as in *Lathyrus sylvestris.*

176. *Ternate*, where there are three leaflets; as in *Trifolium pratensis*, and *Oxalis acetocella.*

177. *Quinate*, there being five leaflets; as in *Potentilla reptans*, and *Lupinus albus.*

178. *Septenate*, with seven; as in *Æsculus hippocastanum.*

179. *Novenate*, nine; as in *Sterculia fœtida.*

180. *Pedate*, a peculiar kind of leaf, being ternate, with its lateral leaflets compounded in their fore part; or a leaf with a bifid footstalk divided into two diverging branches, with an intermediate leaflet, and each supporting two or more lateral leaflets on their anterior edge; as in *Helleborus niger.*

181. *Articulate*, jointed, when one, or a pair of leaflets, grows out of the summit of another, with a sort of joint; as in *Cactus ficus indica*, and *Fagara tragodes.*

Pinnate leaves are called from their number of *pinnæ*, —

182. *Bipinnate*, or *duplicato-pinnate*, doubly pinnate; as in *Tanacetum vulgare.*

183. *Tripinnate*, or *triplicato-pinnate*, thrice pinnate; as in *Scandix odorata.*

From the *number of pairs*, pinnate leaves are termed, —

184. *Biguga;* as in *Mimosa nodosa.*

185. *Triguga;* as in *Cassia emarginata.*

186. *Quadriguga;* as in *Cassia longisiliqua.*

187. *Quinquiguga;* as in *Cassia occidentalis.*

188. *Multiguga;* as in *Cassia javanica.*

The difference in the *termination* of a pinnate leaf, —

189. *Impari-pinnate*, with an odd or terminal leaflet; as *Rosa centifolia.*

190. *Abrupti-pinnate*, with a terminal leaflet; as in *Orobus tuberosus.*

191. *Cirrhosi-pinnate*, when furnished with a tendril in place of an odd leaflet; as in the pea and vetch tribe.

From the mode of *adhesion of the leaflets* arise, —

192. *Oppositely-pinnate*, when the leaflets are opposite, or in pairs; as in *Sium angustifolium.*

193. *Alternately-pinnate*, when alternate; as in *Vicia sativa.*

194. *Interruptedly-pinnate*, when the principal leaflets are arranged alternately with an intermediate series of smaller ones; as in *Spiræa ulmaria.*

195. *Decurrently-pinnate*, when the leaflets are decurrent; as in *Eryngium campestre.*

196. *Jointedly-pinnate*, with apparent joints in the common footstalk; as in *Fagara tragodes.*

197. *Petiolato-pinnate*, the leaflets on footstalks; as in *Robinia pseudacacia.*

198. *Alate-pinnate*, when the footstalk has little wings between the leaflets.

199. *Sessile-pinnate*, with leaflets within any petiole.

200. *Conjugate-pinnate*, confluent; the leaflets growing somewhat together at their margins.

From their *bipinnation*, pinnate leaves are, —

201. *Bigeminate*, two-paired; as in *Mimosa unguis cati.*

202. *Trigeminate*, or *triplicato-geminate*, thrice-paired; as in *Mimosa tergemina.*

From the *tripinnation*, —

203. *Doubly-ternate*, or *duplicato-ternate*, when the common footstalk supports these secondary petioles on its apex, and each of these

support three leaflets; as in *Epimedium alpinum*.

204. *Triternate*, or *triplicato-ternate*, when the common petiole supports on its apex three secondary footstalks, each of which supports three ternary ones, and every one of these three leaflets; as in *Aquilegia vulgaris*, and *Fumaria enneaphylla*.

205. *Multiplicato-pinnate*, there being more than three orders; as in *Ruta hortensis*.

Pinnæ are the leaflets of pinnate leaves.

Pinnulæ, the leaflets of the double and triple range of pinnate leaves.

LEÆ'NA. (Λεαινα, a lioness.) The epithet of a plaster mentioned by Ætius.

Leaflet. See *Foliolum*.

Leafstalk. See *Petiolus*.

LEANNESS. *Extenuatio corporis*. This occurs in many individuals as a natural state compatible with the most perfect health: in other cases it is symptomatic of various diseases. In consumption and atrophy the frame gradually wastes away to an extreme degree of leanness, while, in acute fevers, an equal degree of attenuation is often produced in two or three weeks.

LE'DUM. (*um*, *i*. n.; a name adopted from the Greeks, whose ληδον is generally believed to be a species of *Cistus*.) The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Monogynia*.

LEDUM PALUSTRE. The systematic name of the *Rosmarinus sylvestris*, and *Cistus ledon* of the shops. This plant has a bitter sub-astringent taste, and was formerly used in Switzerland in the place of hops. Its medicinal use is confined to the Continent, where it is occasionally given in the cure of hooping-cough, sore throat, dysentery, and exanthematous diseases.

LEECH. *Hirudo*. *Bdella*. A genus of animals of the order *Annelides*. The body moves either forward or backward. There are several species, principally distinguished by their colour; but that most known to medical men is the *hirudo medicinalis*, or medicinal leech, which grows to the length of two or three inches. The body is of a blackish brown colour, marked on the back with six yellow spots, and edged with a yellow line on each side; but both the spots and lines grow faint, and almost disappear, at some seasons. The head is smaller than the tail, which fixes itself very firmly to any thing the creature pleases. It was till lately supposed to be viviparous, but is now ascertained to be oviparous. It inhabits fresh water marshes and pools throughout Europe. The *Hirudo provincialis*, or Lisbon leech, is now imported into this country in great numbers for medicinal purposes. The *hirudo sanguisuga*, or horse-leech, is larger than these; its skin is smooth and glossy; the body is depressed, the back is dusky; and the belly is of a yellowish green, having a yellow lateral margin. It inhabits stagnant waters. Its bite has been vulgarly believed to be poisonous; but it seems merely to excite more inflammation than that of the medicinal leech, on account of its greater size.

The leech's head is armed with a sharp instrument that makes three wounds at once. It consists of three sharp tubercles, strong enough to cut through the skin of a man, or even of an ox, or horse. The mouth is, as it were, the body of the pump, and the tongue, or fleshy nipple, the sucker. By the working of this piece of mechanism, the blood is made to rise up to the conduit which conveys it to the animal's stomach, which is a membranaceous skin, divided into twenty-four small cells. The blood which is sucked out is there preserved for several months, almost without coagulating, and proves a store of provision to the animal.

Leeches are employed to bleed young children, and for the purposes of topical bleeding, in cases of inflammation, fulness, or pain. They may be used in every case where topical bleeding is thought necessary, or where venesection cannot be performed. If the leech does not fasten, we are told to put a little sugared milk on the spot it is wished to fix on, or to draw a little blood by means of a slight puncture. Rolling the leech in porter will generally be found much more effectual than either. The leech, when used for the hæmorrhoids, should be watched, lest it should find its way into the anus; and when applied to the gums, some contrivance should be used to guard against its creeping down the patient's throat. The best way is to enclose the animal in a case, giving exit only to the head. More blood generally flows from the puncture of a leech after the animal falls off, than is drawn in the act of sucking; but it generally ceases spontaneously, or is easily stopped by the application of lint, &c. Sometimes, however, it is very obstinate, and will not stop till the bite has been cauterised with nitrate of silver. Sulphate of copper is recommended for this purpose, but it seldom answers. In some cases, especially of children, the only way is for a number of assistants to keep up a constant pressure for some hours with the point of the finger, on each orifice.

The introducing a hand, to which any ill-flavoured medicine adheres, into the water in which they are kept, is often sufficient to poison leeches; the application of a small quantity of any saline matter to their skin, immediately occasions the expulsion of the contents of their stomach; and the least flavour of any medicament that has been applied, remaining on the skin, or even the accumulation of the matter of perspiration, will prevent them from fastening. The skin should therefore, previous to their application, be very carefully cleansed from any foulness. They may be applied by taking them by the tail, and presenting their head to the part, or by confining them on the part under a wine-glass, when they generally fix in a short time. On their removal, the rejection of the blood they have drawn may be obtained by the application of salt externally: but it is to be remarked, that a few grains of salt are sufficient for this purpose; and that covering them with it, as is sometimes done, generally destroys them. Leeches should not be kept in spring water, as they very soon die: the vessel should be filled with water from

a pond, and the water changed sufficiently often.

Leek. See *Allium porrum.*

LE'GNA. (From λεγνον, a fringed edge.) The extremities of the pudenda muliebria.

LEGU'MEN. (*en, inis.* n.; from *lego*, to gather: so called because they are usually gathered by the hand.) A legume, or shell of a seed. A peculiar solitary kind of fructification, formed of two oblong valves, without any longitudinal partition, and bearing the seeds along one of its margins only.

From the figure it is called, —

1. *Teres*, round; as in *Phaseolus radiatus.*
2. *Lineare*; as in *Phaseolus vexillatus.*
3. *Compressum*; as in *Pisum sativum.*
4. *Capitatum*; as in *Phaseolus mungo.*
5. *Aciniforme*; as in *Phaseolus lunatus.*
6. *Ovatum*; as in *Lotus hirsutus*, and *Græcus.*
7. *Inflatum*, a cavity filled with air; as in *Astragalus vesicarius*, and *exscapus.*
8. *Cochleatum*, spiral; as in *Medicago polymorpha*, and *marina.*
9. *Lunatum*; as in *Medicago falcata.*
10. *Obcordatum*; as in *Polygala.*
11. *Contortum*; as in *Medicago sativa.*
12. *Quadrangulatum*; as in *Dolichos tetragonolobus.*
13. *Canaliculatum*, the upper suture deeply hollowed; as in *Lathyrus sativus.*
14. *Isthmis interceptum*; as in *Coronilla.*
15. *Echinatum*; as in *Glycyrrhiza echinata.*
16. *Rhombeum*; as in *Cicer aristinum.*

From its insertion, —

1. *Pendulum*; as in *Phaseolus vulgaris.*
2. *Pedicellatum*; as in *Vicia sæpium.*

From its substance, —

1. *Membranaceum*; as in *Phaseolus vulgaris.*
2. *Carnosum*; as in *Cynometra cauliflora.*
3. *Coriaceum*, dry and fleshy; as in *Ceratonia siliqua*, and *Lupinus.*

From the number of seeds, —

1. *Monospermum*; as in *Medicago lupulina.*
2. *Dispermum*; as in *Glycine tomentosa.*
3. *Trispermum*; as in *Trifolium reflexum.*
4. *Tetraspermum*; as in *Trifolium repens.*
5. *Polyspermum*; as in *Trifolium lupinaster.*

LEGU'MINOUS. (*Leguminosus*; from *legumen.*) Appertaining to a legume.

Leienteria. See *Lienteria.*

LEIPOPSY'CHIA. (*a, æ.* f.; from λειπω, to leave, and ψυχη, life.) A swoon. See *Syncope.*

LEIPOTHY'MIA. (*a, æ.* f.; from λειπω, to leave, and θυμος, the mind.) Fainting. See *Syncope.*

LEI'PYRIAS. (Λειπυριας; from λειπω, to leave, and πυρ, heat.) A very malignant continued fever, accompanied with erysipelatous affection of some of the internal viscera, and in which the internal parts are much heated, while the external parts are cold. — *Galen.*

Lemithochorton. See *Helminthocorton.*

Lemon. See *Citrus.*

Lemon, acid of. See *Citric* and *Oxalic acid.*

Lemon scurvy-grass. See *Cochlearia.*

LE'NITIVE. (*Lenitivus*; from *lenis*, gentle.) Applied to medicines which operate mildly.

LENITIVE ELECTUARY. The old name of the *Confectio sennæ composita.*

LENS. (*Lens, tis.* f.) 1. The lentil. See *Ervum lens.*

2. In *Natural Philosophy*, a piece of glass or other transparent material, so shaped as to be capable of refracting the rays of light.

3. In *Anatomy*, an important part of the eye. See *Oculus.*

Lens, crystalline. See *Oculus.*

LENTI'CULA. (*a, æ.* f.; dim. of *lens*, a lentil.) 1. A smaller sort of lentil.

2. A freckle, or a small pustule, resembling a lentil seed.

3. A surgical instrument employed for removing the jagged particles of bone from the edge of the perforation made in the cranium with the trephine.

Lenticula marina. See *Fucus natans.*

LENTI'CULAR. *Lenticularis.* Shaped like a lens. Applied in *Botany*, *Anatomy*, &c.

Lenticular cataract. See *Cataract.*

LENTICULAR GANGLION. The ophthalmic ganglion.

LENTICULARE OS. The os orbiculare of the ear. See *Auris.*

LENTICULAR PAPILLÆ. The papillæ situated at the posterior part of the tongue.

LENTIFORM. The same as *Lenticular.*

LENTI'GO. (*o, onis.* f.: from *lens*, a lentil.) A freckle.

Lentil. See *Ervum lens.*

Lentil, sea. See *Fucus natans.*

LENTI'SCUS. (*us, i.* f.; from *lentesco*, to become sticky: so called from the gumminess of its juice.) The mastich-tree. See *Pistachia.*

LE'NTOR. (*or, oris.* m.; from *lentus*, clammy.) A viscidity or siziness of any fluid.

Leonti'asis. See *Elephantiasis.*

LEO'NTODON. (*on, ontis.* m.; from λεων, the lion, and οδους, a tooth: so called from its supposed resemblance.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia æqualis.* The dandelion.

LEONTODON TARAXACUM. The dandelion or pissabed. Called also, *Dens leonis. Leontodon — caule equalis inferne reflexis, foliis runcinatis, denticulatis, lævibus*, of Linnæus. The young leaves of this plant, in a blanched state, have the taste of endive, and make an excellent addition to those plants eaten early in the spring as salads; and Murray informs us, at Goëttingen, the roots are roasted and substituted for coffee by the poorer inhabitants, who find that an infusion prepared in this way can hardly be distinguished from that of the coffee-berry. The expressed juice of dandelion is bitter and somewhat acrid; but that of the root is bitterer, and possesses more medicinal power than any other part of the plant. It has been long in repute as a detergent and aperient, and its diuretic effects may be inferred from the vulgar name it bears in most of the European languages. It has been employed with alleged advantage in hepatic obstructions, jaundice, dropsy, and some

cutaneous diseases. Dr. Pemberton found it of great service in chronic inflammation and incipient scirrhus of the liver, and in chronic affections of the stomach. The leaves, roots, flowers, stalks, and juice of dandelion, have all been separately employed for medical purposes, and seem to differ rather in degree of strength than in any essential property; therefore the expressed juice, or a strong decoction of the roots, have most commonly been prescribed, from one ounce to four, two or three times a day. The extract, when properly prepared and fresh, seems to have all the virtues of the plant. See *Extractum taraxaci.*

LEONTOPO'DIUM. (*um, ii.* n.; from λεων, a lion, and πους, a foot: so named from its supposed resemblance.) The herb lion's foot, or *Filago leontopodium.*

LEONU'RUS. (*us, i.* f.; from λεων, a lion, and ουρα, a tail: so named from its likeness.) 1. The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Gymnospermia.* Lion's tail.

2. The name, in some pharmacopœias, for the lion's tail. See *Leonurus cardiaca.*

LEONURUS CARDIACA. The mother-wort: called also, *Agripalma gallis, Marrubium,* and *Cardiaca crispa.*

Leonurus — foliis caulinis lanceolatis, trilobis, of Linnæus. The leaves of this plant have a disagreeable smell and a bitter taste, and are said to be serviceable in disorders of the stomachs of children, to promote the uterine discharge, and to allay palpitation of the heart.

Leopard's bane. See *Arnica montana.*

LEPI'DIUM. (*um, ii.* n.; from λεπις, a scale: so named from its supposed usefulness in cleansing the skin from scales and impurities.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia;* Order, *Siliculosa.*

LEPIDIUM IBE'RIS. *Iberis. Cardamantica.* Sciatica cresses. This plant possesses a warm, penetrating, pungent taste, like unto other cresses, and is recommended as an antiscorbutic, antiseptic, and stomachic.

LEPIDIUM SATIVUM. *Nasturtium hortense.* Dittander. This plant possesses warm, nervine, and stimulating qualities, and is given as an antiscorbutic, antiseptic, and stomachic, especially by the lower orders.

LEPIDO'PTERA. (From λεπις, a scale, and πτερον, a wing.) The name of an order of insects which have scaly wings. See *Animal Kingdom.*

LEPIDOSARCO'MA. (From λεπις, a scale, and σαρξ, flesh.) A scaly tumour. Severinus mentions such tumours as occurring in the cavity of the mouth.

LEPIDO'SIS. (*is, is.* m.; from λεπις, *squamma,* a scale.) Scale-skin. See *Ichthyosis.*

LEPORI'NUM LABIUM. (*Lepus,* a hare.) The hare-lip. See *Hare-lip.*

LEPORINUM ROSTRUM. The same.

LE'PRA. (*a, æ.* f.; from λεπρος, *scaber vel asper ex squamulis decedentibus.*) The leprosy. This name has been given to several diseases. See *Lepra arabum, Lepra judaicum,* and *Lepra græcorum;* but it is now restricted to a common form of cutaneous disease, which Dr. Willan describes as characterised by scaly patches, of different sizes, but having always nearly a circular form. In this country, three varieties of the disease are observed, which he has described under the names of *Lepra vulgaris, Lepra alphos,* and *Lepra nigricans.*

1. The *Lepra vulgaris* exhibits first small distinct elevations of the cuticle, which are reddish and shining, but never contain any fluid; these patches continue to enlarge gradually, till they nearly equal the dimensions of a crown piece. They have always an orbicular, or oval form; are covered with dry scales, and surrounded by a red border. The scales accumulate on them, so as to form a thick prominent crust, which is quickly reproduced, whether it fall off spontaneously, or may have been forcibly detached. This species of lepra sometimes appears first at the elbow, or on the fore-arm; but more generally about the knee. In the latter case, the primary patch forms immediately below the patella; within a few weeks, several other scaly circles appear along the fore part of the leg and thigh, increasing by degrees till they come nearly into contact. The disease is then often stationary for a considerable length of time. If it advance further, the progress is towards the hip and loins; afterwards to the sides, back, shoulders, and, about the same time, to the arms and hands. In the greater number of cases, the hairy scalp is the part last affected; although the circles formed on it remain for some time distinct, yet they finally unite, and cover the whole surface on which the hair grows with a white scaly incrustation. This appearance is attended, more especially in hot weather, with a troublesome itching, and with a watery discharge for several hours, when any portion of the crust is detached, which takes place from very slight impressions. The pubes in adults is sometimes affected in the same manner as the head: and if the subject be a female, there is usually an internal *pruritus pudendi.* In some cases of the disorder, the nails, both of the fingers and toes, are thickened, and deeply indented longitudinally. When the lepra extends universally, it becomes highly disgusting in its appearance, and inconvenient from the stiffness and torpor occasioned by it in the limbs. The disease, however, even in this advanced stage, is seldom supposed to terminate spontaneously. It continues nearly in the same state for several years, or sometimes during the whole life of the person affected, not being apparently connected with any disorder of the constitution.

2. *Lepra alphos.* The scaly patches in the alphos are smaller than those of the lepra vulgaris, and also differ from them in having their central parts depressed or indented. This disorder usually begins about the elbow, with distinct, eminent asperities, of a dull red colour, and not much longer than papillæ. These, in a short time, dilate to nearly the size of a silver penny. Two or three days afterwards, the central part of them suffers a depression, within which small white powdery scales may be observed. The surrounding border, however,

still continues to be raised, but retains the same size and the same red colour as at first. The whole of the fore-arm, and sometimes the back of the hand, is spotted with similar patches: they seldom become confluent, excepting round the elbow, which, in that case, is covered with an uniform crust. This affection appears in the same manner upon the joint of the knee, but without spreading far along the thigh or leg. Dr. Willan has seldom seen it on the trunk of the body, and never on the face. It is a disease of long duration, and not less difficult to cure than the foregoing species of lepra: even when the scaly patches have been removed by persevering in the use of suitable applications, the cuticle still remains red, tender, and brittle, very slowly recovering its usual texture. The alphos, as above described, frequently occurs in this country.

3. The *Lepra nigricans* differs little from the lepra vulgaris, as to its form and distribution. The most striking difference is in the colour of the patches, which are dark and livid. They appear first on the legs and fore-arms, extending afterwards to the thighs, loins, neck, and hands. Their central part is not depressed, as in the alphos. They are somewhat smaller in size than the patches of the lepra vulgaris, and not only is the border livid or purplish, but the livid colour of the base likewise appears through the scaly incrustation, which is seldom very thick. It is further to be observed, that the scales are more easily detached than in the other forms of lepra, and that the surface remains longer excoriated, discharging lymph, often with an intermixture of blood, till a new incrustation forms, which is usually hard, brittle, and irregular. The lepra nigricans affects persons whose occupation is attended with much fatigue, and exposes them to cold or damp, and to a precarious or improper mode of diet, as soldiers, brewers, labourers, butchers, stage-coachmen, scullermen, &c.; some women are also liable to it, who are habituated to poor living and constant hard labour.

It would be superfluous to enumerate the catalogue of useless medicines which have been recommended from ancient times for the cure of lepra. There is no one remedy, nor any invariable plan of treatment, which will succeed in lepra, under all the circumstances of its appearance in different instances; and great errors are committed by prescribing for the name of the disease.

In the less irritable conditions of the leprous eruption, such as the alphos usually exhibits, as well as a few cases of the vulgaris, a gently stimulant mode of treatment, at least externally, is requisite; though in all cases of lepra the diet should be light and moderate, and heating liquors should be avoided, especially malt liquors and spirits: for every indulgence in these points will be felt in the aggravation of the symptoms. A frequent use of the warm bath, with which a moderate degree of friction may be combined, contributes to removes the scales, and soften the skin; or, if the eruption be confined to the extremities, local ablution and friction may be sufficient. These cases are benefited by the use of the sulphur waters of Harrogate, Leamington, Crofton, and other well-known springs, both internally and externally, and by the warm sea-water bath. In fact, these gently stimulant ablutions are often sufficient, if persevered in during several weeks, to remove the complaint.

But if the scales adhere tenaciously, or are accumulated into thick crusts, then some more active lotion must be conjoined with the warm ablution, or with the application of steam, in order to clear the surface. Lotions of diluted alkohol, of sulphuretted potash, or the decoction of dulcamara, will aid the exfoliation; and the thick crusts may be softened and loosened by lotions containing a portion of the liquor potassæ, or of the muriatic acid. When these are removed, the cuticle may be restored gradually to its healthy condition by the unguentum picis, or the unguentum hydrargyri nitratis diluted with saturnine cerate, or simple ointment; or lotions containing a small proportion of the oxymuriate of mercury may be substituted. The ointments should be applied at night, and washed off in the morning with warm water, or a slight saponaceous lotion.

The same cases will be accelerated in their progress towards a cure, by the use of those internal remedies which tend to support the strength and to stimulate the cutaneous vessels. For this purpose the arsenical solution is often extremely beneficial, in doses of four or five drops, which may be slowly increased to eight, and persevered in for a month or more. Pitch, administered in the form of pills, is productive of a similar good effect, where the cutaneous circulation is very inert; but both these medicines are liable to aggravate the eruption, where it is connected with much irritability of the skin. The solution of oxymuriate of mercury has appeared to have some efficacy in these inert states; and in thin and delicate girls, of relaxed habits, affected with the lepra alphos, the vinum ferri, or the tartrate of iron, has been taken with much advantage.

One of the most effectual remedies for lepra, however, under all its varieties, is the decoction of the leaves and twigs of the solanum dulcamara, which was introduced to the notice of British practitioners by Sir Alexander Crichton. This medicine is at first administered in doses of two or three ounces thrice every day, which are gradually augmented until a pint is at length consumed daily. When there is a degree of torpor in the superficial vessels, the same decoction, made with a larger proportion of the shrub, is advantageously employed as a lotion; but if there is much inflammatory disposition, this and every other external stimulus must be prohibited.

Where this irritable state of the disease exists, indeed, and it is the most frequent, nothing more stimulating than tepid water, or thin gruel, can be used for the purposes of ablution; and the arseniates, pitch, &c. above mentioned, must be excluded. The disease, under this condition, will be certainly aggravated by sea-bathing, by the external use of the strong sulphureous waters, or of any irritant; but it will be alleviated by the internal employment of

sulphur, with soda or nitre, or the hydrarg. sulphuratus niger with an antimonial, especially when conjoined with the decoction of dulcamara. The caustic potash, or liquor potassæ, in the dose of twenty or thirty drops, alone, or in combination with the precipitated sulphur, is likewise beneficial; and the tinctura veratri, given in such doses as not to disorder the bowels, has occasionally removed this state of the disease.

When the skin is highly inflamed, thickened, and stiff, of a vivid red colour, intermixed with a yellowish hue, where the cuticle is separating in large flakes, the heat, pain, and itching are often extremely troublesome, and the motion of the limbs is almost impracticable. The most effectual relief is obtained, in these cases, by gently besmearing the parts with cream, or a little fresh and well-washed lard, or butter.

LEPRA A'RABUM. The tubercular elephantiasis, or *elephantiasis Græcorum*.

LEPRA GRÆCORUM. The term *lepra* was applied by the Greeks to a scaly disease of the skin, which appears to correspond with the lepra vulgaris of Willan. The *alphos* was considered by them as a milder degree of lepra, and corresponds with the lepra alphoides of Willan. The *melas* was named from its colour, and corresponds with the lepra nigricans of Willan.

LEPRA JUDAICA. Leprosy of the Jews. A disease much spoken of in holy writ. Moses mentions three kinds of leprosy, namely, 1. the *boak*, called *boak* also by the Arabians, which appears to correspond with the *alphos* of the Greeks. 2. The *berat cecha* — *beras asved* of the Arabians, and *melas* of the Greeks. 3. The *berat lebena* — *beras bejas* of the Arabians, and *leuce* of the Greeks. The first kind was considered by the Jewish lawgiver as not contagious, the two latter as contagious. The reader will find the subject of leprosy learnedly discussed by Dr. Mason Good, in the fifth volume of his *Study of Medicine*.

LEPRI'ASIS. (From λεπρος, *scaber*.) The specific name given by Dr. Mason Good to leprosy, which disease he calls *Lepidosis leproriasis*.

Leprosy. See *Lepra*.

LE'PROUS. (*Leprosus*; from *lepra*, the leprosy.) 1. Affected with leprosy, or appertaining to leprosy.

2. In *Botany*, applied to the leprous-like appearance on crustaceous lichens.

LEPTY'NTICA. (From λεπτιζω, to make thin.) Synonymous with *attenuantia*.

LEPTY'SMUS. (Λεπτυσμος; from λεπτος, slender.) Emaciation.

LE'PUS. (*us, oris*. m.) A genus of mammiferous animals of the order *Rodentia*.

LEPUS CUNI'CULUS. The systematic name of the rabbit; the flesh of which, when young and tender, is easy of digestion.

LEPUS TIMIDUS. The systematic name of the common hare; the flesh of which is considered as a delicacy, and easy of digestion.

LE'ROS. (Ληρος; from ληρεω, to trifle.) Slight delirium.

LESION. (*Læsio, onis*. f.; from *lædo*, to hurt.) An injury. This word is now very generally used in pathology; thus we speak of *lesion of structure*, or *organic lesion*; *lesion of function*, &c.

LETA. An alchemical term for a red heat.

LETHA'RGIC. *Lethargicus*. Appertaining to lethargy.

LE'THARGY. (*Lethargus, i*. m.; from ληθη, forgetfulness: so called because with it the person is forgetful.) A heavy and constant sleep, with scarcely any intervals of waking: when awakened, the person answers, but, ignorant or forgetful of what he said, immediately sinks into the same state of sleep. Lethargy is very nearly allied to mild forms of apoplexy, and may arise from the same causes. Retrocedent gout has been known to produce lethargy. The common causes of sleep, whether natural or morbid, are in many cases causes of lethargy. The proximate cause of sleep is to be sought for in a torpitude or exhaustion of sensorial power, from the ordinary stimulants of the day: hence excessive exertion of body or mind may give rise to lethargy. The same effect may result from a defective supply of sensorial power, as well as from exhaustion; and, consequently, the torpitude of sleep may ensue whenever such deficient action or energy exists, even where there is no exposure to its ordinary exciting causes.

The cure of lethargy is to be attempted by a diligent search into the cause, the removal of which generally establishes health. If any suppressed discharge or eruption can be traced, we should endeavour to reproduce it by all possible means; and if any general or local plethora exist, bleeding, purgatives, and active exercise must be resorted to, with an abstemious plan of diet. Lethargy is frequently the result of a determination of blood to the head, but it is also, frequently, a purely nervous affection; and, in the latter case, a generous diet is proper, with blisters, and medicines which stimulate the nervous system, especially ammonia.

LETHE'A. (From ληθη, forgetfulness.) A name of the poppy.

Lettuce. See *Lactuca*.

LEUCACA'NTHA. (*a, æ*. f.; from λευκος, white, and ακανθα, a thorn: so named from its white blossom.) The cotton-thistle.

LEUCA'NTHEMUM. (*um, i*. n.; from λευκος, white, and ανθεμον, a flower: so called from its white floret.) See *Chrysanthemum leucanthemum*.

LEUCA'SMUS. (*us, i*. m. Λευκασμον, whiteness: so named from its appearance.) Veal-skin. See *Vitiligo*.

LEU'CE. (Λευκη; from λευκος, white.) A disease mentioned by the Greek writers, characterised by smooth shining patches on the skin, on which the hairs turned white and silky, and the skin itself, and the subjacent parts, lost their sensibility. It was not scaly like lepra. It is the *Vitiligo alba* of Celsus, and the *beras bejas* of the Arabians. This disease still exists in tropical climates, and has been described by Mr. Robinson as it occurs in India. See *Elephantiasis*. The leuce was regarded by the Greeks as incurable: Mr. Robinson, however, asserts that it is cured in the East Indies by the use of the *Asclepias gigantea*. The leuce appears to be the same with the *berat lebena*, one

of the forms of leprosy mentioned in Scripture. See *Lepra Judaica.*

LEUCELE'CTRUM. (*um, i.* n.; from λευκος, white, and ηλεκτρον, amber.) White amber.—*Blancard.*

LEU'CINE. (From λευκος, white: so named from its appearance.) A white pulverulent matter obtained by digesting equal parts of beef fibre and sulphuric acid together, and, after separating the fat, diluting the acid mixture, and saturating with chalk, filtering and evaporating. A substance tasting like ozmazome is thus procured, which is to be boiled in different portions of alkohol. The alkoholic solutions, on cooling, deposit the white pulverulent matter, or *leucine.*

LEUCOCHRUS. (Λευκοχρους; from λευκος, white, and χροη, a colour.) The Greek epithet of a factitious wine, made by macerating in white wine, raisins previously pounded and steeped in sea water.

LEUCOLA'CHANUM. (From λευκος, white, and λαχανον, a herb: so named from its colour.) The *Valeriana sylvestris.*

LEUCO'MA. (*a, atis.* n.; from λευκος, white.) Leucoma and albugo are often used synonymously, to denote a white opacity of the cornea of the eye. Both of them, according to Scarpa, are essentially different from the nebula, for they are not the consequence of chronic ophthalmy, attended with varicose veins, and an effusion of a milky serum into the texture of the delicate continuation of the conjunctiva over the cornea; but are the result of violent acute ophthalmy. In this state, a dense coagulating lymph is extravasated from the arteries; sometimes superficially, at other times deeply into the substance of the cornea. On other occasions, the disease consists of a firm callous cicatrix on this membrane, the effect of an ulcer, or wound, with loss of substance. The term *albugo* strictly belongs to the first form of the disease, *leucoma* to the last, more particularly when the opacity occupies the whole, or the chief part, of the cornea.

LEUCONYMPHÆ'A. (*a, æ.* f.; from λευκος, white, and νυμφαια, the water-lily.) See *Nymphæa alba.*

LEUCOPHA'GIUM. (*um, ii.* n.; from λευκος, white, and φαγω, to eat.) A name formerly given to a culinary preparation made with some animal jelly and emulsion of sweet almonds, sweetened and variously flavoured. The *blanc-manger* of the present day, made with milk, isinglass, &c., is the descendant of the old leucophagium. These preparations are very nutritious, and form a pleasant and excellent food for debilitated patients.

LEUCOPHLEGMA'SIA. (*a, æ.* f.; from λευκος, white, and φλεγμα, phlegm.) A tendency in the system to a dropsical state, known by a pale colour of the skin, a flabby condition of the solids, and a redundancy of serum in the blood.

LEUCOPHLEGMA'TIC. Affected with or appertaining to leucophlegmasia.

LEUCOPHY'LLON. Λευκοφυλλον. The Greek name of a composition of Samian earth, storax, malabathrum, opobalsamum, and the juice of roses. It was rubbed on the neck and axillæ as a perfume.

LEUCO'PIPER. (*er, eris.* n.; from λευκος, white, and πεπερι, pepper.) White pepper. See *Piper nigrum.*

LEUCORRHŒ'A. (*a, æ.* f.; from λευκος, white, and ῥεω, to flow.) *Fluor albus.* The whites. A secretion of whitish or milky mucus from the vagina of women, arising from debility, and not from the venereal virus. This disease is marked by the discharge of a thin white or yellow matter from the uterus and vagina, attended likewise with some degree of fœtor, smarting in making water, pains in the back and loins, anorexia and atrophy. In some cases the discharge is of so acrid a nature, as to produce effects on those who are connected with the woman somewhat similar to venereal matter, giving rise to excoriations about the glans penis and præputium, and occasioning a weeping from the urethra.

To distinguish leucorrhœa from gonorrhœa, it is necessary to attend to the following circumstances: — In the latter, the running is constant, but in small quantity; there is much ardor urinæ, itching of the pudenda, swelling of the labia, increased inclination to venery, and very frequently an enlargement of the glands in the groin: whereas in the former the discharge is irregular, and in considerable quantities, and is neither preceded by, nor accompanied with, any inflammatory affection of the pudenda.

Immoderate coition, injury done to the part by difficult and tedious labours, frequent miscarriages, immoderate flowings of the menses, profuse evacuations, poor diet, an abuse of tea and other causes, giving rise to general debility or to a laxity of the parts more immediately concerned, are those which usually produce the whites, vulgarly so called from the discharge being commonly of a milky white colour.

Fluor albus, in some cases, indicates that there is a disposition to disease in the uterus or parts connected with it, especially where the quantity of the discharge is very copious, and its quality highly acrimonious. By some the disease has been considered as never arising from debility of the system, but as being always a primary affection of the uterus. Delicate women, with lax fibres, who remove from a cold climate to a warm one, are very apt to be attacked with it, without the parts having previously sustained any kind of injury.

The disease shows itself by an irregular discharge from the uterus and vagina of a fluor which, in different women, varies much in colour, being either of a white, green, yellow or brown hue. In the beginning it is, however, most usually white and pellucid, and in the progress of the complaint acquires the various discolourations, and different degrees of acrimony, from which proceeds a slight degree of smarting in making water. Besides the discharge, the patient is frequently afflicted with severe and constant pains in the back and loins, loss of strength, failure of appetite, dejection of spirits, paleness of the countenance, chilliness and languor. Where the disease has been of long continuance, and very severe, a slow fever

attended with difficult respiration, palpitations, faintings, and swellings of the lower extremities, often ensues.

A perfect removal of the disorder will at all times be a difficult matter to effect; but it will be much more so in cases of long standing, and where the discharge is accompanied with a high degree of acrimony. In these cases, many disorders, such as prolapsus uteri, ulcerations of the organ, atrophy, and dropsy, are apt to take place, which in the end prove fatal.

Where the disease terminates in death, the internal surface of the uterus appears, on dissection, to be pale, flabby, and relaxed; and where organic affections have arisen, much the same appearances are to be met with as have been noticed under the head of menorrhagia.

LEVA'TOR. (*or, oris.* m.; from *levo*, to lift up.) A muscle the office of which is to lift up the part to which it is attached.

Levator anguli oris. *Abducens labiorum*, of Spigelius. *Elevator labiorum communis*, of Douglas. *Caninus*, of Winslow. A muscle situated above the mouth, which draws the corner of the mouth upwards, and makes that part of the cheek opposite to the chin prominent, as in smiling. It arises thin and fleshy from the hollow of the superior maxillary bone, between the root of the socket of the first grinder and the foramen infra orbitarium, and is inserted into the angle of the mouth and under lip, where it joins with its antagonist.

Levator ani. *Levator magnus seu internus*, of Douglas. A muscle of the rectum. It arises from the os pubis, within the pelvis, as far up as the upper edge of the foramen thyroideum and joining of the os pubis with the os ischium, from the thin tendinous membrane that covers the obturator internus and coccygæus muscles, and from the spinous process of the ischium. From these origins, all round the inside of the pelvis, its fibres run down like rays from the circumference to a centre, to be inserted into the sphincter ani, acceleratores urinæ, and anterior part of the two last bones of the os coccygis, surrounding the extremity of the rectum, neck of the bladder, prostate gland, and part of the vesiculæ seminales. Its fibres, joining with those of its fellow, form a funnel-shaped hole, that draws the rectum upwards after the evacuation of the fæces, and assists in shutting it. The levatores ani also sustain the contents of the pelvis, and assist in ejecting the semen, urine, and contents of the rectum, and perhaps, by pressing upon the veins, contribute greatly to the erection of the penis.

Levator ani parvus. The transverse muscle of the perinæum is so called by Riolan.

Levator coccygis. Cowper's name for the *Coccygeus* muscle.

Levator labii inferioris. A muscle of the mouth situated below the lips. *Levator menti*, of Albinus. *Incisivus inferior*, of Winslow. *Elevator labii inferioris proprius*, of Douglas. It arises from the lower jaw, at the roots of the alveoli of two incisor teeth, and the cuspidatus, and is inserted into the under lip and skin of the chin.

Levator labii superioris alæque nasi. *Elevator labii superioris proprius*, of Douglas. *Incisivus lateralis et pyramidalis*, of Winslow. A muscle of the mouth and lips, that raises the upper lip towards the orbit, and a little outwards; it serves also to draw the skin of the nose upwards and outwards, by which the nostril is dilated. It arises by two distinct origins: the first, broad and fleshy, from the external part of the orbitar process of the superior maxillary bone, immediately above the foramen infra orbitarium; the second, from the nasal process of the superior maxillary bone, where it joins the os frontis. The first portion is inserted into the upper lip and orbicularis muscle; the second, into the upper lip and outer part of the ala nasi.

Levator labii superioris proprius. *Musculus incisivus.* A muscle of the upper lip. It arises under the edge of the orbit, and is inserted into the upper lip.

Levator oculi. See *Rectus superior oculi.*

Levator palati. A muscle situated between the lower jaw and the os hyoides, laterally. *Levator pallati mollis*, of Albinus. *Petrosalpingo-staphilinus, vel salpingo-staphilinus internus*, of Winslow. *Salpingo-staphilinus*, of Valsalva. *Pterigo-staphilinus externus vulgo*, of Douglas. *Spheno-staphilinus*, of Cowper. It arises tendinous and fleshy from the extremity of the petrous portion of the temporal bone, where it is perforated by the Eustachian tube, and also from the membraneous part of the same tube, and is inserted into the whole length of the velum pendulum palati, as far as the root of the uvula, and unites with its fellow. Its use is to draw the velum pendulum palati upwards and backwards, so as to shut the passage from the fauces into the mouth and nose.

Levator palati mollis. See *Levator palati.*

Levator palpebræ superioris. *Aperiens palpebrarum rectus. Apertor oculi.* A proper muscle of the upper eyelid, that opens the eyes by drawing the eyelid upwards. It arises from the upper part of the foramen opticum of the sphenoid bone, above the rectus superior oculi, near the trochlearis, and is inserted by a broad thin tendon into the cartilage that supports the upper eyelid.

Levator parvus. See *Transversus perinei.*

Levator propriusscapulæ. See *Levatorscapulæ.*

Levator scapulæ. *Levator proprius scapulæ.* A muscle situated on the posterior part of the neck, that pulls the scapula upwards and a little forwards. This name, which was first given to it by Riolanus, has been adopted by Albinus. Douglas calls it *elevator, seu musculus patientiæ;* and Winslow, *angularis, vulgo levator proprius.* It is a long muscle, nearly two inches in breadth, and is situated obliquely under the anterior edge of the trapezius. It arises tendinous and fleshy from the transverse processes of the four, and sometimes five superior vertebræ colli, by so many distinct slips, which soon unite to form a muscle that runs obliquely downwards and outwards, and is inserted by a flat tendon into the upper angle of the scapula. Its use is to raise the scapula upwards and a little forwards.

Levatores costarum. See *Intercostal muscles.*

LEVER. *Vectis.* An obstetrical instrument for aiding the descent of the child's head through the pelvis. It is applicable to the same cases as the forceps, but the latter is a preferable instrument, and the lever is now hardly ever used. It is improperly called a lever, as it does not act on the principle of the lever; it resembles a single blade of the forceps.

LEVIATHAN PENIS. *Priapus ceti.* The penis of the whale, which, when dried and powdered, was formerly used in leucorrhœa and dysentery.

LEVIGA'TION. (*Lævigatio, onis.* f.; from *lævigo*, to make smooth.) The reduction of a hard substance by trituration to an impalpable powder.

Levi'sticum. See *Ligusticum levisticum.*

LEXIPHA'RMACON. (From ληγω, to terminate, and φαρμακον, poison.) The same as alexipharmacon.

LEXIPYRE'TICUS. (From ληγω, to make cease, and πυρετος, a fever.) Febrifuge.

Ley. See *Lixionum.*

Leyden jar. See *Electricity.*

Leyden phial. See *Electricity.*

LIBA'DIUM. (From λιβαζω, to make moist: so called because it grows in watery places.) The lesser centaury. — *Turton.*

LIBANION. Λιβανιον. The name of a collyrium described by Paul of Ægina.

LIBANO'TIS. (*is, idis.* f.; from λιβανος, frankincense: so called from its resemblance in smell to frankincense.) Rosemary.

LI'BANUS. (*us, i.* m.; from *Libanon* a mountain in Syria, where it grows.) 1. The *Pinus cedrus*, or cedar of Lebanon.

2. The frankincense tree, or *Pinus abies.*

Liber. See *Bark.*

LIBU'RNUM. (*um, i.* n.; from *Liburnia*, the country where it flourished.) The mealy-tree. See *Viburnum lantana.*

LIBYANON. Λιβυανον. The Greek name of several collyria.

LI'CHANUS. (Λιχανος; from λειχω, to lick: so called because it is used in tasting a small portion of any thing.) The fore-finger.

LI'CHEN. (Λειχην, or λιχην. *Lichen, enis.* or *enos.* m.; a term, Dr. Mason Good observes, common to the Greek physiologists, as well as the Greek pathologists. By the former it is applied to an extensive genus of the algæ, or rather to many of its species; and it is conjectured by Pliny that the physicians applied it to this disease from the resemblance it produces, on the surface of the body, to many of the spotty and minutely tuberculated lichens which are found upon stones, walls, barks of trees, &c. Gorræus, however, derives it from λειχω, to lick, because it was supposed to be cured by being licked, or from its lambent or tongue-like form over different parts of the body.) The lichen.

I. In *Pathology*, a disease, defined, by Dr. Willan, an extensive eruption of papulæ affecting adults, connected with internal disorder, usually terminating in scurf; recurrent, not contagious. The varieties of lichen he considers under the denominations of *simplex, agrius, pilaris, lividus, tropicus, circumscriptus*, and *urticatus.*

The *lichen simplex* usually commences with headach, flushing of the face, loss of appetite, general languor, and increased quickness of the pulse. Distinct red papulæ arise first about the cheeks and chin, or on the arms; and, in the course of three or four days, the same appearance takes place on the neck, body, and lower extremities, accompanied with an unpleasant sensation of tingling, which is somewhat aggravated during the night. In about a week, the colour of the eruption fades, and the cuticle begins to separate; the whole surface is at length covered with scurfy exfoliations, which are particularly large, and continue longest in the flexures of the joints. The duration of the complaint is seldom in any two cases alike; ten, fourteen, seventeen, or sometimes twenty days, intervene betwixt the eruption and the renovation of the cuticle. The febrile state, or rather the state of irritation at the beginning of this disorder, is seldom considerable enough to confine the patient to the house. After remaining five or six days, it is generally relieved on the appearance of the eruption. This, as well as some other species of the lichen, occurs about the beginning of summer, or in autumn, more especially affecting persons of a weak and irritable habit; hence women are more liable to it than men. Lichen simplex is also a frequent sequel of acute diseases, particularly fever and catarrhal inflammation, of which it seems to produce a crisis.

Lichen circumscriptus is characterised by clusters or patches of papulæ, which have a well defined margin, and are of an irregularly circular form. Some of them are stationary for a week or two, and disappear; but others extend gradually, by new papulated borders, into large figured forms, which coalesce. As the borders extend, the central areæ become even, but continue slightly red and scurfy. Sometimes, before the scurf is removed, a new crop of papulæ arises, terminating like the former in exfoliations; and by these new eruptions the complaint is prolonged for several weeks. It may be excited either by internal or external causes of irritation. In adults it is occasionally produced by vaccination, and may be deemed a proof of the full affection of the constitution by the virus.

Little medicinal treatment is necessary for these species of lichen. It is sufficient that patients avoid heating themselves by much exercise or by stimulants, and take a light diet with diluent drinks, and a gentle laxative occasionally. The diluted sulphuric acid is a grateful tonic to the stomach during the period of exfoliation; or a light chalybeate may be taken with advantage at the same period. All strong external applications are improper, especially preparations of mercury and of sulphur, which produce severe irritation. The ancients recommended that the parts should be besmeared every morning with saliva; and some demulcent lotion, as a substitute for this uncleanly expedient, prepared with the white of egg, or emulsion of almonds, will relieve the painful sensations of the patient.

The *Lichen agrius* is preceded by nausea

pain in the stomach, headach, loss of strength, and deep-seated pains in the limbs, with fits of coldness and shivering; which symptoms continue several days, and are sometimes relieved by the papulous eruption. The papulæ are distributed in clusters, or often in large patches, chiefly on the arms, the upper part of the breast, the neck, face, back, and sides of the abdomen; they are of a vivid red colour, and have a redness, or some degree of inflammation, diffused round them to a considerable extent, and attending with itching, heat, and a painful tingling. Dr. Willan has observed, in one or two cases where it was produced from imprudent exposure to cold, that an acute disease ensued, with great quickness of the pulse, heat, thirst, pains of the bowels, frequent vomiting, headach, and delirium. After these symptoms had continued ten days, or somewhat longer, the patient recovered, though the eruption did not return. The diffuse redness connecting the papulæ, and the tendency to become pustular, distinguish the lichen agrius from the lichen simplex, and the other varieties of this complaint, in which the inflammation does not extend beyond the basis of the papulæ, and terminates in scurf, or scales.

Lichen pilaris. This is merely a modification of the first species of lichen, and like it, often alternates with complaints of the head, or stomach, in irritable habits. The peculiarity of the eruption is, that the small tubercles or asperities appear only at the roots of the hairs of the skin, being probably occasioned by an enlargement of their bulbs, or an unusual fulness of the blood-vessels distributed to them. This affection is distinguishable from the cutis anserina, by its permanency, by its red papulæ, and by the troublesome itching or tingling which attends it. If a part thus affected be violently rubbed, some of the papulæ enlarge to the size of wheals, but the tumour soon subsides again. The eruption continues more or less vivid for about ten days, and terminates, as usual, in small exfoliations of the cuticle, one of which surrounds the base of each hair. This complaint, as likewise the lichen agrius, frequently occurs in persons accustomed to drink largely of spirituous liquors undiluted.

Lichen lividus. The papulæ characterising this eruption are of a dark red, or livid hue, and somewhat more permanent than in the foregoing species of lichen. They appear chiefly on the arms and legs, but sometimes extend to other parts of the body. They are finally succeeded, though at very uncertain periods, by slight exfoliations of the cuticle, after which a fresh eruption is not preceded nor attended by any febrile symptoms. It principally affects persons of weak constitution, who live on a poor diet, and are engaged in laborious occupations. Young persons, and often children living in confined situations, or using little exercise, are also subject to the lichen lividus; and, in them, the papulæ are generally intermixed with petechiæ, or larger purple spots, resembling vibices. This circumstance points out the affinity of the lichen lividus with the purpura, or land-scurvy, and the connection is further proved by the exciting causes, which are the same in both complaints. The same method of treatment is likewise successful in both cases. They are presently cured by nourishing food, moderate exercise in the open air, along with the use of Peruvian bark and vitriolic acid, or the tincture of muriated steel.

Lichen tropicus. By this term is expressed the *prickly heat*, a papulous eruption, almost universally affecting Europeans settled in tropical climates. The prickly heat appears without any preceding disorder of the constitution. It consists of numerous papulæ, about the size of a small pin's head, and elevated so as to produce a considerable roughness on the skin. The papulæ are of a vivid red colour, and often exhibit an irregular form, two or three of them being in many places united together; but no redness or inflammation extends to the skin in the interstices of the papulæ.

Dr. Bateman has introduced another species — *Lichen urticatus.* In its first appearance it is in irregular, inflamed wheals, so closely resembling the spots excited by the bites of bugs or gnats, as almost to deceive the observer. The inflammation, however, subsides in a day or two, leaving small, elevated, itching papulæ. While the first wheals are thus terminating, new ones continue to appear in succession, until the whole body and limbs are spotted with papulæ, which becomes here and there confluent, in small patches. This eruption is peculiar to children: it commences, in some cases, soon after birth, and sometimes later, and continues with great obstinacy for many months. Both the wheals and the papulæ are accompanied with intense itching, which is exceedingly severe in the night, occasioning an almost total interruption of sleep, and considerable loss of flesh.

Frequent tepid bathing, light covering, especially in bed, with the use of small doses of sulphur, or the hydrargyrus sulphuratus niger, internally, appear to relieve the symptoms. The skin will not bear stimulation, and is irritated even by a bath of too high temperature. When it has occurred in feeble and emaciated children, it is relieved by chalybeate medicines, as the vinum ferri, or the solution of the tartrate before mentioned. This combination of inflamed papulæ, with intense itching, unites the characters of the lichen and prurigo; a union which, it must be allowed, is likewise not unfrequent in young adult persons.

A species of lichen has lately been described by M. Biett under the name of *lichen gyratus*, in which the papulæ are arranged in a spiral form.

II. In *Botany*, the name of a genus of plants (applied by the Romans to a plant, which was supposed by them to cure the lichen or tetter,) in the Linnæan system. Class, *Cryptogamia*; Order, *Algæ*. There are several species, some of which are used in medicine.

Lichen aphthosus. *Muscus camutalis.* This plant is said to have a good effect in some complaints of the intestines, but is not used in the practice of this country.

Lichen arboreus pullus. See *Lichen olivarius.*

Lichen caninus. The systematic name of

the ash-coloured ground liverwort. *Lichen terrestris. Lichen cinereus terrestris. Muscus caninus.* This cryptogamous plant has a weak, faint smell, and a sharpish taste. It was for a long time highly extolled as a medicine of singular virtue, in preventing and curing that dreadful disorder which is produced by the bite of rabid animals, but it is now deservedly forgotten.

Lichen cinereus terrestris. See *Lichen caninus.*

Lichen cocciferus. See *Lichen pyxidatus.*

Lichen coccineus. See *Lichen pyxidatus.*

LICHEN ISLANDICUS. The former name of the Iceland moss, or liverwort. See *Cetraria islandica* in the Supplement.

Lichen marinus. See *Ulva lactuca.*

LICHEN OLIVARIUS. Tree liverwort. *Lichen arboreus pullus.* An infusion of this is considered as strengthening to the lungs, and given in hæmorrhages, and against old coughs.

LICHEN PLICATUS. The systematic name of the *muscus arboreus.* This plant, we are informed by Linnæus, is applied by the Laplanders to parts which are excoriated by a long journey. It is slightly astringent, and is applied with that intention to bleeding vessels.

LICHEN PRUNASTRI. *Muscus arboreus.* This is astringent, and is used to strengthen the lungs.

LICHEN PULMONARIUS. *Lichen arboreus.* Pectoral moss. Tree lungwort. Oak lungs. Hazel crottles. The systematic name of the officinal *muscus pulmonarius quercinus. Pulmonaria arborea.* This sub-astringent and rather acid plant was once in high estimation in the cure of diseases of the lungs, especially coughs, asthmas, and catarrhs. Its virtues are similar, and in no way inferior to those of the lichen islandicus.

LICHEN PYXIDATUS. The systematic name of the cup-moss. *Muscus pyxidatus. Musculus pyxoides terrestris. Lichen pyxidatus major. Lichen coccineus.* The *Lichen cocciferus* and *pyxidatus*, very common little plants, are both used indifferently by the common people in this country in the cure of hooping-cough, in the form of decoction.

LICHEN ROCCELLA. Canary archel. Herb archel. *Roccella. Rocella tinctorum.* The systematic name of the roccella of the shops. This plant has been employed medicinally with success in allaying the cough attendant on phthisis, and in hysterical coughs. The principal use is as a blue dye. It is imported to us as it is gathered: those who prepare it for the use of the dyer grind it betwixt stones, so as thoroughly to bruise, but not to reduce it into powder, and then moisten it occasionally with a strong spirit of urine, or urine itself mixed with quicklime: in a few days, it acquires a purplish red, and, at length, a blue colour; in the first state it is called archel, in the latter lacmus or litmus.

Litmus is used in chemistry as a test, either staining paper with it, or by infusing it in water, when it is very commonly, but with great impropriety, called *tincture of turnsole.* The persons by whom this article was prepared formerly gave it the name of turnsole, pretending that it was extracted from the turnsole, *heliotropium tricoccum*, in order to keep its true source a secret. The tincture should not be too strong, otherwise it will have a violet tinge, which, however, may be removed by dilution. The light of the sun turns it red, even in close vessels. It may be made with spirit instead of water. This tincture, or paper stained with it, is presently turned red by acids; and if it be first reddened by a small quantity of vinegar, or some weak acid, its blue colour will be restored by an alkali.

LICHEN SAXATILIS. The systematic name of the *muscus cranii humani. Usnea.* This moss, when growing on the human skull, was formerly in high estimation, but is now deservedly forgotten.

LICHEN VELLEUS. This has the same virtues as the lichen pulmonarius.

LI'EN. (*en, ēnis.* m.; from λειος, soft or smooth.) The spleen. See *Spleen.*

LIEN SINARUM. The faba Ægyptia. See *Nymphæa nelumbo.*

LIENTE'RIA. (*a, æ.* f.; from λειος, smooth, and εντερον, the intestine.) Lientery. See *Diarrhœa.*

LIFE. Βιος. *Vita.* The word *life* has been used in two acceptations: in the one it means the aggregate of the phenomena resulting from the activities of an organised body; in the other it means the cause of those activities.

The chief points of difference between organised and inorganic bodies, have been noticed in the article *Body.*

Organisation is necessary to the manifestation of life; but it does not seem to be alone sufficient for this end, since a dead animal before the commencement of putrefaction, may, under certain circumstances, retain its organisation unchanged, as far at least as it is cognisable by our senses. Hence the majority of physiologists have supposed the cause of life to reside in an unknown something superadded to the organisation; a few, however, have maintained that the cause of life does indeed consist in the mere organisation, although the mechanical or chemical arrangements from which the phenomena of life result, are so minute and so intricate as to elude our observation.

A great variety of opinions have been held by physiologists in different ages, as to the nature of life: of these we shall here give a very brief review.

Hippocrates recognised a power in the living body, which he calls φυσις, *nature;* and this he represents as acting instinctively, and doing what is needful for the preservation of the frame.

Aristotle divided the vital powers into the *nutritive*, θρεπτικον; *sensitive*, αισθητικον; *appetitive*, ορεκτικον; *locomotive*, κινητικον κατα τοπον and *cogitative*, διανοητικον.

He referred the first four of these to a kind of soul common to man, animals, and plants; but regarded the thinking faculty as appertaining to another kind of soul, capable of a separate and independent existence. The soul common to all organised beings appear

to be no other than a vital principle. This classification of the vital powers will be found to correspond nearly with Bichat's doctrine of the *animal* and *organic* life; the nutritive faculty of Aristotle corresponding with the organic life, and the combined, sensitive, appetitive, and motive faculties, with the animal life.

Galen, perceiving that Aristotle had committed an error in associating phenomena which involve consciousness and will, with those of mere automatic life, proposed a new classification of the vital powers or faculties. These he divided into the *natural*, which is centred in the liver, and presides over nutrition, growth, and generation; the *vital*, which resides in the heart, and communicates life and heat through the arteries to all parts of the frame; and the *animal*, which is seated in the brain, producing the phenomena of the mind, causing sensation and motion by means of the nerves, and presiding over all the other functions. Three kinds of *spirits*, the natural, animal, and vital, formed by a sort of exhalation from the blood, minister to the respective faculties, and convey their influence through the appropriate channels. Besides the three principal faculties, Galen admitted the existence of certain subordinate faculties which presided over particular organs. In this fanciful arrangement we may trace two correct physiological notions; the one of a distinction between those functions which are essential to the existence of a living being, and those which maintain its conscious relations to external things; the other of modifications of the vital force as exercised in different organs. Galen referred the organic faculties to *nature*, φυσις — the vital principle of Hippocrates; the voluntary faculties he ascribed to the *soul*.

The physiological opinions of the ancients remained paramount till the sixteenth century, when Paracelsus appeared as the head of a *chemical school* of physiology. The physiologists of this school, however, by no means excluded a vital principle from their speculations; for Paracelsus and Van Helmont, its two most distinguished teachers, not only admit the existence of a vital principle, but personify it under the name of *Archeus*, whom they seem to regard as a very clever operative chemist, working in the laboratory of the living body. See *Archæus* and *Paracelsists*.

In the seventeenth century, the chemical researches of Hooke and Boyle gave rise to more plausible applications of chemistry to the explanation of vital phenomena, and no less persons than Sylvius, Willis, Mayow, and Helvetius, with others of high reputation, were, to a greater or less extent, disciples of the chemical school. At the same period, the atomic theory of Descartes had given rise to the *mathematical school*, in which it was attempted to explain all the vital phenomena on mechanical principles. Borelli may be considered as the head of this school. See *Iatro-mathematici*.

When the chemical and mathematical doctrines had had their run, a general recognition of their absurdity gave rise to a new school, styled the *dynamic*, because the vital phenomena were attributed to a δυναμις or *power*, acting in a great measure independently of external causes. Stahl is generally considered as the father of this school; and, according to him, the rational soul is the prime agent in the formation of the body and the maintenance of all its functions. The *anima* of Stahl was a very near relation of the *Archeus* of Van Helmont, though its mode of operation was very different. Stahl regarded chemistry, mathematics, and anatomy, as equally inadequate to explain the causes of the vital phenomena. He believed his *anima* to have no particular seat, but to be diffused through the whole frame, endowing every organ and texture with its peculiar vital properties, perceiving in the organs of sense, and causing contraction in the muscles, independently of the influence of the brain. Stahl's system involves the absurdity of an *unconscious intelligence*; it supposes that the soul can contrive and operate without being aware of it.

The views of Stahl were however partially adopted by many distinguished writers, and the tenet that the soul is the cause of all the vital motions, was laboriously maintained by Whytt.

This ingenious physiologist distinguished the vital motions into the *natural*, *involuntary*, and *voluntary*. The natural motions are those which are sustained by the moderate and constant supply of nervous power, uninfluenced by the will or any other stimulus: such are the tension of the sphincters and the general tone of parts; — the involuntary are those excited by stimuli applied to the nerves, in all of which the soul acts automatically and of necessity, but without consciousness; — the voluntary motions are the same as those so designated by other authors. With respect to the first class, it may be observed that Whytt, in common with too many other physiologists, lost sight of the great principle that the state of the living body is one of constant relation to external nature; that numerous extraneous causes are continually operating upon it; and that, consequently, the class of vital motions independent of stimuli is, in all probability, purely imaginary. Again, with respect to the class of involuntary motions, or those in which the soul intervenes without consciousness, if Whytt meant that the soul, even at the moment of its intervention, is actually unconscious of its own operation, the idea is manifestly absurd; since it is impossible to conceive any operation of an intelligent being but as some *mode* of consciousness: but if he meant (as he probably did), that the action of the soul is so slight and transitory as to leave no trace in the memory even a moment after, what evidence can we have that it has taken place?

The chemical, mathematical, and dynamic theories, were tempered and combined by Hoffmann and Boerhaave, who were rather judicious critics than original thinkers on physiology. They insisted upon the controlling influence of the nervous system over all the organic functions, whether performed chemically or mechanically. They thus substituted the nervous energy for the anima of Stahl, forgetful of those lower animals in which the existence of nervous mat-

ter, though probable, is hypothetical; and of plants, in which it does not exist at all, but both of which are nevertheless endowed with life.

The illustrious Haller, turning from empty speculations to the observation of facts, established by experiment the existence of two great modifications of vital power, namely, *sensibility* and *irritability*. The former of these he believed to reside exclusively in the brain and nerves, the latter in the muscular fibre. He believed that the muscles have a nervous power, or *vis nervea*, distributed to them from the brain through the nerves, distinct from their proper irritability, or *vis insita*. During the controversies carried on with contemporary physiologists, it became evident that Haller had taken too limited a view of sensibility and irritability, since many parts unquestionably endowed with life do not possess either of these properties as defined by him. The researches of Haller, however, put physiologists in the right track — that of investigating the phenomena of life as modified by the tissue in which they are developed. Hence we now recognise an *animal* and an *organic sensibility*; an *animal* and an *organic contractility*, of which last *irritability* is one of the species. The study of general anatomy, first raised into importance by Bichat, has extended the field for such investigations, and shown that there are no two textures the vital endowments of which are precisely similar; and, consequently, that if we would attain to just views of the phenomena of life, it must be by tracing the modification of a few general powers in the various textures of which the living body is composed. After Haller's time, John Hunter advanced his great doctrine of the life of the blood, which had, indeed, been zealously maintained by Harvey, but with so much inconsistency and obscurity, that his opinions on this subject are not worthy of much attention. For some time the experiments and reasonings of Hunter did not produce very general conviction; but the doubts of physiologists have been dissipated by further research and reflection; and the blood is now almost universally regarded as endowed with life — perhaps indeed as the original source from which the vital power of the solid parts is derived.

The opinions on life which regard it as the result of mechanical and chemical arrangements, to the exclusion of a vital principle, need not be dilated upon, because they have never been embraced by any school of physiologists, nor defended with any show of reason; and are, in truth, repugnant to the common sense of mankind.

In asserting the existence of a vital principle, we by no means attempt to define its nature, but consider it simply as the *unknown cause of life*.

Several physiologists, particularly Buffon, Needham, and Treviranus, have been of opinion that there is a kind of matter peculiar to living bodies, and alone susceptible of organisation. This doctrine has been ably defended by Treviranus, who concludes, that there is in nature a matter which is ever moving, by which all living beings, animal and vegetable, possess life, and which, though immutable in its essence, is, notwithstanding, variable in its form, and is incessantly changing it.

That this matter is deprived of form itself, but nevertheless ready to take that of life; that it maintains a determinate form under the influence of external causes; that it only continues in that form so long as these causes are active, and that it takes another so soon as new causes influence it.

That the matter capable of life, and the living principle, exist reciprocally, and that death is only a passage of certain forms of this matter to certain others.

This, however, is a subject on which nothing is positively known, or probably ever will be.

There is one physiological error which appears to have been almost universal till of late years, namely, that of regarding the vital principle as self-acting, instead of regarding it as something capable of reacting on the application of extraneous stimuli. The researches of Tiedemann and De Blainville have perhaps gone further than those of any other physiologists to establish a just view of this subject, and to demonstrate that life, as far as we know of it, is a *power of reaction modified in every part according to its texture, and called into operation in each texture by appropriate stimuli*.

The term *vital principle* is to be received only as a general expression for the power by which the phenomena of life are produced: physiologists must not, at present, attempt to determine the nature of this power — whether it reside in one agent or in many — whether it be a property of some particular kind of matter, or something superadded to common matter. These questions, indeed, afford scope for philosophical speculations which may, at some future period, be useful, and are therefore not to be discouraged; but, in the present state of our knowledge, the moment we make a supposed solution of them the basis of any practical views in physiology, we are sure to be led astray.

LI'GAMENT. (*Ligamentum*, *i.* n.; from *ligo*, to bind.) An elastic and strong membrane, connecting theextremities of the moveable bones. Ligaments are divided into *capsular*, which surround joints like a bag, and *connecting* ligaments. The use of the capsular ligaments is to connect the extremities of the moveable bones, and prevent the efflux of synovia; the external and internal connecting ligaments strengthen the union of the extremities of the moveable bones.

Ligamenta ala'ria. Alar ligaments. Two ligaments of the knee-joint, a *major* and a *minor*, are named alar from their wing-like shape.

Ligamenta interspinalia. Interspinous ligaments. The ligaments which pass between the spinous processes of the vertebræ.

Ligamenta intertransversalia. Intertransverse ligaments. The ligaments which pass between the transverse processes of the vertebræ.

Ligamenta radiata. The ligaments passing between the inner end of the clavicle and the sternum: also those which pass from the

extremities of the cartilages of the ribs over the sternum.

Ligamenta subflava. See *Spinal cord.*

Ligaments, crucial. The ligaments which cross each other within the knee-joint.

Ligaments, lateral. Ligaments situated at the sides of a joint, as the lateral ligaments of the knee and wrist.

Ligaments, vaginal. The sheath-like ligaments of the flexor tendons of the fingers.

Ligamentum annulare. Annular or ring-like ligament: the name of a strong ligament on each ankle and each wrist.

Ligamentum arteriosum. The ductus arteriosus of the fœtus, which becomes a ligament after birth, is so called.

Ligamentum brachio-cubitale. The brachio-cubital ligament. The expansion of the lateral ligament, which is fixed in the inner condyle of the os humeri, runs over the capsular, to which it closely adheres, and is inserted like radii on the side of the great sigmoid cavity of the ulna; it is covered on the inside by several tendons, which adhere closely to it, and seem to strengthen it very considerably.

Ligamentum brachio-radiale. The brachio-radial ligament. The expansion of the lateral ligament which runs over the external condyle of the os humeri, is inserted round the coronary ligament, from thence all the way down to the neck of the radius, and also in the neighbouring parts of the ulna. Through all this passage it covers the capsular ligament, and is covered by several tendons adhering closely to both.

Ligamentum capsulare. See *Ligaments.*

Ligamentum ciliare. See *Ciliary ligament.*

Ligamentum conoides. A ligament which passes from the root of the coracoid process to the clavicle.

Ligamentum deltoides. The triangular ligament which passes from the malleolus internus of the tibia to the astragalus os calcis and os naviculare.

Ligamentum denticulatum. A ligament extending the whole length of the spinal marrow.

Ligamentum fallopii. The round ligament of the uterus, and also Poupart's ligament, has been so called.

Ligamentum infundibuliforme. The ligament which joins the atlas to the occipital bone.

Ligamentum interclaviculare. The ligament which joins the two clavicles behind the top of the sternum.

Ligamentum interosseum. The ligament uniting the radius and ulna, and also that between the tibia and fibula.

Ligamentum latum. The broad ligament of the liver, and that of the uterus. See *Liver*, and *Uterus.*

Ligamentum nuchæ. Cervical ligament. A strong ligament which arises from the perpendicular spine of the occipital bone, and descends on the back part of the neck, adhering to the spinous processes of the cervical vertebræ.

Ligamentum orbiculare. The ligament which binds the neck of the radius to the ulna.

Ligamentum ovarii. The thick round portion of the broad ligament of the uterus, by which the ovarium is connected with the uterus.

Ligamentum posticum winslovii. Posterior ligament of Winslow. This consists of irregular bands, passing obliquely over the back part of the capsular ligament of the knee-joint from the external condyle of the femur to the upper and inner part of the tibia.

Ligamentum poupartii. Fallopian ligament. Poupart's ligament. A ligament extending from the anterior superior spinous process of the ilium to the crista of the os pubis.

Ligamentum rhomboides. *Ligamentum rhomboideum.* The ligament which binds the clavicle to the first rib.

Ligamentum rotundum. The round ligament of the uterus. See *Uterus.*

Ligamentum teres. The round ligament of the hip-joint. See *Femoris, os.*

Ligamentum trapezoides. *Ligamentum trapezoideum.* A ligament which passes from the point of the coracoid process of the scapula to the under edge of the clavicle.

Ligamentum triangulare. A ligament extending from the coracacoid to the acromial process of the scapula.

LI'GATURE. (*Ligatura, æ.* f.; from *ligo*, to bind.) A thread, or silk, of various thickness, covered with white wax, for the purpose of tying arteries, or veins, or other parts. Ligatures should be round and very firm, so as to allow their being tied with some force, without risk of breaking. For the effect of ligatures on arteries, see *Aneurism.*

LIGHT. *Lux.* The nature of light has occupied much of the attention of philosophers, and numerous opinions have been entertained concerning it. It has been sometimes considered as a distinct substance, at other times as a quality; sometimes as a cause, frequently as an effect; by some it has been considered as a compound, by others as a simple substance. Philosophers of the present day are mostly agreed as to the independent existence of light, or the cause by which see.

Nature of Light. — Light is that which proceeds from any body producing the sensation of vision, or perception of other bodies, by depicting an image of external objects on the retina of the eye. Hence it announces to animals the presence of the bodies which surround them, and enables them to distinguish these bodies into transparent, opake, and coloured. See *Vision.* These properties are so essentially connected with the presence of light, that bodies lose them in the dark, and become undistinguishable.

Light is regarded by philosophers as a substance consisting of a vast number of exceedingly small particles, which are actually projected from luminous bodies, and which probably never return again to the body from which they were emitted.

It is universally expanded through space. It exerts peculiar actions, and is obedient to the laws of attraction, and other properties of matter.

Explanation of certain terms in optics. — In order to facilitate the doctrine of light, we shall

shortly explain a few terms made use of by philosophers when treating of it; namely, —

A *ray of light* is an exceedingly small portion of light as it comes from a luminous body.

A *medium* is a body which affords a passage for the rays of light.

A *beam of light* is a body of parallel rays.

A *pencil of rays* is a body of diverging or converging rays.

Converging rays are rays which tend to a common point.

Diverging rays are those which come from a point, and continually separate as they proceed.

The rays of light are *parallel* when the lines which they describe are so.

The *radiant point* is the point from which diverging rays proceed.

The *focus* is the point to which the converging rays are directed.

Sources of Light. — Light is emitted from the sun, the fixed stars, and other luminous bodies. It is produced by percussion, during electrisation, combustion, and in various other chemical processes.

Why the sun and stars are constantly emitting light, is a question which probably will for ever baffle human understanding.

The light emitted during combustion exists previously, either combined with the combustible body, or with the substance which supports the combustion. The light liberated during chemical action, formed a constituent part of the bodies which act on each other.

Chemical properties. — The chemical effects of light have much engaged the attention of philosophers. — Its influence upon animal, vegetable, and other substances, is as follows: —

1. *On vegetables.* — Every body knows that most of the discous flowers turn constantly towards the sun till he sets, and again present their faces to him when he appears above the horizon in the morning. It is also well known that the change of position in the leaves of plants, at different periods of the day, is entirely owing to the agency of light; and that plants which grow in windows, in the inside of houses, are, as it were, solicitous to turn their leaves towards the light. Natural philosophers have long been aware of the influence of light on vegetation. It was first observed that plants growing in the shade, or darkness, are pale and without colour. The term *etiolation* has been given to this phenomenon, and the plants in which it takes place are said to be *etiolated*, or *blanched*. Gardeners avail themselves of the knowledge of this fact, to furnish our tables with white and tender vegetables. When the plants have attained a certain height, they compress the leaves, by tying them together, and by this means (or by lying earth over them) deprive them of the contact of light; and thus it is that our white celery, lettuce, cabbages, endive, &c., are obtained. For the same reason, wood is white under the green bark; and roots are less coloured than plants: some of them alter their taste, &c.; they even acquire a deleterious quality when suffered to grow exposed to light. Potatoes are of this kind. Herbs that grow beneath stones, or in places utterly dark, are white, soft, aqueous, and of a mild and insipid taste. The more plants are exposed to the light, the *more colour* they acquire. Though plants are capable of being nourished exceedingly well in the dark, and in that state grow much more rapidly than in the sun (provided the air that surrounds them is fit for vegetation), they are colourless and unfit for use.

Professor Davy found, by experiment, that red rose-trees, carefully excluded from light, produce roses almost white. He likewise ascertained that this flower owes its colour to light entering into its composition; that pink, orange, and yellow flowers, imbibe a smaller portion of light than red ones; and that white flowers contain no light. But vegetables are not only indebted to the light for their colour: taste and odour are likewise derived from the same source.

Light contributes greatly to the maturity of fruits and seeds. This seems to be the cause why, under the burning sun of Africa, vegetables are in general more odoriferous, of a stronger taste, and more abounding with resin. From the same cause it happens, that hot climates seem to be the native countries of perfumes, odoriferous fruits, and aromatic resins.

The action of light is so powerful on the organs of vegetables, as to cause them to pour forth torrents of pure air from the surface of their leaves into the atmosphere, whilst exposed to the sun: whereas, on the contrary, when in the shade, they emit an air of a noxious quality. Take a few handsful of fresh-gathered leaves of mint, cabbage, or any other plant; place them in a bell-glass, filled with fresh water, and invert it into a basin with the same fluid. If the whole be then exposed to the direct rays of the sun, small air bubbles will appear on the surface of the leaves, which will gradually grow larger, and at last detach themselves and become collected at the surface of the water. This is oxygen gas, or vital air.

All plants do not emit this air with the same facility: there are some which yield it the moment the sun acts upon them; as the jacobœa or ragwort, lavender, peppermint, and some other aromatic plants. The leaves afford more air when attached to the plant than when gathered: the quantity is also greater, the fresher and sounder they are, and if full grown, and collected during dry weather. Green plants afford more air than those which are of a yellowish or white colour. Green fruits afford likewise oxygen gas; but it is not so plentifully furnished by those which are ripe. Flowers in general render the air noxious. The nasturtium indicum, in the space of a few hours, gives out more air than is equal to the bulk of all its leaves. On the contrary, if a like bell-glass, prepared in the same manner, be kept in the dark, another kind of air will be disengaged, of an opposite quality.

There is not a substance which, in well-closed glass vessels, and exposed to the sun's light, does not experience some alteration.

Camphire kept in glass bottles, exposed to light, crystallises into the most beautiful sym

metrical figures, on that side of the glass which is exposed to the light.

Yellow wax, exposed to the light, loses its colour, and becomes bleached. Gum guaiacum, reduced to powder, becomes green on exposure to light. Vegetable colours, such as those of saffron, logwood, &c., become pale, or white, &c.

2. *On animals.* — The human being is equally dependent on the influence of light. Animals in general droop when deprived of light: they become unhealthy, and even sometimes die. When a man has been long confined in a dark dungeon (though well aired), his whole complexion becomes sallow; pustules, filled with aqueous humours, break out on his skin; and the person, who has been thus deprived of light, becomes languid, and frequently dropsical. Worms, grubs, and caterpillars, which live in the earth, or in wood, are of a whitish colour; moths, and other insects of the night, are likewise distinguishable from those which fly by day, by the want of brilliancy in their colour. The difference between those insects, in northern and southern parts, is still more obvious.

The parts of fish which are exposed to light, as the back, fins, &c., are uniformly coloured; but the belly, which is deprived of light, is white in all of them.

Birds which inhabit the tropical countries have much brighter plumage than those of the north. Those parts of the birds which are not exposed to the light, are uniformly pale. The feathers on the belly of a bird are generally pale, or white; the back, which is exposed to the light, is almost always coloured; the breast, which is particularly exposed to light in most birds, is brighter than the belly.

Butterflies, and various other animals of equatorial countries, are brighter coloured than those of the polar regions. Some of the northern animals are even darker in summer and paler in winter.

3. *On other substances.* — Certain metallic oxides become combustible when exposed to light; and acids, as the nitric, &c., are decomposed by its contact, and various other substances change their nature.

Light carbonated hydrogen. See *Carburetted hydrogen gas.*

LIGNEUS. Woody. Applied, in *Botany*, to pods, barks, &c., which are of a hard or woody texture; as the strobile of the *Pynus sylvestris.*

Lignin. See *the Supplement.*

Ligno'sus. See *Ligneus.*

LI'GNUM. (*um, i.* n.) Wood.

Lignum agallochi veri. See *Lignum aloes.*

LIGNUM ALOES. *Lignum agallochi veri. Agalluge. Agallugum. Lignum aquilæ. Lignum calambac. Lignum aspalathi. Xylo aloes. Agallochum. Calambac.* Aloes wood. The tree, the wood of which bears this name, is not yet scientifically known. It is by some supposed to be the *Excœaria agallocha*, the bark as well as the milk of which is purgative. It is imported from China in small, compact, ponderous pieces, of a yellow rusty brown colour, with black or purplish veins, and sometimes of a black colour. It has a bitterish resinous taste, and a slight aromatic smell. Hoffmann regarded the essential oil of this wood, when dissolved in spirit of wine, as one of the best cordials and invigorants that pharmacy has ever possessed, and especially in debilitated stomachs accompanied with general depression. It is used to fumigate rooms in eastern countries.

Lignum aquilæ. See *Lignum aloes.*

Lignum aspalathi. See *Lignum aloes.*

Lignum brariliense. See *Cæsalpina.*

Lignum calambac. See *Lignum aloes.*

Lignum campechense. See *Hæmatoxylon.*

Lignum colubrinum. See *Strychnos colubrina.*

Lignum indicum. See *Guaiacum.*

Lignum moluccense. See *Croton tiglium.*

Lignum nephriticum. See *Guilandina.*

Lignum pavanæ. See *Croton tiglium.*

Lignum rhodium. See *Aspalathus.*

Lignum sanctum. See *Guaiacum.*

Lignum santali rubri. See *Pterocarpus.*

Lignum sappan. See *Hæmatoxylon.*

Lignum serpentinum. See *Ophioxylum.*

Lignum vitæ. See *Guiacum officinale.*

LIGNUM'S ANTISCORBUTIC DROPS. A quack preparation of corrosive sublimate. The proprietor's name was Wood.

LI'GULA. (*a, æ.* f.; a strap.) 1. The clavicle.

2. The glottis.

3. A measure containing ten scruples.

4. The small transparent membrane on the margin of the sheath and base of the leaves of grasses.

LIGULA'TUS. Strap-shaped; shaped like a strap or riband: applied to a kind of floret of a compound flower, which is so shaped; as that of the *Tragopogon*, and *Taraxacum.*

LIGUS'TICUM. (*um, i.* n. Λιγυστικον of Dioscorides; so called from *Liguria*, in Italy, its native country.) The name of a genus of plants. Class, *Pentandria;* Order, *Digynia.*

LIGUSTICUM LEVISTICUM. The systematic name of lovage. *Levisticum.* The odour of this plant, *Ligusticum — foliis multiplicibus foliolis superne incicis*, of Linnæus, is very strong, and particularly ungrateful; its taste is warm and aromatic. It abounds with a yellowish gummy resinous juice, very much resembling opoponax, and called English opoponax. Its virtues are supposed to be similar to those of angelica and masterwort; namely, carminative, diaphoretic, and deobstruent; therefore it is chiefly used in hysterical disorders and uterine obstructions. The leaves, eaten in salad, are accounted emmenagogue. The root, which is less ungrateful than the leaves, is said to possess similar virtues, and may be employed in powder.

LIGU'STRUM. (*um, i.* n.; from *ligo*, to bind: so named from its use in making bands.) 1. The name of a genus of plants in the Linnæan system. Class, *Diandria;* Order, *Monogynia.*

2. The pharmacopœial name of the herb privet, the *Ligustrum vulgare.*

LILIA'CEUS. (From *lilium*, a lily.) Liliaceous, or resembling the lily.

LILIACEÆ. The name of an order of plants

in Linnæus's Fragments of a Natural Method, consisting of such as have liliaceous corollæ, and a three-lobed stigma; as colchicum, lilium, crocus, &c.

LILIACI'NUS. Liliacine: applied to colour like that of the lilac, or *Syringa vulgaris*. See *Colour*.

LILIA'GO. (*o, onis*, f.; diminutive of *lilium*, the lily: so named from the resemblance of its flower to that of a lily.) *Liliastrum*. Spider-wort. The *Anthericum liliastrum* of Linnæus, formerly said to be alexipharmic and carminative.

LI'LIUM. (*um, ii.* n.; the Latin name of the lily.) The name of a genus of plants in the Linnæan system. Class, *Hexandria*; Order, *Monogynia*. The lily.

Lilium album. See *Lilium candidum*.

LILIUM CANDIDUM. The systematic name of the white lily. *Lilium album*. *Lilium — foliis sparsis, corollis campanulatis, intus glabris*, of Linnæus. The roots are directed by the Edinburgh Pharmacopœia: they are extremely mucilaginous, and chiefly used, boiled in milk and water, in emollient and suppurating cataplasms, to inflammatory tumours. These lily-roots afford a good substitute, in times of scarcity, for bread. The distilled water has been sometimes used as a cosmetic.

Lilium convallium. See *Convallaria*.

Lilium croceum. See *Hemerocallis*.

LILIUM MARTAGON. The martagon lily. Linnæus tells us that the root of this plant forms a part of the ordinary food of the Siberians.

Lilium purpureum. See *Hemerocallis*.

Lilium rubrum. See *Hemerocallis*.

Lily. See *Lilium*, and *Nymphæa*.

Lily, May. See *Convallaria majalis*.

Lily, water. See *Nymphæa*.

Lily, white. See *Lilium candidum*.

Lily of the valley. See *Convallaria*.

LIMATU'RA. (*a, æ.* f.; from *lima*, a file.) File dust. Filings.

LIMATURA FERRI. Iron filings. These, when taken internally, become more or less oxidised in the stomach and intestines: they act, therefore, as a mild chalybeate. The dose is from gr. v. to ʒ ss.

LIMATURA STANNI. Tin filings. See *Stannum*.

LI'MAX. (*ax, acis.* m.; from *limus*, slime: so named from its sliminess.) The slug. This animal abounds with gelatinous matter, and forms a nutritious decoction with milk or water. It was formerly much used in cases of consumption and atrophy. These decoctions are apparently very nutritious and demulcent, and are recommended in consumptive cases and emaciations.

LIMBUS. (*us, i.* m.) The limb, brim, or border. In *Botany*, applied to a part of the corolla. See *Corolla*.

LIME. *Calx*.

1. The oxide of calcium, one of the primitive earths. It is found in great abundance in nature, though never pure, or in an uncombined state. It is always united to an acid, and very frequently to the carbonic acid, as in chalk, common limestone, marble, calcareous spar, &c. It is contained in the waters of the ocean; it is found in vegetables; and is the basis of the bones, shells, and other hard parts of animals. Its combination with sulphuric acid is known by the name of sulphate of lime (*gypsum*, or plaster of Paris). Combined with fluoric acid it constitutes fluate of lime, or Derbyshire spar.

Properties. — Lime is in solid masses, of a white colour, moderately hard, but easily reducible to powder. Its taste is bitter, urinous, and burning. It changes blue cabbage-juice to a green. It is unalterable by the heat of our furnaces. It splits and falls into powder in the air, and loses its strong taste. It is augmented in weight and in size by slowly absorbing water and carbonic acid from the atmosphere. Its specific gravity is 2·3. It combines with phosphorus by heat, forming a compound which ignites on being thrown into water. It unites to sulphur both in the dry and humid way. It unites with chlorine to form a compound which some consider as a chloride of lime, but which Berzelius regards as a *chlorite*, and Balard as a *hypochlorite*. Mr. R. Phillips regards it as consisting of one equivalent of bi-hydrated chloride of lime, and one of lime. It absorbs sulphuretted hydrogen gas. It unites with some of the metallic oxides. Its slaking by water is attended with heat, hissing, splitting, and swelling up, while the water is partly consolidated and partly converted into vapour; and the lime is reduced into a very voluminous dry powder, when it has been sprinkled with only a small quantity of water. It is soluble, when well prepared, in about 450 parts of water. It unites to acids. It renders silex and alumine fusible, and more particularly these two earths together.

Method of obtaining Lime. — Since the carbonic acid may be separated from the native carbonate of lime, this becomes a means of exhibiting the lime in a state of tolerable purity. For this purpose introduce into a porcelain or earthern retort, or rather into a tube of green glass, well coated over with lute, and placed across a furnace, some powdered Carrara marble, or oyster-shell powder. Adapt to its lower extremity a bent tube of glass, conveyed under a bell. If we then heat the tube, we obtain carbonic acid gas, and lime will be found remaining in the tube or retort.

The burning of lime, in the large way, depends on the disengagement of the carbonic acid by heat; and, as lime is infusible in our furnaces, there would be no danger from too violent a heat, if the native carbonate of lime were perfectly pure; but as this is seldom the case, an extreme degree of heat produces a commencement of vitrification in the mixed stone, and enables it to preserve its solidity, and it no longer retains the qualities of lime, for it is covered with a sort of crust, which prevents the absorption of the water when it is attempted to be slaked. This is called over-burnt lime.

In order to obtain lime in a state of great purity, the following method may be had recourse to: —

Take Carrara marble, or oyster shells; reduce

them to powder, and dissolve the powder in pure acetic acid; precipitate the solution by carbonate of ammonia. Let the precipitate subside, wash it repeatedly in distilled water, let it dry, and then expose it to a white heat for some hours.

The acetic acid, in this operation, unites to the lime, and forms acetate of lime, disengaging at the same time the carbonic acid, which flies off in the gaseous state: on adding to the acetate of lime carbonate of ammonia, acetate of ammonia and an artificial carbonate of lime are formed; from the latter the carbonic acid is again expelled, by exposure to heat, and the lime is left behind in a state of perfect purity. Several preparations of lime are used medicinally. See *Calcis chloridum*, *Calcis liquor*, *Calcii chloridum*, *Calcii chloridi liquor creta præparata*, *Potassa cum calce*.

2. A fruit like a small lemon. See *Citrus limetta*, in the Supplement.

Lime-tree. See *Tilia europæa.*

Lime-water. See *Calcis liquor.*

LI'MON. (Hebrew.) A lemon. See *Citrus medica.*

LIMONADE MINERALE. Mineral lemonade. The French strangely enough give this name to water acidulated with a mineral acid, and sweetened. These preparations are used as cooling drinks in fevers and inflammations.

LIMONADE NITRIQUE. Water acidulated with nitric acid, and sweetened.

LIMONADE SULPHURIQUE. Water acidulated with sulphuric acid, and sweetened.

LIMONADE TARTARIQUE. Water acidulated with tartaric acid, and sweetened.

LIMONIA MALUS. The lemon.

LIMO'NIUM. (*um*, *ii.* n.; from λειμων, a green field: so called from its colour.) This name has been applied to, —

1. The lemon.
2. The *Valeriana rubra.*
3. The *Polygonum fagopyrum.*
4. The *Pyrola rotundifolia.*
5. To the sea-lavender, or *Statice limonium*, of Linnæus, which is said to possess astringent properties.

LIMO'SIS. (*is*, *is.* f.; from λιμος, hunger.) Morbid appetite. The name given by Dr. Good to a genus of diseases, characterised by depraved, excessive, or defective appetite.

LINAGRO'STIS. (*is*, *is.* f.; from λινον, cotton, and αγρωστις, grass: so called from the softness of its texture.) Cotton-grass. The *Eriophorum* of Linnæus.

LINANGI'NA. (*a*, *æ.* f.; from *linum*, flax, and *ango*, to strangle: so called, because it twines itself round flax and chokes it.) See *Cuscuta europæa.*

LINA'RIA. (*a*, *æ.* f.; from *linum*, flax: named from the resemblance of its leaves to those of flax.) See *Antirrhinum linaria.*

LI'NCTUS. (*us*, *ûs.* m.; from *lingo*, to lick.) *Lohoc. Eclegma. Elexis. Elegma. Eclectos. Ecleitos. Illinctus.* A loch, a lambative. A term in pharmacy, that is generally applied to a soft substance, of the consistence of honey, which is licked off the spoon.

LI'NEA. (*a*, *æ.* f.; from *linum*, a thread.) A line: applied to some parts which have a line-like appearance.

LINEA ALBA. *Linea centralis.* A tendinous line that extends from the scrobiculus cordis straight down to the navel, and from thence to the pubes. It is formed by the tendinous fibres of the internal oblique ascending, and the external oblique descending muscles, and the transversalis, interlaced with those of the opposite side.

LINEA ILIO-PECTINEA. The lateral margin of the brim of the pelvis.

Linea innominata. See *Linea ilio-pectinea.*

LINEA SEMILUNARIS. The white line on the outer margin of each rectus muscle of the belly, formed by the union of the abdominal tendons.

LINEÆ TRANSVERSÆ. The lines which cross the recti muscles of the abdomen.

LINEA'RIS. Linear: strap-shaped. Applied to leaves, petals, leafstalks, seeds, &c., of plants, which are narrow, with parallel sides; as the leaves of most grasses, those of the *Narcissus*, *Pseudo-narcissus*, and the petals of the *Tussilago farfara*, leafstalk of the *Citrus medica*, and seeds of the *Crucianella.*

LINEATUS. Lineate, or streaked.

Ling. See *Gadus molva.*

LI'NGUA. (*a*, *æ.* f.; from *lingo*, to lick up.) The tongue. See *Tongue.*

LINGUA AVIS. The seed-vessel of the *Fraxinus*, or ash, is so called, from its supposed resemblance to a bird's tongue. It is also called *lingua passerina*, sparrow's tongue.

LINGUA CANINA. So called from the resemblance of its leaves to a dog's tongue. See *Cynoglossum.*

LINGUA CERVINA. Hart's tongue. See *Scolopendrium vulgare.*

Lingua passerina. See *Lingua avis.*

LINGUA'LIS. (From *lingua*, the tongue.) *Basio-glossus*, of Cowper. A muscle of the tongue. It arises from the root of the tongue laterally, and runs forward between the hyo-glossus and genio-glossus, to be inserted into the tip of the tongue, along with part of the stylo-glossus. Its use is to contract the substance of the tongue, and to bring it backwards.

Linguifo'rmis. See *Lingulatus.*

LINGULA'TUS. (From *lingua*, a tongue.) *Linguiformis.* Tongue-shaped; applied to a leaf of a thick, oblong, blunt figure, generally cartilaginous at the edges; as in the *Mesembryanthemum linguiforme.*

Liniment. See *Linimentum.*

Liniment of ammonia. See *Linimentum ammoniæ.*

Liniment of camphire. See *Linimentum camphoræ.*

Liniment of mercury. See *Linimentum hydrargyri compositum.*

Liniment of turpentine. See *Linimentum terebinthinæ.*

Liniment of verdigris. See *Linimentum æruginis.*

Liniment, volatile. See *Linimentum ammoniæ.*

LINIME'NTUM. (*um*, *i.* n.; from *lino*,

to anoint.) A liniment. A medicament of a mediate consistence, between an ointment and oil, used to rub upon diseased parts. A medicine similarly applied, but of thinner consistence, is called an *embrocation*.

Linimentum æruginis. Liniment of verdigris, formerly called oxymel æruginis, mel Ægyptiacum, and unguentum Ægyptiacum. Take of verdigris, powdered, an ounce; vinegar, seven fluid ounces; clarified honey, fourteen ounces. Dissolve the verdigris in the vinegar, and strain it through a linen cloth; having added the honey gradually, boil it down to a proper consistence.

Linimentum album. Spermaceti ointment has been so called.

Linimentum ammoniæ. *Linimentum ammoniæ fortius. Oleum ammoniatum.* Volatile liniment. Strong liniment of ammonia. Take of solution of ammonia, a fluid ounce; olive oil, two fluid ounces. Shake them together until they unite. A more powerful stimulating application than the former, acting as a rubefacient. In pleurodynia, indolent tumours, stiffness of the joints, and arthritic pains, it is to be preferred to the milder one.

Linimentum ammoniæ sesquicarbonatis. *Linimentum ammoniæ subcarbonatis.* Liniment of subcarbonate of ammonia, formerly called linimentum ammoniæ and linimentum volatile. Take of solution of subcarbonate of ammonia, a fluid ounce; olive oil, three fluid ounces. Shake them together until they unite. A stimulating liniment, mostly used to relieve rheumatic pains, bruises, and paralytic numbness.

Linimentum aquæ calcis. Liniment of lime-water. This consists of equal parts of linseed oil and lime-water, and has long been known, under the name of *carron oil*, as an application to burns and scalds.

Linimentum arcei. Liniment of Arceus. The *Unguentum elemi compositum*.

Linimentum ca'mphoræ. Camphire liniment. Take of camphor, an ounce; olive oil, four fluid ounces. Dissolve the camphire in the oil. In retentions of urine, rheumatic pains, distensions of the abdomen from ascites, and tension of the skin from abscess, this is an excellent application.

Linimentum camphoræ compositum. Compound camphire liniment. Take of camphor, two ounces and a half; solution of ammonia, seven fluid ounces; spirit of lavender, a pint. Mix the solution of ammonia with the spirit in a glass retort; then, by the heat of a slow fire, distil a pint. Lastly, in this distilled liquor dissolve the camphire. An elegant and useful stimulant application in paralytic, spasmodic, and rheumatic diseases. Also for bruises, sprains, rigidities of the joints, incipient chilblains, &c.

Linimentum hydrargyri compositum. Mercurial liniment. Take of strong mercurial ointment, prepared lard, of each four ounces; camphor, an ounce; rectified spirit, a fluid drachm; solution of ammonia, four fluid ounces. First powder the camphor, with the addition of the spirit, then rub it with the mercurial ointment and the lard; lastly, add gradually the solution of ammonia, and mix the whole together. An excellent formula in all surgical cases in which the object is to quicken the action of the absorbents, and gently stimulate the surfaces of parts. It is a useful application for diminishing the indurated state of particular muscles, a peculiar affection every now and then met with in practice; and it is particularly well calculated for lessening the stiffness and chronic thickening often noticed in the joints. If it be frequently or largely applied, it affects the mouth more rapidly than the mercurial ointment.

Linimentum opii. *Linimentum opiatum.* This consists of six fluid ounces of soap liniment, and two of tincture of opium. It is a resolvent anodyne embrocation, adapted to remove indolent tumours of the joints, and those weaknesses which remain after strains, and chilblains before they break.

Linimentum saponis compositum. Compound soap liniment. *Linimentum saponis compositum.* Take of hard soap, three ounces; camphire, an ounce; spirit of rosemary, a pint. Dissolve the camphire in the spirit, then add the soap, and macerate in the heat of a sand-bath, until it be melted. The basis of this form was first proposed by Riverius, and it is now commonly used under the name of opodeldoc. This is a more pleasant preparation, to rub parts affected with rheumatic pains, swellings of the joints, &c. than any of the foregoing, and at the same time not inferior, except where a rubefacient is required.

Linimentum saponis cum opio. Soap liniment, with opium. Take of compound soap liniment, six ounces; tincture of opium, two ounces. Mix. For dispersing indurations and swellings, attended with pain, but no acute inflammation.

Linimentum terebinthinæ. Turpentine liniment. Take of soft soap, two ounces; camphor, an ounce; oil of turpentine, half a pint. Shake them together until they are mixed. This liniment is very commonly applied to burns, and is a modification of that used by Mr. Kentish, of Newcastle.

Linimentum terebinthinæ vitriolicum. Vitriolic liniment of turpentine. Take of olive oil, ten ounces; oil of turpentine, four ounces; vitriolic acid, three drachms. Mix. This preparation is said to be efficacious in chronic affections of the joints, and in the removal of long existing effects of sprains and bruises.

LINNÆ'A. (*a*, *æ*. f.; so named in honour of Linnæus.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*. Order, *Angiospermia*.

Linnæa borealis. A plant inhabiting the northern countries of Europe, which has a bitter subastringent taste. It is used in some places in the form of fomentation, for rheumatic pains; and an infusion with milk is much esteemed in Switzerland in the cure of sciatica.

Linospe'rmum. (*um*, *i*. n.; from λινον, flax, and σπερμα, seed.) Linseed. See *Linum usitatissimum*.

LINOZO'STIS. A name of the herb mercury. — *Dioscorides.* See *Mercurialis.*

Linseed. See *Linum usitatissimum.*

Lint. See *Linteum.*

LI'NTEUM. (*um, ei.* n.) Lint. Charpie. A soft woolly substance, made by scraping old linen cloth, and employed in surgery as the common dressing in all cases of wounds and ulcers, either simply or covered with different unctuous substances.

LI'NUM. (*um, i.* n. Λινον.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Pentagynia.*

2. The pharmacopœial name of the common flax. See *Linum usitatissimum.*

LINUM CATHARTICUM. *Linum minimum. Chamælium.* Purging flax, or mill-mountain. This small plant, *Linum — foliis oppositis ovato-lanceolatis, caule dichotomo, corollis acutis,* of Linnæus, is an effectual and safe cathartic. It has a bitterish and disagreeable taste. A handful infused in half a pint of boiling water is the dose for an adult.

LINUM USITATISSIMUM. The systematic name of the common flax. *Linum sylvestre. Linum — calycibus capsulisque mucronatis, petalis crenatis, foliis lanceolatis alternis, caule subsolitario,* of Linnæus. The seeds of this useful plant, called linseed, have an unctuous, mucilaginous, sweetish taste, but no remarkable smell; on expression they yield a large quantity of oil, which, when carefully drawn without the application of heat, has no particular taste or flavour: boiled in water, they yield a large proportion of a strong flavourless mucilage, which is in use as an emollient or demulcent in cough, hoarsenesses, and pleuritic symptoms, that frequently prevail in catarrhal affections; and it is likewise recommended in nephritic pains and stranguries. The meal of the seeds is also much used externally, in emollient and maturating cataplasms. The expressed oil is an officinal preparation, and is supposed to be of a more healing and balsamic nature than the other oils of this class: it has, therefore, been very generally employed in pulmonary complaints, and in colics and constipations of the bowels. The cake which remains after the expression of the oil contains the farinaceous part of the seed, and is used in fattening cattle, under the name of oil-cake.

Lip. See *Labium.*

LIPAROCE'LE. (From λιπαρος, fat, and κηλη, a tumour.) A fatty tumour. The name has been especially given to a fatty tumour in the scrotum.

LIPAROTRI'CHIA. (From λιπαρος, smooth, and θριξ, a hair.) The name given by Frank to a diseased condition of the hair, in which it is more oily than natural.

LIPA'SMA. (Λιπασμα; from λιπαινω, to grow fat.) The Greek name for any medicine used externally by inunction, for the purpose of fattening the body.

LIPO'MA. (*a, atis.* n.; from λιπος, fat.) An encysted fatty tumour.

LIPOPSY'CHIA. (*a, æ.* f.; from λειπω, to leave, and ψυχη, the soul, or life.) A swoon, or fainting. See *Syncope.*

LIPOTHY'MIA. (*a, æ.* f.; from λειπω, to leave, and θυμος, the mind.) Fainting. See *Syncope.*

LIPPITU'DO. (*o, inis.* f.; from *lippus,* blear-eyed.) Blear-eyedness. A chronic disease, the result often of acute tenacious ophthalmia. It consists in an exudation of a puriform matter from the margin of the eyelids. This matter glues the tarsi of the eyelids together during the night. The margins of the eyelids are red, and tumid, and painful. See *Ophthalmitis.*

Lipy'ria. See *Leipyria.*

LIQUA MUMIA. Human fat. — *Ruland.*

LIQUIDA'MBAR. (From *liquidum,* fluid, and *ambar,* a fragrant substance, generally taken for ambergris; alluding to the aromatic liquid gum which distils from this tree.) The name of a genus of plants in the Linnæan system. Class, *Monœcia.* Order, *Polyandria.*

LIQUIDAMBAR STYRACI'FLUA. The systematic name of the tree which affords both the liquid amber and liquid storax. The liquid amber is a resinous juice of a yellow colour, inclining to red, at first about the consistence of turpentine, by age hardened into a solid brittle mass. It is obtained by wounding the bark of this tree, which is described by Linnæus, the *Liquidambar — foliis palmato-angulatis; foliis indivisis, acutis.* The juice has a moderately pungent, warm, balsamic taste, and a very fragrant smell, not unlike that of the *Styrax calamita,* heightened by a little ambergris. It is seldom used medicinally. The *Styrax liquida* is also obtained from this plant by boiling. There are two sorts distinguished by authors: the one the purer part of the resinous matter, that rises to the surface in boiling, separated by a strainer, of the consistence of honey, tenacious like turpentine, of a reddish or ash-brown colour, moderately transparent, of an acrid unctuous taste, and a fragrant smell, faintly resembling that of the solid styrax, but somewhat disagreeable. The other, the more impure part which remains on the strainer, untransparent, and in smell and taste much weaker than the former. Their use is chiefly as stomachics, in the form of plaster.

LIQUEFACTION. *Liquatio. Liquefi-catio.* The conversion of a liquid. The word is, therefore, in some instances synonymous with *fusion,* in others with *deliquescence,* and in others with *solution.*

LIQUIRI'TIA. (*a, æ.* f.; most likely of *glycyrrhiza.*) Liquorice. See *Glycyrrhiza.*

LI'QUOR. (*or, oris.* m.; from *liqueo,* to become liquid.) A liquor. This term is applied in the later editions of the London Pharmacopœia to some preparations, before improperly called waters; as the *aqua ammoniæ,* &c.

Liquor acetatis plumbi. See *Plumbi diacetatis liquor.*

Liquor acetatis plumbi dilutus. See *Plumbi diacetatis liquor dilutus.*

Liquor ætherous vitriolicus. See *Æther sulphuricus.*

LIQUOR ALUMINIS COMPOSITUS. Compound solution of alum. Take of alum, sulphate of zinc, of each an ounce; boiling water, three pints. Dissolve at the same time the alum and sul-

phate of zinc in the water, and then strain. This water was long known in our shops under the title of *aqua aluminosa Batcana*. It is used for cleansing and healing ulcers and wounds, and for removing cutaneous eruptions, the part being bathed with it hot three or four times a day. It is sometimes likewise employed as a collyrium; and as an injection in fluor albus and gleet.

Liquor ammoniæ. See *Ammonia.*

Liquor ammoniæ acetatis. See *Ammoniæ acetatis liquor.*

Liquor ammoniæ carbonatis. See *Ammoniæ subcarbonatis liquor.*

LIQUOR AMMONIÆ SESQUICARBONATIS. The name in the London Pharmacopœia of 1836, for the preparation before called *liquor ammoniæ subcarbonatis.*

Liquor ammoniæ subcarbonatis. See *Ammoniæ subcarbonatis liquor.*

Liquor of ammonia. See *Ammonia.*

Liquor amnii. See *Amnios.*

Liquor anodynus mineralis. See *Liquor mineralis anodynus Hoffmanni.*

Liquor antimonii tartarizati. See *Antimonii tartarizati liquor.*

LIQUOR ARGENTI NITRATIS. Take of nitrate of silver a drachm, distilled water a fluid ounce. Dissolve the nitrate in the water and strain. Keep it in a well-closed bottle, preserved from the light. This formula is introduced into the London Pharmacopœia of 1836.

Liquor arsenicalis. See *Arsenicalis liquor.*

LIQUOR AQUILEGIUS. Spirit of wine. — *Ruland.*

LIQUOR BARII CHLORIDI. Solution of chloride of barium. Solution of muriate of baryta. Take of chloride of barium a drachm; distilled water a fluid ounce. Dissolve and strain. The dose of this solution is five drops, twice a day, gradually increased to twenty drops or more. For its virtues, see *Baryta.*

Liquor calcii chloridi. See *Calcii chloridi liquor.*

Liquor calcis. See *Calcis liquor.*

Liquor cupri ammoniati. See *Liquor cupri ammonio-sulphatis.*

LIQUOR CUPRI AMMONIO-SULPHATIS. Solution of ammonio-sulphate of copper. This is made, according to the formula of the present London Pharmacopœia, by dissolving a drachm of the ammonio-sulphate in a pint of distilled water. It is a mild escharotic and detergent wash for indolent ulcers, &c.

Liquor ferri alkalini. See *Ferri alkalini liquor.*

Liquor hydrargyri oxymuriatis. See *Hydrargyri bichloridum.*

LIQUOR MINERALIS ANODYNUS HOFFMANNI. Hoffmann's anodyne liquor. See *Spiritus ætheris sulphurici compositus.*

Liquor potassæ. See *Potassæ liquor.*

Liquor subcarbonatis potassæ. See *Potassæ sesquicarbonatis liquor.*

LIQUOR VOLATILIS CORNU CERVI. This preparation of the fluid volatile alkali, commonly termed spirits of hartshorn, is in common use to smell at in faintings, &c. See *Ammoniæ subcarbonas.*

Liquorice. See *Glycyrrhiza.*

Liquorice, Spanish. See *Glycyrrhiza.*

LIRE'LLA. (*a, æ.* f.; diminutive of *lira*, a ridge between two furrows.) In *Botany*, a sessile receptacle, containing polyspermous elytra; as in *opegrapha.*

Lisbon diet drink. See *Decoctum Lusitanicum.*

LITHAGO'GUS. (From λιθος, a stone, and αγω, to bring away.) Lithagogue: having the power of expelling the stone. Formerly applied to medicines supposed to expel small calculi from the kidneys or bladder.

Litharge. See *Lithargyrum.*

Litharge plaster. See *Emplastrum lithargyri.*

LITHA'RGYRUM. (*um, i.* n.; and *us, i.* m.; from λιθος, a stone, and αργυρος, silver.) *Lithargyrus.* Litharge. An oxide of lead, in an imperfect state of vitrification. When silver is refined by cupellation with lead, this latter metal, which is scorified, and causes the scorification of the imperfect metals alloyed with the silver, is transformed into a matter composed of small semitransparent shining plates, resembling mica; which is litharge. Litharge is more or less white or red, according to the metals with which the silver is alloyed. The white is called litharge of silver; and the red has been improperly called litharge of gold.

LITHI'A. (*a, æ.* f.; from λιθειος, stony.) The name of an alkali, discovered in the year 1818 by Arfwedson, at that time employed in the laboratory of Berzelius. It was found in a mineral, from the mine of Uten in Sweden, called *petalite* by D'Andrada, who first distinguished it. Sir H. Davy demonstrated, by voltaic electricity, that the basis of this alkali is a metal, to which the name of *lithium* has been given.

Caustic lithia has a very sharp burning taste. It destroys the cuticle of the tongue like potash. It does not dissolve with great facility in water, and appears not to be much more soluble in hot than in cold water. In this respect it has an analogy with lime. Heat is evolved during its solution in water.

When exposed to the air it does not attract moisture, but absorbs carbonic acid, and becomes opake. When exposed for an hour to a white heat in a covered platinum crucible, its bulk does not appear to be diminished: but it has absorbed a quantity of carbonic acid.

LI'THIAS. (So called because it is formed of the lithic acid.) Lithiate. A salt, formed by the union of the lithic acid, with a salifiable base.

LITHI'ASIS. (*is, is.* f.; from λιθος, stone.) 1. The formation of stone, or gravel.

2. A disease of the eyelids, in which the margins are beset with small hard tumours.

LITHIC ACID. *Acidum lithicum. Acidum uricum.* This was discovered in analysing human calculi, of many of which it constitutes the greater part, and of some, particularly that which resembles wood in appearance, it forms almost the whole. It is likewise present in human urine, and in that of the camel. It is found in those arthritic concretions commonly called chalkstones. It is often called *uric* acid. See *Calculi, urinary.*

Lithic acid calculus. See *Calculi, urinary.*

LITHI'UM. (*um, i.* n.; from its being

the base of lithic acid.) The metallic basis of lithia. See *Lithia*.

Litholi'des. (From λιθος, a stone, and ειδος, likeness: so called from its hardness.) Stone-like: applied to the petrous portion of the temporal bone.

Litho'labum. (From λιθος, a stone, and λαμβανω, to seize.) An instrument for extracting the stone from the bladder. Civiale thus names the forceps he uses in the operation of lithotrity.

LITHO'LOGY. (*Lithologia, æ.* f.; from λιθος, a stone, and λογος, a discourse.) A discourse or treatise on calculi.

LITHONTRI'PTIC. (*Lithontripticus*; from λιθος, a stone, and τριβω, to wear away.) In the strict sense of this term, a lithontriptic medicine should be one which has the power of breaking up and dissolving calculi. It is now generally disbelieved, however, that any medicine possesses such a power; hence the term is applied rather to such medicines as have a power of obviating the calculous diathesis. See *Calculi, urinary*.

Lithopæ'dium. (From λιθος, a stone, and παις, a child.) A fœtus petrified in the body of the mother. See *Abortion*.

LITHOSPE'RMUM. (*um, i.* n.; from λιθος, a stone, and σπερμα, seed: named from the hardness of its seed.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*.

2. The pharmacopœial name of common gromwell. See *Lithospermum officinale*.

Lithospermum officinale. The systematic name of the officinal gromwell; called, also, *Etonychum*. The seeds of this plant — *Lithospermum — seminibus lævibus, corollis vix calycem superantibus, foliis lanceolatis*, of Linnæus, were formerly supposed, from their stony hardness, to be efficacious in calculous and gravelly disorders. Little credit is given to their lithontriptic character, yet they are occasionally used as diuretic for clearing the urinary passages, and for obviating strangury, in the form of emulsion.

LITHO'TOMY. (*Lithotomia, æ.* f.; from λιθος, a stone, and τεμνω, to cut.) The operation of cutting into the bladder, in order to extract a stone. Several methods have been recommended for performing this operation, but there are only two which can be practised with any propriety. One is, where the operation is to be performed immediately above the pubes, in that part of the bladder which is not covered with peritonæum, called the *high operation*. The other, where it is done in the perinæum, by laying open the neck and lateral part of the bladder, so as to allow of the extraction of the stone, called the *lateral operation*, from the prostate gland of the neck of the bladder being laterally cut. The lateral operation is the common one. The high operation is only used under some particular circumstances.

LITHO'TRITY. (*Lithotritia, æ.* f. An ill-constructed term; for if it be from λιθος and τριβω it is hybrid, and if from λιθος and τιτραω it should be *lithotresis*. Vide *Kühn, in Blancardi Lexic.*) The operation of breaking and comminuting a vesical calculus, so that its fragments may be discharged with the urine. This operation has been practised with great success, in many instances, by Civiale, Heurteloup, Costello, and others. It appears to be applicable in a much larger number of cases than might at first have been supposed; but it is the opinion of the best surgeons that, although very extensively useful, it can never entirely supersede lithotomy, which will be required when the stone is above a certain size.

Litmus. See *Lichen roccella*.

Litra. Λιτρα. A pound weight.

Li'tron. See *Nitre*.

Li'tus. A liniment.

LI'VER. Ἡπαρ. *Hepar*. A large abdominal viscus, of a deep red colour, situated under the diaphragm, in the right hypochondrium, its smaller portion occupying part of the epigastric region. In the adult it generally weighs from three to four pounds. In the fœtus it is much larger proportionally than in the adult. The use of the liver is to secrete the bile. In the human body, the liver is divided into two principal lobes, the right of which is by far the largest. They are divided on the upper side by a broad ligament, and on the other side by a considerable depression or fossa. Between and below these two lobes is a smaller lobe, called *Lobulus spigelii*. This is situated betwixt the two greater lobes, but rather belonging to the right great lobe. From its situation deep behind, and from its having a perpendicular papillary projection, it is called also *lobulus posterior*, or *papillatus*. To the left side it has the fissure for the lodgment of the ductus venosus; on the right, the fissure for the vena cava; and above, it has the great transverse fissure of the liver, for the lodgment of the cylinder of the porta; obliquely to the right, and upwards, it has a connexion with the lower concave surface of the great lobe, by the lobulus caudatus, which Winslow calls one of the roots of the lobulus spigelii. It is received into the bosom of the lesser curve of the stomach. On the under surface of the liver there are two small lobes or processes; namely, the *lobulus anonymus* and *lobulus caudatus*. The lobulus anonymus is the anterior point of the right lobe of the liver. Others define it to be that space of the great lobe betwixt the fossa of the umbilical vein and gall-bladder, and extending forward, from the fossa, for the lodgment of the vena portæ, to the anterior margin of the liver. It is called also *lobulus quadratus* and *lobulus accessorius*.

The lobulus caudatus is a tail-like process of the liver, stretching downward from the middle of the great right lobe to the lobulus spigelii. It is behind the gall-bladder, and betwixt the fossa venæ portarum and the fissure for the lodgment of the vena cava.

The *ligaments* of the liver are five in number, and consist of duplicatures of the peritonæum. 1. *The right lateral ligament*, which connects the thick right lobe with the posterior part of the diaphragm. 2. *The left lateral ligament*, which connects the convex surface and margin of the left lobe with the diaphragm, and, in those of whom the liver is very large, with the œsopha-

gus and spleen. 3. *The broad or middle suspensory ligament*, which passes from the diaphragm into the convex surface, and separates the right lobe of the liver from the left. It descends from above through the large fissure to the concave surface, and is then distributed over the whole liver. 4. *The round ligament*, which in adults consists of the umbilical vein, indurated into a ligament. 5. *The coronary ligament*.

The liver has two *surfaces*, one superior, which is convex and smooth, and one inferior, which is concave, and has holes and depressions to receive, not only the contiguous viscera, but the vessels running into the liver.

The *margins* of the liver are also two in number: the one, which is posterior and superior, is obtuse; the other, situated anteriorly and inferiorly, is acute.

The small lobes on the under surface of the liver, which have just been described as the *lobulus anonymus* and *lobulus caudatus*, are called, by some anatomists, *tubercles* of the liver.

Upon looking on the concave surface of this viscus, a considerable fissure is obvious, known by the name of the *fissure of the liver*.

In order to expose the *sinus*, it is necessary to remove the gall-bladder, when a considerable sinus, before occupied by the gall-bladder, will be apparent.

The *blood-vessels* of the liver are the hepatic artery, the vena portæ, and the vena cavæ hepaticæ, which are described under their proper names. The *absorbents* of the liver are very numerous. The liver has *nerves*, from the great intercostal and eighth pair, which arise from the hepatic plexus, and proceed along with the hepatic artery and vena portæ into the substance of the liver. On tearing the substance of the liver, or pressing it between the fingers, it will be perceived to consist of a number of small, hard, glandular bodies, connected by cellular membrane. These are called *acini*, from their resemblance in shape to grape-stones. They are also called lobules; but this creates confusion, because larger masses of the liver are also called lobules. We shall, therefore, designate them as *acini*. The small vessels, which receive the bile secreted by the acini, are called *pori biliarii*: these converge together throughout the substance of the liver towards its under surface, and, at length, form one trunk, called *ductus hepaticus*, which conveys the bile into either the *ductus communis choledochus*, or *ductus cysticus*. See *Gall-bladder*.

The liver and its vessels are invested by a membrane called the capsule of Glisson, which will presently be described; and it is covered by the peritoneum, like the other abdominal viscera.

The well known use of the liver is to secrete the bile. (See *Bilis*.) Various opinions however have been entertained as to the intimate structure of the liver, and the parts immediately concerned in the secretion of the bile. The late researches of Mr. Kiernan have gone far to determine these points. The following is an abstract of his most important observations.

The vessels of the liver are —

I. The hepatic veins, which consist of

a. The *intra-lobular* hepatic veins, which are contained within the lobules: one of these occupies the centre of each lobule, and receives the blood from four or six smaller branches which terminate in it. The intra-lobular veins correspond in their ramifications with the form of the lobules, whose substance is placed around them; and, as will presently be shown, they receive the blood from a plexus formed in the lobule by the *portal vein*.

b. Hepatic veins, which are contained in *canals* formed by the lobules: these, for the sake of perspicuity, we shall call *canalicular* veins. The formation of the canals differs according to the relation of the contained vessel to the intra-lobular veins: where the intra-lobular terminate directly in the canalicular vein, the canal of the latter is necessarily formed by the bases of the lobules resting upon it, and the contained vein is termed *sublobular*; where the canalicular vein is not formed immediately by the intra-lobular, but by the junction of several other canalicular veins, the canal containing it is formed by a tubular inflection of the surface of the liver; so that, in the one case the canals are formed by the continuity of the *bases* of the lobules, and in the other, by the continuity of those surfaces which will be presently described as *capsular*.

II. The *portal veins*, *hepatic ducts*, and *hepatic arteries*, which must be described together because they accompany each other throughout their course, being all contained in the *portal canals*. These canals begin at the transverse fissure, where they are continuous with the concave surface of the liver; and, like those of the larger hepatic veins, they are formed by the *capsular* surfaces of a certain number of the lobules.

To understand the distribution of the vessels contained in these canals, we must trace the course of *Glisson's capsule*. The liver is invested by a membrane, which stands related to it much as the pia mater does to the brain: it is a cellulo-vascular membrane, which is reflected inwards at the transverse fissure, and incloses in a sheath the portal veins, the hepatic arteries, the ducts, the nerves, and the absorbents: it is here that it is called the capsule of Glisson, in the ordinary language of anatomists. A continuation of this membranous sheath accompanies the contained vessels to their minute ramifications; it enters the interlobular fissures, and, with the vessels, forms the *capsules* of the lobules; it finally enters the lobules, and, with the blood-vessels, expands itself over the secreting biliary ducts. Hence arises a natural division of the capsule into three portions — a *vaginal*, an *inter-lobular*, and a *lobular* portion.

At the transverse fissure, the duct, the vein and artery, divide into branches which enter the *portal canals*, invested with the above-described membrane; the membrane lining the canals and enclosing the vessels. These branches, again, divide and subdivide into smaller branches which enter smaller canals; and every canal, however small, contains one principal branch

each of these vessels; frequently, however, two ducts and two arteries are contained in the same canal.

To the larger vessels the terms *hepatic ducts*, *portal veins*, and *hepatic arteries* may be restricted, in order to distinguish them from the branches. The excreting ducts are composed of the hepatic ducts contained in the canals, of their vaginal branches, also contained in canals, and of the interlobular branches, which, arising from the vaginal branches, ramify in the interlobular fissures. The interlobular ducts enter the lobules, in which they form plexuses: these plexuses may be called the *lobular-biliary*, or secreting biliary plexuses, the ducts composing them being the secreting organs of the bile. The excreting ducts and their branches are invariably accompanied by the arteries and portal veins, and their branches, the former conveying blood to their coats, the latter conveying it from them. A duct is never unaccompanied by an artery and a vein; the vein being always a branch of the portal. The veins and arteries also enter the lobules: the veins form plexuses, the branches of which terminate in the intralobular hepatic veins; and, from the blood circulating through these plexuses, the bile is secreted. The lobular arteries are exceedingly minute, and few in number: they are the nutrient vessels of the lobules, and probably terminate in the plexuses formed by the portal vein. From the ducts, veins, and arteries, therefore, three sets of branches arise, namely, the *vaginal*, the *interlobular*, and the *lobular* branches.

It has then been shown that all the vasa vasorum of the liver are branches of the hepatic artery and portal vein; that branches of the portal vein arise in the coats of the hepatic veins themselves; and that the veins of the coats of the vessels constitute the hepatic origin of the portal vein. The arterial blood having circulated through the coats of the vessels, becomes venous, and is conveyed by the veins arising in the coats of the vessels into those branches of the portal vein which correspond to the vessels in the coats of which the veins arise: thus, from the coats of the vaginal ducts, veins, and arteries, they convey the blood into the vaginal veins; and from the coats of the interlobular ducts, veins, and arteries, into the interlobular veins. From the coats of the hepatic veins and inferior cava, the blood is conveyed into the interlobular portal veins. In the vaginal and interlobular veins, the blood conveyed from the coats of the vessels becomes mingled with the proper portal blood. This mixed blood is conveyed by the interlobular veins into the lobular venous plexuses, in which the lobular arteries probably terminate after having nourished the secreting ducts. From the mixed blood circulating through the plexuses, the bile is secreted by the lobular or secreting biliary plexuses.

The blood which enters the liver by the hepatic artery, fulfils three functions: it nourishes the liver; it supplies the excreting ducts with mucus; and, having performed these purposes, it becomes venous, enters the branches of the portal vein, and contributes to the secretion of the bile. The portal vein fulfils two functions; it conveys the blood from the artery, and the mixed blood to the coats of the excreting ducts. It has been called the vena arteriosa, because it ramifies like an artery, and conveys blood for secretion; but it is an arterial vein in another sense, being a vein to the hepatic artery, and an artery to the hepatic vein. The hepatic veins convey the blood from the lobular venous plexuses into the vena cava inferior.

Liver, inflammation of. See *Hepatitis.*

Liver of sulphur. See *Potassæ sulphuretum.*

Liverwort. See *Marchantia.*

Liverwort, ash-coloured. See *Lichen.*

Liverwort, ash-coloured ground. See *Lichen.*

Liverwort, ground. See *Lichen caninus.*

Liverwort, Iceland. See *Cetraria* in the Supplement.

Liverwort, noble. See *Marchantia.*

Liverwort tree. See *Lichen olivarius.*

LI'VOR. (*or, ōris.* m.; from *liveo*, to be black and blue.) Lividity. A dark colour of the skin of any part produced by a bruise or other cause. Certain states of the circulation occasion lividity; thus a part is livid when about to pass from the state of erysipelas into that of gangrene; and the complexion of the face is livid in diseases which obstruct the pulmonary circulation.

LIX. (*Lix, licis.* f.) Ashes, or water mixed with ashes. It is most frequently used to signify wood-ashes.

LIXI'VIAL. *Lixivialis;* from *lix*, wood-ash. Salts are so called which are extracted by lixiviation.

LIXIVIA'TION. *Lixiviatio.* The process employed by chemists of dissolving, by means of warm water, the saline and soluble particles of cinders, the residues of distillation and combustion, coals, and natural earths. Salts thus obtained are called *Lixivial salts.*

LIXI'VIUM. (*um, ii.* n.; from *lix*, wood-ash.) A ley. The liquor in which saline and soluble particles of the residues of distillation and combustion are dissolved.

Lixivium saponarium. See *Potassæ liquor.*

Lixivium tartari. See *Potassæ subcarbonatis liquor.*

LOBA'TUS. (From *lobus*, a lobe.) Lobate: lobes. Applied to leaves which have the margins of the segments lobed, as in *Anemone hepatica*, and to such as are lobed like the vine, thistle, and many geraniums.

Lobe. See *Lobus.*

Lobed leaf. See *Lobatus.*

LOBE'LIA. (*a, æ.* f.; named in honour of Lobel, a celebrated botanist.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Monogamia.*

LOBELIA CARDINALIS. Cardinal flower. The root of this is esteemed vermifuge.

LOBELIA INFLATA. Indian tobacco. This plant, which grows in the United States of America, is a narcotic poison, the operation of which is very similar to that of tobacco. It has been found very useful in some cases of asthma, and has also been employed in other diseases of the air passages. For the mode of administering it, see *Asthma.*

Lobelia syphilitica. The systematic name of the blue cardinal flower. The root is the part directed by the Edinburgh Pharmacopœia for medicinal use; in taste it resembles tobacco, and is apt to excite vomiting. It derived the name of *syphilitica* from its efficacy in the cure of syphilis, as experienced by the North American Indians, who considered it as a specific in that disease, and with whom it was long an important secret, which was purchased by Sir William Johnson, and since published by different authors. The method of employing this medicine is stated as follows: — A decoction is made of a handful of the roots in three measures of water. Of this half a measure is taken in the morning, fasting, and repeated in the evening; and the dose is gradually increased, till its purgative effects become too violent, when the decoction is to be intermitted for a day or two, and then renewed, until a perfect cure is effected. During the use of this medicine, a proper regimen is to be enjoined, and the ulcers are also to be frequently washed with the decoction; or, if deep and foul, to be sprinkled with the powder of the inner bark of the New Jersey tea-tree, *Ceanothus americanus*. Although the plant thus used is said to cure the disease in a very short time, yet it is not found that the antisyphilitic powers of the lobelia have been confirmed in any instance of European practice.

Lobelia tupa. This is a very violent acrid poison. Even the odour of the flowers is said to cause excessive vomiting.

Lobelia urens. This also is a very poisonous plant.

Lobster. See *Cancer gammarus.*

LO'BULUS. (*us, i.* m.; diminutive of *lobus*, a lobe.) A small lobe.

Lobulus accessorius. See *Liver.*

Lobulus anonymus. See *Liver.*

Lobulus caudatus. See *Liver.*

Lobulus spigelii. See *Liver.*

LO'BUS. (*us, i.* m.) A lobe. 1. In *Anatomy*, applied to the more or less separate parts of which some of the viscera are composed; as glands, the ear, the liver, &c.

2. In *Botany*, a principal division of a leaf, the margins of which are in some degree rounded: it is also applied to the divisions of the petals, or any other suitable part. A capsule is sometimes said to be lobed.

LOCAL. *Localis.* Belonging to a part and not the whole. A common division of diseases is into *general* and *local.*

Loca'les. (The plural of *localis.*) The name of the fourth class of Cullen's Nosology, which comprehends morbid affections that are partial, and includes eight orders; viz. *dysæsthesiæ, dysorexiæ, dyscinesiæ, apocenoses, epischeses, tumores, ectopia*, and *dialyses.*

Localis membrana. The pia mater.

LO'CHIA. (From λοχευω, to bring forth.) The cleansings. The serous, and for the most part green-coloured, discharge that takes place from the uterus and vagina of women, during the first four days after delivery.

LOCHIORRHŒ'A. (*a, æ.* f.; from λοχια, and ρεω, to flow.) An excessive discharge of the lochia. — *Sagar.*

Locked-jaw. See *Trismus.*

LOCULAME'NTUM. (*um, i.* n.) In *Botany*, means the space or cell between the valves and partitions of a capsule; distinguished, from their number, into unilocular, bilocular, &c. See *Capsula.*

LOCU'STA. A term sometimes applied to the spikelet of grasses. See *Spicula.* Also the specific name of the corn-salad. See *Valeriana locusta.*

Locustic acid. An acid obtained from the grasshopper (locusta). It differs little from the acetic.

Logwood. See *Hæmatoxylon.*

Lohoch. (Arabic.) *Looch. Loch.* A linctus.

LOIMIC. (*Loimicus*; from λοιμος, a pestilence.) Appertaining to a pestilence.

LOMENTA'CEUS. (From *lomentum*; in allusion to the pulse-like nature of the plants in question, so as to keep in view their analogy with the *papilionaceæ.*) Lomentaceous; of the nature of a lomentum.

Lomenta'ceæ. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of such as have a bivalve pericarpium or legume, and not papilionaceous coorls; as cassia, fumaria, ceretonia, &c.

LOME'NTUM. 1. A Latin name for the meal of beans. 2. Bread made of such meal. 3. The name of a pigment used by the ancients.

4. In *Botany*, a bivalve pericarpium, divided into cells by very small partitions, never lateral like those of the legume.

From its figure is termed,

1. *Articulate*, when the partitions are visible externally; as in *Hedysarum argenteum.*

2. *Moniliform*, necklace-like, consisting of a number of little globules; as in *Hedysarum moliferum.*

3. *Aculeate*; as in *Hedysarum onobrychis.*

4. *Crystate*; as in *Hedysarum caput galli.*

5. *Isthmis interceptum*, when the cells are much narrower than the joints; as in *Hippocrepis.*

6. *Corticose*, the external bark being woody and the inside pulpy; as in *Cassia fistula.*

Lonchi'tis. (*is, idis.* f.; from λογχη, a lance, so named because the leaves resemble the head of a lance.) See *Asplenium ceterach.*

Longaon. *Longanon.* A barbarous name given by Paracelsus to the rectum.

LONGI'SSIMUS. The longest. Parts are so named from their length, compared with that of others; as *longissimus dorsi*, &c.

Longissimus dorsi. This muscle, which is somewhat thicker than the sacrolumbalis, greatly resembles it, however, in its shape and extent, and arises, in common with that muscle, between it and the spine. It ascends upwards along the spine, and is inserted by small double tendons into the posterior and inferior part of all the transverse processes of the vertebræ of the back, and sometimes of the last vertebra of the neck. From its outside it sends off several bundles of fleshy fibres, interspersed with a few tendinous filaments, which are usually inserted into the lower edge of the ten uppermost ribs, not far from their tubercles. In some subjects, how

ever, they are found inserted into a less number, and in others, though more rarely, into every one of the ribs. Towards the upper part of this muscle is observed a broad and thin portion of fleshy fibres, which cross and intimately adhere to the fibres of the longissimus dorsi. This portion arises from the upper and posterior part of the transverse processes of the five or six uppermost vertebræ of the back, by as many tendinous origins, and is usually inserted, by six tendinous and fleshy slips, into the transverse processes of the six inferior vertebræ of the neck. This portion is described, by Winslow and Albinus, as a distinct muscle; by the former under the name of *transversalis major colli*, and by the latter under that of *transversalis cervicis*. But its fibres are so intimately connected with those of the longissimus dorsi, that it may very properly be considered as an appendage to the latter. The use of this muscle is to extend the vertebræ of the back, and to keep the trunk of the body erect; by means of its appendage it likewise serves to turn the neck obliquely backwards, and a little to one side.

Longissimus manus. See *Flexor tertii internodii pollicis.*

Longissimus oculi. See *Obliquus superior oculi.*

LONGITU'DINAL. *Longitudinalis.* Parts are so named from their direction.

Longitudinal sinus. Longitudinal sinus of the dura mater. A triangular canal, proceeding in the falciform process of the dura mater, immediately under the bones of the skull, from the crista galli to the tentorium, where it branches into the lateral sinuses. The longitudinal sinus has a number of fibres crossing it, which are called *Chordæ Willisii*. Its use is to receive the blood from the veins of the pia mater, and convey it into the lateral sinuses, to be carried through the internal jugulars to the heart.

Long-sightedness. See *Presbyopia.*

LO'NGUS. Long. 1. In *Anatomy*, some parts are so named from their comparative length; as *longus colli*, &c.

2. In *Botany*, a cup or calyx is said to be long when it is equal in length to the tube of the blossom.

Longus colli. A muscle, situated close to the anterior and lateral part of the vertebræ of the neck. Its outer edge is in part covered by the rectus internus major. It arises tendinous and fleshy within the thorax, from the bodies of the three superior vertebræ of the back, lately; from the bottom and fore-part of the transverse processes of the first and second vertebræ of the back, and of the last vertebræ of the neck: and likewise from the upper and anterior points of the transverse processes of the sixth, fifth, fourth, and third vertebræ of the neck, by as many small distinct tendons; and is inserted tendinous into the fore-part of the second vertebra of the neck, near its fellow. This muscle, when it acts singly, moves the neck to one side; but, when both act, the neck is brought directly forwards.

LONICE'RA. (*a, æ.* f.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.*

Lonicera diervilla. A species of honeysuckle. *Diervilla.* The young branches of this species, *Lonicera — racemis terminalibus, foliis serratis*, of Linnæus, are employed in North America as a remedy in gonorrhœa and suppression of urine. It has not yet been exhibited in Europe.

Lonicera periclimenum. Common honeysuckle. *Caprifolium.* This beautiful and common plant was formerly used in the cure of asthma, for cleansing sordid ulcers, and removing diseases of the skin. It does not appear to possess any real virtue.

LO'PEZ. *Radix lopeziana. Radix indica lopeziana.* The name of the root of an unknown tree, growing, according to some, at Goa. It is met with in pieces of different thickness, some at least of two inches diameter. The woody part is whitish, and very light; softer, more spongy, and whiter next the bark, including a denser, somewhat reddish, medullary part. The bark is rough, wrinkled, brown, soft, and, as it were, woolly, pretty thick, covered with a thin paler cuticle. Neither the woody nor cortical part has any remarkable smell or taste, nor any appearance of resinous matter. It appears that this medicine has been remarkably effectual in stopping colliquative diarrhœas, which had resisted the usual remedies. Those attending the last stage of consumptions were particularly relieved by its use. It seemed to act, not by an astringent power, but by a faculty of restraining and appeasing spasmodic and inordinate motions of the intestines. Dr. Gaubius, who gives this account, compares its action to that of simarouba, but thinks it more efficacious.

Lopha'dia. (From λοφος, the hinder part of the neck.) *Lophia.* The first vertebra of the neck.

LORDO'SIS. (Λορδωσις; from λορδος, curved, bent.) A curvature. Applied by Hippocrates to a curvature of the spine forwards.

LORI'CA. (From *lorico*, to crust over.) A kind of lute, with which vessels are coated before they are put into the fire.

LORICA'TION. *Loricatio.* The application of a lute of clay, or other material, to chemical vessels.

LO'TION. (*Lotio, onis.* f.; from *lavo*, to wash.) An external fluid application, or wash. Lotions are usually applied by wetting linen with them, and keeping it on the part affected.

Lo'tium. A Latin name of urine.

LO'TUS. (*us, i.* f.; from the nymph *Lotis*, who was changed into this tree; or from λω, to desire.) 1. A tree the fruit of which was said to be so delicious as to make those who tasted it forsake all other desires: hence the proverb, Λωτον εφαγον, *lotum gustavi*: I have tasted lotus.

2. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria.*

Lovage. See *Ligusticum levisticum.*

Love-apple. See *Solanum.*

Loxa'rthros. (From λοξος, oblique, and

αρθρον, a joint.) *Loxarthrus.* An obliquity of the joint, or wrong position of the parts forming a joint, without dislocation or spasm, as in the case of a club-foot.

Lu'dus helmontii. *Ludus Paracelsi.* 1. A species of marle formerly believed to be efficacious in calculous disorders.

2. A calculus from the human bladder.

LU'ES. (*es, is.* f.; from λυω, to dissolve, because it produces dissolution.) A pestilence or poison.

Lues deifica. A name formerly given to epilepsy.

Lues neurodes. A typhus fever.

Lues venerea. The plague of Venus, or the venereal disease. See *Syphilis.*

Lu'jula. (*a, æ.* f.; corrupted or contracted from *Allelujah, Praise the Lord:* so called from its many virtues.) See *Oxalis.*

LUMBA'GO. (*o, inis.* f.; from *lumbus,* the loin.) A rheumatic affection of the muscles about the loins. See *Rheumatism.*

LUMBAR. *Lumbalis.* Belonging to the loins; as lumbar region, &c.

Lumbar abscess. *Abscessus lumbalis.* Psoas abscess: so called from the situation in which the matter is found, namely, upon the side of the psoas muscle, or betwixt that and the iliacus internus. Between these muscles there lies a quantity of loose cellular membrane, in which an inflammation often takes place, either spontaneously or from mechanical injuries. This terminates in an abscess that can procure no outlet but by a circuitous course, in which it generally produces irreparable mischief, without any violent symptoms occurring to alarm the patient. The abscess sometimes forms a swelling about Poupart's ligament; sometimes below it; and frequently the matter glides under the fascia of the thigh. Occasionally, it makes its way through the sacro-ischiatic foramen, and assumes rather the appearance of a fistula in ano. The uneasiness in the loins, and the impulse communicated to the tumour by coughing, evince that the disease arises in the lumbar region; but it must be confessed, that we can hardly ever know the existence of the disorder, before the tumour, by presenting itself externally, leads us to such information. The lumbar abscess is sometimes connected with diseased vertebræ, which may either be a cause or effect of the collection of matter. The disease, however, is frequently unattended with this complication.

The situation of the symptoms of lumbar abscess, renders this affection liable to be mistaken for some other, viz. lumbago and nephritic pains, and, towards its termination, for crural or femoral hernia. The first, however, is not attended with the shivering that occurs here; and nephritic complaints are generally discoverable by attention to the state of the urine. The distinction from crural hernia is more difficult. In both, a soft inelastic swelling is felt in the same situation: but in hernia, it is attended with obstructed fæces, vomiting, &c., and its appearance is always sudden, while the lumbar tumour is preceded by various complaints before its appearance in the thigh. In a horizontal posture, the abscess, also, totally disappears, while the hernia does not.

Lumbar region. Regio lumbalis. The loins.

Lumbaris externus. See *Quadratus lumborum.*

Lumbarus internis. See *Psoas magnus.*

LUMBRICA'LIS. (From *lumbricus,* the earth-worm.) Resembling the earth-worm. An epithet of certain muscles.

Lumbricales manus. *Fidicinales. Flexor primi internodii digitorum manus, vel perforatus lumbricalis,* of Cowper. The small flexors of the fingers which assist the bending the fingers when the long flexors are in full action. They arise, thin and fleshy, from the outside of the tendons of the flexor profundus, a little above the lower edge of the carpal ligaments, and are inserted by long slender tendons into the outer sides of the broad tendons of the interosseal muscles, about the middle of the first joints of the fingers.

Lumbricales pedis. Four muscles like the former, that increase the flexion of the toes, and draw them inwards.

LUMBRICOI'DES. (From *lumbricus,* and ειδος, resemblance.) Like to the *lumbricus,* or earth-worm.

LUMBRI'CUS. (*us, i.* m.; *a lubricate:* from its slipperiness.) A name given to some worms, as the common earth-worm, and the long round worm which inhabits the intestines of man and other animals. See *Entozoa.*

Lumbricus terrestris. The earth-worm. Formerly given internally, when dried and pulverised, as a diuretic.

Lumbus veneris. See *Achillea millefolium.*

LUNA. (*a, æ.* f.; the moon.) The alchemical name of silver.

Luna cornea. Muriate of silver.

Luna fixata. An obsolete name of the oxide of zinc.

Luna plena. An alchemical term which seems to have been variously applied.

Lunar caustic. See *Argenti nitras.*

LUNA'RE OS. One of the bones of the carpus; so named from its shape.

Lunaria. See *Ophiaglossum lunaria.*

Lunaria rediviva. *Bulbonach,* of the Germans. Satin and honesty. The name of a plant formerly esteemed as a warm diuretic.

LU'NATIC. (*Lunaticus;* from *luna,* the moon.) Applied, 1. Adjectively to any disease supposed to be influenced by the changes of the moon.

2. Substantively to a maniac, because it is generally believed that maniacs are worst at the time of the full moon.

Lunatus. See *Lunulatus.*

LUNG. *Pulmo.* The lungs are two viscera situated in the chest, by means of which we breathe. The lung in the right cavity of the chest is divided into three lobes, that in the left cavity into two. They hang in the chest attached at their superior part to the neck by means of the trachea, and are separated by the mediastinum. They are also attached to the heart by means of the pulmonary vessels. The substance of the lungs is of four kinds, viz. vesicular, vascular, bronchial, and parenc-

matous. The vesicular substance is composed of the air-cells. The vascular invests those cells like a network. The bronchial is formed by the ramifications of the bronchia throughout the lungs, having the air-cells at their extremities: and the spongy substance that connects these parts is termed the *parenchyma*. The lungs are covered with a fine membrane, a reflection of the pleura, called *pleura-pulmonalis*. The internal surface of the air-cells is covered with a very fine, delicate, and sensible membrane, which is continued from the larynx through the trachea and bronchia. The arteries of the lungs are the bronchial, a branch of the aorta, which carries blood to the lungs for their nourishment; and the pulmonary, which circulates the blood through the air-cells to undergo a certain change. The pulmonary veins return the blood that has undergone this change, by four trunks, into the left auricle of the heart. The bronchial veins terminate in the vena azygos. The nerves of the lungs are from the eighth pair and great intercostal. The absorbents are of two orders; the superficial, and the deep-seated; the former are more readily detected than the latter. The glands of these viscera are called bronchial. They are muciparous, and situated about the bronchia. See *Respiration*.

Lung-wort. See *Pulmonaria*.

Lung-wort tree. See *Lichen pulmonarius*.

Lunularis. See *Lunulatus*.

LUNULA'TUS. *Lunatus*. *Lunularis*. Lunulate: crescent-shaped, or half-moonlike. A term applied to leaves, pods, &c. which are so shaped, whether the points are directed towards the stalk, or from it; as in the leaves of *Passiflora lunata*, and legumen of *Medicago foliata*.

LU'PIA. (From λυπεω, to molest.) 1. A genus of disease, including encysted tumours, the contents of which are of a pultaceous consistence; as *meliceris*, *atheroma*, *steatoma*, and *osteo-steatoma*.

LUPINO'SUS. (From *lupinus*, the lupin.) Lupin-like: applied to a disease of the skin, the *porrigo lupinosa*.

LUPI'NUS. (*us*, *i*. m.; so called by Pliny and other ancient writers. Professor Martin says the word owes its origin to *lupus*, a wolf, because plants of this genus ravage the ground by over-running it, after the manner of that animal. It is also derived from λυπη, grief: whence Virgil's epithet, *tristes lupini*; from the fanciful idea of its acrid juices, when tasted, producing a sorrowful appearance on the countenance.) The name of a genus of plants. Class, *Diadelphia*; Order, *Decandria*.

2. Under this term the white lupin is directed in some pharmacopœias.

LUPINUS ALBUS. The systematic name of the white lupin. The seed, used as ordinary food in the days of Galen and Pliny, is now forgotten. Its farinaceous and bitter meal is occasionally exhibited to remove worms from the intestines, and made into poultices to resolve indolent tumours.

LU'PULIN. Lupuline. The name given by Dr. Ives to an impalpable yellow powder, in which he believes the virtues of the hop to reside, and which may be obtained by beating and sifting the hops used in brewing. It appears to be peculiar to the female plant, and is probably secreted by the nectaria. In preserving beer from the acetous fermentation, and in communicating an agreeable flavour to it, lupulin was found to be equivalent to ten times its weight of hop-leaves.

LU'PULUS. (*us*, *i*. m.; from λυπη, sorrow: so named from its bitterness.) See *Humulus*.

LU'PUS. (*us*, *i*. m.; a wolf.) 1. A malignant disease of the face, otherwise called *noli me tangere*. See *Noli me tangere*.

2. The term was intended, by Dr. Willan, to comprise together with the "*noli me tangere*," affecting the nose and lips, other slow tubercular affections, especially about the face, commonly ending in ragged ulcerations of the cheeks, forehead, eyelids, and lips, and sometimes occurring in other parts of the body, where they gradually destroy the skin and muscular parts to a considerable depth. Sometimes the disease appears in the cheek circularly, or in the form of a sort of ringworm, destroying the substance, and leaving a deep and deformed cicatrix: other parts are occasionally the seat of this disease.

By the knife or the caustic, a separation has sometimes been made of the morbid from the sound parts, and the progress of the disease arrested. And in some cases, where the ulceration was very slow, and unaccompanied by much inflammation, the internal use of arsenic has been found beneficial; a circumstance which has probably given rise to the opinion that cancer has been cured by that mineral. In some less severe cases of lupous tubercles in the face, which had made no progress towards ulceration, the solution of muriate of barytes, taken internally, has materially amended the complaint.

LU'RIDÆ. (Lurid, ghastly.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of those which are highly poisonous; the corolla mostly monopetalous; as *Datura*, *Solanum*, *Nicotiana*.

LU'SCITAS. (From *luscus*, blind of one eye.) Beer gives this name to a distortion of the eyeball which resembles squinting, but differs from it in the inability to move the affected eye when the other is closed.

LUSTRA'GO. (From *lustro*, to expiate: so called because it was used in the ancient purifications.) Flat or base vervain.

LUSUS NATURÆ. A sport of nature; a monster. See *Monster*.

Lute. See *Lutum*.

Lutea corpora. See *Corpus luteum*.

LUTE'OLA. (*a*, *æ*. f.; from *luteolus*, yellowish, the flowers being of a yellowish colour.) See *Reseda luteola*.

LUTE'OLINE. The colouring matter of the *reseda luteola* is thus named by Chevreuil.

LU'TEUS. Yellow. See *Colour*.

LU'TRUM. Λουτρον. A bath. Also the epithet of an ophthalmic medicine.

LU'TUM. (*um*, *i*. n.; the Latin for clay or mud.) *Cæmentum*. Lute. A composition with

which chemical vessels are covered, to preserve them from the violence of the fire, and to close exactly their joinings to each other, to retain the substances which they contain when they are volatile and reduced to vapour.

LUXA'TION. (*Luxatio*; from *luxo*, to put out of joint.) A dislocation of a bone from its proper cavity. See *Dislocation*.

LYCA'NCHE. (From λυκος, a wolf, and αγχω, to strangle.) A quinsy, so called because wolves were said to be subject to it. Synonymous with *cynanche*.

LYCANTHRO'PIA. (Λυκανθρωπια; from λυκος, a wolf, and ανθρωπος, a man.) A species of melancholy described by the Greek writers, in which the patients leave their houses in the night, and wander about, like wolves, in unfrequented places.

LY'CHNIS. (*is, idis.* f.; said to be derived from λυχνος, a torch: because the ancients used its leaves, rolled up, for torches.) 1. A name of several vegetable productions.

2. The name of a genus of plants. Class, *Decandria*; Order, *Pentagynia*.

Lychnis segetum. See *Agrostemma*.

LYCHNOI'DES. (From *lychnis*, the name of a plant, and ειδος, resemblance.) Like the herb *lychnis*.

Lychnoides segetum. See *Agrostemma*.

LYCO'CTONUM. (*um, i.* n.; from λυκος, a wolf, and κτεινω, to slay: so called because it was the custom of hunters to secrete it in raw flesh, for the purpose of destroying wolves.) A Greek name of aconite; now employed as the specific name of a particular species.

LYCOPE'RDON. (From λυκος, a wolf, and περδω, pedo; so named because it was supposed to spring from the dung of wolves.) The name of a genus of plants in the Linnæan system. Class, *Cryptogamia*; Order, *Fungi*.

2. The pharmacopœial name of the puff-ball. See *Lycoperdon bovista*.

LYCOPERDON BOVISTA. The systematic name of the puff-ball. Mollipuf. Puff-fist. *Crepitus lupi*. A round or egg-shaped fungus: the *Lycoperdon — subrotundum, lacerato dehiscens*, of Linnæus; when fresh, of a white colour, with a very short, or scarcely any pedicle, growing in dry pasture-grounds. When young, it is sometimes covered with tubercles on the outside, and is pulpy within. By age it becomes smooth externally, and dries internally into a very fine, light, brownish dust, which is used by the common people to stop hæmorrhages.

LYCOPERDON CERVINUM. *Boletus*. Deer-ball. This has the character of being aphrodisiac, and increasing the quantity of milk.

LYCOPERDON TUBER. The systematic name of the truffle. *Tuber gulosorum*. *Tubera terræ*. Trubs. *Tuber cibarium*, of Dr. Withering. A solid fungus, of a globular figure, which grows under the surface of the ground, without any roots, or the access of light, and attains a size from a pea to the largest potatoe. It has a rough, blackish coat, and is destitute of fibres. There are several species used in the places in which they are found: as the *Tuber moschatum*; *Tuber albidum*, called *Bianchetti*; *Tuber rufum*, called *Rosetti*; the black truffle with white flesh; and also the *Tuber griseum*, or Piedmont truffle, which has a slight odour of garlick. None of these are poisonous, though so nearly allied to *Lycoperda*, differing only in being fleshy in the inside, instead of being powdery. Cooks are well acquainted with its use and qualities. They are all used to give delicate flavours to soups and sauces. The truffle is found in woods and pastures in some parts of Kent, but is not very common in England. In France and Spain, truffles are very frequent, and grow to a much larger size than they do here. In these places, the peasants find it worth their while to search for them, and they train up dogs and swine for this purpose, who, after they have been inured to their smell by their masters frequently placing them in their way, will readily scrape them up as they ramble the fields and woods.

LYCOPE'RSICUM. (*um, i.* n.; from λυκος, a wolf, and περσικον, a peach: wolf's peach. Why so called we know not.) *Lycopersicon*. The love-apple or tomata. See *Solanum lycopersicon*.

LYCOPO'DIUM. (*um, ii.* n.; from λυκος, a wolf, and πους, a foot: so called from its supposed resemblance.) 1. The name of a genus of plants in the Linnæan system. Class, *Cryptogamia*; Order, *Musci*.

2. The pharmacopœial name of the club-moss. See *Lycopodium clavatum*.

LYCOPODIUM CLAVATUM. The systematic name of the club-moss. Wolf's claw. *Muscus clavatus*. *Lycopodium*. This plant affords a great quantity of pollen, which is much esteemed in some places to sprinkle on young children, to prevent excoriation, and to cure parts that are so. A decoction of the herb is said to be a specific in the cure of the plica polonica.

LYCOPODIUM SELAGO. The systematic name of the upright club-moss. *Muscus erectus*. The decoction of this plant acts violently as a vomit and a purgative, and was formerly, on that account, employed to produce abortions.

LYCO'PSIS. (*is, idis.* f.; from λυκος, a wolf, and οψις, an aspect: so called from its being of the colour of a wolf, or from the circumstance of the flowers being ringent, and having the appearance of a grinning mouth. The herbage is also furnished, says Ambrosinus, with a sort of rigid hairiness, similar to the coat of a wolf.) 1. The name of a genus of plants. Class, *Pentandria*; Order, *Monogynia*.

2. The pharmacopœial name of the wall bugloss, *Echium ægyptiacum*, the *Asperago ægyptiaca* of Wildenow.

LY'COPUS. (*us, i.* m.; from λυκος, a wolf, and πους, a foot: so named from its likeness.) The name of a genus of plants in the Linnæan system. Class, *Diandria*; Order, *Monogynia*. Wolf's claw, or water horehound.

LYCOPUS EUROPÆUS. This plant is sometimes used as an astringent.

LYGMUS. Λυγμος. The hiccup.

LYMPH. *Lympha*. The liquid contained in the lymphatic vessels. Two processes may be employed to procure lymph. One is to lay bare a lymphatic vessel, divide it, and receive the liquid that flows from it; but this is a method difficult to execute, and besides,

the lymphatic vessels are not always filled with lymph, it is uncertain: the other consists in letting an animal fast during four or five days, and then extracting the fluid contained in the thoracic duct.

The liquid obtained in either way has, at first, a slightly opaline rose colour. It has a strong spermatic odour; a salt taste; it sometimes presents a slight yellow tinge, and at other times a red madder colour.

But lymph does not long remain liquid: it congeals. Its rose colour becomes more deep, an immense number of reddish filaments are developed, irregularly arborescent, and very analogous in appearance to the vessels spread in the tissue of organs.

When we examine carefully the mass of lymph thus coagulated, we find it formed of two parts: the one solid, and forming a great many cells, in which the other remains in a liquid state. If the solid part be separated, the liquid congeals again.

The quantity of lymph procured from one animal is but small: a dog, of a large size, scarcely yields an ounce. Its quantity appears to increase according to the time of fasting.

The solid part of the lymph, which may be called *clot*, has much analogy with that of the blood. It becomes scarlet-red by the contact of oxygen gas, and purple when plunged in carbonic acid.

The specific gravity of lymph is to that of distilled water as 1022·28 to 1000·00.

Chevreuil analysed the lymph of the dog.

Water	926·4
Fibrin	004·2
Albumen	61·0
Muriate of soda	6·1
Carbonate of soda	1·8
Phosphate of lime, Phosphate of magnesia, Carbonate of lime	0·5
Total	1000·0

Its specific gravity is greater than that of water; in consistence, it is thin, and somewhat viscid. The quantity in the human body appears to be very great, as the system of the lymphatic vessels forms no small part it. Its constituent principles appear to be albuminous water and a little salt. The lymphatic vessels absorb this fluid from the tela cellulosa of the whole body, from all the viscera, and the cavities of the viscera; and convey it to the thoracic duct, to be mixed with the chyle.

The use of the lymph is to return the superfluous nutritious jelly from every part, and to mix it with the chyle in the thoracic duct, there to be further converted into the nature of the animal; and, lastly, it has mixed with it the superfluous aqueous fluid, which is effused into the cavities of the cranium, thorax, abdomen, &c.

LYMPHA'TIC. (*Lymphaticus*; from *lympha*, lymph.) 1. Of the nature of lymph.

2. The name of an absorbent vessel, that carries a transparent fluid or lymph. The lymphatic vessels of the human body are small and transparent, and originate in every part of the body. With the lacteal vessels of the intestines, they form what is termed the *absorbent system*. Their termination is in the thoracic duct. See *Absorbent*, *Lacteal*, and *Thoracic duct*.

Lymphatics of the head and neck. — Absorbents are found on the scalp and about the viscera of the neck, which unite into a considerable *branch*, that accompanies the jugular vein. Absorbents have not been detected in the human brain, yet there can be no doubt of there being such vessels: it is probable that they pass out of the cranium through the canalis caroticus and foramen lacerum in basi cranii, on each side, and join the above *jugular branch*, which passes through some glands as it proceeds into the chest to the angle of the subclavian and jugular veins.

The absorbents from the right side of the head and neck, and from the right arm, do not run across the neck, to unite with the great trunk of the system: they have an equal opportunity of dropping their contents into the angle betwixt the right subclavian and the jugular vein. These vessels, then uniting, form a trunk, which is little more than an inch, nay, sometimes not a quarter of an inch, in length, but which has nearly as great a diameter as the proper trunk of the left side.

This vessel lies upon the right subclavian vein, and receives a very considerable number of lymphatic vessels: not only does it receive the lymphatics from the right side of the head, thyroid gland, neck, &c., and the lymphatics of the arm, but it receives also those from the right side of the thorax and diaphragm, from the lungs of this side, and from the parts supplied by the mammary artery. Both in this and in the great trunk there are many valves.

Of the upper extremities. — The absorbents of the upper extremities are divided into superficial and deep-seated. The *superficial absorbents* ascend under the skin of the hand in every direction to the wrist, from whence a *branch* proceeds upon the posterior surface of the fore-arm to the head of the radius, over the internal condyle of the humerus, up to the axilla, receiving several branches as it proceeds. Another *branch* proceeds from the wrist along the anterior part of the fore-arm, and forms a *network*, with a *branch* coming over the ulna from the posterior part, and ascends on the inside of the humerus to the glands of the axilla. The *deep-seated absorbents* accompany the larger blood-vessels, and pass through two glands about the middle of the humerus, and ascend to the glands of the axilla. The superficial and deep-seated absorbents having passed through the axillary glands, form *two trunks*, which unite into *one*, to be inserted with the jugular absorbents into the thoracic duct, at the angle formed by the union of the subclavian with the jugular vein.

Lymphatics of the inferior extremities. — These are also superficial and deep-seated. The *superficial ones* lie between the skin and muscles. Those of the toes and foot form a *branch*, which ascends upon the back of the foot, over the tendon of the cruræus anticus, forms, with other branches, *a plexus* above the ankles, then proceeds along the tibia over the knee, sometimes passes through a gland, and proceeds up the

inside of the thigh, to the subinguinal glands. The *deep-seated* absorbents follow the course of the arteries, and accompany the femoral artery, in which course they pass through some glands in the leg and above the knee, and then proceed to some deep-seated subinguinal glands. The absorbents from about the external parts of the pubes, as the penis and perinæum, and from the external parts of the pelvis, in general, proceed to the inguinal glands. The subinguinal and inguinal glands send forth several branches, which pass through the abdominal ring into the cavity of the abdomen.

Of the abdominal and thoracic viscera. — The absorbents of the lower extremities accompany the external iliac artery, where they are joined by many branches from the *uterus*, *urinary bladder*, *spermatic chord*, and some branches accompanying the internal iliac artery; they then ascend to the sacrum, where they form a *plexus*, which proceeds over the psoas muscles, and, meeting with the lacteals of the mesentery, form the thoracic duct, or trunk of the absorbents, which is of a serpentine form, about the size of a crow-quill, and runs up the dorsal vertebræ, through the posterior opening of the diaphragm, between the aorta and vena azygos, to the angle formed by the union of the left subclavian and jugular veins. In this course it receives the *absorbents of the kidneys*, which are superficial and deep-seated, and unite as they proceed towards the thoracic duct; and *the absorbents of the spleen*, which are upon its peritonæal coat, and unite with those of the pancreas, — a *branch* from the plexus of the vessels passing above and below the duodenum, and formed by the absorbents of the *stomach*, which come from the lesser and greater curvature, and are united about the pylorus with those of the pancreas and liver, which converge from the external surface and internal parts towards the portæ of the liver, and also by several branches from the *gall-bladder*.

Use of Lymphatics. — The office of these vessels is to take up substances which are applied to their mouths: thus the vapour of circumscribed cavities, and of the cells of the cellular membrane, are removed by the lymphatics of those parts; and thus mercury and other substances are taken into the system when rubbed on the skin. See *Absorption*.

The principle by which this absorption takes place is a power inherent in the mouths of absorbing vessels, a vis insita, dependent on the high degree of irritability of their internal membrane, by which the vessels contract and propel the fluid forwards. Hence the use of this function appears to be of the utmost importance, viz. to supply the blood with chyle; to remove the superfluous vapour of circumscribed cavities, — otherwise dropsies, as hydrocephalus, hydrothorax, hydrocardia, ascites, hydrocele, &c., would constantly be taking place; to remove the superfluous vapour from the cells of the cellular membrane dispersed throughout every part of the body, that anasarca may not take place; to remove the hard and soft parts of the body, and to convey into the system medicines which are applied to the surface of the body.

Lymphatic gland. See *Gland*.

Lymphatic temperament. See *Temperament*.

Lymphatic veins. The absorbents have been so called.

Lynch's embrocation. This consists of olive oil, scented with some volatile oils, and coloured with alkanet root.

Lyngodes. (Λυγγωδες; from λυγξ, the hiccup.) The epithet of a fever, of which hiccup is a prominent symptom. —*Hippocrates*.

Lypo'ma. See *Lipoma*.

LY'RA. (*a*, *æ*. f.; from λυρα, a lyre, or musical instrument.) *Psalterium*. *Corpus psalloides*. The triangular medullary space between the posterior crura of the fornix of the cerebrum, which is marked with prominent medullary fibres that give the appearance of a lyre.

LYRATUS. (From *lyra*, a musical instrument.) Lyrate, or lyre-shaped. A leaf is so named which is cut into transverse segments generally longer towards the extremity of the leaf which is rounded; as in *Erysimum barbaria*.

Lyre-shaped. See *Lyratus*.

Ly'rus. (From *lyra*, the lyre: so called because its leaves are divided like the strings of a lyre.) See *Arnica montana*.

Lysigy'ia. (Λυσιγυια; from λυω, to loosen and γυιον, a member.) Relaxation of limbs.—*Hippocrates*.

LYSIMA'CHIA. (*a*, *æ*. f.; from *Lysimachus*, who first discovered it.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*.

Lysimachia nummularia. The systematic name of the money-wort; called also, *Nummularia*, *Hirundinaria*, and *Centimorbia*. The plant is very common in our ditches. It was formerly accounted vulnerary; and was said to possess antiscorbutic and restringent qualities. Boerhaave looks upon it as similar to a mixture of scurvy-grass with sorrel.

Lysimachia purpurea. See *Lythrum salicaria*.

Lysimachiæ. A natural family of plants of which the genus *Lysimachia* is the type.

Lysiponion. See *Lysiponos*.

Lysiponos. Λυσιπονος. The epithet of an antidote, consisting of opium, henbane seed, mandrake, and other narcotics, &c.

LYSSA. (*a*, *æ*. f. Λυσσα, *rabies*.) Hydrophobia.

Lyssode'ctus. (Λυσσοδηκτος; from λυσσα canine madness, and δακνυμι, to bite.) One who labours under hydrophobia, in consequence of having been bitten by a rabid animal.

LY'THRUM. (*um*, *i*. n.; from λυθρος blood: so called from its resemblance in colour.) The name of a genus of plants in the Linnæan system. Class, *Dodecandria*; Order, *Digynia*.

Lythrum salicaria. *Lysimachia purpurea*. The systematic name of the common or purple willow-herb. The herb, root, and flowers possess a considerable degree of astringency, and are used medicinally in the cure of diarrhœas and dysenteries, fluor albus, and hæmoptysis.

LYTTA. (*a*, *æ*. f.) The name of a genus of insects. See *Cantharis*.

M.

M. In the language of medicine this letter has two significations. When herbs, flowers, chips, or the like substances, are ordered in a prescription, and M. follows them, it signifies *manipulus*, a handful; and when several ingredients have been directed, it is a contraction of *misce*: thus, *m. f. haust.* signifies mix, and let a draught be made.

Macandou. (Javanese.) A tree growing in Malacca, the fruit of which is roasted and eaten as a cure for dysenteries, cholera morbus, and other complaints. — *Bontius.*

Macapatli. Sarsaparilla.

Mace. See *Myristica moschata.*

Macedonian parsley. See *Bubon.*

Macedonisium semen. See *Smyrnium.*

MA'CER. The bark of the root of a tree growing in Malabar. It is astringent, and used against alvine fluxes. — *Piso.*

MACERA'TION. (*Maceratio, onis.* f.; from *macero*, to soften by water.) In a pharmaceutical sense, this term implies an infusion either with or without heat, wherein the ingredients are intended to be almost wholly dissolved in order to extract their virtues.

Macerona. See *Smyrnium olusatrum.*

MACHAO'NIA ARS. Medicine has been so called from *Machaon*, the son of Æsculapius.

Ma'cies. (*es, ei.* f.; from *maceo*, to grow lean.) Emaciation. See *Marasmus.*

MA'CIS. (*is, idis.* f.) Mace. See *Myristica.*

Mackarel. See *Scomber scomber.*

Macroce'phalus. (*us, i.* m.; from μακρος, long, and κεφαλη, the head.) See *Physeter macrocephalus.*

Ma'crophy'soce'phalus. (*us, i.* m.; from μακρος, long, φυσις, nature, and κεφαλη, the head: so called from the length of the head.) One who has a head unnaturally long and large. This word, according to Turton, is only used by Ambrose Pare.

Macro'piper. (*er, eris.* n.; from μακρος, long, and πεπερι, pepper.) Long pepper. See *Piper longum.*

Macropnœ'a. (*a, æ.* f.; from μακρος, long, and πνεω, to breathe.) That state of the breathing in which the inspiration is long and deep.

MA'CULA. (*a, æ.* f.) A spot, a permanent discolouration of some portion of the skin, often with a change of its texture, but not connected with any disorder of the constitution.

Macula matricis. A mother's mark. See *Nævus maternus.*

Maculæ. The name of an order of Dr. Willan's cutaneous diseases, which comprises those discolourations of the skin which are permanent, and most of which are the result of an alteration of the natural texture of the part. It comprehends *ephelis, nævus, opilus,* and moles.

MACULA'TUS. Spotted: applied, in *Botany*, to stems, petals, &c.; as the stem of the common hemlock, *Conium maculatum;* the *petales* of the *Digitalis purpurea.*

Mad apple. See *Solanum melongena.*

MADARO'SIS. (*is, eos.* f. Μαδαροσις; from μαδαρος, bald, or smooth.) Falling off of the hair, especially of the eye-lashes.

Madden's vegetable essence. This consists chiefly of the *infusum rosæ compositum*, with an increased proportion of acid.

Madder. See *Rubia.*

Madness. See *Insanity.*

Madness, canine. See *Hydrophobia.*

Ma'dor. Moisture. A sweating.

Madwort, Galen's. See *Marrubium.*

Magda'leon. (From μασσω, to knead.) A mass of plaster, or other composition, reduced to a cylindrical form.

Magellanicus cortex. See *Wintera.*

MA'GISTERY. (*Magisterium, ii.* n.; from *magister*, a master.) Magistery. A term used by the old chemists to signify a peculiar and secret method of preparing any medicine, as it were, by a masterly process. The term was also long applied to all precipitates.

Magistery of bismuth. The subnitrate of bismuth. See *Bismuth.*

MAGISTRA'LIS. (From *magister*, a master.) Applied to such medicines as are prescribed extemporaneously, on the authority of the physician, as opposed to those which are officinal.

Magistra'ntia. (From *magistro*, to rule: so called by way of eminence, as exceeding all others in virtue.) See *Imperatoria.*

MA'GMA. (*a, atis.* n.; from μασσω, to blend together.) 1. A thick ointment. 2. The fæces of any thing after the thinner parts are strained off.

3. A confection.

Magnes arsenicalis. Arsenical magnet. A composition of equal parts of antimony, sulphur, and arsenic, mixed and melted together so as to become a glassy body.

Magnes epilepsiæ. An old and obsolete name of native cinnabar.

MAGNE'SIA. (*a, æ.* f.) 1. The ancient chemists gave this name to such substances as they conceived to have the power of attracting any principle from the air. Thus an earth which, on being exposed to the air, increased in weight, and yielded vitriol, they called *magnesia vitriolata:* and later chemists, observing in their process for obtaining magnesia, that nitrous acid was separated, and an earth left behind, supposing it had attracted the acid, called it *magnesia nitri*, which, from its colour, soon obtained the name of *magnesia alba.*

2. The name of one of the primitive earths, having a metallic basis, called *magnesium.* It has been found native in the state of hydrate.

Magnesia may be obtained by pouring into a solution of its sulphate a solution of subcarbonate of soda, washing the precipitate, drying it, and exposing it to a red heat. It is usually procured in commerce, by acting on magnesian limestone with the impure muriate of magnesia, or bittern of the sea-salt manufactories. The muriatic acid goes to the lime, forming a soluble salt, and leaves behind the magnesia of both the bittern and limestone. Or the bittern is decomposed by a crude subcarbonate of ammonia, obtained from the distillation of bones in iron cylinders. Muriate of ammonia and subcarbonate of magnesia result. The former is evaporated to dryness, mixed with chalk, and sublimed. Subcarbonate of ammonia is thus recovered, with which a new quantity of bittern may be decomposed; and thus, in ceaseless repetition, forming an elegant and economical process. 100 parts of crystallised Epsom salt, require for complete decomposition 56 of subcarbonate of potash, or 44 dry subcarbonate of soda, and yield 16 of pure magnesia after calcination.

When magnesia is exposed to the air, it very slowly attracts carbonic acid. It combines with sulphur, forming a sulphuret.

The metallic basis, or *magnesium*, may be obtained in the state of amalgam with mercury, by electrisation.

When magnesia is strongly heated in contact with two volumes of chlorine, this gas is absorbed, and one volume of oxygen is disengaged. Hence it is evident that there exists a combination of magnesium and chlorine, or a true chloride. The salt called muriate of magnesia, is a compound of the chloride and water. When it is acted on by a strong heat, by far the greatest part of the chlorine unites to the hydrogen of the water, and rises in the form of muriatic acid gas; while the oxygen of the decomposed water combines with the magnesium to form magnesia.

Magnesia is often associated with lime in minerals, and their perfect separation becomes an interesting problem in analysis.

Properties. — Pure magnesia does not form with water an adhesive ductile mass. It is in the form of a very white spongy powder, soft to the touch, and perfectly tasteless. It is very slightly soluble in water. It absorbs carbonic acid gradually from the atmosphere. It changes very delicate blue vegetable colours to green. Its attraction to the acids is weaker than those of the alkalis. Its salts are partially decomposed by ammonia, one part of the magnesia being precipitated, and the other forming a triple compound. Its specific gravity is about 2·3. It is infusible even by the most intense heat; but when mixed with some of the other earths it becomes fusible. It combines with sulphur. It does not unite to phosphorus or carbon. It is not dissolved by alkalis in the humid way. When heated strongly, it becomes phosphorescent. With the dense acids it becomes ignited. With all the acids it forms salts of a bitter taste, mostly very soluble.

The magnesia of the present London Pharmacopœia was formerly called *Magnesia calcinata; usta; pura.* It is directed to be made thus: — Take of carbonate of magnesia, four ounces; burn it in a very strong fire, for two hours. It is given as an absorbent, antacid, and eccoprotic, in cardialgia, spasms, convulsions, and tormina of the bowels of infants, pyrosis, flatulencies, and other diseases of the prima viæ; obstipation, leucorrhœa, rickets, scrofula, crusta lactea, and podagra. The dose for an adult is from a scruple to a drachm.

An ingenious preparation of magnesia has been lately made, and is sold in the shops under the name of *ponderous magnesia.* A given weight of this occupies a much smaller space than the same weight of ordinary magnesia; hence it is much more convenient in prescription. There is a similar preparation of the carbonate. The process by which these preparations are made is kept secret.

Magnesia calcinata. See *Magnesia.*

Magnesia usta. See *Magnesia.*

Magnesia vitriolata. See *Magnesia sulphas.*

Magnesia water. *Aerated magnesian water.* This is made by mixing half an ounce of carbonate of magnesia with one gallon of water, and impregnating it with ten times its volume of carbonic acid gas, by means of a forcing pump. It is a good antacid, and the carbonic acid it contains renders it a salutary stimulant to the stomach.

Magnesiæ carbonas. *Magnesiæ subcarbonas. Magnesia alba.* Carbonate of magnesia. The London College direct it to be made as follows: — Take of sulphate of magnesia, four pounds; carbonate of soda, four pounds and eight ounces; distilled water, four gallons. Dissolve the carbonate of soda and the sulphate of magnesia separately in two gallons of the water, and strain; then mix, and boil the liquors, stirring constantly with a spatula for a quarter of an hour; lastly, pour off the liquor, and wash the precipitated powder with boiling distilled water, and dry it. It is in form of very fine powder, considerably resembling flour in its appearance and feel; it has no sensible taste on the tongue; it gives a faint greenish colour to the tincture of violets, and converts turnsole to a blue. It is employed medicinally as an absorbent, antacid, and purgative, in doses from half a drachm to two drachms.

Magnesiæ sulphas. *Sulphas magnesiæ purificata. Magnesia vitriolata. Sal catharticus amarus. Sal catharticum amarum.* Sulphate of magnesia. Epsom salt. Bitter purging salt.

This salt exists in several mineral springs, as that of Epsom, from which it was formerly obtained: it is now afforded, however, in greater abundance and more pure from the bittern left after the extraction of salt from sea-water. It has likewise been found effloresceing on brick walls, both old and recently erected, and in small quantity in the ashes of coals. The capillary salt of Idria, found in silvery crystals mixed with the aluminous schist in the mines of that place, and hitherto considered as a feathery alum, has been ascertained by Klaproth to consist of sulphate of magnesia, mixed with a small portion of sulphate of iron. When pure,

t crystallites in small quadrangular prisms, terminated by quadrangular pyramids or dihedral ummits. Its taste is cool and bitter. It is ery soluble, requiring only an equal weight of old water, and three fourths its weight of hot. t effloresces in the air though but slowly. If t attracts moisture, it contains muriate of magesia or of lime. Exposed to heat, it dissolves n its own water of crystallisation, and dries, ut is not decomposed nor fused, but with xtreme difficulty. It consists, according to Bergman, of 33 acid, 19 magnesia, 48 water. A very pure sulphate is said to be prepared in he neighbourhood of Genoa, by roasting a yrites found there; exposing it to the air in a overed place for six months; watering it occaionally, and then lixiviating.

It is from these saline solutions that the salt s obtained: the method generally adopted for btaining it is evaporation, which causes the salt o crystallise in tetrahedral prisms. It has a ery bitter taste, and is soluble in its own weight f water at 60°, and in three fourths of its veight of boiling water. Sulphate of magesia, when perfectly pure, effloresces; but that f commerce generally contains foreign salts, uch as the muriate of magnesia, which renders t so deliquescent, that it must be kept in a close essel or bladder. By the action of heat it ndergoes the watery fusion, and loses its water f crystallisation, but does not part with its cid. One hundred parts of crystallised sulhate of magnesia consist of 29·35 parts of cid, 17 of earth, and 53·65 of water. The lkalies, strontian, barytes, and all the salts ormed by these salifiable bases, excepting the lkaline muriates, decompose sulphate of magesia. It is also decomposed by the nitrate, arbonate, and muriate of lime.

Epsom salt is a mild purgative, operating vith sufficient efficacy, and in general with ease nd safety, rarely occasioning any gripes, or the ther inconveniences of resinous purgatives. Six or eight drachms may be dissolved in a roper quantity of common water; or four, ve, or more, in a pint or quart of the purging ineral waters. These solutions may likewise e so managed, in small doses, as to produce vacuation from the other emunctories: if the atient be kept warm, they increase perspiration, nd, by moderate exercise in the cool air, the rinary discharge. Some allege that this salt as a peculiar effect in allaying pain, as in colic, ven independently of evacuation.

MAGNE'SIUM. The metallic base of magnesia. See *Magnesia.*

MAGNET. (*Magnes*, etis. m.; Μαγνης. Μαγνητης. Said to be so called from the name f a shepherd, who first observed it.) The oadstone. See *Magnetism.*

MA'GNETISM. There are some native xides of iron which have the remarkable proerty of attracting iron. These are called *oadstones, magnetic iron ores*, or *natural magets.*

If a bar of tempered steel be rubbed in a ertain direction with a loadstone, it acquires a imilar property of attracting iron, and permanently retains this property. If a slender bar of iron be rendered magnetic and poised on a fulcrum, or suspended by a thread, so as to admit of its free horizontal motion, in a situation where it is not influenced by the contiguity of other magnets or pieces of iron, it will vibrate for some time, and ultimately settle in a position in which its extremities point nearly north and south; and if it be put out of this position, it will constantly return to it. The extremities of the magnetic needle are called its *north and south poles;* the direction which the needle assumes when pointing north and south, is termed the *magnetic meridian;* and the disposition to assume this position is termed *polarity.* This property of polarity in the magnetic needle, is the principle on which the mariner's compass is constructed, and the art of navigation founded. When the magnetic needle is so placed as to admit of its free motion in every direction, its north pole is drawn downwards towards the earth, and this phenomenon is called the *dip of the magnetic needle.*

On bringing either pole of a magnet near some iron filings, it will attract them, and the attraction is mutual, for a large mass of iron will draw towards it a small magnet.

If the similar poles of two magnets be presented to each other, they will repel each other; but if the different poles of two magnets be presented to each other, they will attract each other.

If a bar of iron be brought near a magnet, it acquires a temporary magnetism. The production of this temporary state is called *magnetic induction*, and is in many respects analogous to electric induction. For the phenomena of this state we must refer to the treatises on magnetism.

Some other metals besides iron may, under certain circumstances, be rendered magnetic for a time, and nickel may be made permanently so.

MAGNETISM, ANIMAL. In the year 1778, Anthony Mesmer promulgated a theory, according to which all the phenomena of life are referred to the motion of a certain universal magnetic fluid, which admits of being influenced by external agents, and especially by magnetic instruments. Ideas similar in some respects to those of Mesmer, had been entertained by Paracelsus, Van Helmont, Rudolph Goclen, Athanasius Kircher, Valentine Greatrakes, and others. The experiments exhibited by Mesmer, and the cures performed by him at Paris, caused so great a sensation, that a royal commission was appointed to examine into his claims. The commissioners, among whom were Franklin and Lavoisier, after mature investigation, came to the conclusion that the effects produced by Mesmer's operations were referable solely to the imagination of the patients; that they were devoid of all salutary influence, and calculated to do harm. Only one of the commissioners dissented from this opinion. Since that time animal magnetism, or *Mesmerism*, as it is also called, has been in various degrees of estimation, but has never been admitted by the scientific world at large to the rank of a true science. It is to be observed, also, that scarcely any two practitioners of the art have agreed in their

mode of proceeding, or in the results obtained, and that all sorts of effects have been produced in all sorts of ways. The use of magnetic instruments is now quite exploded, and every thing is done by certain *passes* or movements of the hands of the operator. The application of the mineral magnet, however, is alleged by some to produce particular effects on persons in the state induced by animal magnetism. In 1831 animal magnetism was again reported on by a committee of the Royal Academy of Medicine, which had been occupied for five years in experimenting on the subject. The report was favourable to the authenticity of the leading facts adduced by the magnetists; but the committee did not venture on any opinion as to the real cause of those phenomena.

According to Kluge, and other writers who have entered minutely into the subject, there appear to be six distinct stages or degrees of magnetic influence. These are as follows: —

1. The *Waking stage*, in which the patient experiences a powerful aura passing from the head to the extremities, followed by general increase of temperature, redness of the skin, perspiration, and a feeling of lightness and comfort.

2. The stage of *Half-sleep*. In this the phenomena above mentioned become more intense; the heat increases, and appears to radiate from the stomach over the whole body; the pulse becomes fuller, and the breathing slower and deeper; the patient is drowsy, his eyelids close, and he cannot open them, while the magnetizing process is continued; the other senses remain active, although the patient often cannot express himself; flashes of light are seen before the eyes; prickings are felt at the ends of the fingers; there are profuse sweats, rigours, and sometimes spasms of the muscles, and other nervous phenomena.

3. *Magnetic sleep or stupor*. — The patient is now buried in a profound sleep, from which he cannot be awakened even by the loudest cries. Syncope, cataleptic or apoplectic affections, and convulsive shudderings, sometimes occur during this stage. It terminates gradually, the patient sighs, and finally awakes, retaining no recollection of what has happened.

4. *Somnambulism*. — In this degree of the magnetic influence, the patient recovers his internal consciousness while his outward senses are still asleep. In the more perfect developments of this state, the general sense of feeling becomes exalted and modified, so as to supersede the particular senses, the patient sees and hears with the pit of his stomach, the ends of his fingers, &c. &c.

5. *Self-contemplation*, the *clair-voyance* of the French magnetists. When the patient has got this length, he becomes perfectly cognizant of his own anatomy, and if there be disease in any part, he immediately sees what is the matter, and knows what to prescribe. If he be unacquainted with the names of the drugs, he describes them so accurately that they can be recognised by his physician.

This state of *clair-voyance* obtains not only with respect to the patient's own body, but also with respect to the bodies of those with whom he is placed in magnetic relation, and the *clair-voyant* sees their internal economy as clearly as his own.

6. *Universal illumination*. — In this highest stage of magnetism, the patient, or rather prophet, is no longer confined within the limits of time, space, or sense; he enters into the penetralia of nature; he knows what is going on in distant regions, and all that has happened or will happen to those persons with whom he is brought into magnetic relation, and so forth.

It is to be observed, that the different stages of magnetism above alluded to can only be arrived at by degrees. Thus, at the first sitting, even the first degree may not be attained; and it may not be till after many successive and long continued operations that the higher states of magnetism are established. The magnetists admit that there is a great difference of susceptibility in different individuals; but most seem to be of opinion that some effect is produced upon all, if the process be continued long enough. This, however, does not appear to be borne out by experience, since it is pretty notorious that on persons endowed with good health and good sense animal magnetism generally produces no effect whatever. It has been frequently asserted, that all the effects of magnetism may be produced on susceptible individuals, without their being aware that any attempt is being made to magnetise them — as when the operator comes unobserved behind them. This, if established, would sufficiently prove that there must be some real agency in the case, independent of any impression on the mind of the patient. But this assertion requires much more substantial evidence than has yet been adduced, to obtain credence from cautious inquirers.

Such are the principal of the alleged effects of animal magnetism. Of these phenomena the artificial sleep and somnambulism are worthy the attention of sober-minded persons since they are not only in their nature possible but seem in many instances to have actually occurred, and to have been attested by competent witnesses. All that can be said upon the subject at present is, that some new facts in the physiology, or rather pathology, of the nervous system have been observed, and remain to be explained. Possibly a more extended range of observation may afford such explanation, and possibly also the facts may remain unexplained — which is hitherto the case with respect to the very familiar though very wonderful state, namely, that of natural sleep. With respect to *clair-voyance* and *universal illumination*, those physiologists who have actually witnessed such phenomena may believe in them; but the greater part of physiologists never have witnessed them, and we may venture to predict never will.

MAGNETO-ELECTRICITY. M. Faraday observed certain phenomena, which he has described under the names of *volta-electric* and *magneto-electric induction*. In consequence of these phenomena, it occurred to him that magnetism in motion ought to produce a

ectric current, and he succeeded in verifying is important conclusion as follows: — a long iral coil of copper-wire, covered as in the rmer experiments with silk, was connected by extremities with the galvanometer, the de- ction of which would of course announce a rrent of electricity in the spiral and wires nnected with it: he now found, that in the t of introducing the pole of a powerful bar- agnet within the coils of the spiral, a deflection the galvanometer took place in one direction, d in the act of withdrawing it took place in e opposite direction; so that each time the nducting-wire cut the magnetic curves, a rrent of electricity was, for the moment, oduced in it. He afterwards devised the llowing curious modification of this experi- ent: a copper plate was so mounted as to mit of revolving upon its axis; the poles of powerful horse-shoe magnet were so placed as admit of the revolution of the circumference the plate between them; and two conducting ires are so placed, that one is in perfect etallic contact with the axis, and the other ith the circumference of the plate at the point tween the two poles of the magnet, while th wires at their other extremity terminate in galvanometer. When the copper plate is ade to revolve from right to left, a current of ectricity is produced, in the direction of the rows, and deflects the galvanometer accord- gly. If the revolutions of the plate, or the les of the magnet be reversed, the electric rrent moves in the opposite direction. These servations have given rise to a new branch of ience, which is termed *magneto-electricity*.

Mr. Faraday not only succeeded in obtaining lvanometrical indications of an electric cur- nt, but, by another modification of the arrange- ent in which the electric current was induced an electro-magnet, he actually succeeded in taining the electric spark. The electric spark as afterwards obtained from a common mag- t, by Nobili and Antinori, and in this country Professor Forbes. For this purpose, a helix copper wire was formed round the middle of e soft iron holder of a powerful horse-shoe agnet; on making and breaking the contact tween the holder and the magnet, magnetism as alternately created and destroyed within it: these periods of transition, electric currents ere induced in the helix, and on so arranging e conducting-wires as at these moments to ake and break contact with mercury, a brilliant ark was observed at each motion of the holder. y making the poles of a powerful horse-shoe agnet revolve rapidly before a soft iron arma- re supplied as in the former case with a helix, r what is still better, causing the armature and elix to revolve before the poles, an electric rrent is obtained, which not only gives con- nuous sparks, but ignites wire, decomposes ater, and produces powerful shocks. These *agneto-electric machines* are now commonly onstructed with a powerful magnet, and whilst ey furnish a beautiful illustration of the pro- uction of electricity by moving magnetism, em also to promise some advantage in the edical applications of electricity, and have been elegantly applied to the purpose of obtaining instantaneous light, by causing the spark to inflame the wick of a small spirit-lamp.

From the manner in which a magnet in motion induces an electric current, it was presumed that the earth's magnetism might be rendered subservient to the same purpose, and Mr. Faraday found that a soft iron cylinder, introduced into the helix, as above described, and placed in the direction of the dipping needle, occasioned a deviation in the galvanometer; he even found that in a wire, or helix, moved at right angles to the dipping needle, so as to cut the magnetic curves of the earth, an electric current, sensible to the galvanometer, was induced; and that the rotation of a copper globe, or of a plate placed at right angles to the dip, produced the same effect; hence he concludes that the conducting matters of the earth's crust may be similarly affected by its diurnal revolutions, so as to induce electric currents flowing towards the poles, and suggests the possibility of the production of the Aurora, by returning electric currents from the poles into the atmosphere. — *Brande*.

Magnum dei donum. So Dr. Mead called the Peruvian bark. See *Cinchona*.

Magnum os. The third bone of the lower row of bones of the carpus, reckoning from the thumb towards the little finger.

Magy'daris. The root of the laserwort.

Mahagoni. See *Swietenia*.

Mahaleb. A species of cherry.

Mahmoudy. Scammony.

Maidenhair. See *Adianthum*.

Maidenhair, black. See *Asplenium*.

Maidenhair, Canada. See *Adianthum*.

Maidenhair, common. See *Asplenium*.

Maidenhair, English. See *Adianthum*.

Maidenhair, golden. See *Polytrichum*.

Maidenhair-tree. *Ginan itsio*. The *Gingko biloba*. In China and Japan, where this tree grows, the fruit acquires the size of a damask plum, and contains a kernel resembling that of our apricot. These kernels always make part of the dessert at all public feasts and entertainments. They are said to promote digestion, and to cleanse the stomach and bowels. The oil is used at the table.

Maize. Indian corn. See *Zea*.

Majanthemum. See *Convallaria majalis*.

Major helicus. See *Helicus major*.

MAJORA'NA. (*a*, *æ*. f.; *quod mense Maio floreat*, because it flowers in May.) See *Origanum majorana*.

Majorana syriaca. See *Teucrium*.

Mal de la rosa. (So called from the red colour of the skin.) *Rosa Asturica*. *Lepra Asturica*. Asturian rose. A disease endemic in the Asturias. It appears to be a variety of Pellagra.

Mal des ardens. The name of a pestilential erysipelas or carbuncle, which was epidemic in France in the twelfth century.

Mal rouge de cayenne. Cayenne leprosy. A disease which commences with an eruption of red spots, and in the progress of which the body becomes covered with fungative ulcers of a red colour. It appears to be allied to elephantiasis.

MA'LA. (*a*, *æ*. f.) The cheek.

Malabar plum. See *Eujenia jambos.*

MALABATHRI OLEUM. Oil of cassia.

MALABA'THRINUM UNGUENTUM. Ointment of malabathrum. It is compounded of myrrh, spikenard, malabathrum, and many other aromatic ingredients.

MALABA'THRUM. (Μαλαβαθρον; from *Malabar*, in India, whence it was brought, and *betre*, a leaf, Ind.) Indian leaf. The leaf of the *laurus cassia.*

Malacca radix. See *Sagittaria.*

Malacca bean. See *Avicennia tomentosa.*

MA'LACHE. (*e*, *es*. f.; from μαλακος, soft: so called from the softness of its leaf.) The mallow. See *Malva.*

MALA'CIA. (*a*, *æ*. f.; from μαλακος, soft; effeminate.) Whimsical or depraved appetite, such as sometimes occurs in pregnant women, chlorotic girls, &c. See *Pica.*

MALACO'STEON. (*um*, *i*. n.; from μαλακος, soft, and οστεον, a bone.) A softness of the bones. *Mollities ossium.* A disease of the bones, wherein they can be bent without fracturing them, in consequence either of the inordinate absorption of the phosphate of lime, from which their natural solidity is derived, or else of this matter not being duly secreted and deposited in their fabric. In rickets, the bones only yield and become distorted by slow degrees; but in the present disease they may be at once bent in any direction. The mollities ossium is rare, and its causes not well understood. All the cases of this disease on record have proved fatal, no means of cure having yet been found. On dissection of those who have died, all the bones, except the teeth, have been found unusually soft, so that scarcely any of them could resist the knife; the periosteum has been found thicker than usual; and the bones have been found to contain a great quantity of oily matter and little earth.

MALA'CTICA. (Μαλακτικα; from μαλασσω, to soften.) Emollient remedies.

MALAGUETTA. Grains of paradise.

MALAGUETTA. Grains of paradise.

MALA'GMA. (*a*, *atis*. n.; Μαλαγμα; from μαλασσω, to soften.) A cataplasm or emollient application.

MALA'RIA. The Italian name for marsh miasma.

Malarum ossa. See *Jugale os.*

MA'LATE. *Malas.* A salt formed by the union of the malic acid, with a salifiable basis.

MA'LE. Μαλη. The arm-pit.

Male fern. See *Aspidium filix mas.*

Male impotency. See *Sterilitas.*

Male orchis. See *Orchis mascula.*

Male speedwell. See *Veronica officinalis.*

MALIC ACID. *Acidum malicum.* This acid is obtained by saturating the juice of apples with alkali, and pouring in the acetous solution of lead, until it occasions no more precipitate. The precipitate is then to be edulcorated, and sulphuric acid poured on it, until the liquor has acquired a fresh acid taste, without any mixture of sweetness. The whole is then to be filtered, to separate the sulphate of lead. The filtered liquor is the malic acid, which is very pure, remains always in a fluid state, and cannot be rendered concrete. See *Sorbic acid.*

MALI'GNANT. (*Malignus.*) A term applied to pestilential fevers, and to local diseases of an incurable nature, as cancer and fungus hæmatodes.

Malignant fever. See *Typhus.*

Malignant sore throat. See *Tonsillitis.*

MALLEABI'LITY. (*Malleabilitas*; from *malleus*, a hammer.) The property which several metals possess of being extended under the hammer into thin plates, without cracking. The thin leaves of silver and gold afford the best examples of malleability. See *Ductility.*

MALLEAMOTHE. *Pavette. Pavate. Erysipelas curans arbor.* A shrub which grows in Malabar. The leaves, boiled in palm oil, cure the impetigo; the root, powdered and mixed with ginger, is diuretic.

MALLEA'TIO. (From *malleus*, a hammer: because the person strikes the knees with his hands, as if with a hammer.) A form of chorea, in which the person has a convulsive action of one or both hands, which strike the knee like a hammer. If the motion be forcibly stopped, the convulsion becomes afterwards still more violent and general.

Mallei anterior. See *Laxator tympani.*

Mallei externus. See *Laxator tympani.*

Mallei internus. See *Tensor tympani.*

MALLE'OLUS. (*us*, *i*. m.; diminutive of *malleus*, a mallet: so called, from its supposed resemblance to a mallet.) The termination of the tibia at the ankle is called *malleolus internus*, and the corresponding part of the fibula *malleolus externus.*

MA'LLEUS. (*us*, *i*. m.; a hammer.) A bone of the internal ear is so termed from its shape. See *Auris.*

Mallow. See *Malva.*

Mallow, marsh. See *Althæa officinalis.*

Mallow, round-leaved. See *Malva.*

Mallow, vervain. See *Malva alcea.*

MALOGRANA'TUM. (From *malum*, an apple, and *granum*, a grain: so named from its grain-like seeds.) The pomegranate.

MALPI'GHIA. (*a*, *æ*. f.; so named in honour of Malpighi.) The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Trigynia.*

MALPIGHIA GLABRA. This affords the Barbadoes cherry.

MALPIGHIA MOURELLA. The bark is astringent, and is used in Cayenne as a febrifuge.

MALT. Grain which has become sweet, from the conversion of its starch into sugar, by an incipient growth or germination artificially induced, called malting.

MALTHA'CTICUS. (From μαλθακιζω, to soften.) Emollient, softening.

MALTHEORUM. Common salt. — *Ruland.*

MA'LUM. (*um*, *i*. n.) 1. A disease.

2. An apple.

MALUM MORTUUM. A disease that appears in the form of a pustule, which soon forms a dry, brown, hard, and broad crust. It is seldom attended with pain, and remains fixed

for a long time before it can be detached. It is mostly observed on the tibia and os coccygis, and sometimes the face.

Malum insanum. See *Solanum melongena.*

Malum pilare. See *Plica.*

MA'LUS. (*us, i.* f.; an apple-tree.) See *Pyrus malus.*

MALUS INDICA. *Bilimbi billing-bing.* A tree carefully cultivated in the gardens of the East Indies, where it flowers throughout the year. The juice of the root is cooling, and drunk as a cure for fevers. The leaves boiled and made into a cataplasm with rice, are famed in all sorts of tumours, and the juice of the fruit is used in almost all external heats, dipping linen rags in it, and applying them to the parts. It is drunk, mixed with arrack, to cure diarrhœas; and the dried leaves, mixed with betel leaves, and given in arrack, are said to promote delivery. The ripe fruit is eaten as a delicacy, and the unripe made into a pickle for the use of the table.

MA'LVA. (*a, æ.* f.) 1. The name of a genus of plants in the Linnæan system. Class, *Monadelphia;* Order, *Polyandria.* The mallow.

2. The pharmacopœial name of the common mallow. See *Malva sylvestris.*

MALVA A'LCEA. *Malva verbenaca.* The vervain mallow. This plant is distinguished from the common mallow, by its leaves being jagged, or cut in about the edges. It agrees in virtues with the other mallows, but it is the least mucilaginous of any. This, like to the other mallows, abounds with a mucilage, and is good for pectoral drinks.

Malva arborea. See *Alcea rosea.*

MALVA ROTUNDIFOLIA. Round-leaved mallow. The whole herb and root possess similar virtues to the common mallow. See *Malva sylvestris.*

MALVA SYLVESTRIS. The common mallow. *Malva vulgaris. Malva — caule erecto herbaceo, foliis septemlobatis acutis, pedunculis petiolisque pilosis.* This indigenous plant has a strong affinity to the althæa, both in a botanical and a medical respect. See *Althæa.* The leaves and flowers are principally used in fomentations, cataplasms, and emollient enemas. The internal use of the leaves seems to be wholly superseded by the radix althæa.

Malva verbenaca. See *Malva alcea.*

Malva vulgaris. See *Malva sylvestris.*

MALVAVI'SCUS. (*us, i.* m.; from *malva*, the mallow, and *viscus*, glue: so named from its viscidity.) See *Althæa officinalis.*

MALVERN. The village of Great Malvern has, for many years, been celebrated for a spring of remarkable purity, which has acquired the name of the holy well, from the reputed sanctity of its waters, and the real and extensive benefit long derived in various cases from its use.

The holy well water, when first drawn, appears quite clear and pellucid, and does not become sensibly turbid on standing. It possesses somewhat of an agreeable pungency to the taste; but this is not considerable. In other respects it does not differ in taste from pure good water.

It appears to contain no mineral impregnation. It is difficult, therefore, to conceive in what its alleged medicinal efficacy consists. It has, nevertheless, been highly esteemed as an external application to scrofulous ulcerations and ophthalmia, and to many cutaneous affections. Internally it has been used in painful affections of the kidneys and bladder, attended with the discharge of bloody, purulent, or fœtid urine, the hectic fever produced by scrofulous ulceration of the lungs, or very extensive and irritating sores on the surface of the body, and also fistulas of long standing.

It is singular that, notwithstanding its apparent purity, this water is said not to keep well, and soon acquires a fœtid smell, by standing in open vessels.

The internal use of Malvern waters is sometimes attended at first with a slight nausea, and not unfrequently, for the first day or two, it occasions some degree of drowsiness, vertigo, or slight pain of the head, which comes on a few minutes after drinking it. These symptoms go off spontaneously, after a few days, or may readily be removed by a mild purgative. The effects of this water on the bowels are not at all constant; frequently it purges briskly for a few days, but it is not uncommon for the body to be rendered costive by its use; especially, as Dr. Wall observes, with those who are accustomed to malt liquors. In all cases, it is said to increase the flow of urine.

MAMI'LLA. (*a, æ.* f.; diminutive of *mamma*, the breast.) 1. The breast of man.

2. The nipple of the male and female breasts.

MAMI'RA. It is said, by Paulus Ægineta, to be the root of a plant which is of a detergent quality. Some think it is the root of the doronicum: but what it really is cannot be ascertained.

MA'MMA. (*a, æ.* f.) The organ which secretes the milk in mammiferous animals. The mammæ vary in number and position in different animals. In the human female, the mammæ are two globular bodies composed of common integuments, adipose substance, and lacteal glands and vessels, and adhering to the anterior and lateral regions of the thorax of females. On the middle of each breast is a projecting portion, termed the *papilla* or *nipple*, in which the excretory ducts of the glands terminate, and around which is a coloured disc, called the *areola.* The use of the breasts is to suckle the young.

MAMMA'LIA. (From *mamma*, a breast or teat.) A great division of the animal kingdom, comprising animals which suckle their young. See *Animal Kingdom.*

Ma'mmary See *Mammillary.*

MAMMARY ABSCESS. A collection of matter in the breast, arising from previous inflammation of its substance. It is a frequent occurrence in the early period of lactation.

MAMMARY ARTERIES. *Arteriæ mammillares.* The internal mammary artery is a branch of the subclavian, and gives off the mediastinal, thymal, and pericardial arteries. The external mammary arteries are branches of the axillary.

MAMMARY VEINS. *Venæ mammillares.* These

vessels accompany the arteries, and evacuate their blood into the subclavian vein.

MAMMEA. (*a, æ.* f.; so called from its vernacular appellation in the West Indies, *mamei*, and allowed by Linnæus, because of its affinity to *mamma*, a breast, alluding to the shape of its fruit.) The name of a genus of plants. Class, *Polyandria;* Order, *Monogynia.*

MAMMEA AMERICANA. The tree which affords a delicious fruit called *mammea.* It has a very grateful flavour when ripe, and is much cultivated in Jamaica, where it is generally sold in the markets for one of the best fruits of the island. The kernels are mixed with baits, and thrown into the water to intoxicate fish.

MAMMIFERA. The same as *mammalia.*

MAMMILLARY. (*Mammillaris;* from *mamma*, the breast.) Mammary: appertaining to the *mamma*, or breast.

Man. (*Homo, inis.* m.) See *Homo.*

Manchineal. See *Hippomane manicella, in the supplement.*

Mancura'na. See *Origanum vulgare.*

MANDI'BULA. (*a, æ.* f.; from *mando*, to chew.) The jaw. See *Maxilla inferior.*

Mandra'gora. See *Atropa mandragora.*

MANDRAGORI'TES. (From μανδραγορα, the mandrake.) Wine, in which the roots of the mandrake are infused.

Mandrake. See *Atropa mandragora.*

MANDUCA'TION. *Manducatio.* Synonymous with *mastication.*

MANGANE'SE. (*Manganesium, ii.* n.) A metallic substance, which, after iron, seems to be the most frequently diffused metal through the earth: its ores are very common. As a peculiar metal, it was first noticed by Gahn and Scheele, in the year 1774. It is always found in the state of an oxide, varying in the degree of oxidisement. La Peyrouse affirmed, that he had found manganese in a metallic state; but there was probably some mistake in his observation. The ores are distinguished into *grey oxide of manganese, black oxide of manganese, reddish white oxide of manganese,* and *carbonate of manganese.* All these combinations have an earthy texture; they are very ponderous; they occur both amorphous and crystallised: and generally contain a large quantity of iron. Their colour is black, blackish brown, or grey, seldom white. They soil the fingers like soot. They are sometimes crystallised in prisms, tetrahedral, rhomboidal, or striated.

Properties — Manganese is of a whitish grey colour. Its fracture is granulated, irregular, and uneven. It is of a metallic brilliancy, which it, however, soon loses in the air. Its specific gravity is about 8. It is very hard, and extremely brittle. It is one of the most refractory metals, and most difficult to fuse, requiring at least 160° of Wedgwood's pyrometer. Its attraction of oxygen is so rapid, that exposure to the air is sufficient to render it red, brown, black, and friable in a very short time; it can, therefore, only be kept under water, oil, or ardent spirit. It is the most combustible of all the metals. It decomposes water, by means of heat, very rapidly, as well as the greater part of the metallic oxides. It decomposes sulphuric acid. It is soluble in nitric acid. It is fusible with earths, and colours them brown, violet, or red, according to its state of oxidisement. It frees from colour glasses tinged by iron. It does not readily unite with sulphur. It combines with phosphorus. It unites with gold, silver, and copper, and renders them brittle. It unites to arsenic in close vessels, but does not enter into union with mercury.

From the recent investigations of Berzelius, Thomson, and other distinguished chemists, it appears that there are three proper oxides of manganese, and two, which are probably mixtures of the others.

1. The *protoxide* consists of one equivalent of oxygen and one of the metal. It may be obtained by dissolving common black manganese in sulphuric or nitric acid, adding a little sugar, and precipitating by solution of potash. A white powder is obtained, which being heated to redness out of the contact of air, becomes yellow, puce-coloured, and, lastly, red brown. To be preserved, it should be washed in boiling water, previously freed from air, and then dried by distilling off the moisture in a retort filled with hydrogen. The dark olive oxide, when examined in large quantities, appears almost black; but when spread upon white paper, its olive tint is apparent. It takes fire when gently heated, increases in weight, and acquires a browner tint. It slowly absorbs oxygen from the air, even at common temperatures. It dissolves in acids without effervescence. The white powder obtained above, is the hydrated protoxide. The different tints which it assumes by exposure to air, are suposed by Sir H. Davy to depend on the formation of variable quantities of the black-brown oxide, which probably retains the water contained in the white hydrate, and is hence deep puce-coloured.

2. The *sesquioxide.* This occurs in nature nearly pure, and in the state of a hydrate is found abundantly at Jhlefeld in the Hartz. It may be artificially procured by applying heat to the peroxide, or hydrated sesquioxide, or nitrate of manganese. It consists of three equivalents of oxygen and two of manganese. The native sesquioxide is black, as also that prepared from the nitrate; but when obtained from the peroxide or hydrated sesquioxide, it is brownish.

3. The black *peroxide.* This is the common black ore of manganese which is very abundant. Its sp. gr. is 4. It does not combine with any of the acids. It yields oxygen when heated; and, by intense ignition, passes in a great measure into the protoxide. It consists of two equivalents of oxygen, and one of manganese.

4. The *red oxide.* This occurs in nature, and may also be obtained by exposing the sesquioxide or peroxide to a white heat. It is supposed to be a compound of the protoxide and sesquioxide.

5. *Varvicite.* This is a native oxide of manganese, and no similar substance has yet been obtained by art. It is supposed, like the red oxide, to be a compound of the sesquioxide and peroxide.

Method of obtaining manganese. — This metal is obtained by mixing the black oxide, finely powdered, with pitch; making it into a ball, and putting this into a crucible with powdered charcoal, one tenth of an inch thick at the sides, and one fourth of an inch deep at the bottom. The empty space is then to be filled with powdered charcoal; a cover is to be luted on; and the crucible exposed, for an hour, to the strongest heat that can be raised. Or, digest the black oxide of manganese repeatedly, with the addition of one sixteenth of sugar, in nitric acid; dilute the mixture with three times its bulk of water; filter it, and decompose it by the addition of potash; collect the precipitate, form it into a paste with oil, and put it into a crucible, well lined with charcoal. Expose the crucible for at least two hours to the strongest heat of a forge.

Manganeseous acid. See *Manganic acid.*

Manganesic acid. See *Manganic acid.*

Manganic acid. When peroxide of manganese is mixed with an equal weight of nitre or carbonate of potash, and the mixture is exposed to a red heat, a green coloured fused mass is formed, which has been long known under the name of *mineral chameleon.* On putting this substance into water, a green solution is obtained, the colour of which soon passes into blue, purple, and red; and ultimately, a brown flocculent matter, hydrated peroxide of manganese, subsides, and the liquid becomes colourless. These changes take place more rapidly by dilution, or by employing hot water. We are indebted to MM. Chevillot and Edwards for a consistent explanation of these phenomena. They demonstrated that peroxide of manganese, when fused with potash, absorbs oxygen from the atmosphere, and is thereby converted into an acid, which unites with the alkali. They attributed the different changes of colour above mentioned to the combination of this acid with different proportions of potash. Subsequently the subject engaged the attention of Dr. Forchhammer, who rendered it probable that the green and red tints are produced by two distinct acids, one of which forms red and the other green coloured salts; and very lately Mitscherlich has established the existence of these acids, and ascertained their composition.

The names at first applied to these compounds were *manganeseous* and *manganesic* acid, but Mitscherlich proposes to distinguish them by the terms *manganic* and *permanganic* acid. He was led to this suggestion by finding that the green coloured salts are isomorphous with the sulphates and seleniates, and that their acid has a composition similar to that of sulphuric and selenic acids, consisting of three equivalents of oxygen to one equivalent of the other element; whereas the red acid is isomorphous with perchloric acid, and is composed of two equivalents of manganese united with seven equivalents of oxygen; a constitution identical, according to the views of Berzelius, with that of perchloric acid. — *Turner.*

Mangel wursel. See *Beta hybrida.*

MANGI'FERA. (*a, æ.* f.; from *mango*, the name of the fruit which it bears.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.* The mango tree.

Mangifera indica. The systematic name of the mango tree, which is cultivated all over Asia. Mangoes, when ripe, are juicy, of a good flavour, and so fragrant as to perfume the air to a considerable distance. They are eaten either raw or preserved with sugar. Their taste is so luscious, that they soon pall the appetite. The unripe fruits are pickled in the milk of the cocoa-nut, that has stood until sour, with salt, capsicum, and garlick. From the expressed juice is prepared a wine; and the remainder of the kernel can be reduced to an excellent flour for the making of bread.

Mango. See *Mangifera indica.*

Mangostana. See *Garcinia.*

Mangosteen. See *Garcinia mangostana.*

MA'NIA. (Μανια; from *μαινομαι*, to rage.) Furious madness. See *Insanity.*

Ma'nica Hippo'cratis. Hippocrates' sleeve. A strainer of a conical shape, made of linen or flannel, and used for pharmaceutical purposes.

Maniguetta. The grains of paradise. See *Amomum granum paradisi.*

Ma'nihot. See *Jatropha manihot.*

MANI'PULUS. (*us, i.* m.) A handful.

MA'NNA. (*a, æ.* f.; a Hebrew word.) 1. The substance with which the children of Israel were fed in the wilderness, and which appears to have been a kind of honey-dew.

2. The name is now given to a peculiar saccharine matter which exudes from many plants. See *Fraxinus ornus.*

Manna brigantiaca. A species of manna, brought from the neighbourhood of Briançon, in Dauphiny.

Manna calabrina. Calabrian manna.

Manna canulata. Flaky manna, or manna concreted on straw, or chips.

Manna thuris. A coarse powder of olibanum was sold by this name.

Ma'nnite. The sweet principle of manna, which is found to be distinct from sugar.

Manso'rius. (From *mando*, to chew.) The masseter muscle. See *Masseter.*

Mantle, ladies'. See *Athamanta.*

Manubrium manus. Handle of the hand. The radius has been so called.

MA'NUS. (*us, ûs.* f.; the etymology of which is not known.) The hand. See *Hand.*

Manus christi perlatæ. Troches prepared with pearls, sugar, and rose water.

Manus christi simplices. Troches prepared with sugar and rose water. Rose lozenges.

Manus dei. The name of an old resolvent plaster. It consisted of wax, myrrh, olibanum, ammoniacum, mastic, galbanum, oil, &c.

Maple. See *Acer.*

Maple, sugar. See *Acer.*

Mara'nda. A species of myrtle, growing in the island of Ceylon, a decoction of the leaves of which is said to be excellent against the venereal disease.

MARA'NTA. (*a, æ.* f.) 1. The name of a genus of plants in the Linnæan system. Class, *Monandria;* Order, *Monogynia.*

Maranta arundinacea. The root of this

species, and that of the *comesa*, both of which are commonly called arrow-root, is used by the Indians to extract the virus communicated by their poisoned arrows, from whence it has obtained its name. It is cultivated in gardens and provision-grounds in the West Indies; and the starch is obtained from it by the following process: — The roots, when a year old, are dug up, well washed in water, and then beaten in a large deep wooden mortar, to a pulp; this is thrown into a large tub of clean water: the whole is then well stirred, and the fibrous part wrung out by the hands, and thrown away. The milky liquor being passed through a hair sieve, or coarse cloth, is suffered to settle, and the clear water drained off. At the bottom of the vessel is a white mass, which is again mixed with clean water, and drained: lastly, the mass is dried on sheets in the sun, and is pure starch.

Arrow-root contains, in small bulk, a greater proportion of nourishment than any other yet known. The powder, boiled in water, forms a very pleasant transparent jelly, very superior to that of sago or tapioca, and is much recommended as a nutritious diet for children and invalids. The jelly is made in the following manner: — To a dessert spoonful of powder, add as much cold water as will make it into a paste; then pour on half a pint of boiling water: stir it briskly, and boil it a few minutes, when it will become a clear smooth jelly; a little sugar and sherry wine may be added for debilitated patients, but for infants a drop or two of essence of caraway-seeds or cinnamon is preferable, wine being very liable to become acescent in the stomachs of infants, and thus disagree with the bowels. Fresh milk, either alone or diluted with water, may be substituted for the water. For very debilitated frames, and especially for ricketty children, this jelly, blended with an animal jelly, as that of hartshorn, affords a more nutritious diet than arrow-root alone, which may be done in the following manner: — Boil half an ounce of stag's horn shavings, in a pint of water, for fifteen minutes; then strain and add two dessert spoonsful of arrow-root powder, previously well mixed with a tea-cupful of water; stir them briskly together, and boil them for a few minutes. If the child should be much troubled with flatulency, two or three drops of essence of caraway-seeds, or a little grated nutmeg, may be added; but for adults, port wine, or brandy, will answer best.

MARANTA GALA'NGA. *Galanga minor.* The smaller galangal. The roots of this plant are used medicinally. Two kinds of galangal are mentioned in the pharmacopœias: the greater galangal, obtained from the *Kæmpferia galanga* of Linnæus; and the smaller galangal, the root of the *Maranta galanga — caulino simplici foliis lanceolatis subsessilibus*, of Linnæus. The dried root is brought from China, in pieces from an inch to two in length, scarcely half so thick, branched, full of knots and joints, with several circular rings of a reddish-brown colour on the outside, and brownish within. It has an aromatic smell, not very grateful, and an unpleasant, bitterish, hot, biting taste. It was formerly much used as a warm stomachic bitter, and generally ordered in bitter infusions. It is now, however, seldom employed.

MARANTA'CEÆ. A naturalf amily of plants, of which the genus maranta is the type.

MARA'SMUS. (*us, i.* m.; from *μαραινω*, to grow lean.) Emaciation. A wasting away of the flesh. The term marasmus was long ago used collectively to comprehend atrophy, tabes, and phthisis. Extenuation or leanness is not necessarily a disease; for many persons who are peculiarly lean are peculiarly healthy, while some there are who take pains to fall away in flesh, that they may increase in health, and become stronger. But, if an individual grow weaker as he grows leaner, it affords a full proof that he is under a morbid influence; and it is this influence, this conjunction of extenuation and debility, that is imported by the term marasmus, and its synonym emaciation. See *Atrophia*, *Tabes*, *Phthisis*, and *Climactericus*.

MARATHRI'TES. (From *μαραθρον*, fennel.) A vinous infusion of fennel; or wine impregnated with fennel.

MARATHROPHY'LLUM. (*um, i.* n.; from *μαραθρον*, fennel, and *φυλλον*, a leaf: so named because its leaves resemble those of the common fennel.) See *Peucedanum*.

MARA'THRUM. (From *μαραινω*, to wither: so called because its stalk and flowers wither in the autumn.) See *Anethum fœniculum*.

Marathrum sylvestre. See *Peucedanum*.

MARCASI'TA. Marcasite. This name has been applied to all sorts of crude metallic substances, and has indeed no definite meaning. It is most frequently applied to *pyrites*.

MARCASITA ALBA. Bismuth.

MARCASITA PLUMBEA. Antimony.

MARCE'SCENS. (From *marceo*, to wither, decay.) Withering, decaying, marcid: applied to the perianths of the *Pyrus communis*, and *Mespilus germanica*.

MARCHA'NTIA. (*a, æ.* f.; named after Marchant, who wrote several Essays in the Memoirs of the Academy of Science, 1713.) The name of a genus of plants. Class, *Cryptogamia*; Order, *Algæ*.

MARCHANTIA POLYMORPHA. Liverwort; star liverwort: called also, *Hepatica vulgaris*, *fontana*, *terrestris*, *stellata*, and *jecoraria*. A plant very common in this country. It has a slightly pungent and bitter taste. It is recommended as an aperient, resolvent, and antiscorbutic, but is seldom used in this country.

MA'RCOR. (*or, oris.* m.; from *marceo*, to become lean.) Leanness. Emaciation. Wasting away of the body.

MARCO'RES. The first order in the class *Cachexiæ*, of Cullen's Nosology, which embraces those diseases that are characterised by universal emaciation. See *Nosology*.

Marestail. See *Hippuris vulgaris*.

MARGARIC ACID. *Acidum margaricum.* So called on account of its pearly appearance. An acid obtained from fat. See *Adeps*.

MARGARI'TA. (*a, æ.* f.; from *μαργαρον*, a pearl.) 1. The pearl; called also, *Perla*, *Unio*. A small calcareous concretion, of a bright transparent whiteness, found on the inside of the shell of the *Avicula margaritifera*

and *Mya margaritifera*. Pearls consist of alternating concentric layers of membrane and carbonate of lime. They were formerly exhibited as antacids.

2. A tumour upon the eye resembling a pearl.

MARGINA'TUS. Bordered; having a border. A term used in *Botany*.

Marigold. See *Calendula*.

Marigold, marsh. See *Caltha palustris*.

Marine acid. See *Muriatic acid*.

Marine salt. See *Sodæ murias*.

MARI'SCA. (*a, æ.* f.) An hæmorrhoidal tumour.

Marjoram. See *Origanum*.

Marjora'na. See *Origanum*.

MA'RMALADE. (From *marmello*, a quince, Portuguese.) A conserve made of quinces and sugar. The same name is given to conserves of other fruits, as orange marmalade.

MARMA'RYGA. (*a, æ.* f.; μαρμαρυγη, from μαρμαιρω, to shine.) The appearance of sparks or corruscations before the eyes.

MARMOLA'RIA. (*a, æ.* f.; from *marmor*, marble: so named because it is spotted like marble.) See *Acanthus mollis*.

MARMOR METALLICUM. Native sulphate of baryta.

MARMOREUS TARTARUS. The hardest species of *human calculus*.

MARMORIGE. Corrupted from *marmaryga*.

MAROCO'STINUM. A purgative extract made of the marum and costus; originally prescribed by Mindererus.

MARROW. *Medulla*. The fat substance secreted by the small arteries of its proper membrane, and contained in the medullary cavities of the long cylindrical bones. It differs very little from the fat of the cellular membrane.

Marrow, spinal. See *Spinal cord*.

Marrubia'strum. See *Ballota nigra*.

MARRU'BIUM. (*um, ii.* n.; from *marrob*, a bitter juice, Heb.) 1. The name of a genus of plants in the Linnæan system. Class *Didynamia*; Order, *Gymnospermia*.

2. The pharmacopœial name of the common horehound. See *Marrubium vulgare*.

Marrubium album. See *Marrubium vulgare*.

MARRUBIUM ALYSSUM. Galen's madwort. This plant has an established reputation in America, as a specific against the bite of the rattle-snake. Its juice is generally given in combination with that of the common horehound. It has for ages been a popular remedy in canine madness, especially in the north of Europe; and, from an article published by Professor Brande, in the Journal of Sciences and the Arts, we find that it still retains its popular sway and reputation over a great part of the Russian empire; and that, in the government of Isola, it has never failed of effecting a cure in a single instance, for the last five and twenty years. The preparation is simple: the root is reduced to a powder, and the powder is to be eaten by being spread over bread and butter. Two or three doses are said to be sufficient in the worst cases, and will be found to cure mad dogs themselves.

MARRUBIUM AQUATICUM. Water horehound: opening, corroborant.

MARRUBIUM HISPANICUM. Spanish horehound. See *Sideritis syriaca*.

MARRUBIUM NIGRUM FŒTIDUM. The black, stinking horehound, or *Ballote nigra*.

Marrubium verticillatum. See *Sideritis syriaca*.

MARRUBIUM VULGARE. *Marrubium album. Marrubium — dentibus calycinis, setaceis uncinatis*, of Linnæus. Common horehound. The leaves of this indigenous plant have a moderately strong smell of the aromatic kind, but not agreeable; which, by drying, is improved, and in keeping for some months is, in great part, dissipated: their taste is very bitter, penetrating, diffusive, and durable in the mouth. That horehound possesses some share of medicinal power, may be inferred from its sensible qualities; but its virtues do not appear to be clearly ascertained. It is a favourite remedy with the common people in coughs and asthmas. The usual dose is from half an ounce to an ounce, in infusion, two or three times a day. The dose of the extract is from gr. x. to ʒ ss.

MARS. (*s, tis.* m.; the mythological god of war: and hence applied to iron, because war implements are made of it.) The alchemistical name of iron.

MARS ALKALIZATUS. A mixture of iron with an alkali.

MARS SACCHARATUS. Iron mixed with starch and melted sugar.

MARS SOLUBILIS. The ferrum tartarizatum was formerly so called.

MARS SULPHURATUS. Iron filings and sulphur deflagrated together.

Marseilles hart-wort. See *Seseli*.

MARSEILLES VINEGAR. Thieves' vinegar. See *Acetum prophylacticum*.

Marsh-mallow. See *Althæa officinalis*.

Marsh-trefoil. See *Menyanthes*.

MARSHALL'S CERATE. This consists of palm oil, ʒ v.; calomel, ℥ j.; sugar of lead, ℥ ss.; and citrine ointment, ℥ ij.

MARSU'PIAL. (*Marsupialis*; from *marsupium*, a purse.) Applied, 1. To the obturator internus muscle, from its shape.

2. To an animal which has a pouch formed by a reflexion of the skin of the abdomen, in which the young are nourished for some time after their exclusion from the uterus.

MARSUPIA'LIA. Marsupial animals. An order of mammiferous animals characterised by a pouch, formed by a reflexion of the abdominal integuments. The young of these animals are excluded from the uterus at a very early period of gestation, and being received into the marsupium or abdominal pouch, attach themselves to the teats of the mother, in which position they remain till they have attained the degree of development which other animals have at birth. The marsupium continues to afford the young animals a place of refuge, to which they immediately betake themselves in time of danger. The kangaroo and opossum are examples of marsupial animals.

Martagon lily. See *Lilium martagon*.

MARTIAL. (*Martialis*; from *Mars*, iron.)

Relating to iron, or such as are impregnated therewith; as the *Martial regulus of antimony*, &c.

MARTIAL ÆTHIOPS. The protoxide of iron.

Martial regulus of antimony. See *Regulus antimonii martialis.*

MARTIAL SALTS. Salts of iron.

Martiales flores. See *Ferri ammonio-chloridum.*

MARTIA'TUM UNGUENTUM. Soldier's ointment. Ointment of laurel, rue, marjoram, &c.

MA'RTIS LIMATURA PRÆPARATA. Purified filings of iron.

MA'RUM. (*um, i.* n.; from *mar*, Hebrew for bitter: so named from its taste.) Several species of *Teucrium* were so named. See *Teucrium marum.*

Marum creticum. See *Teucrium.*

Marum syriacum. See *Teucrium.*

Marum verum. See *Teucrium marum.*

Marum vulgare. See *Thymus.*

MARVI'SUM. Malmsey wine.

MAS. (*as, aris.* m.; etymology uncertain.) Male. There are two sexes of animals and vegetables, the male and the female. The male of animals is distinguished by his peculiar genital organs, and the analogy is carried to vegetables. A flower is called a male flower, which has stamina only, these being the male organs of fructification.

MA'SCHALE. Μασχαλη. The arm-pit.

MASCHALI'STER. (Μασχαλιστηρ.) The second vertebra of the back.

MASLACH. A medicine of the opiate kind, in use among the Turks.

MA'SPETUM. Μασπετον. The leaf of the assafœtida plant.

MA'SSA, (*a, æ.* f.; from μασσω, to blend together.) A mass. A term generally applied to the compound out of which pills are to be formed.

Massa carnea Jacobi Sylvii. See *Flexor longus digitorum pedis.*

MASSALIS. An alchemical name of mercury.

MASSE'TER. (*er, eris.* m.; from μασσαομαι, to chew: because it assists in chewing.) *Mansorius.* A muscle of the lower jaw, situated on the side of the face. It is a short, thick muscle, which arises, by fleshy and tendinous fibres, from the lower edge of the malar process of the maxillary bone, the lower horizontal edge of the os malæ, and the lower edge of the zygomatic process of the temporal bone, as far backwards as the eminence belonging to the articulation of the lower jaw. From some little interruption in the fibres of this muscle, at their origin, some writers describe it as arising by two, and others by three distinct portions or heads. The two layers of fibres, of which it seems to be composed, cross each other as they descend, the external layer extending backwards, and the internal one slanting forwards. It is inserted into the basis of the coronoid process, and into all that part of the lower jaw which supports the coronoid and condyloid processes. Its use is to raise the lower jaw, and, by means of the above-mentioned decussation, to move it a little forwards and backwards in the act of chewing.

MASSICOT. The yellow oxide of lead.

Massoy cortex. See *Cortex massoy.*

Masterwort. See *Imperatoria.*

Mastic. See *Pistachia lentiscus.*

MASTICA'TION. (*Masticatio*; from *mastico*, to chew.) Chewing. The function by which the food is comminuted, mixed with the saliva, and reduced to a form fit for deglutition, and a state fit for digestion.

MASTICATORY. (*Masticatorium, ii.* n.; from *mastico*, to chew.) A medicine intended for chewing.

MA'STICHE. (*e, es.* f.; μαστιχη.) *Mastix.* See *Pistacia lentiscus.*

Mastich-herb. See *Thymus mastichina.*

Mastich, Syrian. See *Teucrium.*

Mastich-tree. See *Pistacia lentiscus.*

Mastich wood. See *Pistacia lentiscus.*

MASTICHELÆ'UM. (From μαστιχη, mastich, and ελαιον, oil.) Oil of mastich.

MASTI'CHINA. (Diminutive of *mastiche.*) See *Thymus mastichina.*

MA'STICIN. When mastic is subjected to the action of alkohol, all of it is dissolved except about one fifth. This undissolved matter has, when moist, the character of caoutchouc, but becomes brittle when dry; it, therefore, appears to be a peculiar principle, and has been named masticin by Mr. Matthews, who first observed it.

Masticot. See *Massicot.*

MASTI'TIS. (*is, idis.* f.; from μαστος, the breast, and ιτις, which implies inflammation.) Phlegmonous inflammation of the breast of women. This disease may take place at any period of life, but it most commonly affects those who give suck. It is characterised by tumefaction, tension, heat, redness, and pain; and comes sometimes in both breasts, but most commonly in one. Fever generally attends the disease. It is sometimes very quickly formed, and, in general, without any thing preceding to show it; but now and then a slight shivering is the forerunner. This disease terminates either in resolution, in suppuration, or schirrus; if left to itself, it generally terminates in suppuration.

The causes which give rise to this disease are those which produce most of the phlegmasiæ, as cold, violent blows, &c. In women who are lying-in, or giving suck, it mostly arises either from a suppression of the lochia or a retention of milk. Mastitis is seldom of long continuance; it is a very painful disease, and generally proceeds to suppuration. It is no uncommon thing for the suppuration to take place in two or more points, so that several abscesses form close together, and run into one another: and hence it happens that when one points, and an opening is made into it, and its pus let out, the matter from all escapes through this one opening.

The issue of this disease is always favourable, unless there be a morbid taint in the constitution, in which case, especially if the treatment be injudicious, or disease neglected, scrofulous, scirrhous, and carcinomatous tumours result. The termination of the disease by gangrene is never to be apprehended; at least few, if any, have seen the disease terminate in this way.

Mastix. See *Mastiche.*

MASTODY'NIA. (*a*, *æ*. f.: from μαστος, a breast, and οδυνη, pain.) Pain in the mamma. This is not a very uncommon affection, and is generally of a neuralgic character.

MA'STOID. (*Mastoideus*; from μαστος, a breast, and ειδος, resemblance.) Nipple-like. 1. Those processes of bone are so termed that are shaped like the nipple of the breast; as the mastoid process of the temporal bone, &c.

2. The name of a muscle, from its being inserted into the mastoid process. See *Sterno-cleido-mastoideus.*

MASTOID FORAMEN. *Foramen mastoideum.* A hole in the temporal bone of the skull, by the side of the mastoid process. It transmits a vein to the lateral sinus.

Mastoideus lateralis. See *Trachelo-mastoideus.*

MATALI'STA RADIX. A root said to be imported from America, where it is given as a purgative, in the dose of ʒij., its action being rather milder than that of jalap. The plant is not known.

MA'TER. (*ter*, *tris*. f.; a mother.) Two membranes of the brain are thus called, from an old notion that all the other membranes of the body were derived from them, or from their protecting the brain.

MATER METALLORUM. Quicksilver.

Mater perlarum. See *Mother of pearl.*

MATE'RIA. (*a*, *æ*. f.) 1. Matter. 2. A term applied to those substances collectively which are adapted to some particular purpose, which is expressed by adding the name of that purpose; hence, *materia medica*, *materia chemica*, &c.

MATERIA ALIMENTARIA. The various substances which are used for food and drink constitute what is called the *materia alimentaria.* See *Aliment.*

MATERIA MEDICA. By this term is understood a general class of substances, both natural and artificial, which are used in the cure of diseases.

Cartheuser, Newman, Lewis, Gleditsch, Linnæus, Vogel, Alston, Bergius, Cullen, Murray, Paris, Thomson, and other writers on the Materia Medica, have adopted particular arrangements of these articles. Some have disposed them according to their natural resemblances; others according to their real or supposed virtues; others according to their active constituent principles. These arrangements have their peculiar advantages. The first may be preferred by the natural historian, the second by the physiologist, and the last by the chemist. The pharmacopœias published by the Colleges of Physicians of London, Dublin, and Edinburgh, have the articles of the Materia Medica arranged in alphabetical order: this plan is also adopted by almost all the continental pharmacopœias.

Dr. Cullen has arranged the Materia Medica as follows: —

- NUTRIMENTS, which are
  - Food,
  - Drinks,
  - Condiments;
- MEDICINES which act on the
  - Solids,
    - Simple, as
      - *Astringents*,
      - *Tonics*,
      - *Emollients*,
      - *Corrosives*;
    - Living, as
      - *Stimulants*,
      - *Sedatives*,
        - *Narcotics*,
        - *Refrigerants*,
      - *Antispasmodics.*
  - Fluids,
    - Producing a change of
      - Fluidity,
        - *Attenuants*,
        - *Inspissants.*
      - Mixture,
        - Correctors of Acrimony,
          - *Demulcents*,
          - *Antacids*,
          - *Antalkalines*,
          - *Antiseptics.*
    - Evacuants; viz.
      - *Errhines*,
      - *Sialagogues*,
      - *Expectorants*,
      - *Emetics*,
      - *Cathartics*,
      - *Diuretics*,
      - *Diaphoretics*,
      - *Emmenagogues.*

The following is the list of articles which come under the preceding classes: —

I. NUTRIMENTS.

A. Fruits.

a. *Fresh, sweet, acidulous.*
Prunes
Oranges
Lemons
Raspberries
Red and black currants
Mulberries
Grapes, &c.

b. *Dried, sweet, acidulous.*
Raisins
Currants
Figs.

B. Oleraceous Herbs.

Water-cresses
Dandelion
Parsley
Artichoke.

C. Roots.

Carrot
Garlick
Satyrion.

D. Seeds and Nuts.

Almonds, sweet and bitte
Walnuts
Olives.

II. MEDICINES.

1. Astringents.

Red rose
Cinquefoil
Tormentil
Madder
Sorrel
Water-dock
Bistort
Fern
Pomegranate
Oak-bark
Galls
Logwood
Quince
Mulberry
Sloe
Gum-arabic
Catechu
Dragon's blood
Alkanet
Balaustine flower
St. John's wort
Millefoil
Plantain
Convallaria
Bear's berry.

2. Tonics.

Gentian
Lesser centaury
Quassia
Simarouba
Marsh trefoil
Fumitory
Camomile
Tansy
Wormwood
Southernwood
Sea wormwood
Water-germander
Virginian snake-root
Leopard's bane
Peruvian bark.

3. Emollients.

Columniferous.
Marsh mallow
Mallow.
Farinaceous.
Quince-seeds
Fænugreek-seed
Linseed.
Various emollients.
Pellitory
Verbascum
White lily.

4. Corrosives.

5. Stimulants

Verticillated.
Lavender
Balm
Marjoram
Sweet marjoram
Syrian herb mastich
Rosemary
Hyssop
Ivy
Mint
Peppermint
Pennyroyal
Thyme
Mother of thyme
Sage.
Umbellated.
Fennel
Archangel
Anise
Caraway
Coriander
Cumin
Dill
Saxifrage.
Siliquose.
Horse-radish
Water-cress
Mustard
Scurvy-grass.
Alliaceous.
Garlick.
Coniferous.
Fir
Juniper.
Balsamics.
Venice turpentine
Common turpentine
Canada balsam
Copaiba balsam
Tolu balsam
Balm of Gilead.
Resinous.
Guaiacum
Ladanum
Storax
Benzoin.
Aromatics.
Cinnamon
Nutmeg
Mace
Clove
Allspice
Canella
Cascarilla
Black pepper
Long pepper
Indian pepper
Ginger
Lesser cardamom
Zedoary
Virginian snake-root
Ginseng
Aromatic reed.
Acrids.
Wake-robin
Pellitory
Stavesacre.

6. Narcotics.

Rhœadaceous.
White poppy
Red poppy.
Umbellated.
Hemlock
Water hemlock.
Solanaceous.
Belladonna
Henbane
Tobacco
Bitter-sweet
Stramonium.
Varia.
Laurel
Camphire
Saffron
Wine.

7. Refrigerants.

Fruits of plants
Acidulous herbs and roots.

8. Antispasmodics.

Fœtid herbs.
Wormwood
Fœtid goosefoot
Cumin
Pennyroyal
Rue
Savine.
Fœtid gums.
Assafœtida
Galbanum
Opoponax
Valerian.

9. Diluents.

Water.

10. Attenuants.

Alkalies
Sugar
Liquorice
Dried fruits.

11. Inspissants.

Acids
Farinaceous and mucilaginous demulcents.

12. Demulcents.

Mucilaginous.
Gum arabic
—— tragacanth.
Farinaceous.
Starch

Bland oils.

13. Antacids.

Alkalies and earths.

14. Antalkalines.

Acids.

15. Antiseptics.

Acid parts of plants
Acescent herbs
Sugar
Siliquose plants
Alliaceous plants
Astringents
Bitters
Aromatics
Essential oils
Camphire
Gum resins
Saffron
Contrayerva
Valerian
Opium
Wine.

16. Errhines.

Asarabacca
White hellebore
Water iris
Pellitory.

17. Sialagogues.

Archangel
Cloves
Masterwort
Tobacco
Pepper
Pellitory.

18. Expectorants.

Ivy
Horehound
Pennyroyal
Elecampane
Florentine orris-root
Tobacco
Squill
Coltsfoot
Benzoin
Storax
Canada balsam
Tolu balsam.

19. Emetics.

Asarabacca
Ipecacuan
Tobacco
Squill
Mustard
Horse-radish
Bitters.

20. Cathartics.

Milder.

Mild acid fruits
Cassia pulp
Tamarind
Sugar
Manna
Sweet roots
Bland oils
Damask rose
Violet
Polypody
Mustard
Bitters
Balsamics

Acrid.

Rhubarb
Seneka
Broom
Elder
Castor oil
Senna
Black hellebore
Jalap
Scammony
Buckthorn
Tobacco
White hellebore
Coloquintida
Elaterium.

21. Diuretics.

Parsley
Carrot
Fennel
Pimpinel
Eryngo
Madder
Burdock
Bitter-sweet
Wake-robin
Asarabacca
Foxglove
Tobacco
Rue
Savine
Snake-root
Squill
Bitters
Balsamics
Siliquosæ
Alliaceæ.

22. Diaphoretics.

Saffron
Bitter-sweet
Opium
Camphire
Contrayerva
Serpentaria
Sage
Water germander
Guaiacum
Sassafras
Seneka
Vegetable acids
Essential oil
Wine
Diluents.

23. Emmenagogues.

Aloes
Fœtid gums
Fœtid plants
Saffron.

The following is the arrangement of the Materia Medica, according to J. Murray, in his Elements of Materia Medica and Pharmacy: —

A. General stimulants.

- *a.* Diffusible
  - Narcotics
  - Antispasmodics.
- *b.* Permanent
  - Tonics
  - Astringents.

B. Local stimulants.

- Emetics
- Cathartics
- Emmenagogues
- Diuretics
- Diaphoretics
- Expectorants
- Sialagogues
- Errhines
- Epispastics

C. Chemical remedies.

- Refrigerants
- Antacids
- Lithontriptics
- Escharotics.

D. Mechanical remedies.

- Anthelmintics
- Demulcents
- Diluents
- Emollients.

Under the head of Narcotics are included, — Alkohol. Ether. Camphire. Papaver somniferum. Hyoscyamus niger. Atropa belladonna. Aconitum napellus. Conium maculatum. Digitalis purpurea. Nicotiana tabacum. Lactuca virosa. Datura stramonium. Rhododendron chrysanthemum. Rhus toxicodendron. Arnica montana. Strychnos nux vomica. Prunus laurocerasus.

Under the second class, Antispasmodics, are included, — Moschus. Castoreum. Oleum animale empyreumaticum. Petroleum. Ammonia. Ferula assafœtida. Sagapenum. Bubon galbanum. Valeriana officinalis. Crocus sativus. Melaleuca leucadendron.

Narcotics used as Antispasmodics, —

Ether. Camphire. Opium.

Tonics used as Antispasmodics, —

Cuprum. Zincum. Hydrargyrus. Cinchona.

The head of Tonics embraces, —

1. From the *mineral* kingdom,

Hydrargyrum. Ferrum. Zincum. Cuprum. Arsenicum. Barytes. Calx. Acidum. Nitricum. Oxymurias potassæ.

2. From the *vegetable* kingdom,

Cinchona officinalis. Cinchona caribæa. Cinchona floribunda. Cusparia. Aristolochia. serpentaria. Dorstenia contrayerva. Croton eleutheria. Calumba. Quassia excelsa. Quassia simarouba. Swietenia febrifuga. Swietenia mahagoni. Gentiana lutea. Anthemis nobilis. Artemisia absinthium. Chironia centaurium. Marrubium vulgare. Menyanthes trifoliata. Centaurea benedicta. Citrus aurantium. Citrus medica. Laurus cinnamomum. Laurus cassia. Canella alba. Acorus calamus. Ammomum zinziber. Kæmferia rotunda. Santalum album. Pterocarpus santalinus. Myristica moschata. Caryophyllus aromaticus. Capsicum annuum. Piper nigrum. Piper longum. Piper cubeba. Myrtus pimenta. Amomum repens. Carum carui. Coriandrum sativum. Pimpinella anisum. Anethum fæniculum. Anethum graveolens. Cuminum cyminum. Angelica archangelica. Mentha piperita. Mentha viridis. Mentha pulegium. Hyssopus officinalis.

The class of Astringents comprehends the following : —

1. From the *vegetable* kingdom,

Quercus robur. Quercus cerris. Tormentilla erecta. Polygonum bistorta. Anchusa tinctoria. Hæmatoxylon campechianum. Rosa gallica. Arbutus uva ursi. Mimosa catechu. Kino. Pterocarpus draco. Ficus indica. Pistachia lentiscus.

2. From the *mineral* kingdom,

Acidum sulphuricum. Argilla. Supersulphas argillæ et potassæ. Calx. Carbonas calcis. Plumbum. Zincum. Ferrum. Cuprum.

The articles which come under the head of Emetics are,

1. From the *vegetable* kingdom,

Callicocca ipecacuanha. Scilla maritima. Anthemis nobilis. Sinapis alba. Asarum europæum. Nicotiana tabacum.

2. From the *mineral* kingdom,

Antimonium. Sulphas zinci. Sulphas cupri. Subacetas cupri. Ammonia. Hydro-sulphuretum ammoniæ.

Cathartics include,

Laxatives : — Manna. Cassia fistula. Tamarindus Indica. Ricinus communis. Sulphur. Magnesia.

Purgatives : — Cassia senna. Rheum palmatum. Convolvulus jalapa. Helleborus niger. Bryonia alba. Cucumis colocynthis. Momordica elaterium. Rhamnus catharticus. Aloë perfoliata. Convolvulus scammonia. Gambojia gutta. Submurias hydrargyri. Sulphas magnesiæ. Sulphas sodæ. Sulphas potossæ. Supertartras potassæ. Tartras potassæ et sodæ. Murias sodæ. Terebinthina veneta. Nicotiana tabacum.

The medicines arranged under Emmenagogues, are —

1. From the class of Antispasmodics,

Castoreum. Ferula assafœtida. Bubon galbanum.

2. From the class of Tonics,

Ferrum. Hydrargyrus. Cinchona officinalis.

3. From the class of Cathartics,

Aloë. Helleborus niger. Sinapis alba. Rosmarinus officinalis. Rubia tinctorium. Ruta graveolens. Juniperus sabina.

The class of Diuretics includes,

1. Saline diuretics,

Supertartras potassæ. Nitras potassæ. Murias ammoniæ. Acetas potassæ. Potassa.

2. From the *vegetable* kingdom,

Scilla maritima. Digitalis purpurea. Nicotiana tabacum. Solanum dulcamara. Lactuca virosa. Colchicum autumnale. Gratiola officinalis. Spartium scoparium. Juniperus communis. Copaifera officinalis. Pinus balsamea. Pinus larix.

3. From the *animal* kingdom,

Meloe vesicatorius.

Under the class Diaphoretics, are —

Ammonia. Murias ammoniæ. Acetas ammoniæ. Citras ammoniæ. Submurias hydrargyri. Antimonium. Opium. Camphora. Guaiacum officinale. Daphne mezereum. Smilax sarsaparilla. Laurus sassafras. Cochlearia armoracia. Salvia officinalis.

The class Expectorants comprehends, —

Antimonium. Ipecacuanha. Nicotiana tabacum. Digitalis purpurea. Scilla maritima. Allium sativum. Polygala senega. Ammoniacum. Myrrha. Styrax benzoin. Styrax officinalis. Toluifera balsamum. Myrroxylon peruiferum. Amyris gileadensis.

The articles of the class Sialagogues are, — Hydrargyrum. Anthemis pyrethrum. Arum maculatum. Amomum zingiber. Daphne mezereum. Nicotiana tabacum.

The class of Errhines are, — Iris florentina. Æsculus hippocastanum. Origanum majorana. Lavandula spica. Asarum europæum. Veratrum album. Nicotiana tabacum. Euphorbia officinalis.

In the class Epispastics and Rubefacients are, — Meloe vesicatorius. Ammonia. Pix burgundica. Sinapis alba. Allium sativum.

Refrigerants are constituted by the following articles : — Citrus aurantium. Citrus medica. Tamarindus indica. Acidum acetosum. Supertartras potassæ. Nitras potassæ. Boras sodæ.

The list of articles that come under the class Antacids are, — Potassa. Soda. Ammonia. Calx. Carbonas calcis. Magnesia.

In the class Lithontriptics are, — Potassa. Carbonas potassæ. Soda. Carbonas sodæ. Sapo albus. Calx.

In the class Escharotics are, — Acida mineralia. Potassa. Nitras argenti. Murias antimonii. Sulphas cupri. Acetas cupri. Murias hydrargyri. Subnitras hydrargyri. Oxydum arsenici album. Juniperus sabina.

In the class Anthelmintics are, — Dolichos pruriens. Ferri limatura. Stannum pulveratum. Olea europæa. Artemisia santonica. Spigelia marilandica. Polypodium filix mas. Tanacetum vulgare. Geoffræa inermis. Gambojia gutta. Submurias hydrargyri.

Demulcents are, — Mimosa nilotica. Astragalus tragacantha. Linum usitatissimum. Althæa officinalis. Malva sylvestris. Glycyrrhiza glabra. Cycas circinalis. Orchis mascula.

Maranta arundinacea. Triticum hybernum. Ichthyocolla. Olea europæa. Amygdalus communis. Sevum ceti. Cera.

Water is the principal article of the class DILUENTS; and as for the last class, EMOLLIENTS, heat, conjoined with moisture, is the principal, though all unctuous applications may be included.

The London Pharmacopœia of 1836 gives the following list of the Materia Medica: —

Abietis resina
Absinthium
Acacia
Acetosella
Acetum
Acidum arseniosum
Acidum sulphuricum
Aconiti folia
Aconiti radix
Acorus
Adeps
Ærugo
Allium

MATERIA PERLA'TA. If, instead of crystallising the salts contained in the liquor separated from diaphoretic antimony, an acid be poured into it, a white precipitate is formed, which is an oxide of antimony. This has been called materia perlata.

MATERIATU'RA. A barbarous word. According to the editors of Castelli, Gardinius uses the phrase *morbi materiaturæ*, to designate diseases of intemperament, as opposed to *morbi structuræ*, diseases of structure.

MATHIEU'S VERMIFUGE. This consisted of two electuaries, the one for killing the worms, and the other for expelling them. The first was composed of tin filings, ℥j.; fern root, ʒvj.; worm seed, ℥ss.; resinous extract of jalap, sulphate of potash, of each ʒj., with a sufficient quantity of honey.

The second electuary was composed of jalap and sulphate of potash, of each ʒij.; scammony, ʒj.; gamboge, x grs., with a sufficient quantity of honey.

The first electuary was given in the dose of a teaspoonful every three hours for two days, and then the second was used in the same way.

MATLOCK. A village in Derbyshire. It affords a mineral water of the acidulous class, which issues from a limestone rock, near the banks of the Derwent. Several of the springs possess a temperature of 66°. Matlock water scarcely differs from common good spring water, in sensible properties. It is extremely transparent, and exhales no vapour, excepting in cold weather. It holds little or no excess of aërial particles; it curdles soap, when first taken up, but it loses this effect upon long keeping, perhaps from the deposition of its calcareous salts; it appears to differ very little from good spring water when tasted; and its effects seem referable to its temperature. It is from this latter circumstance that it forms a proper tepid bath for the nervous and irritable, and those of a debilitated constitution; hence it is usually recommended after the use of Bath and Buxton waters, and as preparatory to sea-bathing.

MA'TRASS. *Matracium.* A chemical vessel of glass or other material, having a round or oval shaped body, and a long neck.

MATRICA'LIA. (From *matrix*, the womb.) Medicines appropriated to disorders of the uterus.

MATRICA'RIA. (*a*, *æ*. f.; from *matrix*, the womb: so called from its uses in disorders of the womb.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua*.

2. The pharmacopœial name of the Matricaria parthenium. See *Matricaria parthenium*.

MATRICARIA CHAMOMILLA. *Chamæmelum vulgare. Chamomilla nostras. Lucanthemum* of Dioscorides. Common wild corn, or dog's camomile. The plant directed under this name in the pharmacopœias, is the *Matricaria — receptaculis conicis radiis patentibus; squamis calycinis, margine æqualibus*, of Linnæus. Its virtues are similar to those of the *Matricaria parthenium*, but in a much inferior degree.

MATRICARIA PARTHENIUM. *Parthenium febrifuga.* Common fever-few, or febrifuge, and often, but very improperly, feather-few. Mother's wort. The leaves and flowers of this plant, *Matricaria — foliis compositis, planis; foliolis ovatis, incisis; pedunculis ramosis*, have a strong, not agreeable smell, and a moderately bitter taste, both which they communicate, by warm infusion, to water and rectified spirit. The watery infusions, inspissated, leave an extract of considerable bitterness, and which discovers also a saline matter, both to the taste, and in a more sensible manner, by throwing up to the surface small crystalline efflorescences in keeping. The peculiar flavour of the matricaria exhales in the evaporation, and impregnates the distilled water, on which also a quantity of

essential oil is found floating. The quantity of spirituous extract, according to Cartheuser's experiments, is only about one sixth the weight of the dry leaves, whereas the watery extract amounts to nearly one half. This plant is evidently the *Parthenium* of Dioscorides, since whose time it has been very generally employed for medical purposes. In natural affinity, it ranks with camomile and tansy, and its sensible qualities show it to be nearly allied to them in its medicinal character. Bergius states its virtues to be tonic, stomachic, resolvent, and emmenagogue. It has been given successfully as a vermifuge, and for the cure of intermittents; but its use is most celebrated in female disorders, especially in hysteria; and hence it is supposed to have derived the name matricaria. Its smell, taste, and analysis, prove it to be a medicine of considerable activity; we may therefore say, with Murray — *Rarius hodie præscribitur, quam debetur.*

MATRISY'LVA. (*a*, *æ*. f.; from *mater*, and *silva*, the mother of the wood.) See *Asperula.*

MA'TRIX. (*ix*, *icis*. f. Ματηρ.) 1. The womb. See *Uterus.*

2. The earthy or stony matter which accompanies ores, or envelopes them in the earth.

MATTHEW'S INJECTION. A diluted tincture of cantharides, once much in vogue for the cure of fistula in ano.

MATTHEW'S PILLS. These consist of opium, black hellebore, Starkey's soap, of each ℈ iv.; saffron, ℈ viij., made into a mass with a little oil of turpentine.

MATU'RANS. (From *maturo*, to ripen.) That which promotes the suppuration of tumours.

MATURATION. (*Maturatio*; from *maturo*, to make ripe.) That process which succeeds inflammation, by which pus is collected an abscess.

Maudlin. See *Achillea ageratum.*

Maudlin tansey. See *Achillea.*

Mauro-marson. See *Marrubium.*

MAW-WORM. The *Ascaris vermicularis.* See *Entozoa.*

MAXI'LLA. (*a*, *æ*. f.; from μασσαω, to chew.) The jaw, both upper and lower.

MAXILLA INFERIOR. The lower jaw.

MAXILLA SUPERIOR. The upper jaw.

MAXILLARE INFERIUS OS. *Maxilla inferior. Mandibula.* The maxilla inferior, or lower jaw, which, in its figure, may be compared to a horse-shoe, is at first composed of two distinct bones; but these, soon after birth, unite together at the middle of the chin, so as to form only one bone. The superior edge of this bone has, like the upper jaw, a process, called the *alveolar* process. This, as well as that of the upper jaw, to which it is in other respects a good deal similar, is likewise furnished with cavities for the reception of the teeth. The posterior part of the bone, on each side, rises perpendicularly into two processes, one of which is called the *coronoid*, and the other the *condyloid* process. The first of these is the highest: it is thin and pointed; and the temporal muscle, which is attached to it, serves to elevate the jaw. The condyloid process is narrower, thicker, and shorter than the other, terminating in an oblong, rounded head, which is formed for a moveable articulation with the cranium, and is received into the fore part of the fossa described in the temporal bone. In this joint there is a moveable cartilage, which, being more closely connected to the condyle than to the cavity, may be considered as belonging to the former. This moveable cartilage is connected with both the articulating surface of the temporal bone, and the condyle of the jaw, by distinct ligaments arising from its edges all round. These attachments of the cartilage are strengthened, and the whole articulation secured, by an external ligament, which is common to both, and which is fixed to the temporal bone, and to the neck of the condyle. On the inner surface of the ligament, which attaches the cartilage to the temporal bone, and backwards in the cavity, is placed what is commonly called the gland of the joint; at least the ligament is there found to be much more vascular than at any other part. At the bottom of each coronoid process, on its inner part, is a foramen, or canal, which extends under the roots of all the teeth, and terminates at the outer surface of the bone near the chin. Each of these foramina affords a passage to an artery, vein, and nerve, which sends off branches to the several teeth.

This bone is capable of a great many motions. The condyles, by sliding from the cavity towards the eminences on each side, bring the jaw horizontally forwards, as in the action of biting; or the condyles only may be brought forwards, while the rest of the jaw is tilted backwards, as is the case when the mouth is open. The condyles may also slide alternately backwards and forwards from the cavity to the eminence, and *vice versâ*; so that while one condyle advances, the other moves backwards, turning the body of the jaw from side to side, as in grinding the teeth. The great use of the cartilages seems to be that of securing the articulation, by adapting themselves to the different inequalities in these several motions of the jaw, and to prevent any injuries from friction. This last circumstance is of great importance where there is so much motion, and, accordingly, this cartilage is found in the different tribes of carnivorous animals, where there is no eminence and cavity, nor other apparatus for grinding.

The alveolar processes are formed of an external and internal plate, united together by thin bony partitions, which divide the processes at the fore part of the jaw, into as many sockets as there are teeth. But at the posterior part, where the teeth have more than one root, each root has a distinct cell. These processes, in both jaws, begin to be formed with the teeth, accompany them in their growth, and disappear when the teeth fall; so that the loss of the one seems constantly to be attended with the loss of the other.

MAXILLARE SUPERIUS OS. *Maxilla superior.* The superior maxillary bones constitute the most considerable portion of the upper jaw, are two in number, and generally remain distinct through life. Their figure is exceedingly irregular, and not easily to be described. On

each of these bones are observed several eminences. One of these is at the upper and fore part of the bone, and, from its making part of the nose, is called the *nasal* process. Internally, in the inferior portion of this process, is a fossa, which, with the os unguis, forms a passage for the lachrymal duct. Into this nasal process, likewise, is inserted the short round tendon of the *musculus orbicularis palpebrarum*. Backwards and outwards, from the root of the nasal process, the bone helps to form the lower side of the orbit, and this part is therefore called the *orbitar* process. Behind this orbitar process, the bone forms a considerable tuberosity; and at the upper part of this tuberosity is a channel, which is almost a complete hole. In this channel passes a branch of the fifth pair of nerves, which, together with a small artery, is transmitted to the face through the external orbiter foramen, which opens immediately under the orbit. Where the bone on each side is joined to the os malæ, and helps to form the cheeks, is observed what is called the *malar* process. The lower and anterior parts of the bone make a kind of circular sweep, in which are the *alveoli*, or sockets for the teeth: this is called the *alveolar* process. This alveolar process has, posteriorly, a considerable tuberosity on its internal surface. Above this alveolar process, and just behind the fore teeth, is an irregular hole, called the *foramen incisivum*, which, separating into two, and sometimes more holes, serves to transmit small arteries and veins, and a minute branch of the fifth pair of nerves to the nostrils. There are two horizontal lamellæ behind the alveolar process, which, uniting together, form part of the roof of the mouth, and divide it from the nose. This partition, being seated somewhat higher than the lower edge of the alveolar process, gives the roof of the mouth a considerable hollowness. Where the ossa maxillaria are united to each other, they project somewhat forwards, leaving between them a furrow, which receives the inferior portion of the septum nasi. Each of these bones is hollow, and forms a considerable sinus under its orbitar part. This sinus, which is usually, though improperly, called *antrum Highmorianum*, is lined with the pituitary membrane. It answers the same purposes as the other sinuses of the nose, and communicates with the nostrils by an opening, which appears to be a large one in the skeleton, but which in the recent subject is much smaller. In the fœtus, instead of these sinuses, an oblong depression only is observed at each side of the nostrils, nor is the tuberosity of the alveolar process then formed. On the side of the palate, in young subjects, a kind of fissure may be noticed, which seems to separate the portion of the bone which contains the dentes incisores from that which contains the dentes canini. This fissure is sometimes apparent till the sixth year, but after that period it in general wholly disappears.

The ossa maxillaria not only serve to form the cheeks, but likewise the palate, nose, and orbits: and, besides their union with each other, they are connected with the greatest part of the bones of the face and cranium, viz. with the ossa nasi, ossa malarum, ossa unguis, ossa palati, os frontis, os sphenoides, and os ethmoides.

MAXILLARY. (*Maxillaris*; from *maxilla*, the jaw.) Appertaining to the jaw.

Maxillary artery. *Arteria maxillaris.* A branch of the external carotid. The *external maxillary* is the fourth branch of the carotid; it proceeds anteriorly, and gives off the facial or mental, the coronary of the lips, and the angular artery. The *internal maxillary* is the next branch of the carotid; it gives off the spheno-maxillary, the inferior alveolar, and the spinous artery.

Maxillary bone, inferior. See *Maxillare inferius os.*

Maxillary bone, superior. See *Maxillare superius os.*

Maxillary gland. *Glandula maxillaris.* The gland so called is conglomerate, and situated under the angles of the lower jaw. The excretory ducts of these glands are called Warthonian, after their discoverer.

Maxillary nerve. *Nervus maxillaris.* The superior and inferior maxillary nerves are branches of the fifth pair, or trigemini. The former is divided into the spheno-palatine, posterior alveolar, and the infra-orbital nerve. The latter is divided into two branches, the internal lingual, and one more properly called the inferior maxillary.

May apple. See *Podophyllum peltatum.*

May-lily. See *Convallaria majalis.*

May-weed. See *Anthemis cotula.*

Mays, Indian. See *Zea mays.*

MEAD. An old English liquor made from the honeycombs from which honey has been drained out, by boiling in water, and then fermenting. This is often confounded with metheglin.

Meadow crowfoot. See *Ranunculus acris.*

Meadow, queen of the. See *Spiræa.*

Meadow saffron. See *Colchicum.*

Meadow saxifrage. See *Peucedanum.*

Meadow-sweet. See *Spiræa ulmaria.*

Meadow thistle, round leaved. See *Cnicus.*

Measles. See *Rubeola.*

Measures. See *Weights* and *Measures.*

MEA'TUS. (*us, ús.* m.) A passage.

Meatus auditorius externus. The external passage of the ear. See *Auris.*

Meatus auditorius internus. The internal passage of the ear. See *Auris.*

Meatus cæcus. The Eustacian tube.

Meatus cuticularis. A pore of the skin.

Meatus cysticus. The gall-duct.

Meatus urinarius. The orifice of the urethra. In women, this is situated in the vagina, immediately below the symphysis of the pubes, and behind the nymphæ. In men, it is at the end of the glans penis.

Mecca balsam. See *Amyris gileadensis.*

Mechoaca'nna. (From *Mechoacan*, a province in Mexico, whence it is brought.) See *Convolvulus mechoacanna.*

Mechoacanna nigra. See *Convolvulus jalapa.*

Meckel's ganglion. See *Spheno-palatine ganglion.*

ME'CON. (From μηκος, bulk: so named

from the largeness of its head.) The poppy. See *Papaver somniferum*.

Meconic acid. *Acidum meconicum*. An acid so called from μηκων, a poppy, because it forms a constituent of opium. It was discovered by Sertuerner, who procured it in the following way: — After precipitating the *morphia*, from a solution of opium, by ammonia, he added to the residual fluid a solution of the muriate of barytes. A precipitate is in this way formed, which is supposed to be a quadruple compound of barytes, morphia, extract, and the meconic acid. The extract is removed by alkohol, and the barytes by sulphuric acid, when the meconic acid is left merely in combination with a portion of the morphia; and from this it is purified by successive solutions and evaporations. The acid, when sublimed, forms long colourless needles; it has a strong affinity for the oxide of iron, so as to take it from the muriatic solution, and form with it a cherry-red precipitate. It forms a crystallisable salt with lime, which is not decomposed by sulphuric acid; and, what is curious, it seems to possess no particular power over the human body, when received into the stomach. The essential salt of opium, obtained in Derosne's original experiments, was probably the meconiate of morphia.

Robiquet has made a useful modification of the process for extracting meconic acid. He treats the opium with magnesia, to separate the morphia, while meconiate of magnesia is also formed. The magnesia is removed by adding muriate of barytes, and the barytes is afterwards separated by dilute sulphuric acid. A larger proportion of meconic acid is thus obtained.

Meco'nis. Μηκωνις. 1. The poppy.

2. The strong scented lettuce, which is narcotic like the poppy.

MECO'NIUM. (*um, ii.* n.; from μηκων, the poppy.) 1. Opium. The inspissated juice of the poppy.

2. The green excrementitious substance that is found in the large intestines of the fœtus.

ME'DIAN. *Medianus*. This term is applied to vessels, &c. from their situation between others.

Median nerve. The second branch of the brachial plexus.

Median vein. The situation of the veins of the arms is extremely different in different individuals. When a branch proceeds near the bend of the arm, inwardly from the basilic vein, it is termed the *median basilic*, and when a vein is given off from the cephalic in the like manner, it is termed the *median cephalic*. When these two veins are present, they mostly unite just below the bend of the arm, and the common trunk proceeds to the cephalic vein.

Medianum. See *Mediastinum*.

MEDIASTI'NUM. (*um, i.* n.; *quasi in medio stans*, as being in the middle.) The membraneous septum, formed by the duplicature of the pleura, that divides the cavity of the chest into two parts. It is divided into an anterior and posterior portion.

Mediastinum cerebri. The falciform process of the dura mater.

ME'DIATE. *Mediatus*. A term of relation to two extremes, applied to that which is in the middle between them.

Mediate auscultation. See *Auscultation*.

Medica malus. The lemon.

MEDICAL. *Medicus*. Appertaining to medicine.

Medicamenta'ria ars. The art of making and preparing medicines.

MEDICAME'NTUM. (*um, i.* n.; from *medico*, to heal.) A medicine.

MEDICA'STER. (*er, ri.* m.) A pretender to the knowledge of medicine. A quack.

Medicated. *Medicatus*. Imbued with the properties of a medicine. Thus wine of aloes is a medicated wine.

Medicina diæte'tica. That department of medicine which regards the regulation of the non-naturals, especially diet.

Medicina diaso'stica. That part of medicine which preserves health.

Medicina gymna'stica. That part of medicine which relates to exercise.

Medicina hermie'tica. The application of chemical remedies to the cure of diseases.

Medicina prophyla'ctica. That part of medicine which relates to preservation of health, or prevention of diseases.

Medicina tristi'tiæ. Common saffron. So called because it is said to possess exhilarating qualities.

MEDI'CINAL. (*Medicinalis*; from *medicina*, medicine.) Having the power of restoring health, or removing disease. It has sometimes been incorrectly used synonymously with *medical*.

Medicinal days. Critical days. See *Critical days*.

Medicinal hours. Are those wherein it is supposed that medicines may be taken to the greatest advantage, commonly reckoned in the morning fasting, about an hour before dinner, about four hours after dinner, and at going to bed; but in acute cases, the times are to be governed by the symptoms and aggravation of the distemper.

MEDICINE. (*Medicina, æ.* f.; from *medico*, to heal.) 1. The science and art which relate to the preservation of health, and the alleviation or cure of disease.

Medicine admits of numerous divisions, of which the most general are into *Physiology*, which teaches the healthy functions of the body; *Pathology*, which teaches its morbid conditions; *Semeiotics*, which teach the symptoms of disease; *Hygiene*, which teaches how to preserve health; *Therapeutics*, which teach how to treat diseases, and include *physic*, *surgery*, and *obstetrics*; *Pharmacy*, which teaches the nature and virtues of drugs, and the mode of preparing and administering them.

The minor subdivisions of these subjects are noticed under their respective heads.

There are certain sciences which are called *accessory* to medicine. Some of these, although regarded as merely accessory in a logical view of the subject, are in reality the very foundations of medicine. Thus *Anatomy* is the basis

of physiology and pathology; *Botany*, *Chemistry*, and *Mineralogy* are the basis of pharmacy. Philosophically considered, medicine is the application of natural knowledge to the preservation of health, and the alleviation or cure of disease; hence all the natural sciences may be considered as more or less accessory to medicine; and hence the necessity that the practitioner of medicine should be a man of general science.

Opposed to this view of the subject, is the attempt to make medicine rest on experience alone, which gave rise in the days of the Greeks to the division of medicine into *rational* and *empirical*, as respectively practised by the Dogmatists and Empirics. The practice of medicine is, and most likely will always be, empirical to a certain extent; but, in a general way, the improvement of the art has always kept pace with the progress of the science, and an exclusively empirical system of medicine has now no advocates but among the ignorant.

2. Any substance used for the alleviation or cure of a disease.

Medi coctio. A kind of medicated apomel, named after Medus, and described by N. Myrepsus.

ME'DICUS. (From *medico*, to heal.) 1. Substantively, a physician, or one who treats diseases.

2. (Adjectively.) Belonging to medicine; as *materia medica*, &c.

Medi malagma. A digestive malagma named after its inventor, and described by Celsus.

Medina. A species of ulcer, mentioned by Paracelsus.

Medine'nsis vena. (*Medinensis*; so called because it is frequent at *Medina*, and improperly called *vena* for *vermis*; and sometimes *nervus medinensis*.) See *Gordius medinensis*.

MEDITU'LLIUM. (From *medius*, the middle.) The same as *Diploe*, which see.

Medius venter. The middle belly. The thorax. — *Blancard*.

Medlar. See *Mespilus*.

MEDU'LLA. (*a*, *æ*. f.; *quasi in medio ossis*.) 1. The marrow. See *Marrow*, and *Adeps*.

2. The pith or pulp of vegetables. The centre or heart of a vegetable within the wood. "This," says Sir J. Smith, "in parts most endowed with life, as roots and young growing stems or branches, is a tolerably firm juicy substance, of a uniform texture, and commonly a pale green or yellowish colour. In many annual stems the petal, abundant and very juicy while they are growing, becomes little more than a web, lining the hollow of the complete stem; as in some thistles. Concerning the nature and functions of this part various opinions have been held. Du Hamel considered it as merely cellular substance, connected with what is diffused through the whole plant, combining its various parts, but not performing any remarkable office in the vegetable economy. Linnæus, on the contrary, thought it the seat of life, and source of vegetation; that its vigour was the main cause of the propulsion of the branches, and that the seeds were more especially formed from it. This latter hypothesis is not better founded than his idea of the pith adding new layers to the wood. In fact, the pith is soon obliterated in the trunk of many trees, which, nevertheless, keep increasing for a long series of years, by layers of wood added every year from the bark, even after the heart of the tree is become hollow from decay.

Some considerations have led Sir James Smith to hold a medium opinion between these two extremes. There is in certain respects, he observes, an analogy between the medulla of plants and the nervous system of animals. It is no less assiduously protected than the spinal marrow or principal nerve. It is branched off and diffused through the plant, as nerves are through the animal: hence it is not absurd to presume that it may, in like manner, give life and vigour to the whole, though by no means, any more than nerves, the organ or source of nourishment. It is certainly most vigorous and abundant in young and growing branches, and must be supposed to be subservient, in some way or other, to their increase.

Mr. Lindsay, of Jamaica, thought he demonstrated the medulla in the leafstalk of the *Mimosa pudica*, or sensitive plant.

Knight supposes the medulla may be a reservoir of moisture, to supply the leaves whenever an excess of perspiration renders such assistance necessary: but it should be recollected that all the moisture in the medulla of a whole plant is, in some cases, too little to supply one hour's perspiration of a single leaf; and it is not found that the moisture of the medulla varies, let the leaves be ever so flaccid.

3. The white substance of the brain is called medulla, or the medullary part, to distinguish it from the cortical.

Medulla cassiæ. Cassia-pulp.

Medulla oblongata. *Cerebrum elongatum*. The commencement of the spinal cord which rests upon the basilary process of the occipital bone. See *Encephalos*.

Medulla spinalis. The spinal marrow or spinal cord. See *Spinal cord*.

MEDULLARY. (*Medullaris*; from *medulla*, marrow.) Like unto marrow.

Medullary sarcoma. See *Fungus hæmatodes*.

Medullary substance. *Substantia medullaris*. 1. The white or internal substance of the brain.

2. The internal substance of the kidney.

Medullin. The name given by Dr. John to the pith of the sun-flower.

Megalospla'nchnus. (Μεγαλοσπλαγχνος; from μεγας, great, and σπλαγχνον, a bowel.) Hippocrates applies this epithet to one who is pot-bellied.

ME'GRIM. Synonymous with *hemicrania*, from which it is probably derived through the medium of the French *migraine*.

Meibomius's glands. *Meibomii glandulæ*. The small glands which are situated between the conjunctive membrane of the eye, and the cartilage of the eyelid, first described by Meibomius.

MEL. (*Mel, mellis.* n.) Honey. A substance collected by bees from the nectary of flowers, resembling sugar in its elementary properties. See *Apis mellifica.* It has a white or yellowish colour, a soft and grained consistence, and a saccharine and aromatic smell. It is supposed to consist of sugar, mucilage, and an acid. Honey contains some nutriment, and is a softening and slightly aperient remedy: mixed with vinegar, it forms *oxymel,* and it is used in various forms in medicine and pharmacy. It has been particularly recommended to the asthmatic, and those subject to gravel, from its detergent nature. Honey, when mixed with water, is susceptible of the vinous fermentation without the addition of yeast.

Mel acetatum. See *Oxymel.*

Mel boracis. Honey of borax. Take of borax, powdered, a drachm; clarified honey, an ounce. Mix. This preparation is found very useful as a local application in aphthous affections of the mouth and fauces.

Mel despumatum. Clarified honey, which is directed to be made by melting honey in a water-bath, and then removing the scum.

Mel rosæ. Honey of roses. Take of red-rose petals, dried, four ounces; boiling water, two pints and a half; clarified honey, five pounds. Macerate the rose petals in the water for six hours, and strain; then add the honey to the strained liquor, and, by means of a water-bath, boil it down to a proper consistence. An admirable preparation for the base of various gargles and collutories. It may also be employed with advantage, mixed with extract of bark, or other medicines, for children who have a natural disgust to medicines.

Mel scillæ. See *Oxymel scillæ.*

Mela. (Μηλη; from μαω, to search.) A probe.

MELÆ'NA. (*a, æ.* f.; from μελας, black.) Μελαινα νουσος, of the Greeks. The disease so called by Hippocrates, consists in the vomiting of a concrete blood of a blackish red colour, and mixed with a large quantity of insipid, acid, or viscid phlegm. This evacuation is generally preceded by a pungent tensive pain, in both the hypochondria; and the appearance of the disease is attended with anxiety, a compressive pain in the præcordia, and fainting, which last is more frequent and violent when the blood which is evacuated is fœtid and corrupt. The term melæna is applied by modern writers to a discharge of dark coloured grumous pitchy looking stools, usually conjoined with vomiting of blood. It is caused by hæmorrhage from the gastro-enteric mucous membrane, or organic diseases of the abdominal viscera.

Melæna cholæa. The black jaundice.

Melæna cruenta. See *Melæna.*

MELALEU'CA. (*a, æ.* f.; from μελας, black, and λευκος, white: so named by Linnæus, because the principal, and indeed original, species, was called *leucadendron,* and *arbor alba;* words synonymous with its appellation in the Malay tongue, *Caju-puti,* or white tree: but it is not known why the idea of black was associated with white.) The name of a genus of plants in the Linnæan system. Class, *Polyandria;* Order, *Icosandria.*

Melaleuca cajeputi. *Melaleuca leucadendron.* The systematic name of the plant which is said to afford the cajeput oil, *oleum cajeputæ, oleum Wittnebianum, oleum volatile melaleucæ, oleum cajeput.* Cajeput oil is of a green colour, perfectly limpid, and so completely volatile, that it evaporates entirely, leaving no residuum; its odour, when first imported, resembles that of a mixture of turpentine and camphor. It soon, however, acquires a peculiar fragrance. It is a very powerful medicine, and in high esteem in India and Germany, in the character of a general remedy in chronic and painful diseases. Taken into the stomach, in the dose of five or six drops, it heats and stimulates the whole system, proving, at the same time, a very certain diaphoretic, by which, probably, the good effects it is said to have in dropsies and intermittent fevers, are to be explained. For its efficacy in various convulsive and spasmodic complaints, it is highly esteemed. It has also been used, both internally and externally, with much advantage in several other obstinate disorders; as palsies, hypochondriacal and hysterical affections, deafness, defective vision, toothach, gout, rheumatism, &c. The dose is from two to six, or even twelve drops. The tree which affords this oil, by distillation of its leaves, generally was supposed to be the *melaleuca leucadendron* of Linnæus, but it appears from the specimens of the tree producing the true oil, sent home from India, by Christopher Smith, that it is another species, which is therefore named *Melaleuca cajeputi.*

Melamphy'llum. (*um, i.* n.; from μελας, black, and φυλλον, a leaf: so named from the blackness of its leaf.) *Melamphyllon.* See *Acanthus mollis.*

Melampo'dium. (*um, ii.* n.; from *Melampus,* the shepherd who first used it.) See *Helleborus niger.*

MELANAGO'GUS. (From μελας, black, and αγω, to expel.) That which purges off black bile.

Melanchlo'rus. Μελαγχλωρος. The Greek epithet of a troch, and a plaster: so named from their greenish black colour.

MELANCHO'LIA. (*a, æ.* f.; from μελας, black, and χολη, bile: because the ancients supposed that it proceeded from a redundance of black bile.) Melancholy. A form of insanity. See *Insanity.*

Melanic acid. (Μελας, black.) An acid principle discovered by Dr. Marcet in black urine.

Melanoma. See *Melanosis.*

Melano'piper. (*er, eris.* n.; from μελας, black, and πεπερι, pepper.) See *Piper nigrum.*

Melanorrhi'zon. (*um, i.* n.; from μελας, black, and ῥιζα, a root.) Black hellebore. See *Helleborus niger.*

MELANO'SIS. (From μελανοω, to become black.) A species of morbid deposit first described by Laennec. It is of the same colour as the pigmentum nigrum of the choroid membrane of the eye; and, according to Vauquelin and Berzelius, is a similar substance. Melanotic matter is found encysted in irregular masses; infiltrated in the texture of organs; deposited

on the surface of organs, in which case the matter is liquid; lastly, associated with other morbid formations in malignant tumours, as with cancer, fungus hæmatodes, &c. No organ seems to be exempt from this disease; but the cellular and adipose textures are most frequently affected with it. It is not uncommon in the lungs, and gives rise to a form of phthisis. This disease is called *black cancer* by Dupuytren, and *Melanoma* by Dr. Carswell. Melanosis, like cancer and fungus hæmatodes, is a malignant and incurable disease. The only chance of saving the patient is by extirpation or amputation, where these are practicable. Melanosis is more common in the horse than in man, and it is observed that white and gray horses are more subject to it than those of any other colour.

Melante'ria. (From μελας, black: so called because it is used for blacking leather.) Copperas or vitriol.

MELANTHELÆ'UM. (From μελανθιον, the name of a plant, and ελαιον, oil.) Oil expressed from the seeds of the *Nigella sativa*.

Mela'nthium. (From μελας, black, and ανθος, a flower, so named from its black seed.) See *Nigella sativa*.

ME'LAS. (*as, anos.* n.; μελας, black: so called from the colour of the spots.) *Vitiligo nigra. Morphæa nigra. Lepra maculosa nigra.* A scaly disease of the skin, the same with the lepra nigricans of Willan. See *Lepra*.

MELA'SMA. (From μελας, black.) *Melasmus.* A disease that appears not unfrequently upon the tibia of aged persons, in form of a livid black spot, which, in a day or two, degenerates into a very foul ulcer.

Melaspe'rmum. (*um, i.* n.; from μελας, black, and σπερμα, seed.) See *Nigella sativa*.

Melasses. See *Molasses*.

Melassic acid. *Acidum melassicum.* The name of the acid that is present in melasses or treacle, which is by most believed to be the acetic.

Me'lca. (Μελκα; from αμελγω, to milk.) Milk. A food used by the ancients, which, according to Gorrhæus, consisted of milk curdled with boiling vinegar.

MELEA'GRIS. (*is, idis.* f.; from *Meleager*, whose sisters were fabled to have been turned into this bird.) A genus of gallinaceous birds.

2. A species of *fritillaria*: so called because its flowers are spotted like a guinea-fowl.

Meleagris gallipova. The turkey, the flesh of which is light and nutritious, and in general esteem.

Melege'ta. *Meleguetta.* Grains of paradise. See *Amomum granum paradisi*.

Melei'os. (Μελειος; from *Melos*, the island whence it was brought.) A species of alum.

Meli. Μελι. Honey. See *Mel*.

Meliceria. See *Meliceris*.

MELI'CERIS. (*is, idis.* f.; from μελι, honey, and κερος, wax.) *Meliceria.* An encysted tumour, the contents of which resemble honey in consistence and appearance.

Meli'craton. (*um, i.* n.; from μελι, honey, and κερανννμι, to mix.) Wine impregnated with honey.

Meligei'on. (From μελι, honey.) A fœtid humour, discharged from ulcers, attended with a caries of the bone, of the consistence of honey.

Melilot. See *Melilotus*.

Melilo'tus. (*us, i.* f.; from μελι, honey, and λωτος, the lotus; so called from its smell, being like that of honey.) *Melilot.* See *Trifolium melilotus officinalis*.

Melime'lum. (From μελι, honey, and μηλον, an apple.) 1. A liquor prepared with quinces and honey.

2. A particular kind of apple.

Me'linum. (From μηλον, an apple.) The Greek epithet of a plaster: so called from its colour resembling that of an apple or quince.

Meliphy'llum. (*um, i.* n.; from μελι, honey, and φυλλον, a leaf: so called from the sweet smell of its leaf, or because bees gather honey from it.) See *Melissa*.

MELI'SSA. (*a, æ.* f.; from μελισσα, a bee; because bees gather honey from it.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia*. Balm.

Melissa calamintha. The systematic name of the common calamint. *Calamintha. Calamintha vulgaris, Calcimintha officinarum. Melissa — pedunculis axillaribus, dichotomis, longitudine foliorum*, of Linnæus. This plant smells strongly like wild mint, though more agreeable; and is often used by the common people, in form of tea, against weakness of the stomach, flatulent colic, uterine obstructions, hysteria, &c.

Melissa citrina. See *Melissa officinalis*.

Melissa grandiflora. The systematic name of the mountain calamint. *Calamintha magno flore. Calamintha montana.* This plant has a moderately pungent taste, and a more agreeable aromatic smell than the common calamint, and appears to be more eligible as a stomachic.

Melissa nepeta. Field calamint. Spotted calamint. *Calamintha anglica. Calamintha pulegii odore. Nepeta agrestis.* It was formerly used as an aromatic.

Melissa officinalis. The systematic name of balm. *Citrago. Citraria. Melissophyllum. Mellitis. Cedronella. Apiastrum. Melissa citrina. Erotion.* A native of the southern parts of Europe, but very common in our gardens. In its recent state, it has a roughish aromatic taste, and a pleasant smell of the lemon kind. It was formerly much esteemed in nervous diseases, and very generally recommended in melancholic and hypochondriacal affections; but, in modern practice, it is only employed when prepared as tea, as a grateful diluent drink in fevers, &c.

Melissa turcica. See *Dracocephalum*.

Melissophy'llum. (*um, i.* n.; from μελισσα baum, and φυλλον, a leaf.) A species of me littis, with leaves resembling balm. See *Me littis melissophyllum*.

Meliti'smus. (Μελιτισμος; from μελι, honey. The name of a linctus, of which honey was a ingredient.

MELI'TTIS. (*is, is.* f.; from μελιττα which, in the Attic dialect, is the name of bee; so that this word is, in fact, equivalent t

Melissa, and was adopted by Linnæus, therefore, for the bastard balm.) The name of a genus of plants. Class, *Didynamia*; Order, *Gymnospermia*. Bastard balm.

MELITTIS MELISSOPHYLLUM. The systematic name of the mountain balm, or nettle. *Melissophyllum*. This elegant plant is seldom used in the present day: it is said to be of service in uterine obstructions and calculous diseases.

MELITTO'MA. (From μελι, honey.) A confection made with honey.

MELIZO'MUM. (*um*, *i*. n. from μελι, honey, and ζωμος, broth.) Honey-broth. A drink prepared with honey.

MELLA'GO. (*o*, *inis*. f.; from *mel*, honey.) An ancient name for any medicine which has the consistence of honey.

MELLATE. *Mellas*. A compound of mellitic acid with a salifiable base.

Melliceris. See *Meliceris*.

Mellilo'tus. See *Melilotus*.

MELLI'NA. (*a*, *æ*. f.; from *mel*, honey.) Mead. A sweet drink prepared with honey.

MELLITIC ACID. *Acidum melliticum*. Klaproth discovered in the mellite, or honey-stone, what he conceives to be a peculiar acid of the vegetable kind, combined with alumina. This acid is easily obtained by reducing the stone to powder, and boiling it in about seventy times its weight of water, when the acid will dissolve, and may be separated from the alumina by filtration.

ME'LO. 1. The melon. See *Cucumis melo*.

2. A disease of the eye, commonly called *staphyloma*.

MELOCA'RPUS. (From μηλον, an apple, and καρπος, fruit; from its resemblance to an apple.) The fruit of the aristolochia.

ME'LOE. The name of a genus of coleopterous insects.

MELOE PROSCARABÆUS. This insect, when touched, exudes from each joint of its legs an acrid fluid of an oily consistence and deep yellow colour. This fluid has been used in embrocations for chronic rheumatism, with great alleged success. It has also been employed internally in dropsy, and as a specific for hydrophobia. Frederick the Great purchased at a high price a nostrum against hydrophobia, of which these insects were a principal ingredient. They are a strong poison, causing suffocation, vomiting, and death.

MELOE VARIABILIS. This is said to have the same acrid properties as the above.

Meloe vesicatorius. See *Cantharis*.

Melolontha vitis. See *Cantharis vesicatoria*.

Melon. See *Cucumis melo*.

Melon, musk. See *Cucumis melo*.

Melon, water. See *Cucurbita citrullus*.

Melo'ngena. See *Solanum melongena*.

MELO'SIS. (Μηλωσις; from μηλη, a probe.) Exploration by means of a probe; a term frequently used by Hippocrates.

MELO'TIS. Μηλωτις. A little probe: also that particular instrument contrived to search or cleanse the ear with, commonly called *Auriscalpium*.

MELO'THRIA. (*a*, *æ*. f.; borrowed by Linnæus, in his *Hortus Cliffortianus*, from the μηλωθρον, of Dioscorides.) The name of a genus of plants. Class, *Triandria*; Order, *Monogynia*.

MELOTHRIA PENDULA. The systematic name of the small creeping cucumber plant. The American bryony. The inhabitants of the West Indies pickle the berries of this plant, and use them as we do capers.

Membrana. See *Membrane*.

Membrana adiposa. See *Adipose membrane*.

Membrana arachnoidea. See *Arachnoid membrane*.

Membrana cellulosa. See *Feature*.

MEMBRANA HYALOIDEA. The transparent membrane which encloses the vitreous humour of the eye.

MEMBRANA JACOBI. Jacob's membrane. A delicate membrane which invests the external surface of the retina, first described by Dr. Jacob of Dublin. See *Oculus*.

MEMBRANA NICTITANS. *Palpebra tertia*. *Palpebra interna*. A sort of third eyelid, which exists in most quadrupeds, and in birds. It is placed at the inner corner of the eye, and varies in shape and extent in different animals according to circumstances.

Membrana pinguidinosa. See *Adipose membrane*.

MEMBRANA PUPILLARIS. *Velum pupillæ*. A very delicate membrane of a thin and vascular texture, and an ash colour, arising from the internal margin of the iris, and totally covering the pupil in the fœtus till the seventh month, when it gradually disappears.

MEMBRANA RETICULARIS. Cellular membrane.

MEMBRANA RUYSCHIA'NA. The celebrated anatomist Ruysch discovered that the choroid membrane of the eye was composed of two laminæ. He gave the name of Ruyschiana to the internal lamina, leaving the old name of choroides to the external.

MEMBRANA SCHNEIDERIA'NA. The vascular membrane which lines the nose and its cavities, secretes the mucus, and affords a surface for the expansion of the olfactory nerves.

MEMBRANA TYMPANI. The membrane covering the cavity of the drum of the ear, and separating it from the meatus auditorius externus. See *Auris*.

MEMBRANA'CEUS. (From *membrana*, a membrane.) Membranaceous. A term in very general use in *Anatomy* and *Botany*; applied to ligaments, tunics, &c. and to leaves, pods, &c. of a thin and pliable texture; as the leaf of the *Magnolia purpurea*.

MEMBRANE. (*Membrana*, *æ*. f.; *quod membra tegat*: because it covers the limbs.) In *Anatomy*, a thin expanded substance, composed of cellular texture, the elastic fibres of which are so arranged and woven together, as to allow of great pliability. For the varieties of membrane, see *Texture*.

ME'MBRANOUS. (*Membranosus*; from *membrana*.) Of the nature of membrane.

MEMBRANO'LOGY. (*Membranologia*, *æ*. f.; from *membrana*, a membrane, and λογος, a discourse.) A hybrid term, applied to that

part of anatomy which treats of membranes. *Hymenology* is the proper term.

Membranotsus. See *Tensor vaginæ femoris.*

MEMO'RIÆ OS. The occipital bone has been so called, from an old notion that memory was seated in the occipital region.

MEMORY. *Memoria.* See *Mens.*

Menagogue. See *Emmenagogue.*

MENDO'SUS. (From *mendax*, counterfeit.) This term is used, by some, in the same sense as spurious or illegitimate; *Mendosæ costæ*, false or spurious ribs; *Mendosa sutura*, the squamous or bastard suture of the skull.

MENINGE'AL. *Meningeus*, relating to the *meninges* or membranes of the brain.

MENINGEAL ARTERIES. The arteries which creep on the external surface of the dura mater, are so called. The principal is the middle meningeal, *meningea media*, or spinous artery of the dura mater, which is a branch of the internal maxillary, and enters the cranium through the spinous foramen of the sphenoid bone. There are also two small arteries, called *anterior* and *posterior meningeal*, the former a branch of the internal carotid, and the latter of the vertebral.

MENINGI'TIS. (From μηνιγξ, a membrane of the brain.) Inflammation of the membranes of the brain or spinal cord. See *Encephalitis*, and *Spinal cord, diseases of the.*

MENINGO'PHYLAX. (From μηνιγξ, a membrane, and φυλαττω, to guard.) An instrument to guard the membranes of the brain, while the bone is cut, or rasped, after the operation of the trepan.

ME'NINX. (*x, gis.* f. Μηνιγξ.) Before the time of Galen, meninx was the common term of all the membranes of the body; afterwards it was appropriated to those of the brain. See *Dura* and *Pia mater.*

MENISPE'RMIC ACID. *Acidum menispermicum.* The seeds of *Menispermum cocculus* being macerated for twenty-four hours in five times their weight of water, first cold, and then boiling hot, yield an infusion, from which solution of subacetate of lead throws down a menispermate of lead. This is to be washed and drained, diffused through water, and decomposed by a current of sulphuretted hydrogen gas. The liquid, thus freed from lead, is to be deprived of sulphuretted hydrogen by heat, and then forms solution of menispermic acid. By repeated evaporations and solutions in alkohol, it loses its bitter taste, and becomes a purer acid. It occasions no precipitate with lime-water; with nitrate of barytes it yields a grey precipitate; with nitrate of silver, a deep yellow; and with sulphate of magnesia, a copious precipitate.

MENISPE'RMUM. (*um, i.* n.; from μηνη, the moon, and σπερμα, seed, in allusion to the crescent-like form of the seed.) The name of a genus of plants. Class, *Diœcia*; Order, *Dodecandria.* Moon-seed.

MENISPERMUM COCCULUS. The name of the plant the berries of which are well known by the name of *Cocculus indicus.* Indian berries, or Indian cockles. *Coccus indicus. Cocculæ officinarium. Cocci orientales. Bacca piscatoria.* The berry, the produce of the *Menispermum* — *foliis cordatis, retusis, mucronatis; caule lacero*, of Linnæus, is rugous and kidney-shaped, and contains a white nucleus. It is brought from Malabar and the East Indies. It is poisonous if swallowed, bringing on nausea, fainting, and convulsions. The berries possess an inebriating quality, and are supposed to impart that power to most of the London porter. Whilst green, they are used by the Indians to catch fish, which they have the power of intoxicating, and killing. In the same manner they catch birds, making the berry into a paste, forming it into small seeds, and putting these in places where they frequent. A peculiar acid, called *menispermic*, is obtained from these berries.

By recent chemical analysis, this seed is found to contain, 1st, about one half of its weight of a concrete fixed oil; 2d, an albuminous vegeto-animal substance; 3d, a peculiar colouring matter; 4th, one fiftieth of *picrotoxia*; 5th, one half of its weight of fibrous matter; 6th, bimalate of lime and potash; 7th, sulphate of potash; 8th, muriate of potash; 9th, phosphate of lime; 10th, a little iron and silica. It is poisonous, and is frequently employed to intoxicate or poison fishes. The deleterious ingredient is the picrotoxia. See *Picrotoxia.*

Menispermum palmatum. See *Cocculus palmatus.*

MENORRHA'GIA. (*a, æ.* f.; from μηνια, the menses, and ῥηγνυμι, to break out.) *Hæmorrhagia uterina.* Flooding. An immoderate flow of the menses or blood from the uterus, characterised by pains in the back, loins, and belly, similar to those of labour, attended with a preternatural flux of blood from the vagina, or a discharge of menses, more copious than natural. Dr. Cullen distinguishes six species: —

1. *Menorrhagia rubra*; bloody, from women neither with child nor in childbirth.

2. *Menorrhagia alba*, serous; usually called the fluor albus. See *Leucorrhœa.*

3. *Menorrhagia vitiorum*, from some local disease; as ulcer, cancer, &c.

4. *Menorrhagia lochialis*, from women after delivery. See *Lochia.*

5. *Menorrhagia abortus.* See *Abortion.*

6. *Menorrhagia Nabothi*, a serous discharge from the vagina in pregnant women.

This disease seldom occurs before the age of puberty, and is often an attendant on pregnancy. It is in general a very dangerous disease, more particularly if it occur at the latter period, as it is then often so rapid and violent as to destroy the female in a very short time, where proper means are not soon adopted. Abortions often give rise to floodings, and at any period of pregnancy, but more usually before the fifth month than at any other time. Moles, in consequence of an imperfect conception becoming detached, often give rise to a considerable degree of hæmorrhage.

The causes which most frequently give rise to floodings, are violent exertions of strength, sudden surprises and frights, violent fits of passion, great uneasiness of mind, uncommon longings during pregnancy, over-fullness of blood, profuse evacuations, general weakness of the system

external injuries, as blows and bruises, and the death of the child, in consequence of which the placenta becomes partially or wholly detached from the uterus, leaving the mouths of the vessels of the latter, which anastomosed with those of the former, perfectly open. It is necessary to distinguish between an approaching miscarriage and a common flooding, which may be readily done by enquiring whether or not the hæmorrhage has proceeded from any evident cause, and whether it flows gently, or is accompanied with unusual pains. The former usually arises from some fright, surprise, or accident, and does not flow gently and regularly; but bursts out of a sudden, and again stops all at once, and also is attended with severe pains in the back and the bottom of the belly; whereas the latter is marked with no such occurrence. The further a woman is advanced in pregnancy, the greater will be the danger if floodings take place, as the mouths of the vessels are much enlarged during the last stage of pregnancy, and of course a quantity will be discharged in a short time.

The treatment must differ according to the particular causes of the disease, and according to the different states of constitution under which it occurs. The hæmorrhage is more frequently of the active kind, and requires the antiphlogistic plan to be strictly enforced, especially obviating the accumulation of heat in every way, giving cold acidulated drink, and using cold local applications; the patient must remain quiet in the horizontal posture; the diet be of the lightest and least stimulant description; and the bowels kept freely open by cooling laxatives, as the neutral salts, &c. It may be sometimes advisable in robust, plethoric females, particularly in the pregnant state, to take blood at an early period, especially where there is much pain, with a hard pulse; digitalis and antimonials in nauseating doses would also be proper under such circumstances. But where the discharge is rather of a passive character, tonic and astringent medicines ought to be given: rest and the horizontal position are equally necessary, costiveness must be obviated, and cold astringent applications may be materially useful, or the escape of the blood may be prevented mechanically. In alarming cases, perhaps, the most powerful internal remedy is the superacetate of lead, combined with opium; which latter is often indicated by the irritable state of the patient. A nourishing diet, with gentle exercise in a carriage, and the prudent use of the cold bath, may contribute to restore the patient, when the discharge has subsided.

Meno'stasis. (From μην, a month, and στασις, a cessation.) *Menostasia.* A suppression or retention of the menses.

Mens. (*s, tis.* f.; from μενος, *vis animi.*) See *Mind.*

Me'nsa. A table. The second lobe of the liver is so called by some old writers.

Me'nses. (From *mensis,* a month.) See *Menstruation.*

Menses, immoderate flow of the. See *Menorrhagia.*

Menses, interruption of. See *Amenorrhœa.*

Menses, retention of. See *Amenorrhœa.*

Mensis philosophicus. A philosophical, or chemical month. According to some, it is three days and nights; others say it is ten; and there are those who reckon it to be thirty or forty days.

MENSTRUATION. (*Menstruatio, onis.* f.; from *menses.*) From the uterus of every healthy woman who is not pregnant, or who does not give suck, there is a discharge of a red fluid, at certain periods, from the time of puberty to the approach of old age; and from the periods or returns of this discharge being monthly, it is called *menstruation;* and the discharge is called *catamenia,* and *menses.* There are several exceptions to this definition. It is said that some women never menstruate; some menstruate while they continue to give suck; and others are said to menstruate during pregnancy; some are said to menstruate in early infancy, and others in old age; but such discharges, Dr. Denman is of opinion, may with more propriety be called morbid, or symptomatic; and certainly the definition is generally true.

At whatever time of life this discharge comes on, a woman is said to be at puberty, though of this state it is a consequence, and not a cause. The early or late appearance of the menses may depend upon the climate, the constitution, the delicacy or hardness of living, and upon the manners of those with whom young women converse. In Greece, and other hot countries, girls begin to menstruate at eight, nine, and ten years of age, but, advancing to the northern climates, there is a gradual protraction of the time till we come to Lapland, where women do not menstruate till they arrive at maturer age, and then in small quantities, at long intervals, and sometimes only in the summer. But, if they do not menstruate according to the genius of the country, it is said they suffer equal inconveniences as in warmer climates, where the quantity discharged is much greater, and the periods shorter. In this country, girls begin to menstruate from the fourteenth to the eighteenth year of their age, and sometimes at a later period, without any signs of disease; but if they are luxuriously educated, sleeping upon down beds, and sitting in hot rooms, menstruation usually commences at a more early period.

Many changes in the constitution and appearance of women are produced at the time of their first beginning to menstruate. Their complexion is improved, their countenance is more expressive and animated, their attitudes graceful, and their conversation more intelligent and agreeable; the tone of their voice becomes more harmonious, their whole frame, but particularly their breasts, are expanded and enlarged, and their minds are no longer engaged in childish pursuits and amusements.

Some girls begin to menstruate without any preceding indisposition; but there are generally appearances or symptoms which indicate the change which is about to take place. These are usually more severe at the first than in the succeeding periods; and they are similar to those produced by uterine irritation from other causes,

as pains in the back and inferior extremities, complaints of the viscera, with various hysteric and nervous affections. These commence with the first disposition to menstruate, and continue till the discharge comes on, when they abate, or disappear, returning, however, with considerable violence in some women, at every period during life. The quantity of fluid discharged at each evacuation, depends upon the climate, constitution, and manner of living; but it varies in different women in the same climate, or in the same women at different periods: in this country it amounts to about five or six ounces.

There is also a great difference in the time required for the completion of each period of menstruation. In some women the discharge returns precisely to a day, or an hour, and in others there is a variation of several days, without inconvenience. In some it is finished in a few hours, and in others it continues from one to ten days; but the intermediate time, from three to six days, is most usual. Many have questioned whether this discharge arose from a mere rupture of vessels, or whether it was owing to a secretory action. There can be little doubt of the truth of the latter. The secretory organ is composed of the arterial vessels situated in the fundus of the uterus. The dissection of women, who have died during the time of their menstruating, proves this. Sometimes, though very rarely, women, during pregnancy, menstruate, and when this happens, the discharge takes place from the arterial vessels of the vagina. During pregnancy and lactation, when the person is in good health, the catamenia, for the most part, cease to flow. The quantity a female menstruates at each time is very various, depending on climate, and a variety of other circumstances. It is commonly in England from five to six ounces; it rarely exceeds eight. Its duration is from three to four, and sometimes, though rarely, five days. With respect to the nature of the discharge, it differs very much from pure blood: it never coagulates; but is sometimes grumous, and membranes like the decidua are formed in difficult menstruations: in some women it always smells rank and peculiar; in others it is inodorous. The use of this monthly secretion is said to be, to render the uterus fit for the conception and nutrition of the fœtus; therefore girls rarely conceive before the catamenia appear, and women rarely after their entire cessation; but very easily soon after menstruation.

There has been an opinion, probably derived from the Jewish legislature, afterwards adopted by the Arabian physicians, and credited in other countries, that the menstruous blood possesses some peculiar malignant properties. The severe regulations which have been made in some countries for the conduct of women at the time of menstruation; — the expression used, Isaiah, chap. xxx., and in Ezekiel; — the disposal of the blood discharged, or of any thing contaminated with it; — the complaints of women attributed to its retention; — and the effects enumerated by grave writers, indicate the most dreadful apprehensions of its baneful influence. Under peculiar circumstances of health, or states of the uterus, or in hot climates, if the evacuation be slowly made, the menstruous blood may become more acrimonious or offensive than the common mass, or any other secretion from it; but in this country and age no malignity is suspected: the menstruous woman mixes in society as at all other times, and there is no reason for thinking otherwise than that this discharge is of the most inoffensive nature.

At the approach of old age, women cease to menstruate; but the time of cessation is commonly regulated by the original early or late appearance of the menses. With those who began to menstruate at ten or twelve years of age, the discharge will often cease before they arrive at forty; but if the first appearance was protracted to sixteen or eighteen years of age, independently of disease, such women may continue to menstruate till they have passed the fiftieth, or even approach the sixtieth year of their age. But the most frequent time of the cessation of the menses in this country, is between the forty-fourth and forty-eighth year; after which women never bear children. By this constitutional regulation of the menses, the propagation of the species is in every country confined to the most vigorous part of life; and, had it been otherwise, children might have become parents, and old women might have had children, when they were unable to supply them with proper or sufficient nourishment.

MEN'STRUUM. (*um*, *i.* n.) Solvent. All liquors are so called which are used as dissolvents, or to extract the virtues of ingredients by infusion, decoction, &c. The principal *menstrua* made use of in *Pharmacy*, are water, vinous spirits, oils, and acid and alkaline liquors.

Menta. See *Mentula.*

MEN'TAGRA. (*a*, *æ.* f.; from *mentum*, the chin, and αγρα, a prey.) An eruption about the chin, forming a tenacious crust, like that on a scald head. See *Sycosis.*

ME'NTHA. (*a*, *æ.* f.; from *Minthe*, the harlot, who was changed into this herb.) Ἡδυσμος of the Greeks. The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia.* Mint.

Mentha aquatica. *Menthastrum. Sisymbrium menthrastrum. Mentha Rotundifolia palustris.* Water-mint. This plant is frequent in moist meadows, marshes, and on the banks of rivers. It is less agreeable than the spearmint, and in taste bitterer and more pungent. It may be used with the same intentions as the spearmint, to which, however, it is much inferior.

Mentha cataria. See *Nepeta cataria.*

Mentha cervi'na. The systematic name of the hart's penny-royal. *Pulegium cervinum.* This plant possesses the virtues of penny-royal in a very great degree, but is remarkably unpleasant. It is seldom employed but by the country people, who substitute it for penny royal.

Mentha crispa. Curled leaved mint. This species of mentha has a strong and fragrant smell; its taste is warm, aromatic, and slightly bitter. In flatulence of the primæ viæ, hypochondriacal and hysterical affections, it is given with advantage.

MENTHA PIPERITA. The systematic and pharmacopœial name of peppermint. *Mentha piperitis. Mentha — floribus capitatis, foliis ovatis petiolatis, staminibus corolla brevioribus*, of Linnæus. The spontaneous growth of this plant is said to be peculiar to Britain. It has a more penetrating smell than any of the other mints; a strong pungent taste, glowing like pepper, sinking, as it were, into the tongue, and followed by a sense of coolness. The stomachic, antispasmodic, and carminative properties of peppermint, render it useful in flatulent colics, hysterical affections, retchings, and other dyspeptic symptoms, acting as a cordial, and often producing an immediate relief. Its officinal preparations are an essential oil, a simple water, and a spirit.

MENTHA PULEGIUM. The systematic name of the penny-royal. *Pulegium. Pulegium regale. Pulegium latifolium. Glechon.* Pudding-grass. *Mentha — floribus verticillatis, foliis ovatis obtusis subcrenatis, caulibus subteretibus repentibus*, of Linnæus. This plant is considered as a carminative, stomachic, and emmenagogue, and is in very common use in hysterical disorders. The officinal preparations of penny-royal are, a simple water, a spirit, and an essential oil.

Mentha saracenica. See *Tanacetum.*

Mentha sativa. See *Mentha viridis.*

Mentha spicata. See *Mentha viridis.*

MENTHA VIRIDIS. *Mentha vulgaris. Mentha spicata.* Spearmint. *Mentha spicis oblongis, foliis lanceolatis nudis serratis sessilibus, staminibus corolla longioribus*, of Linnæus. This plant grows wild in many parts of England. It is not so warm to the taste as peppermint, but has a more agreeable flavour, and is therefore preferred for culinary purposes. Its medicinal qualities are similar to those of peppermint; but the different preparations of the former, though more pleasant, are perhaps less efficacious. The officinal preparations of spearmint are, an essential oil, a conserve, a simple water, and a spirit.

MENTHA'STRUM. (Diminutive of *mentha.*) See *Mentha aquatica.*

ME'NTULA. (*a, æ.* f.) *Menta.* The penis, or the clitoris.

MENTU'LAGRA. (*a, æ.* f.; from *mentula*, the penis, and αγρα, a prey.) A disorder of the penis, induced by a contraction of the erector muscles, and causing impotence.

ME'NTUM. (*um, i.* n.) The chin.

MENYA'NTHES. (*es, eos.* or *is.* f.; from μην, a month, and ανθος, a flower, and so called because it generally keeps in flower about a month.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.*

MENYANTHES TRIFOLIATA. The systematic name of the buck-bean. *Trifolium paludosum. Trifolium aquaticum. Trifolium fibrinum. Menyanthes.* Water-trefoil, or buck-bean. *Menyanthes — foliis ternatis*, of Linnæus. The whole plant is so extremely bitter, that in some countries it is used as a substitute for hops, in the preparation of malt liquor. It is sometimes employed in country places as an active ecoprotic bitter in hydropic and rheumatic affections. Cases are related of its good effects in some cutaneous diseases of the herpatic and seemingly cancerous kind.

MEPHI'TIC. *Mephiticus.* Applied to that which emits a noxious smell or vapour.

MEPHITIC ACID. The carbonic acid.

Mephitic air. See *Nitrogen.*

MEPHI'TIS. (*is, is.* f.; from *mephuhith*, a blast, Syr.) A poisonous exhalation.

MERCURIA'LIS. (*is, is.* f.; from *Mercurius*, its discoverer.) 1. The name of a genus of plants in the Linnæan system. Class, *Diœcia;* Order, *Enneandria.*

2. The pharmacopœial name of the French mercury. See *Mercurialis annua.*

MERCURIALIS ANNUA. The systematic name of the French mercury. The leaves of this plant have no remarkable smell, and very little taste. It is ranked among the emollient oleraceous herbs, and is said to be gently aperient. Its principal use has been in clysters.

Mercurialis montana. See *Mercurialis perennis.*

MERCURIALIS PERENNIS. The systematic name of what is also called *Cynocrambe, Brassica canina, Mercurialis sylvestris*, and *Mercurialis montana sylvestris.* The dog's mercury. A poisonous plant, very common in our hedges. It produces vomiting and purging, and the person then goes to sleep, from which he does not often awake.

Mercurialis sylvestris. See *Mercurialis perennis.*

MERCU'RIUS. (*us, i.* m.; so called from some supposed relation it bears to the planet of that name.) Mercury. See *Mercury.*

Mercurius acetatus. See *Hydrargyri acetas.*

Mercurius alkalizatus. See *Hydrargyrum cum cretâ.*

Mercurius calcinatus. See *Hydrargyri binoxidum.*

MERCURIUS CHEMICORUM. Quicksilver.

Mercurius cinnabarinus. See *Hydrargyri sulphuretum rubrum.*

Mercurius corrosivus. See *Hydrargyri bichloridum.*

Mercurius corrosivus ruber. See *Hydrargyri nitrico-oxydum.*

Mercurius corrosivus sublimatus. See *Hydrargyri bichloridum.*

Mercurius dulcis sublimatus. See *Hydrargyri chloridum.*

Mercurius emeticus flavus. See *Subsulphas hydrargyri flavus.*

Mercurius mortis. See *Algaroth.*

Mercurius præcipitatus albus. See *Hydrargyri ammonio-chloridum.*

Mercurius præcipitatus dulcis. See *Hydrargyri chloridum.*

Mercurius præcipitatus ruber. See *Hydrargyri nitrico-oxydum.*

Mercurius vitæ. See *Algaroth.*

MERCURY. *Hydrargyrum. Hydrargyrus. Mercurius.* A metal found in five different states in nature.

1. Native, — *native mercury*, adhering in small globules to the surface of cinnabar ores,

or scattered through the crevices or over the surfaces of different kinds of stones.

2. It is found united to silver, in the ore called *amalgam of silver*, or *native amalgam of silver*. This ore exhibits thin places, or grains; it sometimes crystallises in cubes, parallelopipeda, or pyramids. Its colour is of a silver white, or grey; its lustre is considerably metallic.

3. Combined with sulphur, it constitutes *native cinnabar*, or sulphuret of mercury. This ore is the most common. It is frequently found in veins, and sometimes crystallised in tetrahedra, or three-sided pyramids. Its colour is red. Its streak metallic.

4. Mercury oxidised, and united either to muriatic or sulphuric acid, forms the ore called *horn quicksilver*, or corneous mercury. These ores are, in general, semi-transparent, of a grey or white colour, sometimes crystallised, but more frequently in grains.

5. United to oxygen, it constitutes the ore called *native oxide of mercury*. Mercurial ores particularly abound in Spain, Hungary, China, and South America.

Properties. — Mercury, or quicksilver, is the only one of the metals that remains fluid at the ordinary temperature of the atmosphere; but when its temperature is reduced to 40 degrees below 0 on Fahrenheit's thermometer, it assumes a solid form. This is a degree of cold, however, that only occurs in high northern latitudes; in our climate, mercury cannot be exhibited in a solid state, but by means of artificial cold. When rendered solid, it possesses both ductility and malleability. It crystallises in octahedra, and contracts strongly during congelation. It is divisible into very small globules. It presents a convex appearance in vessels to which it has little attraction, but is concave in those to which it more strongly adheres. It becomes electric and phosphorescent by rubbing upon glass and by agitation in a vacuum. It is a very good conductor of caloric, of electricity, and of galvanism. The specific gravity of mercury is 13·563. Although fluid, its opacity is equal to that of any other metal, and its surface, when clean, has considerable lustre. Its colour is white, similar to silver. Exposed to the temperature of somewhat above 600° Fahr., it is volatilised. When agitated in the air, especially in contact with viscous fluids, it becomes converted into a black oxide. At a temperature nearly the same as that at which it boils, it absorbs about 14 or 15 per cent. of oxygen, and then becomes changed into a red crystallisable oxide, which is spontaneously reducible by light and caloric at a higher temperature. The greater number of the acids act upon mercury, or are at least capable of combining with its oxides. It combines with sulphur by trituration, but more intimately by heat. It is acted on by the alkaline sulphurets. It combines with many of the metals: these compounds are brittle or soft when the mercury is in large proportion. There is a slight union between mercury and phosphorus. It does not unite with carbon or the earths.

Method of obtaining Mercury. — Mercury may be obtained pure by decomposing cinnabar, by means of iron filings. For that purpose, take two parts of red sulphuret of mercury; reduce it to powder, and mix it with one of iron filings; put the mixture into a stone retort; direct the neck of it into a bottle, or receiver, filled with water, and apply heat. The mercury will then be obtained in a state of purity.

In this process, the sulphuret of mercury, which consists of sulphur and mercury, is heated in contact with iron, the sulphur quits the mercury and unites to the iron, and the mercury becomes disengaged; the residue in the retort is a sulphuret of iron.

Medical use. — This metal and its combinations are very important articles in the materia medica. There is scarcely a disease against which some of its preparations are not exhibited; and over the venereal disease it is believed by many practitioners to possess a specific power. It is considered to have first gained repute in curing this disease from the good effects it produced in eruptive diseases. In the times immediately following its first appearance, practitioners only attempted to employ this remedy with timorous caution; so that, of several of their formulæ, mercury scarcely composed a fourth part, and few cures were effected. On the other hand, empirics, who noticed the little efficacy of these small doses, ran into the opposite extreme, and exhibited mercury in such large quantities, and with such little care, that most of their patients became suddenly attacked with the most violent salivations, attended with dangerous consequences. From these two very opposite modes of practice, there originated such uncertainty respecting what could be expected from mercury, and such fears of the consequences which might result from its employment, that every plan was eagerly adopted which offered the least chance of cure without having recourse to this mineral. A medicine, however, so powerful, and whose salutary effects were seen by attentive practitioners, amid all its inconveniences, could not sink into oblivion. After efforts had been made to discover a substitute for it, and it was seen how little confidence those means deserved on which the highest praises had been lavished, the attempts to discover its utility were renewed. A medium was pursued, between the too timid methods of those physicians who had first administered it, and the inconsiderate boldness of the empirics. Thus the causes from which both parties failed were avoided; the character of the medicine was revived in a more durable way, and from this period its reputation has always been maintained.

It was about this epoch that mercury began to be internally given: hitherto it had only been externally employed, which was done in three manners. The first was in form of liniment, or ointment; the second as a plaster; and the third as a fumigation. Of the three methods just described, only the first is at present much in use, and even this is very much altered. Mercurial plasters are now only used as topical discutient applications to tumours and indurations. Fumigations, as anciently managed

were liable to many objections, particularly from its not being possible to regulate the quantity of mercury to be used, and from the effect of the vapour on the organs of respiration, frequently occasioning trembling, palsies, &c. Frictions with ointment have always been regarded as the most efficacious mode of administering mercury externally.'

Mercury is carried into the constitution in the same way as other substances, either by being absorbed from the surface of the body, or that of the alimentary canal. It cannot, however, in all cases be taken into the constitution in both ways, for sometimes the absorbents of the skin will not readily receive it; at least no effect is produced, either on the disease or constitution, from this mode of application. On the other hand, the internal absorbents will sometimes not take up the medicine, or, at least, no effect is produced either on the disease or constitution. In many persons the bowels can hardly bear mercury at all; and it should then be given in the mildest form possible, conjoined with such medicines as will lessen or correct its violent effects, although not its specific ones, on the constitution. When mercury can be introduced into the constitution by the external method, it is preferable to the internal plan; because the skin is not nearly so essential to life as the stomach, and is, therefore, in itself capable of bearing much more than the stomach. The constitution is also less injured. Many courses of mercury would kill the patient if the medicine were only given internally, because it proves hurtful to the stomach and intestines when given in any form, or joined with the greatest correctors.

Mercury has two effects: one as a stimulus on the constitution and particular parts, the other as a specific on a diseased action of the whole body, or of parts. The latter action can only be computed by the disease disappearing.

In giving mercury in the venereal disease, the first attention should be to the quantity, and its visible effects in a given time; which, when brought to a proper pitch, are only to be kept up, and the decline of the disease to be watched; for by this we judge of the invisible or specific effects of the medicine, and know what variation in the quantity may be necessary. The visible effects of mercury affect either the whole constitution, or some parts capable of secretion. In the first, it produces universal irritability, making it more susceptible of all impressions. It quickens the pulse, increases its hardness, and occasions a kind of temporary fever. In some constitutions it operates like a poison. In some it produces a hectic fever; but such effects commonly diminish on the patient becoming accustomed to the medicine.

Mercury often produces pains like those of rheumatism, and nodes of a scrofulous nature. The quantity of mercury necessary for the cure of any venereal complaint, must be proportioned to the violence of the disease. A small quantity used quickly, will have equal effects to those of a large one employed slowly; but if these effects are merely local, that is, upon the glands of the mouth, the constitution at large not being equally stimulated, the effects upon the diseased parts must be less, which may be known by the local disease not giving way in proportion to the effects of mercury on some particular part. If it be given in very small quantities, and increased gradually, so as to steal insensibly on the constitution, a vast quantity at a time may at length be thrown in, without any visible effects at all.

The constitution, or parts, are more susceptible of mercury at first than afterwards.

Mercury occasionally attacks the bowels, and causes violent purging, even of blood. This effect is remedied by intermitting the use of the medicine, and exhibiting opium. At other times, it is suddenly determined to the mouth, and produces inflammation, ulceration, and an excessive flow of saliva. To obtain relief in this circumstance, purgatives, nitre, sulphur, gum-arabic, lime-water, camphire, bark, sulphuret of potash, blisters, &c. have been advised. Pearson, however, does not place much confidence in the efficacy of such means; and the mercury being discontinued for a time, he recommends the patient to be freely exposed to cold air, with the occasional use of cathartics, mineral acids, Peruvian bark, and the assiduous application of astringent gargles. The most material objection (says Mr. Pearson) which I foresee against the method of treatment I have recommended, is the hazard to which the patient will be exposed of having the saliva suddenly checked, and of suffering some other disease in consequence of it.

The hasty suppression of a ptyalism may be followed by serious inconveniences, as violent pains, vomiting, and general convulsions.

Cold liquids taken into the stomach, or exposure of the body to the cold air, must be guarded against during a course of mercury. Should a suppression of the ptyalism take place, from any act of indiscretion, a quick introduction of mercury should be had recourse to, with the occasional use of the warm bath.

Mercury, when it falls on the mouth, sometimes produces inflammation, which now and then terminates in mortification. The ordinary operation of mercury does not permanently injure the constitution; but, occasionally, the impairment is very material; mercury may even produce local diseases, and retard the cure of chancres, buboes, and certain effects of the lues venerea, after the poison has been destroyed. Occasionally mercury acts on the system as a poison, quite unconnected with its agency as a remedy, and neither proportionate to the inflammation of the mouth, nor actual quantity of the mineral absorbed. Pearson has termed this morbid state of the system erethismus: it is characterised by great depression of strength, a sense of anxiety about the præcordia, irregular action of the heart, frequent sighing, trembling, a small, quick, and sometimes intermitting pulse, occasional vomiting, a pale contracted countenance, a sense of coldness; but the tongue is seldom furred, and neither the natural or vital functions are much disturbed. When this effect of mercury takes place, its use should be dis-

continued, whatever may be the stage, extent, or violence of the venereal disease. The patient should be exposed to a dry and cool air, in such a way as not to give fatigue; in this way, the patient will often recover in ten or fourteen days. In the early stage, the erethismus may often be averted by leaving off the mercury and giving camphire mixture with volatile alkali. Occasionally, the use of mercury brings on a peculiar eruption, which has received the names of mercurial rash, eczema mercuriale, lepra mercurialis, mercurial disease, and erythema mercuriale.

In order that mercury should act on the human body, it is necessary that it should be oxidised, or combined with an acid. The mercury contained in the unguentum hydrargyri, is an oxide. This, however, is the most simple and least combined form of all its preparations, and hence (says Mr. S. Cooper) it not only operates with more mildness on the system, but with more specific effect on the disease. Various salts of mercury operate more quickly, when given internally, than mercurial frictions; but few practitioners of the present day confide in the internal use of mercury alone, particularly when the venereal virus has produced effects in consequence of absorption. Rubbing in mercurial ointment is the mode of affecting the system with mercury in the present day; and, as a substitute for this mode of applying mercury, Mr. Abernethy recommends the mercurial fumigation, where the patient has not strength to rub in the ointment, and whose bowels will not bear the internal exhibition of it.

The preparations of mercury now in use are, —

1. *Hydrargyrum cum cretâ.*
2. *Hydrargyrum cum magnesiâ.*
3. *Hydrargyri oxydum.*
4. *Hydrargyri oxydum cinereum.*
5. *Hydrargyri binoxidum.*
6. *Hydrargyri persulphas.*
7. *Acetas hydrargyri.*
8. *Hydrargyri ammonio-chloridum.*
9. *Hydrargyrus purificatus.*
10. *Hydrargyri chloridum.*
11. *Hydrargyri bichloridum.*
12. *Liquor hydrargyri bichloridi.*
13. *Hydrargyri bicyanidum.*
14. *Hydrargyri iodidum.*
15. *Hydrargyri biniodidum.*
16. *Hydrargyri sulphuretum cum sulphure.*
17. *Hydrargyri bisulphuretum.*
18. *Subsulphas hydrargyri flavus.*
19. *Pilula hydrargyri.*
20. *Unguentum hydrargyri.*
21. *Unguentum hydrargyri nitratis.*

Mercury, dog's. See *Mercurialis.*

Mercury, English. See *Chenopodium.*

Mercury, French. See *Mercurialis.*

MEROBALNE'UM. (From μερος, a part, and βαλανειον, a bath.) A partial bath, as a hip-bath, bath for the feet, &c.

MEROCE'LE. (*e, es.* f.; from μερος, the thigh, and κηλη, a tumour.) A femoral hernia. See *Hernia.*

ME'ROS. (*Meros, i.* m.; pl. *mera.*) The thigh.

ME'RUS. Applied to several things in the same sense as genuine, or unadulterated; as *merum vinum*, undiluted wine.

MESARÆ'UM. (From μεσος, the middle, and αραια, the belly.) The mesentery.

MESEMBRYA'NTHEMUM. (*um, i.* n.; so called from the circumstance of its flowers expanding at mid-day.) The name of a large genus of plants. Class, *Icosandria*; Order, *Pentagynia.*

MESEMBRYANTHEMUM CRYSTA'LLINUM. The juice of this plant, in a dose of four spoonfuls every two hours, it is asserted, has removed an obstinate spasmodic affection of the neck of the bladder, which would not yield to other remedies.

MESENTERIC. *Mesentericus.* Belonging to the mesentery. See *Mesentery.*

MESENTERIC ARTERY. *Arteria mesenterica.* Two branches of the aorta in the abdomen are so called. The superior mesenteric is the second branch of the abdominal aorta; it is distributed upon the mesentery, and gives off the *ileo-colica, colica dextra*, and *colica media.* The inferior mesenteric is the fifth branch of the abdominal aorta; it sends off the *colica sinistra*, and its termination forms the *internal hæmorrhoidal.*

MESENTERIC GLANDS. *Glandulæ mesentericæ.* These are conglobate, and are situated here and there in the cellular membrane of the mesentery. The chyle from the intestines passes through these glands to the thoracic duct.

MESENTERIC NERVES. *Nervorum plexus mesentericus.* The superior, middle, and lower mesenteric plexuses of nerves are formed by the branches of the great intercostal nerves.

MESENTERIC VEINS. *Venæ mesentericæ.* They all run into one trunk, which evacuates its blood into the vena portæ. See *Vena portæ.*

MESENTERI'TIS. (*is, idis.* f.; from μεσεντεριον, the mesentery.) An inflammation of the mesentery. See *Peritonitis.*

ME'SENTERY. (*Mesenterium, ii.* n. from μεσος, the middle, and εντερον, an intestine.) A membrane in the cavity of the abdomen attached to the vertebræ of the loins and to which the intestines adhere. It is formed of a duplicature of the peritonæum, and contains within it adipose membrane, lacteals, lymphatics, lacteal glands, mesenteric arteries, veins, and nerves. Its use is to sustain the intestines in such a manner that they possess both mobility and firmness; to support and conduct with safety the blood-vessels, lacteals, and nerves; to fix the glands, and give an external coat to the intestines.

It consists of three parts: one uniting the small intestines, which is the proper mesentery; another connecting the colon, termed mesocolon; and a third, attached to the rectum, termed mesorectum. See *Mesocolon.*

MESERA'IC. *Meseraicus.* The same as mesenteric.

Mese'rion. See *Daphne mezereum.*

MESI'RE. A disorder of the liver, mentioned by Avicenna, accompanied with a sense of heaviness, tumour, inflammation, pungent pain, and blackness of the tongue.

Mesmerism. See *Magnetism, animal.*

MESOCÆ'CUM. The reflexion of the peritonæum which keeps the cæcum in its place.

MESOCO'LON. (*on, i.* m.; from *μεσος*, the middle, and *κωλον*, the colon.) The portion of the mesentery to which the colon is attached. The mesentery and mesocolon are the most important of all the productions of the peritonæum. In the pelvis, the peritonæum spreads itself shortly before the rectum. But where that intestine becomes loose, and forms the semilunar curve, the peritonæum there rises considerably from the middle iliac vessels, and region of the psoas muscle, double, and with a figure adapted for receiving the hollow colon. But above, on the left side, the colon is connected with almost no intermediate loose production to the peritonæum, spread upon the psoas muscle as high as the spleen, where this part of the peritonæum, which gave a coat to the colon, being extended under the spleen, receives and sustains that viscus in a hollow superior recess.

Afterwards the peritonæum, from the left kidney, from the interval between the kidneys, from the large vessels, and from the right kidney, emerges forwards under the pancreas, and forms a broad and sufficiently long continuous production, called the transverse mesocolon, which, like a partition, divides the upper part of the abdomen, containing the stomach, liver, spleen, and pancreas, from the lower part. The lower plate of this transverse production is continued singly from the right mesocolon to the left, and serves as an external coat to a pretty large portion of the liver, and descending part of the duodenum. But the upper plate, less simple in the course, departs from the lumbar peritonæum at the kidney, and region of the vena cava, farther to the right than the duodenum, to which it gives an external membrane, not quite to the valve of the pylorus; and beyond this intestine, and beyond the colon, it is joined with the lower plate, so that a large part of the duodenum lies within the cavity of the mesocolon. Afterwards, in the region of the liver, the mesocolon is inflected, and descending over the kidney of the same side much shorter, it includes the right of the colon, as far as the intestinum cæcum, which rests upon the iliac muscle and the appendix, which is provided with a peculiar long curved mesentery. There the mesocolon terminates, almost at the bifurcation of the aorta.

The whole of the mesocolon and of the mesentery is hollow, so that the air may be forced in between its two laminæ, in such a manner as to expand them into a bag. At the place where it sustains the colon, and also from part of the intestinum rectum, the mesocolon, continuous with the outer membrane of the intestine, forms itself into small slender bags, resembling the omentum, for the most part in pairs, with their loose extremities thicker and bifid, and capable of admitting air blown in between the plates of the mesocolon.

MESOCRA'NIUM. (*um, ii.* n.; from *μεσος*, the middle, and *κρανιον*, the skull.) The crown of the head, or vertex.

MESOGA'STRIUM. (*um, ii.* n.; from *μεσος*, the middle, and *γαστηρ*, the belly.) The umbilical region of the abdomen.

MESOGLO'SSUS. (*us, i.* m.; from *μεσος*, the middle, and *γλωσσα*, the tongue.) The *genioglossus* muscle has been so called.

MESOME'RIA. (From *μεσος*, the middle, and *μηρος*, the thigh.) The parts between the thighs. See *Meros.*

MESOMPHA'LIUM. (*um, ii.* n.; from *μεσος*, the middle, and *ομφαλος*, the navel.) The navel.

MESO'PHRYUM. (*um, i.* n.; from *μεσος*, the middle, and *οφρυα*, the eyebrows.) The part between the eyebrows.

MESOPLEU'RII. From *μεσος*, the middle, and *πλευρον*, a rib.) The intercostal muscles.

MESORE'CTUM. (*um, i.* n.; from *μεσος*, the middle, and *rectum*, the straight gut.) The portion of peritonæum which connects the rectum to the pelvis.

MESO'THENAR. (*ar, aris.* n.; from *μεσος*, the middle, and *θεναρ*, the palm of the hand.) The name given by Winslow to the muscular mass consisting of the abductor, and part of the short flexor of the thumb.

ME'SPILUS. (*us, i.* f. *Οτι εν τω μεσω πιλος*, because it has a cap or crown in the middle of it.) 1. The name of a genus of plants in the Linnæan system. Class, *Icosandria*; Order, *Pentagynia.*

2. The pharmacopœial name of the medlar. See *Mespilus germanica.*

MESPILUS GERMANICA. The medlar tree. The fruit, and also its seeds, have been used medicinally. The immature fruit is serviceable in checking diarrhœas; and the seeds were formerly esteemed in allaying the pain attendant on nephritic diseases.

META'BASIS. (From *μεταβαινω*, to digress.) *Metabole.* A change of remedy, of practice, or disease; or any change from one thing to another, either in the curative indications, or the symptoms of a distemper.

Meta'bole. See *Metabasis.*

METACARPAL. *Metacarpalis.* Belonging to the metacarpus.

Metacarpal bones. See *Metacarpus.*

METACA'RPUS. (From *μετα*, after, and *καρπος*, the wrist.) *Metacarpium.* That part of the hand which is between the wrist and the fingers. It has five longitudinal bones that are situated between the wrist and the fingers, which are distinguished into the metacarpal bone of the thumb, fore-finger, &c.

METACO'NDYLOS. (From *μετα*, after, and *κονδυλος*, a knuckle.) The last joint of a finger, which contains the nail.

METACORE'SIS. (*Μεταχωρησις*; from *μεταχωρεω*, to digress.) Synonymous with *metastasis.*

METALLU'RGIA. (*a, æ.* f.; from *μεταλλον*, a metal, and *εργον*, work.) *Metallurgy.* That part of chemistry which relates to the treatment of metals.

METAL. (*Metallum, i.* n. *Μεταλλον.*) Metals are the most numerous class of undecompounded chemical bodies, distinguished by the following general characters: —

1. They possess a peculiar lustre, which

continues in the streak, and in their smallest fragments.

2. They are fusible by heat; and in fusion retain their lustre and opacity.

3. They are all, except selenium, excellent conductors both of electricity and caloric.

4. Many of them may be extended under the hammer, and are called malleable; or under the rolling press, and are called laminable; or drawn into wire, and are called ductile. This capability of extension depends, in some measure, on a tenacity peculiar to the metals, and which exists in the different species with very different degrees of force.

5. When their saline combinations are electrised, the metals separate at the resino-electric or negative pole.

6. When exposed to the action of oxygen, chlorine, or iodine, at an elevated temperature, they generally take fire; and, combining with one or other of these three elementary dissolvents in definite proportions, are converted into earthy or saline-looking bodies, devoid of metallic lustre and ductility, called oxides, chlorides, or iodides.

7. They are capable of combining in their melted state with each other, in almost every proportion, constituting the important order of metallic alloys; in which the characteristic lustre and tenacity are preserved.

8. From this brilliancy and opacity conjointly, they reflect the greater part of the light which falls on their surface, and hence form excellent mirrors.

General Table of the Metals.

NAMES.	Sp. gr.	Precipitants.	Colour of Precipitates by			
			Ferroprussiate of potash.	Infusion of galls.	Hydrosulphurets.	Sulphuretted hydrogen.
1 Platinum	21·47	Mur. ammon.	0	0		Black met. powd.
2 Gold	19·30	Sulph. iron / Nitr. mer.	Yellowish-white	Green ; met.	Yellow	Yellow
3 Silver	10·45	Common salt	White	Yel.-brown	Black	Black
4 Palladium	11·8	Prus. Mercury	Deep orange		Blackish-brown	Black-brown
5 Mercury	13·6	Common salt / Heat	White passing to yellow	Orange-yellow	Brownish-black	Black
6 Copper	8·9	Iron	Red-brown	Brown	Black	Ditto
7 Iron	7·7	Succin. soda / with perox.	Blue or White passing to blue	Protox. 0. / Perox. black	Black	0
8 Tin	7·29	Cor. sublim.	White	0	Protox. black / Perox. yellow	Brown
9 Lead	11·35	Sulph. soda	Ditto	White	Black	Black
10 Nickel	8·4	Sulph. potash ?	Ditto	Grey-white	Ditto	0
11 Cadmium	8·6	Zinc	Ditto	0	Orange-yellow	Orange-yellow
12 Zinc	6·9	Alk. carbonates	Ditto	0	White	Yellowish-white
13 Bismuth	9·88	Water	Ditto	Yellow	Black-brown	Black-brown
14 Antimony	6·70	Water / Zinc	With dilute solutions white.	White from water	Orange	Orange
15 Manganese	8	Tartr. pot.	White	0	White	Milkiness
16 Cobalt	8·6	Alk. carbonates	Brown-yellow	Yellow-white	Black	0
17 Tellurium	6·115	Water / Antimony	0	Yellow	Blackish	
18 Arsenic	8·35 ? / 5·76 ?	Nitr. lead	White		Yellow	Yellow
19 Chromium	5·90	Ditto	Green	Brown	Green	
20 Molybdenum	8·6	Ditto ?	Brown	Deep brown		Brown
21 Tungsten	17·4	Mur. lime ?	Dilute acids			
22 Columbium	5·6 ?	Zinc or inf. galls	Olive	Orange	Chocolate	
23 Selenium	4·3 ?	Iron / Sulphite amm.				
24 Osmium	?	Mercury		Purple passing to deep blue		
25 Rhodium	10·65	Zinc ?	0		0	
26 Iridium	18·68	Do. ?	0	0		
27 Uranium	9·0	Ferropr. pot.	Brown-red	Chocolate	Brown-yellow	0
28 Titanium	?	Inf. galls.	Grass-green	Red-brown	Grass-green	0
29 Cerium	?	Oxal. amm.	Milk-white	0	White	0
30 Potassium	0·865	Mur. plat. / Tart. acid.	0	0	0	0
31 Sodium	0·972					
32 Lithium						
33 Calcium						
34 Barium						
35 Strontium						
36 Magnesium						
37 Yttrium						
38 Glucinum						
39 Aluminum						
40 Thorinum						
41 Zirconium						
42 Silicium						

The first 12 are malleable; and so are the 30th, 31st, and 32d, in their congealed state.

The first 16 yield oxides which are neutral salifiable bases.

The metals 17, 18, 19, 20, 21, 22, and 23, are acidifiable by combination with oxygen. Of th oxides of the rest, up to the 30th, little is known. The remaining metals form, with oxygen, th alkaline and earthy bases.

9. Most of them combine in definite proportions with sulphur and phosphorus, forming bodies frequently of a semi-metallic aspect; and others unite with hydrogen, carbon, and boron, giving rise to peculiar gaseous or solid compounds.

10. Many of the metals are capable of assuming, by particular management, crystalline forms; which are, for the most part, either cubes or octohedrons.

All the metals are found in the bowels of the earth, though sometimes they are on the surface. They are met with in different combinations with other matters, such as sulphur, oxygen, and acids; particularly with the carbonic, muriatic, sulphuric, and phosphoric acids. They are also found combined with each other, and sometimes, though rarely, in a pure metallic state, distinguishable by the naked eye.

In their different states of combination, they are said to be mineralised, and are called *ores*. The ores of metals are, for the most part, found in nature in mountainous districts; and always in such as form a continued chain. There are mountains which consist entirely of iron ore, but, in general, the metallic part of the mountain bears a very inconsiderable proportion to its bulk. Ores are also met with in the cavities or crevices of rocks, forming what are termed *veins*, which are more easily discovered in these situations than when they lie level in plains.

The metallic matter of ores is very generally incrusted, and intermingled with some earthy substance, different from the rock in which the vein is situated; which is termed its *matrix*. This, however, must not be confounded with the mineralising substance with which the metal is combined, such as sulphur, &c.

The relations of the metals to the various objects of chemistry, are so complex and diversified, as to render their classification a task of peculiar difficulty. — *Ure*.

METALLIC. Of the nature of a metal, or consisting of metal.

Metallic brush. An instrument recommended by Westring for the purpose of conveying galvanism to a part. It consists of a plate of ebony fitted to another of gold, in which are fixed threads of the same metal. The brush is connected with the voltaic pile.

Metallic tractors. Towards the close of the last century, Dr. Elisha Perkins, of Norwich in Connecticut, introduced a method of treating diseases by drawing over the affected part two small metallic rods, made not of the same, but of different metals. These rods were called *metallic tractors*, and the operation was called *tractoration*. The use of tractors has been called *Perkinism*, as that of animal magnetism has been called *Mesmerism*. It is almost needless to say, that metallic tractors have no operation but on the fancy of the patient.

METALLOID. (From μεταλλον, a metal, and ειδος, resemblance.) The metallic bases of the alkalis and earths were at first called *metalloids*, but they are now classed with the metals.

METAPE'DIUM. (*um*, *ii*. n.; from μετα, after, and πους, the foot.) See *Metatarsus*.

METAPHRENUM. (*um*, *i*. n.; from μετα, after, and φρενες, the diaphragm.) That part of the back which is behind the diaphragm.

Metaporopoie'sis. (From μετα, πορος, a duct, and ποιεω, to make.) A morbid change in the extremities of the capillary vessels. — *Galen*.

METAPTO'SIS. (From μεταπιπτω, to digress.) A change or transition of one disease into another.

META'STASIS. (From μεθιστημι, to change, to translate.) The translation of a disease from one part to another: as that of gout to the stomach, or of rheumatism to the heart.

Metasy'ncrisis. (From μετασυγκρινω, to transmute.) Synonymous with *metaporopoiesis*.

Metasyncri'tica. Medicines calculated to remove a *metasyncrisis*.

METATARSAL. *Metatarsalis*. Belonging to the metatarsus.

METATA'RSUS. (From μετα, after, and ταρσος, the tarsus.) That part of the foot between the tarsus and toes. It consists of five longitudinal bones, which are distinguished into the metatarsal bone of the great toe, fore-toe, &c.

Mete'lla nux. See *Strychnos nux vomica*.

METEORI'SMUS. (*us*, *i*. m.; μετεωρισμος; from μετεωριζω, to raise on high.) A distension of the abdomen, or any part of it, with wind.

ME'TEOROLITE. A meteoric stone. A peculiar solid compound of earthy and metallic matters, of singular aspect and composition, which occasionally descends from the atmosphere, usually from the bosom of a luminous meteor. Meteoric stones are of various sizes, weighing from a few ounces to several hundred weights. Their composition appears to be very uniform, consisting in oxide of iron, metallic iron, pyrites, chromium, nickel, and earthy matters. The nickel has sometimes, though rarely, been absent; but the chromium seems to be a constant component. It has been supposed, by some philosophers, that meteorolites are discharged from volcanoes in the moon; but their frequent connexion with the appearance of meteors, renders it much more probable that they are of atmospheric origin, although the process by which they may be formed is entirely unknown.

METHE'GLIN. A drink prepared from honey by fermentation. It is often confounded with mead. It is made in the following way: Honey, one hundred weight; boiling water, enough to fill a thirty-two gallon cask, or half a hogshead: stir it well for a day or two, then add yeast and ferment. Some boil the honey in water with one ounce of hops to each gallon, for an hour or two; but this boiling hinders its fermentation.

Methemeri'nus. (Μεθημερινος; from μετα, and ημερα, a day.) Synonymous with quotidian.

METHODIC MEDICINE. Medicine as practised by the methodic sect. See *Methodici*.

METHO'DICI. A sect of ancient physicians, of which Themison was the head. They

endeavoured to reduce medicine to exact rules, and supposed that all diseases arose from constriction or rigidity of the fibres.

Methodus medendi. See *Therapia.*

METO'PION. Μετωπιον. An ointment used by the ancients, which was thus called because it had galbanum in it, which was called *Metopium* by the Egyptians. — *Dioscorides.*

METOROSCOPY. (*Metoposcopia*; from μετωπον, the forehead, and σκοπεω, to explore.) Synonymous with physiognomy.

METO'PUM. (*um, i.* n. Μετωπον; from μετα, after, and ωψ, the eye.) The forehead.

ME'TRA. (*a, æ.* f.; from μητηρ, a mother.) The womb. See *Uterus.*

METRE'NCHYTA. (From μητρα, the womb, and εγχυω, to pour into.) Injections for the womb.

METRE'NCHYTES. (From μητρα, the womb, and εγχυω, to pour in.) A syringe to inject fluids into the womb.

METRI'TIS. (*is, idis.* f.; from μητρα, the womb.) Inflammation of the womb. See *Hysteritis.*

METROCE'LE. (*is, idis.* f.; from μητρα, the womb, and κηλη, a tumour.) A vaginal hernia. See *Hernia vaginalis.*

METROMA'NIA. (*a, æ.* f.) This term has been used in two acceptations. 1. Synonymously with nymphomania, in which case it is derived from μητρα, the womb, and μανια, madness. 2. Synonymously with *musomania*, a strange form of disease, in which the patient recites verses extempore. In the latter case it is derived from μουσα, a song, and μανια, madness. See *Musomania*, in the Supplement.

METROPTO'SIS. (*is, is.* f.; from μητρα, the uterus, and πιπτω, to fall down.) *Prolapsus uteri.* The descent of the uterus through the vagina.

METRORRHA'GIA. (*a, æ.* f.; from μητρα, the womb, and ῥηγνυμι, to break out.) This term has been applied to hæmorrhage from the womb; but improperly, as it would signify rupture of the womb itself, not the bursting of blood from it.

Meʹu. See *Æthusa meum.*

ME'UM. (*um, i.* n.; from μειον, μηον.) *Meu.* See *Æthusa meum.*

Meum athamanticum. See *Æthusa.*

Merican seed. See *Ricinus.*

Mexican tea. See *Chenopodium ambrosioides.*

Mezereon. See *Mezereum.*

MEZE'REUM. (*um, ii.* n.; a word of some barbarous dialect.) *Mezereon.* See *Daphne.*

MEZEREUM ACETATUM. Thin slices of the bark of fresh mezereon root are to be steeped for twenty-four hours in common vinegar. Some practitioners direct this application to issues, when a discharge from them cannot be encouraged by the common means. It generally answers this purpose very effectually in the course of one night, the pea being removed, and a small portion of the bark applied over the opening. See *Daphne gnidium.*

MIA'SMA. (*a, atis.* n. Μιασμα; from μιαινω, to infect.) Miasma is a Greek word, importing pollution, corruption, or defilement generally; and contagion a Latin word, importing the application of such miasm or corruption to the body by the medium of touch. There is hence, therefore, says Dr. Good, neither parallelism nor antagonism, in their respective significations; there is nothing that necessarily connects them, either disjunctively or conjunctively. Both equally apply to the animal and vegetable worlds, or to any source whatever of defilement or touch, and either may be predicated of the other; for we may speak correctly of the miasm of contagion, or of contagion produced by miasm.

MICROCOSMIC SALT. A triple salt of soda, ammonia, and phosphoric acid, obtained from urine, and much used in assays with the blowpipe.

MICROGLO'SSIA. (From μικρος, small, and γλωσσα, the tongue.) Congenital smallness of the tongue, which, according to Andral, is owing to an arrest of development, so that only the hyoid portion of the organ exists.

MICROLEUCONYMPHÆA. (*a, æ.* f.; from μικρος, small, λευκος, white, and νυμφαια, the water-lily.) The small white water-lily.

MICRONYMPHÆ'A. (*a, æ.* f.; from μικρος, small, and νυμφαια, the water-lily.) The small water-lily.

MICRO'RCHIS. (*is, idis.* m.; from μικρος, small and ορχις, a testicle.) One whose testicles are unusually small.

MICROSPHY'XIA. (*a, æ.* f.; from μικρος, small, and σφυξις, the pulse.) A debility and smallness of the pulse.

Midriff. See *Diaphragma.*

MIDWIFE. A woman who assists other women in child-birth.

MIDWIFERY. That branch of medicine which relates to the management of parturition, and the treatment of women after delivery. The term is a barbarous one, and should be banished from scientific language. See *Obstetrics.*

MIGRA'NA. A corruption of *hemicrania.*

Milfoil. See *Achillea millefolium.*

MILIA'RIA. (*a, æ.* f.; from *milium*, millet: so called because the small vesicles upon the skin resemble millet-seed.) Miliary fever. A disease characterised by fever; cold stage considerable; hot stage attended with anxiety and frequent sighing; perspiration of a strong and peculiar smell; eruption, preceded by a sense of pricking, first on the neck and breast, of small red pimples, which in two days become white vesicles, desquamate, and are succeeded by fresh pimples. Miliary fever has been observed to affect both sexes, and persons of all ages and constitutions: but females of a delicate habit are most liable to it, particularly in child-bed. Moist variable weather is most favourable to its appearance, and it occurs most usually in the spring and autumn. It is by some said to be a contagious disease, and has been known to prevail epidemically.

Very violent symptoms, such as coma, delirium, and convulsive fits, now and then attend miliary fever, in which case it is apt to prove fatal. A numerous eruption indicates more danger than a scanty one. The eruption being steady is to be considered as more favourable

than its frequently disappearing and coming out again, and it is more favourable when the places covered with the eruption appear swelled and stretched than when they remain flaccid. According to the severity of the symptoms, and depression of the system, is the danger greater. The fever, and other symptoms of miliaria, point out the necessity of supporting the patient through the disease: but every thing that heats and stimulates the skin should be avoided. The bowels are to be kept open, by cooling laxatives of sulphate of magnesia in infusion of roses, cascarilla, colomba, and the like, which, with cooling drinks, light bed-clothes, and a cool atmosphere, will, in most instances, effect a cure.

When miliary eruptions come out in other diseases, it is generally from continued sweating, and requires bark, wine, and acids.

MILI'OLUM. (Diminutive of *milium*, millet.) A small tumour on the eye-lids, resembling in size a millet-seed.

Militaris herba. The *Achillea millefolium* was so called on account of its supposed virtues as a vulnerary.

MI'LIUM. (*um*, *ii*. n.; from *mille*, a thousand. So named from the great number of the seeds.) 1. Millet. See *Panicum mileaceum*.

2. A very white and hard tubercle, in size and colour resembling a millet-seed. Its seat is immediately under the cuticle, so that, when pressed, the contents escape, appearing of an atheromatous nature.

Milium solis. See *Lithospermum*.

MILK. *Lac*. A fluid secreted by peculiar glands, in the breasts of the class of animals called *Mammalia*, for the nourishment of their young. It is of an opake white colour, a mild saccharine taste, and a slightly aromatic smell. It is separated immediately from the blood, in the breasts or udders of female animals. Mammiferous animals alone secrete milk. All other animals are destitute of the organs which secrete this fluid. Milk differs greatly in the several animals.

The following are the general *Properties* of animal milk: —

Milk separates spontaneously into *cream*, *cheese*, and *serum of milk*; and that sooner in a warm situation than in a cold one. In a greater temperature than that of the air, it acesces, and coagulates, but more easily and quicker by the addition of acid salts, or coagulating plants. *Lime-water* coagulates milk imperfectly. It is not coagulated by pure *alkali*; which indeed dissolves its caseous part. With carbonated *alkali* the caseous and cremoraceous parts of milk are changed into a liquid soap, which separates in the form of white flakes; such milk, by boiling, is changed to a yellow and then to a brown colour. Milk, distilled to dryness, gives out an insipid water, and leaves a whitish brown extract, called the *extract of milk*, which, dissolved in water, makes a milk of less value. Milk fresh drawn, and often agitated in a warm place, by degrees goes into the vinous fermentation, so that alkohol may be drawn over by distillation, which is called *spirit of milk*. It succeeds quicker if yeast be added to the milk. Mares' milk, as it contains the greatest quantity of the sugar of milk, is best calculated for vinous fermentation.

The *Principles* of milk are,

1. The *aroma*, or odorous volatile principle, which flies off from fresh-drawn milk in the form of visible vapour.

2. *Water*, which constitutes the greatest part of milk. From one pound to eleven ounces of water may be extracted by distillation. This water, with the sugar of milk, and some salts, forms the *serum of the milk*.

3. *Bland oil*, which, from its lightness, swims on the surface of milk after standing, and forms the *cream of milk*. See *Cream*.

4. *Cheese*, separated by coagulating milk, falls to the bottom of the vessel, and is the animal gluten.

5. *Sugar*, obtained from the serum of milk by evaporation. It unites the caseous and butyraceous part with the water of the milk.

6. Some *neutral salts*, as the muriate of potash and muriate of lime, which are accidental, not being found at all times, nor in every milk. These principles of milk differ widely in respect to quantity and quality, according to the diversity of the animals.

The *aroma* of the milk is of so different an odour, that persons accustomed to the smell, and those whose olfactory nerves are very sensible, can easily distinguish whether milk be that of the cow, goat, mare, ass, or human. The same may be said of the serum of the milk, which is properly the seat of the aroma. The *serum* of milk is thicker and more copious in the milk of the sheep and goat, than in that of the ass, mare, or human milk. The *butter* of goats' and cows' milk is easily separated, and will not again unite itself with the butter-milk. Sheep's butter is soft, and not of the consistence of that obtained from the cow and goat. Ass's, mare's, and human butter can only be separated in the form of cream; which cream, by the assistance of heat, is with ease again united to the milk from which it is separated. The *cheese* of cows' and goats' milk is solid and elastic, that from asses and mares soft, and that from sheep's milk almost as soft as gluten. It is never separated spontaneously from the milk of a woman, but only by art, and is wholly fluid. The *serum* abounds most in human, ass's, and mare's milk. The milk of the cow and goat contain less, and that of the sheep least of all. The *sugar* of milk is in the greatest quantity in the mare's and ass's, and somewhat less in the human milk.

When milk is left to spontaneous decomposition, at a due temperature, it is found to be capable of passing through the vinous, acetous, and putrefactive fermentations. It appears, however, probably on account of the small quantity of alkohol it affords, that the vinous fermentation lasts a very short time, and can scarcely be made to take place in every part of the fluid at once by the addition of any ferment. This seems to be the reason why the Tartars, who make a fermented liquor, or wine, from mare's milk, called *koumiss*, succeed by using large quantities at a time, and agitating it very frequently. They add as a ferment a sixth part

of water, and an eighth part of the sourest cow's milk they can get, or a smaller portion of koumiss already prepared: cover the vessel with a thick cloth, and let it stand in a moderate warmth for 24 hours; then beat it with a stick, to mix the thicker and thinner parts, which have separated: let it stand again 24 hours in a high narrow vessel, and repeat the beating, till the liquor is perfectly homogenous. This liquor will keep some months, in close vessels, and a cold place; but must be well mixed by beating or shaking every time it is used. They sometimes extract a spirit from it by distillation. The Arabs prepare a similar liquor by the name of *leban*, and the Turks by that of *yaourt*. Eton informs us, that, when properly prepared, it may be left to stand till it becomes quite dry; and in this state it is kept in bags, and mixed with water when wanted for use.

The saccharine substance, upon which the fermenting property of milk depends, is held in solution by the whey, which remains after the separation of the curd in making cheese. This is separated by evaporation in the large way, for pharmaceutical purposes, in various parts of Switzerland. When the whey has been evaporated by heat, to the consistence of honey, it is poured into proper moulds, and exposed to dry in the sun. If this crude sugar of milk be dissolved in water, clarified with whites of eggs, and evaporated to the consistence of syrup, white crystals, in the form of rhomboidal parallelopipedons, are obtained.

Sugar of milk has a faint saccharine taste, and is soluble in three or four parts of water. It yields by distillation the same products that other sugars do, only in somewhat different proportions. It is remarkable, however, that the empyreumatic oil has a smell resembling flowers of benzoin. It contains an acid frequently called the *saccholactic*; but, as it is common to all mucilaginous substances, it is more generally termed mucic. See *Mucic acid*.

Milk, according to Berzelius, consists of,

Water, ...	928·75
Curd, with a little cream, ...	28·00
Sugar of milk, ...	35·00
Muriate of potash, ...	1·70
Phosphate of potash, ...	0·25

Milk, ass's. *Lac asininum.* Ass's milk has a very strong resemblance to human milk in colour, smell, and consistence. When left at rest for a sufficient time, a cream forms upon its surface, but by no means in such abundance as on women's milk. Ass's milk differs from cow's milk, in its cream being less abundant and more insipid; in its containing less curd; and in its possessing a greater proportion of sugar.

Milk, cow's. *Lac vaccinum. Lac bubulum.* The milk of women, mares, and asses, nearly agree in their qualities; that of cows, goats, and sheep, possess properties rather different. Of these, cow's milk approaches nearest to that yielded by the female breast, but differs very much in respect to the aroma; it contains a larger proportion of cream and cheese, and less serum, than human milk; also less sugar than mare's or ass's milk.

Cow's milk forms a very essential part of human sustenance, being adapted to every state and age of the body; but particularly to infants, after being weaned.

Milk, ewe's. *Lac ovillum.* This resembles almost precisely that of the cow; its cream, however, is more abundant, and yields a butter, not so consistent as cow's milk butter. It makes excellent cheese.

Milk, goat's. *Lac caprinum. Lac capræ.* It resembles cow's, except in its greater consistence; like that milk, it throws up abundance of cream, from which butter is easily obtained.

Milk, human. *Lac humanum.* The white, sweetish fluid secreted by the glandular structure of the breasts of women. The *secretory organ* is constituted by the great conglomerate glands situated in the fat of both breasts, above the musculus pectoralis major. From each acinus composing a mammary gland, there arises a radicle of a *lactiferous* or *galactiferous* duct. All these canals, gradually converging, are terminated, without anastomosis, in the papillæ of the breasts, by many orifices, which, upon pressure, pour forth milk. The smell of fresh-drawn milk is peculiar, animal, oleaginous, and not disagreeable; its taste sweetish, soft, bland, agreeable. Its specific gravity is greater than that of water, but it is lighter than blood; hence it swims on it. Its colour is white and opake. In consistence it is oily and aqueous. A drop put on the nail flows slowly down, if the milk be good.

Time of secretion. — The milk most frequently begins to be secreted in the last months of pregnancy: but on the third day after delivery, a serous milk, called *colostrum*, is separated; and at length pure milk is secreted so copiously in the breasts, that from its abundance it often spontaneously drops from the nipples.

If the secretion of milk be daily promoted by suckling an infant, it often continues many years, unless a fresh pregnancy supervene. The quantity usually secreted within twenty-four hours, by nurses, is various, according as the nourishment may be more or less chylous. It appears that not more than two pounds of milk are obtained from five or six pounds of meat. But there have been known nurses who have given from their breasts two, or even more than three pounds, in addition to that which their child has sucked. That the origin of the milk is derived from chyle carried with the blood of the mammary arteries into the glandular fabric of the breasts, is evident from its more copious secretion a little after meals; its diminished secretion from fasting; from the smell and taste of food or medicines in the secreted milk; and, lastly, from its occasional spontaneous *acescence*; for humours perfectly animal become putrid.

The *milk of a woman* varies, — 1. In respect

to *food*. The milk of a woman who suckles, living upon vegeto-animal food, never acesces nor coagulates spontaneously, although exposed for many weeks to the heat of a furnace. But it evaporates gradually in an open vessel, and the last drop continues thin, sweet, and bland. The reason appears to be that the caseous and cremoraceous parts cohere together by means of the sugar, more intimately than in the milk of animals, and do not so easily separate: hence its acescence is prevented. It does *acesce*, if mixed or boiled with vinegar, juice of lemons, supertartrate of potash, dilute sulphuric acid, or with the human stomach. It is *coagulated* by the acid of salt, or nitre, and by an acid gastric juice of the infant; for infants often vomit up the coagulated milk of the nurse. The milk of a suckling woman, who lives upon vegetable food only, like cow's milk, easily and of its own accord acesces, and is acted upon by all coagulated substances, like the milk of animals. 2. In respect *of the time of digestion*. During the first hours of digestion the chyle is crude, and the milk less subacted; but towards the twelfth hour after eating, the chyle is changed into blood, and then the milk becomes yellowish and nauseous, and is spit out by the infant. Hence the best time for giving suck is about the fourth or fifth hour after meals. 3. In respect *of the time after delivery*. The milk secreted immediately after delivery, which is called *colostrum*, is very thin and serous. In the course of a few days, however, it becomes thicker and more pure, and the longer a nurse suckles, the thicker the milk is secreted; thus new-born infants cannot retain the milk of a nurse who has given suck for a twelvemonth, on account of its spissitude. 4. In respect *of food and medicines*. Thus, if a nurse eat garlic, the milk becomes highly impregnated with its odour, and is disagreeable. If she indulge too freely in the use of wine or beer, the infant becomes ill. From giving a purging medicine to a nurse, the child also is purged; and, lastly, children affected with tormina of the bowels, arising from acids, are often cured by giving the nurse animal food. 5. In respect *of the affections of the mind*. Much less is believed on this subject now than formerly; but we are told of infants being seized with convulsions from sucking mothers irritated by anger; and also that infants at the breast in a short time pine away, if the nurse be afflicted with grievous care. 6. In respect of *certain functions of the mother*: thus we are told that coition and menstruation sometimes affect the health of the child.

The uses of the mother's milk are, — 1. It affords the natural *aliment* to the new-born infant. Those children are the strongest who are nourished the longest by the mother's milk. 2. The *colostrum* is said to have a laxative power, and to purge off the meconium; for which opinion, however, there seems to be no sufficient foundation. 3. *Lactation* defends the mother from a dangerous reflux of the milk into the blood, whence lacteal metastasis, and leucorrhœa, are so frequent in lying-in women who do not give suck. The motion of the milk also being so hastened through the breast by the sucking of the child, prevents the very common induration of the breast, which arises in consequence of the milk being stagnated. 4. Adults may live upon milk, unless they have been accustomed to the drinking of wine. For all nations, the Japanese alone excepted, use milk, and many live upon it principally.

Milk, mare's. *Lac equinum*. This is thinner than that of the cow, but scarcely so thin as human milk. Its cream cannot be converted into butter by agitation. The whey contains sugar.

Milk-blotch. The *crusta lactea*, a species of porrigo. See *Porrigo larvalis*.

Milk-fever. See *Febris lactea*.

Milk-teeth. See *Teeth*.

Milk-thistle. See *Carduus marianus*.

Milk-vetch. See *Astragalus excapus*.

Milk-wort. See *Polygala vulgaris*.

Milk-wort, rattle-snake root. See *Polygala senega*.

Millefo'lium. (*um, ii.* n.; from *mille*, a thousand, and *folium*, a leaf: named from its numerous leaves.) Milfoil. See *Achillea millefolium*.

Millemo'rbia. (From *mille*, a thousand, and *morbus*, a disease: so called from its use in many diseases.) See *Scrofularia nodosa*.

MI'LLEPES. (*es, edis.* m.; from *mille*, a thousand, and *pes*, a foot: named from its numerous feet.) Several insects are known under this name, and have been confounded with each other in the pharmacopœias, in which they once had a place. These insects are, 1. The *Armadillo vulgaris*, or *officinalis*, commonly called the pill millepede; 2. The *porcellio scaber*, formerly prized in Scotland, and called in the vernacular language of that country *sclater*; 3. The *oniscus asellus*, or common wood-louse. All these insects have had medicinal virtues ascribed to them. See their respective titles.

Millet. See *Panicum miliaceum*.

Millet, Indian. See *Panicum italicum*.

Mill-mountain. See *Linum*.

Milpho'sis. Μιλφωσις. A baldness of the eyebrows.

Mi'ltos. Μιλτος. Red lead.

Miltwaste. See *Asplenium ceterach*.

Milzade'lla. (From *milza*, the Spanish for the spleen: so called from its supposed virtues in diseases of the spleen.) See *Angelica archangelica*.

MIMO'SA. (*a, æ.* f.; from *mimus*, an actor, or imitator, meaning a sort of imitative plant, the motions of which mimic the sensibility of animal life.) The name of a genus of plants in the Linnæan system. Class, *Polygamia*; Order, *Monœcia*. The sensitive plant.

Mimosa catechu. See *Acacia catechu*.

Mimosa nilotica. See *Acacia vera*.

Mimosa senegal. See *Acacia vera*.

MIND. This term, like *life*, is used in two acceptations: in the one, it signifies the phenomena arising from the exercise of the power of thinking; in the other, it signifies the thinking power or principle itself. Some philosophers regard the phenomena of thought merely as a function of the brain, just as the secretion of bile is a function of the liver: these philoso-

phers are called *materialists.*" The greater part of reasoning men, however, have always regarded the mental phenomena as appertaining to a distinct, incorporeal being, called the *soul*, connected with the body by some relation which is beyond our comprehension. Without pretending to dogmatise on the subject, we humbly conceive, that the latter will ever be the opinion of persons endowed with common sense, and not mystified by false philosophy. However this may be, it is manifest that man possesses certain faculties, which are called *sensation*, *association*, *memory*, *imagination*, *judgment*, and *will*.

1. *Sensation* gives rise to simple ideas.

2. *Association* combines simple ideas, to form those which are complex.

3. *Memory* is the power by which ideas are retained, and recalled in the order in which they were originally impressed on the mind.

4. *Imagination* combines the ideas of things which have been actually perceived, to form a whole which has no existence but in the mind: thus we may imagine a landscape, such as we never saw, but it will be composed of the ideas of objects which we have seen.

5. *Judgment* is the power by which we compare the ideas acquired by the exercise of the other faculties, determine their relations, and discern truth from falsehood.

6. *Will* is the power which determines to action, and rules those functions which are called *voluntary*, as opposed to those which are involuntary: thus we are able, by the exercise of the will, to apply the mind to the investigation of any subject; but we cannot, by an effort of the will, prevent certain ideas from rising in the mind at the sight of certain objects: again, we can by an effort of the will, throw any of the voluntary muscles into action, or restrain that action, but we cannot by any effort of the will, accelerate or restrain the action of the heart.

Perception has been sometimes considered as a primary power of the mind, but an attentive consideration of the subject will easily show, that it results from the combined exercise of sensation and association.

It is evident that the greater part of our ideas are originally derived from sensation, and according to the doctrine of Locke, all our ideas whatsoever are derived from the ideas of sensation, and the minds own operation upon them. Other metaphysicians again contend that certain ideas are innate, and present to the mind from its first existence. This is too large a question to be discussed here.

A very singular view of the constitution of the mind, and one in many respects much opposed to the opinions of the greatest metaphysicians, has been promulgated by Drs. Gall and Spurzheim. See *Phrenology*.

MINERAL. (*Mineralis*; from *mina*, a mine of metal.) The term mineral is properly applied to any inorganic substance, but it is frequently applied also, to substances found in the bowels of the earth, which in reality are of organic origin, as some kinds of coal, &c.

MINERAL KINGDOM. That department of nature, which includes minerals or inorganic bodies.

Mineral acids. See *Acid, mineral.*

Mineral caoutchouc. See *Caoutchouc.*

MINERAL OIL. Petroleum.

MINERAL PITCH. Bitumen.

Mineral poisons. See *Poisons.*

Mineral salts. See *Salts.*

MINERAL WATERS. *Aquæ minerales.* Natural springs of water are found in many places which are so strongly impregnated with substances foreign to the common composition of water, that they exert some marked action on the animal economy, and are hence unfit for the ordinary purpose of drinking, while they are, in many instances, medicines of great power and utility.

Mineral waters may be arranged into the five following classes: — 1. ACIDULOUS WATERS; 2. ALKALINE WATERS; 3. CHALYBEATE WATERS; 4. SULPHUREOUS WATERS; 5. SALINE WATERS. We shall first give a sketch of the physical characters and medicinal properties of each of these classes; and then describe the method of determining the ingredients, and their proportions, contained in any mineral water.

1. ACIDULOUS WATERS owe their properties chiefly to carbonic acid. They sparkle when drawn from the spring, or when poured into a glass; have an acidulous taste, and become vapid when exposed to the air. Besides free carbonic acid, on the presence of which these qualities depend, acidulous waters contain generally also carbonates of soda, bicarbonates of lime, of magnesia, and of iron.

They may be divided into *thermal*, or *warm acidulous waters*, and *cold acidulous waters*; the temperature of the former, however, does not exceed 72°, while that of the latter is generally about 55°.

Of this kind are the springs of Cleves in Germany; Granshaw in Ireland; Languac, Upper Loire; Orston, and Thorston, Nottinghamshire; Passi, near Paris; Stonefield, Lincolnshire; Tonstein in Germany; Wisbaden, in Nassau; and Bandola in Italy; but the most celebrated springs of this class are Pyrmont, Seltzer, Spa, and Carlsbad. They are tonic and diuretic; and in large doses produce a sensible degree of exhilaration. They all afford a grateful and moderate stimulus to the stomach; but the Pyrmont and Spa, containing carbonate of iron, are especially useful in all cases of impaired digestion; while those which contain alkaline carbonates, as the Carlsbad and Seltzer, are more particularly employed as palliatives in calculous affections.

2. ALKALINE WATERS owe their properties to a free alkali, or one very slightly carbonated. They display an alkaline reaction. Alkaline springs are not very numerous.

3. CHALYBEATE WATERS owe their properties to iron, in combination generally with carbonic acid; and as this is usually in excess, they are often acidulous as well as chalybeate. The metal is found also in the form of a sulphate, but the instances of this are very rare.

Chalybeate waters have a styptic or inky taste; they are, when newly drawn, transparent, and strike a black with tincture of nut-galls; but an ochry sediment, a hydrated peroxide of iron,

soon falls, and the water loses its taste. If the iron be in the state of sulphate and hydrochlorate, however, no sediment falls; and the black colour is produced by the above test, even after the water has been boiled and filtered. Chalybeate springs are very numerous. On the Continent are those of Abcourt, St. Germain; Aumale and Forges, near Rouen; Bologne; Buzot, in Spain (*a warm spring*); Caroline baths, Bohemia; Daswild, Baden, Germany; Driburgin, Westphalia; Naptha, in Russia; Nisdeniee, in Germany; Swalbach, in Nassau, Ponges, Hassenfratz; Perekop, Russia; Sarepta, Russia; Scolliensis, Switzerland; Suchalda, Hungary; and Vechy, near Moulins. There are many chalybeates in Great Britain; as, for instance, those of Arbroath and Peterhead in Scotland; Ashton, in Wiltshire; Balemore, Worcestershire; Ballycastle, Antrim; Ballynahinch, Down; Ballyspellan, Kilkenny; Bandon, Cork; Bromley, Kent; Brownstown, Kilkenny; Castlecomer, Kilkenny; Castleconnel, Limerick; Castlemain, Kerry; Coalcullen, Kilkenny; Corville, Tipperary; Coventry; Crosstown, Waterford; Doneraile, Cork; Dunnard, Dublin; Galway; Garry-hill, Carlow; Haigh, Lancashire; Hampstead; Hartfell, Scotland; Islington; Kilcoran, Clare; Kilagee, Down; Kirby, Westmoreland; Lancaster; Llandridad, Wales; Luz, Essex; Listerlin, Kilkenny; Milltown, Mallay, Clare; Newton Stuart, Tyrone; Oakfield, Cavan; Phœnix Park, Dublin; Scool, Clare; Shadwell, near London; Somersham, Huntingdonshire; and many others: but the most celebrated are Tunbridge, Brighton, and Peterhead; the Cheltenham spring also contains carbonate of iron; but on account of the large proportion of saline matter, and its strong purgative properties, it is not ranked in this class. The Spa springs also belong to this class.

Chalybeate waters are powerful tonics, and are employed in dyspepsia, scrofulous affections, cancer, amenorrhœa, chlorosis, and the other diseases of debility for which the artificial preparations of iron are used. Much of the benefit derived from the use of chalybeate waters depends on the extreme division of the metallic salts they contain, as well as the vehicle in which it is held in solution; while at the same time their operation is much modified by the carbonic acid by which the iron is suspended. When the water is a carbonated chalybeate, it should be drunk the moment it is drawn from the spring; but the same precaution is not necessary with a water containing sulphate of iron.

4. Sulphureous Waters derive their character chiefly from sulphuretted hydrogen gas; which in some of them is uncombined, while in others it is united with lime or an alkali. They are transparent when newly drawn from the spring, and have the fœtid odour of rotten eggs, which is gradually lost by exposure to the air, and the water becomes turbid. When they are strongly impregnated with the gas, they redden infusion of litmus; and, even in a weak state, they blacken silver and lead. Besides containing sulphuretted hydrogen gas, they are not unfrequently, also, impregnated with carbonic acid. They generally contain chloride of magnesium, or other saline matters, which modify their powers as a remedy.

The most important sulphureous springs in this island are those of Kilburn, Harrowgate, and Moffat; but the following are also of some note: — Annaduff, Leitrim; Askeron in Yorkshire; Broughton in Yorkshire; Clonmel, Tipperary; Codsalwood, Staffordshire; Derrylister, Cavan; Drumasnane, Leitrim; Dudley, Worcestershire; Kedlistone, Derbyshire; Killashen, Fermanagh; Loansbury, Yorkshire; Maudley, Lancashire; Nottington, Dorsetshire; Ripon, Yorkshire; Shapmoor, Westmoreland; Wardrew, Northumberland; and Wirksworth in Derbyshire. On the Continent, Aix-la-Chapelle; Barège; Baden; Baia, Italy; Dux, Bayonne; Ems, Germany; Montmorency, near Paris; Motte, near Grenoble; Viterbo, in Italy; and St. Amands, near Valenciennes; which are resorted to chiefly for the cure of cutaneous eruptions, and are applied locally as well as drunk. They are slightly sudorific and diuretic, and are apt to occasion in some patients headach of short duration, directly they are drunk. They are also employed for curing visceral and scrofulous obstructions, torpor of the intestines, and some dyspeptic and hypochondriacal cases.

5. Saline Mineral Waters owe their properties altogether to saline compounds. Those which predominate, and give their character to the waters of this class, are either,

1. Salts, the basis of which is lime;
2. Chlorides of sodium and magnesium;
3. Sulphate of magnesia;
4. Alkaline carbonates; particularly carbonate of soda.

They are mostly purgative, the powers of the salts they contain being very much increased by the large proportion of water in which they are exhibited. The most celebrated saline springs are those of Cheltenham, Leamington, Bristol, Kinalton, Pancras near London, Scarborough, Sydenham, and Thirsk in Yorkshire, in England; Pitcaithly, in Scotland; and Seidlitz on the Continent. They are employed in diseases which require continued and moderate intestinal evacuations; such as dyspepsia, hypochondriasis, chronic hepitatis, jaundice, and strumous swellings. They are more grateful to the stomach when carbonic acid also is present; and when they contain iron, as in the case of the Cheltenham spring, their tonic powers, combined with their purgative qualities, render them still more useful in dyspeptic complaints and amenorrhœa.

To this class the water of the ocean belongs. The quantity of saline matter Sea Water contains varies in different latitudes; thus, between 10° and 20° it is rather more than $\frac{1}{24}$; at the equator it is $\frac{1}{25}$; and at 57° north it is only $\frac{1}{27}$. The saline ingredients, in 10·000 parts of seawater, according to the last analysis of Dr. Murray, are chloride of sodium, 220·01; chloride of calcium, 7·84; chloride of magnesium, 42.08; and sulphate of soda, 33·16. When brought up from a great depth, its taste is purely saline; but when taken from the surface it is disagreeably bitter, owing, perhaps to the animal and vegetable matters suspended in it. Its specific gravity varies from 1·0269 to 1·0285; and it does

not freeze until cooled down to 28·5° Fahrenheit. Its medicinal properties are the same as those of the saline purging waters, but more powerful; and as a bath, its efficacy is much superior to that of fresh water.

The general effects of mineral waters are modified by temperature, whether they be taken internally, or be externally applied. In some springs, as those of Bath, Matlock, Buxton, Wildbad in Germany, Bagnols in France, Bonnes in the Lower Pyrenees, Borset near Aix-la-Chapelle, Canteries in the Upper Pyrenees, Digne in the Lower Alps, Klintschysela in Russia, Lucca in Italy, Plombieres in Lorraine, and Pontigibault in France: their virtues depend almost altogether on temperature; and in others, as Malvern, which has been found to contain scarcely any foreign matter, the simple diluent power of the pure water seems to produce the benefit that results from drinking them. Some of the good effects of all of them, however, must be allowed to proceed from change of scene, relaxation from business, amusement, temperance, and regular hours; and in these circumstances, the drinking the waters at the springs possesses advantages which cannot be obtained from artificial waters, however excellent the imitations may be; nor even from the natural waters, when bottled and conveyed to a distance from the springs. — *A. T. Thomson.*

Some more particular account of the principal mineral waters will be found under their respective heads.

For the method of analysing mineral waters we must refer the reader to the treatises on chemistry.

Mineralis. See *Mineral.*

MINERALISED. Metallic substances are said to be mineralised when deprived of their usual properties by combination with some other substance.

MINERA'LOGY. (*Mineralogia*, *æ*, f.; from *mineralis*, a mineral, and λογος, a discourse.) That part of natural history which relates to minerals. See *Mineral.*

MINIA'TUS. A dull red: applied, in *Natural History*, to designate colour. See *Colour.*

Minim. See *Minimum.*

MI'NIMUM. (*um*, *i.* n.) A minim. The sixtieth part of a fluid drachm. An important change has been adopted in the London Pharmacopœia, for the mensuration of liquids, and the division of the wine pint, to insure accuracy in the measurement of quantities of liquids below one drachm. The number of drops contained in one drachm has been assumed to be sixty; and taking water as a standard, this number, though by no means accurate, would still be sufficient for ordinary purposes; but when other liquids of less specific gravity are used, a much larger number is required to fill the same measure, as of proof spirit, 140 drops are required to equal the bulk of 60 of water, dropped from the same vessel. If, therefore, in the composition of medicines, measures suited to the standard of water were used occasionally only, and it was generally assumed that 60 drops were equal to one fluid drachm, and one fluid drachm was substituted for 60 drops prescribed, twice the dose intended would be given. There are further objections to the use of drops; that their bulk is influenced by the quantity of liquid contained in the bottle from which they fall, by the thickness of the lip, and even by the inequalities on the surface of the lip of the same bottle; that volatile liquids, to which this mode is most commonly applied, are thus exposed with extensive surfaces, and their evaporation promoted; and, on all these accounts, the adoption of some more accurate, convenient, and uniform measure became necessary. The subdivision of the wine pint has, therefore, been extended to the sixtieth part of the fluid drachm, which is termed minim; and glass measures, expressive of such subdivision, have been adopted by the college.

MI'NIUM. Red oxide of lead. See *Lead.*

MINIUM GRÆCORUM. Native cinnabar.

Mint. See *Mentha.*

Mint, pepper. See *Mentha piperita.*

Mint, water. See *Mentha aquatica.*

Miscarriage. See *Abortion.*

MISERE'RE MEI. (*Have compassion on me*; so named from its torments.) Ileus was formerly so called. See *Ileac passion.*

Mislaw. See *Musa paradisiaca.*

Misletoe. See *Viscum.*

MISTU'RA. (*a*, *æ*. f.) A mixture. A fluid composed of two or more ingredients. It is mostly contracted in prescriptions thus, *mist.* e. g. — *f. mist.*, which means, let a mixture be made.

MISTURA ACACIÆ. (*Mucilago acaciæ.*) Mixture of acacia. Mucilage of gum-arabic. Take of acacia powdered, ten ounces; boiling water, a pint. Rub the acacia with the water gradually poured in till it be dissolved. For its uses, see *Acacia vera.*

MISTURA AMMONIACI. *Lac ammoniaci.* Mixture of ammoniacum. Take of ammoniacum, five drachms; water, a pint; rub the ammoniacum with the water gradually added, till they are thoroughly mixed.

MISTURA AMYGDALÆ. *Lac amygdalæ.* Almond mixture, or emulsion. Take of almond confection, two ounces and a half; distilled water, a pint; gradually add the water to the almond confection, rubbing them together, till properly mixed; then strain.

MISTURA ASSAFŒTIDÆ. *Lac assafœtidæ.* Mixture of assafœtida. Take of assafœtida, five drachms; water, a pint: rub the assafœtida with the water, gradually poured in till they are thoroughly mixed.

MISTURA CAMPHORÆ. Camphor mixture. Camphor julep. Take of camphor, half a drachm; rectified spirit, ten minims; water, a pint. First rub the camphor with the spirit, then with the water gradually added, and strain the liquor. A very elegant preparation of camphor, for delicate stomachs, and those which cannot bear it in substance, as an antispasmodic and nervine. There is a great loss of camphor in making it as directed by the Pharmacopœia. Water can only take up a certain quantity. For its virtues, see *Laurus camphora.*

MISTURA CASCARILLÆ COMPOSITA. Compound mixture of cascarilla. Take of infusion of cascarilla, seventeen fluid ounces: vinegar of squill, a fluid ounce; compound tincture of camphor, two fluid ounces. Mix.

A tonic and expectorant preparation. It is useful in chronic bronchitis, &c. Dose ℥j. or ℥jss. twice or three times a day.

Mistura cornu usti. *Decoctum album.* Decoction of hartshorn. Take of hartshorn, burnt and prepared, two ounces; acacia gum, powdered, an ounce; water, three pints. Boil down to two pints, constantly stirring, and strain. This is a much weaker absorbent than the mistura cretæ, but is much more agreeable to most people. It forms an excellent drink in fevers attended with diarrhœa, and acidities of the primæ viæ.

Mistura cretæ. Chalk mixture. Cretaceous mixture. Take of prepared chalk, half an ounce; sugar, three drachms; mixture of acacia, a fluid ounce and a half; cinnamon water, eighteen fluid ounces. Mix. A very useful and pleasant form of administering chalk as an astringent and antacid. It is particularly calculated for children, in whom it allays the many deranged actions of the primæ viæ, which are produced by acidities. Dose, one ounce to three, frequently. See *Creta*, and *Carbonas calcis.*

Mistura ferri composita. — Take of myrrh, powdered, two drachms; carbonate of potash, a drachm; rose water, eighteen fluid ounces; sulphate of iron, powdered, two scruples and a half; spirit of nutmeg, a fluid ounce; sugar, two drachms. Rub together the myrrh, the spirit of nutmeg, and the carbonate of potash; and, during the trituration, add gradually, first, the rose-water with the sugar, and last, the sulphate of iron. Pour the mixture immediately into a proper glass vessel, and stop it. This preparation is the celebrated mixture of Dr. Griffiths. A chemical decomposition is effected in forming this mixture, a subcarbonate of iron is formed, and a sulphate of potash.

Mistura gentianæ composita. Compound mixture of gentian. Take of compound infusion of gentian, twelve fluid ounces; compound infusion of senna, six fluid ounces; compound tincture of cardamom, two fluid ounces. Mix. A laxative and tonic mixture introduced into the London Pharmacopœia of 1836. Dose ℥j. to ℥js.

Mistura guai'aci. — Take of guaiacum resin, three drachms; sugar, half an ounce; mixture of acacia, half an ounce; cinnamon water, nineteen fluid ounces. Rub the guaiacum with the sugar, then with the mixture of acacia; and, when they are mixed, pour on the cinnamon-water gradually, rubbing them together. For its virtues, see *Guaiacum.*

Mistura moschi. — Take of musk, acacia, powdered, sugar, of each three drachms; rose-water, a pint. Rub the musk first with the sugar, then with the gum, and add the rose-water by degrees. An excellent antispasmodic. It is by far the best form for administering musk, when boluses cannot be swallowed. Dose, one ounce to three frequently.

Mite. See *Acarus.*

Mithridate mustard. See *Thlaspi campestre.*

MITHRIDA'TIUM. (*um, ii.* n.; so named after Mithridates, king of Pontus and Bithynia, who, experiencing the virtues of the simples separately, afterwards combined them.) *Mithridate. Confectio Damocratis. Theriaca Andromachi. Theriaca Veneti.* This composition originally consisted of but few ingredients; viz. twenty leaves of rue, two walnuts, two figs, and a little salt: of this we are informed that Mithridates took a dose every morning, to guard himself against the effects of poison. It was afterwards altered, and the number of ingredients increased to sixty-one. In this more complex form it contained opium, and was in effect an aromatic opiate, of which the opiate confection of the present day may be considered as a simplification. The mithridate is still prepared in some shops, and is occasionally, though very rarely, prescribed. The dose is from ten grains to a scruple.

Mitral valve. *Valvula mitralis.* The valve at the orifice of the left ventricle of the heart: so named from its resemblance to a mitre.

Mi'va. An old name of marmalade.

Mixed fever. See *Synochus.*

MIXTURE. 1. In *Pharmacy.* See *Mistura.*

2. In *Chemistry*, mixture should be distinguished from solution: in the former, the aggregate particles can again be separated by mechanical means, and the proportion of the different particles determined; but, in solution, no mechanical power whatsoever can separate them.

Mochli'a. (Μοχλια. Μοχλεια from μοχλευω, to use a lever.) The reduction of a dislocated bone.

MODI'OLUS. (*us, i.* m.; diminutive of *modius*, a measure.) The central pillar of the cochlea of the ear. See *Auris.*

Mofette. See *Nitrogene.*

MOFFAT. A village situated about fifty-six miles south-west of Edinburgh. It affords a cold sulphureous water, of a very simple composition: when first drawn, it appears rather milky and bluish; the smell is exactly similar to that of Harrowgate: the taste is sulphureous and saline, without any thing bitter. It sparkles somewhat on being poured from one glass into another.

According to Dr. Garnett's analysis, a wine gallon of Moffat water contains thirty-six grains of muriate of soda, five cubic inches of carbonic acid gas, four of azotic gas, and ten of sulphuretted hydrogen, making altogether nineteen cubic inches of gas. Moffat water, therefore, is not very dissimilar in composition to the sulphureous springs of Harrowgate, with which also it agrees in medicinal efficacy. If kept in an open vessel it soon loses the hepatic gas, on which depends the greatest part of its medicinal power. The only sensible effect of this water is that of increasing the flow of urine; when it purges, it appears to do so rather from the excessive dose than from its mineral ingredients. This water appears to be useful chiefly in cutaneous eruptions, and, as an external application at an increased temperature, scrofula in its early stage, is thought to be alleviated by it. It is also used as an external application to irritable ulcers, and is recommended in dyspepsia, and in torpid states of the alimentary canal.

Mogila'lia. (From μογις, with difficulty, and λαλεω, to speak.) A difficulty of articulating certain syllables.

MO'LA. (*a, æ.* f.) 1. The knee-pan: so named because it is shaped like a millstone.

2. A mole, or shapeless mass of flesh in the uterus. See *Mole.*

MOLARES DENTES. (*Molarisa*, millstone.) The grinding-teeth. See *Teeth.*

MOLARES GLANDULÆ. Molar glands. Two salivary glands situated on each side of the mouth, between the masseter and buccinator muscles, the excretory ducts of which open near the last dens molaris.

Molasses. See *Saccharum officinale.*

Molassic. See *Melassic.*

Moldavica. See *Dracocephalum.*

MOLE. *Mola.* By this term authors have intended to describe different productions of, or excretions from, the uterus.

By some it has been used to signify every kind of fleshy substance, particularly those which are properly called polypi; by others, those only which are the consequence of imperfect conception, or when the ovum is in a morbid or decayed state; and by many, which is the most popular opinion, every coagulum of blood which continues long enough in the uterus to assume somewhat of an organised form, and to have only the fibrous part, as it has been called, remaining, is denominated a mole. There is surely much impropriety, says Dr. Denman, in including, under one general name, appearances so contrary, and substances so different.

1. For an account of the first kind, see *Polypus.*

2. Of the second kind, which has been defined as an *ovum deforme*, as it is the consequence of conception, it might more justly be arranged under the class of monsters; for, though it has the appearance of a shapeless mass of flesh, if examined carefully with a knife, various parts of a child may be discovered, lying together in apparent confusion, but in actual regularity. The pedicle also, by which it is connected to the uterus, is not of a fleshy texture, like that of the polypus, but has a regular series of vessels like the umbilical cord, and there is likewise a placenta and membranes containing water. The symptoms attending the formation, growth, and expulsion of this apparently confused mass from the uterus, correspond with those of a well-formed child.

3. With respect to the third sort of mole, an incision into its substance will discover its true nature; for, although the external surface appears at the first view to be organised flesh, the internal part is composed merely of coagulated blood. As substances of this kind, which mostly occur after delivery, would always be expelled by the action of the uterus, there seems to be no reason for a particular inquiry, if popular opinion had not annexed the idea of mischief to them, and attributed their formation or continuance in the uterus to the negligence or misconduct of the practitioner. Hence the persuasion arose of the necessity of extracting all the coagula of blood out of the uterus, immediately after the expulsion of the placenta, or of giving medicines to force them away; but abundant experience has proved that the retention of such coagula is not, under any circumstances, productive of danger, and that they are most safely expelled by the action of the uterus, though at very different periods after their formation.

MO'LECULE. The smallest particles into which a mass can be conceived to be divided. Molecules are distinguished into integrant and constituent. *Integrant molecules* are the smallest particles into which a simple body can be conceived to be divided, or the smallest particles into which a compound body can be conceived to be divided without being resolved into its elements. *Constituent molecules* are the molecules of each element which form an integrant molecule of a compound.

MOLENDINA'CEOUS. (From *mola*, a mill.) Like a windmill; resembling the sails of a windmill. Applied in botany to seeds which have many wings. See *Ala.*

Molle. See *Schinus molle.*

MOLLIFICA'TIO. (Low Latin.) Softening. Relaxation. Applied to a palsy arising from relaxation of the muscles.

MOLLI'TIES. (*es, ei.* f.; from *mollis*, soft.) A softness: applied to bones, nails, and other parts.

Mollities ossium. See *Malacosteon.*

MOLLITIES UNGUIUM. A preternatural softness of the nails: it often accompanies chlorosis.

MOLLU'SCA. (From *mollis*, soft.) A great division of invertebral animals. See *Animal kingdom.*

MOLLUSCUM. A tubercular disease of the skin, characterised by the appearance of numerous tubercles, of slow growth and little sensibility, and of various sizes, from that of a vetch to that of a pigeon's egg. These contain an atheromatous matter, and are of various forms, some being sessile, globular, or flattish, and some attached by a neck, and pendulous. The growth of the tubercles is apparently unconnected with any constitutional disorder: they show no tendency to inflammation or ulceration; but continue through life, having apparently no natural termination. A very extraordinary instance of this cutaneous deformity, which occurred in a poor man, who was living in good health at Muhlberg, in 1793, and whose body, face, and extremities were thickly studded with these atheromatous tubercles, has been described by Professor Tilesius, who has given portraits of the naked patient in three positions, in a pamphlet, edited at Leipsic, in that year, by Professor Ludwig.

Molluccense lignum. See *Croton.*

MO'LY. Μολυ. The specific name of a species of garlic, the *Allium moly* of Linnæus. An herb called *moly* is celebrated by Homer as the means by which Ulysses resisted the enchantments of Circe. What herb the moly of Homer was, can now only be matter of conjecture.

MOLY'BDATE. *Molybdas.* A salt formed by the union of the molybdic acid with salifiable bases: thus, *molybdate of antimony*, &c.

MOLYBDE'NUM. (*um, i.* n.; from μολυβδος, lead.) *Molybdena.* A metal which exists mineralised by sulphur in the ore, called *sulphuret of molybdena.* This ore, which is very scarce, is so similar in several of its properties to plumbago, that they were long considered as

varieties of the same substance: and it is the only one known which contains this metal, for the accurate analysis of which we are indebted to Mr. Hatchet.

MOLY'BDIC. (*Molybdicus*, from *molybdenum*, its base.) The name of an acid.

Molybdic acid. *Acidum molybdicum*. The native sulphuret of molybdenum being roasted for some time, and dissolved in water of ammonia, when nitric acid is added to this solution, the molybdic acid precipitates in fine white scales, which become yellow on melting and subliming them. It changes the vegetable blues to red, but less readily and powerfully than the molybdous acid.

Molybdena. See *Molybdenum*.

Molybditis. See *Molybdenum*.

Moly'bdos. (Μολυβδος.) Lead.

Molybdous acid. *Acidum molybdosum*. This forms salts with different alkaline, earthy, and metallic bases.

Moly'za. (Diminutive of μωλυ, moly.) A kind of garlic mentioned by Hippocrates.

Momi'scus. (From μωμος, a blemish.) That part of the teeth which is next the gums, and which is often covered with a foul tartareous crust.

MOMO'RDICA. (*a*, *æ*. f.; from *mordeo*, to bite, from its sharp taste.) The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Syngenesia*.

Momordica elaterium. The systematic name of the wild or squirting cucumber; called also, *Elaterium*, *Cucumis agrestis*, *Cucumis asininus*, *Cucumis sylvestris*, *Elaterium officinarum*, *Boubalios*, *Charantia*, and *Guarerba orba*. *Momordica — pomis hispidis cirrhis nullis*, of Linnæus. The dried sediment from the juice of this plant is the elaterium of the shops. It has neither smell nor taste, and is the most powerful cathartic in the whole Materia Medica. Its efficacy in dropsies is said to be considerable; it, however, requires great caution in the exhibition. From the eighth to the half of a grain should be given at first, and repeated at proper intervals until it operates. The cathartic power of this substance is derived from a small portion of a very active principle, which Dr. Paris, in his *Pharmacologia*, has called *elatin*. From ten grains of elaterium he obtained,

Water	0·4
Extractive	2·6
Fecula	2·8
Gluten	0·5
Woody matter	2·5
Elatin, Bitter principle	1·2
	10·

MONADE'LPHIA. (*a*, *æ*.; from μονος, alone, and αδελφια, a brotherhood.) A class of plants in the sexual system of Linnæus, consisting of plants with hermaphrodite flowers, in which all the stamina are united below into one body or cylinder, through which the pistil passes.

MONA'NDRIA. (*a*, *æ*, f.; from μονος, alone, and ανηρ, a husband.) The name of a class of plants in the sexual system of Linnæus, consisting of plants with hermaphrodite flowers, which have only one stamen.

MONA'RDA. (*a*, *æ*. f.; so called in honour of Nicholas Monardes, a Spanish physician and botanist.) The name of a genus of plants in the Linnæan system. Class, *Diandria*; Order, *Monogynia*.

Monarda fistulosa. The purple monarda. The leaves of this plant have a fragrant smell, and an aromatic and somewhat bitter taste, possessing nervine, stomachic, and deobstruent virtues. An infusion is recommended in the cure of intermittent fevers.

Mone'lli. A species of *Anagallis*.

Money-wort. See *Lysimachia*.

MONILIFO'RMIS. (From *monile*, an ornament for any part of the body, especially a necklace or collar, and *forma*, likeness.) Moniliform: necklace-like. Applied to the pod of the *Hedysarum moniliferum*, from its necklace appearance.

Monk's rhubarb. See *Rumex alpinus*.

Monkshood. See *Aconitum napellus*.

MONOCOTYLE'DON. (*on*, *onis*. f.; from μονος, one, and κοτυληδων, a cotyledon.) Having one cotyledon.

Monocotyle'dones. A tribe of plants which are supposed to have only one cotyledon; as the grass and corn tribe, palms, and the orchis family. See *Cotyledon*.

Monocolum. A barbarous name of the cæcum.

Mono'culus. The name of a bandage adapted to cover only one of the eyes.

MONŒ'CIA. (*a*, *æ*. f.; from μονος, alone, and οικια, a house.) The name of a class of plants in the sexual system of Linnæus, consisting of those which have male and female organs in separate flowers, but on the same plant.

MONOGY'NIA. (*a*, *æ*. f.; from μονος, alone, and γυνη, a woman, or wife.) The name of an order of plants of the sexual system of Linnæus. It contains those plants which, besides their agreement in the classic character, have only one style.

Monohe'meros. (Μονοημερος; from μονος, one, and ημερα, a day.) A term applied by the Greeks to a disease of one day's duration, or to a medicine which cures in one day.

MONO'ICUS. (*us*, *i*. m.; from μονος, one, and οικια, a house.) Linnæus calls flowers *monoici*, monœcious, when the stamens and pistils are situated, in different flowers, on the same individual plant, because they are confined to one house, as it were, or dwelling; and if the barren and fertile flowers grow from separate roots, *flores dioici*, or diœcious flowers.

Mono'machon. The intestinum cæcum is so called in the book *de compagine membrorum*, falsely ascribed to Galen.

MONOMA'NIA. (*a*, *æ*. f.; from μονος, one, and μαινομαι, to rage: *i. e.* being irrational on one subject only.) A form of insanity. See *Insanity*.

Monope'gia. (From μονος, single, and πηγνυμι, to compress.) A name given to hemicrania by Valesco de Taranta.

MONOPE'TALOUS. (*Monopetalus*; from μονος, one, and πεταλον, a leaf.) One-petalled; applied to a flower which has only one petal; as that of the *Convolvulus*, *Primula*, &c.

MONOPHY'LLOUS. (*Monophyllus*; from

μονος, one, and φυλλον, a leaf.) One-leafed; having only one leaf; applied to the perianthium of flowers; thus the flower-cup of the *Datura stramonium* is monophyllous, or formed of one leaf.

MONO'RCHIS. (*is, idis.* f.; from μονος, one, and ορχις, a testicle.) An epithet for a person that has but one testicle.

MONOSPERMOUS. (*Monospermus*; from μονος, one, and σπερμα, a seed.) Having one seed: applied to seed-vessels.

Mons veneris. The triangular eminence immediately over the os pubis of women, that is covered with hair.

MONSTER. (*Monstrum, i.* n.) Any remarkable exception to the ordinary laws of nature. In physiology the term is applied to anomalies of organisation in which the individual differs greatly in physical conformation or dimension from other individuals of the species to which it belongs. See *Anomalies of organisation* in the Supplement.

Moon-wort. See *Ophioglossum lunaria.*

Morbid temperature. See the Supplement.

MORBI'LLI. (*i, orum.* m.; diminutive of *morbus*, a disease.) The measles. See *Rubeola.*

Morbus. See *Disease.*

Morbus arquatus. The jaundice.

Morbus attonitus. The epilepsy and apoplexy are so called by some writers.

Morbus cæruleus. See the Supplement.

Mo'rbus coxa'rius. Hip disease. The morbus coxarius is a scrofulous disease nearly allied to white swelling. It most commonly makes its attacks without any apparent cause, before the age of puberty; but the disease is not necessarily confined to youth, as it sometimes occurs in middle life and even in old age, in which cases it can be most commonly traced to a blow. Like other scrofulous affections of the bones, it is of such an insidious nature that in general it has made considerable progress before it is observed, as it is apt to be mistaken either for growing pains or rheumatism. The patient for a long time complains only of a weakness and weariness of the limb, attended with a slight halt in walking and a particular uneasiness about the knee. There is at this time so little pain in the hip-joint, that the disease has been frequently mistaken for some affection of the knee. But if the diseased limb be compared with the sound one, it will be found much emaciated and considerably lengthened. By the thickening of the soft parts within the joint, in consequence of the inflammation, the head of the bone will be raised to a certain extent from the socket, and this might, at first sight, seem to account for the elongation of the limb; but we shall soon find that this cause is inadequate, as the limb is frequently lengthened to the extent of some inches.

Mr. Hunter ascribes the lengthening of the limb to the diseased side of the pelvis falling lower than the other; and, upon a careful examination, the tuberosity of the ischium will be found to be situated lower than that of the opposite side. This is always the case when the elongation prevails to a marked extent, and can only be ascribable to the oblique position in which the patient places his body in throwing the weight on the sound leg, which he always does, as he is unable to bear any pressure on the diseased limb. Although the patient, in this incipient stage of the disease, actually complains of more pain in the knee than in the hip joint, it will be perceived that the pain in the knee is not increased upon motion; whereas, if the acetabulum be pressed upon, or the joint rudely handled, the pain in it is exquisite. If the nates be examined after the disease has made a little more progress, that of the affected side will be found to be larger, to have lost its natural roundness, and to have acquired a flattened form, all arising from the increased size of the joint, and from the emaciation of the glutæi muscles. — When the disease has arrived at this stage, there is considerable pain, on the joint being pressed upon, particularly on the fore part a little below the groin, and towards the outside of the thigh, where the joint is more superficial.

At this period of the disease, the lymphatic inguinal glands, as in white swellingof the knee, are sometimes enlarged.

This series of symptoms characterises the inflammatory stage of the disease.

The second stage, is that which is accompanied by or terminates in suppuration, and takes place with greater or less rapidity, according to the activity of the inflammation. When suppuration ensues, the disease generally terminates in one of two ways. Either, after the suppuration is established, the head of the thigh bone and the acetabulum being carious, an anchylosis takes place without the matter pointing externally; or, the sinovial membrane and capsular ligament ulcerating, the soft parts surrounding the joint, inflaming, swelling, and forming an abscess, the matter bursts out externally, and a serous fluid is discharged, mixed with curdly flakes. Not unfrequently in this case, the patient dies, exhausted by the profuse discharge and hectic fever.

From the great irritation which accompanies diseases of the joints, hectic fever sometimes appears early; but its symptoms are most obvious after the formation of matter, and are always greatly increased when the abscess bursts, or is opened by art. When the inflammation within the joint is increasing and running on to suppuration, the pain becomes very acute; the patient is hot and restless during the night; he starts in his sleep; and when the limb is attempted to be moved, he screams in agony.

In the secondary stage of the disease, when it has terminated in suppuration, there takes place a remarkable retraction or shortening of the limb. The head of the bone is now plainly out of the socket; and, in consequence of the destruction of the cartilages, ligaments, and bone forming the acetabulum, the muscles, more especially those which are implanted into the trochanters, retract the bone and shorten the limb to a considerable extent. When the disease has been of long duration, not only all the soft parts immediately connected with the joint are destroyed, but the caries destroying the acetabulum, penetrates deep into the bones of the pelvis, attacks the head of the femur, and even extends to its neck.

It is probable that this disease, like true white swelling, always originates in the bones; and it

has been found, upon dissection, that it generally if not always, commences in the acetabulum. The cartilages soon inflame and ulcerate, the articular cavity soon becomes carious, and, in the progress of the disease, the caries extends to the head of the os femoris. The Morbus Coxarius, by an inexperienced practitioner, might be mistaken in the stage of suppuration for lumbar abscess; but it may always be distinguished by the wasting and shortening of the limb, by the enlargement and flatness of the hip, and by the pain in the site of the joint, which is aggravated on pressure or motion.

Amongst the ancients from the time of the Arabian physicians, the actual and potential cauteries were much employed for the cure of pains of the bones and diseases of the joints; and by them, therefore, this affection was treated much in the same manner as it is now. In the early stage of the disease, it has been proposed to employ fomentations, the Bath water, blistering, cupping and tropical blood-letting; but there is nothing we can place any dependence on except the caustic issue. Perhaps blistering and topical blood-letting conjoined with rest, may have some effect when employed very early; and where there is evidently much acute inflammation, the application of leeches with warm fomentations is highly proper. But we should never waste time on trifling and insignificant remedies, when we can employ the caustic issue, which the concurring testimony of the ancients and moderns declares to be the only efficacious remedy in this disease. It is useful at all periods of the disease, and when employed early, before the suppurative stage commences, it never fails to effect a perfect cure. Even when suppuration had taken place, and the pain was exquisitely acute, the caustic has been known to give such relief, that the patient was able to sleep sound, the night of its application, although the pain of the disease had prevented him from doing so for many weeks. The caustic issue seems to act not so much by the discharge it produces, as by the external irritation it excites, by which the internal inflammation is relieved, or a state induced favourable to anchylosis. The issue should be large and frequently renewed; its use ought to be persevered in for a length of time; and, during its employment, the limb should be kept completely at rest, by confinng the patient to a couch. If the joint has suppurated or become carious, the limb ought to be kept extended, because, should it anchylose, the extended position is the most serviceable in which the limb can be fixed. The place most favourable for the introduction of the issue, is the hollow immediately behind and below the great trochanter. While we pursue these local means, the constitutional treatment in the advanced stage of the disease, should be the same as in lumbar abscess — opiates to mitigate pain, diluted sulphuric acid to restain hectic sweats, and bark, wine, and generous diet to support the strength.—*Allan's System of Surgery.*

Morbus gallicus. The venereal disease.

Morbus herculeus. The epilepsy.

Morbus indicus. The venereal disease.

Morbus infantilis. The epilepsy.

Morbus magnus. The epilepsy.

Morbus niger. See *Melæna.*

Morbus regius. The jaundice.

Morbus sacer. The epilepsy.

MORCHE'LLA. (*a*, *æ*. f.; a name of Persoon's, of the derivation of which nothing is known.) The name of a genus of plants. Class, *Cryptogamia*; Order, *Fungi*. The morel.

Morchella esculenta. This and the *gigas* are the morels mostly used. All the morchellæ are also very wholsome and agreeable in sauces and made dishes. They are distinguished from the stinkhorns, or phalli, by the absence of the fœtid juice of the latter, and also of the volva which envelopes the young phalli.

MORDANT. In dyeing, the substance combined with the vegetable or animal fibre, in order to fix the dye.

Morel. See *Morchella esculenta.*

More'tus. (From *morum*, the mulberry.) A cordial julep in which syrup of mulberries was an ingredient.

MO'RIA. (*a*, *æ*. f.; from μωρος, foolish.) *Morocis.* A term of somewhat vague application, but most generally used to signify that variety of monomania in which the illusion is of a joyous character, and the patient a hero, a great genius, &c.

Moringa aptera. See the Supplement.

Mo'ro. (From *morum*, a mulberry.) A small abscess resembling a mulberry.

Morochtus lapis. *Morochites.* An ancient name of the agaric mineral.

Morosis. See *Moria.*

MORO'XYLATE. (*Moroxylas*, *atis*. f.) A compound of moroxylic acid with a salifiable basis.

MOROXY'LIC ACID. *Acidum moroxylicum.* In the botanic garden at Palermo, Mr. Thomson found an uncommon saline substance on the trunk of a white mulberry tree. It appeared as a coating on the surface of the bark in little granulous drops of a yellowish and blackish-brown colour, and had likewise penetrated its substance. This salt was found to be a compound of lime and a peculiar vegetable acid, with some extractive matter.

MORPHE'A. (*a*, *æ*. f.; from μορφη, form.) A barbarous name given by the translators of the Arabians to the *alphos* of the Greeks; *lepra alphoides* of Willan.

Morphew. (*Morphea*, low Latin.) An old English name given to various cutaneous affections of the face.

MO'RPHIA. (*a*, *æ*. f.) A vegetable alkali, extracted from opium, of which it constitutes the narcotic principle. See *Papava somniferum.*

Morphiæ acetas. Acetate of morphia. See *Papaver somniferum.*

Morphine. See *Morphia.*

Mo'rpio. The crab-louse. See *Pediculus pubis.*

Morsel'lus. A lozenge.

Mo'rsulus. An ancient name for that form of medicine which was to be chewed in the mouth as a lozenge; the word signifying a little mouthful.

MO'RSUS. (*us*, *ûs*. m.; from *mordeo.*) A bite, sting, or grasp.

Mo'rsus dia'boli. A whimsical name of the umbriæ of the Fallopian tubes.

Mort de chien. (Said to be a French corruption of the Indian *mordezym*, or Arabic *mordekie*.) A name of the spasmodic cholera of hot climates.

Morta. See *Pemphigus.*

Mortari'olum. (Diminutive of *mortarium*, mortar.) 1. In *Chemistry*, a sort of mould for making cupels with.

2. A little mortar.

3. In *Anatomy*, the socket of a tooth.

MORTIFICATION. (*Mortificatio, onis.* f.; from *mors*, death, and *fio*, to become.) When any part of a living individual loses its vitality, so that the circulation and all the other functions naturally carried on in the part entirely cease, that part is said to be in a state of mortification. Mortification is divided into *acute* and *chronic*, the former is also sometimes called *humid gangrene*, and the latter *dry gangrene.*

The terms gangrene and mortification are often used synonymously; but *gangrene* properly signifies the state which immediately precedes mortification, while the complete mortification, or absolute death of a part, is called *sphacelus.* A part which has passed into the state of sphacelus is called a *slough.* When a part becomes gangrenous, it loses its natural heat and sensibility, it becomes livid, and vesications appear on its surface. Although this state generally leads to that of complete mortification, a degree of vitality remains, and in some rare instances the circulation is re-established, and the part restored to health. When sphacelus has taken place, the part becomes black and putrid; it is entirely dead and disorganised, and the living system must either cast it off, or sink from the effects of the absorption of putrid matter.

The ordinary causes of mortification are, inflammation, particularly that of the erysipelatous kind,—(See *Inflammation*)—interruption of the circulation or innervation of parts — severe mechanical injury — intense cold — certain poisonous articles of food — and specific contagion. Chemical agents which destroy the texture of parts, as high degrees of heat, and caustics, are sometimes enumerated among the causes of mortification; but the destruction of parts induced by these cannot properly be called mortification, as it is simply the chemical decomposition of the textures.

Mortification, supervening on inflammation or injury, is attended with a sudden and overwhelming depression of the vital powers; the pulse is very rapid and feeble, the countenance cadaverous, and the surface of the body covered with a cold sweat. Hiccough is a common symptom, especially in mortification of the abdominal viscera; as in cases of strangulated hernia.

Besides the common forms of mortification arising from inflammation, injury, or debility of parts, there are three which have peculiar characters, viz.

1. The *gangræna senilis*, or dry gangrene of old age, which usually commences in the shape of a purple or black spot on the under surface of one of the smaller toes, and gradually extends up the limb. It is sometimes attended with great pain and constitutional disturbance, proving rapidly fatal, and at other times with hardly any pain, little derangement of the system, and a more protracted, though equally fatal, issue.

2. The *mortification arising from ergotism.* See *Secale cornutum.*

3. *Hospital gangrene. Phagedæna gangrenosa*, which is generally supposed to arise from specific contagion. It consists in a very rapid destruction of parts, not by the formation of ordinary sloughs, but by the conversion of the parts into an ash-coloured viscid substance interspersed with bloody specks. It appears to be an affection intermediate between phagedenic ulceration and ordinary gangrene. It prevails only in hospitals, where it is sometimes a perfect scourge, attacking every wound, however trivial, so that the slightest operation cannot be performed with safety.

The treatment of mortification is constitutional and local. The following remarks upon it are taken from the late Mr. Allan's *System of Pathological and Operative Surgery.* "By attending to the progress of the disease from its incipient state to its final completion, we shall frequently be able to observe two distinct stages; the knowledge of which is of great utility, as it not only enables us to arrange our ideas, but regulates the whole of our practice. The first stage, or the incipient state of gangrene, is most commonly a state of morbidly increased action; the pulse is full, and strong, the febrile symptoms continue unabated, and the mortification seems to take place from the violence of the inflammatory action. This stage most frequently presents itself when mortification follows inflammation in consequence of external injury. The second stage is a state of extreme debility, the pulse sinks, the powers of life are languid, and all the actions of the system are brought low. Now it is evident, that our practice must differ, as the one or the other of these stages prevails. In the stage of increased action, we bleed, purge, and enjoin the strictest antiphlogistic regimen, as we do in acute inflammation, especially if the patient be young, and the inflammatory fever high. In the stage where the symptomatic fever is gone, where the pulse is sunk, or the fever of the typhoid kind, we pursue an opposite plan, and prescribe strong soups, wine, and medicines of the class of tonics or stimulants. Our constitutional treatment must, therefore, be regulated according as either of these stages prevails. In the stage of increased action, or where the inflammatory fever is violent, we bleed, and repeat it if necessary. We keep up the action of the bowels by brisk cathartics; interdict all animal food and strong liquors; give acidulated drinks, and keep the patient low and cool. But if called to a patient when the symptomatic inflammatory fever is gone, or when the stage of debility is present, we pursue an opposite plan, which consists in exhibiting bark and wine, strong soups, opium, and other stimulants. Bark was, at one time, considered a specific in mortification, as mercury is in the venereal disease; but its high reputation

has been for some years past on the decline. Mr. Sharp had no faith in bark for the cure of mortifiation. Mr. Pott says, that in mortification of the feet and toes it is inefficacious; and in every case where I have tried it, and my practice at one time was pretty extensive, I never found it of the smallest utility. It is always exhibited in combination with port wine. As bark belongs to the class of tonics, we must remember, that it cannot be given with safety during the inflammatory symptoms, and is only adapted for the completely-formed state of the disease. Opium is another medicine which has been much recommended of late years. It was much used by Mr. Pott in gangrene of the feet and toes. It is one of the best medicines, particularly in the advanced stages of mortification; and it should always be exhibited in small doses, frequently repeated. Bark, port wine, and opium, have been the constitutional remedies most generally employed in the cure of mortification; but the whole class of stimulants may be occasionally resorted to with more or less advantage.

"The best local application during the stage of increased action or high inflammation, are warm emollient poultices, and warm fomentations. The poultices may be made of bread and milk, or of oatmeal and the powder of linseed boiled in water, or the yeast, the turnip, or carrot poultice, may be employed. They should be applied as hot as the patient can easily bear, and renewed every three or four hours. At each renewal of the poultice, the gangrened and adjacent inflamed parts should be well fomented with flannels, wrung out of a decoction of poppy-heads, and henbane or hemlock leaves, to which a little opium may be added.

"If the gangrene has passed into the second stage, and all inflammation gone, it will be advisable to apply stimulant remedies to excite the ulcerative inflammation, by which the dead are separated from the living parts, as cloths dipped in camphorated spirits of wine, turpentines, and resins, in the form of hot dressings, tincture of myrrh and bark, warm vinegar, the red oxide of mercury, carbonic acid gas, the fumes of nitrous acid, &c.

"When the gangrene is situated in the extremities, and the farther progress of the disease is stopped, we either wait for the natural separation, treating the ulcerated surface like a common sore, or we perform amputation at a higher point in the limb. In general, it will be better to amputate as soon as the gangrene has stopped, and the line of separation is fairly marked; because, in this case, we have it in our power to remove the limb at the place most convenient for making a serviceable stump. We heal the wound by the first intention, by which we effect a cure in a far shorter time than we could cicatrise a large ulcerated surface; and we always procure a stump, covered by a cushion of strong integuments, including the true skin; whereas, after natural separation, the stump is only covered with a tender cuticle, which is prone to ulcerate upon the slightest accident."

Mo'rum. (*um, i.* n.) See *Morus nigra.*

MO'RUS. (*us, i.* f.; from *μαυρος*, black: so called from the colour of its fruit when ripe.) The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Tetrandria.* The mulberry tree.

Morus nigra. The systematic name of the mulberry tree. *Morus—foliis cordatis scabris,* of Linnæus. Mulberries abound with a deep violet-coloured juice, which, in its general qualities, agrees with that of the fruits called *acido-dulces,* allaying thirst, partly by refrigerating, and partly by exciting an excretion of mucus from the mouth and fauces. It was formerly in high esteem as an antiseptic and corroborant, and was much used in low fevers. The London College directs a *syrupus mori,* which is an agreeable vehicle for various medicines. The bark of the root of this tree is said, by Andrée, to be useful in cases of tænia.

Moschelæ'um. A compound aromatic oil containing musk.

Mosaic gold. See *Aurum musivum.*

Moschata nux. See *Myristica moschata.*

Mosch. 1. The same as musk.

2. A name given by Ludovicus Bilsius to certain vessels in the kidney, which nobody had seen before him, and nobody hath seen since.

MOSCHA'TUS. (From *moschus,* musk.) Musky: applied to plants, &c.

MO'SCHUS. (*us, i.* m. *Mosch,* Arabian.) Musk. See *Moschus moschiferus.*

Moschus moschiferus. The systematic name of the musk animal, a ruminating quadruped, resembling the antelope. An unctuous substance is contained in excretory follicles about the navel of the male animal, the strong and permanent smell of which is peculiar to it. It is contained in a bag placed near the umbilical region. The best musk is brought from Tonquin, in China; an inferior sort from Agria and Bengal; and a still worse from Russia. It is slightly unctuous, of a black colour, having a strong durable smell and a bitter taste. It yields part of its active matter to water, by infusion; by distillation the water is impregnated with its flavour; alkohol dissolves it, its impurities excepted. Chewed, and rubbed with a knife or paper, it looks bright, yellowish, smooth, and free from grittiness. Laid on a red-hot iron, it catches fire, and burns almost entirely away, leaving only an exceedingly small quantity of light greyish ashes. If any earthy substances have been mixed with the musk, the impurities will discover them. The medicinal and chemical properties of musk and castor are very similar; the virtues of the former are generally believed to be more powerful, and hence musk is preferred in cases of imminent danger. It is prescribed as a powerful antispasmodic, in doses of three grains or upwards, even to half a drachm, in the greater number of spasmodic diseases, especially in hysteria and singultus, and also in diseases of debility. In typhus it is employed to remove subsultus tendinum, and other symptoms of a spasmodic nature. In cholera, it frequently stops vomiting; and, combined with ammonia, it is given to arrest the progress of gangrene. It is best given in the form of bolus. To children it is given in the form of enema

and is an efficacious remedy in the convulsions arising from dentition. It is also given in hydrophobia, and in some forms of mania.

Moseley's pills. These consist of rhubarb and ginger.

Mosquito. See *Culex.*

MOSS. The English name for several species of *musci*, which grow on walls, old wood, trees, damp ground, &c.

Moss, pectoral. See *Lichen pulmonarius.*

Moss, sea. See *Fucus helminthochorton.*

MOSY'LLUM. Μοσυλλον. The best cinnamon.

MOTHER. 1. See *Mater.*

2. This term was applied to many chemical preparations and plants, from whimsical more than good reasons.

Mother of thyme. See *Thymus serpyllum.*

Mother of pearl. The shining internal part of those shells which produce pearls. It is similar in its composition to pearl. See *Margarita.*

Mother-water. When sea-water, or any other solution containing various salts, is evaporated, and the crystals taken out, there always remains a fluid containing deliquescent salts, and the impurities, if present. This is called the mother-water.

Mother-wort. See *Leonurus.*

Motility. *Motivity.* The power of moving.

Motion, muscular. See *Muscular motion.*

Motion, peristaltic. See *Peristaltic motion.*

MOTOR. (*or, oris.* m.; from *moveo*, to move.) A mover or stirrer: applied to muscles, &c.

Motor oculi. See *Motores oculorum.*

Moto'res oculorum. (*Nervi motores oculorum:* so called because they supply the muscles which move the eye.) The third pair of nerves of the brain. They arise from the crura cerebri, and are distributed on the muscles of the bulb of the eye.

Motos. Μοτος. Lint.

Mould. See *Fontanella.*

Mountain parsley, black. See *Athamanta oreoselinum.*

Mouse-ear. See *Hieracium pilocella.*

MOUTH. *Os.* 1. The aperture in animals by which the food is taken in. In man, parts which constitute it are the common integuments, the lips, the muscles of the upper and under jaw, the palate, two alveolar arches, the gums, the tongue, the cheeks, and salivary glands. The bones of the mouth are the two superior maxillary, two palatine, the lower jaw, and thirty-two teeth. The arteries of the external parts of the mouth are branches of the infra orbital, inferior alveolar, and facial arteries. The veins empty themselves into the external jugulars. The nerves are branches from the fifth and seventh pair. The use of the mouth is for mastication, speech, respiration, deglutition, suction, and taste.

2. A part of the corolla of flowers. See *Faux.*

Mo'xa. (*a, æ.* f.; a Japanese word. See *Artemisia chinensis.*

Moxa Japanica. See *Artemisia chinensis.*

Mucic acid. *Acidum mucicum.* This acid was originally called *saccholactic*, because it was first obtained by Scheele from sugar of milk; but as all the gums appear to afford it, and the principal acid in sugar of milk is the oxalic, it is now generally called *mucic* acid.

If one part of gum be heated gently with three of nitric acid, till a small quantity of nitrous gas and of carbonic acid is disengaged, the dissolved mass will deposit, on cooling, the mucic acid. According to Fourcroy and Vauquelin, different gums yield from 14 to 26 hundredths of this acid.

This pulverulent acid is soluble in about sixty parts of hot water, and, by cooling, a fourth part separates in small shining scales, that grow white in the air. It is decomposed by a strong heat. It acts very little on the metals, but forms with their oxides salts scarcely soluble. With potash and soda it forms salts soluble in boiling water; the latter more so than the former. Both these salts are still more soluble when the acid is in excess. It forms nearly insoluble salts with lime, baryta, and magnesia. With ammonia, it forms one which is decomposed by heat, the ammonia being liberated.

MU'CATE. Mucas. A salt is formed by the mucic acid, with a base.

MU'CILAGE. (*Mucilago, inis.* f.; from *mucus.*) An aqueous solution of gum. See *Gum.*

MUCILAGINOUS. (*Mucilaginosus;* from *mucilago*, mucilage.) Gummy.

Mucilaginous extracts. Extracts that readily dissolve in water, scarcely at all in spirits of wine, and undergo spirituous fermentation.

Mucilago. See *Mucilage.*

Mucilago acaciæ. Mucilage of acacia. *Mucilago gummi arabici.* Take of acacia gum, powdered, four ounces; boiling water, half a pint. Rub the gum with the water, gradually adding, until it incorporates into a mucilage. A demulcent preparation, more frequently used to combine medicines than in any other form.

Mucilago a'myli. Starch mucilage. Take of starch, three drachms; water, a pint. Rub the starch, gradually adding the water to it; then boil until it incorporates into a mucilage. This preparation is mostly exhibited with opium, in the form of clyster in diarrhœas and dysenteries, where the tenesmus arises from an abrasion of the mucus of the rectum.

Mucilago arabici gumma. See *Mistura acaciæ.*

Mucilago seminis cydonii. See *Decoctum cydoniæ.*

Mucilago tragacanthæ. Mucilage of tragacanth, joined with syrup of mulberries, forms a pleasant demulcent, and may be exhibited to children, who are fond of it.

Mucoca'rneus. M. A. Severinus applies this epithet to an abcess, which is partly fleshy and partly mucous.

Mucocele. A distention of the lachrymal sac with mucus.

MU'COUS. (*Mucosus;* from *mucus.*) Of the nature of mucus.

Mucous acid. See *Mucic acid.*

Mucous glands. *Glandulæ mucosæ.* Mucipalous glands. Glands that secrete mucus, such as the glands of the Schneiderian membrane of the nose, the glands of the fauces, œsophagus, stomach, intestines, bladder, urethra, &c.

Mucous membrane. *Mucous web.* See *Texture.*

Mucous web. See *Mucous membrane.*

Mucronata cartilago. *Mucronatum os.* The ensiform cartilage of the sternum.

MUCRONA'TUS. (From *mucro*, a sharp point.) Sharp-pointed; dagger-pointed. See *Cuspidatus.*

MUCUS. (*us, i.* m.; from μυξα, the mucus of the nose.) A name given to the two following substances: —

1. *Mucus, animal.* One of the primary fluids of an animal body, perfectly distinct from gelatine, and vegetable mucus. Tannin, which is a delicate test for gelatine, does not effect mucus. This fluid is transparent, glutinous, thready, and of a saline taste; it reddens litmus paper, contains a great deal of water, muriate of potash and soda, lactate of lime and of soda, and phosphate of lime. According to Fourcroy and Vauquelin, the mucus, secreted by all the mucous membranes, is the same. On the contrary, Berzelius thinks it variable, according to the situation in which it is formed.

Mucus forms a layer of greater or less thickness on the surface of the mucous membranes, and it is renewed with more or less rapidity; the water it contains evaporates under the name of *mucous exhalation;* it also protects these membranes against the action of the air, of the aliment, the different glandular fluids, &c.; it is, in fact, to these membranes nearly what the epidermis is to the skin. Independently of this general use, it has others that vary according to the parts of mucous membranes. Thus, the mucus of the nose is favourable to the smell; that of the mouth gives facility to the taste; that of the stomach and the intestines assists in the digestion; that of the genital and urinary ducts serves in the generation, and the secretion of the urine, &c.

A great part of the mucus is absorbed again by the membranes which secrete it; another part is carried outwards, either alone, as in blowing the nose, or spitting, or mixed with the pulmonary transpiration, or else mixed with the excremental matter, or the urine, &c.

Animal mucus differs from that obtained from the vegetable kingdom, in not being soluble in water, swimming on its surface, nor capable of mixing oil with water, and being soluble in mineral acids, which vegetable mucus is not.

2. *Mucus, vegetable.* See *Gum.*

Mu'cus malpighia'nus. The *Rete mucosum.* See *Cutis.*

MU'GIL. *Mugilis.* The name of a genus of fishes, of the order *Malocopterygii abdominales.*

Mugil cephalus. The silvery grey mullet. An excellent fish, but not often found in our market. It is easy of digestion, and was much esteemed by the Romans.

Mugilis. See *Mugil.*

Mugwort. See *Artemesia vulgaris.*

Mugworth, chinense. See *Artemisia chinense.*

Mu'læ. Pustules contracted either by heat or cold.

Mulberry. See *Morus nigra.*

Mule. See *Hybrid.*

Mule's fern. See *Asplenium hemionitis.*

Mullein. See *Verbascum.*

Mullet. See *Mugil*, and *Mullus.*

MU'LLUS. The name of a genus of fishes, of the order *Thoracici.* The surmullet.

Mullus barbatus. *Mullus ruber.* The red surmullet, found in the Mediterranean and Northern Seas, where it comes to the length of 12 or 15 inches. Its colour is an elegant rose-red, tinged with olive on the back, and a silvery cast towards the belly. Its flesh is esteemed very delicious. The Romans held it in such high repute, that prodigious sums of money were given for it.

Mullus sarmuletus. The striped surmullet. This is found of all sizes, from four inches to a foot long. As an article of food, it is equally esteemed with the red mullet.

Mulsum. See *Hydromeli.*

MULTA'NGULAR. (*Multangularis;* from *multus*, many, and *angulus*, a corner.) Many cornered.

MULTI'FIDUS. (From *multus*, many, and *findo*, to divide.) Divided into many parts. 1. In *Anatomy*, applied to a muscle which is deeply and much divided.

2. In *Botany*, applied to leaves, petals, &c. the borders of which are cleft into many segments.

Multifidus Spinæ. *Transverso-spinalis lumborum; Musculus sacer; Semi-spinalis internus, sive transverso-spinalis dorsi; Semi-spinalis, sive transverso spinalis colli, pars interna*, of Winslow. *Transversalis lumborum, vulgo sacer; Transversalis dorsi; Transversalis colli*, of Douglas. The generality of anatomical writers have unnecessarily multiplied the muscles of the spine, and hence their descriptions of these parts are confused, and difficult to be understood. Under the name of *multifidus spinæ*, Albinus has, therefore, very properly included those portions of muscular flesh, intermixed with tendinous fibres, which lie close to the posterior part of the spine, and which Douglas and Winslow have described as three distinct muscles, under the names of *transversales*, or *transverso-spinales*, of the loins, back, and neck. The multifidus spinæ arises tendinous and fleshy from the upper convex surface of the os sacrum, from the posterior adjoining part of the ilium, from the oblique and transverse processes of all the lumbar vertebræ, from the transverse processes of all the dorsal vertebræ, and from those of the cervical vertebræ, excepting the three first. From all these origins the fibres of the muscles run in an oblique direction, and are inserted, by distinct tendons, into the spinous processes of all the vertebræ of the loins and back, and likewise into those of the six inferior vertebræ of the neck. When this muscle acts singly, it extends the back obliquely, or moves it to one side; when both muscles act they extend the vertebræ backwards.

MULTIFLO'RUS. (From *multus*, many, and *flos*, a flower.) Many-flowered. Applied to the flower-stalk of plants, which is so called when it bears many flowers; as the *Daphne laureola.* See *Pedunculus.*

Multiforme os. See *Ethmoid bone.*

MULTILO'CULAR. (*Multilocularis;* from

ultus, many, and *loculus*, a little place or cell.) Having many cells: applied to the seed-vessels of plants.

MU'LTIPARTITE. *Multipartitus.* Having many and deep divisions: applied to leaves, &c.

MU'LTIPES. (From *multus*, many, and *pes*, a foot.) 1. The wood-louse.

2. The polypus.

3. Any animal having more than four feet.

MU'LTIVALVE. *Multivalvis.* Having more than two valves. Applied in zoology and botany.

Mumps. See *Parotitis.*

MUNDICATI'VUS. (From *mundo*, to cleanse.) *Mundificans.* Having the property of purifying and cleansing away foulness.

Mundificans. See *Mundicativus.*

Mungos. See *Ophiorrhiza mungos.*

MURÆ'NA. (*a*, *æ*. f.) The name of a genus of fishes of the order *Apodes.* The eel.

MURÆNA ANGUILLA. The common eel, which is found almost everywhere in fresh waters. The flesh of this fish, when boiled, stewed, baked, or fried, is very tender: it is easy of digestion to some stomachs, but uniformly disagrees with others. It is prepared in a variety of ways for the tables of the rich, when its compounded state renders it more difficult to digest.

MURÆNA CONGER. The conger eel. An extremely voracious fish, which sometimes acquires a considerable size, weighing a hundred pounds. It is found in European seas. There is a fishery for congers at Mount Bay, in Cornwall, where they form a considerable article of commerce. They are exported in a dried state to Spain and Portugal, where, being reduced to powder, they are used for enriching soup. The fresh fish is considered coarse, difficult of digestion, even when well boiled or stewed. It is, however, eaten by the common people.

MURÆNA HELENA. *Muræna Romana.* The Roman eel. This fish is found in great plenty along the coasts of the Mediterranean Sea, and was the celebrated favourite of the ancient Romans, who kept it in reservoirs appropriated for that purpose, and are said to have tamed it to such a degree as to come at a call to receive its food.

MURA'LIS. (From *murus*, a wall.) Appertaining to a wall. Applied as a specific name to some plants which grow on walls.

MURA'RIA. (*a*, *æ*. f.; from *murus*, a wall: because it grows about walls.) A species of maiden-hair; the *Asplenium murale.*

MURIA. 1. A kind of sauce or pickle made from the tunny, used by the ancient Romans.

2. Brine.

MURIACITE. Gypsum.

MU'RIAS. (*as*, *atis*. f.; so called because formed with the muriatic acid.) A muriate, or salt, formed by the union of the muriatic acid with a salifiable base. The term muriate is still in daily use, but the substances called muriates are in reality chlorides when dry, and hydrochlorates when dissolved: thus common salt is *chloride of sodium* when dry, but becomes a *hydrochlorate of soda.* The term muriate, therefore, is still convenient to designate such substances, whether in the moist or dry state.

MURIAS AMMONIÆ. See *Ammoniæ murias.*

MURIAS ANTIMONII. See *Antimony.*

Murias barytæ. See *Baryta.*

MURIAS CALCIS. See *Calcii chloridum.*

Murias ferri. See *Tinctura ferri sesquichloridi.*

MURIAS FERRI AMMONIACALIS. See *Ferri ammonio-chloridum.*

MURIAS HYDRARGYRI. There are two muriates of mercury. See *Hydrargyri chloridum* and *Hydrargyri bichloridum.*

MURIAS HYDRARGYRI AMMONIACALIS. See *Hydrargyri ammonio-chloridum.*

Murias hydrargyri oxygenatus. See *Hydrargyri bichloridum.*

Murias potassæ. See *Potassii chloridum.*

Murias potassæ oxygenatus. See *Potassæ chloras.*

Murias sodæ. See *Sodii chloridum.*

Murias stibii. See *Antimony.*

MURIA'TIC. (*Muriaticus*; from *muria*, brine.) Belonging to sea-salt.

Muriatic acid. See *Hydrochloric acid.*

Muriatic acid, oxygenated. See *Chlorum.*

Muriatic ether. See *Ether hydrochloric.*

MURICA'TUS. Sharp-pointed: applied generally in *Natural History*, and particularly to seeds; as those of the *Ranunculus parviflorus*, and *Sida ciliaris.*

MU'SA. (*a*, *æ*. f. This word is corrupted, or rather refined, from *Mauz*, the Egyptian appellation of this valuable plant; and is made classical in the works of Linnæus, by an allusion to *Musa*, a muse; or, with much greater propriety, to *Antonius Musa*, the physician of Augustus, who, having written on some botanical subjects, may justly be commemorated in the above name.) The name of a genus of plants. Class, *Polygamia*; Order, *Monœcia.* The plantain and banana tree.

MUSA PARADISI'ACA. The plantain-tree; called also, *Musa*, *Palma humilis*, *Ficus indica*, *Bala*, and *Platanus.* It grows spontaneously in many parts of India, but has been immemorially cultivated by the Indians in every part of the continent of South America. It is an herbaceous tree, growing to the height of fifteen or twenty feet. The fruit are nearly of the size and shape of ordinary cucumbers, and when ripe, of a pale yellow colour, of a mealy substance, a little clammy, with a sweetish taste, and will dissolve in the mouth without chewing. The whole spike of fruit often weighs forty or fifty pounds. When they are brought to table by way of dessert, they are either raw, fried, or roasted; but, if intended for bread, they are cut before they are ripe, and are then either roasted or boiled. The trees being tall and slender, the Indians cut them down to get at the fruit; and in doing this they suffer no loss, for the stems are only one year's growth, and would die if not cut; but the roots continue, and new stems soon spring up, which in a year produce ripe fruit also. From the ripe plantains they make a liquor called *mistaw.* When they make this, they roast the fruit in their husks, and, after totally beating them to a mash, they pour water upon them, and, as the liquor is wanted,

it is drawn off. But the nature of this fruit is such, that they will not keep long without running into a state of putrefaction; and therefore, in order to reap the advantage of them at all times, they make cakes of the pulp, and dry them over a slow fire, and, as they stand in need of mistaw, they mash the cakes in water, and they answer all the purposes of fresh fruit. These cakes are exceedingly convenient to make this liquor in their journeys, and they never fail to carry them for that purpose. The leaves of the tree, being large and spacious, serve the Indians for tablecloths and napkins.

Musa sapientum. The systematic name of the banana tree; called also, *Banana*, *Bananeira*, *Ficoides*, *Ficus indica*, *Musa fructu cucumerino breviori*, *Senoria*, and *Pacæira*. This and the plantain-tree are among the most important productions of the earth. The banana tree is cultivated, on a very extensive scale, in Jamaica; without the fruit of which, Dr. Wright says, the island would scarcely be habitable, as no species of provision would supply their place. Even flour, or bread itself, would be less agreeable, and less able to support the laborious negro, so as to enable him to do his business, or to keep in health. Plantains also fatten horses, cattle, swine, dogs, fowls, and other domestic animals. The leaves, being smooth and soft, are employed as dressings after blisters. The water from the soft trunk is astringent, and employed by some to check diarrhœas. Every other part of the tree is useful in different ways in rural economy. The leaves are used as napkins and tablecloths, and are food for hogs. The second sort, musa sapientum, or banana tree, differs from the paradisaica, in having its stalks marked with dark purple stripes and spots. The fruit is shorter, straighter, and rounder; the pulp is softer, and of a more luscious taste. It is never eaten green; but, when ripe, is very agreeable, either eaten raw or fried in slices as fritters, and is relished by all ranks of people in the West Indies. Both the above plants were carried to the West Indies from the Canary Islands, whither, it is believed, they had been brought from Guinea, where they grow naturally.

Musadi. *Sal ammoniac.*

MU'SCA. (*a*, *æ*. f. Μυισκη; from *μύζω*, to murmur.) A very extensive genus of insects, of the order *Diptera*. The fly.

Muscadell. Clary wine. A sweet wine made from the flowers of the clary. *Salvia sclarea.*

Muscæ volitantes. See *Pseudoblepsis.*

Musce'rda. 1. The dung of mice. See *Album nigrum.*

2. A kind of lozenge to correct fœtor of the breath.

MUSCLE. (*Musculus*, *i*. m.; a diminutive of *mus*, a mouse, from its resemblance to a flayed mouse.) The parts that are usually included under this name consist of distinct portions of flesh, susceptible of contraction and relaxation; the motions of which, in a natural and healthy state, are subject to the will, and for this reason they are called *voluntary* muscles. Besides these, there are other parts of the body that owe their power of contraction to their muscular fibres: thus the heart is a muscular texture, forming what is called a hollow muscle; and the urinary bladder, stomach, intestines, &c. are enabled to act upon their contents, merely because they are provided with muscular fibres; these are called *involuntary* muscles, because their motions are not dependent on the will. The muscles of respiration, being in some measure influenced by the will, are said to have a *mixed* motion. The names by which the voluntary muscles are distinguished, are founded on their size, figure, situation, use, or the arrangement of their fibres, or their origin and insertion; but, besides these particular distinctions, there are certain general ones that require to be noticed. Thus, if the fibres of a muscle are placed parallel to each other, in a straight direction, they form what anatomists term a *rectilinear* muscle; if the fibres cross and intersect each other, they constitute a *compound* muscle; when the fibres are disposed in the manner of rays, a *radiated* muscle; when they are placed obliquely with respect to the tendon, like the plume of a pen, a *penniform* muscle. Muscles that act in opposition to each other are called *antagonists*; thus every extensor has a flexor for its antagonist, and *vice versâ*. Muscles that concur in the same action are termed *congeneres*. The muscles being attached to the bones, the latter may be considered as levers, that are moved in different directions by the contraction of those organs. That end of the muscle which adheres to the most fixed part, is usually called the *origin*; and that which adheres to the more moveable part, the *insertion* of the muscle. In almost every muscle, two kinds of fibres are distinguished: the one soft, of a red colour, sensible, and irritable, called *fleshy* fibres, or *Muscular fibre*; the other of a firmer texture, of a white glistening colour, insensible without irritability or the power of contracting, and named *tendinous* fibres. They are occasionally intermixed, but the fleshy fibres generally prevail in the belly, or middle part of the muscle, and the tendinous ones in the extremities. When these tendinous fibres are formed into a round slender cord, they form what is called the *tendon* of the muscle: on the other hand, if they are spread into a broad flat surface, it is termed an *aponeurosis.*

Each muscle is surrounded by a very thin and delicate covering of cellular membrane, which encloses it, as it were, like a sheath, and dipping down into its substance, surrounds the most minute fibres we are able to trace, connecting them to each other, lubricating them by means of the fat, which its cells contain in more or less quantity in different subjects, and serving as a support to the blood-vessels, lymphatics, and nerves which are so plentifully distributed through the muscles. This cellular membrane, which in no respect differs from what is found investing and connecting the other parts of the body, has been sometimes mistaken for a membrane peculiar to the muscles; and hence we often find writers giving it the name of *membrana propria musculosa.* The

muscles owe the red colour which so particularly distinguishes their belly part, to an infinite number of arteries, which are every where dispersed through the whole of their reticular substance; for their fibres, after having been macerated in water, are (like all other parts of the body divested of their blood) found to be of a white colour. These arteries usually enter the muscles by several considerable branches, and ramify so minutely through their substance, that we are unable, even with the best microscopes, to trace their ultimate branches. Ruysch fancied that the muscular fibre was hollow, and a production of a capillary artery; but this was merely conjectural. The veins, for the most part, accompany the arteries, but are found to be larger and more numerous. The lymphatics, likewise, are numerous, as might be expected from the great proportion of reticular substance which is every where found investing the muscular fibres. The nerves are distributed in such abundance to every muscle, that the muscles of the thumb alone are supplied with a greater proportion of nervous influence than the largest viscera; as the liver, for instance. They enter the generality of muscles by several trunks, the branches of which, like those of the blood-vessels, are so minutely dispersed through the cellular substance, that their number and minuteness soon elude the eye and the knife of the anatomist. This has given rise to a conjecture, as groundless as all the other conjectures on this subject, that the muscular fibre is ultimately nervous.

A Table of the Muscles. — The generality of anatomical writers have arranged muscles according to their several uses; but this method is evidently defective, as the same muscle may very often have different and opposite uses. The method here adopted is that more usually followed at present; they are enumerated in the order in which they are situated, beginning with those that are placed nearest the integuments, and proceeding from these to the muscles that are more deeply seated.

[The reader will observe, that all the muscles are in pairs, except those marked thus *.]

Muscles of the integuments of the cranium: — *Occipito frontalis.** *Corrugator supercilii.*

Muscles of the eyelids: — *Orbicularis palpebrarum. Levator palpebræ superioris.*

Muscles of the eyeball: — *Rectus superior. Rectus inferior. Rectus internus. Rectus externus. Obliquus superior. Obliquus inferior.*

Muscles of the nose and mouth: — *Levator palpebræ superioris alæque nasi. Levator labii superioris proprius. Levator anguli oris. Zygomaticus major. Zygomaticus minor. Buccinator. Depressor anguli oris. Depressor labii inferioris. Orbicularis oris.* Depressor labii superioris alæque nasi. Constrictor nasi. Levator menti vel labii inferioris.*

Muscles of the external ear: — *Superior auris. Anterior auris. Posterior auris. Helicis major. Helicis minor. Tragicus. Antitragicus. Transversus auris.*

Muscles of the internal ear: — *Laxator tympani. Membrana tympani. Tensor tympani. Stapedius.*

Muscles of the lower jaw: — *Temporalis. Masseter. Pterygoideus externus. Pterygoideus internus.*

Muscles about the anterior part of the neck: — *Platysma myoides. Sterno-cleidomastoideus.*

Muscles between the lower jaw and os hyoides: — *Digastricus. Mylo-hyoideus. Genio-hyoideus. Genio-glossus. Hyo-glossus. Lingualis.*

Muscles situated between the os hyoides and trunk: — *Sterno-hyoideus. Crico-hyoideus. Sterno-thyroideus. Thyro-hyoideus. Crico-thyroideus.*

Muscles between the lower jaw and os hyoides laterally: — *Stylo-glossus. Stylo-hyoides. Stylo-pharyngeus. Circumflexus. Levator palati mollis.*

Muscles about the entry of the fauces: — *Constrictor isthmi faucium. Palatopharyngeus. Azygos uvulæ.**

Muscles situated on the posterior part of the pharynx: — *Constrictor pharyngis superior. Constrictor pharyngis medius. Constrictor pharyngis inferior.*

Muscles situated about the glottis: — *Crico-arytænoideus posticus. Crico-arytænoideus lateralis. Thyro-arytænoideus. Arytænoideus obliquus.* Arytænoideus transversus.* Thyro-epiglottideus. Arytæno-epiglottideus.*

Muscles situated about the anterior part of the abdomen: — *Obliquus descendens externus. Obliquus ascendens internus. Transversalis abdominis. Rectus abdominis. Pyramidalis.*

Muscles about the male organs of generation: — *Dartos.* Cremaster. Erector penis. Accelerator urinæ. Transversus perinei.*

Muscles of the anus: — *Sphincter ani.* Levator ani.**

Muscles of the female organs of generation: — *Erector clitoridis. Sphincter vaginæ.*

Muscles situated within the pelvis: — *Obturator internus. Coccygeus.*

Muscles situated within the cavity of the abdomen: — *Diaphragma.* Quadratus lumborum. Psoas parvus. Psoas magnus. Iliacus internus.*

Muscles situated on the anterior part of the thorax: — *Pectoralis major. Subclavius. Pectoralis minor. Serratus major anticus.*

Muscles situated between the ribs, and within the thorax: — *Intercostales externi. Intercostales interni. Triangularis.*

Muscles situated on the anterior part of the neck, close to the vertebræ: — *Longus colli. Rectus internus capitis major. Rectus capitis internus minor. Rectus capitis lateralis.*

Muscles situated on the posterior part of the trunk: — *Trapezius. Latissimus dorsi. Serratus posticus inferior. Rhomboideus. Splenius. Serratus superior posticus. Spinalis dorsi. Levatores costarum. Sacro lumbalis. Longissimus dorsi. Complexus. Trachelo mastoideus. Levator scapulæ. Semi-spinalis dorsi. Multifidus spinæ. Semi-spinalis colli. Transversalis colli. Rectus capitis posticus minor. Obliquus capitis superior. Obliquus capitis inferior. Scalenus. Interspinales. Intertransversales.*

Muscles of the superior extremities: — *Supra-spinatus. Infra-spinatus. Teres minor. Teres major. Deltoides. Coracobrachialis. Subscapularis.*

Muscles situated on the os humeri : — *Biceps flexor cubiti. Brachialis internus. Biceps extensor cubiti. Anconeus.*

Muscles situated on the fore-arm : — *Supinator radii longus. Extensor carpi radialis longior. Extensor carpi radialis brevior. Extensor digitorum communis. Extensor minimi digiti. Extensor carpi ulnaris. Flexor carpi ulnaris. Palmaris longus. Flexor carpi radialis. Pronator radii teres. Supinator radii brevis. Extensor ossis metacarpi pollicis manus. Extensor primi internodii. Extensor secundi internodii. Indicator. Flexor digitorum sublimis. Flexor digitorum profundus. Flexor longus pollicis. Pronator radii quadratus.*

Muscles situated chiefly on the hand : — *Lumbricales. Flexor brevis pollicis manus. Opponens pollicis. Abductor pollicis manus. Adductor pollicis manus. Abductor indicis manus. Palmaris brevis. Abductor minimi digiti manus. Abductor minimi digiti. Flexor parvus minimi digiti. Interossei interni. Interossei externi.*

Muscles of the inferior extremities : — *Pectinalis. Triceps adductor femoris. Obturator externus. Gluteus maximus. Gluteus minimus. Gluteus medius. Pyriformis. Gemini. Quadratus femoris.*

Muscles situated on the thigh : — *Tensor vaginæ femoris. Sartorius. Rectus femoris. Vastus externus. Vastus internus. Cruralis. Semi-tendinosus. Semi-membranosus. Biceps flexor cruris. Popliteus.*

Muscles situated on the leg : — *Gastrocnemius externus. Gastrocnemius internus. Plantaris. Tibialis anticus. Tibialis posticus. Peroneus longus. Peroneus brevis. Extensor longus digitorum pedis. Extensor proprius pollicis pedis. Flexor longus digitorum pedis. Flexor longus pollicis pedis.*

Muscles chiefly situated on the foot : — *Extensor brevis digitorum pedis. Flexor brevis digitorum pedis. Lumbricales pedis. Flexor brevis pollicis pedis. Abductor pollicis pedis. Adductor pollicis pedis. Abductor minimi digiti pedis. Flexor brevis minimi digiti pedis. Transversales pedis. Interossei pedis externi. Interossei pedis interni.*

MUSCULAR. (*Muscularis*; from *musculus*, a muscle.) Belonging to a muscle.

Muscular fibre. *Fibra muscularis.* The fibres that compose the body of a muscle are disposed in fasciculi, or bundles, which are easily distinguishable by the naked eye ; but these fasciculi are divisible into still smaller ones; and these again are probably subdivisible *ad infinitum.* The most minute fibre we are able to trace seems to be somewhat plaited; these plaits disappearing when the fibre is put upon the stretch, seem evidently to be the effect of contraction, and have probably induced some writers so assert, that the muscular fibre is twisted or spiral. Various have been the opinions concerning the structure of these fibres, their form, size, position, and the nature of the atoms that compose them. A fibre is essentially composed of *fibrine* and ozmazome, receives a great deal of blood, and, at least, one nervous filament. All other suppositions are founded only on conjecture, and therefore we shall mention only the principal ones, and this with a view rather to gratify the curiosity of the reader, than to afford him information. Borelli supposes them to be so many hollow cylinders, filled with a spongy medullary substance, which he compares to the pith of elder, *spongiosa ad instar sambuci.* These cylinders, he contends, are intersected by circular fibres, which form a chain of very minute bladders. This hypothesis has since been adopted by a great number of writers, with certain variations. Thus, for instance, Bellini supposes the vesicles to be of a rhomboidal shape; whereas Bernouilli contends that they are oval. Cowper went so far as to persuade himself that he had filled these cells with mercury ; a mistake, no doubt, which arose from its insinuating itself into some of the lymphatics. It is observable, however, that Leeuwenhoeck says nothing of any such vesicles. Here, as well as in many other of her works, Nature seems to have drawn a boundary to our inquiries, beyond which no human penetration will probably ever extend. By chemical analysis, muscle is found to consist chiefly of fibrine, with albumen, gelatine, extractive, phosphate of soda, phosphate of ammonia, phosphate and carbonate of lime, and sulphate of potash.

Muscular motion. Muscular motions are of three kinds: namely, voluntary, involuntary and mixed. The *voluntary motions* of muscles are such as proceed from an immediate exertion of the active powers of the will : thus the mind directs the arm to be raised or depressed, the knee to be bent, the tongue to move, &c. The *involuntary motions* of muscles are those which are performed by organs, seemingly of their own accord, without any attention of the mind, or consciousness of its active power; as the contraction and dilatation of the heart, arteries, veins, absorbents, stomach, intestines, &c. The *mixed motions* are those which are in part under the control of the will, but which ordinarily act without our being conscious of their acting ; and is perceived in the muscles of respiration, the intercostals, the abdominal muscles, and the diaphragm.

When a muscle acts, it becomes shorter and thicker ; both its origin and insertion are drawn towards its middle. The sphincter muscles are always in action ; and so, likewise, are antagonist muscles, even when they seem at rest. When two antagonist muscles move with equal force the part which they are designed to move remains at rest ; but if one of the antagonist muscles remains at rest, while the other acts, the part is moved towards the centre of motion.

When a muscle is divided, it contracts. If a muscle be stretched to a certain extent, it contracts, and endeavours to acquire its former dimensions, as soon as the stretching cause is removed : this takes place in the dead body, in muscles cut out of the body, and also in parts not muscular ; and is called, by the immortal Haller, *vis mortua*, and by some *vis elastica.* It is greater in living than in dead bodies, and is called the *tone* of the muscles.

When a muscle is wounded, or otherwise irritated, it contracts independent of the will. This power is called *irritability*, and, by Hal-

is insita: it is a property peculiar to, and inherent in, the muscles. The parts of our body which possess this property are called irritable; as the heart, arteries, muscles, &c., to distinguish them from those parts which have no muscular fibres. With regard to the degree of this property peculiar to various parts, the heart is the most irritable, then the stomach and intestines; the diaphragm, the arteries, veins, absorbents, and, at length, the various muscles follow; but the degree of irritability depends upon the age, sex, temperament, mode of living, climate, state of health, idiosyncrasy, and likewise upon the nature of the stimulus.

When a muscle is stimulated, either through the medium of the will or any foreign body, it contracts; and its contraction is greater or less in proportion as the stimulus applied is greater or less. The contraction of muscles is different according to the purpose to be served by their contraction: thus, the heart contracts with a jerk; the urinary bladder slowly and uniformly; puncture a muscle, and its fibres vibrate; and the abdominal muscles act slowly in expelling the contents of the rectum. Relaxation generally succeeds the contraction of muscles, and alternates with it.

Muscular contraction, such as takes place in the ordinary state of life, supposes the free exercise of the brain, of the nerves which enter the muscles, and of the muscles themselves. The discoveries of Sir C. Bell and M. Magendie have shown that the anterior columns of the spinal cord are the immediate seat of that modification of nervous power on which the action of the voluntary muscles depends. Every one of these organs ought to receive arterial blood, and the venous blood ought not to remain too long in its tissue. If one of these conditions is wanting, the muscular contraction is weakened, injured, or rendered impossible.

Phenomena of Muscular Contraction. — When a muscle contracts, its fibres shorten, become hard, with more or less rapidity, without any preparatory oscillation or hesitation: they acquire, all at once, such an elasticity, that they are capable of vibrating or producing sounds. The colour of the muscle does not appear to change in the instant of contraction; but there is a certain tendency to become displaced, which the *aponeuroses* oppose.

There have been discussions about the size of a muscle in its contracted and relaxed state. The question does not seem to be resolved in which of these states it is most voluminous: it is, happily, of small consequence.

The whole of the sensible phenomena of muscular contraction passes in the muscles; but, to a certainty, no action can take place without the immediate action of the brain and the nerves.

If the brain of a man or of an animal is compressed, the faculty of contracting the muscles ceases: the nerves of a muscle being cut, it loses all power.

What change happens in the muscular tissue during the state of contraction? This is totally unknown. In this respect there is no difference between muscular contraction and the vital actions, of which no explanation can be given. There is no want of attempts to explain the action of the muscles, as well as that of the nerves and the brain, in muscular contraction; but none of the proposed hypotheses can be received.

Instead of following such speculations, which can be easily invented or refuted, and which ought to be banished from physiology, it is necessary to study in muscular contraction, — 1st, the intensity of the contraction; 2dly, its duration; 3dly, its rapidity; 4thly, its extent.

The intensity of muscular contraction, that is, the degree of power with which the fibres draw themselves together, is regulated by the action of the brain; it is generally regulated by the will, according to certain limits, which are different in different individuals. A particular organisation of the muscles is favourable to the intensity of their contraction: this organisation is a considerable volume of fibres, strong, of a deep red, and striated transversely. With an equal power of the will, these will produce much more powerful effects than muscles, whose fibres are fine, colourless, and smooth. However, should a very powerful cerebral influence, or a great exertion of the will, be joined to such fibres, the contraction will acquire great intensity; so that the cerebral influence, and the disposition of the muscular tissue, are the two elements of the intensity of muscular contraction.

A very great cerebral energy is rarely found united, in the same individual, with that disposition of the muscular fibres which is necessary to produce intense contractions: these elements are almost always in an inverse ratio. When they are united, they produce astonishing effects. Perhaps this union existed in the *athletæ* of antiquity: in our times it is observed in certain mountebanks.

The muscular power may be carried to a wonderful degree by the action of the brain alone: we know the strength of an enraged person, of maniacs, and of persons in convulsions.

The will governs the duration of the contraction: it cannot be carried beyond a certain time, however it may vary in different individuals. A feeling of weariness takes place, not very great at first, but which goes on increasing until the muscle refuses contraction. The quick development of this painful feeling depends on the intensity of the contraction and the weakness of the individual.

To prevent this inconvenience, the motions of the body are so calculated that the muscles act in succession, the duration of each being but short: our not being able to rest long in the same position is thus explained, as an attitude which causes the contraction of a small number of muscles cannot be preserved but for a very short time.

The feeling of fatigue occasioned by muscular contraction soon goes off, and, in a short time, the muscles recover the power of contracting.

The quickness of the contractions are, to a certain degree, subject to cerebral influence: we have a proof of this in our ordinary motions;

but, beyond this degree, it depends evidently on habit. In respect of the rapidity of motion, there is an immense difference between that of a man who touches a piano for the first time, and that which the same man produces after several years' practice. There is, besides, a very great difference in persons, with regard to the quickness of contractions, either in ordinary motions, or in those which depend on habit.

As to the extent of the contractions, it is directed by the will; but it must necessarily depend on the length of the fibres: long fibres having a greater extent of contraction than those that are short.

After what has been said, we see that the will has generally a great influence on the contraction of muscles: it is not, however, indispensable: in many circumstances, motions take place, not only without the participation of the will, but even contrary to it: we find very striking examples of this in the effects of habit, of the passions, and of diseases.

Musculus. See *Muscle.*

Musculus cutaneus. See *Platysma myoides.*

Musculus fasciæ latæ. See *Tensor vaginæ femoris.*

Musculus patientiæ. See *Levator scapulæ.*

Musculus stapedius. See *Stapedius.*

Musculus supercilii. See *Corrugator supercilii.*

Musculus tubæ novæ. See *Circumflexus palati.*

MU'SCUS. (*us, i.* m.; the moss of a tree: from μοσχος, tender: so called from its delicate and tender consistence.) A moss. A cryptogamous plant, which has its fructification contained in a capsule.

Mosses are distinguished, according to the splitting of the capsule, into, —

1. *Musci frondosi*, the capsule of which is *operculate*, having a lid and the fronds very small.

2. *Musci hepatici*, liverworts; the capsules of which split into *valves*, and the herbage is *frondose* and stemless.

The parts of the capsule of frondose mosses, which are distinguished by particular names, are, —

1. The *surculus*, which bears the leaves.

2. The *seta*, or fruit-stalk, which goes from the surculus, and supports the theca.

3. The *theca*, or capsule; the dry fructification adhering to the apex of the frondose stem.

4. The *operculum*, or lid, found in the fringe.

5. The *peristoma*, *peristomium*, or fringe, which, in most mosses, borders the opening of the theca.

6. The *calyptra*, the veil, placed on the capsule like an extinguisher on a candle; as in *Bryum cæspititium.*

7. The *perichætium*, a slender or squamous membrane at the base of the fruit-stalk.

8. The *fimbria*, or fringe; a dentate ring of the operculum, by the elastic force of which the operculum is displaced.

9. The *epiphragma*, a slender membrane which shuts the fringe; as in *Polytricum.*

10. The *sphrongidium*, or *columnula*; the last column or filament which passes the middle of the capsule, and to which the seeds are attached.

Mosses are found in the hottest and coldest climates. They are extremely tenacious of life; and, after being long dried, easily recover their health and vigour by moisture. Their beautiful structure cannot be too much admired. Their species are numerous, and difficult to determine.

Muscus arboreus. See *Lichen plicatus.*

Muscus caninus. See *Lichen caninus.*

Muscus clavatus. See *Lycopodium.*

Muscus cranii humani. See *Lichen saxatilis* and *Usnea.*

Muscus camutalis. See *Lichen aphthosus.*

Muscus erectus. See *Lycopodium selago.*

Muscus islandicus. See *Lichen islandicus.*

Muscus marinus. See *Conferva rupestris.*

Muscus maritimus. See *Corallina officinalis.*

Muscus pulmonarius quercinus. See *Lichen pulmonarius.*

Muscus pyridatus. See *Lichen pyridatus.*

Muscus squamosus terrestris. See *Lycopodium.*

Mushroom. See *Agaricus.*

Mushroom, goat's beard. See *Clavaria.*

Mushroom, hedgehog. See *Hydnum erinaceum.*

MU'SIA PATTRÆ. A name of moxa.

Musk. See *Moschus.*

MUSK, ARTIFICIAL. Let three fluid drachms and a half of nitric acid be gradually dropped on one fluid drachm of rectified oil of amber, and well mixed. Let it stand twenty-four hours, then wash it well, first in cold, and then in hot water. One drachm of this resinous substance, dissolved in four ounces of rectified spirit, forms a good tincture, of which the mean dose is twenty minims. In preparing the above great attention should be given to the washing the resin, otherwise it is offensive to the stomach.

Musk-cranesbill. See *Geranium moschatum.*

Musk-melon. See *Cucumis melo.*

Musk-seed. See *Hibiscus abelmoschus.*

Mussel. See *Mytilus.*

MUSSE'NDA. (A Ceylonese word.) The name of a genus of plants. Class, *Pentandria.* Order, *Monogynia.*

MUSSENDA PONDOSA. Ray attributes a cooling property to an infusion or decoction of this plant, which the Indians drink by the name of *beleson.*

MUST. The expressed juice of the grape. By fermentation it forms wine.

Mustard. See *Sinapis.*

Mustard, hedge. See *Erysimum alliaria.*

Mustard, mithridate. See *Thlaspi.*

Mustard, treacle. See *Thlaspi.*

Mustard, yellow. See *Sinapis.*

MU'TICUS. (From *mutilus*, without horns. Beardless; awnless: applied to the arista or awn of plants. *Glumæ muticæ*, beardless husks. See *Gluma.*

MUTI'TAS. (*as, atis.* f.; from *mutus*, dumb.) Dumbness. See *Aphonia.*

Muza. See *Musa.*

MYACA'NTHA. (*a, æ.* f.; from μυς, a mouse, and ακανθα, a thorn: so called because its prickly leaves are used to cover whatever is intended to be preserved from mice.) The plant butcher's broom. See *Ruscus aculeatus.*

MY'CES. Μυκης. A fungus.

MYCTE'RES. Μυκτηρης. The nares.

MYCTEROPHO'NIA. (From μυκτηρες, the nostrils, and φωνη, the voice.) Nasal voice; that defect of voice which consists in speaking through the nose, as it is called. — *Plouquet.*

MYDE'SIS. (From μυδαω, to abound with moisture.) It imports, in general, a corruption of any part from a redundant moisture; but Galen applies it particularly to a purulent discharge from the eyelids.

MY'DON. (Μυδων; from μυδαω, to grow putrid.) A fleshy fungus in a fistulous ulcer. — *Julius Pollux.*

MYDRI'ASIS. (*is, is.* f. Μυδριασις, derivation doubtful.) A preternatural dilatation of the pupil.

MYELI'TIS. (From μυελος, marrow.) This name has been given to inflammation of the substance of the spinal cord, but it signifies simply inflammation of marrow. As the word μυων is used by Hippocrates to signify the spinal cord, *æonitis* might be adopted to express this disease.

MYLABRIS. A genus of coleopterous insects..

MYLABRIS VARIABILIS. This is brought from China, and is used as a substitute for cantharides.

MYLABRIS CICHORII. This species is said to be the same with the *buprestis* of the Greeks, which Pliny tells us was used as a vesicatory.

MYLA'CRIS. (From μυλη, a grindstone: so called from its shape.) The patella, or knee-pan.

MY'LE. Μυλη. 1. The knee-pan.

2. A mole in the uterus.

MY'LO HYOIDE'US. This muscle, which was first described by Fallopius, is so called from its origin near the *dentes molares* (μυλοι), and its insertion into the os hyoides. It is a thin, flat muscle, situated between the lower jaw and the os hyoides, and is covered by the anterior portion of the digastricus. It arises fleshy, and a little tendinous, from all the inner surface of the lower jaw, as far back as the insertion of the pterygoideus internus, or, in other words, from between the last dens molaris and the middle of the chin, where it joins its fellow, to form one belly, with an intermediate tendinous streak, or *linea alba*, which extends from the chin to the os hyoides, where both muscles are inserted into the lower edge of the basis of that bone. This has induced Riolanus, Winslow, Albinus, and others, to consider it as a single penniform muscle. Its use is to pull the os hyoides upwards, forwards, and to either side.

Mylo-pharyngeus. See *Constrictor pharyngis superior.*

MYOCE'PHALUM. (*um, i.* n.; from μυια, a fly, and κεφαλη, a head: from its resemblance to the head of a fly.) An incipient staphyloma.

MYOCOILI'TIS. (*is, idis.* f.; from μυς, a muscle, and κοιλια, a belly.) Inflammation of the muscles of the belly.

MYO'DESO'PSIA (*a, æ.* f.; from μυια, a fly, ειδος, resemblance, and οψις, vision.) An ill-constructed term which has been applied to that state of vision in which *muscæ volitantes* are seen before the eyes.

MYO'LOGY. (*Myologia, æ.* f.; from μυς, a muscle, and λογος, a discourse.) The doctrine of the muscles.

MYO'PIA. (*a, æ.* f.; from μυω, to contract, and ωψ, the eye.) Near-sightedness: persons are considered near-sighted who cannot see distinctly above twenty inches. The term is also applied to the exercise of vision at shorter distances than usual. The proximate cause is the adunation of the rays of light in a focus before the retina. This disease arises from,

1. Too great a convexity of the cornea. The cause of this convexity is either congenital, or consists in a greater secretion of the aqueous humour: hence on one day there shall be a greater myopia than on another.

2. Too great a longitude of the bulb. This length of the bulb is native, or acquired from a congestion of the humours in the eye: hence artificers occupied on minute objects, as the engravers of seals, and persons reading much, frequently, after puberty, become myopes.

3. Too great a convexity of the anterior superficies of the crystalline lens. This is likewise from birth. The image will so much sooner be formed as the cornea or lens is more convex. This perfectly accounts for short-sightedness; but too great convexity of the cornea is the most common cause.

4. Too great a density of the cornea, or humours of the eye; for optics teach us, that the rays of light are forced into a focus so much the sooner, as the diaphanous body is denser.

5. Too dilated a pupil.

6. Infants, from the great convexity of the cornea, are often myopes; but, by degrees, as they advance in years, they perceive objects more remotely, by the cornea becoming less convex. The best palliatives of this disease are concave spectacles.

MY'OPS. (*Ops, opis.* n.; from μυω, to contract, and ωψ, the eye.) One who is near-sighted. See *Myopia.*

MYO'SIS. (*is, is.* f. Μυωσις.) A disease of the eye, which consists in a contraction or too small perforation of the pupil.

MYOSI'TIS. (*is, idis.* f.; from μυς, a muscle.) Inflammation of a muscle. It is the term applied by Sagar to acute rheumatism.

MYOSO'TIS. (*is, is.* f. Μυς, a muscle, and ους, ωτος, an ear: so called because its leaves are hairy, and grow longitudinally, like the ear of a mouse.) See *Hieracium pilosella.*

MYO'TOMY. (*Myotomia, æ.* f.; from μυς, a muscle, and τεμνω, to cut.) The anatomy of the muscles.

MYRI'CA. (*a, æ.* f.; a name borrowed from the ancient Greeks, whose μυρικη, however, appears to be the *Tamarix gallica.*) The name of a genus or family of plants. Class, *Diœcia;* Order, *Tetrandria.*

MYRICA CERI'FERA. A North American plant, the berries of which yield a green wax, which is made into candles. The root is strongly astringent.

MYRICA GALE. The systematic name of the Dutch myrtle or sweet willow; called also, *Myrtus brabantica, Myrtus Anglica, Myrtifolia belgica, Gale, Gagel, Rus sylvestris, Acaron, Elæagnus, Elæagnus cordo, Chamælæagnus,* and *Dodonæa.* The leaves, flowers, and seeds of this plant have a strong, fragrant smell, and a bitter

taste. They are said to be used amongst the common people for destroying moths and cutaneous insects, and the infusion is given internally, as a stomachic and vermifuge.

MYRI'CIN. The ingredient of wax which remains after digestion in alkohol. It is insoluble, also, in water and æther; but very soluble in fixed and volatile oils. Dr. John, who discovered it, gave it this name, because it is very abundant in the wax of the myrica cerifera.

MYRIOPHY'LLON. (*um*, *i.* n.; from *μυριος*, infinite, and *φυλλον*, a leaf: named from the number of its leaves.) Milfoil, a species of Achillea. See *Achillea millefolium*.

MYRI'STICA. (*a*, *æ.* f.) The name of a genus of plants in the Linnæan system. Class, *Diœcia*; Order, *Monadelphia*.

MYRISTICA AROMATICA. Swart's name for the nutmeg-tree.

MYRISTICA MOSCHATA. The nutmeg and mace tree.

1. The nutmeg; called also, *Myristicæ nucleus*, *Nux moschata*, *Nucista*, *Nux myristica*, *Chrysobalanus Galeni*, *Unguentaria*, *Assala*, and *Nux aromatica*. The seed, or kernel, of the *Myristica—foliis lanceolatis*, *fructu glabro*, of Linnæus. It is a spice that is well known, and has been long used, both for culinary and medical purposes. Distilled with water, it yields a large quantity of essential oil, resembling in flavour the spice itself: after the distillation, an insipid sebaceous matter is found swimming on the water; the decoction, inspissated, gives an extract of an unctuous, very slightly bitterish taste, and with little or no astringency. Rectified spirit extracts the whole virtue of nutmegs, by infusion, and elevates very little of it in distillation: hence the spirituous extract possesses the flavour of the spice in an eminent degree. Nutmegs, when heated, yield to the press a considerable quantity of limpid, yellow oil. There are three kinds of unctuous substances, called oil of mace, though really expressed from the nutmeg. The best is brought from the East Indies, in stone jars: this is of a thick consistence, of the colour of mace, and has an agreeable fragrant smell. The second sort, which is paler coloured, and much inferior in quality, comes from Holland, in solid masses, generally flat, and of a square figure. The third, which is the worst of all, and usually called common oil of mace, is an artificial composition of suet, palm oil, and the like, flavoured with a little genuine oil of nutmeg. The nutmeg is aromatic, and stomachic, and hence it has been much used in diarrhœas and dysenteries. There is also reason to believe that it has a narcotic power, which resides in the essential oil. See *Agrypnia*.

2. *Mace* is the middle bark of the nutmeg. A thick, tough, reticulated, unctuous membrane, of a lively, reddish yellow colour, approaching to that of saffron, which envelopes the shell of the nutmeg. The mace, when fresh, is of a blood red colour, and acquires its yellow hue in drying. It is dried in the sun, upon hurdles fixed above one another, and then, it is said, sprinkled with sea-water, to prevent its crumbling in carrying. It has a pleasant, aromatic smell, and a warm, bitterish, moderately pungent taste. It is in common use as a grateful spice, and appears to be in its general qualities nearly similar to the nutmeg. The principal difference consists in the mace being much warmer, more bitter, less unctuous, and sitting easier on weak stomachs. Mace possesses qualities similar to those of nutmeg, but is less astringent, and its oil is supposed to be more volatile and acrid.

Myristica nux. See *Myristica moschata*.

MYRISTICA OTOBA. This species grows in Santa Fé; and also produces a nutmeg.

MYRME'CIUM. *Μυρμηκιον*; from *μυρμηξ*, an ant: so called either from some fancied resemblance, or from its occasioning a pain like the sting of an ant. A moist soft wart, about the size of a lupin, with a broad base, deeply rooted, and very painful. It grows on the palms of the hands, and soles of the feet.

Myro'balan. See *Myrobalanus*.

MYROBA'LANUS. (*us*, *i.* f.; from *μυρος*, an unguent, and *βαλανος*, a nut: so called because it was formerly used in ointments.) A myrobalan. A dried fruit of the plum kind, brought from the East Indies. All the myrobalans have an unpleasant bitterish, very austere taste, and strike a black colour, with solutions of iron. They are said to have a gently purgative, as well as an astringent and corroborating virtue. In this country they have been long expunged from the pharmacopœias. Of this fruit there are several species.

MYROBALANUS BELLIRICA. The belliric myrobalan. The fruit is of a yellowish grey colour, and an irregular roundish or oblong figure, about an inch in length, and three quarters of an inch thick.

MYROBALANUS CHE'BULA. The chebule myrobalan. This resembles the yellow in figure and ridges, but is larger, of a darker colour, inclining to brown or blackish, and has a thicker pulp.

MYROBALANUS CITRINA. Yellow myrobalan. This fruit is somewhat longer than the belliric with generally five large longitudinal ridges and as many smaller between them, somewha pointed at both ends.

MYROBALANUS E'MBLICA. The emblic myrobalan is of a dark blackish grey colour, roundish about half an inch thick, with six hexagona faces, opening from one another.

MYROBALANUS INDICA. The Indian or blacl myrobalan, of a deep black colour, oblong, oc tangular, differing from all the others in havin no stone, or only the rudiments of one, fro which circumstance they are supposed to hav been gathered before maturity.

MYROLE'. (From *μυρον*, a perfumed oil. A French term for a medicated volatile oil.

MY'RON. (*Μυρον*; from *μυρω*, to flow drop.) An ointment, or medicated oil.

MYRO'XYLON. (*um*, *i.* n.; from *μυρο* an ointment, and *ξυλον*, wood.) The name a genus of plants in the Linnæan system. Clas *Diandria*; Order, *Monogynia*.

MYROXYLON PERUIFERUM. The systemat name of the tree which gives out the Peruvi balsam. *Balsamum peruvianum*. *Putzochi Indian*, *Mexican*, and *American balsam*. *Ca bareiba* is the name of the tree from which, a

ording to Piso and Ray, it is taken. It is the *Myroxylon peruiferum* of Linnæus, which grows n the warmest provinces of South America, nd is remarkable for its elegant appearance. Every part of the tree abounds with a resinous uice; even the leaves being full of transparent esinous points, like those of the orange tree.

Balsam of Peru is of three kinds; or rather, t is one and the same balsam, having three everal names: — 1. The balsam of incision; 2. The dry balsam; 3. The balsam of lotion. The virtues of this balsam, as a cordial, pectoral, nd restorative stimulant and tonic, are, by some, hought to be very great. It is given with adantage from 5 to 10 or 15 drops for a dose, in yspepsia, atonic gout, in consumptions, asthmas, ephritic complaints, obstructions of the viscera, nd suppressions of the menses. It is best aken dropped upon sugar. The yoke of an gg, or mucilage of gum-arabic, will, indeed, issolve it: it may, by that way, be made into n emulsion; and it is less acrid in that form han when taken singly. It is often made an ngredient in boluses and electuaries, and enters nto two of the officinal compositions, — the nctura balsami Peruviani composita, and the rochisci glycyrrhizæ. Externally, it is recomnended as an useful application to relaxed ulcers, ot disposed to heal.

MY'RRHA. (*a*, *æ*. f.; a Hebrew word.) Σμυρνη. Μυῤῥα. The name *stacte* has also been pplied to this among other substances. Myrrh. The plant which affords this drug is not known. Bruce conjectured it to be an *acacia*. Nees Von Esenbek refers it to the genus *balsamodendron*. The tree that affords the myrrh, which is obained by incision, grows on the eastern coast of Arabia Felix, and in that part of Abyssinia hich is situated near the Red Sea, and is called y Bruce, *Troglodyte*. Good myrrh is of a urbid black-red colour, solid and heavy, of a eculiar smell, and bitter taste. Its medicinal ffects are warm, corroborant, and antiseptic: has been given as an emmenagogue, in doses rom 5 to 20 grains. It is also given in cahexies, and applied externally as an antiseptic nd vulnerary. In doses of half a drachm, Dr. Cullen remarks that it heated the stomach, prouced sweat, and agreed with the balsams in ffecting the urinary passages. It has lately ome more into use as a tonic in hectical cases, nd is said to prove less heating than most ther medicines of that class. Myrrh dissolves most totally in boiling water; but, as the quor cools, the resinous matter subsides. Recfied spirit dissolves less of this concrete than ater; but extracts more perfectly that part in hich its bitterness, virtues, and flavour reside: e resinous matter which water leaves unssolved is very bitter; but the gummy matter hich the spirit leaves undissolved is insipid, e spirituous solution containing all the active art of the myrrh: it is applied to ulcers, and ther external affections of a putrid tendency; nd also as a wash, when diluted, for the teeth nd gums. The tincture of myrrh is officinal, nd it forms an ingredient in several officinal edicines. See *Mistura ferri composita*, and *ilula aloes cum myrrha*.

MY'RRHIS. (From μυρρα, myrrh: so named from its myrrh-like smell.) Sweet cicely. See *Scandix odorata*.

MYRSINELÆ'UM. (From μυρσινη, the myrtle, and ελαιον, oil.) Oil of myrtle.

MYRTACA'NTHA. (*a*, *æ*. f.; from μυρτος, a myrtle, and ακανθα, a thorn: so called from its likeness to myrtle, and from its prickly leaves.) Butcher's broom. See *Ruscus*.

MYRTI'DANUM. (From μυρτος, the myrtle.) An excrescence growing on the trunk of the myrtle; formerly used as an astringent.

Myrtiform caruncles. See *Caruncula myrtiformes*.

Myrtiform glands. See *Caruncula myrtiformes*.

Myrtillus. See *Vaccinium myrtillus*.

MYRTI'TES. An old medicine prepared with honey and the juice of the myrtle berries.

Myrtle. See *Myrtus*.

Myrtle, Dutch. See *Myrica gale*.

MY'RTOCHEI'LIDES. (From μυρτον, the clitoris, and χειλος, a lip.) The nymphæ of the female pudenda.

MYRTOI'DEÆ. A natural family of plants, of which the myrtle is the type.

MY'RTON. Μυρτον. The clitoris.

MY'RTUS. (*us*, *i*. f.; from μυρρα, because of its smell; or from *Myrrha*, a virgin who was fabled to have been turned into this tree.) 1. The name of a genus of plants in the Linnæan system. Class, *Icosandria*; Order, *Monogynia*.

2. The pharmacopœial name of the myrtle. See *Myrtus communis*.

Myrtus brabantica. See *Myrica gale*.

MYRTUS CARYOPHY'LLATA. The tree which affords the clove bark. *Cassia caryophyllata*. The bark of this tree, *Myrtus — pedunculis trifido-multifloris, foliis ovatis*, of Linnæus, is a warm aromatic, of the smell of clove spice, but weaker, and with a little admixture of the cinnamon flavour. It may be used with the same views as cloves, or cinnamon.

MYRTUS COMMUNIS. The common myrtle.

MYRTUS COMMUNIS ITALICA. *Oxymyrrhine. Oxymyrsine*. The berries of this plant are recommended in alvine and uterine fluxes, and other disorders from relaxation and debility. They have a roughish, and not unpleasant taste, and appear to be moderately astringent and aromatic.

MYRTUS PIMENTA. The tree which bears the Jamaica pepper, or allspice. *Pimento. Piper caryophyllatum. Cocculus. Indi aromaticus. Piper chiapæ. Amomum pimenta. Caryophyllus aromaticus. Caryophyllus americanus. Piper odoratum jamaicense. Myrtus — floribus trichotoma-paniculatis, foliis oblongo-lanceolatis*, of Linnæus. This spice, which was first brought over for dietetic uses, has been long employed in the shops as a succedaneum to the more costly Oriental aromatics: it is moderately warm, of an agreeable flavour, somewhat resembling that of a mixture of cloves, cinnamon, and nutmegs. The pharmacopœias direct an aqueous and spirituous distillation to be made from these berries; and also an essential oil.

MY'STAX. (*ax*, *acis*. f. Μυσταξ.) 1. The

hair which forms the beard in man, on each side the upper lip.

2. The upper lip itself.

MY'STRUM. *Μυστρον.* An ancient measure.

MYSTRUM MAGNUM. A measure containing three ounces and eight scruples, when applied to wine, and three ounces when applied to oil.

MYSTRUM PARVUM. A measure containing twenty scruples of wine, or six drachms of oil.

MY'TILUS. (*us, i.* m.; said to be derived from *μυς.*) The name of a genus of shell-fish. Class, *Vermes;* Order, *Testacea.* The mussel or muscle.

MYTILUS EDU'LIS. The edible or eatable muscle. This is found in the European seas, in vast beds, and generally adhering to other bodies by a long silky beard. The flesh is esteemed by some, when boiled; for it is never eaten raw. It is not so easy of digestion as the oyster; and a small quantity often disagrees. It sometimes acts as a poison, producing in some cases violent bowel complaints; in others a nettle rash, accompanied with asthma; and in others a peculiar comatose affection. The circumstances under which the muscle becomes poisonous are not understood.

MYTILUS MARGARITI'FERUS. The pearl muscle, found in the American and Indian seas. It is about eight inches long, and still broader than it is long. The inside is beautifully polished; produces the true mother of pearl, and frequently the most valuable pearls. It was formerly referred to the genus *ostrea.*

MYU'RUS. (*Μυουρος*; from *μυς*, a mouse, and *ουρα*, a tail.) A whimsical name given by the Greeks to a sort of sinking pulse, the second stroke of which is less than the first, the third than the second, &c., the pulse thus diminishing towards the end like a mouse's tail. Of this there are two kinds; the first is, when the pulse sinks progressively, till it ceases; the other, when it rallies again, in some degree, but finally fails.

MYXA. *Μυξα.* Mucus.

MYXOSARCO'MA. (From *μυξα*, mucus, and *σαρξ*, flesh.) A tumour which is partly fleshy and partly mucous.

MY'XTER. (From *μυξα*, the mucus of the nose.) The nose or nostril.

N.

N. In prescriptions, this letter is a contraction for *numero*, in number. Thus, Pil. Hydrarg. N. xij., means mercurial pills, twelve in number.

NA'CTA. An abscess of the breast.

NA'DUCEM. A uterine mole.

NÆ'VUS. (*us, i.* m.) A natural mark, spot, or blemish.

NÆVUS MATERNUS. *Macula matricis. Stigma. Metrocelis.* A mother's mark. A mark on the skin of children, which is born with them, and which is said to be produced by the longing of the mother for particular things, or her aversion to them; hence these marks resemble mulberries, strawberries, grapes, pines, bacon, &c.

NA'I CORONA. A name of the cowhage.

Nail. See *Unguis.*

Naja. See the Supplement.

Naked. See *Nudus.*

NA'KIR. A name given by Schenk to wandering pains in the limbs, supposed to arise from wind.

NANCEIC ACID. (*Acidum nanceicum:* so called by Braconnot, in honour of the town of Nancy, where he lived.) Zumic acid. He discovered it in many acescent vegetable substances; in sour rice; in putrefied juice of beet-root; in sour decoction of carrots, peas, &c. He imagines that this acid is generated at the same time as vinegar in organic substances, when they become sour. It is without colour, does not crystallise, and has a very acid taste.

Nanus. See *Dwarf.*

NAPE'LLUS. (*us, i.* m.; diminutive of *napus:* so called because it has a bulbous root like that of the *napus.*) See *Aconitum.*

NA'PHÆ FLORES. Orange flowers are sometimes so called. See *Citrus aurantium.*

NA'PHTHA. (*a, æ.* f. *Ναφθα.*) A native combustible liquid of a yellowish white colour, perfectly fluid and shining. It feels greasy, and exhales an agreeable bituminous smell. It occurs in considerable springs on the shores of the Caspian sea, in Sicily, and Italy. It is used instead of oil, and differs from petroleum obtained by distilling coal only by its greater purity and lightness. This fluid has been used as an external application for removing old pains, nervous disorders, such as cramps, contractions of the limbs, paralytic affections, &c.

Naphtha vitrioli. See *Æther sulphuricus.*

NA'PHTHALINE. A greyish white substance found during the rectification of the petroleum of the coal-gas works, incrusting the pipes. It may be obtained in thin white scales of a pearly brightness, by slow re-sublimation in glass vessels. Its specific gravity is 1·048. It has a strong odour of naphtha, is insoluble in water, but very soluble in ether, and moderately so in alkohol and oils. According to Dr. Ure's analysis, it is a solid bicarburet of hydrogen.

Napifolia. See *Brassica.*

Napium. See *Lapsana communis.*

Napta. See *Natta.*

Napus. See *Brassica.*

Napus dulcis. See *Brassica rapa.*

Napus sylvestris. See *Brassica rapa.*

Napy. See *Sinapi.*

NARCA'PHTHUM. Ναρκαφθον. An aromatic bark brought from India. It was used in fumigations.

NA'RCEINE. A principle detected by Pelletier in opium. Little is yet known concerning it.

NARCI'SSUS. (*us, i.* m.) A genus of plants in the Linnæan system. Class, *Hexandria;* Order, *Monogynia.*

NARCISSUS PSEUDONARCISSUS. Common daffodil. The root of this plant is emetic and cathartic, and the flowers are said to be antispasmodic. The dose of the former is ʒij. That of the latter, ʒj. or more.

NARCO'SIS. (*is, is.* f.; ναρκωσις; from ναρκοω, to stupify.) The effect of a narcotic.

NARCO'TIC. (*Narcoticus;* from ναρκοω, to stupify.) A term applied substantively and adjectively to medicines which have the power of stupifying and diminishing the activity of the nervous system. Most narcotics have a degree of stimulating power, and this is manifested chiefly when they are given in small doses, while a full dose generally produces the narcotic effect at once, without any apparent stimulation preceding it. Cullen believed that the stimulating effect is owing to the resistance offered by the *vis medicatrix naturæ* to the sedative influence of the medicine; and hence, that a large dose is immediately sedative, because the resistance of the system is overpowered. Brown, on the contrary, maintained that narcotics are in reality highly diffusible stimuli, which exhaust the system by the rapidity of their action.

Thus, Cullen regarded them as directly sedative and indirectly stimulant; and Brown, directly stimulant and indirectly sedative. The hypothesis of Cullen seems much preferable to that of Brown; but neither of them is now generally received, and we are content to confess that we do not know how narcotics act. To the class of narcotics belong opium, hemlock, henbane, belladonna, aconite, stramonium, camphor, digitalis, tobacco, alkohol, ether, nux vomica, leopard's bane, hop, strong scented lettuce, and a variety of other substances. Prussic acid has been considered as a narcotic, but it does not seem properly referrible to this class. It seems to be direct sedative, and never to exert any stimulating power.

NA'RCOTINE. (*a. æ,* f.; so called because of its stupifying power.) An active principle of opium. See *Papaver somniferum.*

Nard. See *Valeriana celtica.*

Nard, Indian. See *Andropogon nardus.*

NARDO'STACHYS. (*ys, os.* f.; from ναρδος, spikenard, and σταχυς, sage.) A species of wild sage, resembling spikenard in its leaves and smell.

NA'RDUS. (*us, i.* f.; from *nard,* Syrian.) Spikenard. See *Lavendula spica.*

Nardus celtica. See *Valeriana celtica.*

Nardus indica. See *Andropogon nardus.*

Nardus italica. See *Lavendula spica.*

Nardus montana. See *Asarum.*

Nardus rustica. See *Asarum.*

NARIFUSO'RIA. (From *nares,* the nostrils, and *fundo,* to pour.) Medicines dropped into the nostrils have been so called.

NA'RIS. (*is, is.* f.) The nostril. The cavity of the nostrils is of a pyramidal figure, and is situated under the anterior part of the cranium, in the middle of the face. The two nostrils are composed of fourteen bones, viz. the frontal, two maxillary, two nasal, two lachrymal, two inferior spongy, the sphenoid, the vomer, the ethmoid, and two palatine bones, which form several eminences and cavities. The eminences are the septum narium, the cavernous substance of the ethmoid bone, called the superior conchæ, and the inferior spongy bones. The cavities are three pair of pituitary sinuses, namely, the frontal, sphenoid, and maxillary; the anterior and posterior foramina of the nostrils; the ductus nasalis, the spheno-palatine foramina, and anterior palatine foramina. All these parts are covered with periosteum, and a pituitary membrane which secretes the mucus of the nostrils. The arteries of this cavity are branches of the internal maxillary. The veins empty themselves into the internal jugulars. The nerves are branches of the olfactory, ophthalmic, and superior maxillary. The use of the nostrils is for smelling, respiration, and speech.

Naris compressor. See *Compressor naris.*

NA'RTA. (Ναρτα, *ex nardi odore,* from its smell.) A plant used in ointments.

NASAL. (*Nasalis;* from *nasus,* the nose.) Appertaining to the nose.

NASAL FOSSÆ. The cavity of the nares. See *Naris.*

NASAL NERVE. A branch of the ophthalmic which passes to the inside of the orbit, and gives off a branch which enters the nose by the foramen orbitarium internum anterius, re-enters the cranium through the cribriform plate of the ethmoid bone, and again descends through the same plate to the nose.

Nasalis labii superioris. See *Orbicularis oris.*

NASA'RIUM. (From *nasus,* the nose.) The mucus of the nose. — *Turton.*

NASCA'LE. 1. A pessary.

2. A compress of lint, or other soft material impregnated with some medicament, intended to be introduced into the vagina. — *P. Morel.*

NASCA'PHTHUM. Νασκαφθον. The same as *narcapthon.*

Nasi depressor. See *Depressor labii superioris alæque nasi.*

NASI OSSA. The two small bones of the nose, that are so termed, form the bridge of the nose. In figure they are quadrangular and oblong.

NA'SO-LOBA'RIS. The name given by Chaussier to one of the filaments of the nasal nerve.

NA'SO-OCULA'RIS. Soëmmering's name for the nasal branch of the ophthalmic nerve.

NA'SO-PA'LATINE GANGLION. A small ganglion situated in the anterior palatine foramen.

NASO-PALATINE NERVE. A twig sent out from the sphenopalatine ganglion.

NA'SO-PA'LPEBRAL MUSCLE. The orbicular muscle of the eye. — *Chaussier.*

NA'SO-SUPERCILIA'RIS. The corrugator supercilii muscle.

NASTU'RTIUM. (*um, i.* n.; *quod nasum torqueat,* because the seed, when bruising, irri-

tates the nose!) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia;* Order, *Siliquosa.*

Nasturtium aquaticum. See *Sisymbrium nasturtium.*

Nasturtium hortense. See *Lepidium.*

Nasturtium indicum. See *Tropæolum.*

NA'SUS. (*us, i.* m.) The nose. The external part of this organ is composed of the *dorsum*, or bridge of the nose; the *lobe*, or tip of the nose; the *alæ nasæ*, or sides of the nostrils; and the *columna*, or inferior termination of the septum. For the internal structure of the nose, see *Naris* and *Smell.*

Nata. See *Natta.*

NA'TANS. (From *nato*, to swim.) Floating. Applied to leaves on the surface of the water, in opposition to those which are naturally under, and different, and are called demersed, immersed, and submersed; as in *Potamogeton natans.*

NA'TES. (*es, is.* f.; from *nato* to flow: because the excrements are discharged from them.) 1. The buttocks.

2. Two of the eminences of the brain, called tubercula quadrigemina, are so named from their resemblance.

Nates cerebri. See *Tubercula quadrigemina.*

NA'TRON. (Indeclinable. So called from *Natron*, a lake in Judæa, where it was found.) *Natrum.* 1. The name formerly given to the alkali now called soda. See *Soda.*

2. A native salt, which is found crystallised in Egypt, in the lake called Natron, and in other hot countries, in sands surrounding lakes of salt water. It is an impure subcarbonate of soda, and there are two kinds of it, the common and the radiated.

3. The name of an impure subcarbonate of soda, obtained by burning various marine plants. See *Soda.*

Natron muriatum. See *Sodæ murias.*

Natron præparatum. See *Sodæ subcarbonas.*

Natron tartarisatum. See *Soda tartarizata.*

Natron vitriolatum. See *Sodæ sulphas.*

NATTA. *Nata. Napta.*

NA'TULÆ. (Diminutive of *nates*, the buttocks: so called from their resemblance.) The two uppermost of four small eminences of the brain. See *Nates.*

NATURAL. *Naturalis.* Appertaining to nature.

Natural actions. See *Actions.*

Natural functions. See *Actions.*

NATURAL ORDERS. A division or arrangement of animals, plants, &c., from their external habits or characters. See *Vegetable Kingdom.*

NATURA'LIA. (*a, um.* pl. n.; from *natura*, nature.) The parts of generation.

NAU'CLEA. The name of a genus of plants.

NAUCLEA GAMBIR. The plant which yields the East Indian kino. See *Kino.*

NAU'SEA. (*a, æ.* f. Ναυσεα; from *navs*, a ship: because it is a sensation similar to that produced by sailing in a ship.) An inclination to vomit without effecting it. See *Sickness.*

Nausiosis. See *Nausea.*

Nautia. See *Nausea.*

NAUTICUS MUSCULUS. The sailor's muscle. The tibialis posticus was so named by Spigelius, because it is employed in the act of climbing.

Navew. See *Brassica rapa.*

Navew, garden. See *Brassica rapa.*

Navew, sweet. See *Brassica rapa.*

NAVI'CULAR. (*Navicularis;* from *navicula*, a little boat.) 1. Boat-like. See *Naviculare os.*

2. Applied to parts of plants; as the valves of the seed-vessels of the *Isatis tinctoria*, and the lower petal of many of the papilionaceous blossoms.

NAVICULA'RE OS. *Naviforme os. Cymba.* A bone of the tarsus is so called, from its supposed resemblance to a boat.

Naviformis. See *Navicular.*

NEAPOLITA'NUS MO'RBUS. The venereal disease has been so called, because it was supposed to have made its first appearance in the army of Charles the Eighth of France, during the siege of Naples, in 1495.

Near-sightedness. See *Myopia.*

NE'BULA. (*a, æ.* f.; from νεφελη. 1. A superficial opacity of the cornea, occupying only its outer layer.

2. The cloud-like appearance in the urine, after it has been a little time at rest.

NECK. *Collum.* The parts which form the neck are divided into external and internal.

1. The *external* parts are the common integuments, several muscles, eight pair of cervical nerves, the eighth pair of nerves of the cerebrum, and the great intercostal nerve; the two carotid arteries, the two external jugular veins, and the two internal; the glands of the neck, viz. the jugular, submaxillary, cervical, and thyroid.

2. The *internal* parts are the fauces, pharynx, œsophagus, larynx, and trachea.

3. The bones of the neck are the seven cervical vertebræ.

NECROSCOPICAL. (From νεκρος, dead, and σκοπεω, to explore.) Relating to the examination of dead bodies.

NECRO'SIS. (*is, is.* f.; from νεκροω, to destroy.) This word, the strict meaning of which is only mortification, is, by the general consent of surgeons, confined to an affection of the bones. The death of parts of bones was not distinguished from caries, by the ancients. However, necrosis and caries are essentially different; for, in the first, the affected part of the bone is deprived of the vital principle; but this is not the case when it is simply carious. Caries is very analogous to ulceration; while necrosis is exactly similar to mortification of the soft parts.

NECROSIS USTILAGI'NEA. A painful convulsive contraction of the limbs. See *Raphania.*

NE'CTAR. (*ar, aris.* n. Νεκταρ, the drink of the gods.) A drink made of wine and honey.

NECTA'RIUM. (*um, ii.* n.; from nectar, because it contains a sweet honey-like fluid.) The nectary or honey-cup. An accidental part of a flower, which does not come under the description of any of its organs. It may be de-

fined that part of the corolla which contains or which secretes honey, though it is not necessary to a nectary that honey be present.

Scarce a flower can be found that has not more or less honey, though it is far from being universally, or even generally formed, by an apparatus separate from the petals.

In monopetalous flowers, as the *Lamium album*, the dead nettle, the tube of the corolla contains, and probably secretes, the honey, without any evident nectary.

Sometimes the part under consideration is a production or elongation of the corolla, as in the violet: sometimes, indeed, of the calyx, as in the garden nasturtium, *Tropæolum*, the coloured calyx of which partakes much of the nature of the petals.

Sometimes it is distant from both, either resembling the petals, as in *Aquilegia*; or more different, as in *Epimedium*, *Aconitum*, *Helleborus*, *Delphinium*. Such, at least, is what Linnæus and his followers understand of the four last-mentioned plants.

The most indubitable of all nectaries, as actually secreting honey, are those of a glandular kind. In the natural order of cruciform plants, composing the class *Tetradynamia*, there are generally four green glands at the base of the stamens, as in *Dentaria* and *Sisymbrium*; whilst in *Pelargonium*, the nectary is a tube running down one side of the flower-stalk. The elegant *Parnassia* has a most elaborate apparatus or nectary. — *Smith*.

From the figure of the nectary, it is said to be, —

1. *Calcarate*, or spur-like; as in *Aquilegia vulgaris*, *Delphinium ajax*, and *Antirrhinum linaria*.

2. *Cucullate*, hooded; as in *Impatiens balsamina*, *Aconitum*, and *Asclepias vincetoxicum*.

3. *Foveate*, a little depression in the claw of the petal; as in *Fritillaria imperialis*.

4. *Campanulate*; as in *Narcissus jonquilla*, and *Pseudonarcissus*.

5. *Crown-like*; as in *Passiflora cærulea*.

6. *Pedicellate*, resting on a partial flower-stalk; as in *Aconitum napellus*.

7. *A bilabiate tube*; as in *Helleborus fœtidus*, and *Nigella*.

8. *Poriform*, there being three pores in the germen; as in the Hyacinths.

9. *Squamate*, a little scale on the claw; as in *Ranunculus*.

10. *Glandular*, little nectiferous glands between the stamens and pistils; as in *Sinapis alba*.

11. *Stellate*, a double star covering the internal organs; as in *Stapelia*.

12. *Pilous*, fine hairy fascicles at the base of the stamina; as in *Parnassia palustris*.

13. *Bearded*; as in *Iris germanica*.

14. *Forniciform*, arched; small prolongations at the opening of the corolla, and covering the internal organs; as in *Symphytum officinale*, and *Myosotis scorpioides*.

15. *Bristle-like*, fine horn-like filaments around the internal organs; as in *Periploca græca*.

16. *Rotate*; as in *Cissampelos*.

17. *Scrotiforme*, behind the flower; as in *Satyrium*.

18. *Horn-like*, behind the flower; as in *Orchis*.

19. *Sandaliform*, slipper-like; as in *Cypripedium calceolus*.

20. *Globose*, investing the germen; as in *Mirabilis jalappa*.

21. *Cyathiform*, cup-like; as in *Urtica urens*.

22. *Conical*; as in *Utricularia foliosa*.

23. *Ascidiforme*, pitcher-like, a membranous tube, containing water, and behind the flower; as in *Ascium*, and *Ruyschia*.

24. *Calycine*, adhering to the calyx by a spur; as in *Tropæolum majus*.

NEDY'IA. (Νηδυϊα; from νηδυς, the belly.) The intestines.

NEDYS. Νηδυς. The belly.

Needle. See *Acus*.

Needle-shaped leaf. See *Acerosus*.

Needle zeolite. See *Zeolite*.

Negro cachexy. See *Cachexia*.

NEIÆRA. Νειαιρα; (from νειαρος, furthermost.) The lower part of the belly.

NEMOROSUS. (From *nemus*, a grove.) Appertaining to a grove. The specific name of many plants which grow in woods; as *Anemone nemosa*.

Nep. See *Nepeta cataria*.

Nepa theophrasti. See *Spartium*.

NEPE'NTHES. (Νηπενθες; from νη, priv. and πενθος, grief. 1. A remedy much celebrated among the ancients for allaying grief. According to Diodorus Siculus, the Theban women alone possessed the secret of its composition. It is generally thought to have contained opium; but Adanson believes it to have been the preparation of hemp, now known in the East under the name of *bangue*. The word νηπενθες occurs in Homer, and the critics have worked hard to discover what substance, or the produce of what plant, Homer designated by this name. Now, the truth is, that, in the passage in question, the word is not a *name*, but an *epithet*. Homer tells us that Helen cast into the wine "*a drug* banishing sorrow, allaying wrath, and causing oblivion of all evils."

Αυτικ' αρ' εις οινον βαλη φαρμακον ενθεν επινον,
Νηπενθες τ'ακολον τε κακων επιληθον ἁπαντων.
Odyss. lib. iv. v. 220.

But Homer does not say what drug it was, and νηπενθες is no more the name of the drug than ακολον, or κακων επιληθον ἁπαντων. It is merely an epithet of the φαρμακον. It is very likely, therefore, that the poet had no particular drug in view; and hence, that those who know what the φαρμακον νηπενθες was, know more of Homer's meaning than he knew himself. However this may be, it is singular that the word *nepenthes*, as used by Homer, should have been so continually mistaken for the name of a drug; since the reverse is not only very obvious, but was long ago clearly explained by Pierre Petit, in his treatise entitled *Homeri Nepenthes; sive, de Helenæ Medicamento*, &c.

2. A name given by Theodore Zwinger, and other old writers, to a composition of opium, saffron, lignum aloes, crocus solis, and ambergris. It was to this preparation that Paracelsus first gave the name of *laudanum*.

3. The name of a genus of plants of the Class *Diœcia*, and Order *Polyandria*.

NE'PETA. (*a*, *æ*. f.; from *nepte*, German.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia*.

Nepeta cataria. The systematic name of the nep, or catmint; called also, *Herba felis*, *Mentha felina*, *Calamintha*, *Nepetella*, and *Mentha cataria*. The leaves of this plant, *Nepeta — floribus spicatis; verticillis subpedicellatis; foliis petiolatis, cordatis, dentato-serratis*, of Linnæus, have a moderately pungent aromatic taste, and a strong smell, like an admixture of spearmint and pennyroyal. The herb is recommended in uterine disorders, dyspepsia, and flatulency.

Nepete'lla. (*a*, *æ*. f.; diminutive of *nepeta*.) The lesser catmint.

Ne'phela. (*a*, *æ*. f.; diminutive of νεφος, a cloud.) The same as *nebula*.

Nephelo'des. (From νεφελη, a cloud, and ειδος, a likeness.) Cloudy: applied to the urine.

NEPHRA'LGIA. (*a*, *æ*. f.; from νεφρος, the kidney, and αλγος, pain.) Pain in the kidney.

NEPHRITIC. (*Nephriticus*; from νεφρος, the kidney.) Appertaining to the kidney, or acting on the kidney.

Nephritic wood. *Lignum nephriticum*. See *Moringa aptera* in the Supplement.

Nephritica. Medicines which act on the kidneys.

Nephritica aqua. A spirituous distillation of nutmeg and hawthorn flowers.

NEPHRI'TIS. (*is*, *idis* f.; from νεφρος, a kidney.) Inflammation of the kidney. This disease is known by fever, pain in the region of the kidneys, and shooting along the course of the ureter; drawing up of the testicles; numbness of the thigh; vomiting; urine high coloured, and frequently discharged; costiveness, and colic pains. Nephritis is symptomatic of calculus, gout, &c.

This inflammation may be distinguished from the colic by the pain being seated very far back, and by the difficulty of passing urine, which constantly attends it; and it may be distinguished from rheumatism, as the pain is but little influenced or increased by motion.

Nephritis is to be distinguished from a calculus in the kidney or ureter, by the symptoms of fever, accompanying, or immediately following, the attack of pain, and these continuing without any remarkable intermission; whereas, in a calculus of the kidney or ureter, they do not occur until a considerable time after violent pain has been felt. In the latter case, too, a numbness of the thigh, and a retraction of the testicle on the affected side, usually takes place.

The causes which give rise to nephritis are external contusions, strains of the back, acrids conveyed to the kidneys in the course of the circulation, violent and severe exercise, either in riding or walking, calculous concretions lodged in the kidneys or ureters, and exposure to cold. In some habits, there is an evident predisposition to this complaint, particularly the gouty, and in these there are often translations of the matter to the kidneys, which very much imitate nephritis.

An inflammation of the kidney is attended with a sharp pain on the affected side, extending along the course of the ureter; and there is a frequent desire to make water, with much difficulty in expelling it. The body is costive, the skin is dry and hot, the patient feels great uneasiness when he endeavours to walk, or sit upright; he lies with most ease on the affected side, and is generally troubled with nausea and frequent vomiting.

When the disease is protracted beyond the seventh or eighth day, and the patient feels an obtuse pain in the part, has frequent returns of chillness and shiverings, there is reason to apprehend that matter is forming in the kidney, and that a suppuration will ensue.

Dissections of nephritis show the usual effects of inflammation on the kidney; and they likewise often discover the formation of abscesses, which have destroyed its whole substance. In a few instances, the kidney has been found in a scirrhous state.

The disease is to be treated by bleeding, general and local, the warm bath, or fomentations to the loins, emollient clyster, mucilaginous drinks, and the general antiphlogistic plan. The bowels should be effectually cleared at first by some sufficiently active formula; but the saline catharties are considered not so proper, as they may add to the irritation of the kidney. Calomel, with antimonial powder, followed by the infusion of senna, or the ol ricini, may be given in preference, and repeated occasionally. It will be right, also, to endeavour to promote diaphoresis, by moderate doses of antimonials especially. Blisters are inadmissible in this disease; but the linimentum ammoniæ, or other rubefacient application, may in some measure supply their place. Opium will often prove useful, particularly where the symptoms appear to originate from calculi, given in the form of glyster or by the mouth; in which latter mode of using it, however, it will be much better joined with other remedies, which may obviate its heating effect, and determine it rather to pass off by the skin. A decoction of the dried leaves of the peach-tree is said to have been serviceable in many cases of this disease. In affections of a more chronic nature, where there is a discharge of mucus or pus, by urine, in addition to suitable tonic medicines, the uva ursi in moderate doses, or some of the terebinthinate remedies may be given with probability of relief.

Nephroce'le. (Νεφρος, the kidney, and κηλη, a tumour.) Hernia of the kidney — a very rare case.

Nephro'lithos. (Νεφρος, the kidney, and λιθος, a stone.) A renal calculus.

Nephrople'gia. (Νεφρος, the kidney, and πλησσω, to strike.) Paralysis of the kidney.

Nephropyosis. (Νεφρος, the kidney, and πυωσις, suppuration.) Suppuration of the kidney.

NE'PHROS. Νεφρος. The kidney. See *Kidney*.

NEPHRO'TOMY. (*Nephrotomia*, *æ*. f. from νεφρος, a kidney, and τεμνω, to cut.) T

peration of extracting a stone from the kidney, —a proceeding which, perhaps, has never been ctually put in practice. The cutting into the idney, the deep situation of this viscus, and the vant of symptoms by which the lodgment of a tone in it can be certainly discovered, will lways be strong objections to the practice.

NE'RIUM. (*um, ii.* n.; from *νηρος*, humid: o called because it grows in moist places.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.*

NERIUM ANTIDYSENTE'RICUM. The systemtic name of the tree, *Nerium — foliis ovatis, cuminatis, petiolatis,* of Linnæus, which affords he Codaga pala bark; which is also called, *Conessi cortex, Cortex codagæ palæ, Cortex Belaye,* and *Cortex profluvii.* It grows on the oast of Malabar. It is of a dark black colour xternally, and generally covered with a white noss, or scurf. It is very little known in the hops; has an austere, bitter taste; and is recommended in diarrhœa, dysentery, &c., as an stringent.

NERIUM TINCTORIUM. This tree grows in Hindostan, and, according to Dr. Roxburgh, ffords indigo.

NE'ROLI OLEUM. Essential oil of orange owers. See *Citrus aurantium.*

NERVA'LIA OSSA. The parietal bones have een so called, why we know not.

Nervalis. See *Nervous.*

NERVE. (*Nervus, i.* m.; from *νεῦρον.*)

A. In the anatomy of the ancients, the nerves nd the tendons were confounded under this ame; and this accounts for the opposite meanngs of the word *nervous*, which sometimes ignifies strong, sinewy, and at others, weak and rritable. In the language of modern anatomy, he nerves are those long white cords which rise from the brain and spinal cord, and are istributed to all parts of the frame, endowing with sensation and voluntary motion. The erves are distinguished into *cerebral* and *spinal:* he cerebral nerves are generally reckoned as ine pairs; the spinal are thirty pairs, and are ivided into twelve pair of dorsal, five pair of umbar, and five of sacral.

CEREBRAL NERVES.

1. The *first pair*, or *olfactory.* These rise from he under and back part of the anterior lobes of he cerebrum, by three filaments, two which are hite, and one grey. One of the white filaents may be traced into the corpus striatum. Each olfactory nerve forms a bulb on the ribriform plate of the ethmoid bone, on each de the crista galli. From this bulb numerous laments, which are distinguished into internal, iddle, and external, pass through the foramina f the cribriform plate, and are distributed to the chneiderian membrane.

2. The *second pair*, or *optic nerves.* These rise partly from the nates, and partly from the ptic thalami. They proceed forward, beneath he crura cerebri, to which they adhere, and meet rom the opposite sides, in front of the sella urcica, forming a commissure, on the nature of hich there is great difference of opinion. (See *Optic commissure.*) The nerves then divaricate, and each passes through the foramen opticum into the orbit, and expands into the retina.

3. The *third pair*, or *motores oculorum.* These arise from the under, inner, and back part of the crura cerebri. They penetrate the dura mater, pass through the cavernous sinuses, and proceed through the foramina lacera anteriora, into the orbit, where they are distributed to all the muscles of the eye-ball, except the superior oblique and the abductor. Each gives a filament to the ophthalmic ganglion.

4. The *fourth pair, pathetici*, or *trochleares.* These arise from the valve of Vieussens. They pass between the crura cerebri and cerebellum, to the cavernous sinus, along the outer side of which they run to the *foramina lacera anteriora*, through which they enter the orbit, and are distributed chiefly to the superior oblique muscle of the eyeball. They are the smallest of the cerebral nerves.

5. The *fifth pair*, or *trigemini.* These are the largest of the cerebral nerves. One is given off on each side, from the lower and anterior part of the crus cerebelli, near its junction with the tuber annulare. It consists of very numerous filaments, which are divisible into two fasciculi, of which the anterior or smaller may be traced through the pons varolii to the medullary fibres prolonged from the corpus pyramidale, while the posterior and larger fasciculus is found to arise from the corpus restiforme. The compound nerve, thus constituted, enters the dura mater just below the the tentorium, and passes into a canal formed for it by that membrane. Here the fasciculi, which form the nerve, diverge: those derived from the posterior root form the Gasserian ganglion; while those derived from the anterior root pass forward beneath the ganglion. From the anterior margin of the Gasserian ganglion arise the *ophthalmic, superior maxillary*, and *inferior maxillary* nerves. The portion which separates from the rest, and passes beneath the ganglion, makes its exit from the cranium at the same foramen as the inferior maxillary nerve, with which it immediately afterwards incorporates. Now, the ophthalmic and superior maxillary are nerves of sense only; but the inferior maxillary is also a motor nerve, which power it derives from that portion which has been just described as unconnected with the ganglion. Hence the trigeminal nerve taken as a whole, is a compound nerve, entirely analogous to those of the spine. For the distribution of the three great branches of this nerve, see *Ophthalmic nerve*, and *Maxillary nerve.*

6. The *sixth pair*, or *abducentes.* These arise on each side from the tuber annulare, near the groove which divides it from the medulla oblongata. They pass along the basilar process of the occipital bone, penetrate the dura mater, pass through the cavernous sinus, and enter the orbit through the foramen lacerum anterius, to be distributed to the abductor muscle of the eye-ball.

7. The *seventh pair.* Each of these consists of two nerves, the *facial* or *portio dura*, and the *auditory* or *portio mollis.* See *Portio dura*, and *Portio mollis.*

8. The *eighth pair*. These consist on each side of three distinct nerves, the *glosso-pharyngeal*, the *nervus vagus*, and the *nervus accessorius*.

The glosso-pharyngeal nerve and the nervus vagus, are situated at the upper and lateral part of the medulla oblongata. The nervus accessorius ascends along the side of the spinal cord and medulla oblongata, to join the other two nerves.

The *Glosso-pharyngeal nerve* arises on each side by several filaments from the lateral part of the medulla oblongata, immediately below the tuber annulare, and behind the corpus olivare. These filaments unite into a single nerve, which is situated directly above the nervus vagus. It is distributed to the root of the tongue, pharynx, and larynx.

The *Nervus vagus* arises by many filaments, arranged perpendicularly along the lateral part of the medulla oblongata, immediately below the origins of the glosso-pharyngeal nerve. These filaments form six or eight cords, which are united in the form of a flattened band.

The glosso-pharyngeal nerve and the nervus vagus, proceed together outwards and forwards to the foramen lacerum posterius, through which they pass out of the cranium.

The *Nervus accessorius* arises by several filaments from the lateral part of the spinal cord, between the anterior and posterior origins of the cervical nerves. They unite into a single nerve, which ascends through the foramen magnum into the skull, and thence proceeds outwards to the foramen lacerum posterius, through which it passes with the two other divisions of the eighth pair.

For the distribution of the two latter nerves, see *Pneumogastric nerve*, and *Accessorius nervus*.

9. The *ninth pair*, *lingual*, *hypoglossal*, or *motores linguæ*. Each nerve arises by numerous filaments from the furrow between the corpus pyramidale and corpus olivare. It passes through the anterior condyloid foramen, descends behind the posterior portion of the digastric muscle, and forms an arch with its convexity downwards; it then passes between the mylohyoid and hyoglossus muscles to the tongue, throughout the muscular substance of which it is distributed. From the above-mentioned arch, a twig, termed *descendens noni*, runs down in front of the sheath of the common carotid artery, to the sterno-hyoid, sterno-thyroid, and adjacent muscles.

Soëmmering, and other anatomists, have divided the encephalic nerves into twelve pairs: viz. 1. *The olfactory*. 2. *The optic*. 3. *Motores oculorum*. 4. *Pathetici*. 5. *Trigemini*. 6. *Abducentes*. 7. *Facial*. 8. *Auditory*. 9. *Glosso-pharyngeal*. 10. *Nervus vagus*. 11. *Accessory nerves*. 12. *Lingual*.

This arrangement, though not commonly adopted, is the true and natural one, as the twelve pairs of nerves just enumerated are perfectly distinct.

Spinal Nerves.

Those nerves are called *spinal* which pass out through the lateral or intervertebral foramina of the spine. They consist of thirty-one pairs; and each nerve has two roots, the one rising from the anterior, and the other from the posterior column of the cord. The fibres of the posterior root converge, and, while yet enclosed in the sheath of the cord, form a ganglion. The fibres of the anterior root converge in like manner, passing by the ganglion, unite with the fibres of the posterior root, and form one nerve. Each nerve thus formed, is therefore a compound nerve. The researches of Sir C. Bell have demonstrated that the spinal nerves have a double function; the anterior nerves being *motor* nerves, and the posterior, *sensatory* nerves. The spinal nerves are divided into *cervical*, *dorsal*, *lumbar*, and *sacral* nerves.

Cervical Nerves.

The *cervical nerves* are *eight* pairs.

The *first* are called the *occipital* or *suboccipital*: they arise from the beginning of the spinal marrow, pass out between the margin of the occipital foramen and atlas, form a ganglion on its transverse process, and are distributed about the occiput and neck.

The *second* pair of cervical nerves send a branch to the accessory nerve of Willis, and proceed to the parotid gland and external ear.

The *third* cervical pair supply the integuments of the scapula, the trapezius, and triangularis muscles, and send a branch to form with others the diaphragmatic nerve.

The *fourth*, *fifth*, *sixth*, *seventh*, and *eighth* pair, all converge to form the *brachial plexus*, from which arise the six following: —

Nerves of the upper Extremities.

1. The *supra scapular*.
2. The *subscapular*.
3. The *thoracic*, which are usually three in number. Two of them are anterior, and distributed to the pectoral muscles. The third, a very long branch, is posterior, and distributed to the serratus magnus muscle.
4. The *circumflex*, or *axillary* nerve, which sometimes arises from the radial nerve. It runs backwards and outwards around the neck of the humerus, and ramifies in the muscles of the scapula.
5. The *external cutaneal*, which perforates the caraco-brachialis muscle to the bend of the arm, where it accompanies the median vein as far as the thumb, and is lost in its integuments.
6. The *internal cutaneal*, which descends on the inside of the arm, where it bifurcates. From the bend of the arm the anterior branch accompanies the basilic vein, to be inserted into the skin of the palm of the hand; the posterior branch runs down the internal part of the fore-arm, to vanish in the skin of the little finger.
7. The *median* nerve, which accompanies the brachial artery to the cubit, then passes between the brachialis internus, pronator rotundus, and the perforatus and perforans, under the ligament of the wrist to the palm of the hand, where it sends off branches in every direction to the muscles of the hand, and then supplies the digital nerves, which go to the extremities of the thumb, fore, and middle fingers.
8. The *ulnar* nerve, which descends between the brachial artery and basilic vein, between

internal condyle of the humerus and the cranon, and divides in the fore-arm into an *ernal* and *external* branch. The former passes er the ligament of the wrist and sesamoid ne, to the hand, where it divides into three nches, two of which go to the ring and little ger, and the third forms an arch towards the umb, in the palm of the hand, and is lost in e contiguous muscles. The latter passes over e tendon of the extensor carpi ulnaris and ck of the hand, to supply also the two last gers.

9. The *radial* nerve, which sometimes gives the axillary nerve. It passes backwards, out the os humeri, descends on the outside the arm, between the brachialis externus and ternus muscles, to the cubit; then proceeds, tween the supinator longus and brevis, to the perior extremity of the radius, giving off rious branches to adjacent muscles. At this ace it divides into two branches; *one* goes ong the radius, between the supinator longus d radialis internus, to the back of the hand, d terminates in the interosseus muscles, the umb, and three first fingers; the *other* passes tween the supinator brevis and head of the lius, and is lost in the muscles of the fore-m.

Dorsal Nerves.

The *dorsal* nerves are twelve pairs in numr. The first pair gives off a branch to the achial plexus. The upper dorsal nerves are stributed to the muscles of the back, interstals, serrati, pectoral, abdominal muscles, and aphragm. The five inferior pairs go to the uscles of the thorax and abdomen.

Lumbar Nerves

The five pair of lumbar nerves are bestowed out the loins and muscles, skin of the abmen and loins, scrotum, ovaria, and diaragm. The second, third, and fifth pair nite and form the *obturator nerve*, which deends over the psoas muscle into the pelvis, d passes through the foramen thyroideum to e obturator muscle, triceps, pectineus, &c.

The third and fourth, with some branches of e second pair, form the *crural nerve*, which sses under Poupart's ligament with the feoral artery, sends off branches to the adjacent rts, and descends, in the direction of the sarrius muscle, to the internal condyle of the mur, whence it accompanies the saphena vein the internal ankle, to be lost in the skin the great toe.

The fifth pair are joined to the first pair of e sacral nerves.

Sacral Nerves, and Nerves of the Inferior Extremities.

There are five pair of *sacral* nerves, all of hich arise from the *cauda equina*, or termination the medulla spinalis, so called from the nerves sembling the tail of a horse. The four first ir give off branches to the pelvic viscera, and e afterwards united to the last lumbar, to rm a large *plexus*, which gives off

The *ischiatic nerve*, the largest in the body. he ischiatic nerve, immediately at its origin, nds off branches to the bladder, rectum, and rts of generation; proceeds from the cavity of the pelvis through the ischiatic notch, between the tuberosity of the ischium and great trochanter, to the ham, where it is called the *popliteal nerve*. In the ham it divides into two branches.

1. The *peroneal*, which descends on the fibula, and distributes many branches to the muscles of the leg and back of the foot.

2. The *tibial*, which penetrates the gastrocnemii muscles to the internal ankle, passes through a notch in the os calcis to the sole of the foot, where it divides into an *internal* and *external plantar* nerve, which supply the muscles and aponeurosis of the foot and the toes.

Besides the encephalic and spinal nerves, there is a set of nerves constituting what is called the *sympathetic* or *ganglionic* system. This has, till of late years, been described as a single nerve, called the great sympathetic or great intercostal, arising from the fifth and sixth cerebral nerves; but it is, in truth, a great collection of ganglia, connected by filaments with each other, and with almost every nerve of the frame. For a description of its course, see *Intercostal nerve*.

According to the views of Sir C. Bell, there is a particular system of nerves which minister to respiration. The medulla oblongata is composed of three fasciculi on each side: an anterior, which gives origin to nerves of motion; a posterior, which gives origin to nerves of sensation; and a middle, which gives rise to *respiratory* nerves.

A great portion of the spinal nerves concur in producing the respiratory movements; but there are certain nerves which are the special respiratory nerves of particular regions, and are therefore most important.

These are, —

1. The *portio dura*, or respiratory of the face.

2. The *nervus vagus*, or respiratory of the larynx.

3. The *glosso-pharyngeal*.

4. The *accessory nerve*, or *superior respiratory*.

5. The *phrenic*, or *great internal respiratory*.

6. The *posterior thoracic*, or *external respiratory*.

B. In *Botany*, applied to a cluster of vessels that runs like a rib or chord on certain leaves; as that of the *Laurus cinnamomum*, and *Arctium lappa*.

Nerveless. See *Enervis*.

NE'RVINE. (*Nervinus*; from *nervus*, a nerve.) Neurotic. Applied to that which relieves disorders of the nerves. All the antispasmodics, and the various preparations of bark and iron.

Nervorum resolutio. Apoplexy and palsy have been so called.

NERVOUS. *Nervosus*. Appertaining to a nerve. Applied, 1. In *Medicine*, to fevers and affections of the nerves, and to medicines which act on the nervous system.

2. In *Anatomy* and *Physiology*, to the structure and functions of parts.

3. In *Botany*, to leaves which have hard fibres or nerve-like cords.

Nervous diseases. See *Neuroses*.

Nervous fever. *Febris nervosa.* See *Typhus.*

Nervous fluid. See *Nervous system.*

Nervous headach. See *Cephalalgia.*

NERVOUS SYSTEM. This consists of the encephalos and its nerves; the spinal cord and its nerves; and the ganglia of the sympathetic, and filaments connecting them with each other. These parts are described under their respective heads, and we shall here merely notice the functions which they are supposed to perform.

1. The *brain* has been generally considered as the seat and organ of the mind; but if the real amount of our knowledge on the subject be carefully weighed, it will be found that all we are warranted in asserting is, that *the brain is the general receptacle of all impressions made on the external senses, and the centre from which volition is communicated to the organs subservient to the will.* We are entirely ignorant of the nature of mind, and know not whether thought has any organ, or the mind has any seat. If the mind be *immaterial*, as most philosophers have believed, it must be connected with the organism by some relation which it is impossible for us, in the present state of our existence, to understand, and which evidently cannot involve the idea of *position*. Physiologists, in general, have considered the brain as a single organ. Drs. Gall and Spurzheim, however, regard it as a congeries of organs, each of which is the seat of some particular intellectual power, moral quality, or animal instinct. See *Phrenology.*

2. Several conjectures have been formed as to the particular function of the *cerebellum*. Of these, the only two which seem worthy of any attention, are those of Flourens and Gall. Flourens found in his experiments on animals, that when the cerebellum was removed, the animals retained the power of moving their muscles; but were no longer able to combine their action into orderly movements, and were incapable of standing, walking, springing, flying, &c. M. Flourens hence concludes that the cerebellum is the *regulator of motion*, and this opinion is countenanced in some degree by the experiments of several other physiologists. Dr. Gall regards the cerebellum as the *organ of the sexual instinct* — an opinion which, on the whole, does not seem to be countenanced either by comparative anatomy or pathological observation.

3. It has been established, by the discoveries of Sir C. Bell, that the spinal cord is the immediate seat of the power by which the muscles are moved, and of the common sensibility of parts. The anterior columns of the cord are the motory portion, and the posterior the sensatory.

Sir C. Bell regards the central portion of the *medulla oblongata* as presiding over respiration, and giving origin to the nerves which minister to that function. The opinions of Sir C. Bell on this subject, though generally influential, have not received so unlimited an assent as those with respect to the motory and sensatory powers of the spinal cord.

4. Less is positively known of the functions of the *sympathetic*, than of any other portion of the nervous system. The most prevalent ideas are, that it is either the source of that power by which the organic functions are carried on, or the medium through which the actions of the different parts of the nervous system are in some way combined and modified for the production of the organic functions.

5. Attempts have been made at different times to explain the intimate actions which take place in the nerves when thrown into operation. Thus, it has been supposed that the nerves contain a subtle fluid, called the *nervous fluid*, on the motions of which sensation and voluntary motion depend. Another hypothesis, which was maintained by the celebrated Hartley, refers all the phenomena of the nervous system to vibrations in the nervous substance. It is scarcely necessary to do more than mention such hypotheses, which are now generally discarded, because, as they explain nothing which cannot be explained as well without them, and are supported by no kind of direct evidence, they serve merely to place us one remove further from the truth.

Dr. Wilson Philip, from his well known and striking experiments on the power of galvanism in sustaining the action of parts after their nervous communication with the brain is cut off, infers that the nervous and galvanic energies are identical; but this conclusion has not been adopted, and cannot, in truth, be legitimately deduced from the experiments, which merely prove that when a nerve is divided, its distant extremity retains a susceptibility of stimulation, and that galvanism is an agent capable of stimulating it.

Nervous quinsy. Heberden gives this name to the *Globus hystericus.*

Nes'tis. Νηστις. The jejunum.

Nests, edible. See *Alcyon.*

Nettle. See *Urtica.*

Nettle, dead. See *Lamium album.*

Nettle-rash. See *Urticaria.*

NEURA'LGIA. (*a*, *æ*. f.; from νευρον a nerve, and αλγος, pain.) Pain in a nerve. Various parts of the body are liable to be affected with excruciating pain, which is quite independent of any inflammation of the part and which may often be traced in the course of the nerves. Such affections all come under the head of *neuralgia.* In many cases, they appear to be strictly idiopathic; in some, they are symptomatic of derangement of the digestive or other functions, and in a third class of cases they are the result of injuries of the nerves from accidents or surgical operations. The principal seats of neuralgia are, the branches of the fifth pair of nerves; the sacro-sciatic nerve; the nerves of the female breast; and those of the hands and feet. When the disease occupies the branches of the fifth pair of nerves, it is called *neuralgia facialis*, or *tic douloureux*; when it is seated in the sacro-sciatic nerve, it is often confounded with very different affections, under the name of *sciatica.* In a few cases of neuralgia, the neurilemma has been observed to be inflamed; and hence it has been hastily inferred that neuralgia consists in inflammation of

nerve; in the majority of cases, however, no such appearances are to be detected; and hence, when they occur, they are to be regarded as merely an effect of the disease.

The treatment of neuralgia will vary greatly according to its cause. Where it is symptomatic, the primary disease is to be attacked; when it is idiopathic, powerful tonic medicines and local counter-irritation are generally found the most effectual means of cure. Carbonate of iron, in large doses, seems to have been more frequently successful than any other remedy, but bark and arsenic are also in many instances decidedly useful. Where the disease has any tendency to periodicity, the bark is to be preferred to any other medicine. Division of the affected nerve has often been resorted to, but the relief derived from this is very temporary, for the nervous connexion is no sooner re-established, than the pain returns. In a few melancholy instances, neuralgia is utterly incurable, and the patient dies worn out by years of torture, which admits of only partial relief from large quantities of opium.

NEURILE'MMA. (*a, atis.* n.; from νευρον, a nerve, and λεμμα, the bark or covering.) The membranous sheath which invests the nerves, and also the several fibrils of which they are composed.

NEUROLOGY. (*Neurologia, æ.* f.; from νευρον, a nerve, and λογος, a discourse.) The doctrine of the nerves. See *Nerve.*

NEUROME'TORES. (From νευρον, a nerve, and μητηρ, a matrix.) The psoas muscles are so called by Fallopius, as being the repository of many small nerves.

NEURO'PTERA. (From νευρον, a nerve, and πτερον, a wing.) The name of an order of insects. See *Animal kingdom.*

NEURO'SES. (The plural of *neurosis.*) Nervous diseases. The second class of Cullen's nosology is so called: it comprehends affections in which sense and motion are disturbed, without either idiopathic pyrexia, or topical disease.

NEURO'TICUS. (From νευρον, a nerve.) Nervous; appertaining to the nerves: applied — 1. Diseases of the nervous system. 2. Nervine medicines.

NEURO'TOMY. (*Neurotomia, æ.* f.; from νευρον, a nerve, and τεμνω, to cut.) The dissection of the nerves, or the division of a nerve.

NEUTRAL. (*Neutralis;* from *neuter,* neither one nor the other.) 1. In *Chemistry,* applied to saline compounds of an acid and an alkali, which are so called, because they do not possess the characters of acid or alkaline salts; such are Epsom salts, nitre, and all the compounds of the alkalis with the acids.

2. In *Botany,* applied to such flowers or plants as contain neither stamens nor pistils, and of course produce no seed.

NEUTRALISA'TION. *Neutralisatio.* When acid and alkaline matter are combined in such proportions that the compound does not change the colour of litmus or violets, they are said to be neutralised.

Nicked leaf. See *Emarginatus.*

NI'CKEL. A metal found in nature generally in the metallic state, more rarely in that of an oxide. Its ores have a coppery red colour, generally covered more or less with a greenish-grey efflorescence. The most abundant ore is that termed *sulphuret of nickel;* besides which there is what is called *native oxide of nickel,* or *nickel ochre;* the sulphuret, and *martial nickel.*

Nickel is a metal of great hardness, of an uniform texture, and of a colour between silver and tin; very difficult to be purified, and magnetical. It even acquires polarity by the touch.

NICOTIA'NA. (*a, æ.* f.; from Nicott, who first brought it into Europe. Tobacco. 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.*

2. The former pharmacopœial name of the tobacco. See *Nicotiana tabacum.*

NICOTIANA AMERICANA. American or Virginian tobacco. See *Nicotiana tabacum.*

Nicotiana minor. See *Nicotiana rustica.*

NICOTIANA RUSTICA. The systematic name of the English tobacco; called also, *Nicotiana minor, Priapeia,* and *Hyoscyamus luteus.* This plant is much weaker than the Virginian tobacco; the leaves are chiefly used to smoke vermin, though they promise, from their more gentle operation, to be a safer remedy in some cases than the former.

NICOTIANA TABA'CUM. The systematic name of the Virginian tobacco-plant, which is also called *Petum,* by the Indians, *Tabacum, Hyoscyamus-peruvianus,* and *Picelt.*

Nicotiana — foliis lanceolato-ovatis sessilibus decurrentibus florentibus acutis, of Linnæus.

The use of this herb for smoking is now general throughout the greater part of the world. There has been much dispute as to the salubrity of this habit; some contending that it is conducive to health, and others maintaining that it is an absolute slow poison. It disagrees with some constitutions, but in a general way appears to have no effect on the health one way or another. Where shall we find healthier men than in our navy? Yet almost all sailors smoke tobacco, and many chew it.

This plant is also employed medicinally. It is narcotic, emetic, purgative, diuretic, and sternutatory. A decoction of the leaves is sometimes applied as a wash, in porrigo, scabies, and other cutaneous affections. The fumes and infusion are employed as enemata, in strangulated hernia, and some other cases; they occasion extreme faintness and relaxation, and require to be used with proper caution, lest these effects take place to a fatal extent. Vauquelin has obtained a peculiar principle from this plant, in which its active properties reside. See *Nicotin.*

NI'COTIN. A peculiar principle obtained by Vauquelin from tobacco. It is colourless, and has the peculiar taste and smell of the plant. It dissolves both in water and alkohol: it is volatile and poisonous.

NICTITA'TIO. Twinkling, or winking of the eyes. It is a natural and instinctive action for the purpose of cleansing and moistening the

eyeball, and rendering it better fitted for vision; but in nervous persons, it is sometimes repeated so frequently as to become a morbid habit.

NIDI ESCULENTI. Edible birds' nests. See *Alcyon.*

NI'DULANS. (From *nidulor*, to place in a nest.) Nidulate: applied to the seeds of some fruits, which nestle, as it were, or are embedded on their surface; as those of the strawberry.

NIGE'LLA. (*a*, *æ*. f.; *quasi nigrella*; from *niger*, black: so named from its black seed.) 1. The name of a genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Pentagynia.*

2. The pharmocopœial name of the *nigella sativa.*

Nigella officinarum. See *Agrostemma githago.*

NIGELLA SATIVA. The systematic name of the devil in a bush. Fennel-flower. *Melanthium. Melaspermum.* This plant was formerly employed medicinally as an expectorant and deobstruent, but is now fallen into disuse.

NIGELLA'STRUM. (*um*, *i*. n.; from *nigella*, fennel-flower.) See *Agrostemma githago.*

NIGER. Black. Applied very generally in *Natural History*, to designate the colour of animals, plants, minerals, &c.; as *Sambucus niger*; and in *Anatomy* and *Pathology* thus: *pigmentum nigrum*, *morbus niger*, &c. See *Colour.*

Night-blindness. See *Hemeralopia.*

Nightmare. See *Ephialtes.*

Nightshade. See *Solanum*, *Phytolacca*, and *Atropa.*

Nightshade, American. See *Phytolacca.*

Nightshade, deadly. See *Atropa.*

Nightshade, Palestine. See *Solanum.*

Nightshade, woody. See *Solanum.*

NIGRI'TIES. (From *niger*, black.) A caries is called *nigrities ossium*, a blackness of the bones.

NIHIL ALBUM. *Nihilum album.* A name formerly given to the flowers or oxide of zinc.

Ninzi radix. See *Sium ninsi.*

Ninzin. See *Sium ninsi.*

NIPPLE. *Papilla.* The small projecting body in the middle of the breasts of men and women. See *Mamma.*

Nipple-wort. See *Lapsana.*

NIRLES. A popular name of Herpes phlyctænodes.

NISUS FORMATIVUS. A creative or formative effort. This phrase is used by Blumenbach synonymously with vital activity.

NI'TIDUS. Polished; smooth; shining; glossy. Applied, in *Botany*, to parts of plants; as the stem of the *Chærophyllum sylvestre*, the leaves of the *Ilex*, *Hedera*, *Buxus*, &c.

NI'TRAS. (*as*, *atis*. f.) A nitrate. A salt formed by the union of the nitric acid with a salifiable base; as the nitrate of potash, soda, silver, &c.

NITRAS AMMONIÆ. *Ammonia nitrata. Sal ammoniacus nitrosus. Alkali volatile nitratum.* Nitrate of ammonia. This salt has been employed internally as a diuretic and deobstruent, and externally as a discutient. It is also sialagogue.

Nitras argenti. See *Argenti nitras.*

NITRAS CALCIS. Nitrate of lime. Calcareous nitre. By particular treatment this salt becomes phosphorescent. See *Baldwin's phosphorus.*

Nitras potassæ. See *Potassæ nitras.*

NITRAS POTASSÆ FUSUS. *Sal Prunellæ. Nitrum tabulatum.* This salt, besides the nitric acid and potash, contains a little sulphuric acid.

NITRAS SODÆ. *Alkali minerale nitratum. Nitrum cubicum.* Nitrate of soda. A neutral salt composed of soda and nitric acid. Its virtues are similar to those of nitrate of potash, for which it may be safely substituted.

Nitrate. See *Nitras.*

Nitrate of potash. See *Nitre.*

Nitrate of silver. See *Argenti nitras.*

NI'TRE. (Νιτρον. *Nitrum*, *i*. n.) *Alaurat. Algali. Atac. Baurack. Acusto. Halinitrum. Saltpetræ. Potassæ nitras.* Saltpetre. A perfect neutral salt, formed by the union of the nitric acid with the vegetable alkali, thence called nitrate of potash. Nitre exists in large quantities in the earth, and is continually formed in inhabited places; it is found in great quantities upon walls which are sheltered from the rain. It is found ready formed in the East Indies, in Spain, in the kingdom of Naples, and elsewhere, in considerable quantities; but nitrate of lime is still more abundant. Far the greater part of the nitrate made use of is produced by a combination of circumstances which tend to compose and condense nitric acid. This acid appears to be produced in all situations where animal matters are completely decomposed with access of air, and of proper substances with which it can readily combine. Grounds frequently trodden by cattle, and impregnated with their excrements, or the walls of inhabited places where putrid animal vapours abound, such as slaughter-houses, drains, or the like, afford nitre by long exposure to the air. Artificial nitre beds are made by an attention to the circumstances in which this salt is produced by nature. Dry ditches are dug, and covered with sheds open at the side, to keep off the rain. The are filled with animal substances, such as dung or other excrements, with the remains of vegetables, and old mortar, or other loose calcareous earth; this substance being found to be the best and most convenient receptacle for the acid to combine with. Occasional watering, and turning up from time to time, are necessary to accelerate the process, and increase the surface to which the air may apply; but too much moisture is hurtful. When a certain portion of nitrate is formed, the process appears to go on more quickly; but a certain quantity stops it altogether; and after this cessation, the materials will go on to furnish more, if what is formed be extracted by lixiviation. After a succession of many months, more or less, according to the management of the operation, in which the action of a regular current of fresh air is of the greatest importance, nitre is found in the mass. If the beds contained much vegetable matter, a considerable portion of the nitrous salt will be common saltpetre; but

herwise, the acid will, for the most part, be mbined with the calcareous earth. It consists 6·75 acid + 6 potash.

To extract the saltpetre from the mass of rthy matter, a number of large casks are pre- red, with a cock at the bottom of each, and a antity of straw within, to prevent its being pped up. Into these the matter is put, to- ther with wood-ashes, either strewed at top, added during the filling. Boiling water is n poured on, and suffered to stand for some ne; after which it is drawn off, and another ter added in the same manner, as long as any ine matter can be thus extracted. The weak ne is heated, and passed through other tubs, til it becomes of considerable strength. It is n carried to the boiler, and contains nitre l other salts, the chief of which is common linary salt, and sometimes muriate of mag- sia. It is the property of nitre to be much re soluble in hot than cold water; but com- n salt is very nearly as soluble in cold as in water. Whenever, therefore, the evapora- n is carried by boiling to a certain point, ch of the common salt will fall to the tom, for want of water to hold it in solution, ugh the nitre will remain suspended by tue of the heat. The common salt thus se- rated is taken out with a perforated ladle, l a small quantity of the fluid is cooled, from e to time, that its concentration may be own by the nitre which crystallises in it. hen the fluid is sufficiently evaporated, it is en out and cooled, and great part of the e separates in crystals; while the remaining mmon salt continues dissolved, because equally uble in cold and in hot water. Subsequent poration of the residue will separate more re in the same manner. By the suggestion Lavoisier, a much simpler plan was adopted; ucing the crude nitre to powder, and wash- it twice with water.

This nitre, which is called nitre of the first ling, contains some common salt, from which ay be purified by solution in a small quantity water, and subsequent evaporation; for the stals thus obtained are much less contami- ed with common salt than before; because proportion of water is so much larger, with pect to the small quantity contained by the e, that very little of it will crystallise. For purposes, the solution and crystallisation of e are repeated four times. The crystals of e are usually of the form of six-sided flat- ed prisms, with dihedral summits. Its taste enetrating; but the cold produced by placing salt to dissolve in the mouth, is such as to dominate over the real taste at first. Seven ts of water dissolve two of nitre, at the tem- ature of sixty degrees; but boiling water olves its own weight. 100 parts of alkohol, heat of 176°, dissolve only 2·9.

On being exposed to a gentle heat, nitre s; and in this state, being poured into lds, so as to form little round cakes, or s, it is called *sal prunella*, or *crystal mineral*. s, at least, is the way in which this salt is usually prepared, conformably to the directions of Boerhaave, though in most dispensatories a twenty-fourth part of sulphur was directed to be deflagrated on the nitre before it was poured out. This salt should not be left on the fire after it has entered into fusion, otherwise it will be converted into a *nitrate* of potash. If the heat be increased to redness, the acid itself is decomposed, and a considerable quantity of tolerably pure oxygen gas is evolved, succeeded by nitrogen.

This salt powerfully promotes the combustion of inflammable substances. Two or three parts mixed with one of charcoal, and set on fire, burn rapidly; azote and carbonic acid gas are given out, and a small portion of the latter is retained by the alkaline residuum, which was formerly called *clyssus of nitre*. Three parts of nitre, two of subcarbonate of potash, and one of sulphur, mixed together in a warm mortar, form the *fulminating powder*; a small quantity of which, laid on a fire-shovel, and held over the fire till it begins to melt, explodes with a loud sharp noise. Mixed with sulphur and charcoal, it forms *gunpowder*.

Three parts of nitre, one of sulphur, and one of fine sawdust, well mixed, constitute what is called the powder of fusion. If a bit of base copper be folded up and covered with this powder in a walnut-shell, and the powder be set on fire with a lighted paper, it will detonate rapidly, and fuse the metal into a globule of sulphuret without burning the shell.

Silex, alumina, and barytes, decompose this salt in a high temperature, by uniting with its base. The alumina will affect this even after it has been made into pottery.

The uses of nitre are various. Beside those already indicated, it enters into the composition of fluxes, and is extensively employed in metallurgy; it serves to promote the combustion of sulphur in fabricating its acid; it is used in the art of dyeing; it is added to common salt for preserving meat, to which it gives a red hue; it is an ingredient in some frigorific mixtures; and it is prescribed in medicine as cooling, febrifuge, and diuretic; and some have recommended it, mixed with vinegar, as a very powerful remedy for the sea scurvy. It is of great use in the arts; it is the principal ingredient in gunpowder; and burned with different proportions of tartar, forms the substances called fluxes. It is of considerable importance in medicine, as a febrifuge, diuretic, and antiphlogistic remedy, in doses of from five to twenty grains. It is from this salt we obtain one of the most powerful acids, namely, the *nitric*.

NI'TRIC. (*Nitricus*; from *nitrum*.) Of or belonging to nitre.

Nitric acid. *Acidum nitricum*. This acid is composed of the two principal constituents of our atmosphere; which, when in certain proportions, are capable, under particular circumstances, of combining chemically, and forming nitric acid. If oxygen and nitrogen, in a gaseous state, be mixed in a proper proportion in a glass tube about a line in diameter, over mercury, and a series of electric shocks be passed through them for some hours, they will form

nitric acid; or, if a solution of potash be present with them, nitrate of potash will be obtained. The constitution of this acid may be further proved, analytically, by driving it through a red-hot porcelain tube, as thus it will be decomposed into oxygen and nitrogen gases. For all practical purposes, however, the nitric acid is obtained from nitrate of potash, from which it is expelled by sulphuric acid.

Three parts of pure nitrate of potash, coarsely powdered, are to be put into a glass retort, with two of strong sulphuric acid. This must be cautiously added, taking care to avoid the fumes that arise. Join to the retort a tubulated receiver of large capacity, with an adopter interposed, and lute the junctures with glazier's putty. In the tubulure fix a glass tube, terminating in another large receiver, in which is a small quantity of water; and if you wish to collect the gaseous products, let a bent glass tube from this receiver communicate with a pneumatic trough. Apply heat to the receiver by means of a sand-bath. The first product that passes into the receiver is generally red and fuming; but the appearances gradually diminish, till the acid comes over pale, and even colourless, if the materials used were clean. After this it again becomes more and more red and fuming, till the end of the operation; and the whole mingled together will be of a yellow or orange colour.

Empty the receiver, and again replace it. Then introduce by a small funnel, very cautiously, one part of boiling water in a slender stream, and continue the distillation. A small quantity of a weaker acid will thus be obtained, which can be kept apart. The first will have a specific gravity of about 1·500, if the heat have been properly regulated, and if the receiver was refrigerated by cold water or ice. Acid of that density, amounting to two thirds of the weight of the nitre, may thus be procured; but commonly the heat is pushed too high, whence more or less of the acid is decomposed, and its proportion of water uniting to the remainder, reduces its strength. It is not profitable to use a smaller proportion of sulphuric acid, when a concentrated nitric is required. But when only a dilute acid, called in commerce *aquafortis*, is required, then less sulphuric acid will suffice, provided a portion of water be added. One hundred parts of good nitre, sixty of strong sulphuric acid, and twenty of water, form economical proportions.

In the large way, and for the purposes of the arts, extremely thick cast iron or earthen retorts are employed, to which an earthen head is adapted, and connected with a range of proper condensers. The strength of the acid, too, is varied, by putting more or less water in the receivers. The nitric acid thus made, generally contains sulphuric acid, and also muriatic, from the impurity of the nitrate employed. If the former, a solution of nitrate of barytes will occasion a white precipitate; if the latter, nitrate of silver will render it milky. The sulphuric acid may be separated by a second distillation from very pure nitre, equal in weight to an eighth of that originally employed; or by precipitating with nitrate of barytes, decanting the clear liquid, and distilling it. The muriatic acid may be separated by proceeding in the same way with nitrate of silver, or with litharge, decanting the clear liquid, and redistilling it, leaving an eighth or tenth part in the retort. The acid for the last process should be condensed as much as possible, and the redistillation conducted very slowly; and if it be stopped when half is come over, beautiful crystals of muriate of lead will be obtained on cooling the remainder, if litharge be used, as Steinacher informs us; who also adds, that the vessel should be made to fit tight by grinding, as any lute is liable to contaminate the product.

As this acid still holds in solution more or less nitrous gas, it is not in fact nitric acid, but a kind of nitrous. It is therefore necessary to put it into a retort, to which a receiver is added, the two vessels not being luted, and to apply a very gentle heat for several hours, changing the receiver as soon as it is filled with red vapours. The nitrous gas will thus be expelled, and the nitric acid will remain in the retort as limpid and colourless as water. It should be kept in a bottle secluded from the light, otherwise it will lose part of its oxygen.

What remains in the retort is a bisulphate of potash, from which the superfluous acid may be expelled by a pretty strong heat, and the residuum, being dissolved and crystallised, will be sulphate of potash.

As nitric acid, in a fluid state, is always mixed with water, different attempts have been made to ascertain its strength, or the quantity of real acid contained in it.

The nitric acid is of considerable use in the arts. It is employed for etching on copper; as a solvent of tin, to form with that metal a mordant for some of the finest dyes; in metallurgy and assaying; in various chemical processes, on account of the facility with which it parts with oxygen, and dissolves metals; in medicine as a tonic, and as a substitute for mercurial preparations in syphilis and affections of the liver, as also in form of vapour to destroy contagion. For the purposes of the arts it is commonly used in a diluted state, and contaminated with the sulphuric and muriatic acids, by the name of *aquafortis*. This is generally prepared by mixing common nitre with an equal weight of sulphate of iron, and half its weight of the same sulphate calcined, and distilling the mixture; or by mixing nitre with twice its weight of dry powdered clay, and distilling in a reverberatory furnace. Two kinds are found in the shops, one called *double aquafortis*, which is about half the strength of nitric acid; the other simply *aquafortis*, which is half the strength of the double.

A compound made by mixing two parts of the nitric acid with one of muriatic, known formerly by the name of *aqua regia*, and now by that of *nitro-muriatic acid*, has the property of dissolving gold and platina. On mixing the two acids, heat is given out, an effervescence takes place, and the mixture acquires an orange

colour. This is likewise made by adding gradually to an ounce of powdered muriate of ammonia four ounces of double aquafortis, and keeping the mixture in a sand heat till the salt is dissolved, taking care to avoid the fumes, as the vessel must be left open; or by distilling nitric acid with an equal weight, or rather more, of common salt.

On this subject we are indebted to Sir H. Davy for some excellent observations, published by him in the first volume of the Journal of Science. If strong *nitrous* acid, saturated with nitrous gas, be mixed with a saturated solution of muriatic acid gas, no other effect is produced than might be expected from the action of nitrous acid of the same strength on an equal quantity of water; and the mixed acid so formed has no power of action on gold or platina. Again, if muriatic acid gas, and nitrous gas, in equal volumes, be mixed together over mercury, and half a volume of oxygen be added, the immediate condensation will be no more than might be expected from the formation of nitrous acid gas. And when this is decomposed, or absorbed by the mercury, the muriatic acid gas is found unaltered, mixed with a certain portion of nitrous gas.

It appears, then, that *nitrous* acid and muriatic acid gas have no chemical action on each other. If *colourless nitric* acid and muriatic acid of commerce be mixed together, the mixture immediately becomes yellow, and gains the power of dissolving gold and platinum. If it be gently heated, pure chlorine arises from it, and the colour becomes deeper. If the heat be longer continued, chlorine still rises, but mixed with nitrous acid gas. When the process has been very long continued, till the colour becomes very deep, no more chlorine can be procured, and it loses its power of acting upon platinum and gold. It is now *nitrous* and muriatic acids. It appears then, from these observations, which have been very often repeated, that nitro-muriatic acid owes its peculiar properties to a mutual decomposition of the nitric and muriatic acids; and that water, chlorine, and nitrous acid gas, are the results. Though nitrous gas and chlorine have no action on each other when perfectly dry, yet, if water be present, there is an immediate decomposition, and nitrous acid and muriatic acid are formed. 118 parts of strong liquid nitric acid being decomposed in this case, yield 67 of chlorine. *Aqua regia* does not oxidise gold and platina: it merely causes their combination with chlorine.

With different saline, earthy, and metallic bases, the nitric acid forms the class of salts denominated *nitrates*.

The nitrates used in the cure of diseases are,

1. The nitrate of soda.
2. ——————— potash.
3. ——————— silver.
4. ——————— mercury.
5. The subnitrate of bismuth.

Besides these, chemists are well acquainted with nitrates of baryta, soda, strontia, lime, magnesia, glucine, zirconia, and yttria.

NITRIC ACID, OXYGENISED. The apparent oxygenation of nitric acid by Thénard, ought to be regarded merely as the conversion of a portion of its combined water into deutoxide of hydrogen. See *Hydrogen*.

Nitric oxide. See *Nitrogen, deutoxide of.*

Nitric oxide of mercury. See *Hydrargyri nitrico-oxydum.*

Nitrico-oxydum hydrargyri. See *Hydrargyri nitrico-oxydum.*

NITROGEN. (*Nitrogenium, ii.* n.; from νιτρον, nitre, and γενναω, to generate: so called because it is the generator of nitre.) Azote; Azot. An important elementary or undecomposed principle. As it constitutes four fifths of the volume of atmospheric air, the readiest mode of procuring azote is to abstract the oxygen with which it is associated by the combustion of phosphorus or hydrogen. It may also be obtained from animal matters, subjected in a glass retort to the action of nitric acid, diluted with 8 or 10 times its weight of water.

It is a disputed point whether the nitrogen and oxygen of the atmosphere are chemically combined, or only mechanically mixed. See *Atmosphere*.

Azote possesses all the physical properties of air. It extinguishes flame and animal life. It is absorbable by about 100 volumes of water. Its spec. gravity is 0·9722. 100 cubic inches weigh 29·65 grains. It has neither taste nor smell. Exclusive of atmospheric air, there are five known compounds of nitrogen and oxygen, viz. the *protoxide*, the *deutoxide*, *hyponitrous acid*, *nitrous acid*, and *nitric acid*.

I. *Protoxide of azote.* This combination of nitrogen and oxygen was formerly called the *dephlogisticated nitrous gas*, but now gaseous oxide of nitrogen, or nitrous oxide. It was first discovered by Priestley.

Sir Humphrey Davy has examined with uncommon accuracy the formation and properties of all the substances concerned in its production.

It exists in the form of a permanent gas. A candle burns with a brilliant flame and crackling noise in it; before its extinction, the white inner flame becomes surrounded with a blue one. Phosphorus introduced into it, in a state of *actual* inflammation, burns with increased splendour, as in oxygen gas. Sulphur introduced into it when burning with a feeble blue flame is instantly extinguished; but when in a state of *vivid inflammation*, it burns with a rose-coloured flame. Ignited charcoal burns in it more brilliantly than in atmospheric air. Iron wire, with a small piece of wood affixed to it, when inflamed, and introduced into a vessel filled with this gas, burns vehemently, and throws out bright scintillating sparks. No combustible body, however, burns in it, unless it be previously brought to a state of vivid inflammation. Hence sulphur may be melted, and even sublimed in it: phosphorus may be liquefied in it without undergoing combustion. Nitrous oxide is pretty rapidly absorbed by water that has been boiled: a quantity of gas equal to rather more than half the bulk of the water may be thus made to disappear: the water acquires a sweetish taste, but its other properties do not differ perceptibly from com-

mon water. The whole of the gas may be expelled again by heat. It does not change blue vegetable colours. It has a distinctly sweet taste, and a faint but agreeable odour. It undergoes no diminution when mingled with oxygen or nitrous gas. Most of the liquid inflammable bodies, such as ether, alkohol, volatile and fat oils, absorb it rapidly and in great quantity. Acids exert but little action on it. The affinity of the neutro-saline solutions for gaseous oxide of nitrogen is very feeble. Green muriate and green sulphate of iron, whether holding nitrous gas in solution, or not, do not act upon it. None of the gases, when mingled with it, suffer any perceptible change at common temperatures; the muriatic and sulphureous acid gases excepted, which undergo a slight expansion. Alkalis freed from carbonic acid, exposed in the dry or solid form, have no action upon it; they may, however, be made to combine with it in the nascent state, and then constitute *saline compounds* of a peculiar nature. These combinations deflagrate when heated with charcoal, and are decomposed by acids; the gaseous oxide of nitrogen being disengaged. It undergoes no change whatever from the simple effect of light. The action of the electric spark, for a long while continued, converts it into a gas, analogous to atmospheric air and nitrous acid: the same is the case when it is made to pass through an ignited earthen tube. It explodes with hydrogen in a variety of proportions, at very high temperatures; for instance, when electric sparks are made to pass through the mixture. Sulphuretted, heavy, and light carburetted hydrogen gases, and gaseous oxide of carbon, likewise burn with it when a strong red heat is applied. 100 parts by weight of nitrous oxide contain 36·7 of oxygen, and 63·3 of nitrogen; 100 cubic inches weigh 50 grains at 55° temperature and 30 inches atmospheric pressure. Animals, when wholly confined in gaseous oxide of nitrogen, give no signs of uneasiness for some moments, but they soon become restless, and then die.

When mingled with atmospheric air, and then received into the lungs, this gas generates highly pleasurable sensations: the effects it produces on the animal system are eminently distinguished from every other chemical agent. It excites every fibre to action, and rouses the faculties of the mind, inducing a state of great exhilaration, an irresistible propensity to laughter, a rapid flow of vivid ideas, and unusual vigour and fitness for muscular exertions, in some respects resembling those attendant on the pleasantest period of intoxication, without any subsequent languor, depression of the nervous energy, or disagreeable feelings; but more generally followed by vigour, and a pleasurable disposition to exertion, which gradually subsides.

Gaseous oxide of nitrogen is produced when substances, having a strong affinity with oxygen, are brought into contact with nitric acid, or with nitrous gas. It may, therefore, be obtained by various processes, in which nitrous gas or nitric acid is decomposed by substances capable of attracting the greater part of their oxygen. The most commodious and expeditious, as well as the cheapest, mode of obtaining it, is by decomposing nitrate of ammonia.

II. *Deutoxide of nitrogen;* termed likewise nitrous gas, or nitric oxide.

This is an elastic, colourless, gaseous fluid, having no sensible taste: it is neither acid nor alkaline: it is exceedingly hurtful to animals, producing instant suffocation whenever they attempt to breathe it. The greater number of combustible bodies refuse to burn in it. It is, nevertheless, capable of supporting the combustion of some of these bodies. Phosphorus burns in nitrous gas when introduced into it in a state of inflammation: pyrophorus takes fire in it spontaneously.

Ardent spirits, saccharine matters, hydro-carbonates, sulphureous acid, and phosphorus, have no action on it at the common temperature. It is not sensibly changed by the action of light. Heat dilates it. It rapidly combines with oxygen gas at common temperatures, and converts it into nitrous acid. Atmospheric air produces the same effect, but with less intensity. It is absorbable by green sulphate, muriate and nitrate of iron, and decomposable by alkaline, terrene, and metallic sulphurets, and other bodies that have a strong affinity for oxygen; but it is not capable of combining with them chemically, so as to form saline compounds. From the greatest number of bodies which absorb it, it may be again expelled by the application of heat.

It communicates to flame a greenish colour before extinguishing it: when mixed with hydrogen gas this acquires the property of burning with a green flame. It is absorbable by nitric acid, and renders it fuming.

When exposed to the action of caloric, in an ignited porcelain tube, it experiences no alteration; but when electric sparks are made to pass through it, it is decomposed and converted into nitrous acid, and nitrogen gas. Phosphorus does not shine in it. It is composed of about eight parts of oxygen, and seven of nitrogen.

Methods of obtaining deutoxide of nitrogen. — 1. Put into a small proof, or retort, some copper wire, or pieces of the same metal, and pour on it nitric acid of commerce diluted with water: an effervescence takes place, and nitrous gas will be produced. After having suffered the first portions to escape, on account of the atmosphoric air contained in the retort, collect the gas in the water apparatus as usual. In order to obtain the gas in a pure state, it must then be shook for some time in contact with water. The water, in this instance, suffers no alteration; on the contrary, the acid undergoes a partial decomposition; the metal robs some of the nitric acid of the greatest part of its oxygen, and becomes oxidised; the acid having lost so much of its oxygen, becomes thereby so altered, that, at the usual temperature, it can exist no longer in the liquid state, but instantly expands and assumes the form of gas, ceasing, at the same time, to act as an acid, and exhibiting different properties: but the acid remaining undecomposed combines with the oxide of copper, and forms nitrate of copper.

III. *Hypo-nitrous acid.* This substance has not yet been obtained in a free state. If deutoxide of nitrogen be added in excess to oxygen gas, in a tube over mercury, which tube contains a strong solution of pure potash, the gases combine to form hypo-nitrous acid, which is instantly absorbed by the potash forming a hypo-nitrate of potash. The same product may be obtained by keeping deutoxide of nitrogen for three months over mercury in a glass tube containing a strong solution of pure potash: the deutoxide is resolved into protoxide and hypo-nitrous acid; the former remains in the tube, and the latter combines with the potash.

When an acid is added to the hypo-nitrate of potash, the hypo-nitrous acid is decomposed and converted into nitrous acid and deutoxide of nitrogen. Hypo-nitrous acid is presumed to consist of one equivalent of nitrogen and three of oxygen.

IV. *Nitrous acid.* See *Nitrous acid.*

V. *Nitric acid.* See *Nitric acid.*

Nitrogen combines with chlorine and iodine, to form two very formidable compounds: —

1. The *chloride of nitrogen.* Put into an evaporating porcelain basin a solution of one part of nitrate or muriate of ammonia in 10 of water, heated to about 100°, and invert into it a wide-mouthed bottle filled with chlorine. As the liquid ascends by the condensation of the gas, oily-looking drops are seen floating on its surface, which collect together, and fall to the bottom in large globules. This is *chloride of azote.* It should be formed only in very small quantities. Thus obtained, it is an oily-looking liquid, of a yellow colour, and a very pungent intolerable odour, similar to that of chlorocarbonous acid. This experiment, and indeed every one with the chlorides and iodides of azote, require the greatest caution, as they detonate from slight causes, and produce serious injuries.

2. *Iodide of nitrogen.* Azote does not combine directly with iodine.

It may be obtained by putting pulverulent iodine into common water of ammonia; and this is the best way of preparing it. It is pulverulent, and of a brownish-black colour. It detonates from the smallest shock, and from heat, with a feeble violet vapour. When properly prepared, it often detonates spontaneously.

The strongest arguments for the compound nature of azote are derived from its slight tendency to combination, and from its being found abundantly in the organs of animals which feed on substances that do not contain it.

Its uses in the economy of the globe are little understood. This is likewise favourable to the idea that the real chemical nature is as yet unknown, and leads to the hope of its being decomposable.

It would appear that the atmospheric azote and oxygen spontaneously combine in other proportions, under certain circumstances, in natural operations. Thus we find, that mild calcareous or alkaline matter favours the formation of nitric acid, in certain regions of the earth; and that they are essential to its production in our artificial arrangements, forming nitre by decomposing animal and vegetable substances.

Nitrogen, deutoxide of. See *Nitrogen.*

Nitrogen, protoxide of. See *Nitrogen.*

NITRO-LEU'CIC ACID. *Acidum nitro-leucicum. Leucine* is capable of uniting to nitric acid, and forming a compound, which Braconnot has called the nitro-leucic acid. When we dissolve leucine in nitric acid, and evaporate the solution to a certain point, it passes into a crystalline mass, without any disengagement of nitrous vapour, or of any gaseous matter: if we press this mass between blotting paper, and redissolve it in water, we shall obtain from this, by concentration, fine, divergent, and nearly colourless needles. These constitute the new acid. It unites to the bases, forming salts which fuse on red-hot coals. The nitro-leucates of lime and magnesia are unalterable in the air.

NI'TRO-MURIA'TIC ACID. *Aqua regia.* When nitric and muriatic acids are mixed, they become yellow, and acquire the power of readily dissolving gold, which neither of them possessed separately. This mixture evolves chlorine, a partial decomposition of both acids having taken place; and water, chlorine, and nitrous acid gas, being thus produced. Aqua regia, therefore, is a mixture of chlorine, nitrous acid, and water.

NITRO-SA'CCHARIC ACID. *Acidum nitro-saccharicum.* Nitro-saccharine acid. When we heat the *sugar of gelatine* with nitric acid, they dissolve without any apparent disengagement of gas; and if we evaporate this solution to a proper degree, it forms, on cooling, a crystalline mass. On pressing this mass between the folds of blotting paper, and recrystallising them, we obtain beautiful prisms, colourless, transparent, and slightly striated. These crystals are very different from those which serve to produce them; and constitute, according to Braconnot, a true acid, which results from the combination of the nitric acid itself with the sweet matter of which the first crystals are formed. Thénard conceives it is the *nitrous* acid which is present.

Nitro-saccharic acid has a taste similar to that of the tartaric, only it is a little sweetish. Exposed to the fire in a capsule, it froths much, and is decomposed with the diffusion of a pungent smell. Thrown on burning coals, it acts like saltpetre. It produces no change in saline solutions. Finally, it combines with the bases, and gives birth to salts which possess peculiar properties. For example, the salt which it forms with lime is not deliquescent, and is very little soluble in strong alkohol. That which it produces with the oxide of lead detonates to a certain degree by the action of heat. *Ann. de Chimie et de Phys.* xiii. 113.

NI'TROUS. *Nitrosus.* Of or belonging to nitre, or its combinations.

NITROUS ACID. *Acidum nitrosum.* Fuming nitrous acid. This acid appears to form a distinct genus of salts, that may be termed *nitrites.* But these cannot be made by a direct union of their component parts, being obtainable only by exposing a nitrate to a high temperature, which expels a portion of its oxygen in the state of

gas, and leaves the remainder in the state of a nitrite, if the heat be not urged so far, or continued so long, as to effect a complete decomposition of the salt. In this way the nitrites of potash and soda may be obtained, and perhaps those of barytes, strontian, lime, and magnesia. The nitrites are particularly characterised, by being decomposable by all the acids, except the carbonic, even by the nitric acid itself, all of which expel from them nitrous acid. We are little acquainted with any one except that of potash, which attracts moisture from the air, changes blue vegetable colours to green, is somewhat acrid to the taste, and, when powdered, emits a smell of nitric oxide.

The acid itself is best obtained by exposing nitrate of lead to heat in a glass retort. Pure *nitrous* acid comes over in the form of an orange-coloured liquid. It is so volatile as to boil at the temperature of 82°. Its specific gravity is 1·450. When mixed with water it is decomposed, and nitrous gas is disengaged, occasioning effervescence. It is composed of one volume of oxygen united with two of nitrous gas. It therefore consists ultimately, by weight, of 1·75 nitrogen + 4 oxygen; by measure, of 2 oxygen + 1 nitrogen. The various coloured acids of nitre are not *nitrous* acids, but nitric acid impregnated with nitrous gas, the deutoxide of nitrogen or azote.

Nitrous oxide. See *Nitrogen.*

Nitrum. See *Nitre.*

Nitrum Purificatum. See *Nitre.*

NITRUM STIBIATUM. *Nitrum antimoniatum. Anodynum minerale.* An old preparation made by dissolving the *antimonium diaphoreticum* in water, and evaporating to dryness.

Nitrum vitriolatum. See *Sodæ sulphas.*

NO'BILIS. (*Quasi noscibilis;* from *nosco*, to know.) Noble. Some objects of Natural History so called by way of eminence: thus gold and silver are called *noble metals*, and *nobilis* is the specific name of several plants.

NOCTAMBULA'TION. (*Noctambulatio, onis.* f.; from *nox*, night, and *ambulo*, to walk.) Sleep-walking. See *Oneirodynia activa.*

NOCTISU'RGIUM. (*um, ii.* n.; from *nox*, night, and *surgo*, to arise.) Sleep-walking. See *Oneirodynia activa.*

Nocturnal blindness. See *Hemeralopia*, and *Nyctalopia.*

Nocturnal emisson. See *Gonorrhœa.*

Nodding. See *Nutans.*

NODE. (*Nodus, i.* m.; from *anad*, Hebrew, to tie.) 1. In *Surgery*, a hard circumscribed tumour, proceeding from a bone, and caused by a swelling of the periosteum. Nodes appear on every part of the body, but are more common on such as are thinly covered with muscles, as the os frontis, forepart of the tibia, radius, and ulna. As they increase in size, they become more painful, from the distension they occasion in the periosteum. When they continue long, the bone becomes completely carious.

2. In *Botany*, applied to joints that have small elevations, as observed in the stems of some grasses.

NODO'SUS. Nodose: knotty; as the seed-vessel of the *Cucurbita melopepo.*

NO'LI ME' TA'NGERE. *Lupus.* A species of malignant herpes, or lupus, affecting the skin, and not unfrequently the cartilages of the nose, very difficult to cure, because it is exasperated by most applications. The disease generally commences with small, superficial spreading ulcerations, which become more or less concealed beneath furfuraceous scabs. The whole nose is frequently destroyed by the progressive ravages of this peculiar disorder, which sometimes cannot be stopped or retarded by any treatment, external or internal.

NO'MA. (*a, æ.* f.; from νεμω, to eat.) An ulcer that attacks the skin, and often the cheek or vulva of young girls. It appears in the form of red and somewhat livid spots; is not attended with pyrexia, pain, or tumour, and in a few days becomes gangrenous.

Nomenclature, anatomical. See the Supplement.

NONI DESCENDENS. A branch of the ninth pair of nerves. See *Nerve.*

NON-NATURALS. *Res non-naturales.* Under this term, the old physicians comprehended air, eating and drinking, sleep and watching, motion and rest, the retentions and excretions, and the affections of the mind; or, in other words, those principal matters which do not enter into the composition of the body, but at the same time are necessary to its existence.

NOOTH'S APPARATUS. An apparatus contrived by Dr. Nooth for impregnating water with gases, particularly the carbonic acid.

NO'PAL. *Nopalnochetzth.* The plant that feeds the cochineal insect.

Norlandica bacca. See *Rubus.*

NORRIS'S DROPS. According to Dr. Paris, this is a solution of emetic tartar in rectified spirit, with the addition of some vegetable colouring matter.

NORTON'S DROPS. A coloured solution of corrosive sublimate.

Nose. Nasus. See *Nares*, and *Smell.*

Nose, bleeding of the. See *Epistaxis.*

NOSOCOMIA'LIS. Nosocomial. Appertaining to a hospital, as *febris nosocomialis*, hospital fever.

NOSOCOMI'UM. (*um, ii.* n.; νοσοκομειον; from νοσος, a disease, and κομεω, to take care of.) *Nosodochium.* A hospital or infirmary for the sick.

NOSODOCHI'UM. (Νοσοδοχειον; from νοσος, a disease, and δοκειον, a receptacle.) A hospital.

NOSO'GRAPHY. *Nosographia;* from νοσος, a disease, and γραφω, to describe. The description of diseases.

NOSO'LOGY. (*Nosologia, æ.* f.; from νοσος, a disease, and λογος, a discourse.) This term is, from its derivation, synonymous with pathology; but it is always applied to that division of medical science which considers the most appropriate names of diseases, and their methodical arrangement or classification.

A number of celebrated authors have occupied themselves in the classification of diseases; but the increased cultivation of pathology has tended to diminish greatly the importance of nosological systems. The principal are those of Sauvages, Linnæus, Vogel, Sagar, Macbride,

Cullen, and Good. Others, as those of Darwin, Crichton, Par, Pinel, Young, &c. have attracted less attention. In this country, Cullen's nosology is the one generally used, and is perhaps more convenient than any other. The following is a synoptical view of it: —

CLASS I. — PYREXIÆ.

Order I. FEBRES.

§ 1. *Intermittentes.*

1. Tertiana.
2. Quartana.
3. Quotidiana.

§ 2. *Continuæ.*

4. Synocha.
5. Typhus.
6. Synochus.

Order II. PHLEGMASIÆ.

7. Phlogosis.
8. Ophthalmia.
9. Phrenitis.
10. Cynanche.
11. Pneumonia.
12. Carditis.
13. Peritonitis.
14. Gastritis.
15. Enteritis.
16. Hepatitis.
17. Splenitis.
18. Nephritis.
19. Cystitis.
20. Hysteritis.
21. Rheumatismus.
22. Odontalgia.
23. Podagra.
24. Arthropuosis.

Order III. EXANTHEMATA.

25. Variola.
26. Varicella.
27. Rubeola.
28. Scarlatina.
29. Pestis.
30. Erysipelas.
31. Miliaria.
32. Urticaria.
33. Pemphigus.
34. Aphtha.

Order IV. HÆMORRHAGIÆ.

35. Epistaxis.
36. Hæmoptysis.
37. Hæmorrhois.
38. Menorrhagia.

Order V. PROFLUVIA.

39. Catarrhus.
40. Dysenteria.

CLASS II. — NEUROSES.

Order I. COMATA.

41. Apoplexia.
42. Paralysis.

Order II. ADYNAMIÆ.

43. Syncope.
44. Dyspepsia.
45. Hypochondriasis.
46. Chlorosis.

Order III. SPASMI.

47. Tetanus.
48. Convulsio.
49. Chorea.
50. Raphania.
51. Epilepsia.
52. Palpitatio.
53. Asthma.
54. Dyspnœa.
55. Pertussis.
56. Pyrosis.
57. Colica.
58. Cholera.
59. Diarrhœa.
60. Diabetes.
61. Hysteria.
62. Hydrophobia.

Order IV. VESANIÆ.

63. Amentia.
64. Melancholia.
65. Mania.
66. Oneirodynia.

CLASS III. — CACHEXIÆ.

Order I. MARCORES.

67. Tabes.
68. Atrophia.

Order II. INTUMESCENTIÆ.

§ 1. *Adiposæ.*

69. Polysarcia.

§ 2. *Flatuosæ.*

70. Pneumatosis.
71. Tympanites.
72. Physometra.

§ 3. *Aquosæ.*

73. Anasarca.
74. Hydrocephalus.
75. Hydrorachitis.
76. Hydrothorax.
77. Ascites.
78. Hydrometra.
79. Hydrocele.

§ 4. *Solidæ.*

80. Physconia.
81. Rachitis.

Order III. IMPETIGINES.

82. Scrofula.
83. Syphilis.
84. Scorbutus.
85. Elephantiasis.
86. Lepra.
87. Framboesia.
88. Trichoma.
89. Icterus.

CLASS IV. — LOCALES.

Order I. DYSÆSTHESIÆ.

90. Caligo.
91. Amaurosis.
92. Dysopia.
93. Pseudoblepsis.
94 Dysecoea.
95. Paracusis.
96. Anosmia.
97. Agheustia.
98. Anæsthesia.

Order II. DYSOREXIÆ.

§ 1. *Appetitus erronei.*

99. Bulimia.
100. Polydipsia.
101. Pica.
102. Satyriasis.
103. Nymphomania.
104. Nostalgia.

§ 2. *Appetitus deficientes.*

105. Anorexia.
106. Adipsia.
107. Anaphrodisia.

Order III. DYSCYNESIÆ.

108. Aphonia.
109. Mutitas.
110. Paraphonia.
111. Psellismus.
112. Strabismus.
113. Dysphagia.
114. Contractura.

Order IV. APOCENOSES.

115. Profusio.
116. Ephidrosis.
117. Epiphora.
118. Ptyalismus.
119. Enuresis.
120. Gonorrhœa.

Order V. EPISCHESES.

121. Obstipatio.
122. Ischuria.
123. Dysuria.
124. Dyspermatismus.
125. Amenorrhœa.

ORDER VI.
TUMORES.

126. Aneurisma.
127. Varix.
128. Ecchymoma.
129. Scirrhus.
130. Cancer.
131. Bubo.
132. Sarcoma.
133. Verruca.
134. Clavus.
135. Lupia.
136. Ganglion.
137. Hydatis.
138. Hydarthrus.
139. Exostosis.

ORDER VII.
ECTOPIÆ.

140. Hernia.
141. Prolapsus.
142. Luxatio.

ORDER VIII.
DYALYSES.

143. Vulnus.
144. Ulcus.
145. Herpes.
146. Tinea.
147. Psora.
148. Fractura.
149. Caries.

NOSTA'LGIA. (*a*, *æ*. f.; from *νοστος*, a return, and *αλγος*, pain.) A vehement desire for revisiting one's country, attended with melancholy, loss of appetite, and want of sleep. A genus of disease in the class *Locales*, and order *Dysorexiæ*, of Cullen. The Swiss are particularly subject to this affection, which is also observed sometimes in other mountaineers.

Nostoc. See *Temella nostoc.*

NOSTOMA'NIA. (From *νοστος*, a return, and *μανια*, madness.) The highest degree of nostalgia.

Nostril. See *Naris.*

NO'STRUM. This word means *our own*, and is applied to all quack medicines, the composition of which is kept secret.

NO'TENCE'PHALUS. (From *νωτος*, the back, and *εγκεφαλος*, the brain.) A monster in which the brain forms a hernia behind, and rests upon the dorsal vertebræ which are open posteriorly. — *G. St. Hilaire.*

Notched. See *Erosus.*

NO'THUS. (*Νοθος*, spurious) Spurious. Bastard. See *Bastard.*

NOTIÆ'US. (From *νωτον*, the back.) An obsolete epithet of the spinal marrow.

NOTIO'DES. (From *νοτις*, moisture.) An obsolete word, applied to a fever attended with a vitiation of the fluids, or a colliquative wasting.

NUBA. Copper. — *Ruland.*

NUBE'CULA. (*a*, *æ*. f.; diminutive of *nubes*, a cloud.) The same as *nebula.*

Nucamentum. See *Amentum.*

Nucesta. See *Myristica moschata.*

NU'CHA. (*a*, *æ*. f.; Arabic.) *Nucha capitis.* The hind part or nape of the neck. The part is so called where the spinal marrow begins.

NUCI'STA. The nutmeg.

NU'CLEUS. (*us*, *i*. m.; *a nuce*, from the nut.) 1. A kernel or fruit enclosed in a hard shell.

2. When the centre of a tumour or morbid concretion, as a stone of the bladder, has an obvious difference from the surrounding parts, that is called the nucleus: thus, a cherry-stone and other things have been found in calculi of the bladder, forming the nucleus of that concretion.

NU'CULA. (*a*. *æ*. f.; diminutive of *nux*, a nut.) A little nut.

Nucula saponaria. See *Sapindus saponaria.*

NU'DUS. Naked: applied to flowers, leaves, stems, receptacles, seeds, &c. of plants. A flower is said to be naked when the calyx is wanting, as in the tulip, and white lily; and a leaf when it is destitute of all kinds of clothing or hairiness, as in the genus *orchis:* the stem is naked that bears no leaves, scales, or any other vesture, as *Cuscuta europea;* the receptacle of the *Leontodon taraxacum*, and *Lactuca;* the seeds of the gymnospermous plants, &c.

NUMI'DIA. (The name of the country whence the bird comes.) The name of a genus of birds, of the order *Gallinæ.*

NUMIDIA MELEA'GRIS. The guinea-fowl, the flesh of which is of easy digestion.

NUMMULA'RIA. (*a*, *æ*. f.; from *nummus*, money: so called because its leaves are round, and of the size of the old silver twopence.) See *Lysimachia nummularia.*

Nut. See *Nux.*

Nut, Barbadoes. See *Jatropha curcas.*

Nut, cocoa. See *Cocos nucifera.*

Nut, pistachio. See *Pistacia vera.*

Nut, purging. See *Jatropha curcas.*

NU'TANS. (From *nuto*, to bend.) Nutant: drooping, or nodding. Applied to stems, &c. when bent towards the end near the flower; as the *Narcissus*, *Scilla nutans*, &c.

Nutmeg. See *Myristica moschata.*

NUTRITION. (*Nutritio*, *onis*. f.) Nutrition may be considered the completion of the assimilating functions. The food, changed by a series of decompositions, animalised and rendered similar to the being which it is designed to nourish, applies itself to those organs, the loss of which it is to supply; and this identification of nutritive matter to our organs constitutes nutrition.

The living body is continually losing its constituent parts.

From the state of the embryo to the most advanced old age, the weight and volume of the body are almost continually changing; the different organs and tissues present infinite variations in their consistence, colour, elasticity, and sometimes their chemical composition. The volume of the organs augments when they are often in action; on the contrary, their size diminishes when they remain long at rest. By the influence of one or other of these causes, their chemical and physical properties present remarkable variations. Many diseases often produce, in a very short time, remarkable changes in the exterior conformation, and in the structure of a great number of organs.

If madder is mixed with the food of an animal, in fifteen or twenty days the bones present a red tint, which disappears when the use of it is left off.

There exists, then, in the organs, an insensible motion of the particles which produce all these modifications. It is this that is called *nutrition*, or *nutritive action.*

This phenomenon, which the observing spirit of the ancients had not permitted to escape, was to them the object of many ingenious suppositions that are still admitted. For example, it is said that, by means of the nutritive action, the whole body is renewed, so that, at a certain period, it does not possess a single particle of the matter that composed it formerly. Limits have even been assigned to this total renewal: some have fixed the period of three years; others think it not complete till seven: but there is nothing to give probability to these conjectures; on the contrary, certain well-proved facts seem to render them of no avail.

It is well known that soldiers, sailors, and several savage nations colour their skins with substances which they introduce into the tissue of this membrane itself: the figures thus traced preserve their form and colour during their lives, should no particular circumstances occur. How can this phenomenon agree with the renewal of the skin according to these authors? The recent use of nitrate of silver internally, in the cure of epilepsy, furnishes a new proof of this kind. After some months' use of this substance, some sick persons have had their skin coloured of a greyish blue, probably by a deposition of the salt in the tissue of this membrane, where it is immediately in contact with the air. Several individuals have been in this state for some years without the tint becoming weaker; whilst, in others, it has diminished by degrees, and disappeared in two or three years.

It is admitted, in the metaphorical language now used in physiology, that the atoms of the organs can only serve for a certain period, in their composition; that in time they *wear*, and become at last improper to enter into their composition; and that they are then absorbed and replaced by new atoms proceeding from the food.

It is added, that the animal matters of which our excretions are composed are the *detritus* of the organs, and that they are principally composed of atoms that can no longer serve in their composition, &c.

Instead of discussing these hypotheses, we shall mention a few facts from which we have some idea of the nutritive movement.

A. In respect to the rapidity with which the organs change their physical and chemical properties by sickness or age, it appears that nutrition is more or less rapid according to the tissues. The glands, the muscles, the skin, &c., change their volume, colour, consistence, with great quickness; the tendons, the fibrous membranes, the bones, the cartilages, appear to have a much slower nutrition, for their physical properties change but slowly by the effect of age and disease.

B. If we consider the quantity of food consumed proportionally to the weight of the body, the nutritive movement seems more rapid in infancy and youth, than in the adult and in old age; it is accelerated by the repeated action of the organs, and retarded by repose. Indeed, children and young people consume more food than adults and old people: these last can preserve all their faculties by the use of a very small quantity of food. All the exercises of the body, and hard labour, require necessarily a greater quantity, or more nutritive food; on the contrary, perfect repose permits of longer abstinence.

C. The blood appears to contain most of the principles necessary to the nutrition of the organs; the fibrine, the albumen, the fat, the salts, &c. that enter into the composition of the tissues, are found in the blood. They appear to be deposited in their parenchyma at the instant when the blood traverses them; the manner in which this deposit takes place is entirely unknown. There is an evident relation between the activity of the nutrition of an organ and the quantity of blood it receives. The tissues that have a rapid nutrition have larger arteries; when the action of an organ has determined an acceleration of its nutrition, the arteries increase in size.

Many proximate principles that enter into the composition of the organs are not found in the blood: as ozmazome, the cerebral matter, gelatine, &c. They are, therefore, formed from other principles in the parenchyma of the organs, in some chemical but unknown manner.

D. Since chemical analysis has made known the nature of the different tissues of the animal economy, they have been all found to contain a considerable portion of azote. Our food being also partly composed of this simple body, the azote of our organs likewise probably comes from them; but several eminent authors think that it is derived from respiration; others believe that it is formed by the influence of life solely. Both parties insist particularly upon the example of the herbivorous animals, which are supported exclusively upon non-azotised matter; upon the history of certain people that live entirely upon rice and maize; upon that of negroes who can live a long time without eating any thing but sugar; lastly, upon what is related of *caravans*, which, in traversing the deserts, have for a long time had only gum in place of every sort of food. Were it, indeed, proved by these facts, that men can live a long time without azotised food, it would be necessary to acknowledge that azote has an origin different from the food; but the facts cited by no means prove this. In fact, almost all the vegetables upon which man and the animals feed contain more or less azote: for example, the impure sugar that the negroes eat presents a considerable portion of it; and with regard to the people, as they say, who feed upon rice or maize, it is well known that they eat milk, or cheese: now *casein* is the most azotised of all the nutritive proximate principles.

E. A considerable number of tissues in the economy appear to have no nutrition, properly so called; as the epidermis, the nails, the hair, the teeth, the colouring matter of the skin, and, perhaps, the cartilages.

These different parts are really secreted by particular organs, as the teeth and the hair; or by parts which have other functions at the same time, as the nails and the epidermis. The most of the parts formed in this mode wear by the friction of exterior bodies, and are con-

stantly renewed: if they are entirely carried away, they are capable of reproduction. A very singular fact is, that they continue to grow several days after death. — *Magendie's Physiology.*

NUTRITUM UNGUENTUM. A composition of litharge, vinegar, and oil.

NUX. (*x, cis.* f.) A nut, or fruit which has a hard shell.

Botanists consider this as distinct from the drupa, and define it a pericarp, the seed being contained in a hard bony shell.

From the number of seeds it contains, it is called, —

1. *Monosperm*, having one; as in *Corylus ellana.*

2. *Disperm*, with two; as in *Halesia.*

From its loculaments:

1. *Unilocular, bilocular, trilocular*, with one, two, or three; as in *Corylus, Lygeum*, and *Elais.*

From its figure:

1. *Alate*, winged; as in *Pinus thuja.*
2. *Angulate*; as in *Cypressus.*
3. *Ovate*; as in *Corylus*, and *Carpinus.*
4. *Quadrangular*; as in *Halesia.*
5. *Tetragonal*; as in *Peladium* and *Mesua.*
6. *Reniform*; as in *Anacardium.*
7. *Spinous*; as in *Trapa natans.*

Nux aquatica. See *Trapa natans.*

Nux aromatica. See *Myristica.*

Nux barbadensis. See *Jatropha curcas.*

Nux basilica. See *Juglans regia.*

Nux ben. See *Moringa aptera*, in the Supplement.

Nux moschata. See *Myristica.*

Nux myristica. See *Myristica.*

Nux persica. See *Juglans regia.*

Nux pistacia. See *Pistacia vera.*

Nux purgans. See *Jatropha curcas.*

Nux scrapionis. See *Ignatia amara.*

Nux vomica. See *Strychnos.*

NYCTALO'PIA. (*a, æ.* f.; from *νυξ*, the night, and *ωψ*, an eye.) A defect in vision, by which the person sees little or nothing in the day, but in the evening and night sees tolerably well. This disease is dependent upon a peculiar irritability of the retina, produced by two very different causes: a sudden exposure to a stronger light than the eye has been wont to sustain; and a deficiency of the pigmentum nigrum. From the first cause, the disease is common with those who have been accustomed to a privation of light, by living in caverns, mines, dungeons, &c., or who have recently had a cataract depressed or extracted, the growth of which excluded the light from the retina. Ramazini asserts, that this affection is common with the peasants in Italy, who are employed in agriculture; and many Æthiopians, Africans, and Asiatics have it, most probably from the clearness of the atmosphere, the brightness of the sky, and the warmth of the air, the joint operation of which is likely to produce habitual debility of the iris, and irritability of the retina. A deficiency of the pigmentum nigrum is occasionally found in persons of a fair complexion and light hair; and, as the retina is hereby deprived of the natural shade that softens the light in its descent upon this very sensible membrane, its morbid irritability is not to be wondered at.

Sedative applications, as dilute tincture of belladonna, and the internal use of hyoscyamus, and conium, with cinchona or cascarilla, are likely to be beneficial where the disease proceeds from an accidental irritability, taking care to remove the causes. In old age, and an early deficiency of the black pigment, medicine can do but little.

Modern critics are greatly at variance as to the etymology and signification of the term *nyctalopia*; nor is the question to be settled by an appeal to the ancients, for the Greek writers on medicine do not agree in their definitions of it. For the benefit of the curious reader we quote the following authorities:

Hippocrates says, *Οἱ δε της νυκτος ὁρωντες, οὑς δη νυκταλωπες καλεομεν* — those who see by night, whom we call nyctalopes. — *Prorrhet.* lib. ii. sect. 2. edit. *Foës.* tom. i. p. 110.

Galen, in his *Exegesis*, or exposition of the terms used by Hippocrates, defines *nyctalopes* as *οἱ της νυκτος αλαοι* — those who are blind by night.

The author of the *Definitiones Medicæ*, ascribed to Galen, says, *Νυκταλωψ εστι παθος και διαθεσις οφθαλμων διχα φανερας αιτιας, συμβαινει δε τοις οὑτω διακειμενοις ἡμερας μεν μη ὁραν, νυκτος δε βλεπειν.* Nyctalops is a disease and disposition of the eyes without a manifest cause: it happens to those who are thus affected not to see in the day time, but to see at night. — *Galeni Op. Om. Basil.* 1538. tom. iv. p. 400.

In the *Isagoge*, ascribed to Galen, it is said, *Νυκταλωπας δε λεγουσιν ὁταν ἡμερας μεν βλεπωσιν αμαυροτερον, δυομενου δε ἡλιου λαμπροτερον, νυκτος δε ετι μαλλον· η ὑπεναντιως ἡμερας μεν ολιγα, ἑσπερας δε η νυκτος ουδολως.* They call those *nyctalopes* who see dimly in the day, more clearly at sunset, and better still at night; or who, on the contrary, see but little in the day, and not at all in the evening and night. — Cap. xv. *sub fine. Galeni Op. Om. Basil.* 1538. tom. iv. p. 387.

Oribasius says, "nyctalopem vocant eum qui per diem videt, sole occidente obscurius, nocte vero omnino nihil cernit." They call him nyctalops who sees (clearly) in the day, more obscurely at sunset, and at night not at all. — *Synopseos*, lib. viii. c. 46. We quote the Latin translation of Janus Cornarius, in the *Medicæ Artis Principes.*

Aëtius says, *Νυκταλωπα δε λεγουσιν ὁταν συμβη την μεν ἡμεραν βλεπειν, δυνοντος δε του ἡλιου, αμαυρωτερον ὁραν· ειτα νυκτος γενομενης, μηδολως βλεπειν.* They call him nyctalops who sees (distinctly) in the day, but when the sun sets more obscurely, and when night comes can discern nothing at all. — *Tetrabibl.* ii. serm. 3. c. 46. Edit. Ald.

Paul of Ægina says, Νυκταλωπα λεγουσιν, ὁταν συμβη την μεν ἡμεραν βλεπειν· δυομενου τε ἡλιου αμαυροτερον ὁρᾶν· νυκτος δε γενομενης ονδαμως ὁρᾶν. They call a person nyctalops when he can see (clearly) in the day-time, more obscurely at sunset, and when the night comes not at all. — Lib. iii. c. 27. Edit. Ald. p. 35.

The meaning of the term *Hemeralopia* can only be settled as the opposite to that of *Nyctolopia*, since the former term, though used by the author of the *Isagoge*, is not defined by him or any other Greek writer. See *Hemeralopia*. Such being the confusion which arises from the use of these terms, it is evident that they ought both to be discarded, and new ones framed.

NY'CTALOPS. (*ops, opis.* c. g.; from νυξ, the night, and ωψ, the eye.) One who sees only in the night: also the disease more commonly called *nyctalopia*.

NYCTO'BASIS. (*is, is.* f.; from νυξ, the night, and βαινω, to go.) Walking in the sleep.

NY'MPHA. (*a, æ.* f.; from νυμφα, a water-nymph: so called because it stands in the water-course.) A membranous and fleshy fold, situated just within the external labia of the female parts of generation, one on each side. They have been also denominated, *Alæ internæ minores clitoridis, Colliculi, Collicula, Myrtocheilides*, and *Labia minora*.

NYMPHÆ'A. (*a, æ.* f.; from νυμφα, a water-nymph: because it grows in watery places.) The name of a genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Monogynia*. The water-lily.

Nymphæa alba. The systematic name of the white water-lily: also named, *Leuco-nymphæa, Nenuphar*, and *Micro-leuconymphæa*. This beautiful plant was formerly employed medicinally, as a demulcent and slightly anodyne remedy. It is now laid aside.

Nymphæa glandifera. See *Nymphæa nelumbo*.

Nymphæa lotus. The Egyptian lotus. An aquatic plant, a native of Egypt and both Indies. The root is conical, firm, about the size of a middling pear, covered with a blackish bark, and set round with fibres. It has a sweetish taste, and, when boiled or roasted, becomes as yellow within as the yolk of an egg. The plant grows in abundance on the banks of the Nile, and is there much sought after by the poor, who, in a short time, collect enough to supply their families with food for several days.

Nymphæa lutea. The systematic name of the yellow water-lily. *Nymphæa major lutea*, of Caspar Bauhin. This beautiful plant was employed formerly with the same intentions as the white water-lily, and, like it, is now fallen into disuse. Lindestolpe informs us that, in some parts of Sweden, the roots, which are the strongest part, were, in times of scarcity, used as food, and did not prove unwholesome.

Nymphæa nelumbo. The pontic, or Ægyptian bean. The *Faba ægyptica, Bentamara, Bemtamara, Cyamus ægyptiacus, Nymphæa indica*, and *Nymphæa glandifera*, of old writers. This plant grows on marshy grounds in Egypt, and some of the neighbouring countries. The fruit is eaten either raw or boiled, and is a tonic and astringent.

Nymphoi'des. (From νυμφαια, the water-lily, and ειδος, likeness.) Resembling the water-lily; thus *Menyanthes nymphoides*.

NYMPHOMA'NIA. (*a, æ.* f.; from νυμφα, nympha, which is the seat of the irritation, and μανια, madness.) Excessive and violent desire for coition in women; called also, *Furor uterinus, Acrai, Brachuna, Arascon, Arsatum, Œstromania*. This affection acknowledges the same causes as satyriasis; but as females, especially in warm climates, have a more irritable fibre, they are apt to suffer more severely than the males.

It is a species of temporary madness, or an high degree of hysterics. The effects, as described by Juvenal, in his sixth satire, are most humiliating to human nature. Its immediate cause is a preternatural irritability of the uterus and nymphæ and clitoris of women, or an unusual acrimony of the fluids in these parts. Its presence is known by the wanton behaviour of the female; she speaks and acts with unrestrained obscenity, and, as the disorder increases, she scolds, cries, and laughs by turns. While reason is retained, she is silent, and seems melancholy, but her eyes discover an unusual wantonness. The symptoms are better or worse, until the greatest degree of the disorder approaches, and then, by every word and action, her condition is too manifest. The strong and sanguineous require bleeding and cooling purgatives, with an abstemious diet, to remove this disease; and the nervous and irritable, sedatives, tonics, and a more generous diet. Marriage, or sexual intercourse, is the most natural remedy.

Nympho'tomy. (*Nymphotomia, æ.* f.; from νυμφα, the nympha, and τεμνω, to cut.) The operation of removing the nympha, when too large or diseased.

NYSTA'GMUS. (*us, i.* m.; from νυσταω, to nod sleepily.) An involuntary movement of the eyes, such as happens when a person is very sleepy. Authors also define nystagmus to be an involuntary agitation of the ocular bulb. It is known by the instability or involuntary and constant motions of the globe of the eye, from one canthus to another, or in some other directions. Sometimes it is accompanied with a hippus, or an alternate and repeated dilatation and constriction of the pupil.

O.

O. A contraction used in medical formulæ for *octarium*, a pint.

Oak. See *Quercus.*

Oak, Jerusalem. See *Chenopodium botrys.*

Oak, sea. See *Fucus vesiculosus.*

Oak, willow-leaved. See *Quercus phellos.*

Oak leather. See *Xylostroma giganteum.*

Oak lungs. See *Lichen pulmonarius.*

Oat. See *Avena.* and *Triticum.*

OBCORDA'TUS. Obcordate, or inversely heart-shaped; that is, with the point of the heart next to the stem: applied to leaves, seed-vessels, &c.; as the pericarp of the *Thlaspi bursa pastoris*, and leaves of some of the trefoils.

OBELÆ'A. (Οβελαια; from οβελος, a dart.) An epithet of the sagittal suture of the skull.

OBELI'SCOTHE'CA. (From οβελισκος, an obelisk, and θηκα, a bag: so called from the shape of its seed-bags.) The dwarf sun-flower. See *Cystus helianthemum.*

OBE'SITY. (*Obesitas, atis*, f.; from *obesus*, fat.) See *Polysarcia.*

OBLI'QUUS. Oblique. 1. In *Anatomy*, a term applied to parts from their direction.

2. In *Botany*, it means the same as *radix obliquus*, but sometimes it means twisted. *Folium obliquum*, for example, is a leaf, one part of which is vertical, the other horizontal; as in *Fritillaria obliqua.*

Obliquus ascendens abdominis. See *Obliquus internus abdominis.*

Obliquus ascendens internus. See *Obliquus internus abdominis.*

Obliquus auris. See *Laxator tympani.*

Obliquus descendens externus. See *Obliquus externus abdominis.*

Obliquus externus. See *Obliquus externus abdominis.*

OBLIQUUS EXTERNUS ABDOMINIS. A muscle of the abdomen, so named by Morgagni, Albinus, and Winslow. It is the *Obliquus descendens* of Vesalius and Douglas, and the *Obliquus major* of Haller, and some others. It is a broad, thin muscle, fleshy posteriorly, and tendinous in the middle and lower part, and is situated immediately under the integuments, covering all the other muscles of the lower belly. It arises from the lower edges of the eight, and sometimes, though rarely, of the nine inferior ribs, not far from their cartilages, by as many distinct fleshy portions, which indigitate with corresponding parts of the serratus major anticus, and the latissimus dorsi. From these several origins, the fibres of the muscle descend obliquely forwards, and soon degenerate into a broad and thin aponeurosis, which terminates in the linea alba. About an inch and a half above the pubes, the fibres of this aponeurosis separate from each other, so as to form an aperture, which extends obliquely inwards and forwards, and more than an inch in length, and is wider above than below, being nearly of an oval figure. This is what is sometimes, though erroneously, called the *ring* of the abdominal muscles, *annulus abdominis*, for it belongs only to the external oblique, there being no such opening either in the obliquus internus, or in the transversalis, as some writers, and particularly Douglas and Cheselden, would give us to understand. This opening, or ring, serves for the passage of the spermatic vessels in men, and of the round ligament of the uterus in women, and is of a larger size in the former than in the latter. The two tendinous portions, which, by their separation, form this aperture, are called the *columns* of the ring. The anterior, superior, and inner column, which is the broadest and thickest of the two, passes over the symphysis pubis, and is fixed to the opposite os pubis; so that the anterior column of the right obliquus externus intersects that of the left, and is, as it were, interwoven with it, by which means their insertion is strengthened, and their attachment made firmer. The posterior, inferior, and exterior column approaches the anterior one as it descends, and is fixed behind and below it to the os pubis of the same side. The fibres of that part of the obliquus externus which arises from the two inferior ribs, descend almost perpendicularly, and are inserted, tendinous and fleshy, into the outer edge of the anterior half of the spine of the ilium. From the anterior superior spinous process of that bone, the external oblique is stretched tendinous to the os pubis, forming what is called *Poupart*'s, and sometimes *Fallopius*'s ligament, Fallopius having first described it. Winslow, and many others, name it the *inguinal* ligament. But, after all, it has no claim to this name, it being nothing more than the tendon of the muscle, which is turned or folded inwards at its interior edge. It passes over the blood-vessels of the lower extremity, and is thickest near the pelvis; and in women, from the greater size of the pelvis, it is longer and looser than in men. Hence we find that women are most liable to crural herniæ: whereas men, from the greater size of the ring of the external oblique, are most subject to the inguinal. From this ligament, and from that part of the tendon which forms the ring, we observe a detachment of tendinous fibres, which are lost in the *fascia lata* of the thigh. This may, in some measure, account for the pain which, in cases of strangulated herniæ, is felt when the patient stands upright, and which is constantly relieved upon bending the thigh upwards. This muscle serves to draw down the ribs in expiration; to bend the trunk forwards when both muscles act,

or to bend it obliquely in one side, and, perhaps, to turn it slightly upon its axis, when either acts singly; it also raises the pelvis obliquely when the ribs are fixed; it supports and compresses the abdominal viscera, assists in the evacuation of the urine and fæces, and is likewise useful in parturition.

Obliquus inferior. See *Obliquus inferior capitis,* and *Obliquus inferior oculi.*

Obliquus inferior capitis. This muscle of the head, the *obliquus inferior sive major,* of Winslow, is larger than the obliquus superior capitis. It is very obliquely situated between the two first vertebræ of the neck. It arises tendinous and fleshy from the middle and outer side of the spinous process of the second vertebra of the neck, and is inserted tendinous and fleshy into the lower and posterior part of the transverse process of the first vertebra. Its use is to turn the first vertebra upon the second, as upon a pivot, and to draw the face towards the shoulder.

Obliquus inferior oculi. *Obliquus minor oculi,* of Winslow. An oblique muscle of the eye, that draws the globe of the eye forwards, inwards, and downwards. It arises by a narrow beginning from the outer edge of the orbitar process of the superior maxillary bone, near its junction with the lachrymal bone, and, running obliquely outwards, is inserted into the sclerotic membrane of the eye.

Obliquus inferior sive major. See *Obliquus inferior capitis.*

Obliquus internus. See *Obliquus internus abdominis.*

Obliquus internus abdominis. *Musculus acclivis.* A muscle of the abdomen. The *obliquus ascendens,* of Vesalius, Douglas, and Cowper; the *obliquus minor,* of Haller; the *obliquus internus,* of Winslow; the *obliquus ascendens internus,* of Innes. It is situated immediately under the external oblique, and is broad and thin like that muscle, but somewhat less considerable in its extent. It arises from the spinous processes of the three inferior lumbar vertebræ, and from the posterior and middle part of the os sacrum, by a thin tendinous expansion, which is common to it, and to the serratus posticus inferior; by short tendinous fibres, from the whole spine of the ilium, between its posterior tuberosity and its anterior and superior spinous process; and from two thirds of the posterior surface of what is called Fallopius's ligament, at the middle of which we find the round ligament of the uterus in women, and the spermatic vessels in men, passing under the thin edge of this muscle; and in the latter, it likewise sends off some fibres, which descend upon the spermatic chord, as far as the tunica vaginalis of the testis, and constitute what is called the *cremaster* muscle, which surrounds, suspends, and compresses the testicle. From these origins, the fibres of the internal oblique run in different directions: those of the posterior portion ascend obliquely forwards; the middle ones become less and less oblique, and at length run in an horizontal direction; and those of the anterior portion extend obliquely downwards. The first of these are inserted, by very short tendinous fibres, into the cartilages of the fifth, fourth, and third of the false ribs; the fibres of the second, or middle portion, form a broad tendon, which, after being inserted into the lower edge of the cartilage of the second false rib, extends towards the linea alba, and separates into two layers: the anterior layer, which is the thickest of the two, joins the tendon of the obliquus externus, and runs over the two upper thirds of the rectus muscle, to be inserted into the linea alba; the posterior layer runs under the rectus, adheres to the anterior surface of the tendon of the transversalis, and is inserted into the cartilages of the first of the false, and the last of the true ribs, and likewise into the linea alba. By this structure we may perceive that the greater part of the rectus is enclosed, as it were, in a sheath. The fibres of the anterior portion of the internal oblique, or those which arise from the spine of the ilium and the ligamentum Fallopii, likewise form a broad tendon, which, instead of separating into two layers, like that of the other part of the muscle, runs over the lower part of the rectus, and adhering to the under surface of the tendon of the external oblique, is inserted into the fore part of the pubes. This muscle serves to assist the obliquus externus; but it seems to be more evidently calculated than that muscle is to draw the ribs downwards and backwards. It likewise serves to separate the false ribs from the true ribs, and from each other.

Obliquus major abdominis. See *Obliquus externus abdominis.*

Obliquus major capitis. See *Obliquus inferior capitis.*

Obliquus major oculi. See *Obliquus superior oculi.*

Obliquus minor abdominis. See *Obliquus internus abdominis.*

Obliquus minor capitis. See *Obliquus superior capitis.*

Obliquus minor oculi. See *Obliquus inferior oculi.*

Obliquus superior capitis. Riolanus, who was the first that gave particular names to the oblique muscles of the head, called this muscle *obliquus minor,* to distinguish it from the inferior, which, on account of its being much larger, he named *obliquus major.* Spigelius afterwards distinguished the two, from their situation with respect to each other, into *superior* and *inferior;* and in this he is followed by Cowper and Douglas. Winslow retains both names. This little muscle, which is nearly of the same shape as the *recti capitis,* is situated laterally between the occiput and the first vertebra of the neck, and is covered by the complexus and the upper part of the splenius. It arises, by a short thick tendon, from the upper and posterior part of the transverse process of the first vertebra of the neck, and ascending obliquely inwards and backwards, becomes broader, and is inserted, by a broad flat tendon, and some few fleshy fibres, into the occipitis, behind the back part of the mastoid process, under the insertion of the complexus and splenius, and a little above that of the rectus major. The use of this muscle is to draw the head backwards, and perhaps to assist in its rotatory motion.

Obliquus superior oculi. *Trochlearis. Longissimus oculi. Obliquus major*, of Winslow. An oblique muscle of the eye, that rolls the globe of the eye, and turns the pupil downwards and outwards. It arises, like the straight muscles of the eye, from the edge of the foramen opticum at the bottom of the orbit, between the rectus superior and rectus internus; from thence runs straight along the papyraceous portion of the ethmoid bone to the upper part of the orbit, where a cartilaginous trochlea is fixed to the inside of the internal angular process of the os frontis, through which its tendon passes, and runs a little downwards and outwards, enclosed in a loose membranaceous sheath, to be inserted into the sclerotic membrane.

Obliquus superior sive minor. See *Obliquus superior capitis.*

Obliquus superior sive trochlearis. See *Obliquus superior oculi.*

OBLITERA'TION. In medical language, the disappearance of any part of the animal body that has become useless: thus the *ductus venosus* is obliterated after birth.

OBLO'NGUS. Oblong. A term used very generally. In *Botany*, it is applied to leaves, petals, seeds, &c., which are three or four times longer than broad. The term is used with great latitude, and serves chiefly in a specific character to contrast a leaf which has a variable, or not very decided, form, with others that are precisely round, ovate, linear, &c.

The *petals* of the genus Citrus and Hedera, and those of the Narcissus moschatus, are *oblong*, and the *seeds* of the Boerhaavia diffusa.

OBOVA'TUS. Obovate. Used to designate shape, and applied to leaves, &c. which are ovate, with a broader end uppermost; as those of the primrose and daisy. Linnæus first used the words *obsersi ovatum.*

Obsidia'num. 1. The name of a mineral — *obsidian.*

2. Libavius gives this name to glass of antimony.

OBSOLETE. *Obsoletus.* In the language of *Botany* it is applied to parts of plants which are by nature imperfectly developed, or of which only a *vestigium* remains.

OBSTE'TRIC. (*Obstetricus*; from *obstetrix*, a midwife.) Belonging to midwifery.

OBSTE'TRICS. Midwifery. The art of assisting women in childbirth, and treating their diseases during pregnancy and after delivery.

Obstipa'tion. (*Obstipatio, onis.* f.; from *obstipo*, to stop up.) See *Costiveness.*

OBSTRUENS. (From *obstruo*, to shut up.) Closing the orifices of the ducts, or vessels. Medicines supposed to have this power have been called *obstruentia.*

Obtundens. (From *obtundo*, to make blunt.) Having the property of obviating or blunting irritation; as bland, oily, or mucilaginous matters, which form a covering on inflamed and irritable surfaces, particularly those of the stomach, lungs, and anus.

OBTURA'TOR. (*or, oris.* m.; from *obturo*, to shut up.) A stopper up, or that which covers any thing.

Obturator externus. A small flat muscle, situated obliquely at the upper and anterior part of the thigh, between the pectinalis and the fore part of the foramen thyroideum, and covered by the abductor brevis femoris. It arises tendinous and fleshy from all the inner half of the circumference of the foramen thyroideum, and likewise from part of the obturator ligament. Its radiated fibres collect and form a strong roundish tendon, which runs outwards; and, after adhering to the capsular ligament of the joint, is inserted into a cavity at the inner and back part of the root of the great trochanter. The chief uses of this muscle are to turn the thigh obliquely outwards, to assist in bending the thigh, and in drawing it inwards. It likewise prevents the capsular ligament from being pinched in the motions of the joint.

Obturator internus. *Marsupialis, seu obturator internus*, of Douglas. *Marsupialis, seu bursalis*, of Cowper; and *Intrapelvio-trochanterien*, of Dumas. A considerable muscle, a great part of which is situated within the pelvis. It arises, by very short tendinous fibres, from somewhat more than the upper half of the internal circumference of the foramen thyroideum of the os innominatum. It is composed of several distinct fasciculi, which terminate in a roundish tendon that passes out of the pelvis, through the niche that is between the spine and the tuberosity of the ischium; and after running between the two portions of the gemini, which enclose it as in a sheath, is inserted into the cavity at the root of the great trochanter, after adhering to the adjacent part of the capsular ligament of the joint. This muscle rolls the os femoris obliquely outwards, by pulling it towards the ischiatic niche, upon the cartilaginous surface of which its tendon, which is surrounded by a membranous sheath, moves as upon a pulley.

Obturator nerve. A nerve of the thigh, that is lost upon the muscles situated on the inside of the thigh.

OBTUSE. *Obtusus.* Blunt; not pointed. In general use in every department of science.

OBTU'SUS. Blunt: applied to a leaf which terminates in a segment of a circle; as that of the *Linum catharticum*, the petals of the *Tropæolum majus.* This form of leaf has sometimes a small point, *obtusum cum acumine*, in the *Statyce limonium.*

OCCI'PITAL. *Occipitalis.* Belonging to the occiput or back part of the head.

Occipital bone. *Os occipitis. Os memoriæ. Os nervosum. Os basilare.* This bone, which forms the posterior and inferior part of the skull, is of an irregular figure, convex on the outside, and concave internally. Its external surface, which is very irregular, serves for the attachment of several muscles. It affords several inequalities, which sometimes form two semicircular hollows separated by a scabrous ridge. The inferior portion of the bone is stretched forwards in form of a wedge, and hence is called the *cuneiform* process, or basilary process. At the base of this process, situated obliquely on each side of the foramen magnum, are two flat, oblong protuberances, named *condyles.* They are covered with cartilage, and serve for the

articulation of the head with the first vertebra of the neck. In the inferior portion of this bone, at the basis of the cranium, and immediately behind the cuneiform process, we observe a considerable hole, through which the medulla oblongata passes into the spine. The nervi accessorii, the vertebral arteries, and sometimes the vertebral veins likewise, pass through it. Man being designed for an erect posture, this foramen magnum is found nearly in the middle of the basis of the human cranium, and at a pretty equal distance from the posterior part of the occiput, and the anterior part of the lower jaw; whereas in quadrupeds it is nearer the back part of the occiput. Besides this hole, there are four other smaller foramina, viz. two before, and two behind the condyles. The former serve for the transmission of the ninth pair of nerves, and the two latter for the veins which pass from the external parts of the head to the lateral sinuses. On looking over the internal surface of the os occipitis, we perceive the appearance of a cross, formed by a very prominent ridge, which rises upwards from near the foramen magnum, and by two transverse sinuosities, one on each side of the ridge. This cross occasions the formation of four fossæ, two above and two below the sinuosities. In the latter are placed the lobes of the cerebellum, and in the former the posterior lobes of the brain. The two sinuosities serve to receive the lateral sinuses. In the upper part of this bone is seen a continuation of the sinuosity of the longitudinal sinus; and at the basis of the cranium we observe the inner surface of the cuneiform process made concave, for the reception of the medulla oblongata. The occipital bone is thicker and stronger than any of the other bones of the head, except the petrous part of the ossa temporum; but it is of unequal thickness. At its lateral and inferior parts, where it is thinnest, it is covered by a great number of muscles. The reason for so much thickness and strength in this bone seems to be, that it covers the cerebellum, in which the least wound is of the utmost consequence; and that it is, by its situation, more liable to be fractured by falls than any other bone of the cranium. For if we fall forwards, the hands are naturally put out to prevent the forehead touching the ground; and if on one side, the shoulders, in a great measure, protect the sides of the head; but if a person fall backwards, the hind part of the head consequently strikes against the earth, and that, too, with considerable violence. Nature, therefore, has wisely constructed this bone so as to be endowed with the greatest strength at its upper part, where it is the most exposed to injury. The os occipitis is joined, by means of the cuneiform process, to the sphenoid bone, with which it often ossifies, and makes but one bone in those who are advanced in life. It is connected to the parietal bones by the lamboidal suture, and to the temporal bones by the additamentum of the temporal suture. The head is likewise united to the trunk by means of this bone. The two condyles of the occipital bone are received into the superior oblique processes of the atlas, or first vertebra of the neck, and it is by means of this articulation that a certain degree of motion of the head backwards and forwards is performed. But it allows only very little motion to either side; and still less of a circular motion, which the head obtains principally by the circumvolution of the atlas on the second vertebra, as is described more particularly in the account of the vertebræ. In the fœtus, the os occipitis is divided by an unossified cartilaginous substance into four parts. One of these, which is the largest, constitutes all that portion of the bone which is above the foramen magnum; two others, which are much smaller, compose the inside of the foramen magnum, and include the condyloid processes; and the fourth is the cuneiform process. This last is sometimes not completely united with the rest, so as to form one bone, before the sixth or seventh year.

Occi'pito-fronta'lis. *Digastricus cranii. Epicranius,* of Albinus. *Frontalis et occipitalis,* of Winslow and Cowper. A single, broad, digastric muscle, that covers the cranium, pulls the skin of the head backwards, raises the eyebrows upwards, and at the same time draws up and wrinkles the skin of the forehead. It arises from the posterior part of the occiput, goes over the upper part of the os parietale and os frontis, and is lost in the eyebrows.

O'CCIPUT. (*ut, itis.* n.) The hinder part of the head.

OCCLU'SUS. Occluse: shut up. Applied to the florets of the fig, which are shut up in the fleshy receptacle that forms the fruit.

OCCU'LT. *Occultus.* Hidden. A term formerly applied to things, concerning which, authors wrote without understanding their own meaning: thus magic and alchemy were *occult sciences;* phenomena which could not be explained were referred to *occult causes;* and when the doctors met with a disease that they could make nothing of, they called it an *occult disease.*

Ochetheu'ma. (Οχετευμα; from οχετος, a duct.) The opening of the nostril.

O'chetus. (From οχεω, to convey.) A canal or duct: applied formerly to the urinary or intestinal canal.

O'cheus. (Οχεος; from οχεω, to carry.) The scrotum.

O'CHRA. (*a, æ.* f.; from ωχρος, pale: so named because it is often of a pale colour.) 1. Ochre. An argillaceous earth, impregnated with iron, of a red or yellow colour. The Armenian bole, and other earths, are often adulterated with ochre.

2. The fore-part of the tibia.

OCHRA'CEUS. Ochrelike: applied to designate a yellowish colour striped with brown. See *Colour.*

Ochtho'des. Οχθωδες. An epithet for ulcers which have callous and tumid edges, and are consequently difficult to heal.

Ocima'strum. (Diminutive of *ocimum,* basil.) A species of basil.

O'CIMUM. (*um, i.* n.; from ωκυς, swift: so called from its quick growth.) *Ocymum.* The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Gymnospermia.*

Ocimum basi'licum. The systematic name

of the common or citron basil. *Basilicum. Herba regia. Ocimum—foliis ovatis glabris; calycibus ciliatis,* of Linnæus. This plant is supposed to possess nervine qualities, but is seldom employed but as a condiment to season high dishes, to which it imparts a grateful odour and taste.

Ocimum caryophylla'tum. *Ocimum minimum* of Caspar Bauhin. Small or bush basil. This plant is mildly balsamic. Infusions are drunk as tea, in catarrhal and uterine disorders, and the dried leaves are made into cephalic and sternutatory powders. They are, when fresh, very juicy, of a weak aromatic and very mucilaginous taste, and of a strong and agreeable smell, improved by drying.

Ocob. Sal ammoniac. — *Ruland.*

OCO'TEA. A genus of plants of the laurel tribe.

Ocotea puchu'ry. This plant as well as the *Laurus pichurim,* is said to yield the pichurim bean.

Ocotea cy'mbarum. This affords the Orinoco sassafras.

O'CREA. A term applied by Rotball to the membrane that enfolds the flower-stalks in *Cyperus,* and which Sir J. Smith thinks is a species of bractea.

OCTA'NUS. (From *octo,* eight.) The eighth: applied to an erratic intermitting fever, which returns every eighth day.

OCTA'NDRIA. (*a. æ.* f.; from οκτω, eight, and ανηρ, a husband.) The name of a class of plants in the sexual system of Linnæus, consisting of those which have hermaphrodite flowers, furnished with eight stamina.

Octavus humeri. See *Teres minor.*

Octavus humeri Placentini. See *Teres minor.*

Ocula'ria. (*a, æ.* f.; from *oculus,* the eye: so called from its uses in disorders of the eye.) See *Euphrasia officinalis.*

Ocula'ris communis. A name for the nerve called *Motor oculi.*

O'CULUS. (*us, i.* m.; from οκκος, *i. e.* οφθαλμος, the eye.) The eye. The globular organ which occupies the cavity of the orbit and constitutes the apparatus of vision. There are certain parts called appendages of the eye: these are the *eyelids,* see *Tarsi;* the *lachrymal apparatus,* the *plica semilunaris,* the *caruncula lachrymalis,* see these titles; the *blood-vessels and nerves of the eye,* see *Ophthalmic Artery, Optic Nerve,* &c.; lastly, the muscles of the eye, which are six in number. See *Rectus* and *Obliquus.*

The globe of the eye is situated at the internal and anterior part of the orbital fossa, which lodges it and its appendages: its form is that of a spheroid, slightly compressed at the four opposite points of its circumference, which correspond with the insertion of the recti muscles. The direction of the axis of the globe of the eye does not correspond with that of the orbit; the axes of the eye are parallel with one another, whilst those of the orbits diverge considerably in front, and if prolonged backwards would decussate behind the body of the sphenoid bone; hence, as the optic nerves coincide in their direction with that of the axes of the orbits, each of them enters the globe of the corresponding eye to the inner side of its axis, and consequently of the axis of vision. When viewed in profile, the globe appears to be composed of segments of two spheres, of which the anterior is smaller and more prominent; hence, when its different diameters are compared, it will be found that the antero-posterior exceeds the others by about a line. Anteriorly, the globe of the eye is in relation with the conjunctiva, which is reflected from the eyelids upon it; posteriorly, with the vessels and nerves (optic and ciliary) which enter it, and with a quantity of adipose substance in which it is in some measure embedded; round its circumference, with the six muscles inserted into it; superiorly, and towards its outer side, with the lachrymal gland; and internally, with the caruncula, tensor tarsi, and lachrymal sac.

The globe, or, as it is often called, the ball of the eye, is composed of membranes placed one within the other, and of humours or fluids which they inclose; the former are not unfrequently called coats, or tunics; but as none of them forms a complete investment, the term is not so applicable as that here adopted. The membranes are the conjunctiva, sclerotica, cornea, choroid, retina, and iris, the capsule of the crystalline lens, the hyaloid membrane, and that of the aqueous humour. The humours are the aqueous, vitreous, and the crystalline lens.

The Conjunctiva. — The conjunctiva (*membrana conjunctiva, sive adnata*) is included by some writers amongst the accessory structures of the globe of the eye, and not amongst its proper membranes; as if it were a tegument or means of connexion with adjacent structures, and did not form part of the organ itself, considered as an optical instrument. Be this as it may, the membrane lines the free border and inner surface of the eye-lids, from which it is reflected upon the globe of the eye, so as to cover its anterior third. Along the borders of the lids it is continuous with the skin, and by lining the *puncta lachrymalia,* forms a continuous surface with the mucous membrane of the lachrymal passages and nasal fossæ. It is red and vascular on the lids, but firm and pale on the sclerotica: it becomes thin and transparent on the cornea, so much so that some anatomists have doubted whether it extends over the entire of its surface. At present very few persons continue sceptical on this point; for even *à priori* we should infer its extension over the cornea, as every structure of the kind is known to require the protection of a tegumentary membrane. Moreover, in reptiles which cast their epidermis at stated times, the covering of the cornea comes away together with the rest; and finally, in the mus typhlus it is covered with hairs.

The Sclerotica.—The sclerotic (σκληρος, hard; *cornea opaca*) belongs to the class of fibrous membranes; it is firm and resistent in its texture, and forms about four-fifths of the external investment of the eye, extending from the entrance of the optic nerve to the border of the cornea. Its external surface is convex, and in relation with the conjunctiva, with the tendinous expansions of the muscles, and the vessels and

nerves of the orbit: the internal surface is concave and in apposition with the choroid membrane, with which it is connected by vascular and nervous filaments, and by some delicate cellular tissue. Posteriorly it is pierced by a small circular aperture for the transmission of the optic nerve, situated a little to the inner side of the axis of the globe: anteriorly it is truncated, so as to leave an aperture about six lines in diameter, but somewhat greater in the transverse than in the vertical direction. The inner edge of this aperture is slightly bevelled off, so as to allow the cornea to be inserted into it, somewhat as a watch-glass is into its case. The sclerotica being a fibrous membrane, its fibres interlace intimately, but do not assume any assignable direction. It is thicker posteriorly than towards its anterior part; but in this latter situation it is strengthened by the tendinous expansions of the muscles, which some anatomists have considered as a distinct membrane, and denominated *tunica albuginea*. At the back part of the globe it is about a line in thickness; at the insertion of the recti muscles it is scarcely half a line; but near the cornea it thickens somewhat. The aperture for the optic nerve is a little nearer to the nasal than to the temporal side of the globe, and is found to be divided by a number of septa, so as to constitute a *cribriform plate*, through which the pulp of the nerve may be made to ooze as if through minute pores. In the middle will be found one of these of larger size than the rest, which is named *porus opticus*. It gives passage to the arteria centralis retinæ. At its exit from the skull, the nerve receives an investment from the dura mater, which accompanies it to the point at which it pierces the sclerotica, where it separates from the nerve, and becomes blended with the substance of the latter membrane.

The Cornea. — The cornea (*cornea pellucida*) occupies the anterior fifth of the globe of the eye, its transverse diameter being about seven lines, the vertical a little less. The anterior surface, which is convex and prominent, is in contact with the conjunctiva; the posterior is concave, and is lined by the membrane of the aqueous humour: its circumference, nearly circular in the human subject, is received within the anterior border of the sclerotica, with which it is so intimately united as not to be separable from it without long-continued maceration. Its degree of convexity varies in different individuals, and at different periods of life. It is composed of five or six concentric lamellæ, united by some connecting medium, probably a fine cellular tissue, the interstices of which contain an aqueous or serous fluid. It is thicker than the sclerotica, which may be readily seen by making a section of both; but it is by no means so dense; its layers will be found to slide almost upon one another when it is pressed between the fingers. The lamellated structure of the cornea is beautifully adapted to the functions of the eye. Were it fibrous, like the sclerotica, even though at the same time translucent, it would cause a dispersion of the rays of light, and thereby resolve them into their primitive or prismatic rays, which would necessarily produce a coloured and confused image. The effect may be readily exemplified by looking at a lighted taper through a feather: the flame will instantly appear surrounded by a halo of coloured images; and were the cornea made up of fibres woven ever so finely, the effect would be similar.

Ciliary Ligament. — The ciliary ligament (*orbiculus ciliaris*, Haller) is a ring of light grey matter, about a line and a half in breadth, which is attached to the inner surface of the sclerotica, just at its junction with the cornea. Externally, it is united, though slightly, with the sclerotica; posteriorly, with the choroid membrane; and anteriorly, with the iris, which may be said to be inserted into its substance. It adheres more firmly to the choroid than to the other textures: for though it is separated by a slight effort from the latter, it remains securely attached to the former. The ciliary arteries pass through it, and distribute some twigs to it, as do the ciliary nerves in their course to the iris. Its external surface or circumference presents a slight groove which runs around it, so that when in apposition with the sclerotica a minute canal is inclosed between them. Fontana appears to have been the first who noticed this circumstance. Some anatomists have considered the ciliary ligament as a ganglion in which the ciliary nerves terminate, and from which branches proceed to the iris; but no instance can be adduced in which a nervous ganglion forms the medium of union and connexion between parts in the same way that this structure does, as we find it attached to the sclerotica, and giving attachment to the iris, choroid membrane, and ciliary processes.

The Choroid. — The choroid membrane (*tunica vasculosa, choroidea*) lies between the sclerotica and the retina, extending from the entrance of the optic nerve as far as the ciliary ligament. In the greater part of its extent it is connected, though loosely, to the sclerotica by cellular tissue, and by the vessels which pass from without to reach it; but anteriorly, the union is established through the medium of the ciliary ligament. The inner surface is in apposition with the retina, or rather with Jacob's membrane. Posteriorly, the choroid presents a foramen, with a well-defined margin, for the transmission of the optic nerve: its anterior termination requires a particular description, as some difference of opinion has existed with regard to it. The membrane consists of two lamellæ, which, though separable at the posterior, are united at the anterior part, where it becomes connected with the ciliary ligament; there it drops inwards towards the axis of the eye, and is drawn into a number of delicate folds, the aggregate of which forms a complete circle, resting, like a collar, round the border of the crystalline lens, and the anterior surface of the vitreous humour. In this manner are formed the ciliary processes, the aggregate of which has been variously named by different anatomists (*corpus ciliare, corona ciliaris*).

The choroid membrane is essentially vascular in its structure, being composed of minute arteries and veins, united by cellular tissue. When the sclerotica is removed so as fully to

expose the choroid membrane, we find lying upon its surface, if the dissection has been carefully executed, the ciliary nerves compressed and flat: their destination is the ciliary ligament and iris. Two long arteries will also be found (long ciliary arteries) passing horizontally forwards, maintaining little, if any, connexion with the choroid; for, after having pierced the sclerotica, they lie between the latter and the choroid, without giving branches to either; and when they reach the ciliary ligament, they turn inwards and divide into branches, which are exclusively distributed to the iris. These vessels are situated at opposite sides of the globe, nearly on a line with its axis; the external one, however, is a little above, the internal a little below it. But there is a set of vessels which are intimately connected with this membrane, being distributed to it exclusively, viz. the *short ciliary arteries*, which pierce the sclerotica nearer to the optic nerve than the long ones, and soon divide into branches; these run at first parallel with one another, and mutually send twigs of communication, so that they all freely anastomose, particularly towards the anterior part of the choroid, where they form a circle, consisting of a most minute interlacement of vessels. The veins are readily distinguishable from the arteries by their greater size, as well as by their peculiar arrangement. They extend from before backwards in a radiated form, describing arches as they converge to the posterior part of the eye, and form by this union three or four small vessels, which pierce the sclerotica, and open into some of the secondary branches of the ophthalmic vein. As the veins of the choroid membrane are disposed in whirls, they are usually denominated *vasa vorticosa;* they occupy for the most part the external, and the arteries the internal surface of the membrane. On this distribution of the vessels is founded the division of the choroid into two lamellæ, of which the internal is denominated *tunica Ruyschiana*, in compliment to Ruysch, who was the first that succeeded in demonstrating its structure by injection. The inner surface of the membrane, from its villous or fleecy appearance, has been called tapetum; when minutely injected, it is of a deep scarlet colour. It appears to secrete the colouring matter (*pigmentum nigrum*), which is a viscid and apparently mucous secretion, deposited upon the anterior surface of the membrane. Its quantity varies in different parts, being more abundant anteriorly and in the interstices of the ciliary processes.

Ciliary processes. — The ciliary processes formed, as has been above stated, of the anterior margin of the choroid, are from sixty to eighty in number. The form of each lamella, or process, is triangular; one side looks forward to the iris, the other backward to the crystalline lens and vitreous humour, with which it is in contact; the third or internal one, the shortest, is free. The processes are alternately long and short, and in their arrangement resemble the plicæ observable on the under surface of a mushroom. The intervals between the processes are filled by a pigment similar to the pigmentum nigrum in every particular, which leaves on the surface of the lens and of the vitreous humour a number of dark striated lines, corresponding not with the processes, but with the intervals between them. When removing the ciliary processes, it will be observed that they are not merely in contact with the anterior part of the hyaloid membrane; minute plicæ of the latter project into the interstices between the processes, and seem to be connected with them. The name ciliary body (corpus ciliare) is usually given to the aggregate of the ciliary process.

Retina. — The retina (*tunica nervea*) is placed between the choroid membrane and the vitreous humour, with which it is merely in apposition. It extends from the bottom of the eye, where it is continuous with the optic nerve, forwards as far as the commencement of the ciliary processes, where it appears to terminate by a defined and rather prominent line. Its structure is soft and pulpy; in the living subject it is transparent, and so continues for some hours after death, but then becomes of a pale white colour. When the ophthalmic artery has been minutely injected, the membrane can be shown to consist of two lamellæ, of which the internal is vascular, and presents several small vessels, which arise from the centralis retinæ artery; the external lamella appears to consist of white nervous matter. If the eye be macerated for some days in water, the latter part of the retina can be washed away, leaving the vascular lamella in its natural position. About two lines outside the entrance of the optic nerve may be observed in the retina a small hole and a yellow spot, first described by Sœmmering, and named by him, the one *foramen centrale*, the other *limbus luteus*. The yellow spot appears to coincide with the axis of vision; the appearance which has been called a foramen is owing to a transparent point in the retina, and not to a perforation of its substance; the outer or medullary layer is merely deficient.

Exclusively of the two layers here noticed, the retina is found to be covered on its external surface by a delicate transparent membrane, united to it by cellular substance and vessels. If the sclerotica be removed, and the choroid membrane carefully torn and averted, small portions of the structure here alluded to can be detached, or a globule of air, or even of quicksilver, may be insinuated beneath it, by which means it is raised, and can be seen distinctly if held towards the light." This is now known as *Jacob's membrane*. It cannot be said to be a part of the retina, or to consist of its medullary lamella detached by the process resorted to in the dissection of the organ; for the yellow spot of Sœmmering is not distinctly seen until Jacob's membrane is removed; and when this has been effected we can still show the retina to consist of its two lamellæ.

The Iris. — The iris, which presents the coloured circle seen through the transparent cornea, resembles a partition placed vertically so as to divide, but very unequally, the interval between the cornea and the lens into two parts. This interval is filled by the aqueous humour,

so that the iris moves freely in the fluid. The space between it and the cornea, which is much the larger, is called the *anterior chamber;* that behind it is the *posterior chamber:* both communicate through the pupil. The iris presents two flat surfaces and two circumferences; on the anterior surface, which is differently coloured in different individuals, may be observed two concentric rings, of which the external (annulus major) is broader than the internal, but not so deeply coloured: it is marked by several striated lines, which pass from the great circumference inwards to the pupil, where they seem to bifurcate. The inner ring (annulus minor) is more deeply coloured, and surrounds the pupil. The posterior surface contiguous to the ciliary processes is covered by a dark pigment similar to that of the choroid; it is usually called *uvea*. When this is washed off, a number of fine lines, or fibres, may be observed, with the assistance of a magnifying power, converging from the greater circumference to the pupil: these are distinct from one another in the former situation, but in the latter are blended so as to form a membranous zone.

The great circumference of the iris corresponds with the ciliary ligament, into which it may be said to be inserted; the smaller forms the border of the aperture called the *pupil* (pupilla). The pupillary aperture is closed in the fœtus, up to the seventh month, by a delicate transparent membrane, called, from this circumstance, *membrana pupillaris*. If examined after the vessels of the eye have been injected, it will be found distinct from the iris, and appearing as if inserted into its margin, so as to cut off all communication between the two chambers. It becomes reticulated a little after the time referred to, then a few fragments of it only remain, and finally, it disappears before birth. According to M. Jules Cloquet's account, it is a sort of mediastinum formed by the contiguous sides of two small culs-de-sac, one of which is the membrane of the aqueous humour continued across upon the front of the iris, the other the lining membrane of the posterior chamber, both being in apposition at the pupil.

The iris is abundantly supplied with nerves from the ciliary nerves: it receives the two long ciliary arteries which pass along between the choroid and sclerotica, and the smaller, or anterior ones, which pierce the ciliary ligament from without. These vessels approach the iris from four opposite directions, and at its greater circumference freely anastomose, so as to form the larger vascular circle of the iris. From this circle branches pass inwards, converging, and form at a little distance from the pupil another circle, by a second anastomosis. Finally, from this inner circle minute filaments pass inwards, and seem to terminate at the pupillary margin of the iris. The veins, in general, take the same course as the arteries, but the greater number open into the vasa vorticosa. The ciliary nerves, after having passed through the ciliary ligament, incline inwards upon the anterior surface of the iris, where they divide into fine filaments, which soon elude our research, even with the aid of a microscope.

Aqueous Humour. — The *aqueous* humour is a thin, pellucid fluid, which fills up the two chambers of the eye, occupying the space between the cornea and crystalline lens. Its specific gravity and chemical composition differ little, if at all, from that of the vitreous humour; it is moreover inclosed in a thin transparent membrane, which secretes it in the first instance, and reproduces it when evacuated by accident, or during operations. This membrane, usually called the *capsule* of the aqueous humour, lines the cornea and the anterior surface of the iris, but does not seem to extend into the posterior chamber.

Crystalline Lens. — The crystalline lens is situated at the union of the anterior third with the two posterior thirds of the eye, lying behind the iris, surrounded by the ciliary processes, and embedded in the vitreous humour; it is perfectly transparent, soft in the greater part of its extent, but of high refracting power. The lens is doubly convex; but the posterior segment which is received into the vitreous humour is more convex than the anterior; the convexity of both is greater in infancy than in adult age. The greatest thickness of the lens is about two lines and a half; its circumference measures from twelve to fourteen. It consists externally of a soft and homogeneous substance, presenting no trace of organisation; but the central part, more dense and firm, is made up of concentric lamellæ.

The lens is inclosed in a delicate capsule, which invests it all round, but without any distinguishable adherence to it, and is thicker and firmer on the anterior than on the posterior surface. If a puncture be made in the membrane, a small quantity of a pellucid fluid, which is termed *liquor Morgagni*, issues from the incision. When macerated in a dilute acid, or suddenly plunged into boiling water, the capsule becomes opaque and corrugated, presenting a pale, milky appearance. The lens and its capsule are both inclosed within a duplicature of the hyaloid membrane; or rather, after investing the vitreous humour, this membrane approaches the circumference of the lens, where it may be conceived to divide in two lamellæ, of which one passes before, the other behind that body. By this arrangement an interstice of a triangular form is left, the apex of which is at the point of division of the membrane, the base at the margin of the lens; and as this is continued all round, it forms a canal named the *canal of Petit*. When distended with air, which can be easily done by puncturing it and inserting the point of a blowpipe, it presents the appearance of a chain of minute vesicles disposed round the lens, communicating freely, inasmuch as the air passes from one to the other.

The capsule of the lens receives a minute branch from the arteria centralis retinæ, which ramifies on its posterior segment, but none of its branches have been found to extend to the substance of the lens. The lens has been

supposed to be muscular in its structure, and thereby to possess the power of altering its form, so as to adapt the eye to the different distances within which distinct vision obtains. This opinion was first promulgated by Dr. Pemberton, in a thesis written at Leyden. Dr. Young brought it forward again some years ago, and several physiologists have assented to it. Chemical analysis, however, has long since shown that the lens consists of pure albumen, some gelatine, and water, without the slightest admixture of fibrine, the essential constituent of muscle. Moreover, were it muscular, it must consist of fibres of some sort; and were these ever so minute or so fine, the density of the points corresponding with the fibres must be greater than that of the intervals, for intervals there must be where there are striæ, or lines; and to suppose a muscle without lines and intervals, is to suppose what has not yet been seen in nature. Were such a structure as this made a medium for the transmission of light, the rays must be dispersed and resolved into their primitive or prismatic rays, producing of necessity a colouration of the image and indistinctness of vision. The remarks and the experiment above cited, to show that the cornea must be homogeneous, apply with equal force to the structure of the lens.

Vitreous Humour. — The vitreous humour (*humor vitreus, corpus vitreum*) fills up the posterior two thirds of the globe of the eye. It consists of a thin transparent fluid inclosed in a fine membrane (*hyaloid membrane*); this not only invests it externally, but forms a number of processes, projecting inwards, and dividing it into detached masses, which may thus be said to be lodged within the areolar intervals of the membrane. This structure, though thin and transparent, is yet firm, particularly at the forepart. The term *corpus vitreum* is sometimes applied to the fluid and the capsule taken together. Anteriorly, at the central part, is a slight depression which lodges the posterior segment of the crystalline lens, and farther out, where it corresponds with the ciliary processes, is an annulus, or disk, called the zonula of Zinn: we here observe a number of dark lines converging like radii, and disposed in the form of a disk round the lens. But, besides the dark lines, which are merely streaks left by the pigment which had exuded from the intervals between the ciliary processes, there are also some delicate plicæ in the membrane itself: these project so as to be received between the contiguous ciliary processes, and form a connexion with them. This part of the membrane appears to differ somewhat from the rest of it, which induced Zinn to consider it a distinct structure; hence he called it "membranula," and the coloured disk and plicæ "zonula coronæ ciliaris."

When the eye is examined as an optical instrument, with a view to determine the influence which it can exert upon the rays of light, it becomes necessary to examine the dimensions, form, densities, &c. of its different components. The humours being so many media of transmission, their effects can be calculated only by knowing their density, refracting, and dispersive powers. And as the membranes serve to inclose the area within which all the changes take place, the form of the space, its axis, and diameters, require to be subjected to accurate measurement. — *Quain.*

Oculi levator. See *Rectus superior.*

Oculi obliquus inferior. See *Obliquus inferior oculi.*

Oculi obliquus major. See *Obliquus superior oculi.*

Oculi obliquus minor. See *Obliquus inferior oculi.*

Oculo-musculares. Vicq D'Azyr gives this name to the third pair of nerves.

Oculo-musculares communes. Chaussier thus calls the third pair of nerves.

Oculo-musculares externi. Chaussier gives this name to the sixth pair of nerves.

Oculum movens primus. See *Rectus internus.*

Oculum movens quartus. See *Rectus inferior.*

Oculum movens secundus. See *Rectus externus.*

Oculum movens tertius. See *Rectus superior.*

Oculus bovinus. See *Hydrophthalmia.*

Oculus bovis. See *Chrysanthemum.*

Oculus bubulus. See *Hydrophthalmia.*

Oculus christi. Austrian flea-bane; a species of *inula*, sometimes used as an astringent by continental physicians.

Oculus elephantinus. See *Hydrophthalmia.*

Oculus genu. The knee-pan.

Oculus lachrymans. Weeping eye. See *Epiphora.*

Oculus mundi. A species of *opal*, generally of a yellowish colour. By lying in water it becomes of an amber colour, and also transparent. This and other kinds of opal were formerly esteemed corroborant, alexipharmic, &c.

ODAXE'SMOS. (Οδαξησμος.) A pungent itching; especially that which is felt in the gums of children before the protrusion of the teeth.

ODONTAGO'GOS. (*us, i.* m.; from οδους, a tooth, and αγω, to draw.) The name of an instrument to draw teeth, one of which, made of lead, Forrestus relates to have been hung up in the temple of Apollo, denoting, that such an operation ought not to be performed but when the tooth was loose enough to be drawn with as little force as was required with it.

ODO'NTAGRA. (*a, æ.* f.; from οδους, a tooth, and αγρα, a seizure.) 1. An instrument for drawing teeth.

2. A toothach arising from retrocedent gout.

ODONTA'LGIA. (*a, æ.* f.; from οδους, a tooth, and αλγος, pain.) *Odontia. Odaxismus.* The toothach. This well-known disease makes its attack by a most violent pain in the teeth, most frequently in the molares, more rarely in

the incisorii, reaching sometimes up to the eyes, and sometimes backwards into the cavity of the ear. Toothach arises from a variety of causes.

1. The most common cause is caries of the tooth in which the pain is. When pain takes place in a carious tooth, it is from the admission of cold air, which irritates the exposed nervous fibrils in the hollow or carious part. The pain thus produced will sometimes cease very suddenly; especially upon the application of an opiate, some acrid essential oil, or solution of pure potash: but the irritation is often communicated to the internal periosteum, which inflames and swells, and hence the pain becomes permanent and distressing, for the inflamed membrane is incapable of relieving itself by stretching. In all these cases, the inflammation must be removed by bleeding the gums, blisters, or extraction. If the pain abate without extraction, which should always be avoided when there is inflammation present, the carious part may be filled with gold or zinc, or such compositions as dentists use.

There are very many cures for toothach from caries; burning the nerve with a hot iron wire; or destroying it by caustic, cajeput oil, oil of thyme, the root of the *peteveria alliacea*, or guinea-hen-weed; the sedative juice of the *coccinella septem punctata*, or ladybird, brandy, alkohol, the tincture of pyrethrum, and various other sialogogues.

2. The next cause of toothach is rheumatism. This may affect a carious tooth, and often does. Rheumatic odontalgia is known by the soreness that attends the gums and face from the very beginning, and from the pains communicating to the muscles about the jaw. It requires the remedies for rheumatism—blisters behind the ears, fomentations, the internal exhibition of Dover's powder; antimony, with opium and calomel; saline medicines: guaiacum is an excellent medicine against rheumatic toothach: washing the mouth with stimulating gargles composed of sialagogues, as the pyrethrum, seseli vulgare, or laserpitium siler.

3. Cutting the permanent teeth and wise teeth. When toothach results from this cause, it is from inflammation of the gums, and requires that the gums be scarified, and the person put on an antiphlogistic diet.

The toothach is sometimes merely a rheumatic affection, arising from cold, but a carious tooth is a more frequent cause. It is also a symptom of pregnancy, and takes place in some nervous disorders. It may attack persons at any period of life, though it is most frequent in the young and plethoric. From the variety of causes which may produce this affection, it has been named by authors odontalgia cariosa, scorbutica, catarrhalis, arthritica, gravidarum hysterica, stomachica, and rheumatica.

Many empirical remedies have been proposed for the cure of the toothach, but have not in any degree answered the purpose. When the affection is purely rheumatic, blistering behind the ear will almost always remove it; but when it proceeds from a carious tooth, the pain is much more obstinate. In this case it has been recommended to touch the pained part with a hot iron, or with oil of vitriol, in order to destroy the aching nerve; to hold spirits in the mouth; to put a drop of oil of cloves into the hollow of the tooth, or a pill made of camphire, opium, and oleum caryophylli. Others recommend gum mastich, dissolved in oleum terebinthinæ, applied to the tooth upon a little cotton. The great Boerhaave is said to have applied camphire, opium, oleum caryophylli, and alkohol, upon cotton. The caustic oil which may be collected from writing paper, rolled up tight, and set fire to at the end, will sometimes destroy the exposed nervous substance of a hollow tooth. The application of radix pyrethri, by its power of stimulating the salivary glands, either in substance or in tincture, has also been attended with good effects. But one of the most useful applications of this kind is strong nitrous acid, diluted with three or four times its weight of spirit of wine, and introduced into the hollow of the tooth, either by means of a hair pencil, or a little cotton. When the constitution has had some share in the disesase, the Peruvian bark has been recommended, and perhaps with much justice, on account of its tonic and antiseptic powers. When the pain is not fixed to one tooth, leeches applied to the gum are of great service. But very often all the foregoing remedies, will fail, and the only infallible cure is to draw the tooth.

ODONTA'LGIC. (*Odontalgicus*; from οδονταλγια, the toothach.) Relating to the toothach.

ODONTIA. (*a, æ.* f.; from οδους, a tooth.) The toothach. See *Odontalgia*.

ODONTI'ASIS. (*is, is.* f.; from οδοντιαω, to put forth the teeth.) Dentition, or the cutting of the teeth. See *Dentition*.

ODO'NTICUS. (From οδους, a tooth.) *Odontic.* Appertaining to the teeth.

ODON'TIS. (From οδους, a tooth: so called because its decoction was supposed useful in relieving the toothach.) A species of lychnis.

ODONTI'TIS. (*is, idis.* f.; from οδους, a tooth, and ιτις.) Inflammation of a tooth.

ODONTOGLY'PHUM. (*um, i.* n.; οδοντογλυφον, from οδους, a tooth, and γλυφω, to scrape.) An instrument for scaling and scraping the teeth.

ODO'NTOID. (*Odontoides*; from οδους, a tooth, and ειδος, form: because it is shaped like a tooth.) Tooth-like. See *Dentatus*.

ODONTO'LITHOS. (*us, i.* m.; from οδους, a tooth, and λιθος, a stone.) The tartar, or stony crust upon the teeth.

ODONTO'LOGY. (*Odontologia*; from οδους, a tooth, and λογος, a discourse.) The anatomy of the teeth.

ODONTOPHY'IA. (*a, æ.* f.; from οδους, a tooth, and φυω, to grow.) Dentition, or cutting teeth. See *Teething*.

ODONTOTRI'MMA. (From οδους, a tooth, and τριβω, to wear away.) A dentifrice, or medicine to clean the teeth.

Odor. See *Odour*.

ODORI'FEROUS. (*Odoriferous*; from *odor*, a smell, and *fero*, to bear.) Having a smell.

ODORIFEROUS GLANDS. *Glandulæ odoriferæ.* Small glands which are situated around the

corona glandis of the male, and under the skin of the labia majora and nymphæ of females. They secrete a cebaceous matter, which emits a peculiar odour.

O'DOUR. (*Odor, oris.* m. ; from *odeo*, i. e. *oleo*, to smell.) Smell. This, which is the emanation of an odoriferous body, is generally ascribed to a portion of the body itself, converted into vapour : but, from some experiments of M. Robiquet, it would seem probable, that in many cases the odour is owing not to the substance itself, but to a gas or vapour resulting from its combination with an appropriate vehicle, capable of diffusion in space.

Œ'A. (Οιη ; from *οιω*, to bear : so named from its fruitfulness.) The *Cratægus torminalis*, or service tree.

ŒCONOMY. *Œconomia, æ.* f. ; from *οικος*, a house, and *νομος*, a law.) The conduct of Nature, in any of her departments, in preserving bodies and following her usual order : thus animal œconomy, vegetable œconomy, &c.

ŒCONOMY, ANIMAL. (*Œconomia animalis.* The aggregate of those organs, functions, and laws on which the life of an animal depends.

ECONOMY, VEGETABLE. The aggregate of the organs, functions, and laws on which the life of a vegetable depends.

ŒDE'MA. (*a, atis.* n. Οιδημα, *οιδος* ; from *οιδεω*, to swell.) This word is sometimes used by Hippocrates for a tumour of any kind, but it is now restricted to a minor degree of anasarca. See *Anasarca*.

ŒDE'ME DE LA GLOTTE. *Angina œdematosa.* An œdematous swelling of the mucous membrane, surrounding the aperture of the glottis. It occurs chiefly in persons debilitated by chronic diseases, or convalescents from acute ones. It produces paroxysms of suffocation with crowing inspiration, which last a few minutes and return at intervals. The intervals become shorter as the disease advances, and the patient dies, generally in the course of a few days. The affection is almost uniformly fatal, and no treatment makes any impression on it.

ŒDE'MATO'DES. (From *οιδεω*, to swell, and *ειδος*, resemblance.) Like to an œdema.

ŒDE'MOSA'RCA. (From *οιδημα*, a swelling, and *σαρξ*, flesh.) A tumour mentioned by Severinus, of a middle nature, betwixt an *œdema* and *sarcoma*.

ŒNA'NTHE. (*e, es.* f. ; from *οινος*, wine, and *ανθος*, a flower : so called because its flowers smell like the vine.) 1. The name of a genus of the umbelliferous plants. Class, *Pentandria ;* Order, *Digynia*.

2. The pharmacopœial name of the hemlock dropwort. See *Œnanthe crocata*.

ŒNANTHE CROCATA. The hemlock dropwort. *Œnanthe — chærophylli foliis*, of Linnæus. An active poison, that has too often proved fatal, by being eaten in mistake instead of water-parsnep. The juice, nevertheless, cautiously exhibited, promises to be an efficacious remedy in inveterate scorbutic eruptions. The root of this plant is not unpleasant to the taste. It is esteemed to be the most deleterious of all the vegetables which this country produces. Mr. Howel, surgeon at Haverfordwest, relates, that "eleven French prisoners had the liberty of walking in and about the town of Pembroke. Three of them being in the fields a little before noon, dug up a large quantity of this plant, which they took to be wild celery, to eat with their bread and butter for dinner. After washing it, they all three ate, or rather tasted of the roots. As they were entering the town, without any previous notice of sickness at the stomach, or disorder in the head, one of them was seized with convulsions. The other two ran home, and sent a surgeon to him. The surgeon endeavoured first to bleed, and then to vomit him ; but those endeavours were fruitless, and he died presently. Ignorant of the cause of their comrade's death, and of their own danger, they gave of these roots to the other eight prisoners, who ate of them with their dinner. A few minutes afterwards the remaining two who gathered the plants were seized in the same manner as the first, of whom one died ; the other was bled, and a vomit, with great difficulty, forced down, on account of his jaws being, as it were, locked together. This operated, and he recovered, but was some time affected with dizziness in his head, though not sick, or the least disordered in the stomach. The other eight, being bled and vomited immediately, were soon well." At Clonmell, in Ireland, eight boys mistaking this plant for water-parsnep, ate plentifully of its roots. About four or five hours after, the eldest boy became suddenly convulsed, and died : and before the next morning, four of the other boys died in a similar manner. Of the other three, one was maniacal several hours, another lost his hair and nails, but the third escaped unhurt. Stalpaert Vander Wiel mentions two cases of the fatal effects of this root : these, however, were attended with great heat in the throat and stomach, sickness, vertigo, and purging ; they both died in the course of two or three hours after eating the root. Allen, in his Synopsis Medicinæ, also relates that four children suffered greatly by eating this poison. In these cases great agony was experienced before the convulsions supervened : vomitings likewise came on, which were encouraged by large draughts of oil and warm water, to which their recovery is ascribed. The late Sir William Watson, who refers to the instances here cited, also says, that a Dutchman was poisoned by the leaves of the plant boiled in pottage. It appears, from various authorities, that most brute animals are not less affected by this poison than man : and Lightfoot informs us, that a spoonful of the juice of this plant given to a dog rendered him sick and stupid : but a goat was observed to eat the plant with impunity. The great virulence of this plant has not, however, prevented it from being taken medicinally. In a letter from Dr. Pulteney to Sir William Watson, we are told that a severe and inveterate cutaneous disorder was cured by the juice of the root, though not without exciting the most alarming symptoms. Taken in the dose of a spoonful, in two hours afterwards, the head was affected in a very extraordinary manner, followed with violent sickness and

vomiting, cold sweats, and rigors; but this did not deter the patient from continuing the medicine, in somewhat less doses, till it effected a cure.

ŒNA'REA. (Οιναρεη; from *οιναρα*, the cuttings of vines.) The ashes prepared of the twigs, &c. of vines.

ŒNELÆ'UM. (Οινελαιον; from *οινος*, wine, and *ελαιον*, oil.) A mixture of oil and wine. It was used by the old surgeons as a dressing for wounds of the head.

ŒNO'GALA. (*a*, *æ*. f. Οινογαλα; from *οινος*, wine, and *γαλα*, milk.) A sort of potion, made of wine and milk, used by the Greeks. According to some, it was wine as warm as new milk.

ŒNO'GARUM. (*um*, *i*. n. Οινογαρον; from *οινος*, wine, and *γαρον*, garum.) A mixture of wine and garum.

ŒNO'MELI. (*i*, *itis*. n. Οινομελι; from *οινος*, wine and *μελι*, honey.) Wine sweetened with honey.

ŒNOSTA'GMA. (From *οινος*, wine, and *σταζω*, to distil.) Spirit of wine.

Œ'NOTHIO'NIC ACID. (So called from *οινος*, wine, and *θειον*, sulphur.) The sulpho-vinic acid. See *Æther sulphuricus*.

ŒSOPHAGÆ'US. (From *οισοφαγος*, the gullet.) This name has been given to the muscular fibres surrounding the upper part of the œsophagus.

ŒSOPHAGI'SMUS. (*us*, *i*. m.; from *οισοφαγος*, the gullet.) A term applied by some to inflammation of the œsophagus, by others to dysphagia, and by Vogel to spasmodic structure of the œsophagus.

ŒSOPHAGI'TIS. (*is*, *idis*. f.; from *œsophagus*, the seat of the disease, and *itis*, which implies inflammation.) Inflammation of the œsophagus. It is not a common disease, but does exist both in a phlegmonous and erysipelatous form. The cellular tissue that connects its coats may be the seat of the inflammation, which, like phlegmonous inflammation in any other part, may be resolved, or end in suppuration. The surface of the membrane which lines the œsophagus may be inflamed, and extend more or less throughout its whole extent.

The symptoms of this disease are, a sense of heat or burning in the œsophagus, with painful and difficult deglutition, and these generally circumscribed, or confined to a part which is pointed out by the patient: if it be high in the canal, it will be in the neck; if low, in the back, between the shoulders, and under the sternum.

As an idiopathic disease, œsophagitis is very rare, although it is much exposed to many of the causes of inflammation. Dissections have found inflammation here in fatal cases of hydrophobia.

In stricture, small-pox, measles, and tumours in the neighbourhood, the disease often is symptomatic.

The cure is to be effected by the usual means, bleeding, saline purgatives, and blistering; and if the fever which attends be of the phlogistic character, and urgent, by a perseverance in their use, and the exhibition of diaphoretics.

ŒSOPHAGO'TOMY. (*Œsophagotomia* from *οισοφαγος*, the gullet, and *τεμνω*, to cut.) The operation of cutting into the gullet to extract a foreign body.

ŒSO'PHAGUS. (*us*, *i*. m.; from *οιω*, to carry, and *φαγω*, to eat: because it carries the food into the stomach.) The membranous and muscular tube that descends from the pharynx to the upper orifice of the stomach. It is composed of three tunics or membranes, viz. a common, muscular, and mucous. Its arteries are the œsophageal branches, which arise from the aorta. The veins empty themselves into the vena azygos. Its nerves are from the eighth pair and great intercostal; and it is every where, under the internal or mucous membrane, supplied with glands that separate the mucus of the œsophagus, in order that the masticated bole may readily pass down into the stomach.

ŒSTROMA'NIA. (*a*, *æ*. f.; from *οιστρος*, the venereal orgasm, and *μαινομαι*, to rage.) See *Nymphomania*.

Œ'STRUM. (*um*, *i*. n.; from *œstrus*, a gadbee, which, by its bite, or sting, agitates cattle.) The orgasm, or strong excitement, experienced during the operation of the appetites or passions.

ŒSTRUM VENEREUM. 1. The pleasurable sensation experienced during coition.

2. The clitoris has been so called, as being the seat of the sensation.

Œ'SYPUS. (Οισυπος; from *οις*, a sheep, and *ρυπος*, sordes.) *Œsype*. The oily matter boiled out from the wool of sheep, and skimmed from the surface of the water. It was used as an emollient in rigidity of the joints.

OFFA ALBA. (*Offa*, from *phath*, a fragment, Hebrew.) Van Helmont thus calls the white coagulum formed by a mixture of a rectified spirit of wine with urine.

Offa helmontiana. See *Offa alba*.

OFFI'CINAL. (*Officinalis*; from *officina*, a shop.) Any medicine directed by the colleges of physicians to be kept in the shops, is so termed.

Oil. See *Oleum*.

Oil, ætherial. See *Oleum æthereum*.

Oil, almond. See *Amygdalus*.

Oil of allspice. See *Oleum pimentæ*.

Oil of amber. See *Oleum succini*.

Oil of caraway. See *Oleum carui*.

Oil, castor. See *Ricinus communis*.

Oil of chamomile. See *Anthemis nobilis*.

Oil of juniper. See *Oleum juniperi*.

Oil of lavender. See *Lavandula*.

Oil of linseed. See *Oleum lini*.

Oil of mace. See *Oleum macis*.

Oil, olive. See *Olea europæa*.

Oil of origanum. See *Oleum origani*.

Oil, palm. See *Cocos butyracea*.

Oil of pennyroyal. See *Oleum pulegii*.

Oil of peppermint. See *Oleum menthæ piperitæ*.

Oil, rock. See *Petroleum*.

Oil of spearmint. See *Mentha viridis*.

Oil, sulphuretted. See *Oleum sulphuratum*.

Oil of turpentine. See *Oleum terebinthinæ*.

Oil of vitriol. See *Sulphuric acid*.

Ointment. See *Unguentum*.

OLDENLA'NDIA. (*a*, *æ*. f.; so called in honour of Oldenland, the Danish botanist.)

The name of a genus of plants. Class, *Pentandria*; Order, *Digynia*.

Oldenlandia umbella'ta. The roots of this plant, which grows wild on the coast of Coromandel, and is also cultivated there, are used by dyers and calico printers, for the same purposes as madder in this country, giving the beautiful red so much admired in the Madras cottons.

O'LEA. (*a, æ.* f.; Ελαια.) The name of a genus of plants in the Linnæan system. Class, *Monandria*; Order, *Monogynia*.

Olea europæa. The systematic name of the plant from which the olive oil is obtained; called also *Oliva*, and *Olea sativa*. *Olea — foliis lanceolatis integerrimis, racemis axillaribus coarctatis*, of Linnæus. The olive-tree, in all ages, has been greatly celebrated, and in held peculiar estimation, as the bounteous gift of heaven. It was formerly exhibited in the religious ceremonies of the Jews, and is still mentioned as emblematic of peace and plenty. The varieties of this tree are numerous, distinguished not only by the form of the leaves, but also by the shape, size, and colour, of the fruit; as the large Spanish olive, the small oblong Provence olive, &c. &c. These, when pickled, are well known to us by the names of Spanish and French olives, which are extremely grateful to many stomachs, and said to excite appetite and promote digestion: they are prepared from the green unripe fruit, which is repeatedly steeped in water, to which some quicklime or alkaline salt is added, in order to shorten the operation: after this, they are washed and preserved in a pickle of common salt and water, to which an aromatic is sometimes added. The principal consumption, however, of this fruit is in the preparation of the common salad oil, or *oleum olivæ* of the pharmacopœias, which is obtained by grinding and pressing them when thoroughly ripe: the finer and purer oil issues first by gentle pressure, and the inferior sorts on heating what is left, and pressing it more strongly. The best olive oil is of a bright pale amber colour, bland to the taste, and without any smell: it becomes rancid by age, and sooner if kept in a warm situation. With regard to its utility, oil, in some shape, forms a considerable part of our food, both animal and vegetable, and affords much nourishment. With some, however, oily substances do not unite with the contents of the stomach, and are frequently brought up by eructation: this happens more especially to those whose stomachs abound with acid. — Oil, considered as a medicine, is supposed to correct acrimony, and to lubricate and relax the fibres; and therefore has been recommended internally to obviate the effects of various stimuli, which produce irritation, and consequent inflammation: on this ground it has been generally prescribed in coughs, catarrhal affections, and erosions. The oil of olives is successfully used in Switzerland against the *tænia osculis superficialibus*; and it was formerly much employed in this and other countries, against nephritic pains, spasms, colic, constipation of the bowels, &c. Externally, it has been found an useful application to bites and stings of various poisonous animals; also to burns, tumours, and other affections, both by itself, or mixed in liniments or poultices. Oil rubbed over the body was formerly thought serviceable in dropsies, particularly ascites. Olive oil enters several officinal compositions, and when united with water, by the intervention of alkali, is sometimes given in coughs and hoarsenesses.

Olea'men. (*en, inis.* n.; from *oleum*, oil.) *Oleamentum*. Any soft liniment composed of oils.

Olea'nder. (*er, ri.* m.; from *olea*, the olive-tree, which it resembles.) The rose-bay. See *Nerium oleander*, in the supplement.

Olea'ster. (*er, ri.* m.; diminutive of *olea*, the olive-tree.) The wild olive.

OLE'CRANON. (*on, i.* n.; from ωλενη, the ulna, and κρανον, the head.) The elbow, or process of the ulna, upon which a person leans. See *Ulna*.

Olefiant gas. See *Carburetted hydrogen*.

Oleic acid. *Acidum oleicum*. An acid discovered by Chevreuil in fat. See *Adeps*.

O'lene. Ωλενη. The cubit, or ulna.

Oleo-resins. The native combinations of resins with essential oils, which form various terebinthinate and balsamic substances.

O'leo-ri'cinate. A salt formed by oleoricinic acid with a base.

O'leo-rici'nic acid. *Elaiodic acid*. An acid obtained by MM. Bussy and Lecanu from saponified castor oil.

OLEOSA'CCHARUM. (*um, i.* n.; from *oleum*, oil, and *saccharum*, sugar.) An essential oil, ground up with sugar.

OLERA'CEOUS. (*Oleraceus*; from *olus*, a potherb.) Partaking of the nature of potherbs.

Olera'ceæ. (From *olus*, a pot-herb.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of such as have incomplete inelegant flowers, heaped together in the calyces; as beta, chenopodium, spinacia, &c.

O'LEUM. (*um, ei.* n.; from *olea*, the olive: this name being at first confined to the oil expressed from the olive.) A proper juice of a fat or unctuous nature, either solid or fluid, indissoluble in water, combustible with flame, and volatile in different degrees. Oils are never formed but by organic bodies; and all the substances in the mineral kingdom, which present oily characters, have originated from the action of vegetable or animal life. They are distinguished into fat, and essential oils. Under the former head are comprehended oil of olives, almonds, rape, ben, linseed, hemp, cocoa, &c. Essential oils differ from fat oils by the following characters: their smell is strong and aromatic; their volatility is such that they arise with the heat of boiling water, and their taste is very acrid; they are likewise much more combustible than fat oils; they are obtained by pressure, distillation, &c., from strong-smelling plants, as that of peppermint, aniseed, caraway, &c. The use of fat oils in the arts, and in medicine, is very considerable: they are medicinally prescribed as relaxing, softening, and laxative remedies; they enter into many medical

compounds, such as balsams, unguents, plasters, &c., and they are often used as food on account of the mucilage they contain. See *Olea*. Essential oils are employed as cordial, stimulant, and antispasmodic remedies. See *Adeps*.

Oleum abietinum. The resinous juice which exudes spontaneously from the silver and red firs. It is supposed to be superior to that obtained by wounding the tree.

Oleum æthereum. Ethereal oil. *Oleum vini*. Take of rectified spirit, two pounds; sulphuric acid, four pounds; solution of potash, distilled water of each a fluid ounce, or as much as may be sufficient. Mix the acid and spirit cautiously. Let the liquor distil until a black froth rises, then immediately remove the retort from the fire. Separate the supernatant liquor from the heavier, and expose the former to the air for a day. Add to it the solution of potash mixed with the water, and agitate. Lastly, when sufficiently washed, separate the ethereal oil which subsides.

According to Serrullac and Dumas, this oil is a sulphate of ether, and consists of one equivalent of sulphuric acid and one of ether. It is of a yellow colour, penetrating aromatic odour, and somewhat sharp and bitter taste. Its specific gravity variable. Hennel states it at 1·5, and Dumas at 1·133. It is insoluble in water, but soluble in alkohol and ether. It is used only for the preparation of the *spiritus ætheris sulphurici compositus*.

Oleum amygdalæ. See *Amygdalus*.

Oleum animale. *Oleum animale Dippelii*. An empyreumatic oil obtained by distillation from bones and animal substances. It is sometimes exhibited as an antispasmodic and diaphoretic, in the dose of from ten to forty drops.

Oleum animale Dippelii. See *Oleum animale*.

Oleum ani'si. *Oleum essentiale anisi; Oleum e seminibus anisi*. Oil of anise. The essential oil of aniseed possesses all the virtues attributed to the anisum, and is often given as a stimulant and carminative, in the dose of from five to eight drops, mixed with an appropriate vehicle. See *Pimpinella anisum*.

Oleum anthe'midis. Oil of chamomile; formerly called, *Oleum e floribus chamæmeli*. See *Anthemis nobilis*.

Oleum camphoratum. See *Linimentum camphoræ*.

Oleum carpathicum. See *Balsamum carpathicum*.

Oleum ca'rui. Formerly called *Oleum essentiale carui; Oleum essentiale e seminibus carui*. The oil of caraway is an admirable carminative, diluted with rectified spirit into an essence, and then mixed with any proper fluid. See *Carum*.

Oleum caryophy'lli aromatici. A stimulant and aromatic preparation of the clove. See *Eugenia caryophyllata*.

Oleum ce'drinum. *Essentia de cedro*. The oil of the peel of citrons, obtained without distillation, in Italy.

Oleum cinnamo'mi. A warm stimulant, and pleasant stomachic. Given in the dose of from one to three drops, rubbed down with some yolk of egg, in a little wine, it allays disturbance of the stomach from morbid irritability, and is particularly serviceable in debility of the primæ viæ, after cholera.

Oleum cornu cervi. This is applied externally as a stimulant in paralytic affections of the limbs.

Oleum e vitellis. Oil of eggs. This is obtained by boiling the yolks of eggs and pressing them. It is used on the Continent for oxidising mercury.

Oleum gabianum. See *Gabianum oleum*.

Oleum juni'peri. *Oleum essentiale juniperi baccæ; Oleum essentiale e baccis juniperi*. Oil of juniper. Oil of juniper-berries possesses stimulant, carminative, and stomachic virtues, in the dose of from two to four drops, and in a larger dose proves highly diuretic. It is often administered in the cure of dropsical complaints, when the indication is to provoke the urinary discharge. See *Juniperus communis*.

Oleum lava'ndulæ. *Oleum essentiale lavendulæ; Oleum essentiale e floribus lavendulæ*. Oil of lavender. Though mostly used as a perfume, this essential oil may be exhibited internally, in the dose of from one to five drops, as a stimulant in nervous headachs, hysteria, and debility of the stomach. See *Lavandula spica*.

Oleum lauri. *Oleum laurinum*. It is expressed from bay-berries, and is sometimes rubbed on sprains and bruises unattended with inflammation.

Oleum limo'nis. The essential oil of lemons possesses stimulant and stomachic powers, but is principally used externally, mixed with ointments, as a perfume.

Oleum lini. Linseed oil is emollient and demulcent, in the dose of from half an ounce to an ounce. It is frequently given in the form of clyster in colics and obstipation. Cold-drawn linseed oil, with lime-water and extract of lead, forms, in many instances, the best application for burns and scalds. See *Linum usitatissimum*.

Oleum lucii piscis. See *Esox lucius*.

Oleum macis. *Oleum myristicæ expressum*. Oil of mace. A fragrant sebaceous substance, expressed in the East Indies from the nutmeg. There are two kinds. The best is brought in stone jars, is somewhat soft, of a yellow colour, and resembles in smell the nutmeg. The other is brought from Holland, in flat square cakes. The weak smell and faint colour warrants our supposing it to be the former kind sophisticated. Their use is chiefly external, in form of plaster, unguent, or liniment. See *Myristica moschata*.

Oleum macis stillatitium. See the Supplement.

Oleum malabathri. An oil similar in flavour to that of cloves, brought from the East Indies, where it is said to be drawn from the leaves of the cassia tree.

Oleum martis per deliquium. The liquid muriate of iron was formerly so called.

Oleum menthæ piperitæ. Formerly called *Oleum essentiale menthæ piperitidis*. Oil of peppermint. Oil of peppermint possesses all the active principles of the plant. It is mostly used to make the simple water. Mixed with rectified spirit, it forms an essence, which is put into a variety of compounds, as sugar-drops

and troches, which are exhibited as stimulants, carminatives, and stomachics. See *Mentha piperita.*

Oleum menthæ viridis. Formerly called *Oleum essentiale menthæ sativæ.* Oil of spearmint. This essential oil is mostly in use for making the simple water, but may be exhibited in the dose of from two to five drops as a carminative, stomachic, and stimulant. See *Mentha viridis.*

Oleum myri'sticæ. The essential oil of nutmeg is an excellent stimulant and aromatic, and may be exhibited, in every case where such remedies are indicated, with advantage. See *Myristica moschata.*

Oleum myristicæ expressum. Commonly called oil of mace. See *Oleum macis.*

Oleum neroli. See *Neroli oleum.*

Oleum olivæ. See *Olea europæa.*

Oleum origani. Formerly called *Oleum essentiale origani.* Oil of origanum. A very acrid and stimulating essential oil. It is employed for alleviating the pain arising from caries of the teeth, and for making the simple water marjoram. See *Origanum.*

Oleum palmæ. See *Cocos butyracea.*

Oleum petræ. Naphtha.

Oleum petræ vulgare. Common oil of petre. This is variously made, but most frequently with oil of turpentine, Barbadoes tar, and oil of rosemary.

Oleum pimentæ. See *Myrtus pimenta.*

Oleum pulegii. Formerly called *Oleum essentiale pulegii.* Oil of pennyroyal. A stimulant and antispasmodic oil, which may be exhibited in hysterical and nervous affections. See *Mentha pulegium.*

Oleum ricini. See *Ricinus communis.*

Oleum rosmarini. Formerly called *Oleum essentiale roris marini.* Oil of rosemary. The essential oil of rosemary is an excellent stimulant, and may be given with great advantage in nervous and spasmodic affections of the stomach. See *Rosmarinus officinalis.*

Oleum sabi'næ. Oil of savine. See *Juniperus sabina.*

Oleum sassafras. Obtained from the root of sassafras by distillation with salt water. An agreeable stimulating carminative and sudorific.

Oleum sina'peos. This is pressed from the husks of black mustard seed. It resembles coarse linseed oil, and has but little acrimony. It is used as a liniment in rheumatism.

Oleum su'ccini. *Oleum succini rectificatum.* Put amber into an alembic, and with the heat of a sand-bath, gradually increased, distil over an acid liquor, an oil, and a salt contaminated with oil. Then redistil the oil a second and a third time. Oil of amber is mostly used externally, as a stimulating application to paralytic limbs, or those affected with cramp and rheumatism. Hooping-cough, and other convulsive diseases, are said to be relieved also by rubbing the spine with this oil. See *Succinum.*

Oleum sulphuratum. See *Balsamum sulphuris.*

Oleum Syriæ. See *Dracocephalum Moldavicum.*

Oleum templi'num. *Oleum templinum verum.* A terebinthinate oil, obtained from the fresh cones of the *Pinus pumilio* of Linnæus.

Oleum terebinthinæ purificatum. *Oleum terebinthinæ rectificatum.* Take of oil of turpentine, a pint; water, four pints. Distil the oil cautiously. Stimulant, diuretic, and sudorific virtues are attributed to this preparation, in the dose of from ten drops to twenty, which are given in rheumatic pains of the chronic kind, especially sciatica. Its chief use internally, however, is as an anthelmintic and styptic. In cases of tapeworm it is given in doses of from ℥ ss. to ℥ ij. every eight hours, till the worm is expelled. It is a remedy of extraordinary power in such cases. Uterine, pulmonic, gastric, intestinal, and other hæmorrhages, when passive, are more effectually relieved by oil of turpentine than by any other medicine. Externally, it is applied, mixed with ointments and other applications, to bruises, sprains, rheumatic pains, indolent ulcers, burns, and scalds.

Oleum terræ. See *Petroleum.*

Oleum vini. See *Oleum æthereum.*

Oleum vitrioli. See *Sulphuric acid.*

Olfactory nerves. *Nervi olfactorii.* The first pair of nerves are so termed, because they are the organs of smelling. See *Nerve.*

OLFA'CTUS. The sense of smell, or, the act of smelling. See *Smell.*

OLI'BANUM. (*um, i.* n.; from *lebona,* Chaldean.) See *Juniperus lycia.*

OLIGOTROPHI'A. (*a, æ.* f.; from ολιγος, small, and τρεφω, to nourish.) Deficient nourishment.

Olisthe'ma. (Ολισθημα; from ολισθαινω, to fall out.) A luxation.

Oli'va. (*a, æ.* f.; from ελαια.) The olive. See *Olea europæa.*

Oliva'ceous. Of an olive colour.

OLIVA'RIS. (From *oliva,* the olive.) Resembling the olive: applied to two eminences on the lower part of the medulla oblongata, called *corpora olivaria.* See *Encephalos.*

Olive. See *Olea europæa.*

Olive, spurge. See *Daphne mezereum.*

Olive-tree. See *Olea europæa.*

O'LIVILE. The name given by Pelletier to the substance which remains after gently evaporating the alkoholic solution of the gum which exudes from the olive-tree. It is a white, brilliant, starchy powder.

Olophly'ctis. (From ολος, whole, and φλυκτις, a pustule.) Synonymous with *phlyctæna.*

OLUSA'TRUM. (*um, i.* m.; *id est, olus atrum,* the black herb, from its black leaves.) See *Smyrnium olusatrum.*

O'MAGRA. (*a, æ.* f.; from ωμος, the shoulder, and αγρα, a seizure.) The gout in the shoulder.

OMENTI'TIS. (*is, idis.* f.; from *omentum* the caul.) *Epiploitis.* Inflammation of the omentum or epiploon. It usually occurs only in connexion with general inflammation of the peritoneum. See *Peritonitis.*

OME'NTUM. (*um, i.* n.; from *omen,* an omen: so called because the soothsayers prophesied from an inspection of this part.) The

omentum or caul, called also *epiploon*, is an adipose membranous viscus of the abdomen, attached to the stomach, and lying on the anterior surface of the intestines. It is thin and easily torn, being formed of a duplicature of the peritonæum, with more or less of fat interposed. It is distinguised into the great omentum and the little omentum.

1. The *omentum majus*, which is also termed *omentum gastrocolicum*, arises from the whole of the great curvature of the stomach, and even as far as the spleen, from whence it descends loosely behind the abdominal parietes, and over the intestines to the navel, and sometimes into the pelvis. Having descended thus far, its inferior margin turns inwards and ascends again, and is fastened to the colon and the spleen, where its vessels enter.

2. The *omentum minus*, or *omentum hepitaco gastricum*, arises posteriorly from the transverse, fissure of the liver. It is composed of a duplicature of peritonæum, passes over the duodenum and small lobe of the liver: it also passes by the lobulus spigelii and pancreas, proceeds into the colon and small curvature of the stomach, and is implanted ligamentous into the œsophagus. It is in this omentum that Winslow discovered a natural opening, which goes by his name. If air be blown in at this *foramen of Winslow*, which is always found behind the lobulus spigelii, between the right side of the liver and hepatic vessels, the duodenum, the cavity of the omentum, and all its sacs, may be distended.

The omentum is always double, and between its lamellæ, closely connected by very tender cellular substance, the vessels are distributed and the fat collected. Besides the greater and lesser omentum above described, some anatomists distinguish a *colic omentum* which binds down the colon, and a *gastro splenic* omentum, which passes between the stomach and the spleen.

Omentum colicum. See *Omentum.*

Omentum gastro-colicum. See *Omentum.*

Omentum gastro-splenicum. See *Omentum.*

Omentum hepatico-gastricum. See *Omentum.*

Omentum majus. See *Omentum.*

Omentum minus. See *Omentum.*

O'MOCO'TYLE. (*e, es.* f.; from ωμος, the shoulder, and κοτυλη, a cavity.) The cavity in the extremity of the neck of the scapula, in which the head of the humerus is articulated.

O'MO-HYOIDE'US. A muscle situated between the os hyoides and shoulder, that pulls the os hyoides obliquely downwards. *Coracohyoideus*, of Albinus and Douglas. It arises broad, thin, and fleshy, from the superior costa of the scapula, near the semilunar notch, and from the ligament that runs across it; thence ascending obliquely, it becomes tendinous below the sternocleido-mastoideus, and, growing fleshy again, is inserted into the base of the os hyoides.

O'MOPLA'TA. (*a, æ.* f.; from ωμος, the shoulder, and πλατυς, broad.) See *Scapula.*

Omoplato-hyoideus. See *Omo-hyoideus.*

OMO'TRIBES. (From ωμος, crude, and τριβω, to bruise.) Oil expressed from unripe olives.

OMPHA'CINUM. (From ομφακιον, the juice of unripe grapes.) Oil expressed from unripe olives.

OMPHA'CION. (From ομφακος, an unripe grape.) *Omphacium.* The juice of unripe grapes; and by some applied to that of wild apples, or crabs, commonly called *Verjuice.*

OMPHACI'TES. (From ομφακος, an unripe grape.) Wine prepared from unripe grapes.

OMPHACO'MELI. (From ομφακος an unripe grape, and μελι, honey.) An oxymel made of the juice of unripe grapes and honey.

O'MPHALOCA'RPUS. (From ομφαλος, the navel, and καρπος, fruit: so called because its fruit resembles a navel.) Cleavers. See *Galium aparine.*

O'MPHALOCE'LE. (*e, es.* f.; from ομφαλος, the navel, and κηλη, a tumour.) See *Hernia umbilicalis.*

O'MPHALOMANTI'A. (From ομφαλος, the navel, and μαντεια, a prophecy.) The foolish vaticination of midwives, who pretend to foretell the number of the future offspring from the number of knots in the navel-string of the child that is born.

O'MPHALOS. (*us, i.* m.; Ομφαλος.) The navel. See *Umbilicus.*

ONEIRODY'NIA. (*a, æ.* f.; from ονειρον, a dream, and οδυνη, anxiety.) Disturbed imagination during sleep. There are two species: —

1. *Oneirodynia activa*, walking in the sleep.

2. *Oneirodynia gravans*, or nightmare. See *Ephialtes.*

ONEIRO'GMOS. (From ονειρωττω, to dream.) 1. A venereal dream. 2. An emission of the semen during sleep.

ONEIRO'GONOS. (From ονειρος, a dream, and γονη, the seed.) *Oneirogmos.* An emission of the semen during sleep.

Onion. See *Allium cepa.*

Onion, sea. See *Scilla.*

ONI'SCUS. (*us, i.* m.; from ονος, an ass: so called because, like the ass, it requires much beating before it is useful.) 1. The stock-fish.

2. The slow-worm.

3. The name of a genus of apterous insects.

ONISCUS ASELLUS. The systematic name of the woodlouse: called also, hoglouse, churchbug, sow-bug. These insects were formerly esteemed as diuretics. They have generally been confounded in the pharmacopœias with other insects. See *Millepedes.*

ONOBRY'CHIS. (From ονος, an ass, and βρυχω, to bray: so called, according to Blanchard, because the smell or taste makes asses bray.) See *Hedysarum onobrychis.*

ONO'NIS. (*is, is.* f.; from ονος, an ass: because it interrupts asses when at plough.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria.*

2. The pharmacopœial name of the rest-harrow.) See *Ononis spinosa.*

Ononis arvensis. See *Ononis spinosa.*

ONONIS SPINOSA. The systematic name of the rest-harrow: called, also, *Resta bovis, Arresta bovis*, and *Remora aratri.* The roots of this plant have a faint unpleasant smell, and a sweetish,

bitterish, somewhat nauseous taste. Their active matter is confined to the cortical part, which has been sometimes given in powder, or other forms, as an aperient and diuretic.

ONOPO'RDIUM. (*um. ii.* n. Ονοπορδον; from *ονος*, an ass, and *περδω*, to break wind, said to be so named from its having that effect upon asses.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia æqualis.*

2. The pharmacopœial name of the cotton thistle. See *Onopordium acanthium.*

ONOPORDIUM ACANTHIUM. The systematic name of the cotton thistle. Called also, *Carduus tomentosus.* The plant distinguished by this name is thus described by Linnæus: *Onopordium — calycibus squamosis; squamis patentibus; foliis ovato-oblongis, sinuatis.* Its expressed juice has been recommended as a cure for cancer, either applied by moistening lint with it, or mixing some simple farinaceous substance, so as to form a poultice, which should be in contact with the disease, and renewed twice a day.

ONO'SMA. (*a, æ.* f.; from *οσμη*, a sweet smell or savour.) The name of a genus of plants. Class, *Pentandria*; Order, *Monogynia.*

ONOSMA ECHIOIDES. The systematic name of the plant, the root of which is called *Anchusa lutea* in some pharmacopœias. It is supposed to possess emmenagogue virtues.

ONY'CHIA. (*a, æ.* f.; from *ονυξ*, the nail.) A whitlow at the side of the finger-nail.

O'NYX. (*yx, ychis.* m. Ονυξ.) In *Surgery*, an abscess, or collection of pus between the lamellæ of the cornea: so called from its resemblance to the stone called onyx, and *unguis* from its resemblance to the nail of the finger. The diagnostic signs are, a white spot or speck, prominent, soft, and fluctuating. It is sometimes superficial, arising from inflammation; not dangerous, for it vanishes when the inflammation is resolved by the use of astringent collyria.

In other instances, it is a deep abscess, seated between the lamellæ of the cornea, sometimes breaking internally, and forming an hypopium: when it opens externally, it leaves a fistula upon the cornea; whenever the pus is exsiccated, there remains a leucoma.

OOEI'DES. (From *ωον*, an egg, and *ειδος*, a likeness.) An epithet for the aqueous humour of the eye.

OPACITY. (*Opacitas, atis.* f.) The faculty of obstructing the passage of light.

OPERCULATE. *Operculatus.* Having a lid-like cover. Applied in zoology and botany.

OPE'RCULUM. (*um, i.* n.; a cover or lid.) The lid or cover of the *peristomum* or fringe of mosses. It is either *convex, acuminate, flat,* or *permanent,* never leaving the fringe; as in *Phascum.*

OPHI'ASIS. (*is, is.* f.; from *οφις*, a serpent: so called from the serpentine direction in which the disease travels round the head.) A form of porrigo decalvans, which commences at the occiput, and winds to each ear, and sometimes to the forehead.

OPHIOGLO'SSUM. (*um, i.* n.; from *οφις*, a serpent, and *γλωσσα*, a tongue: so called from the resemblance of its fruit. The name of a genus of plants. Class, *Cryptogamia*; Order, *Filices.*

OPHIOGLOSSUM LUNARIA. Moon-wort. *Lunaria. Osmunda lunaria.* The leaves are astringent, and used by the country people against fluxes.

Ophioglossum osmunda. See *Osmunda regalis.*

OPHIOGLOSSUM SPICATUM. Adder's tongue: called also, *Brassidella, Brassadella, Ophioglossum vulgatum,* and *Ophioglossum.* This was formerly a celebrated vulnerary.

OPHIORRHI'ZA. (*a, æ.* f.; from *οφις*, a serpent, and *ριζα*, a root: because the plant, says Hermann, is regarded in Ceylon as a grand specific for the bite of the naja or ribband snake.) The name of a genus of plants. Class, *Pentandria*; Order, *Monogynia.*

OPHIORRHIZA MUNGOS. The systematic name of the plant, the root of which is called *Radix serpentum* in the pharmacopœias. *Mungos radix.* The bitter root is much esteemed in Java, Sumatra, &c., as preventing the effects which usually follow the bite of the *naja*, a venomous serpent, and those of the bite of a mad dog, or hydrophobia, with which view it is eaten by them; and Kæmpfer highly extols it. Gremmius, who practised with great reputation at Columbo, employed it against the bite of a mad dog very largely. It is also said to be exhibited medicinally in the cure of intestinal worms.

OPHIOSCO'RODON. (*um, i.* n.; from *οφις*, a serpent, and *σκοροδον*, garlic: so named because it is spotted like a serpent.) Broad-leaved garlic.

OPHIOSTA'PHYLUM. (*um, i.* n.; from *οφις*, a serpent, and *σταφυλη*, a berry: so called because serpents feed upon its berries.) See *Bryonia alba.*

OPHIO'XYLUM. (*um. i.* n.; from *οφις*, and *ξυλον*: because its root spreads in a zigzag manner, like the twisting of a serpent.) The name of a genus of plants. Class, *Pentandria*; Order, *Monogynia.* Serpentine-wood plant.

OPHIOXYLUM SERPENTI'NUM. The systematic name of the tree, the wood of which is termed lignum serpentum. The nature of this root does not appear to be yet ascertained. It is very bitter. In the cure of the bite of venomous serpents, and malignant diseases, it is said to be efficacious.

O'PHRYS. (*ys, os.* f. Οφρυς; from *οφυς*, the eyebrow.) 1. The lowest part of the forehead, where the eyebrows grow.

2. An herb so called because its juice was used to make the hair of the eyebrows black.

OPHTHA'LMIA. (*a, æ.* f.; from *οφθαλμος*, the eye.) A term universally applied to an inflammation of the membranes of the eye, or of the whole bulb of the eye; but which, according to the modern nomenclature of diseases, should be called ophthalmitis. See *Ophthalmitis.*

OPHTHALMIC. (*Ophthalmicus, i.* m.; from *οφθαλμος*, an eye.) Relating to the eye; as ophthalmic nerve, muscle; ophthalmic remedy, disease, &c.

Ophthalmic artery. See the Supplement.

Ophthalmic ganglion. *Ganglion ophthalmicum.* Lenticular ganglion. This ganglion is formed in the orbit by the union of a branch of the third or fourth pair with the first branch of the fifth pair of nerves.

Ophthalmic nerve. *Nervus ophthalmicus.* The first branch given off from the Gasserian ganglion of the fifth pair of nerves. It divides into the *lachrymal*, *frontal*, and *nasal* nerves, and gives a filament to the great sympathetic.

Ophthalmici externi. See *Motores oculorum.*

OPHTHALMI'TIS. (*itis, itidis.* f.; from ὀφθαλμος, the eye.) *Ophthalmia.* An inflammation of one or more of the membranes constituting the eye, or of the whole bulb of the eye. It has the following species: —

1. *Ophthalmitis conjunctivæ.* Conjunctival ophthalmia. This is the common inflammation of the eye, which is usually produced by a cold easterly wind, dust, or any external irritation, &c. It generally begins with the appearance of a network of blood-vessels on some part of the conjunctiva of the eyeball or eyelids. The eyelids become swollen and tender, and the redness soon covers the whole of the tunica conjunctiva, the vessels of which are turgid with florid blood. There is more or less of constant pain, and a sensation as if particles of fine sand, or some gritty substance, had insinuated themselves under the eyelid, accompanied by a great heat and pricking pain. A glutinous matter is now secreted, especially in the night, which causes the eyelids to stick very firmly together. It is no unusual thing for the disease to commence in one eye, and in a day or two, to seize the other. Mild cases of conjunctival ophthalmitis generally run their course in a few days, and cease spontaneously, or are removed by the application of a few leeches to the temples, a purgative, and abstaining from the usual diet. The best local applications are a warm and filtered decoction of poppy-heads, or one fluid drachm of the tinctura opii, in eight fluid ounces of distilled water. The eye should be well cleansed from the glutinous matter, with warm milk and water; and when the pain abates, and the vessels of the inflamed part become relaxed, solutions of acetate of lead, sulphate of alumen, and zinc, will be best calculated to remove the disease.

Inflammation of the conjunctiva is not always so mild a disease, but is sometimes very acute, all the symptoms enumerated being very violent in a few days, with excessive pain in the head, and active fever; and, when so, it requires not only continued application of leeches, or cupping, and blisters behind the ears, but general blood-letting and purgatives, a strict antiphlogistic diet, and the use of opium as occasion may require. The light of the room should be diminished, and the air temperate. Iced water may be applied to the forehead, and the eye-waters should also have their temperature reduced by being kept in cold water. Nauseating doses of emetic tartar are much depended upon by some practitioners in acute external ophthalmia. Conjunctival ophthalmitis presents itself under other forms than that just mentioned.

a. The whole of the membrane becomes very rapidly inflamed, and the albuginea of an universal red colour, and swelled so as to be raised above the transparent cornea, which does not present any appearance of disease, but has the appearance of a gap or aperture, from which circumstance it received the name of *chemosis.* If the inflamed conjunctiva be attentively examined, the radiated or arborescent vessels will not be so perceptible as in the common ophthalmitis, and the cellular structure beneath the conjunctive membrane will be seen filled with a sanguineous secretion, which elevates the membrane, and stops at the edge which marks the line of separation between the cornea opaca and cornea transparens.

This form of conjunctival inflammation requires precisely the same treatment as the former.

b. Another form of conjunctival ophthalmitis is when the internal surface of the palpebræ is very much inflamed, as well as the conjunctiva of the ball of the eye, and there is a copious secretion of a purulent fluid. Of this purulent inflammation of the conjunctiva, there are three distinct varieties mentioned by writers on the diseases of the eyes: — the Egyptian, the gonorrhœal, and that which takes place in infants.

The *Egyptian ophthalmia* is that which our soldiers brought from Egypt, and which was so destructive to the armies of the French and English in their respective expeditions to the banks of the Nile. It was at first ascribed to the minute and glassy spiculæ of the sands: but it has since been traced either to a peculiar miasm, generated in marsh lands, or to sleeping on damp or swampy grounds, with insufficient covering, and surrounded by a moist atmosphere; and as these causes exist also in other parts of the world, the disease has been since detected in other parts as well. A peculiar miasm, however, formed in hot and swampy soils, is perhaps the real cause, and renders it epidemic. This cause acts on the mucous follicles of the conjunctive membrane, which secretes a puriform fluid, impregnated with the specific contagion; and hence it is propagated with great rapidity between those who come in contact with each other, or with materials, as towels, &c., that have been used by the infected.

The symptoms and their progress are like those of common ophthalmitis; and, from the violence of the inflammation, the eyelids soon become excessively tense and œdematous, sometimes inseparably closed, with the edges drawn inwards, and sometimes gaping, with the edges broad, turgid, and everted. The secretion of a puriform fluid and of tears is very great. An ulceration soon takes place, and, in some cases, during the first night of the attack. It commences usually in the cornea, which, from the onset of the disease, looks more or less muddy, or is studded with white spots. The ulcerative process is sometimes checked before it spreads over the whole disk of the pupil, and in this case the sight is partially preserved; but very generally it makes a rapid and irresistible advance over the entire cornea, lays open the

iris, and works its way internally: the humours escape; the iris protrudes, and more or less adheres to the ulcerated cornea; and the eye loses its figure, as well as its power of vision. The pain, through the whole progress, is intolerable: in the eye itself there is a sense of scalding or burning, and an agony in the head that is indescribable.

In some cases, the symptoms are less violent, and gradually subside, without ulceration, in a few days, and especially where the disease has been actively opposed by prompt and proper means. But innumerable granulations form, in some cases, in a few days, on the conjunctiva of one or both eyelids, and a destructive irritation is hereby kept up, which becomes a secondary source of blindness.

The treatment of this horrible disease was at first similar to that of the common acute inflammation of the eye. The French and English surgeons both naturally resorted to blood-letting generally and locally, to blisters, purgatives, detergent lotions, and the ordinary antiphlogistic regimen; according to the former with decidedly good effect: but, under the direction of the latter, this plan generally failed, which induced the late Mr. Saunders to give his attention to the disease. He first discovered that the blindness which is apt to follow, even after the first attack of the inflammation has subsided, proceeded from the friction upon the transparent cornea of innumerable irritating granulations, thrown forth from the surface of the tunica conjunctiva that lines the interior of the eyelids, and which became a new source of inflammation, less violent, indeed, but as fatal in its effects; and the disease has hence been very correctly divided into two stages, that of the primary, and that of the secondary or granulating inflammation. Mr. Saunders endeavoured to cut the disease short in the first stage, by exciting nausea, and maintaining it for a considerable length of time, so as to lower the living power, and hereby take off the inflammatory action: and where the disease had proceeded to the granulating stage, he removed the minute caruncles from the membrane, by cutting them off with a pair of scissars, and afterwards applied a solution of nitrate of silver, to prevent their sprouting again. The late Sir William Adams proceeded with the same practice, but more boldly: he gave a grain or two of tartar emetic, every one, two, or three hours, to vomit briskly, and went on with it through the whole of the disease, and pared or sliced away the diseased surface of the conjunctive membrane with a knife, and washed the parts with a solution of alum. His practice was more radical and effectual.

The *Gonorrhœal form of ophthalmia* presents the symptoms of purulent inflammation of the conjunctiva in its most intense form. It was formerly believed to arise from a metastasis of the disease, from the genital organs to the eyes; but more accurate investigation has shown that where the ophthalmic affection is really connected with gonorrhœa, it arises from the gonorrhœal matter being in some accidental manner directly applied to the eye. The treatment does not differ from that of the other forms of purulent ophthalmia.

The other variety attacks *new-born children*. This purulent ophthalmia of infants occurs very soon after birth, and is usually produced by cold; though, in some instances, it may arise from the irritation of acrimonious or specific secretions. It usually makes its appearance within the first week or fortnight from birth. The eyelids look red, and swell rapidly to such a size that it is difficult to separate them. A discharge of a yellow purulent fluid quickly succeeds, which, upon opening the lids, is found to cover the whole globe of the eye; and, from the forcible pressure of lid against lid, both are greatly thickened, and not unfrequently everted.

The late Mr. Ware, whose practice was very extensive, always found the aqua camphorata of Bates's pharmacopœia the best application: others prefer the solution of alum and acetate of lead, in the proportion of one grain to an ounce of distilled water. One of these should be passed round the eye, by means of an ivory syringe, about every six or eight hours; and this should be performed by a skilful operator. The child's bowels are to be kept open, and, if the disease do not give way, a small blister, kept on a few hours, may be serviceable.

Of late years, a very important improvement has been introduced in the treatment of the different forms of purulent inflammation of the conjunctiva, namely, the application of nitrate of silver to its surface. Dr. Ridgway recommended an aqueous solution, in the proportion of twelve grains to an ounce of water. Mr. Guthrie uses an ointment containing ten grains of the nitrate, to a drachm of lard. The caustic must be very finely levigated, and reduced to an impalpable powder, otherwise any granules that may remain will prove a source of severe irritation.

II. *Ophthalmitis tarsalis*. Here the inflammation is confined to the eyelids, and especially to the sebaceous glands, between the conjunctive membrane and the tarsus. Mr. Ware and Dr. Plenk called it *psorophthalmia*. It consists in an inflamed state of Meibomius's or the sebaceous glands, the ducts of which open on the edge of each eyelid, which causes them to pour forth a viscid or glutinous matter, that encrusts and hardens, and during sleep, when the eyelids have been for some time in contact, cements them so firmly together, that they cannot be separated without many a painful effort. This secretion, instead of being mild and lubricant, as in health, is now not only viscid, but acrimonious and erosive: whence the eye is irritated, and the edges of the lids ulcerated; and the disease is apt to become chronic, and will sometimes last for years, or even for life.

Measles and small-pox produce this disease, and any of the common exciting causes of inflammation upon a scrofulous habit.

It is more under the influence of local stimulants than any other medicines. The unguentum hydrargyri nitratis is, of all others, the best, lowered by common cerate, so as just to produce a bearable pain, when applied by a

pencil-brush every night, or occasionally. A drop of the vinum opii into the eye at bed-time, has, in some cases, been useful; and the vapour of oil of turpentine in others.

The several varieties of ophthalmitis which have been considered, occasionally leave a chronic form of disease, called *lippitudo*, which consists in a weakness and weeping of the eyes, with more or less, and generally very little, redness, and a thickened tarsus, which is sometimes inverted, with a permanent redness of the edge.

Scarifying the eyelid is serviceable before any inversion takes place; but nothing short of an operation will return the eyelid, when everted. The astringent collyria are all serviceable in their turn; and the unguentum hydrargyri nitrati is here, also, an excellent application. See *Lippitudo*, and *Ectropium*.

III. *Sclerotitis.* Inflammation of the sclerotica. In this affection the inflamed vessels are distinctly seen to be under the conjunctiva, and a bright red zone round the cornea. The cornea and pupil look hazy, and sometimes the iris participates in the inflammation, but seldom in any severe degree. The pupil, however, is generally somewhat contracted and sluggish in its movements. The pain becomes aggravated towards night, and there is a considerable degree of symptomatic fever and derangement of the general functions of the system.

This form of disease has been called *rheumatic ophthalmia*, but it does not appear to have any connexion with rheumatism. The treatment is not materially different from that of conjunctival ophthalmia, with this exception, that the application of nitrate of silver, which is so eminently useful in the purulent ophthalmia, is always injurious in sclerotitis.

IV. *Corneitis.* Inflammation of the cornea. This is a chronic disease, most common in the scrofulous constitution, and about the age of puberty. It lasts for months, and sometimes for years. It occupies chiefly the conjunctiva covering the cornea, and the superficial layers of the cornea itself. The redness of the inflamed part is not considerable: the inflamed vessels are small, forming a zone round the cornea, and sometimes ramifying towards its centre. The cornea is somewhat opake and rough, and sometimes streaked or speckled with white. In some cases the convexity of the cornea is increased, which is generally attributed to an augmented secretion of the aqueous humour. There is fever at the commencement of the case, but this soon disappears. The constitutional treatment is that of chronic inflammation in general, with the occasional application of leeches. In the early stage, the local remedies are those adapted to acute ophthalmia; when all active inflammation has ceased, the vinum opii and astringent collyria are applicable. Blisters are very useful throughout the disease.

V. *Iritis.* Inflammation of the iris. This may be acute or chronic, idiopathic or symptomatic, common or specific; and according to these circumstances the symptoms vary considerably. The general symptoms of iritis are a zone of a pale pink colour around the cornea, formed by vessels traversing the sclerotica: as the inflammation advances the redness of the vessels increases, and those of the conjunctiva also become injected; the iris undergoes a remarkable change of colour; if it be naturally dark it becomes reddish brown, if naturally light it becomes greenish. This change of colour arises from the deposition of coagulating lymph in its texture, from which cause, also, its brightness and natural fibrous texture disappear, and it becomes dull and confused; the pupil is irregularly contracted and sluggish. In the severer cases lymph is effused into the chambers of the eye, and the iris contracts adhesions to the capsule of the lens, the cornea, or the ciliary processes; the power of vision is much diminished, and sometimes fails altogether; there is deep-seated pain in the orbit, forehead, and side of the head, which is frequently increased at night.

Acute iritis is usually acompanied with inflammatory fever, but the degree of this varies much in different cases.

Iritis arises from wounds of the iris, from cold, and the other common causes of inflammation, from syphilis, scrofula, gout, and rheumatism.

In the *syphilitic* iritis there is usually more tendency to the effusion of lymph than in the other forms, and the depositions are in the shape of tubercles of a reddish or yellowish brown colour. There is also a yellowish brown discolouration of the inner circle of the iris. The pupil is distorted and drawn to an angle. Like other venereal affections, its symptoms are exacerbated at night. The nature of the case is also pointed out by the pre-existence or concomitancy of syphilitic symptoms. It has been supposed by some that this peculiar variety of iritis is caused, not by syphilis, but by the mercury used for the cure of that disease; but this idea is now known to be incorrect, as syphilitic iritis has been observed in many cases where no mercury had been taken.

In the *gouty* iritis, lymph is usually effused from the margin of the pupil, but in less abundance, and not in a distinct form; and the adhesions are generally white. There is generally more intolerance of light, and more copious flow of tears, in this than in the other forms of iritis. The pupil is contracted, but generally not distorted. A white zone is discernible between the red one and the margin of the cornea. The rheumatic does not differ materially from the gouty iritis.

In common iritis there is less disposition to the effusion of lymph than in the specific forms above mentioned, but little yellow abscesses rise from the surface of the iris, which break and effuse a yellow matter, which subsides to the bottom of the anterior chamber.

Notwithstanding the distinctions laid down by authors between the several varieties of iritis, an attentive consideration of the history of the case will generally be found the best means of diagnosis. There are three prominent indications in the treatment of iritis: first, *to allay the inflammation* which is to be effected by the same means as in common cases of acute ophthal-

mia; secondly, *to prevent the effusion of lymph*, for which the antiphlogistic treatment is available in some degree, but which is most effectually fulfilled by bringing the system speedily under the action of mercury, the effect of which should be induced in a strong degree, and sustained till all danger is over; thirdly, *to prevent adhesions*, which is fulfilled by keeping the pupil dilated with belladonna, but which can only be effected after the acute symptoms are subdued, as the belladonna has no effect on the pupil while active inflammation prevails.

In the treatment of the specific forms of iritis, we must have reference not only to general principles, but to the particular diseased state of the constitution of which they are symptomatic, and select our remedies accordingly: thus colchicum is thought to be particularly efficacious in the arthritic forms, and mercury in the venereal.

VI. The choroid coat and the retina are also liable to inflammation. *Choroiditis* seldom occurs except in connexion with iritis. *Retinitis* is generally the result of over exertion of the sight, in the examination of objects, or of exposure to too vivid a light. Its tendency is to produce amaurosis more or less rapidly, as it is more or less acute. The acute form requires absolute rest of the eye, entire darkness, and the antiphlogistic treatment.

Such are some of the chief phenomena of inflammation, as developed in the different textures of the eye. In many cases the common forms of ophthalmia are combined in one general inflammation of the eyeball, which, if not subdued, terminates in suppuration, and the complete destruction of the organ, which bursts, evacuates its contents, and shrinks into the orbit.

OPHTHALMODY'NIA. (*a*, *æ*. f.; from *οφθαλμος*, an eye, and *οδυνη*, pain.) A vehement pain in the eye, without, or with very little redness, and not produced by inflammation. The sensation of pain is various, as itching, burning, or as if gravel were between the globe of the eye and lids, or a heavy dull pain, or a most excruciating one. It may be the result of rheumatism, gout, hysteria, &c.; or produced by incipient organic diseases, as cancer, fungus hæmatodes; or an affection purely of the nerves. The cure requires the removal of the cause. When an intermittent affection, the internal use of bark is beneficial.

OPHTHALMOPO'NIA. (*a*, *æ*. f.; from *οφθαλμος*, the eye, and *πονος*, pain.) An ill-constructed term, applied by Heister to inflammation of the eye.

OPHTHALMOPTO'SIS. (*is*, *is*. f.; from *οφθαλμος*, an eye, and *πτωσις*, a fall.) A protrusion of the globe of the eye on the cheek, canthus, or upwards, the globe itself being scarce altered in magnitude. The cause is a relaxation of the muscles, and ligamentous expansions of the globe of the eye. It is produced, —

1. By a violent contusion or strong stroke, as happens sometimes in boxing. The eye falls out of the socket on the cheek or canthus of the eye, and, from the elongation and extension of the optic nerve, occasions immediate blindness.

2. By a tumour within the orbit. An exostosis, toph, abscess, encysted tumour, as atheroma, hygroma, or scirrhus, forming within the orbit, or induration of the orbital fat, may throw the bulb of the eye out of the socket upwards, downwards, or towards either canthus.

3. Or it is caused by a palsy of the recti muscles, whence a stronger power in the oblique muscles of the bulb.

4. Sometimes by a staphyloma, when it depresses the inferior eyelid, and extends on the cheek.

O'PIANE. Another name for *narcotine*.

O'PIATE. (*Opiatum*; from the effects being like that of opium.) 1. Any preparation of opium.

2. A medicine that procures sleep, &c. See *Anodyne*.

O'PION. *Οπιον*. Opium.

OPI'STHENAR. (*ar*, *aris*. n.; from *οπισω* backwards, and *θεναρ*, the palm.) The back part of the hand.

OPISTHOCRA'NIUM. (*um*, *ii*. n.; from *οπισθεν* backward, and *κρανιον*, the head.) The occiput or hinder part of the head.

OPI'STHOCYPHO'SIS. (From *οπισθεν*, backward, and *κυφωσις*, a gibbosity.) A curvature of the spine backward.

OPISTHO'TONOS. (*os*, *i*. m.; from *οπισθεν*, backwards, and *τεινω*, to draw.) The form of tetanus, in which the body is bent backwards. See *Tetanus*.

OPISTO-GASTRIC. (*Opisto-gastricus*; from *οπισθεν*, behind, and *γαστηρ*, the stomach.) The Cœliac artery is thus named by Chaussier.

O'PIUM. (*um*, *ii*. n. *Οπιον*, probably from *οπος*, juice.) The inspissated juice of the poppy. See *Papaver somniferum*.

Opium de Rousseau. See *Rousseau's drops*.

OPOBA'LSAMUM. (*um*, *i*. n.; from *οπος*, juice and *βαλσαμον*, balsam.) See *Amyris gileadensis*.

Opocalpason. See *Opocarpason*.

OPOCARPASON. *Opocalpason*. *Οποκαρπασον*. *Οποκαλπασον*. See *Carpasus*.

OPODELDOC. A term of no meaning frequently employed by Paracelsus. Formerly it signified a plaster for all external injuries, but now is confined to the camphorated soap liniment.

OPODELDOC, STEER'S. This is composed of Castille soap, rectified spirit, camphor, oils of rosemary and marjoram, and solution of ammonia.

OPODEOCE'LE. A term applied by Sagar to an ischiatic hernia. How he derived it I pretend not to say.

OPO'PANAX. (*ax*, *acis*. f.; from *οπος* juice, and *παναξ*, the panacea.) See *Pastinaca opopanax*.

OPO'PIA. (*Οπωπια*; from *οπτομαι*, to see. The bones of the eyes.

OPOPONAX. Improperly written for *opopanax*.

OPO'RICE. (*e*, *es*. f.; *Οπωρικη*; from *οπωρα*, autumnal fruits.) A conserve made of ripe fruits.

OPPILA'TION. (*Oppilatio*, *onis*, f.;

oppilo, to shut up.) *Oppilation* is a close kind of obstruction: for, according to Rhodius, it signifies not only shutting out but also filling up.

OPPILATI'VUS. (From *oppilo*, to shut up.) Shutting up the pores of the skin.

OPPO'NENS. Opposing. A name given to some muscles from their office.

Opponens pollicis. See *Flexor ossis metacarpi pollicis.*

OPPOSITIFO'LIUS. (From *oppositus*, set, put, or placed against or opposite to, and *folium*, a leaf.) Applied to a flower-stalk when opposite to a leaf; the *Geranium molle*, and *Sium angustifolium*, afford examples of the *Pedunculus oppositifolius.*

OPPO'SITUS. Opposite to each other: used in *Natural History*, and applied to leaves, branches, &c.; as the leaves of *Saxifraga oppositifolia* and *Ballota nigra.*

OPPRE'SSION. (*Oppressio, onis.* f.) 1. A sensation of weight, as oppression of breathing, when it seems to be difficult to breathe from a sense of weight obstructing respiration: and in like manner, *oppressio præcordiorum*, which is a feeling of pressure about the *præcordia.*

2. The Catalepsy has been called *oppressio cerebri.*

OPSI'GONOS. (From *οψι*, late, and *γινομαι*, to be born.) A late-cut tooth; as the *dens sapientiæ.*

OPTIC. (*Opticus*; from *οπτομαι*, to see.) Relating to vision.

OPTIC COMMISSURE. The union of the optic nerves, in front of the sella turcica. A considerable difference of opinion exists concerning the disposition of the fibrillæ of the optic nerves at their commissure. Some of the earlier anatomists supposed that they were merely applied one to the other, without any actual admixture of their substance; this opinion has now no supporters. Several physiologists are of opinion that a decussation between the nerves of opposite sides takes place, the fibres of that on the right side passing to the left, and *vice versâ*. Others, on the contrary, contend that the decussation, or crossing, exists only to a certain extent, being confined to the fibres on the inner side of each nerve, the rest passing on uninterruptedly. The anatomical examination of the fibrillæ, after the nerves have been macerated in dilute nitric acid, seems to indicate that those on the external border of each of them proceed forwards without admixture, but that several pass obliquely inwards through the commissure, and afterwards form part of the fibres which proceed to the eye of the opposite side: this, at least, is the result of Caldani's observations. Little account can be made of conclusions deduced from experiments on animals; the quantity of injury inflicted by opening the skull, in order to divide the nerves or their commissure, is sufficient to confound all the sensations of the animal, and render any inferences nugatory that may be drawn from them. Observations on the morbid conditions of the nerves have been adduced in support of both opinions: thus, in a case in which the right eye had been destroyed, the optic nerve was found altered and wasted back to the commissure on that side, and thence to the brain at the opposite side; thus supporting the theory of decussation. Some cases have also occurred in which blindness of one eye was traced to a morbid alteration of the nerve of the opposite side, at its origin from the brain. Some other instances, however, would go to prove that the decussation is only partial. In one instance in which the eye had been destroyed, and its nerve altered in texture for some way, it was found that the external fibres of the diseased nerve could be traced from the commissure directly backwards to the brain at the same side, so could the external fibres of the sound nerve; thus showing that no decussation took place between them; but the internal fibres of the diseased nerve could be traced obliquely through the commissure, and also backwards along the inner side of the opposite nerve to its origin, whilst the inner fibres of the sound nerve seemed, but not so distinctly, to cross also to the opposite side. Each of these opposing opinions, then, is borne out by the observations to a certain extent; so that the advocates of them are not warranted in concluding that either is universally true. Professor Meckel supposes that the anterior or orbital parts of the nerves issue from a common point (the commissure), produced by a union of the fibres which are prolonged from the brain, and that the mode of union is not quite identical in all cases, for that, in the different other structures which are joined along the middle line, varieties in the manner and degree of their union are constantly observed to occur.

Otto remarks, that in cyclopic monsters, and in hemicephalic cases, the optic nerves have been seen to run apart and without a commissure; and that in dropsy of the brain, the commissure has been observed torn asunder, and, instead of crossing, only connected by a transverse portion of nerve. — *Quain.*

OPTIC NERVES. *Nervi optici.* The second pair of nerves of the brain. See *Nerve.*

OPU'NTIA. (*a, æ.* f.; *ab opunte*, from the city *Opus*, near which it flourished.) See *Cactus.*

ORA SERRATA. The posterior serrated edge of the ciliary processes is so called.

Orache. See *Atriplex sativa*, and *Chenopodium.*

Orange. See *Citrus aurantium.*

ORANGE PEAS. The immature fruit of the Curaçoa orange. See *Aurantia curassaventia.*

Orange, Seville. See *Citrus aurantium.*

Orange, shaddock. See *Shaddock.*

ORBI'CULAR. (*Orbicularis*; from *orbiculus*, a little ring.) Round: a term in very general use in *Natural History*, *Anatomy*, &c. See *Orbiculatus.*

ORBICULA'RE OS. 1. The name of a bone of the carpus.

2. A very small bone of the internal ear. See *Auris.*

ORBICULARIS ORIS. *Sphincter labiorum*, of Douglas; *semi-orbicularis*, of Winslow; *constrictor oris*, of Cowper. A muscle of the mouth, formed in a great measure by those of the lips; the fibres of the superior descending

those of the inferior ascending and decussating each other about the corner of the mouth, they run along the lip to join those of the opposite side, so that the fleshy fibres appear to surround the mouth like a sphincter. Its use is to shut the mouth, by contracting and drawing both lips together, and to counteract all the muscles that assist in opening it.

Orbicularis palpebrarum. A muscle common to both the eyelids. *Orbicularis palpebrarum ciliaris*, of authors. It arises by a number of fleshy fibres from the outer edge of the orbitar process of the superior maxillary bone, and from a tendon near the inner angle of the eye; these fibres run a little downwards and outwards, over the upper part of the cheek, below the orbit, covering the under eyelid, and surround the external angle, being closely connected only to the skin and fat; they then run over the superciliary ridge of the os frontis, towards the inner canthus, where they mix with the fibres of the occipito-frontalis and corrugator supercilii: then covering the upper eyelid, they descend to the inner angle opposite to their inferior origin, and firmly adhere to the internal angular process of the os frontis, and to the short round tendon which serves to fix the palpebræ and muscular fibres arising from it. It is inserted into the nasal process of the superior maxillary bone, by a short round tendon, covering the anterior and upper part of the lachrymal sac, which tendon can be easily felt at the inner canthus of the eye. The use of this muscle is to shut the eye, by drawing both lids together, the fibres contracting from the outer angle towards the inner, press the eyeball, squeeze the lachrymal gland, and convey the tears towards the puncta lachrymalia.

Orbicularis palpebrarum ciliaris. See *Orbicularis palpebrarum.*

ORBICULA'TUS. Orbiculate: round and flat. Applied to a leaf that is circular or orbicular, the length and breadth being equal, and the circumference an even circular line. Precise examples of this are scarcely to be found. Some species of pepper approach it, and the leaf of the *Hedysarum styracifolium* is perfectly orbicular, except a notch at the base.

Orbiculus ciliaris. The ciliary circle. See *Oculus.*

O'RBIT. (*Orbitum, i.* n.) The two cavities under the forehead, in which the eyes are situated, are termed orbits. Each orbit is composed of seven bones, viz., the frontal, maxillary, jugal, lachrymal, ethmoid, palatine, and sphenoid. The use of this bony socket is to maintain and defend the organ of sight, and its adjacent parts.

Orbitary foramina. See *Frontis os.*

Orchi'deæ. The name of an order in Linnæus's Fragments of a Natural Method, consisting of plants which are allied to the orchis.

Orchilla. Archil. See *Lichen roccella.*

O'RCHIS. (*is, is.* m. Ορχις.) 1. A testicle.

2. (*Orchis, itis.* f.; so called *quia habet radices instar testiculorum.*) The name of a genus of plants in the Linnæan system. Class, *Gynandria;* Order, *Diandria.*

Orchis bifolia. The systematic name of the butterfly orchis, the root of which is used indifferently with that of the male orchis. See *Orchis mascula.*

Orchis mascula. The systematic name of the male orchis; called also, dog's stones, male orchis, and satyrion.

Orchis — bulbis indivisis, nectarii labio quadrilobo crenulato, cornu obtuso petalis dorsalibus reflexus, of Linnæus. The root had once a place in the Materia Medica of the Edinburgh Pharmacopœia, on account of the glutinous slimy juice which it contains. The root of the *orchis bifolia* is also collected. Satyrion root has a sweetish taste, a faint and somewhat unpleasant smell. Its mucilaginous or gelatinous quality has recommended it as a demulcent. Salep, which is imported here from the East, is a preparation of an analogous root which is considered as an article of diet, is accounted extremely nutritious, as containing a great quantity of farinaceous matter in a small bulk. The supposed aphrodisiac qualities of this root, which have been noticed ever since the days of Dioscorides, seem to be founded on the fanciful doctrine of signatures.

Orchis morio. The systematic name of the orchis plant, from the root of which the salep is made. Salep is a farinaceous powder imported from Turkey. It may be obtained from several other species of the same genus of plants. It is an insipid substance, of which a small quantity, by proper management, converts a large portion of water into a jelly, the nutritive powers of which have been greatly over-rated. Salep forms a considerable part of the diet of the inhabitants of Turkey, Persia, and Syria. The method of preparing salep is as follows: — The new root is to be washed in water, and the fine brown skin which covers it is to be separated by means of a small brush, or by dipping the root in warm water, and rubbing it with a coarse linen cloth. The roots thus cleaned are to be spread on a tin plate, and placed in an oven heated to the usual degree, where they are to remain six or ten minutes. In this time they will have lost their milky whiteness, and acquired a transparency like horn, without any diminution of bulk. Being arrived at this state they are to be removed in order to dry and harden in the air, which will require several days to effect; or they may be dried in a few hours, by using a very gentle heat. Salep, thus prepared, contains a great quantity of vegetable aliment: as a wholesome nutriment, it is much superior to rice; and has the singular property of concealing the taste of salt water. Hence, to prevent the dreadful calamity of famine at sea, it has been proposed that the powder of it should constitute part of the provisions of every ship's company. With regard to its medicinal properties, it may be observed, that its restorative, mucilaginous, and demulcent qualities render it of considerable use in various diseases when employed as aliment, particularly in scurvy, diarrhœa, dysentery, symptomatic fevers arising from the absorption of pus, and the stone or gravel.

ORCHI'TIS. (*is, idis.* f.; from ορχις testicle.) Inflammation of the testicle: which

being always accompanied by a swelling, and the swelling being simultaneous nearly with the inflammation, the disease is better known by the name of swelled testicle than inflamed testicle. The most common cause of it is a suppression of the discharge of a clap; but it takes place from blows, and all the causes of inflammation. When it takes place in the progress of a clap it is a sympathetic inflammation, and it often follows every kind of irritation on the urethra, whether produced by strictures, injections, or bougies. The swelling and inflammation appear suddenly, and as suddenly disappear, or go from one testicle to the other. The epididymis remains swelled, however, even for a considerable time afterwards.

The first appearance of swelling is generally a soft pulpy fulness of the body of the testicle, which is tender to the touch: this increases to a hard swelling, accompanied with considerable pain. The epididymis, towards the lower end of the testicle, is generally the hardest part. The hardness and swelling, however, often pervade the whole of the epididymis. The spermatic cord, and especially the vas deferens, are often thickened, and sore to the touch. The spermatic veins sometimes become varicose. A pain in the loins, and sense of weakness there, and in the pelvis, are other casual symptoms. Colicky pains, uneasiness in the stomach and bowels, flatulency, sickness, and even vomiting, are not unfrequent. The whole testicle is swelled, and not merely the epididymis, as has been asserted.

The inflammation of the part most probably arises from its sympathising with the urethra. The swelling of the testicle coming on, either removes the pain in making water, and suspends the discharge, which does not return till such swelling begins to subside, or else the irritation in the urethra, first ceasing, produces a swelling of the testicle, which continues till the pain and discharge return; thus rendering it doubtful which is the cause and which the effect. Occasionally, however, the discharge has become more violent, though the testicle has swelled; and such swelling has even been known to occur after the discharge has ceased; but the latter has returned with violence, and remained as long as the hernia humoralis.

Orchitis, with stoppage of the discharge, is apt to be attended with strangury. A very singular thing is, that the inflammation more frequently comes on when the irritation in the urethra is going off, than when at its height.

This disease requires perfect rest, and the same treatment as inflammation of any other viscus. Blood must be taken from the arm, and from the part; the general blood-letting repeated according to the degree of the accompanying fever, and the leeches to be repeated as long as there is much local heat: after which, cold lotions to the part. The bowels are to be purged from time to time, and a strict antiphlogistic diet enforced as long as there is feverish excitement. Opiates at bed-time are required when there is much pain.

O'RCHOS. (From *ορχος*, a plantation or vineyard: so called from the regularity with which the hairs are inserted.) The extremities of the eyelids, where the eyelashes grow.

ORCHO'TOMY. (*Orchotomia*, *æ.* f.; from *ορχις*, a testicle, and *τεμνω*, to cut.) Castration. The operation of extracting a testicle.

OREOSELI'NUM. (*um*, *i.* n.; from *ορος*, a mountain, and *σελινον*, parsley: so named because it grows wild upon mountains.) See *Athamanta oreoselinum*.

ORE'XIS. (From *ορεγομαι*, to desire.) A desire or appetite.

ORGAN. (*Οργανον*. *Organum*, *i.* n.) An organ is a part of an animal or vegetable which has a determined office in its economy: thus the eye is the organ of vision, and the ear of hearing; the muscles are the organs of motion, &c. A catenation of organs destined to one function is called an apparatus: thus, although the lungs be the immediate organ of respiration, the *apparatus* of respiration consists of the lungs, air passages, muscles and nerves, &c. of respiration, without which the function could not be performed.

ORGA'NIC. (*Organicus*; from *organum*, an organ.) 1. Possessed of organs; appertaining to organisation, or susceptible of organisation: thus we speak of organic bodies, organic functions, and organic matter.

2. Relating to an organ: pathologists call those *organic diseases* in which there is a visible change in the structure of the organ, as opposed to *diseases of function*, in which the action only of the organ is changed.

ORGANISA'TION. *Organisatio*. The construction of the parts of an animal or vegetable body, with reference to a determined function.

O'RGANISM. This term is generally applied to the sum total of the organs and powers which give rise to the phenomena of life in any living being.

O'RGASM. (*Orgasmus*, *i.* m. *Οργασμος*; from *οργαω*, to desire vehemently.) A state of excitement and vital turgescence of any organ: applied especially to the organs of generation, the excitement of which is termed the *venereal orgasm*.

ORGA'STICA. Diseases affecting the *orgasm*. The second order of the class *genetica* in Good's Nosology.

Orichalcum. See *Aurichalcum*.

ORI'CIA. (From *Oricus*, a city of Epirus, near which it grew.) A species of fir or turpentine tree, from Oricus.

ORIENTA'LIA FOLIA. The leaves of senna were so called.

ORI'GANUM. (*um*, *i.* n.; *Ορειγανον*.) 1. The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia*.

2. The pharmacopœial name of the wild marjoram. See *Origanum vulgare*.

Origanum creticum. See *Origanum dictamnus*.

ORIGANUM DICTAMNUS. The systematic name of the dittany of Crete. *Dictamnus creticus*; called also, *Origanum creticum*, and *Onitis*. The leaves of this plant, *Origanum — foliis inferioribus tomentosis, spicis nutantibus*, are now rarely used. They have been recommended as emmenagogue and alexipharmic.

Origanum marjora'na. The systematic name of sweet marjoram: called also, *Majorana*. This plant, *Origanum — foliis ovatis obtusis, spicis subrotundis compactis pubescentibus*, of Linnæus, has been long cultivated in our gardens, and is in frequent use for culinary purposes. The leaves and tops have a pleasant smell, and a moderately warm, aromatic, bitterish taste. They yield their virtues to aqueous and spirituous liquors, by infusion, and to water in distillation, affording a considerable quantity of essential oil. The medicinal qualities of the plant are similar to those of the wild plant (see *Origanum vulgare*); but being much more fragrant, it is thought to be more cephalic, and better adapted to those complaints known by the name of nervous; and may therefore be employed with the same intentions as lavender. It was directed in the *pulvis sternutatorius*, by both pharmacopœias, with a view to the agreeable odour which it communicates to the asarabacca, rather than to its errhine power, which is very inconsiderable; but it is now wholly omitted in the Pharm. Lond. In its recent state, it is said to have been successfully applied to scirrhous tumours of the breast.

Origanum syri'acum. The Syrian herb mastich. See *Teucrium marum*.

Origanum vulgare. The systematic name of the wild marjoram; also named, *Agriioriganum*, *Marjorana*, *Mancurana*, *Origanum heracleoticum*, *Onitis*, and *Zazarhendi herba*.

Origanum — spicis subrotundis paniculatis conglomeratis, bractis calyce longioribus ovatis, of Linnæus. This plant grows wild in many parts of Britain. It has an agreeable aromatic smell, approaching to that of marjoram, and a pungent taste, much resembling thyme, to which it is likewise thought to be more allied in its medicinal qualities, and therefore deemed to be emmenagogue, tonic, stomachic, &c. The dried leaves, used instead of tea, are said to be exceedingly grateful. They are employed in medicated baths and fomentations.

Oris constrictor. See *Orbicularis oris*.

Orleana terra. Annotto. See *Bixa orellana*.

Ormskirk medicine. An alleged remedy for hydrophobia, invented by a Mr. Hill of Ormskirk. See *Hydrophobia*.

ORNITHOPO'DIUM. (*um, ii.* n.; from *ορνις*, a bird, and *πους*, a foot: so called from the likeness of its pods to a bird's claw.) Bird's foot. The *Ornithopus perpusillus*, and the *Ornithopus scorpioides*, of Linnæus, have been both so called.

OROBA'NCHE. (*e, es.* f.; from *οροβος*, the wild pea, and *αγχω*, to suffocate: so called because it twines round the orobus, and destroys it.) The name of a genus of plants in the Linnæan system. Classes, *Gynandria* and *Didynamia*; Order, *Angiospermia*.

Orobry'chis. (From *οροβος*, the wood-pea, and *βρυχω*, to eat.) The same as orobanche.

O'ROBUS. (*us, i.* m.; from *ερεπτω*, to eat.) (?) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria*.

2. The pharmacopœial name of the ervum. See *Ervum*.

Orobus tuberosus. The heath-pea. The root of this plant is said to be nutritious. The Scotch islanders hold these peas in great esteem, and chew them like tobacco.

Oroselinum. See *Oreoselinum*.

ORPIMENT. (*Orpimentum, i.* n.) A sulphuret of arsenic. See *Arsenic*.

Orpine. See *Sedum telephium*.

O'rrhos. (Ὀρρὸς.) Serum; whey.

Orrhos. (Ὄρρος.) 1. The perinæum.

2. The extremity of the sacrum.

Orris. See *Iris*.

Orris, Florentine. See *Iris florentina*.

Orseille. See *Lichen roccella*.

ORTHOCO'LON. (*on, i.* m.; from *ορθος*, straight, and *κωλον*, a limb.) A stiff joint with an extended state of the limb.

ORTHOPNŒ'A. (*a, æ.* f.; from *ορθος*, erect, and *πνοη*, breathing.) Inability of breathing in the recumbent posture, so that the patient is obliged to sleep propped up by pillows, as in hydrothorax and other cases.

Orva'le. (*Orvale*, French.) A species of clary or horminum.

Orvieta'num. A medicine once celebrated as an antidote to poisons; so named from a mountebank, called *Orvietanus*, who invented it, or from *Orvieto*, a town in the Papal territories where it was invented.

ORY'ZA. (*a, æ.* f.; from *orez*, Arabic.) 1. The name of a genus of plants in the Linnæan system. Class, *Triandria*; Order, *Digynia*. The rice plant.

2. The pharmacopœial name for rice. See *Oryza sativa*.

Oryza sativa. The systematic name of the plant which affords the rice, which is the principal food of the inhabitants in all parts of the East, where it is boiled, and eaten either alone or with their meat. Large quantities of it are annually sent into Europe, and it meets with a general esteem for family purposes. The people of Java have a method of making puddings of rice which seems to be unknown here; but it is not difficult to put in practice if it should merit attention. They take a conical earthen pot, which is open at the large end, and perforated all over. This they fill about half full with rice, and putting it into a large earthen pot of the same shape, filled with boiling water, the rice in the first pot soon swells, and stops the perforations, so as to keep out the water. By this method the rice is brought to a firm consistence, and forms a pudding, which is generally eaten with butter, oil, sugar, vinegar, and spices. The Indians eat stewed rice with good success against the bloody flux; and in most inflammatory disorders they cure themselves with only a decoction of it. The spirituous liquor called arrack is made from this grain. Rice grows naturally in moist places, and will not come to perfection, when cultivated, unless the ground be sometimes overflowed, or plentifully watered. The grain is of a grey colour when first reaped; but the growers have a method of whitening it before it is sent to market. The manner of performing this, and beating it out, in Egypt, is thus described by Hasselquist: — They have hollow iron cylin-

drical pestles, about an inch in diameter, lifted by a wheel worked with oxen. A person sits between the pestles, and, as they rise, pushes forward the rice, whilst another winnows and supplies fresh parcels. Thus they continue working until it is entirely free from chaff. Having in this manner cleaned it, they add one thirtieth part of salt, and rub them both together, by which the grain acquires a whiteness; then it is passed through a sieve, to separate the salt again from it. In the island of Ceylon they have a much more expeditious method of getting out the rice; for, in the field where it is reaped, they dig a round hole, with a level bottom, about a foot deep, and eight yards in diameter, and fill it with bundles of corn. Having laid it properly, the women drive about half a dozen oxen continually round the pit; and thus they will tread out forty or fifty bushels a day. This is a very ancient method of treading out corn, and is still practised in Africa upon other sorts of grain.

OS. 1. (*Os, ossis.* n.; supposed to be derived from the Hebrew *ozam*, strength.) A bone: a hard, dry, insensible part of the body, of a whitish colour, and composed of a spongy, compact, or reticular substance. Bones vary much in their appearances, some being long and hollow, others flat and compact, &c. The greater number of bones have several processes and cavities, which are distinguished from their figure, situation, use, &c. Thus, processes extended from the end of a bone, if smooth and round, are called *heads;* and *condyles*, when flattened either above or laterally. That part which is beneath the head, and which exceeds the rest of the bone in smallness and levity, is called the neck. Rough, unequal processes are called *tuberosities*, or tubercles: but the longer and more acute, *spinous*, or *styloid* processes, from their resemblance to a thorn. Thin broad processes, with sharp extremities, are known by the name of *cristæ*, or *sharp edges*. Other processes are distinguished by their form, and called *alar*, or *pterygoid; mamillary*, or *mastoid; dentiform*, or *odontoid*, &c. Others, from their situation, are called *superior*, *inferior*, *exterior*, and *interior*. Some have their name from their direction; as *oblique*, *straight*, *transverse*, &c.; and some from their use, as *trochanters*, *rotators*, &c. *Furrows*, *depressions*, and *cavities*, are destined either for the reception of contiguous bones, to form an articulation with them, when they are called *articular cavities*, which are sometimes deeper, sometimes shallower; or they receive hard parts, but do not constitute a joint with them. Cavities serve also for the transmission and attachment of soft parts. Various names are given to them, according to the magnitude and figure of bones. If they be broad and large at the beginning, and not deep, but contracted at their ends, they are called *foveæ*, or *pits*. Furrows are open canals, extending longitudinally in the surface of bones. A hollow, circular tube, for the most part of the same diameter from beginning to end, and more or less crooked or straight, long or short, is named a *canal*. *Foramina* are the apertures of canals, or they are formed of the excavated margins of two bones, placed against each other. If such be the form of the margin of a bone, as if a portion were taken out of it, it is called a *notch*. Respecting the formation of bones, see *Osteogeny*.

Chemical analysis. — Calcined human bones, according to Berzelius, are composed, in 100 parts, of 81·9 phosphate of lime, 3 fluate of lime, 10 lime, 1·1 phosphate of magnesia, 2 soda, and 2 carbonic acid. 100 parts of bones by calcination are reduced to 63. Fourcroy and Vauquelin found the following to be the composition of 100 parts of ox bones: 51 solid gelatine, 37·7 phosphate of lime, 10 carbonate of lime, and 1·3 phosphate of magnesia; but Berzelius gives the following as their constituents: 33·3 cartilage, 55·35 phosphate of lime, 3 fluate of lime, 3·85 carbonate of lime, 2·05 phosphate of magnesia, and 2·45 soda, with a little common salt.

About 1-30th of phosphate of magnesia was obtained from the calcined bones of fowls, by Fourcroy and Vauquelin. When the enamel of teeth, rasped down, is dissolved in muriatic acid, it leaves no albumen like the other bones. Fourcroy and Vauquelin state its components to be, 27·1 gelatine and water, 72·9 phosphate of lime. Messrs. Hatchett and Pepys rate its composition at 78 phosphate of lime, 6 carbonate of lime, and 16 water and loss. Berzelius, on the other hand, found only 2 per cent. of combustible matter in teeth. The teeth of adults by Mr. Pepys, consist of 64 phosphate of lime, 6 carbonate of lime, 20 cartilage, and 10 water or loss. The fossil bones from Gibraltar are composed of phosphate of lime and carbonate, like burnt bones. Much difference of opinion exists with regard to the existence of fluoric acid in the teeth of animals, some of the most eminent chemists taking opposite sides of the question. It appears that bones buried for many centuries still retain their albumen, with very little diminution of its quantity.

Fourcroy and Vauquelin discovered phosphate of magnesia in all the bones they examined, except human bones. The bones of the horse and sheep afford about 1-36th of phosphate of magnesia; those of fish nearly the same quantity as those of the ox. They account for this by observing, that phosphate of magnesia is found in the urine of man, but not in that of animals, though both equally take in a portion of magnesia with their food.

The experiments of Mr. Hatchett show, that the membranous or cartilaginous substance, which retains the earthy compound within its interstices, and appears to determine the shape of the bone, is albumen. Mr. Hatchett observes, that the enamel of tooth is analogous to the porcellaneous shells, while mother-of-pearl approaches in its nature to true bone.

A curious phenomenon with respect to bones is the circumstance of their acquiring a red tinge, when madder is given to animals with their food. The bones of young pigeons will thus be tinged of a rose-colour in twenty-four hours, and of a deep scarlet in three days; but the bones of adult animals will be a fortnight in acquiring a rose-colour. The bones most remote from the heart are the longest in acquiring this tinge. Mr. Gibson informs us, that extract of log-wood, too, in considerable quantity, will tinge the bones of young pigeons purple. On desisting from the use of this food, however, the colouring matter is again taken up into the circulation, and carried off, the bones regaining their natural hue in a short time. It was said by Du Hamel, that the bones would become coloured and colourless in concentric layers, if an animal were fed alternately one week with madder, and one week without; and hence he inferred that the bones were formed in the same manner as the woody parts of trees. But he was mistaken in the fact; and indeed, had it been true, with the inference he naturally draws from it, the bones of animals must have been out of all proportion larger than they are at present.

Bones are of extensive use in the arts. In their natural state, or dyed of various colours, they are made into handles of knives and forks, and numerous articles of turnery. The manufacture is now very general of volatile alkali from bones, the coal of which forms bone-black; or if they be afterwards calcined to whiteness in the open air, they constitute the bone ashes of which cupels are made, and which, finely levigated, are used for cleaning articles of paste, and some other trinkets, by the name of burnt hartshorn. The shavings of hartshorn, which is a species of bone, afford an elegant jelly; and the shavings of other bones, of which those of the calf are the best, are often employed in their stead. On this principle, Mr. Proust has recommended an economical use of bones, particularly with a view to improve the subsistence of the soldier. He first chops them into small pieces, throws them into a kettle of boiling water, and lets them boil about a quarter of an hour. When this has stood till it is cold, a quantity of fat, excellent for culinary purposes when fresh, and at any time fit for making candles, may be taken off the liquor. This, in some instances, amounted to an eighth, and in others even to a fourth, of the weight of the bones. After this the bones may be ground, and boiled in eight or ten times their weight of water, of which that already used may form a part, till about half is wasted, when a very nutritious jelly will be obtained. The boiler should not be of copper, as this metal is easily dissolved by the jelly; and the cover should fit very tight, so that the heat may be greater than that of boiling water, but not equal to that of Papin's digester, which would give it an empyreuma. The bones of meat that have been boiled are nearly as productive as fresh bones; but Dr. Young found those of meat that had been roasted afforded no jelly, at least by simmering, or gentle boiling.

2. (*Os, oris.* n.; from *οσσα*, the voice.) (?) The mouth. 1. In *Anatomy*, applied to openings of parts; as *externum* and *internum*, *os tincæ*, &c.

2. In *Botany*, applied to flowers, &c. which resemble the mouth of certain animals; as the flower of the snapdragon, which is called *os leonis*, &c. See *Faux*, and *Mouth*.

Os EXTERNUM. The entrance into the vagina is so named, in opposition to the mouth of the *uterus*, which is called the *os internum*.

Os INTERNUM. The orifice or mouth of the uterus.

Os leonis. The *Antirrhinum linaria*.

Os spongiosum. The spongy bones are two in number, and are called *ossa spongiosa inferiora*. The ethmoid bone has two turbinated portions, which are sometimes called the superior spongy bones. These bones, which, from their shape, are sometimes called *ossa turbinata*, have, by some anatomists, been described as belonging to the ethmoid bone; and by others, as portions of the ossa palati. In young subjects, however, they are evidently distinct bones. They consist of a spongy lamella in each nostril. The convex surface of this lamina is turned towards the septum narium, and its concave part towards the maxillary bone, covering the opening of the lachrymal duct into the nose. From their upper edge arise two processes: the posterior of these, which is the broadest, hangs, as it were, upon the edge of the antrum highmorianum; the anterior one joins the os unguis, and forms a part of the lachrymal duct. These bones are complete in the fœtus. They are lined with the pituitary membrane; and, besides their connexion with the ethmoid bone, are joined to the ossa maxillaria superiora, ossa palati, and ossa unguis. Besides these ossa spongiosa inferiora, there are sometimes two others, situated lower down, one in each nostril. These are very properly considered as a production of the sides of the maxillary sinus turned downwards. In many subjects, likewise, we find other smaller bones standing out into the nostrils, which, from their shape, might also deserve the name of *turbinata*, but they are uncertain in their size, situation, and number.

Os tincæ. See *Tincæ os*.

Osce'do. (*o, inis.* f.) The thrush. Also yawning. — *Turton*.

O'scheal. (*Oschealis*; from οσχεον, the scrotum.) Relating to the scrotum.

OSCHEOCE'LE. (*e, es.* f.; from οσχεον, the scrotum, and κηλη, a tumour.) 1. Any tumour of the scrotum.

2. A scrotal hernia. See *Hernia*.

O'SCHEON. Οσχεον. The scrotum.

Oscheophy'ma. (*a, atis.* n.; from οσχεον, the scrotum, and φυμα, a tumour.) A swelling of the scrotum.

Oscilla'tio. Oscillation. Boerhaave gives this name to muscular irritability.

Osculato'rius. (From *osculo*, to kiss: so called because the action of kissing is performed by it.) The sphincter muscle of the lips.

O'SMAZOME. If cold water, which has been digested for a few hours on slices of raw muscular fibre, with occasional pressure, be evaporated, filtered, and then treated with pure alkohol, a peculiar animal principle will be dissolved, to the exclusion of the salts. By dissipating the alkohol with a gentle heat, osmazome is obtained. It has a brownish yellow colour, and the taste and smell of soup. Its aqueous solution affords precipitates, with infusion of nut-galls, nitrate of mercury, and nitrate and acetate of lead. According to some experiments lately published by Gsell, Gmelin, and Vienholt, osmazome has been found in most of the component parts of the body, as well solids as fluids, although in very different proportions.

OS'MIUM. A metal discovered by Tennant among fragments of crude platina, and so called by him from the pungent and peculiar smell of its oxide.

Osmund. See *Osmunda regalis*.

OSMU'NDA. (*a, æ.* f.; from *Osmund*, who first used it.) The name of a genus of plants. Class, *Cryptogamia*; Order, *Filices*.

Osmunda lunaria. See *Ophioglossum lunaria*.

Osmunda regalis. The systematic name of the osmund-royal. *Filix florida*. *Ophioglossum osmunda*. Its root possesses astringent and emmenagogue virtues. The young shoots, made into a conserve, are said to be a specific for the rickets.

O'sphys. Οσφυς. The loins.

Ossa incisoria. See *Ossa Intermaxillaria*.

Ossa intermaxillaria. Quadrupeds have two bones of the face which do not exist in man. They are situated between the superior maxillary bones, and are called *ossa intermaxillaria*, *ossa incisoria*, or *ossa labialia*. These bones contain the roots of the incisor teeth in animals which possess these teeth, but they exist also in the edentata.

Ossa labialia. See *Ossa intermaxillaria*.

Ossa spongiosa. See *Os spongiosum*.

O'sseous. (*Osseus*; from *os*, a bone.) Bony.

OSSI'CULUM. (*um, i.* n.; diminutive of *os*, a bone.) A little bone.

Ossicula auditus. The small bones of the internal ear are four in number; viz. the malleus, incus, stapes, and os orbiculare; and are situated in the cavity of the tympanum. See *Auris*.

Ossicula Bertini. *Cornua sphenoidalia*. The triangular processes of the sphenoid bone, or *ossa triangularia*, are so named after Bertin, who described them.

OSSIFICA'TION. (*Ossificatio, onis*, f.; from *os*, a bone, and *facio*, to make.) Ossification, or the formation of bone. See *Osteogeny*.

Ossi'fragus. (*us, i.* m.; from *os*, a bone, and *frango*, to break.) *Ossifraga*. Bone-breaker. See *Osteocolla*.

OSSI'VORUS. (From *os*, a bone, and *voro*, to devour.) An epithet given by Ruysch to a particular kind of tumour occurring in the thigh.

OS'TAGRA. (From οστεον, a bone, and αγρα, seizure.) A forceps to take out bones with.

Ostei'tes. (From οστεον, a bone.) The bone-binder. See *Osteocolla*.

OSTEOCO'LLA. (*a, æ.* f.; from οστεον, a bone, and κολλαω, to glue.) Glue-bone, stone, or bone-binder: called also, *Ossifraga*, *Holosteus*, *Osteites*, *Amosteus*, *Osteolithos*, and *Stelochites*. A particular carbonate of lime found in some parts of Germany, particularly in the Marché of Brandenburg, and in other countries. It is met with in loose sandy grounds, spreading from near the surface to a considerable depth, into a number of ramifications, like the roots of a tree. It is of a whitish colour, soft whilst under the earth, friable when dry, rough on the surface, for the most part either hollow within, or filled with a solid wood, or with a powdery white matter. It was formerly celebrated for promoting the coalition of fractured bones, and the formation

of callus, which virtues are not attributed to it in the present day.

Osteogene'ticus. (From *οστεον*, a bone, and *γενναω*, to generate.) Applied to that which favours the formation of bone or callus.

Osteoge'nicus. Improperly written for *osteogenecticus*.

OSTEO'GENY. (*Osteogenia*, *æ*. f.; from *οστεον*, a bone, and *γενεια*, generation.) The growth of bones. Bones are either formed between membranes, or in the substance of cartilage; and the bony deposition is effected by a determined action of arteries. The secretion of bone takes place in cartilage in the long bones, as those of the arm, leg, &c.; and betwixt two layers of membrane, as in the bones of the skull, where true cartilage is never seen. Often the bony matter is formed in distinct bags, and there it grows into form, as in the teeth; for each tooth is formed in its little bag, which, by injection, can be filled and covered with vessels. An artery of the body can assume this action, and deposit bone, which is formed also where it should not be, in the tendons and in the joints, in the great arteries and in the valves, in the flesh of the heart itself, or even in the soft and pulpy substance of the brain.

Most of the bones in the fœtus are merely cartilage before the time of birth. This cartilage is never hardened into bone, but, from the first, it is an organised mass. It has its vessels, which are at first transparent, but which soon dilate; and whenever the red colour of the blood begins to appear in them, ossification very quickly succeeds, the arteries being so far enlarged as to carry the coarser parts of the blood. The first mark of ossification is an artery which is seen running into the centre of the jelly which is formed. Other arteries soon appear, and a network of vessels is formed; and then a centre of ossification begins, stretching its rays according to the length of the bone; and then the cartilage begins to grow opaque, yellow, and brittle: it will no longer bend, and a bony centre may easily be discovered. Other points of ossification are successively formed, preceded by the appearance of arteries. The ossification follows the vessels, and buries and hides those vessels by which it is formed. The vessels advance towards the end of the bone, the whole body of the bone becomes opaque, and there is left a small vascular circle only at either end. The heads are separated from the body of the bone by a thin cartilage; and the vessels of the centre, extending still towards the extremities of the bone, perforate the cartilage, pass into the head of the bone, and then its ossification also begins, and a small nucleus of ossification is formed in its centre. Thus the heads and the body are at first distinct bones, formed apart, joined by a cartilage, and not united till the age of fifteen or twenty years. Then the deposition of bone begins: and while the bone is laid by the arteries, the cartilage is conveyed away by the absorbing vessels; and while they convey away the superfluous cartilage, they model the bone into its due form, shape out its cavities, cancelli, and holes, remove the thinner parts of the remaining cartilage, and harden it into due consistence. The earth which constitutes the hardness of bone, and all its useful properties, is inorganised, and lies in the interstices of bone, where it is made up of gelatinous matter, to give it consistence and strength, furnished with absorbents to keep it in health, and carry off its wasted parts; and pervaded by blood-vessels to supply it with new matter. During all the process of ossification, the absorbents proportion their action to the stimulus which is applied to them: they carry away the serous fluid, when jelly is to take place; they remove the jelly as the bone is laid; they continue removing the bony particles also, which (as in a circle) the arteries continually renew. This renovation and change of parts goes on even in the hardest bones, so that after a bone is perfectly formed, its older particles are continually being renewed, and new ones are deposited in their place. The bony particles are so deposited in the flat bones of the skull as to present a radiated structure, and the vacancies between the fibres which occasion this appearance, are found, by injection, to be chiefly passages for blood-vessels. As the fœtus increases in size, the osseous fibres increase in number, till a lamina is produced; and as the bone continues to grow, more laminæ are added, till the more solid part of a bone is formed. The ossification which begins in cartilage is considerably later than that which has its origin between membranes. The generality of bones are incomplete until the age of puberty, or between the fifteenth and twentieth years, and, in some few instances, not until a later period. The small bones of the ear, however, are completely formed at birth.

OSTEO'GRAPHY. (*Osteographia*, *æ*. f.; from *οστεον*, a bone, and *γραφω*, to describe.) The description of the bones. See *Os*.

Osteo'lithos. (From *οστεον*, a bone, and *λιθος*, a stone.) See *Osteocolla*.

OSTEO'LOGY. (*Osteologia*, *æ*. f.; from *οστεον*, a bone, and *λογος*, a discourse.) The doctrine of the bones.

Osteopœ'dion. (*on*, *ii*. n.; from *οστεον*, a bone, and *παις*, *παιδος*, an infant.) An ossified fœtus. See *Abortion*.

O'STEO-SARCO'MA. (From *οστεον*, a bone, and *σαρκωμα*, a fleshy tumour.) *Osteosarcosis*. A term that is very vaguely applied to any tumour which contains a mixture of bony and soft matter. It is most commonly applied, however, to a tumour commencing in the medullary structure of a bone, and afterwards blended with osseous matter. Such tumours may be of a malignant character or otherwise.

Osteo-sarcosis. See *Osteo-sarcoma*.

OSTHE'XIA. (*a*, *æ*. f.; from *οστωδης*, osseous or bony, and *εξις*, habit.) Osthexy, or the ossific diathesis.

Ostia'rius. (From *ostium*, a door.) The pylorus has been so called.

OSTI'OLUM. (*um*, *i*. n.; diminutive of *ostium*, a door.) A little door. The valves of the heart have been called *ostiola*. The term is also applied to small openings or mouths of vessels.

O'STIUM. (*um*, *ii*. n.) A door or opening. Applied to foramina or openings.

O'STREA. (*a*, *æ*. f.; from *οστρακον*, a shell.) The oyster. The name of a genus of shell-fish. Class, *Vermes;* Order, *Testacea*.

Ostrea edu'lis. The common oyster. Of this well-known and highly esteemed species there are six varieties, found in different parts of the European and Indian seas, affixed to rocks, or to large beds. The shell is of various sizes, forms, and colours, white within, and often glossy, like mother of pearl. It is supposed by naturalists to be an hermaphrodite animal. The spawn, which they cast in May, adheres to the rocks, and other substances at the bottom of the sea, and the shell is said to be formed in twenty-four hours.

Oysters are of different colours in different places. In Spain they are found of a red and russet colour; in Illyria they are brown, but the fish is black; and in the Red Sea, of the colour of the rainbow. The green oyster which is eaten in Paris, is brought from Dieppe. The oysters from Brittany have been long famous; but those which are brought from Merennes, in Saintonge, are in the highest estimation. Britain has been long noted for its oysters; and the ancient Romans, who were extremely fond of this fish, had their layers or stews for oysters, as we have at present. Sergius Orata was the inventor of them, as early as the time of Lucius Crassus, the orator. This country still preserves its superiority in oysters over other countries, and they are found in plenty in most parts of our coast.

As an article of diet or luxury, oysters are in very general use. When deprived of their beards or fringe-like part, and the harder flesh by which they adhere to the shell, they are easy of digestion, and very nutritious, either raw, boiled, stewed, or roasted. For weak stomachs they are often recommended; and they are in general use in sauces and minced meats, to give a flavour which is highly esteemed.

The shell of this fish is occasionally used medicinally: its virtues are similar to those of the carbonate of lime. See *Creta*.

Ostrea maxima. The scallop. This is found in most of the European seas, in large beds. The shell is that which was formerly worn by pilgrims, on the hat or coat, as a mark that they had crossed the sea, for the purpose of paying their devotions in the Holy Land. The flesh of this species is much more coarse than that of the oyster, and should never be indulged in, for it is very difficult of digestion unless it is well stewed; and even then it requires the addition of some warm stimulating substance.

Ostruthium. See *Imperatoria ostruthium*.

OSY'RIS. (*is*, *is*. f. Οσυρις, of Dioscorides, which he describes as a small shrub, with numerous dark, tough branches; and Professor Martyn conjectures its derivation from *οζος*, a branch. Some take the *antirrhinum linaria* for the true *Osyris*.) The name of a genus of plants in the Linnæan system. Class, *Diœcia;* Order, *Triandria*.

Osyris alba. Poet's cassia or gardrobe; Poet's rosemary. *Cassia poetica lobelii. Cassia latinorum. Cassia lignea monspeliensium. Cassia monspeliensium.* The whole shrub is astringent. It grows in the southern parts of Europe.

OTA'LGIA. (*a*, *æ*. f.; from *ους*, the ear, and *αλγος*, pain.) The earache.

OTE'NCHYTES. (From *ωτος*, the genitive of *ους*, an ear, and *εγχυω*, to pour in.) A syringe for the ears.

O'TICUS. (From *ους*, the ear.) Appertaining to the ear: thus, *medicamenta otica;* medicines against diseases of the ear.

Oti'tes. (From *ους*, the ear.) An epithet of the little finger, because it is commonly made use of in scratching the ear.

OTI'TIS. (*is*, *idis*. f.; from *ους*, the ear.) The term applies to inflammation of the external ear, properly so called; and also to the internal ear, to which it is generally confined. Otitis is known by pain in the internal part of the ear, confusion of sound, deafness, and more or less of fever. It is not uncommon with children, but is seldom attended with much disturbance of the system. It is generally produced by cold; and occasionally by extraneous bodies that have, by accident or otherwise, got into the meatus auditorius externus, as worms, insects or their larvæ, cherry-stones, &c., of which many curious accounts are published in medical journals.

It is sometimes a serious disease, producing much fever, and ending in suppuration. Several very acute cases of inflammation of the internal ear of adults, which caused active fever and delirium, have occurred to the author; which, but for copious and repeated bleeding, blisters, and purges, as directed against inflammation of the brain, would have terminated, most probably, fatally.

Otopla'stice. (From *ους*, the ear, and *πλασσω*, to form.) An operation practised by Taliacotius for the restoration of the external ear when destroyed.

Otoplatos. Improperly used by Vogel instead of *otoplados*. A foul ulcer behind the ear; from *ους*, the ear, and *πλαδος*, redundant moisture.

OTOPYO'SIS. (*is*, *is*. f.; from *ους*, the ear, and *πυον*, pus.) A purulent discharge from the ear.

OTORRHÆ'A. (*a*, *æ*. f.; from *ους*, the ear, and *ρεω*, to flow.) A discharge from the ear.

Otto of roses. See *Oleum rosæ*.

OVA'LIS. Oval. Some parts of animals and vegetables are so called from being of this shape; as *foramen ovale, centrum ovale, folium ovale, receptaculum ovale*.

OVA'RIAN. (*Ovarianus*, from *ovarium*.) Ovarial: belonging to the ovarium.

OVA'RIUM. (*um*, *ii*. n.; diminutive of *ovum*, an egg.) The ovaria are two flat oval bodies, about an inch in length, and rather more than half in breadth and thickness, suspended in the broad ligaments, about the distance of one inch from the uterus behind, and a little below the Fallopian tubes. To the ovaria, according to the idea of their structure entertained by different anatomists, various uses have been assigned, or the purpose they answer has been differently explained. Some have supposed

that their texture was glandular, and that they secreted a fluid equivalent and similar to the male semen; but others, who have examined them with more care, assert that they are ovaria in the literal acceptation of the term, and include a number of vesicles, or ova, to the amount of twenty-two of different sizes, joined to the internal surface of the ovaria by cellular threads or pedicles; and that they contain a fluid which has the appearance of thin lymph. These vesicles are, in fact, to be seen in the healthy ovaria of every young woman. They differ very much in their number in different ovaria, but are very seldom so numerous as has just been stated. All have agreed that the ovaria prepare whatever the female supplies towards the formation of the fœtus; and this is proved by the operation of spaying, which consists in the extirpation of the ovaria; after which the animal not only loses the power of conceiving, but desire is for ever extinguished. The outer coat of the ovaria, together with that of the uterus, is given by the peritonæum; and whenever an ovum is passed into the Fallopian tube, a fissure is observed at the part through which it is supposed to have been transferred. These fissures healing, leave small longitudinal cicatrices on the surface, which are said to enable us to determine, whenever the ovarium is examined, the number of times a woman has conceived. The corpora lutea are oblong glandular bodies of a yellowish colour, found in the ovaria of all animals when pregnant, and, according to some, when they are salacious. They are said to be calyces, from which the impregnated ovum is dropped; and their number is always in proportion to the number of conceptions found in the uterus. They are largest and most conspicuous in the early state of pregnancy, and remain for some time after delivery, when they gradually fade and wither till they disappear. The corpora lutea are very vascular, except at their centre, which is whitish; and in the middle of the white part is a small cavity, from which the impregnated ovum is thought to have immediately proceeded. The ovaria are the seat of a particular kind of dropsy, which most commonly happens to women at the time of the final cessation of the menses, though not unfrequently at a more early period of life. It is of the encysted kind, the fluid being sometimes limpid and thin, and at others discoloured and gelatinous. In some cases it has been found contained in one cyst, often in several; and in others the whole tumefaction has been composed of hydatids not larger than grapes. The ovaria are also subject, especially a short time after delivery, to inflammation, terminating in suppuration, and to scirrhous and cancerous diseases, with considerable enlargement. In the former state, they generally adhere to some adjoining part, as the uterus, rectum, bladder, or external integuments, and the matter is discharged from the vagina, by stool, by urine, or by an external abscess of the integuments of the abdomen.

OVA'TUS. Ovate: egg-shaped. 1. Leaves, petals, seeds, &c., are so called when of the shape of an egg, cut lengthwise, the base being rounded, and broader than the extremity, — a very common form of leaves; as in *Vinca major*, and *Urtica pilulifera*; the *petals* of the *Allium flavum*, and *Narcissus pseudo-narcissus*; and the *receptacle* of the *Omphalea*.

2. A shape resembling the solid substance of an egg; as the seeds of the *Quercus*.

O'VIDUCT. (*Oviductus*; from *ovum*, an egg, and *ductus*, a canal.) The duct or canal through which the ovum, or egg, passes. In the human species, the Fallopian tube is so called, which runs from the ovary to the bottom of the womb.

OVI'PAROUS. (*Oviparus*; from *ovum*, an egg, and *pario*, to bring forth.) Animals are so called which exclude their young contained in an egg.

OVIS. The name of a genus of animals. Class, *Mammalia*; Order, *Pecora*, The sheep.

Ovis aries. The common sheep. The flesh of this animal is the best of all food for man, being easy of digestion, and highly nutritious. The lamb is considered as a delicacy.

Ovorum testæ. Egg-shells. A testaceous absorbent.

Ovu'liger. (Bearer of little eggs.) The name given by M. Raspail to a kind of hydatid found in the wrist joint, which he considers as intermediate between the genera cysticercus and cœnurus.

O'VULUM. (*um*, *i.* n.; diminutive of *ovum*.) A little egg. See *Egg*.

O'VUM. (*um*, *i.* n.; from the Greek ᾠόν, an egg.) An egg. In physiological language this term is applied to the capsule containing the prolific germ of animals. Thus the egg of a bird, the vesicles found in the ovarium in mammiferous animals, the spawn of fishes, are all *ova*.

I. *Of the Egg of the Domestic Fowl or Hen.*

The form of this is somewhat oval, larger at one extremity than the other, which is more pointed. It is of a white colour mostly, and about two inches long, and one and a half in its broadest diameter, weighing generally about two ounces.

The parts of which an egg are composed are, the shell, the membranes, and the semi-fluid substances.

1. The *shell*. This is a calcareous investment, the *cortex* or *putamen* of old anatomists. It is secreted from the internal surface of that part of the oviduct which is called the uterus. It adheres firmly to the external membrane of the egg, and is of the thickness of the nail of our thumb. It is composed of carbonate of lime principally, with a little phosphate, and the particles are held in connection by a little gelatine. This part of the hen's egg was formerly much esteemed in the cure of diseases, as an antacid and absorbent; and even in the present day, *testæ ovarum* are directed in fine powder by old practitioners, in the dose of from one to three scruples.

2. The *external membrane*. Blumenbach calls this *membrana albuminis*. It possesses exactly the form of the shell, which adheres firmly to it like a lining. It is very delicate and smooth on the side next to the egg. It is composed of two laminæ, which at the great

nd of the egg are separate, thus forming a pace: this space is called the *folliculus æris*, or *ir-cell*.

3. The semifluid substances are the white nd the yolk, which together form nearly the whole bulk of the egg.

a. The white was called, by Aristotle, μοριον λευκον; by Pliny, *liquor albus ovi*; by Celsus, *candidum ovi*; by Apicius, *album et albimentum ovi*; nd by Fabricius ab Aquapendente, *albumen*; which latter name is now generally used. This part of the egg is a white, viscid, tenacious, emifluid mass, commonly called the white of he egg. It does not float about promiscuously hrough the egg, but adheres to the membrane ining the small end of the egg, and always preserves its proper relative position to the yolk. In its natural state, it has little taste or smell. When spread thin and slowly over any body, it forms a varnish similar to what is made from um-acacia. It soon putrefies, unless dried; n which state it may be preserved for any length f time. It is insoluble in alkohol and æther. Acids do not disssolve it, unless it be coagulated, nd heat employed. When mixed by agitation with water, and alkalies are added, no apparent hange takes place; but if a concentrated solution of pure potash be triturated with the white f the egg for some time, and then allowed to e at rest, a coagulation gradually takes place. t then hardens; and, at a particular period of ts drying, it resembles very much the crystalline ens of the eye. When quite dry, it is brittle nd transparent.

According to the chemical analysis which has een made of the white of the egg, 100 parts f it contain 80 of water, 4·5 of uncoagulable natter, and 15·5 of pure albumen. By distilation it affords water, carbonate of ammonia, nd empyreumatic oil; a coal remaining in he retort, which yields soda and phosphate of me.

The white of the egg is well known to be oagulable by heat, acids, and alkohol.

b. The yolk, or yellow, is called *vitellus*. It s the spherical mass which occupies the centre f the egg, and is surrounded by the white. It s smaller in quantity than the white. It is sually of a bright yellow colour. The substances into which the yolk of eggs is resolvable re, water, oil, albumen, and gelatine. If, after eing boiled, the yolk be heated in a pan, it oftens; and when squeezed between the fingers, rops of oil exude: if put into linen in this tate and pressed, an oil will be forced out. This il is of a yellow colour, and insipid. Its properties are those of fixed oil, or rather of semiuid fat. The residue, after the separation of he oil, possesses properties of albumen.

The *vitellus ovi* is used in the preparation of ome medicines, to combine some of its articles, nd give a smoothness to the mixture: in this ay it is employed in the *Julepum vitæ Batenum* in emulsions, with resin, oil, camphire, nd various linctuses: but its principal use is s an article of diet, either alone, variously ressed, or entering into almost every pudding, ustard, forced meat, and a vast variety of other limentary articles.

II. *Of the Eggs of the Human Ovarium.*

The vesicles in the ovarium of females are called the eggs, *ova* or *ovula*. When fecundation takes place in one or more of these, they pass, after a short time, along the Fallopian tube into the uterus.

Development of the ovum in the uterus. — The ovum in the first moments of its abode in the uterus, is free and unattached; its volume is nearly that which it had in quitting the ovarium; but, in the course of the second month, its dimensions increase, it becomes covered with filaments of about a line in length, which ramify in the manner of blood-vessels, and are implanted into the *decidua*. In the third month they are seen only on one side of the ovum, the others have nearly disappeared; but those which remain have acquired a greater extent, thickness, and consistence, and are more deeply implanted into the deciduous membrane; taken together, they form the *placenta*. The ovum, in the rest of its surface, presents only a soft flocculent layer called *decidua reflexa*. The ovum continues to increase until the end of pregnancy, when its volume is nearly equal to that of the uterus; but its structure suffers important changes, which we will examine.

At first its two membranes have yielded to its enlargement, whilst becoming thicker or more resisting: the exterior is called *chorion*; the other *amnion*. The liquid contained by the latter augments in proportion to the volume of the ovum. In the second month of pregnancy there exists also a certain quantity of liquid between the chorion and amnion, but it disappears during the third month.

Up to the end of the third week, the ovum presents nothing indicative of the presence of the germ; the contained liquid is transparent, and partly coagulable as before. At this period there is seen, on the side where the ovum adheres to the uterus, something slightly opaque and gelatinous, all the parts of which appear homogeneous; in a short time, certain points become opaque, two distinct vesicles are formed, nearly equal in volume, and united by a pedicle, one of which adheres to the amnion by a small filament. Almost at the same time a red spot is seen in the midst of this last, from which yellowish filaments are seen to take their rise: this is the heart, and the principal sanguiferous vessels. At the beginning of the second month, the head is very visible, the eyes form two black points, very large in proportion to the volume of the head; small openings indicate the place of the ears and nostrils; the mouth, at first very large, is contracted afterwards by the development of the lips, which happens about the sixtieth day, with that of the ears, nose, extremities, &c.

The development of all the principal organs happens successively until about the middle of the fourth month; then the state of the *embryo* ceases, and that of the *fœtus* begins, which is continued till the termination of pregnancy. All the parts increase with more or less rapidity during this time, and draw towards the form which they must present after birth. Before the sixth month, the lungs are very small, the

heart large, but its four cavities are confounded, or at least difficult to distinguish: the liver is large, and occupies a great part of the abdomen: the gall-bladder is not full of bile, but of a colourless fluid, not bitter; the small intestine, in its lower part, contains a yellowish matter, in small quantity, called *meconium*; the testicles are placed upon the sides of the superior lumbar vertebræ; the ovaria occupy the same position. At the end of the seventh month, the lungs assume a reddish tint which they had not before; the cavities of the heart become distinct; the liver preserves its large dimensions, but removes a little from the umbilicus; the bile shows itself in the gall-bladder; the meconium is more abundant, and descends lower in the great intestine; the ovaria tend to the pelvis; the testicles are directed to the inguinal rings. At this period the fœtus is capable of life, that is, it could live and breathe if expelled from the uterus. Every thing becomes more perfect in the eighth and ninth months. We cannot here follow the interesting details of this increase of the organs; they belong to anatomy: we shall consider the physiological phænomena that relate to them.

Functions of the ovum, and of the fœtus. — The ovum begins to grow as soon as it arrives in the cavity of the uterus; its surface is covered with asperities that are quickly transformed into sanguiferous vessels; there is then life in the ovum. But we have no idea of this mode of existence; probably the surface of the ovum absorbs the fluids with which it is in contact, and these, after having undergone a particular elaboration by the membranes, are afterwards poured into the cavity of the amnion.

What was the germ before its appearance? Did it exist, or was it formed at that instant? Does the little almost opaque mass that composes it contain the rudiments of all the organs of the fœtus and the adult, or are these created the instant they begin to show themselves? What can be the nature of a nutrition so complicated, so important, performed without vessels, nerves, or apparent circulation? How does the heart move before the appearance of the nervous system? Whence comes the yellow blood that it contains at first? &c. &c. No reply can be given to any of these questions in the present state of science.

We know very little of what happens in the embryo, whose organs are only yet rudely delineated; nevertheless, there is a kind of circulation recognised. The heart sends blood into the large vessels, and into the rudimentary placenta; probably blood returns to the heart by veins, &c. — But when the new being has reached the fœtal state, as most of the organs are very apparent, then it is possible to recognise some of the functions peculiar to that state.

The circulation is the best known of the functions of the fœtus: it is more complicated than that of the adult, and is performed in a manner quite different.

In the first place, it cannot be divided into venous and arterial; for the fœtal blood has sensibly every where the same appearance, that is, a brownish red tint: in other respects, it is much the same as the blood of the adult; it coagulates, separates into clot and serum, &c. Some learned chemists have believed that it does not contain fibrin.

The placenta is the most singular, and one of the most important organs of the circulation of the fœtus; it succeeds to those filaments which cover the ovum during the first months of pregnancy. Very small at first, it soon acquires a considerable size. It adheres, by its exterior surface, to the uterus, presents irregular furrows, which indicate its division into several lobes or *cotyledons*, the number and form of which are not determined. Its fœtal surface is covered by the chorion and amnion, except at its centre, into which the umbilical cord is inserted. Its parenchyma is formed of sanguiferous vessels, divided and subdivided. They belong to the divisions of the umbilical arteries, and to the radicles of the vein of the same name. The vessels of one lobe do not communicate with those of the adjoining lobes: but those of the same *cotyledon* anastomose frequently, for nothing is more easy than to make injections pass from one to another.

The *umbilical cord* extends from near the centre of the placenta to the umbilicus of the child; its length is often near two feet; it is formed by the two umbilical arteries and the vein, connected by a very close cellular tissue, and it is covered by the two membranes of the ovum.

In the first months of pregnancy, a vesicle, which receives small vessels, being a prolongation of the mesenteric artery and the meseraic vein, is found in the body of the cord, between the chorion and the amnion, near the umbilicus. This vesicle is not analogous to the *allantoid*; it represents the membranes of the yolk of birds and reptiles, and the umbilical vesicle of the *mammalia*. It contains a yellowish fluid, which seems to be absorbed by the veins of its parietes.

The umbilical vein, arising from the placenta, and then arriving at the umbilicus, enters the abdomen, and reaches the inferior surface of the liver; there it divides into two large branches, one of which is distributed to the liver, along with the *vena porta*, whilst the other soon terminates in the *vena cava* under the name of *ductus venosus*. This vein has two valves, one at the place of its bifurcation, and the other at the junction with the vena cava.

The heart and large vessels of the fœtus capable of life, are very different from what they become after birth: the valve of the vena cava is large; the partition of the auricles presents a large opening, provided with a semilunar valve called *foramen ovale*. The pulmonary artery, after having sent two small branches to the lungs, terminates almost immediately in the aorta, in the concave aspect of the arch; it is called, in this place, *ductus arteriosus*.

The last character proper to the circulating organs of the fœtus, is the existence of the *umbilical arteries*, which arise from the internal iliacs, are directed over the sides of the bladder, attach themselves to the *urachus*, pass out of

e abdomen by the umbilicus, and go to the acenta, where they are distributed as just entioned.

According to this disposition of the circuting apparatus of the fœtus, it is evident that ae motion of the blood ought to be different in from that in the adult. If we suppose that he blood sets out from the placenta, it evidently passes through the umbilical vein as far s the liver; there one part of the blood passes nto the liver, and the other into the vena cava; hese two directions carry it to the heart by the nferior vena cava; being arrived at this organ, penetrates into the right auricle, and into the eft by the *foramen ovale*, at the instant in which the auricles are dilated. At this instant, he blood of the inferior vena cava is inevitably nixed with that of the superior. How, indeed, could two liquids of the same nature, or nearly so, remain isolated in a cavity in which hey arrive at the same time, and which contracts to expel them? However it may be, the ontraction of the auricles succeeds their dilatation; the blood is thrown into the two ventricles the instant they dilate; these, in their urn, contract, and drive out the blood, the eft into the aorta, and the right into the pulmonary artery; but as this artery terminates n the aorta, it is clear that all the blood of he two ventricles passes into the aorta, except very small portion that goes to the lungs. Under the influence of these two agents of mpulsion, the blood is made to flow through ll the divisions of the aorta, and returns to he heart by the venæ cavæ. Lastly, it is carried to the placenta by the umbilical arteries, nd returns to the fœtus by the vein of the ord.

It is easy to conceive the use of the foramen ovale, and the ductus arteriosus; the left auricle, receiving little or no blood from the lungs, could not furnish any to the left ventricle, if it did not receive it from the opening in the partition of the auricles. On the other hand, the ungs having no functions to fulfil, if all the lood of the pulmonary artery were distributed n them, the impulsive force of the right ventricle would have been vainly consumed; whilst, by means of the ductus arteriosus, the force of both ventricles is employed to move the blood of the aorta: without the joint action of both ventricles, probably the blood could not have reached the placenta, and returned again to he heart.

The motions of the heart are very rapid in the fœtus; they generally exceed 120 in a minute: he circulation possesses necessarily a proportionate rapidity.

A delicate question now presents itself for examination. What are the relations of the circulation of the mother with that of the fœtus? In order to arrive at some precise notion on this point, the mode of junction of the uterus and placenta must first be examined.

Anatomists differ in this respect. It was long believed that the uterine arteries anastomosed directly with the radicles of the umbilical vein, and that the last divisions of the arteries of the placenta opened into the veins of the uterus but the acknowledged impossibility of making matters injected into the uterine veins pass into the umbilical veins, and reciprocally to cause liquid matters injected into the umbilical arteries to reach the veins of the uterus, caused this idea to be renounced. It is at present generally admitted, that the vessels of the placenta and those of the uterus do not anastomose.

Notwithstanding the high authority of Boerhaave, it cannot be admitted that the fœtus continually swallows the water of the amnion, and digests it for its nourishment. Its stomach, indeed, contains a viscid matter in considerable quantity; but it has no resemblance to the *liquor amnii*; it is very acid and gelatinous; towards the pylorus, it is somewhat grey, and opake; it appears to be converted into chyme in the stomach, in order to pass into the small intestine, where, after having been acted upon by the bile, and perhaps by the pancreatic juice, it furnishes a peculiar chyle. The remainder descends afterwards into the large intestine, where it forms the meconium, which is evidently the result of digestion during gestation. Whence does the digested matter come? It is probably secreted by the stomach itself, or descends from the œsophagus; there is nothing, however, to prevent the fœtus from swallowing, in certain cases, a few mouthfuls of the liquor amnii; and this seems to be proved by certain hairs, like those of the skin, being found in the meconium. It is important to remark, that the meconium is a substance containing very little azote. Nothing is yet known regarding the use of this digestion of the fœtus; it is probably not essential to its growth, since infants have been born without a stomach, or any thing similar. Some persons say they have seen chyle in the thoracic duct of the former.

Exhalations seem to take place in the fœtus; for all its surfaces are lubricated nearly in the same manner as afterwards: fat is in abundance; the humours of the eye exist; cutaneous transpiration very probably takes place also, and mixes continually with the liquor amnii. With regard to this last liquor, it is difficult to say whence it derives its origin; no sanguiferous vessels appear to be directed to the amnion, and it is nevertheless probable that this membrane is its secreting organ.

The cutaneous and mucous follicles are developed, and seem to possess an energetic action, especially from the seventh month; the skin is then covered by a pretty thick layer of fatty matter, secreted by the follicles; several authors have improperly considered it as a deposit of the liquor amnii. The mucus is also abundant in the two last months of gestation.

All the glands employed in digestion have a considerable volume, and seem to possess some activity: the action of the others is little known. It is not known, for example, whether the kidneys form urine, or whether this fluid is injected by the urethra into the cavity of the amnion. The testicles and mammæ seem to form a fluid that resembles neither milk nor semen, and which is found in the *vesiculæ seminales* and lactiferous canals.

What can be said about the nutrition of the fœtus? Physiological works contain only vague conjectures on this point: it appears certain that the placenta draws from the mother the materials necessary for the development of the organs, but what these materials are, or how they are directed, we do not know. — *Magendie.*

Ovum philosophicum. *Ovum chymicum.* A cucurbit.

Ox. See *Bos taurus.*

Ox-eye daisy. See *Chrysanthemum.*

Ox's tongue. See *Picris echioides.*

O'XALATE. (*Oxalas, atis.* m.; so called, because formed with the oxalic acid.) A salt formed by the combination of the oxalic acid with a salifiable basis; thus, *oxalate of ammonia.*

OXA'LIC ACID. *Acidum oxalicum.* This acid abounds in wood-sorrel. Combined with a small portion of potash, as it exists in that plant, it has been sold under the name of *salt of lemons*, to be used as a substitute for the juice of that fruit, particularly for discharging ink-spots and iron-moulds, and was long supposed to be analogous to that of tartar. In the year 1776, however, Bergman discovered, that a powerful acid might be extracted from sugar by means of the nitric; and, a few years afterwards, Scheele found this to be identical with the acid existing naturally in sorrel. Hence the acid began to be distinguished by the name of *saccharine*, but has since been generally known by that of oxalic.

It may be obtained, readily and economically, from sugar, in the following way: — To six ounces of nitric acid in a stoppered retort, to which a large receiver is luted, add, by degrees, one ounce of lump sugar, coarsely powdered. A gentle heat may be applied during the solution, and nitric oxide will be evolved in abundance. When the whole of the sugar is dissolved, distil off a part of the acid, till what remains in the retort has a syrupy consistence; and this will form regular crystals, amounting to 58 parts from 100 of sugar. These crystals must be dissolved in water, recrystallised, and dried on blotting paper.

Oxalic acid crystallises in quadrilateral prisms, the sides of which are alternately broad and narrow, and summits dihedral; or, if crystallised rapidly, in small irregular needles. They are efflorescent in dry air, but attract a little humidity if it be damp; are soluble in one part of hot and two of cold water; and are decomposable by a red heat, leaving a small quantity of coaly residuum. 100 parts of alkohol take up near 56 at a boiling heat, but not above 40 cold. Their acidity is so great, that when dissolved in 3600 times their weight of water, the solution reddens litmus paper, and is perceptibly acid to the taste.

The oxalic acid is a good test for detecting lime, which it separates from all the other acids, unless they are present in excess. It has, likewise, a greater affinity for lime than for any other of the bases, and forms with it a pulverulent insoluble salt, not decomposable except by fire, and turning syrup of violets green.

Oxalic acid acts as a violent poison, when swallowed in the quantity of 2 or 3 drachms and several fatal accidents have occurred in consequence of its being improperly sold instead of Epsom salts. Its vulgar name of *salts* under which the acid is bought for the purpose of whitening boot-tops, has frequently occasioned these lamentable mistakes. But the powerfully acid taste of the latter substance, joined to its prismatic or needle-formed crystallisation, are sufficient to distinguish it from every thing else. The immediate rejection from the stomach of this acid by an emetic, aided by copious draughts of warm water containing bicarbonate of potash, or soda, chalk or carbonate of magnesia, are the proper remedies.

With *baryta* it forms an insoluble salt.

The *oxalate of strontia* and *magnesia* are also insoluble, unless the acid be in excess.

The *oxalate of potash* exists in two states, that of a neutral salt, and that of an acidule. The latter is generally obtained from the juice of the leaves of the *oxalis acetosella*, wood-sorrel, or from the *rumex acetosa*, or common sorrel. The expressed juice, bring diluted with water, should be set by for a few days, till the feculent parts have subsided, and the supernatant fluid is become clear; or it may be clarified, when expressed, with the whites of eggs. It is then to be strained off, evaporated to a pellicle, and set in a cool place to crystallise. The first product of crystals being taken out, the liquor may be further evaporated, and crystallised; and the same process repeated till no more can be obtained.

It unites with barytes, magnesia, soda, ammonia, and most of the metallic oxides, into triple salts. It attacks iron, lead, tin, zinc, and antimony.

This salt, besides its use in taking out ink-spots, and as a test of lime, forms with sugar and water a pleasant cooling beverage; and, according to Berthollet, it possesses considerable powers as an antiseptic.

The neutral oxalate of potash is very soluble, and assumes a gelatinous form, but may be brought to crystallise in hexahedral prisms with dihedral summits, by adding more potash to the liquor than is sufficient to saturate the acid.

Oxalate of soda likewise exists in two different states, those of an acidulous and a neutral salt, which, in their properties, are analogous to those of potash.

The *acidulous oxalate of ammonia* is crystallisable, not very soluble, and capable, like the preceding acidules, of combining with other bases, so as to form triple salts.

The oxalic acid readily dissolves *alumina*, and the solution gives, on evaporation, a yellowish transparent mass, sweet and a little astringent to the taste, deliquescent, and reddening tincture of litmus, but not syrup of violets. This salt swells up in the fire, loses its acid, and leaves the alumina a little coloured.

O'XALIS. (*is, is.* f.; from ὀξυς, sharp: so called from the sharpness of its juice.) The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Pentagynia.* Wood-sorrel.

Oxalis acetosella. The systematic name of the wood-sorrel; called also, *Lujula*, and *Alleluja*.

Oxalis — foliis ternatis, scapo unifloro, flore albo, capsulis pentagonis elasticis, radice squamoso-articulata, of Linnæus. This plant grows wild in the woods, and flowers in April and May. The leaves are shaped like a heart, standing three together on one stalk. The acetosella is totally inodorous, but has a grateful acid taste, on which account it is used in salads. Its taste is more agreeable than the common salad, and approaches nearly to that of the juice of lemons, or the acid of tartar, with which it corresponds in a great measure in its medical effects, being esteemed refrigerant, antiscorbutic, and diuretic.

Its sourness is derived from the presence of a quodroxalate of potash.

It is recommended by Bergius, in inflammatory, bilious, and putrid fevers. The principal use, however, of the acetosella, is to allay inordinate heat, and to quench thirst; for this purpose, a pleasant whey may be formed by boiling the plant in milk, which, under certain circumstances, may be preferable to the conserve which was formerly directed by the pharmacopœias, and much esteemed by practitioners. Many have employed the root of lujula, probably on account of its beautiful red colour rather than for its superior efficacy. A salt is prepared from this plant, known by the name of essential salt of lemons, which is an acidulous oxalate of potash, and commonly used for taking ink-stains out of linen. See *Oxalic acid*. The leaves of wood-sorrel are sometimes applied externally as a suppurative cataplasm, particularly in indolent scrofulous tumours.

Oxa'lme. (*e, es.* f.; from *οξυς*, sharp, and *ἁλς*, salt.) A mixture of vinegar and salt.

OXIDA'TION. (*Oxidatio, onis.* f.) The process of converting metals and other substances into oxides, by combining with them a certain portion of oxygen. It differs from acidification in the addition of oxygen not forming an acid with the substance oxidated.

O'XIDE. (*Oxydum, i.* n.) A substance combined with oxygen, without being in the state of an acid. Many substances are susceptible of several stages of oxidisement, on which account chemists have employed various terms to express the characteristic distinctions of the several oxides. The specific name is often derived from some external character, chiefly the colour: thus we have the black and red oxides of iron, and of mercury; the white oxide of zinc: but, in most instances, the denominations proposed by Dr. Thompson are adopted. When there are several oxides of the same substance, he proposes the terms *protoxide, deutoxide, tritoxide*, signifying the first, second, and third stage of oxidisement. Or, if two oxides only are known, he proposes the appellation of *protoxide* for that at the minimum, and of *peroxide* for that at the maximum of oxidation.

Oxide of carbon, gaseous. See *Carbonic oxide.*

Oxide, nitric. See *Nitrogen.*

Oxide, nitrous. See *Nitrogen.*

Oxiodic acid. See *Iodic acid.*

Orydum antimonii. See *Antimonii oxydum.*

Oxydum arsenici album. See *Arsenic.*

Oxydum cupri viride acetatum. Verdigris. See *Æruge.*

Oxydum ferri luteum. See *Ferri sesquioxydum.*

Oxydum ferri nigrum. Black oxide of iron. The scales which fall from iron, when heated, consist of iron combined with oxygen. This oxide is found not to be a protoxide, as formerly supposed, but a mixture of variable proportions of the protoxide and peroxide. See *Iron*. These have been employed medicinally, producing the general effects of chalybeates, but not very powerfully.

Oxydum ferri rubrum. Red oxide of iron, which is the peroxide. Its properties in medicine are similar to those of the other oxides of iron, but it is less active.

Oxydum hydrargyri cinereum. See *Hydrargyri oxydum.*

Oxydum hydrargyri nigrum. See *Hydrargyri oxydum.*

Oxydum hydrargyri rubrum. See *Hydrargyri binoxidum.*

Oxydum plumbi album. See *Plumbi subcarbonas.*

Oxydum plumbi rubrum. See *Minium.*

Oxydum plumbi semivitreum. See *Lithargyrus.*

Oxydum stibii album. See *Antimonii oxydum.*

Oxydum stibii semivitreum. Glass of antimony. See *Antimonii vitrum.*

Oxydum stibii sulphuratum. Crocus of antimony. See *Antimony.*

Oxydum zinci. See *Zinci oxydum.*

Oxydum zinci sublimatum. See *Zinci oxydum.*

Oxyca'ntha. (*a, æ.* f.; from *οξυς*, sharp, and *ακανθα*, a thorn: so called from the acidity of its fruit.) See *Berberis.*

Oxycantha Galeni. See *Berberis.*

Oxyce'drus. (*us, i.* f.; from *οξυς*, sharp, and *κεδρος*, a cedar: so called from the sharp termination of its leaves.) 1. A kind of cedar.

2. Spanish juniper, a species of *juniperus.*

Oxychloric acid. See *Perchloric acid.*

Oxyco'ccos. (*os, i.* m.; from *οξυς*, acid, and *κοκκος*, a berry: so named from its acidity.) See *Vaccinium oxycoccos.*

OXY'CRATUM. (*um, i.* n.; from *οξυς*, acid, and *κεραννυμι*, to mix.) Oxycrate: vinegar mixed with such a portion of water as is required, and rendered still milder by the addition of a little honey.

Oxycro'ceum empla'strum. (From *οξυς*, sharp, and *κροκος*, saffron.) An old plaster which consisted of wax, pitch, colophony, saffron, turpentine, galbanum, ammoniacum, myrrh, olibanum, and mastiche. It was used by surgeons as a strengthening and anodyne plaster.

Oxyde'rcicus. (From *οξυς*, acute, and *δερκω*, to see.) Having the property of strengthening the sight.

Oxyecoi'a. (From *οξυς*, sharp, and *ακοη*, the sense of hearing.) Preternatural acuteness of the sense of hearing. It is generally symptomatic of irritation of the brain.

OXY'GARUM. (*um*, *i.* n.; from οξυς, acid, and γαρον, garum.) A composition of garum and vinegar.

O'XYGEN. (*Oxygenium*, *ii.* n.; from οξυς, acid, and γενναω, to generate: because it is a generator of acidity.) This substance, although existing sometimes in a solid and sometimes in an aëriform state, is never distinctly perceptible to the human senses but in combination.

We know it only in combination by its effects. Nature never presents it solitary: chemists do not know how to insulate it. It is a principle which was long unknown. It is absorbable by combustible bodies, and converts them into oxides or acids. It exists universally dispersed through nature, and is a constituent part of atmospheric air, of water, acids, earths, and alkalis, and of all bodies of the animal and vegetable kingdoms.

One of the most remarkable combinations into which it is capable of entering, is that which it forms with light and caloric, in which state it constitutes *oxygen gas*.

Oxygen gas is an elastic invisible fluid. It has neither taste nor odour. According to Dulon and Berzelius, its specific gravity is 1·1026; and 100 cubic inches weigh 34·109 grains. It is not absorbed by water, but entirely absorbable by combustible bodies, which, at the same time, disengage its caloric and light, producing in consequence a strong heat and flame. Its power of refracting light is less than that of any other known substance. It is indispensable to respiration. It hastens germination. It is the great *supporter of combustion*. See *Combustion*. It combines with every combustible body, with all the metals, and with the greater number of vegetable and animal substances.

The act of its combining with bodies is called *oxidisement*, or *oxygenation*; and the bodies with which it is combined are either *oxides*, or *acids*. Lavoisier regarded oxygen as the sole acidifying principle, an opinion which is now known to be erroneous. See *Acid*.

There are a great number of bodies from which we may, by art, obtain oxygen gas. It is most amply obtained from the oxides of manganese, lead, or mercury; from nitrate of potash; from the green leaves of vegetables, and from chlorate of potash or soda. Besides these, there are a great many other substances from which oxygen gas may be procured.

1. In order to procure oxygen gas in a state of great purity, pure chloride of potash or soda must be made use of. With this view, put some of the salt into a small earthen or glass retort, the neck of which is placed under the shelf of the pneumatic trough, filled with water, and heat the retort by means of a lamp. The salt will begin to melt, and oxygen gas will be obtained in abundance, and of great purity, which may be collected and preserved over water.

Chlorate of potash consists of oxygen, chlorine, and potash. At an elevated temperature, a decomposition takes place, the oxygen unites with the caloric, and forms oxygen gas. The chlorate becomes therefore converted into chloride of potash.

2. Oxygen gas may likewise be obtained from the green leaves of vegetables.

For this purpose, fill a bell-glass with water, introduce fresh-gathered green leaves under it, and place the bell or receiver, inverted, in a vessel containing the same fluid; expose the apparatus to the rays of the sun, and very pure oxygen gas will be liberated.

The emission of oxygen gas is proportioned to the vigour of the plant and the vivacity of the light: the quantity differs in different plants and under different conditions.

It is an established fact that plants decompose carbonic acid, and probably water, which serve for their nourishment: they absorb the hydrogen and carbon of these fluids, disengaging a part of the oxygen in a state of purity. Light, however, favours this decomposition greatly: in proportion as the oxygen becomes disengaged, the hydrogen becomes fixed in the vegetable, and combines, partly with the carbon and partly with the oxygen, to form the oil, &c. of the vegetable.

3. Nitrate of potash is another substance frequently made use of for obtaining oxygen gas in the following manner: —

Take any quantity of this salt, introduce it into a coated earthen or glass retort, and fit to it a tube, which must be plunged into the pneumatic trough, under the receiver filled with water. When the apparatus has been properly adjusted, heat the retort gradually till it becomes red hot; the oxygen gas will then be disengaged rapidly.

Nitrate of potash consists of nitric acid and potash. Nitric acid consists again of oxygen and nitrogen. On exposing the salt to ignition a partial decomposition of the acid takes place: the greatest part of the oxygen of the nitric acid unites with caloric, and appears under the form of oxygen gas. The other part remains attached to the potash, forming a nitrate of potash.

If two much heat be applied, particularly towards the end of the process, a total decomposition of the nitric acid takes place: the oxygen gas, in that case, will therefore be mingled with nitrogen gas. The weight of the two gases when collected, will be found to correspond very exactly with the weight of the acid which had been decomposed. The residue then left in the retort is potash.

4. Black oxide of manganese, however, is generally made use of for obtaining oxygen gas on account of its cheapness. This native oxide is reduced to a coarse powder: a stone, or rather an iron retort, is then charged with it and heated. As soon as the retort becomes ignited, oxygen gas is obtained plentifully.

Black oxide of manganese is the metal called manganese fully saturated with oxygen, together with many earthy impurities: on applying heat, part of the solid oxygen quits the metal and unites with caloric, to form oxygen gas; the remainder of the oxygen remains united to the metal with a forcible affinity. The metal, therefore, approaches to the metallic state, or is found in the state of a grey oxide of manganese.

One pound of the best manganese yields

wards of 1400 cubic inches of oxygen gas, nearly pure. If sulphuric acid be previously added to the manganese, the gas is produced by a less heat, and in a larger quantity: a glass retort may then be used, and the heat of a lamp is sufficient.

5. Red oxide of mercury yields oxygen gas in a manner similar to that of manganese.

This oxide consists likewise of solid oxygen and mercury, the combination of which takes place on exposing mercury to a heat of about 510° Fahr. At this degree it attracts oxygen, and becomes converted into an oxide; but if the temperature be increased, the attraction of oxygen is changed. The oxygen then attracts caloric more strongly than it did the mercury; it therefore abandons the latter, and forms oxygen gas, while the mercury re-appears in its metallic state.

6. Red oxide of lead yields oxygen gas on the same principle.

Oxygenated muriatic acid. See *Chlorine.*

OXYGENA'TION. (*Oxygenatio, onis.* f.; from *oxygen*, and γενναω, to generate.) This word is often used synonymously with oxidation; but it is generally employed in a wider sense: every union with oxygen, whatever the product may be, is called an *oxygenation*; while the term *oxidation* is applied only when an oxide is formed.

Oxygenised muriatic acid. See *Chlorine.*

OXY'GLYCUM. (*um, i.* n. Οξυγλυκυ; from οξυς, acid, and γλυκυς, sweet.) A kind of apomel.

OXYIODE. A term applied by Sir H. Davy to the triple compounds of oxygen, iodine, and the metallic basis. Lussac calls them *iodates.*

OXYLA'PATHUM. (*um, i.* n.; from οξυς, acid, and λαπαθον, the dock: so named from its acidity.) See *Rumex acutus.*

O'XYMEL. (*el, elis.* n.; from οξυς, acid, and μελι, honey.) Honey and vinegar boiled to a syrup. Called also *Adipson*, and *Mel acetatum.* — Take of clarified honey, ten pounds; acetic acid, a pint and a half. Heat the honey, and add the acid to it. This preparation of honey and vinegar possesses expectorant virtues; and is given, with this intention, in humoral asthma and other diseases of the chest, in doses of one or two drachms. It is also employed in the form of gargle, when diluted with water.

Oxymel æruginis. See *Linimentum æruginis.*

OXYMEL CO'LCHICI. Oxymel of meadow saffron is an acrid medicine, but is nevertheless employed, for its diuretic virtues, in dropsies.

OXYMEL SCILLÆ. Take of clarified honey, three pounds; vinegar of squills, a pint and a half. Boil them in a glass vessel, with a slow fire, to the proper thickness. Oxymel is an excellent expectorant. In an over dose it acts as an emetic. The dose is from ʒss. to ʒij. It is a very frequent ingredient in cough mixtures.

Oxymel simplex. See *Oxymel.*

Oxymurias hydrargyri. See *Hydrargyri bichloridum.*

Oxymurias potassæ. See *Potassæ chloras.*

Oxymuriatic acid. See *Chlorine.*

OXYMY'RRHINE. (*e, es.* f.; from οξυς, acute, and μυρρινη, the myrtle: so called from its resemblance to myrtle, and its pointed leaves.) See *Myrtus communis.*

Oxymy'rsine. See *Myrtus communis.*

OXYNI'TRUM. (From οξυς, acid, and νιτρον, nitre.) A plaster described by Aëtius, composed of cerusse, rock salt, nitre, oil, and vinegar.

Oxyodic. See *Iodic.*

OXYO'PIA. (*a, æ.* f.; from οξυς, acute, and ωψ, the eye.) The faculty of seeing more acutely than is usual. Thus there have been instances known of persons who could see the stars in the day-time. The proximate cause is a preternatural sensibility of the retina. It has been known to precede the gutta serena; and it has been asserted that prisoners who have been long detained in darkness have learned to read and write in darkened places.

OXYPHLEGMA'SIA. (*a, æ.* f.; from οξυς, acute, and φλεγω, to burn.) An acute inflammation.

OXYPHŒ'NIA FRUCTUS. (Οξυς, acid, and φοινιξ, reddish.) The tamarind has been so called, on account of its colour.

OXYPHO'NIA. (*a, æ.* f.; from οξυς, sharp, and φωνη, the voice.) An acuteness of voice. See *Paraphonia.*

OXYPRUSSIC ACID. The chloro-cyanic acid has been so called.

OXYRE'GMIA. (*a, æ.* f.; from οξυς, acid, and ερευγω, to break wind.) An acid eructation.

Oxyrinchus. See *Raia oxyrinchus.*

OXYRRHO'DINON. (From οξυς, acid, and ροδινον, oil of roses.) A composition of the oil of roses and vinegar.

OXYSA'CCHARUM. (*um, i.* n.; from οξυς, acid, and σακχαρον, sugar.) A composition of vinegar and sugar.

OXYSU'LPHURET. The sulphuret of a metallic oxide.

OXYTA'RTARUS. An old name of acetate of potash.

OXY'TOCUS. (Οξυτοκος; from οξυς, quick, and τικτω, to bring forth.) Expediting delivery.

OXYTRIPHY'LLUM. (*um, i.* n.; from οξυς, acid, and τριφυλλον, trefoil: so named from its acidity.) See *Oxalis acetosella.*

OXYU'RIS. (*is, is.* m.; from οξυς, sharp, pointed, and ουρα, the tail.) The name given by Rudolphi, and adopted by Bremser, to the thread-worm, or ascaris. See *Vermes.*

Oyster. See *Ostrea edulis.*

Oyster green laver. See *Ulva lactuca.*

Oyster-shell. See *Ostrea edulis.*

OZÆ'NA. (*a, æ.* f.; from οζη, a stench.) An ulcer situated in the nose, discharging a fetid purulent matter, and sometimes accompanied with caries of the bones. Some authors have signified by the term, an ill-conditioned ulcer in the antrum. The first meaning is the original one. The disease is described as coming on with a trifling tumefaction and redness about the ala nasi, accompanied with a discharge of mucus, with which the nostril becomes obstructed. The matter gradually as-

sumes the appearance of pus, is most copious in the morning, and is sometimes attended with sneezing, and a little bleeding. The ulceration occasionally extends round the ala nasi to the cheek, but seldom far from the nose, the ala of which also it rarely destroys. The ozæna is often connected with scrofulous and venereal complaints. In the latter cases, portions of the ossa spongiosa often come away. After the complete cure of all venereal complaints, an exfoliating dead piece of bone will often keep up symptoms similar to those of the ozæna, until it is detached. Mr. Pearson remarks that the ozæna frequently occurs as a symptom of the cachexia syphiloidea. It may perforate the septum nasi, destroy the ossa spongiosa, and even the ossa nasi. Such mischief is now more frequently the effect of the cachexia syphiloidea, than of lues venerea. The ozæna must not be confounded with abscesses in the upper jaw-bone.

O'zymum. See *Ocymum.*

P.

P. A contraction of *pugillus*, a pugil, or eighth part of a handful, and sometimes a contraction of *pars* or *partes*, a part or parts.

P. Æ. A contraction of *partes æqualis.*

P. P. A contraction of *præparatus*; also of *pulvis patrum*, that is, powdered cinchona.

PA'BULUM. (*um*, *i.* n.; from *pasco*, to feed.) Food; aliment.

Pabulum vitæ. The food of life. Such are the different kinds of aliment. The animal heat and spirits were also so called.

PACHYDE'RMA. (Παχυδερμος; from παχυς, thick, and δερμα, the skin.) An order of mammiferous animals, characterised by the thickness of their hide, as the elephant, rhinoceros, &c. This term is sometimes improperly written *pachydermata*. Compare *Echinoderma.*

Pachy'ntica. (From παχυνω, to incrassate.) Medicines which have the property of incrassating or thickening the fluids.

PÆDA'NCHONE. (*e*, *es.* f.; from παις, a child, and αγχω, to strangle.) A fatal kind of angina peculiar to children, described by some old writers.

PÆ'DARTHRO'CACE. (*e*, *es.* f.; from παις, a boy, αρθρον, a joint, and κακον, an evil.) The joint evil. The scrofulous affection of the joints to which children are subject.

PÆ'DO-NOSO'LOGY. (*Pædonosologia.* From παις, a child, νοσος, a disease, and λογος, a discourse.) The study of the diseases of children.

Pænea. See *Penæa.*

PÆO'NIA. (*a*, *æ.* f.; from *Pæon*, who cured Pluto with it, when wounded by Hercules.) Pæony.

1. The name of a genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Digynia.*

2. The pharmacopœial name of the common pæony. See *Pæonia officinalis.*

Pæonia officinalis. The systematic name of the common pæony; male and female pæony. This plant, *Pæonia*, —*foliis oblongis*, of Linnæus, has long been considered as a powerful medicine; and, till lately, had a place in the catalogue of the Materia Medica, in which the two common varieties of this plant are indiscriminately directed for use; and, on the authority of G. Bauhin, improperly distinguished into male and female pæony.

The roots and seeds of the pæony have, when fresh, a faint, unpleasant smell, somewhat of the narcotic kind, and a mucilaginous subacrid taste, with a slight degree of bitterness and astringency. In drying, they lose their smell and part of their taste. Extracts made from them by water are almost insipid, as well as inodorous: but extracts made by rectified spirits are manifestly bitterish, and considerably astringent. The flowers have rather more smell than any of the other parts of the plant, and a rough sweetish taste, which they impart, together with their colour, both to water and spirit.

The roots, flowers, and seeds of pæony have been esteemed in the character of an anodyne and corroborant, but more especially the roots which, since the days of Galen, have been very commonly employed as a remedy for the epilepsy. For this purpose, it was usual to cut the root into thin slices, which were to be attached to a string, and suspended about the neck as an amulet: if this failed of success, the patient was to have recourse to the internal use of the root, which Willis directs to be given in the form of a powder, and in the quantity of a drachm, two or three times a day, by which, as we are informed, both infants and adults were cured of this disease. Other authors recommended the expressed juice to be given in wine and sweetened with sugar, as the most effectual way of administering this plant. Many writers, however, especially in modern times, from repeated trials of the pæony in epileptic cases have found it of no use whatever; though Professor Home, who gave the radix pæoniæ to two epileptics at the Edinburgh infirmary, declares that one received a temporary advantage from its use. Of the good effects of this plant in other disorders, we find no instances recorded.

PA'GINA. (*a*, *æ.* f.) The surface of a leaf.

Paigil. See *Primula veris.*

Pain. See *Dolor.*

Painter's colic. See *Colica pictonum.*

Pakfong. The white copper of the Chinese said to be an alloy of copper, nickel, and zinc.

Palate. See *Palatum.*

Palati circumflexus. See *Circumflexus palati.*

Palati levator. See *Levator palati.*

PALA'TI OS. The palate bone. The palate is formed by two bones of very irregular figure. They are placed between the ossa maxillaria superiora and the os sphenoides, at the back part of the roof of the mouth, and extend from thence to the bottom of the orbit.

Each of these bones may be divided into four parts, viz. the inferior, or square portion, the pterygoid process, the nasal lamella, and orbitar process. The first of these, or the square part of the bone, helps to form the palate of the mouth. The upper part of its internal edge rises into a spine, which makes part of the septum narium. The *pterygoid* process, which is smaller above than below, is so named from its being united with the pterygoid process of the sphenoid bone, with which it helps to form the pterygoid fossæ. It is separated from the square part of the bone, and from the nasal lamella, by an oblique fossa, which, applied to such another in the os maxillare, forms a passage for a branch of the fifth pair of nerves. The *nasal* lamella is nothing more than a very thin bony plate, which arises from the upper side of the external edge of the square part of the bone. Its inner surface is concave, and furnished with a ridge, which supports the back part of the os spongiosum inferius. Externally it is convex, and firmly united to the maxillary bone. The *orbitar* process is more irregular than any other part of the bone. It has a smooth surface, when it helps to form the orbit; and when viewed in its place, we see it contiguous to that part of the orbit which is formed by the os maxillare, and appearing as a small triangle at the inner extremity of the orbitar process of this last-mentioned bone. This fourth part of the os palati likewise helps to form the zygomatic fossa on each side, and there its surface is concave. Between this orbitar process and the sphenoid bone a hole is formed, through which an artery, vein, and nerve are transmitted to the nostrils. This hole is called the posterior palatine foramen. The ossa palati are complete in the fœtus. They are joined to the ossa maxillaria superiora, os sphenoides, os ethmoides, ossa spongiosa inferiora, and vomer.

Palati tensor. See *Circumflexus palati.*

PA'LATINE. *Palatinus.* Appertaining to the palate.

PALATINE FORAMINA. There are two, the *anterior* and *posterior.* See *Foramen incisorium* and *Palati os.*

PALA'TO-PHARYNGE'US. (So called from its origin in the palate and insertion in the pharynx.) A muscle situated at the side of the entry of the fauces. *Thyro-staphilinus,* of Douglas. *Thyro-pharyngo-staphilinus,* of Winslow. It arises by a broad beginning from the middle of the velum pendulum palati, at the root of the uvula, posteriorly, and from the tendinous expansion of the circumflexus palati. The fibres are collected within the posterior arch behind the tonsils, and run backwards to the top and lateral part of the pharynx, where the fibres are scattered and mixed with those of the stylopharyngeus. It is inserted into the edge of the upper and back part of the thyroid cartilage. Its use is to draw the uvula and velum pendulum palati downwards, and backwards, and at the same time to pull the thyroid cartilage and pharynx upwards, and shorten it; with the *constrictor superior pharyngis* and tongue, it assists in shutting the passage into the nostrils; and in swallowing, it thrusts the food from the fauces into the pharynx.

PALA'TO-SALPINGE'US. (From *palatum,* the palate, and σαλπιγξ, a trumpet: so called from its origin in the palate, and its trumpet-like shape.) See *Circumflexus.*

Palato-staphilinus. See *Azygos uvulæ.*

PALA'TUM. (*um, i.* n.; from *palo,* to hedge in: because it is staked in, as it were, by the teeth.) 1. The palate, or roof of the mouth.

2. An eminence of the inferior lip in the inner part of the mouth of gaping blossoms, which closes them; as in *Antirrhinum.* See *Corolla.*

PALATUM DURUM. The hard palate, or that part which is the fore-part of the roof of the mouth, and has the bones of the palate to form it.

PALATUM MOLLE. The soft palate. This lies behind the bony palate; and from the middle of it the uvula hangs down.

PA'LEA. (*a, æ.* f.; chaff.) *Palæa.* Chaff. Applied, in the language of botany, to short, linear, obtuse, dry scales.

PALEA'CEUS. (From *palea,* chaff.) Paleaceous: chaffy, or covered with chaff. Applied, by botanists, to the receptacles of plants; as those of *Xeranthemum, Zinnia, Anthemis,* &c. See *Receptaculum.*

PALIMPI'SSA. (From παλιν, again, and πισσα, pitch.) Dioscorides says that dry pitch is thus named, because it is prepared of pitch twice boiled.

PALINDRO'MIA. (Παλιν, again, and δρομος, a course.) This term is used by Hippocrates for any regurgitation of humours to the more noble parts; and sometimes for the return of a distemper.

PALIU'RUS. (From παλλω, to move, and ουρον, urine: or from παλιν, again, and ουρον, urine, so called from its diuretic qualities.) The *Rhamnus paliurus.*

PALLA'DIUM. (*um, ii.* n.) A metal, discovered by Dr. Wollaston, associated with platina, among the ores of which he supposes its ores to exist, or an alloy of it with iridium and osmium; scarcely distinguishable from the crude platina, though it is harder and heavier.

PALLIATIVE. (*Palliativus;* from *pallio,* to dissemble.) Applied to any thing which is given with an intent to palliate or relieve a disease, but is not capable of effecting a cure.

Palm. See *Palma.*

Palm oil. See *Cocos butyracea.*

Palm tree. See *Palmæ.*

PA'LMA. (*a, æ.* f.; from παλλω, to move.) 1. The palm of the hand.

2. A palm tree. See *Palmæ.*

Palma ady. See *Ady.*

Palma Christi. See *Ricinus.*

PA'LMÆ. (From *palma*, the hand: so called because the leaves are extended from the top, like the fingers upon the hand.) Palms. One of the natural families of plants which have trunks similar to trees, but come under the term stipes, the tops being frondescent, that is, sending off leaves. Palms are the most lofty, and, in some instances, the most long-lived of plants, and are, therefore, commonly considered as trees. But they are, in reality, perennial herbaceous plants, having nothing in common with the growth of trees in general. Palms are formed of successive circular crowns of leaves, which spring directly from the root. These leaves, and their footstalks, are furnished with bundles of large sap-vessels, and returning vessels, like the leaves of trees: when one circle of them has performed its office, another is formed within it, which, being confined below, necessarily arises a little above the former. Thus, successive circles grow one above the other; by which the vertical increase of the plant is almost without end. Each circle of leaves is independent of its predecessor, and has its own cluster of vessels; so that there can be no aggregation of woody circles.

PALMAR ARCH. The radial artery forms an arch in the palm of the hand, which is called the *deep palmar arch*, and the ulnar artery one which is called the *superficial palmar arch*. See *Radial artery* and *Ulnar artery*.

Palmar aponeurosis. See *Palmaris longus.*

PALMA'RIS. (From *palma*, the hand.) Belonging to the hand.

PALMARIS BREVIS. *Palmaris brevis vel caro-quadrata*, of Douglas. A small, thin, cutaneous, flexor muscle of the hand, situated between the wrist and the little finger. Fallopius tells us that it was discovered by Cananus. Winslow names it *palmaris cutaneus*. It arises from a small part of the internal annular ligament and inner edge of the aponeurosis palmaris, and is inserted by small bundles of fleshy fibres into the os pisiforme, and into the skin and fat that cover the abductor minimi digiti. This muscle seems to assist in contracting the palm of the hand.

Palmaris cutaneus. See *Palmaris brevis.*

PALMARIS LONGUS. A flexor muscle of the arm, situated on the fore-arm, immediately under the integuments. *Ulnaris gracilis*, of Winslow. It arises tendinous from the inner condyle of the os humeri, but soon becomes fleshy; and, after continuing so about three inches, terminates in a long slender tendon, which, near the wrist, separates into two portions, one of which is inserted into the internal annular ligament, and the other loses itself in a tendinous membrane, that is nearly of a triangular shape, and extends over the palm of the hand, from the carpal ligament to the roots of the fingers, and is called *aponeurosis palmaris*. Some of the fibres of this expansion adhere strongly to the metacarpal bones, and separate the muscles and tendons of each finger. Several anatomical writers have considered this aponeurosis as a production of the tendon of this muscle, but seemingly without reason, because we now and then find the latter wholly inserted into the carpal ligament, in which case it is perfectly distinct from the aponeurosis in question; and, in some subjects, the palmaris longus is wanting, but the aponeurosis is always to be found. Rhodius, indeed, says that the latter is now and then deficient; but there is good reason to think that he was mistaken. This muscle bends the hand, and may assist in its pronation; it likewise serves to stretch the aponeurosis palmaris.

PALMA'TUS. Palmate: hand-shaped. Applied to leaves cut, as it were, into several oblong, nearly equal segments, about half-way, or rather more, towards the base, leaving an entire space like the palm of the hand; as in *Passiflora cærulea*.

PALMI'PIDES. (From *palma*, the palm of the hand, and *pes*, a foot.) An order of birds, including those which are web-footed.

PA'LMOS. (Παλμος; from παλλω, to beat.) A palpitation of the heart.

PA'LMULA. (*a*, *æ*. f.; diminutive of *palma*, the hand; so called from its shape.) 1. A date.

2. The broad and flat end of a rib. — *Newton.*

Palo de vaca. See *Galactodendron*, in the Supplement.

PALPA'TION. *Palpatio.* (From *palpo*, to feel.) Manual examination. See *Exploratio.*

PA'LPEBRA. (*a*, *æ*. f.; *à palpitando*, from their frequent motion.) The eyelid, distinguished into upper and under; at each end they unite and form the canthi.

Palpebræ superioris, levator. See *Levator palpebræ superioris.*

Palpebrarum aperiens rectus. See *Levator palpebræ superioris.*

PA'LPEBRAL. Appertaining to the palpebra or eyelid.

PALPITA'TION. (*Palpitatio, onis*. f.; from *palpito*, to beat, leap, or throb.) A throbbing motion of any part, particularly of the heart.

PA'LPUS. Palpitation of the heart. See *Heart diseases of the.*

Palsy. See *Paralysis.*

Palsy, mercurial. See *Diseases of artizans.*

PALUDA'PIUM. (*um*, *ii*. n.; from *palus*, lake, and *apium*, smallage: so named because it grows in and about rivulets.) A species of smallage.

PALUS SANCTUS. Guaiacum wood.

PAMPHI'LIUM. (*um*, *ii*. n.; from πας, all and φιλος, grateful: so called from its extensive usefulness.) A plaster described by Galen.

PAMPI'NIFORM. (*Papiniformis*; from *pampinus*, a tendril, and *forma*, a likeness.) Resembling a tendril: applied to the spermatic chord, and the thoracic duct.

PANACE'A. (*a*, *æ*. f.; from παν, the neuter of πας, all, and ακεομαι, to cure.) An epithet given by the ancients to those remedies which they conceived would cure every disease. Unfortunately for men of the present day there are no such remedies.

PANACEA ANGLICA. Magnesia.

PANACEA DULCIS HOLSATIÆ. The sulphate of potash.

PANACEA DUPLICATA. Sulphate of potash.

PANACEA GLAUBERI. Sulphate of potash.
PANACEA HOLSATICA. Sulphate of potash.
PANACEA LAPSORUM. The *Arnica montana*.
PANACEA MERCURIALIS. Calomel.
PANACEA SOLUTIVA. Magnesia.
PANACEA VEGETABILIS. Saffron.

PANA'DA. (*a, æ.* f.; diminutive of *pane*, read, Ital.) *Panata. Panatella.* Bread boiled n water to the consistence of pap. Dry biscuits soaked are the best for this purpose.

PANALE'THES. (Παναληθες; from παν, all, and ληθης, true.) A name of a cephalic plaster, rom its universal efficacy.

PA'NARIS. (Corrupted from *paronychia.*) See *Paronychia.*

PANARI'TIA. (Corrupted from *paronychia.*) See *Paronychia.*

PA'NAX. (*ax, acis.* f.; a name borrowed rom the old Greek botanists, whose παναξ, or ρανακης, was so denominated, from παν, all, and κος, medicine, because of its universal virtues. The name being unoccupied, Linnæus adopted t for the Chinese ginseng, that famous restorative and panacea, the reputed virtues of which ield in no respect to the ancient panax.) 1. The name of a genus of plants in the Linnæan ystem. Class, *Polygamia*; Order *Diœcia.*

2. A name of the Hercules' all-heal. See *Laserpitium chironium.*

PANAX QUINQUEFOLIUM. The systematic ame of the plant which affords the ginseng oot.

Panax —*foliis ternis quinatis*, of Linnæus. The root is imported into this country scarcely he thickness of the little finger, about three or our inches long, frequently forked, transversely vrinkled, of a horny texture, and both internally nd externally of a yellowish-white colour. To he taste it discovers a mucilaginous sweetness, pproaching to that of liquorice, accompanied vith some degree of bitterness, and a slight romatic warmth. The Chinese ascribe extraordinary virtues to the root of ginseng, and have o confidence in any medicine, unless in combination with it. In Europe, however, it is very seldom employed.

PANCHRE'STOS. (*os, i.* m.; from παν, all, nd χρηστος, useful: so named from its general sefulness.) *Panchreston.* An epithet of several Greek collyria.

PANCHYMAGO'GUS. (From παν, all, χυμος, umour, and αγω, to expel. A term anciently pplied to medicines that were supposed to purge all humours alike.

PANCŒ'NUS. (From παν, all, and κοινος, ommon.) Synonymous with *epidemic.*

PANCRA'TIUM. (*um, ii.* n.; from παν, all, nd κρατος, strength: and derived by some from ρας, all, and κρατεω, to conquer; and applied o plants from their supposed power in overcoming all obstructions.) 1. An athletic exercise used by the Greeks.

2. The squill. See *Scilla maritima.*

PA'NCREAS. (*as, atis.* n.; from παν, all, and κρεας, flesh: so called from its fleshy consistence.) A glandular viscus of the abdomen, of a long gure, compared to a dog's tongue, situated in he epigastric region under the stomach. The prolonged portion at the right extremity has been called *Pancreas Asellii*, after Caspar Asselli the anatomist. It is composed of innumerable small glands, the excretory ducts of which unite and form one duct, called the pancreatic duct; which perforates the duodenum with the ductus communis choledochus, and conveys a fluid, in its nature similar to saliva, into the intestines. The pancreatic artery is a branch of the splenic. The veins evacuate themselves into the splenic vein. Its nerves are from the par vagum and great intercostal. The use of the pancreas is to secrete the pancreatic juice, which is to be mixed with the chyle in the duodenum. The quantity of the fluid secreted is uncertain; but it must be very considerable, if we compare it with the weight of the saliva, the pancreas being three times larger, and seated in a warmer place. It is expelled by the force of the circulating blood, and the pressure of the incumbent viscera in the full abdomen. Its great utility appears from its constancy, being found in almost all animals: nor is this refuted by the few experiments, in which a part of it was cut out from a robust animal, without occasioning death; because the whole pancreas cannot be removed without the duodenum; for even a part of the lungs may be cut out without producing death, but they are not therefore useless. It seems principally to dilute the viscid cystic bile, to mitigate its acrimony, and to mix it with the food. Hence it is poured into a place remote from the duct, from the liver, as often as there is no gall-bladder. Like the rest of the intestinal humours, it dilutes and resolves the mass of aliments, and performs every other office of the saliva.

Pancreas asellii. See *Pancreas.*

PANCREA'TIC. (*Pancreaticus*; from *pancreas*, the name of a viscus.) Of or belonging to the pancreas.

Pancreatic duct. See *Ductus pancreaticus.*
Pancreatic juice. See *Pancreas.*

PANCREATI'TIS. Inflammation of the pancreas.

PANCREATO'NCUS. (From παγκρεας, the pancreas, and ογκος, a tumour.) A hard tumour of the pancreas.

PANCRE'NE. (From παν, all, and κρηνη, a fountain.) A name that has been given to the pancreas.

PANDALI'TIUM. A whitlow.

PANDE'MIC. (*Pandemicus*; from παν, all, and δημος, the people.) Synonymous with epidemic.

PANDICULA'TION. (*Pandiculatio, onis.* f.; from *pandiculo*, to gape and stretch.) Yawning and stretching; such as often accompanies the cold fit of an ague.

PANDU'RIFORM. *Panduriformis.* Fiddle-shaped. Applied to a leaf which is oblong, broad at the two extremities, and contracted in the middle, as in the fiddle-dock, *Rumex pulcher.*

PANI'CULA. (*a, æ.* f.) A panicle. A species of compound inflorescence which bears the flowers in a sort of loose, subdivided bunch or cluster, without any order, appearing like a *branched* spike. The flowers of the *Æsculus hippocastanum*, *Rhus cotinus*, *Gypsophila paniculata*, and *Syringa vulgaris*, are good examples of a panicle: but this species of inflorescence

occurs most in grasses; as in *Poa aquatica*. A panicle is said to be,

1. *Patulous*, when the stalks are distant, lax, or spreading; as in *Panicula patula*, and *Campanula patula*.

2. *Coarctate*, when dense or crowded; as in *Campanula rapunculus*.

3. *Dichotomous*, forked; as in *Linum flavum*.

4. *Brachiate*, crossing each other in pairs; as in *Salvia paniculata*.

5. *Divaricate*, a more spreading one than the patulous; as in the *Prenanthes muralis*.

PANICULA'TUS. Paniculate: bunched like a panicle.

PA'NICUM. (*um*, *i*. n.; *à paniculis*, from its many panicles: the spike consisting of innumerable thick seeds, disposed in many panicles.) The name of a genus of plants in the Linnæan system. Class, *Triandria*; Order, *Digynia*.

PANICUM ITALICUM. The systematic name of the plant which affords the Indian millet-seed, which is much esteemed in Italy, being a constant ingredient in soups, and made into a variety of forms for the table.

PANICUM MILIACEUM. The systematic name of the plant which affords the millet-seed. They are esteemed as a nutritious article of diet, and are often made into puddings in this country.

PA'NIS. (*is*, *is*. m.) Bread. See *Bread*.

Panis cuculi. See *Oxalis acetosella*.

PANIS PORCI'NUS. A species of cyclamen.

PANNI'CULUS. (*us*, *i*. m.; a small piece of cloth; from *pannus*, cloth.) Applied, in *Anatomy*, to the adipose membrane — *panniculus adiposus*; and to the subcutaneous muscle of quadrupeds and birds — *panniculus carnosus*.

PANNO'NICA. (*a*, *æ*. f.; from *pannus*, a rag: so called because its stalk is divided into many uneven points, like the end of a piece of rag.) See *Hypochæris maculata*.

PA'NNUS. (*us*, *i*. m.; a piece of cloth.) 1. A tent for a wound.

2. A disease of the eye. See *Pterygium*.

3. An irregular mark upon the skin.

PANO'CHIA. A bubo in the groin.

PANOPHO'BIA. (*a*, *æ*. f.; from Παν, a Greek deity, and φοβος, fear.) That kind of melancholy which is principally characterised by groundless fears.

Pansy. See *Viola tricolor*.

PANTAGO'GUS. (From πας, all, and αγω, to drive out.) Expelling all morbid humours.

PANTO'LMIUS. (From πας, all, and τολμαω, to dare: so named from its general uses.) The name of a troch described by Ægineta.

Pantophobia. See *Panophobia*.

PA'NUS. (*us*, *i*. m.; a weaver's roll.) 1. A glandular tumour or bubo.

2. Synonymous with *phygethlon*.

PAPA'VER. (*er*, *eris*. n.; from *pappa*, pap: so called because nurses used to mix this plant in children's food to relieve the colic and make them sleep.) 1. The name of a genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Monogynia*. The poppy.

2. The pharmacopœial name of the white poppy. See *Papaver somniferum*.

PAPAVER ALBUM. The white poppy. See *Papaver somniferum*.

Papaver erraticum. See *Papaver rhœas*.

PAPAVER NIGRUM. The black poppy. This is merely a variety of the white poppy producing black seeds. See *Papaver somniferum*.

PAPAVER RHŒAS. The systematic and pharmacopœial name of the red corn poppy: called also *Papaver erraticum*.

Papaver — capsulis glabris globosis, caule-piloso multifloro; foliis pennatifidis incisis, of Linnæus. The heads of this species, like those of the somniferum, contain a milky juice of a narcotic quality, from which an extract is prepared that has been successfully employed as a sedative. The flowers have somewhat of the smell of opium, and a mucilaginous taste, accompanied with a slight degree of bitterness. A syrup of these flowers is directed in the London Pharmacopœia, which has been thought useful as an anodyne and pectoral, and is prescribed in coughs and catarrhal affections. See *Syrupus rhœados*.

PAPAVER SOMNI'FERUM. The systematic name of the white poppy, from which opium is obtained.

Linnæus describes the plant: — *Papaver — calycibus, capsulisque glabris, foliis amplexicaulibus incisis*. This drug is also called *opium thebaicum*, from being anciently prepared chiefly at Thebes: *Opion*, and *manus Dei*, from its extensive medical virtues, &c. The Arabians called it *affion* and *afium*. It is the concreted milky juice of the capsule or head of the poppy. It is brought from Turkey, Egypt, the East Indies, and other parts of Asia, where poppies are cultivated for this use in fields, as corn among us. The manner in which it is collected has been described long ago by Kæmpfer and others; but the most circumstantial detail of the culture of the poppy, and the method of procuring the opium, is that given by Kerr, as practised in the province of Bahar. He says, "The field being well prepared by the plough and harrow, and reduced to an exact level superficies, it is then divided into quadrangular areas of seven feet long, and five feet in breadth, leaving two feet of interval, which is raised five or six inches, and excavated into an aqueduct for conveying water to every area, for which purpose they have a well in every cultivated field. The seeds are sown in October or November. The plants are allowed to grow six or eight inches distant from each other, and are plentifully supplied with water; when the young plants are six or eight inches high, they are watered more sparingly. But the cultivator spreads all over the areas a nourishing compost of ashes, human excrements, cow-dung, and a large portion of nitrous earths, scraped from the highways and old mud walls. When the plants are nigh flowering, they are watered profusely, to increase the juice. When the capsules are half grown, no more water is given, and they begin to collect the opium. At sunset they make two longitudinal double incisions upon each half-ripe capsule, passing from below upwards, and taking care not to penetrate the internal cavity of the capsule. The incisions

are repeated every evening until each capsule has received six or eight wounds; then they are allowed to ripen their seeds. The ripe capsules afford little or no juice. If the wound was made in the heat of the day, a cicatrix would be too soon formed. The night dews, by their moisture, favour the exstillation of the juice. Early in the morning, old women, boys, and girls collect the juice, by scraping it off the wounds with a small iron scoop, and deposit the whole in an earthern pot, where it is worked by the hand, in the open sunshine, until it becomes of a considerable spissitude. It is then formed into cakes of a globular shape, and about four pounds in weight, and laid into little earthern basins to be further exsiccated. These cakes are covered over with leaves, and dried until they are fit for sale. Opium is frequently adulterated with cow-dung, the extract of the poppy-plant procured by boiling, and various other substances which they keep in secrecy." This process, however, is now but rarely practised, the consumption of this drug being too great to be supplied by that method of collection.

It comes to the European market in flattish cakes, sprinkled with pieces of dried leaves, and with the seed capsules of some species of rumex. It should be of a rich brown colour, a tough consistency, and a tolerably smooth and uniform texture. Its peculiar narcotic smell should be strong and fresh, and unaccompanied by any burnt odour. Its taste is nauseously bitter, and slightly warm and acrid. Those pieces which are very soft, full of herbaceous impurities, containing patches of a very dark brown or black extract, of an empyreumatic odour, or not smelling duly narcotic, are in general adulterated; and it is not uncommon to find bullets concealed in masses even of the best opium. When good opium is carefully dried, it becomes brittle, and affords a yellow brown powder. It burns with flame, and exhales an odour in which may be traced some resemblance to that of animal matter. These are the characters of the most genuine opium which reaches this country, and which is imported from Turkey: an inferior article, of a much darker colour, a less narcotic odour, and more bitter in taste, is imported under the name of *East India opium*. It is frequently mixed with the Turkey opium, an article which, on account of its large consumption, and high price, is open to a great variety of adulterations, both abroad and at home: indeed, it is not probable that much unadulterated opium ever reaches this country. Opium of a very excellent quality has been grown in *England*; and in medicinal powers it has been found fully as effective as the foreign: but the coldness and changeable nature of our climate renders it unlikely that it should ever be produced here in any considerable quantity, so as even to supply a small part of the commercial demands for this drug.

The chemical nature of opium has long been matter of inquiry: but it is only lately that the subject has been at all satisfactorily investigated, and that, through the researches of Sertuerner, Robiquet, and several other chemists, we have been made acquainted with the existence of a peculiar salifiable base in opium, to which the name of *morphia* has been given, and to which its activity as a narcotic may probably be exclusively ascribed.

Morphia, not in a very pure state, is copiously precipitated by adding ammonia to a strong solution of opium; but a better mode of obtaining it is to triturate powdered opium into a thin paste with acetic acid, and afterwards to add six or eight parts of water. The liquor may be filtered off through coarse paper, and the residue treated with a small additional portion of acetic acid and water, as before. Add excess of ammonia to the filtered liquors, which will occasion a precipitate, to be collected in a filter: evaporate the filtered liquor to about one fifth its bulk; add a little more ammonia, and a second precipitate is obtained, which may be added to the former. These precipitates are impure morphia: they may be cleansed by digestion in small quantities of cold alkohol, which will remove the chief part of the colouring matter, and the residue being dissolved in boiling alkohol furnishes crystals of pure morphia, as the liquid cools. In this process the salt of morphia (*meconate of morphia?*), existing in opium, is decomposed by acetic acid, and a solution of acetate of morphia obtained, which the ammonia decomposes. Robiquet's process for obtaining morphia is as follows: — Boil a concentrated solution of opium for a quarter of an hour with a small quantity of magnesia (about two hundred grains of magnesia to a pound of opium is sufficient): filter, and wash the grey precipitate with cold water: dry it, and digest it in warm but weak alkohol, by which much colour is dissolved; then collect it upon a filter, boil it in highly rectified alkohol, and filter the solution while hot: as it cools, it deposits crystallised morphia. In this process, the meconate of morphia, originally existing in the opium, is decomposed by the magnesia, and the precipitate consists of morphia, mixed with meconate of magnesia and a portion of uncombined magnesia. The morphia is separated from the precipitate by boiling alkohol. It seems probable that, in opium, the morphia is combined with an acid, which, being in excess, gives to solutions of opium the property of reddening vegetable blues. This acid (the meconic?) may be obtained from the residuum of the magnesian precipitate, left undissolved by alkohol in the above process for procuring morphia. For this purpose, the magnesian residue is dissolved in very dilute sulphuric acid, and muriate of barytes added to the sulphuric solution: a red precipitate, consisting of sulphate and meconate of barytes, falls. This precipitate is to be boiled with very dilute sulphuric acid, by which the meconate of barytes is decomposed; and the meconate acid may be obtained from the filtered liquor by due evaporation. It may be purified by sublimation at a gentle heat. This acid has no narcotic effect.

By digesting opium in ether, and slowly evaporating the filtered etherial tincture, a crystallised substance, contaminated by a little oil and caoutchouc, is obtained, which is perfectly dis-

tinct from, and independent of, morphia. This is the substance which has been termed *narcotine*, and, from its discoverer, *salt of Derosne*. Upon this the exciting and stimulating power of opium, which usually precedes its sedative effects, is by some supposed to depend. It is insoluble in water, scarcely soluble in alkohol, and not alkaline.

Morphia is a colourless substance, of a bitter taste, and crystallises in quadrangular prisms. It is very little soluble, even in boiling water, but it dissolves in boiling alkohol, and the solution deposits crystals as it cools. It reddens turmeric, and converts vegetable blues to green, in the manner of an alkali: it also combines with the acids, forming with most of them crystallisable salts.

Pure morphia, in consequence of its difficult solubility, is uncertain in its operation as a narcotic; but some of its salts may probably be found useful substitutes for opium. The acetate of morphia is said to have been employed with advantage; and, indeed, acetic tincture of opium, which may be presumed to contain acetate of morphia, has long been used as a preparation less liable to stimulate and excite than most others of opium. It has also been supposed that some advantage may be derived by separating the narcotine from opium, which may be effected by washing the extract of opium, before it is sufficiently inspissated, with repeated portions of sulphuric ether. There is, however, no satisfactory evidence of any improvement in the medical effects of opium derived from such a process.

Exclusive of its active principles, opium contains inert extractive matter, gum, gluten, and a few saline substances: but these, as well as the morphia, vary extremely in their relative proportions, so that it is of little use to state those afforded by any individual sample of the drug. Dr. A. T. Thompson states in his Dispensatory, that fine Turkey opium contains nearly three times the quantity of morphia yielded by the same weight of East Indian opium. "From a very carefully prepared sample of English opium, I procured," says Professor Brande, "rather a larger quantity of morphia than from the same weight of Turkey opium." The average produce of morphia from a pound of good opium may be estimated at about five hundred grains, or one fourteenth its weight; but it is improbable that the whole is separated in any of our processes.

Morphia, according to its discoverer, melts in a gentle heat; and in that state has very much the appearance of melted sulphur. On cooling, it again crystallises. It burns easily; and, when heated in close vessels, leaves a solid resinous black matter, having a peculiar smell. Morphia acts with great energy on the animal economy. A grain and a half, taken at three different times, produced such violent symptoms upon three young men of seventeen years of age, that Sertuerner was alarmed lest the consequences should have proved fatal.

The use of opium, though not unknown to Hippocrates, can be clearly traced to Diagoras, who was nearly his contemporary; and its importance has ever since been gradually advanced by succeeding physicians of different nations. Its extensive practical utility, howev , has not been long well understood; and in this country, perhaps, may be dated from the time of Sydenham. Opium is the chief narcotic now employed: it acts directly upon the nervous power, diminishing the sensibility, irritability, and mobility of the system; and, according to Cullen, in a certain manner suspending the motion of the nervous fluid to and from the brain, and thereby inducing sleep, one of its principal effects. From this sedative power of opium, by which it allays pain, inordinate action, and restlessness, it naturally follows that it may be employed with advantage in a great variety of diseases. Indeed, there is scarcely any disorder in which, under some circumstances, its use is not found proper; and though in many cases it fails of producing sleep, yet, if taken in a full dose, it occasions a pleasant tranquillity of mind, and a drowsiness which approaches to sleep, and which always refreshes the patient. Besides the sedative power of opium, it is known to act more or less as a stimulant, exciting the motion of the blood. By a certain conjoined effort of this sedative and stimulant effect, opium has been thought to produce intoxication, a quality for which it is much used in eastern countries.

The principal indications which opium is capable of fulfilling are, supporting the actions of the system, allaying pain and irritation, relieving spasmodic action, inducing sleep, and checking morbidly increased secretions. It is differently administered, as it is designed to fulfil one or other of these indications.

Where opium is given as a stimulus, it ought to be administered in small doses, frequently repeated, and slowly increased, as by this mode the excitement it produces is best kept up. But where the design is to mitigate pain or irritation or the symptoms arising from these, it ought to be given in a full dose, and at distant intervals by which the state of diminished power and sensibility is most completely induced.

One other general rule, with respect to the administration of opium, is, that it ought not to be given in any purely inflammatory affection, at least until evacuations have been used, or unless means are employed to determine it to the surface, and produce a diaphoresis.

In continued fevers, not of the pure inflammatory kind, opium is administered sometimes as a general stimulus, and at other times to allay irritation. The great practical rule in such cases is, that it ought to be given in such quantities only that the pulse becomes slower and fuller from its operation. Its exhibition is improper where local inflammation, especially of the brain or of its membranes, exists.

In intermittent fever, an opiate renders the paroxysms milder, and facilitates the cure. Dr. Cullen recommends the union of opium with bark, which enables the stomach to bear the latter in larger doses, and adds considerably to its efficacy.

In the profluvia and cholera, opium is employed to lessen the discharge, and is frequen

he principal remedy in effecting the cure. In passive hæmorrhage, it is useful by its stimulant power. In retrocedent gout it is used as a powerful stimulant.

In convulsive and spasmodic diseases it is advantageously administered, with the view of relieving symptoms, or even of effecting a cure; and in several of them it requires to be given to a very great extent.

In lues venerea it promotes the action of mercury, and relieves the irritation arising either from that remedy or the disease.

In the year 1779, opium was introduced into practice as a specific against the lues venerea. It was employed in several of the military hospitals, where it acquired the reputation of a most efficacious remedy; and Dr. Michaelis, physician of the Hessian forces, published an account of a great number of successful experiments made with it, in the first volume of the Medical Communications, in the year 1784. Opium was afterwards given as an antivenereal remedy in some foreign hospitals. Many trials were also made of its virtues in several of the London hospitals, and in the Royal Infirmary at Edinburgh. Very favourable reports of its efficacy in removing venereal complaints were published by different practitioners; but, at the same time, so many deductions were to be made, and so many exceptions were to be admitted, that it required little sagacity to discover that most of the advocates for this medicine reposed but a slender and fluctuating confidence in its antivenereal powers. Mr. Pearson made several experiments on the virtues of opium in lues venerea, at the Lock Hospital, in the years 1784 and 1785; and published a narrative of its effects, in the second volume of the Medical Communications. "The result of my experiments," says he, "was very unfavourable to the credit of this new remedy; and I believe that no surgeon in this country relies on opium as a specific against the venereal virus. I have been long accustomed to administer opium with great freedom during the mercurial course; and the experience of nearly twenty years has taught me that, when it is combined with mercury, the proper efficacy of the latter is not in any measure increased; that it would not be safe to rely upon a smaller quantity of the mineral specific, nor to contract the mercurial course within a shorter limit than where no opium has been employed. This representation will not, I presume, admit of controversy; yet we frequently hear people expressing themselves upon this head, as if opium manifested some peculiar qualities in venereal complaints, of a distinct nature from its well-known narcotic properties, and thus afforded an important aid to mercury in the removal of lues venerea." Perhaps it may not be useless to disentangle this subject from the perplexity in which such indefinite language necessarily involves it. Opium, when given in conjunction with mercury, by diminishing the sensibility of the stomach and bowels, prevents many of those inconveniences which this mineral is apt to excite in the primæ viæ; and thus its admission into the general system is facilitated. Mercury will likewise often produce a morbid irritability, accompanied with restlessness and insomnolescence; and it sometimes renders venereal sores painful, and disposed to spread. These accidental evils, not necessarily connected with venereal disease, may be commonly alleviated, and often entirely removed, by a judicious administration of opium; and the patient will consequently be enabled to persist in using the mineral specific. It, however, must be perfectly obvious that opium, in conferring this sort of relief, communicates no additional virtues to mercury; and that, in reality, it assists the constitution of the patient, not the operation of the medicine with which it is combined. The salutary effects of mercury as an antidote may be diminished or lost by the supervention of vomiting, dysentery, &c. Opium will often correct these morbid appearances, and so will spices, wine, and appropriate diet, &c.; yet it would be a strange use of words to urge, wherever these articles of food were beneficial to a venereal patient, that they concurred in augmenting the medicinal virtues of mercury. It may be supposed that the majority of medical men would understand by the terms, "to assist a medicine in curing a contagious disease," that the drug conjoined with the specific actually increased its medicinal efficacy: whereas, in the instances before us, it is the human body only which has been aided to resist the operation of certain noxious powers, which would render a perseverance in the antidote prejudicial or impossible. The soothing qualities of this admirable medicine can scarcely be estimated too highly. Yet we must beware of ascribing effects to them which have no existence; since a confidence in the antivenereal virtue of opium would be a source of greater mischief than its most valuable properties would be able to compensate.

Opium is employed with laxatives in colic, and often prevents ileus and inflammation, by relieving the spasm.

It is given also to promote healthy suppuration, and is a principal remedy in arresting the progress of gangrene.

The sudorific property of opium is justly considered of considerable power, more especially in combination with ipecacuan or antimony. The compound powder of ipecacuan, consisting of one part of ipecacuan, one part of opium, and eight of sulphate of potash, is a very powerful sudorific, given in a dose of from 15 to 25 grains. The combination of opium with antimony is generally made by adding 30 or 40 drops of antimonial wine to 25 or 30 drops of tincture of opium, and forming them into a draught.

Opium, taken into the stomach in immoderate doses, proves a narcotic poison, producing vertigo, tremors, convulsions, delirium, stupor, stertor, and, finally, fatal apoplexy.

Where opium has been taken so as to produce these dangerous consequences, the contents of the stomach are first to be evacuated by a powerful emetic, as a solution of the sulphate of zinc. Large draughts of vinegar, or any of the native vegetable acids, are then to be swallowed. Moderate doses of brandy, or a strong infusion of coffee, have also been found useful.

Respecting the external application of opium, authors seem not sufficiently agreed. Some allege that, when applied to the skin, it allays pain and spasm, procures sleep, and produces all the salutary or dangerous effects which result from its internal use; while others say that, thus applied, it has little or no effect whatever. It has also been asserted, that when mixed with caustic, it diminishes the pain which would otherwise ensue; and, if this be true, it is probably by decreasing the sensibility of the part. Injected by the rectum, it has all the effect of opium taken into the stomach; but, to answer this purpose, double the quantity is to be employed. Applied to the naked nerves of animals, it produces immediate torpor and loss of power in all the muscles with which the nerves communicate.

The requisite dose of opium varies in different persons, and in different states of the same person. A quarter of a grain will in one adult produce effects which ten times the quantity will not do in another; and a dose that might prove fatal in cholera or colic, would have no effect at all in many cases of tetanus, or mania. The lowest fatal dose to those unaccustomed to take it, seems to be about four grains; but a dangerous dose is so apt to produce vomiting, that its fatal consequences are often averted in this way. When given in too small a dose, it often produces disturbed sleep, and other disagreeable consequences; and, in some cases, it seems impossible to be made to agree in any dose or form. Often, on the other hand, from a small dose, sound sleep and alleviation of pain will be produced; while a larger one occasions vertigo and delirium. Some prefer the repetition of small doses; others the giving a full dose at once: its operation is supposed to last about eight hours. This, however, must depend upon circumstances. The usual dose is one grain.

The following are the officinal preparations of this drug: — *Opium purificatum; Confectio opii; Electuarium opii; Electuarium catechu comp.; Pilulæ opii; Pilulæ saponis cum opio; Pulvis opiatus; Pulvis cornu usti cum opio; Pulvis cretæ comp. cum opio; Pulvis ipecacuanhæ comp.; Tinctura opii; Tinctura camphoræ comp.; Tinctura opii ammoniata; Acetum opii; Vinum opii; Trochisci glycyrrhiræ cum opio; Emplastrum opii; Linimentum saponis cum opio; Enema opii*, &c. The capsules of the poppy are also directed for medicinal use in the form of fomentation; see *Decoctum papaveris:* and the *syrupus papaveris*, prepared from them, is an useful anodyne, which often succeeds in procuring sleep where opium fails: it is, however, more especially adapted to children. The seeds of this species of poppy contain a bland oil, and in many places are eaten as food: as a medicine, they have been usually given in the form of emulsion in catarrhs, stranguries, &c.

Papaw. The fruit of a species of *carica*. See *Carica papaya*.

PAPILIONA'CEOUS. (From *papilio*, a butterfly, which it resembles.) *Papilionaceus*. Butterfly-like. Applied to the corolla of plants when they are irregular and spreading, and thus resemble somewhat the butterfly. The various petals which compose such a flower are distinguished by appropriate names: *vexillum*, the standard, the large one at the back; *alæ*, the two side petals; and *carina*, the heel, consisting of two petals united or separate, embracing the internal organs.

PAPI'LLA. (*a, æ.* f.; from *pappus*, down.) 1. The nipple of the breast. See *Mamma*.

2. The fine termination of a nerve, &c.; as the nervous papillæ of the tongue, skin, &c.

Papillæ medullares. Small eminences on the medulla oblongata.

Papillaris alba. See *Lapsana*.

PAPILLO'SUS. (From *papilla*.) Papillose: pimpled. Applied to stalks connected with soft tubercles; as the ice plant, *Mesembryanthemum crystallinum*.

PAPPO'SUS. Pappose: furnished with a pappus of seed-down; as the seeds of the *Leontodon taraxacum*.

PA'PPUS. (*us, i.* m.; from παππος.) 1. In *Anatomy*, the hair on the middle of the chin. See *Capillus*.

2. In *Botany*, the *seed-down*. This is restrained by Gærtner to the chaffy, feathery, or bristly crown of many seeds that have no pericarpium, and which originates in a partial calyx crowning the summits of each of these seeds, and remaining after the flower is fallen; as in the seeds of dandelion, goat's-beard, &c.

The same term is used by the generality of botanists for the feathery crown of seeds furnished with a capsule, as well as for a similar appendage to the base or sides of any seeds; neither of which can originate from a calyx. For the former of these, Gærtner adopts the term *coma;* for the latter, *pubes;* which last also serves for any downiness or wool about the *testa* of a seed; as in the cotton-plant, and *Blandfordia nobilis*.

The varieties of the pappus are,

1. *Sessile*, on the apex of the seed, without any footstalk; as in *Asclepias, Syriaca, Nerium oleander*, and *Epilobium*.

2. *Stipitate*, elevated on a footstalk; as in *Leontodon taraxacum*..

3. *Plumose*, when the radii of the footstalked pappus are hairy laterally; as in *Tragopogon pratense*.

The *lana pappiformis* of authors is not a pappus, but hairs which only surround the seed; as in *Eryophorum*.

PA'PULA. (*a, æ.* f.; diminutive of *pappa*, a dug or nipple.) A very small and acuminated elevation of the cuticle, with an inflamed base, not containing a fluid, nor tending to suppuration. The duration of papulæ is uncertain, but they terminate for the most part in scurf.

Papulæ. Pimples. The name of an order in Dr. Willan's arrangement of cutaneous diseases, characterised by very small and acuminated elevations of the cuticle, with an inflamed base, very seldom containing a fluid, or suppurating, and commonly terminating in scurf. They appear to originate in an inflammation of the papillæ of the skin, by which these are enlarged, elevated, and indurated, and made

ssume more or less of a red colour. Sometimes even a slight effusion of lymph takes place, which gives a vesicular appearance to several of he papillæ; but the fluid is re-absorbed without breaking the cuticle, and they terminate, for the most part, in scurf. The order contains *strophulus*, *lichen*, and *prurigo*.

PA'R. (*ar, aris.* n.; a pair.) A pair.

PAR CUCULLARE. So Casserius calls the *Cricoarytænoid muscle*.

PAR VAGUM. The eighth pair of nerves. See *Pneumogastric nerve*.

PARABY'SMA. (*a, atis.* n.; Παραβυσμα; from παραβυω, to intrude, to cram in, to congest.) Turgescence. Dr. Good has applied his term to a genus of diseases comprehended by Cullen and others under that of physconia.

PARACELSISTS. The followers of Paracelsus. This enthusiast, whose real name was Philip Hochener, was born about 1403, and died in 1541. He may be regarded as the father of he sect of chemical physicians. His doctrines were derived from an extraordinary mixture of experimental chemistry, empirical medicine, astrological and alchemical dreams, and cabalistical superstitions; the whole forming a mass of imposing absurdity, the like of which has never been known before or since. The Paracelsists were a numerous sect till towards the close of he seventeeth century. However ridiculous many of their opinions may have been, we owe o their labours many important discoveries in chemistry, and the introduction of many active and useful substances into the *materia medica*.

PARACENTE'SIS. (*is, is.* f.; from παρακεντεω, to pierce through.) Tapping. The operation of evacuating the water in ascites, dropsy of the ovarium, &c.

PARACMA'STICOS. (From παρακμαζω, to decline.) See *Acmasticos*.

PARA'COE. (From παρα, diminutive, and ακουω, to hear.) Dulness of hearing.

PARACOLLE'TICUS. (From παρακολλαομαι, to glue together.) Agglutinant: causing the union of parts preternaturally separated.

PARA'COPE. (Παρακοπη; from παρακοπτω, to be delirious.) A slight delirium. — *Hippocrates*.

PARACORO'LLA. Link gives this name to the little second corolla that is found within the perigonium of the narcissus.

PARACRU'SIS. (Παρακρουσις; from παρακρουομαι, to be delirious.) A slight delirium.

PARACU'SIS. (*is, is.* f.; from παρα, wrong, and ακουω, to hear.) Depraved hearing. This may be occasioned by any thing that proves injurious to the ear, as loud noises from the firing of cannon, violent colds, particularly affecting the head, inflammation or ulceration of the membrane, hard wax, or other substances interrupting sounds, too great a dryness, or too much moisture in the parts; or by atony, debility, or paralysis of the auditory nerves. In some instances it ensues in consequence of preceding diseases, such as fever, syphilis, &c., and in others it depends upon an original defect in the structure or formation of the ear. In the last instance, the person is usually not only deaf, but likewise dumb. There are two species: —

1. *Paracusis imperfecta*, or deafness; when existing sounds are not heard as usual.

2. *Paracusis imaginaria*; when imaginary sounds are heard, not from without, but excited within the ear. In attempting the removal of deafness, the first thing to be done is to remove from the auditory canal every thing that may obstruct the ingress of the ear, as wax, tumours, &c., which will cause the person to hear. If the internal ear, or the immediate organ of hearing, be the seat of the cause of deafness, little can be done, because the cause is not known; but blisters behind the ear, stimulating applications to the auditory canal, and around the ear, are often useful.

PARACYE'SIS. (*is, is.* f.; from παρα, badly, and κυησις, pregnancy.) Extra uterine pregnancy.

PARACYNA'NCHE. (*e, es.* f.; from παρα, κυων, a dog, and αγχω, to strangle.) See *Cynanche*.

Paradise, grains of. See *Amomum granum paradisi*.

Paradisi grana. See *Amomum*.

PARAGEU'SIS. (*is, is.* f.; from παρα, badly, and γευω, *gustum præbeo*.) Morbid taste.

PARAGLO'SSA. (*a, æ.* f.; from παρα, and γλωσσα, the tongue.) A swelled tongue. A prolapsus or displacement of the tongue.

PARAGO'GE. (From παραγω, to adduce.) This term signifies that fitness of the bones to one another which is discernible in their articulation; and bones which are thereby easier of reduction, when dislocated, are by Hippocrates called παραγωγοτερα.

PARALA'MPSIS. (From παραλαμπω, to shine a little.) Some writers use this word to express a cicatrix in the transparent part of the cornea of the eye.

PARA'LIUS. (Παραλιος. Belonging to the sea.) The trivial name of a species of euphorbia. See *Euphorbia paralias*.

PARALLA'GMA. (From παραλλαττω, to transpose.) *Parallaxis*. The transposition of a solid part from its proper place; as where one part of a broken bone lies over another.

Parallaxis. See *Parallagma*.

PARALLE'LA. (From παραλληλος, parallel.) A scurfy syphilitic eruption affecting only the palms of the hands, and running down them in parallel lines.

PARALO'PHIA. (*a, æ.* f.; from παρα, near, and λοφια, the first vertebra of the back.) The lower and lateral part of the neck near the vertebræ, according to some anatomical writers, as Keil, &c.

PARA'LYSIS. (*is, is.* f.; from παραλυω, to loosen, or weaken.) *Catalysis. Attonitus morbus.* The palsy. A disease known by a loss or diminution of the power of voluntary motion, affecting any part of the body. The most usual form of palsy is when one side of the body is affected: it not uncommonly seizes the lower extremities, or all parts below the pelvis; sometimes the arms only; and occasionally a part, as one side of the face, one eyelid, the tongue, or the muscles of degluti-

tion; and hence the Cullenian arrangements into, —

1. *Paralysis partialis*, when partial, or palsy of some particular muscle.

2. *Paralysis hemiplegica*, when it affects one side longitudinally.

3. *Paralysis paraplegica*, palsy of one half of the body, taken transversely, as both legs and thighs.

4. *Paralysis venenata*, when it arises from the sedative effects of poison.

Paralysis is also symptomatic of several diseases; as worms, scrofula, syphilis, &c.

It may arise in consequence of an attack of apoplexy. It may likewise be occasioned by any thing that prevents the flow of the nervous power from the brain into the organs of motion; as tumours pressing on the spinal cord or on the nerves. It may also be occasioned by the metastasis of morbid actions to the head, by the suppression of usual evacuations, and by the pressure made on the nerves by luxations, fractures, wounds, or other external injuries. The long-continued application of sedatives will likewise produce palsy, as we find those whose occupations subject them to the constant handling of white lead, and those who are much exposed to the poisonous fumes of metals or minerals, are very apt to be attacked with it. Whatever tends to relax and enervate the system may likewise prove an occasional cause of this disease.

Palsy usually comes on with a sudden and immediate loss of the motion and sensibility of the parts; but, in a few instances, it is preceded by a numbness, coldness, and paleness, and sometimes by slight convulsive twitches. When the head is much affected, the eye and mouth are drawn on one side, the memory and judgment are much impaired, and the speech is indistinct and incoherent. If the disease affects the extremities, and has been of long duration, it not only produces a loss of motion and sensibility, but likewise a considerable flaccidity and wasting away in the muscles of the parts affected.

When palsy attacks any vital part, such as the brain, heart, or lungs, it soon terminates fatally. When it arises as a consequence of apoplexy, it generally proves very difficult to cure. Paralytic affections of the lower extremities, ensuing from any injury done to the spinal marrow, by blows and other accidents, usually prove incurable. Palsy, although a dangerous disease in every instance, particularly at an advanced period of life, is sometimes removed by the occurrence of a diarrhœa or fever.

The morbid appearances to be observed on dissections in palsy are various lesions of the brain and spinal cord, more frequently the former. Where hemiplegia is a consequence of apoplexy, sanguineous effusion is generally found to have taken place in the brain on the side opposite to that which is paralysed.

The general indications are, to remove, as far as possible, any compressing cause, and to rouse gradually the torpid portion of the nervous system. It will sometimes be proper, where the attack is sudden, the disease originating in the head, with great determination of blood to that part, particularly in a plethoric habit, to open the temporal artery or jugular vein, or apply cupping-glasses to the neck, and exhibit active purges, with the other means pointed out under apoplexy. But where the patient is advanced in life, of a debilitated constitution, and not too full of blood, the object should rather be to procure regular and healthy discharges from the bowels, obviate irritation in the brain by blisters in the neighbourhood, and procure a steady determination to the skin by gently stimulant diaphoretics, as ammonia, guaiacum, &c. in moderate doses regularly persevered in. Emetics have been sometimes very useful under these circumstances, but would be dangerous where congestion in the brain existed. Certain narcotic substances have been found occasionally successful, as aconite, arnica, toxicodendron, nux vomica, and opium: but the tendency of the latter to produce fulness of the vessels of the head must greatly limit its use. Various local means of increasing the circulation and nervous energy in the affected parts are resorted to in this complaint, often with decided benefit. In all cases it is proper to keep up sufficient warmth in the limb, or the disease may be rendered incurable. But in addition to this, in tedious cases, fomentations, the vapour bath, friction, electricity, and a variety of stimulant, rubefacient, or even vesicatory, embrocations, liniments, and plasters, may assist materially in the recovery of the patient. In the use of some of these it should be a rule to begin near the boundary of the disease, and carry them onward, as the amendment proceeds, not only as they will be more likely to answer a good purpose, but also because there would be some risk in stimulating too powerfully an extreme part. A suitable diet, according to the habit of the patient, warm clothing, the prudent use of the cold bath, and other means calculated to strengthen the system, must not be neglected.

PARALYSIS AGITANS. The shaking palsy. See *Synclonus ballismus*.

PARALYSIS HERBA. So called from its use in paralytic disorders. The cowslip and primrose have been so termed. See *Primula veris*, and *Primula vulgaris*.

PARAME'NIA. (*a*, *æ*. f.; from παρα, badly, and μην, the menses.) Disordered menstruation.

PARAME'RIA. (Παραμηρια; from παρα, near, and μηρος, the thigh.) The inner part of the thigh.

PARA'MESUS. (Παραμεσος; from παρα, near, and μεσος, the middle.) The ring-finger, or that which is between the middle and the little fingers.

PARAMO'RPHIA. (From παρα, wrong, and μορφη, form.) Morbid structure. Applied to organic diseases.

PARANEURI'SMUS. (From παρα, wrong, and νευρον, a nerve.) A nervous disease.

PARANŒ'A. (*a*, *æ*. f.; from παρα, diminutive, and νοεω, to understand.) *Paranoia*. Synonymous with *dementia*.

PARAPE'CHYUM. (*um*, *ii*. n. Παραπηχυον; from παρα, near, and πηχυς, the cubit.) That part of the arm from the elbow to the wrist.

PARAPHIMO'SIS. (*is, is.* f.; from παρα, about, and φιμοω, to bridle.) A disorder wherein the prepuce, being retracted towards the root of the penis, cannot be returned again over the glans, but makes a sort of ligature behind the corona. It is easily known: the glans is uncovered, the skin tumefied on the corona, and above it forms a circular collar or stricture, which, from the skin being unequally extended, becomes indented, and makes several rings round the part. This disease may proceed from three causes: —

1. From the imprudence of young people, and sometimes also of grown persons, who, having the end of their prepuce too straight, cannot uncover their glans without pain, and when they have done it, neglect returning it so soon as they ought; and thus the contracted part of the prepuce forms a constriction behind the glans. Soon after, the glans and penis swell, and the prepuce, being consequently very much distended, is affected in the same manner: an inflammation seizes upon both, and swellings quickly appear upon the stricture formed by the prepuce, so that the whole may be liable to a gangrene, if not speedily relieved.

2. It may arise from common inflammation of the prepuce, especially if there be a phymosis, in which state, if the foreskin be accidentally retracted, the glans penis swells, and cannot be drawn back, and a paraphymosis is the consequence.

3. It is often the result of the venereal virus. In adults, whose glans is uncovered, there frequently arise venereal chancres in the prepuce after impure coition, which are attended with inflammation more or less considerable. This inflammation is alone sufficient to render the prepuce too straight for the size of the penis, in consequence of which a swelling or inosculation may ensue like that before mentioned.

Cold lotions and leeches generally reduce the inflammation, and remove the constriction; but if it does not give way to these, and the glans is strangulated, it will be necessary to divide the prepuce in order to set it at liberty. When the inflammation is very violent, it has been known to produce a gangrene of the glans which has sloughed away; but this rarely happens when early recourse is had to surgical aid. See *Phymosis.*

PARAPHO'NIA. (*a, æ.* f.; from παρα, wrong, and φωνη, sound.) Alteration of the voice. Dr. Cullen makes the following species: —

1. *Paraphonia puberum.* About the age of puberty the change of voice from an acute and soft to a grave and harsh tone.

2. *Paraphonia rauca.* The voice hoarse and rough, from dryness of flaccid tumour of the fauces.

3. *Paraphonia resonans.* Rough voice, from obstruction of the nares, with hissing sound in the nose.

4. *Paraphonia palatina.* From the uvula wanting, or divided, and commonly attended with hare-lip, the voice rough, obscure, and disagreeable.

5. *Paraphonia clangens.* An acute, shrill, and weak-toned voice.

6. *Paraphonia comatosa.* A sound emitted at inspiration, from relaxation of the velum palati, and of the glottis.

In all these instances the change of the voice is symptomatic, and the cure depends on the removal of the primary disease.

PARA'PHORA. (*a, æ.* f.; from παραφερω, to transfer.) A slight kind of delirium, or light-headedness in a fever. Some use this word for a delirium in general.

PARAPHRENE'SIS. (*is, is.* f.) A delirium; also a paraphrenitis.

PARAPHRENI'TIS. (*is, idis.* f.; from παρα, *malè*, not rightly, and *phrenitis*, inflammation of the brain: so called because its symptoms resemble those of phrenitis, or inflammation of the brain, which it is not.) See *Diaphragmatitis.*

PARAPHRO'SYNE. (From παραφρονεω, to be estranged in mind.) Mental derangement: used in the same sense as mania.

Paraphymosis. See *Paraphimosis.*

PARAPLE'GIA. (*a, æ.* f.; from παραπλησσω, to strike inharmoniously.) Palsy of the upper or lower half of the body. See *Paralysis.*

PARAPOPLE'XIA. (*a, æ.* f.; from παρα, diminutive, and αποπληξια, an apoplexy.) A slight apoplexy.

PARA'PSIS. (*is, is.* f.; from παρα, *perperam*, and ἁπτομαι, *tango.*) Mason Good's generic name for disorders of the sense of touch. See *Dysæsthæsia.*

PARARTHRE'MA. (*a, atis.* n.; from παρα, and αρθρον, a joint.) A subluxation or slight displacement of a bone from its articulation.

PARARRHY'THMOS. (From παρα, and ῥυθμος, rhythm.) The Greek epithet of a pulse not suitable to the age of the person.

PARASCEPA'STRA. (From παρα, and σκεπαζω, to cover.) A cap or bandage to go round the whole head. — *Galen.*

PARA'SCHIDE. (From παρα, and σχιζω, to cleave.) A fragment or splinter of a broken bone.

PARASI'TÆ. The name of an order of plants in Linnæus's Fragments of a Natural Method.

PARASI'TICAL. (*Parasiticus*; from παρασιτος, a parasite, or hanger on.) Parasitic. An animal is so termed that receives its nourishment in the bodies of others; as worms, polypi, hydatids, &c.

A plant is so called that does not take root in the earth, but sends its roots into other plants, from which it draws its nourishment; as the *Epidendrum vanilla.*

Parasiticus. See *Parasitic.*

PARASI'TA. Parasites. An order of the class *Insecta.* See *Animal kingdom.*

PARASI'TUS. (*us, i.* m.; παρασιτος, a parasite.) A parasite: applied to animals and vegetables which draw their nourishment from others of the same kingdom, living within the interior of animals, or having their roots fixed in the bark of vegetables.

PARA'SPHAGIS. (Παρασφαγις; from παρα, near, and σφαγη, the throat.) The part of the neck contiguous to the clavicles.

PARA'STATES. (Παραστατης; from παριστημι, to stand near.) Any thing situated near another. Applied by the Greek anatomists to the epididymis, to the prostate gland, and to the commencement of the vas deferens.

PARASTRE'MMA. (From παραστρεφω, to distort.) A convulsive distortion of the mouth, or any part of the face.

Parasynanche. See *Cynanche.*

PARA'THENAR. (*ar, aris.* n.; from παρα, near, and θεναρ, the sole of the foot.) Winslow called a portion of the abductor of the little toe by the name of *parathenar major*, and the short flexor of the same toe he called *parathenar minor.*

PAREC'CRISIS. (*is, is.* f.; from παρα, wrong, and εκκρινω, to secern or secrete.) Disordered secretion.

PAREGO'RIC. (*Paregoricus;* from παραγορεω, to mitigate, to assuage.) Anodyne.

PAREGORIC ELIXIR. This name is given in England to the *Tinctura camphoræ composita*, but in Scotland it is applied to the *Tinctura opii ammoniata* of the Edinburgh pharmacopœia. These preparations are of very different strength, the English paregoric containing only a grain of opium in half an ounce; and the Scotch the same quantity in a drachm.

PAREI'A. Παρεια. That part of the face which is between the eye and chin. The cheek.

PAREI'RA BRAVA. (The Spanish name of the American wild vine.) See *Cissampelos pareira.*

PARENCE'PHALIS. (Παρεγκεφαλις; from παρα, near, and εγκεφαλος, the brain.) The cerebellum. See *Encephalos.*

PARE'NCHYMA. (*a, atis.* n.; from παρεγχυω, to strain through: because the ancients believed the blood was strained through it.) 1. The spongy and cellular substance or tissue that connects parts together. It is applied to the connecting medium of the substance of the viscera.

2. The green juicy layer of the bark which lies immediately under the epidermis of trees.

PA'RESIS. (*is, is.* f.; from παριημι, to relax.) An imperfect palsy.

PARI'ETAL. (*Parietalis;* from *paries*, a wall.) Appertaining to a wall.

PARIETA'LE OS. (So called because it defends the brain like a wall.) *Os verticis. Os sincipitis. Os verticale vel bregmatis.* The parietal bones are two arched and somewhat quadrangular bones, situated one on each side of the superior part of the cranium. Each of these bones forms an irregular square. They are thicker above than below; but are somewhat thinner, and at the same time more equal and smooth than the other bones of the cranium. The only foramen we observe in them is a small one towards the upper and posterior part of each. It has been named the parietal foramen, and serves for the transmission of a small vein to the longitudinal sinus. In many subjects this foramen is wanting. On the inner surface of these bones are the marks of the vessels of the dura mater, and of the convoluted surface of the brain. On the inside of their upper edge we may likewise observe a considerable furrow, which corresponds with the longitudinal sinus of the dura mater; and lower down, towards their posterior and inferior angle, is a smaller one for part of the lateral sinuses. These bones are joined to each other by the sagittal suture; to the os sphenoides and ossa temporum by the squamous suture; to the os occiptis by the lambdoidal suture; and to the os frontis by the coronal suture. Their connexion with this latter bone is well worthy our attention. We shall find that in the middle of the suture, where the os frontis from its size and flatness is the most in danger of being injured, it rests upon the arch formed by the parietal bones: whereas, at the sides, the parietal bones are found resting upon the os frontis, because this same arch is there in the greatest danger from pressure. In new-born infants, the ossa parietalia are separated from the middle of the divided os frontis by a portion of the cranium, then unossified. When the finger is applied to this part, the motion of the brain, and the pulsation of the arteries of the dura mater, may be easily distinguished. In general, the whole of this part is completely ossified before we are seven years of age.

PARIETA'RIA. (*a, æ.* f.; from *paries*, a wall: because it grows upon old walls, among rubbish.) 1. The name of a genus of plants in the Linnæan system. Class, *Polygamia;* Order, *Monœcia.*

2. The pharmacopœial name of the wall pellitory. See *Parietaria officinalis.*

PARIETARIA OFFICINALIS. The systematic name of the wall pellitory; called also, *Perdicium*, and *Helxine.*

Parietaria —foliis lanceolato-ovatis, pedunculis, dichotomis, calycibus diphyllis, of Linnæus. This plant has no smell, and its taste is simply herbaceous. In the practice of the present day it is wholly laid aside, although it was formerly in high estimation as a diuretic.

PARI'LLINE. An alkali recently discovered by Pallotta in the root of sarsaparilla.

PA'RIS. (Etymology uncertain; perhaps so called in reference to the youth of that name who adjudged the golden apple to Venus, the herb bearing but one seed.) 1. The name of a genus of plants in the Linnæan system. Class, *Octrandria;* Order, *Tetragynia.*

2. The pharmacopœial name of the herb Paris. See *Paris quadrifolia.*

PARIS QUADRIFOLIA. The systematic name of the herb Paris, or true love. The color and smell of this plant indicate its possessing narcotic powers. The leaves and berries are said to be efficacious in the cure of hooping cough, and to act like opium. Great caution is requisite in their exhibition, as convulsions and death are caused by an overdose. The root possesses emetic qualities.

PARI'STHMIA. (From παρα, and ισθμον, the fauces.) 1. The parts constituting the fauces.

2. The term used by Hippocrates for inflammation of the fauces.

PARISTHMIO'TOMUS. (*us. i.* m.; from παρ

θμια, the tonsils, and τεμνω, to cut.) An old instrument with which the tonsils were scarified.

PARISTHMI'TIS. (*is, idis.* f.; from παρισθμιον, the tonsil gland.) Inflammation of the fauces.

Park-leaves. See *Hypericum androsæmum.*

PARODO'NTIS. (From παρα, near, and οδους, a tooth.) A painful tubercle upon the gums.

PARONI'RIA. (*a, æ.* f.; from παρα, and ονειρος, a dream.) Disturbance of the sleep by unpleasant dreams.

PARONY'CHIA. (*a, æ.* f.; from παρα, about, and ονυξ, the nail.) A whitlow, or whitloe. Any collection of pus formed in the fingers is termed by authors *panaris*, or whitlow, and is an abscess of the same nature with those arising in other parts of the body. These abscesses are situated more or less deep, which has induced the writers upon the subject to divide them into several species: accordingly they have ranged them under four heads, agreeably to the places where they are formed. The first kind is formed under the cuticle, on one side of the nail, and sometimes all round it. The second is seated in the fat lying under the skin, between that and the sheath which involves the flexor tendons. The third is described by authors to be formed within the sheath; and they still add a fourth species, arising between the periosteum and the bone, which they call *felon*. Poultices are particularly useful in these several forms of whitlow, for their moisture is imbibed by the cuticle, which it softens, as it does also the skin, and even the nail, and thus lets out the pus from under the nail. When this does not result, and in all cases where the pus is deep seated, the abscess must be opened with the lancet.

PARO'PIÆ. (Παροπιαι; from παρα, near, and ωψ, the eye.) The external angles of the eyes.

PARO'PSIS. (*is, is.* f.; from παρα, *badly*, and οψις, *visus*, sight.) Mason Good's generic term for disorders of the sense of vision.

PAROPTE'SIS. (From παρα, and οπταω, to roast.) A provocation of sweat, by making a patient approach the fire, or by placing him in a dry bath.

PARORA'SIS. (Παρορασις; from παρα, and οραω, to see.) Weak or depraved sight. — *Galen.*

PARORCHI'DIUM. (*um, ii.* n.; from παρα, and ορχιδιον, a testicle.) Malposition of the testicle, whether consisting in its detention in the abdomen or at the groin, or in a retraction of the organ into the groin.

PARO'STIA. (*a, æ.* f.; from παρα, and οστεον, a bone.) Defective ossification. — *Mason Good.*

PAROTIDE'US. (From παρα, about, and ους, the ear.) 1. The epithet of a gland. See *Parotid gland.*

2. Appertaining to the gland so named. The trivial name of a species of sore throat, the *cynanche parotidea.*

PAROTID GLAND. *Glandula parotidea. Parotis.* A large conglomerate and salival gland, situated under the ear, between the mammillary process of the temple-bone and the angle of the lower jaw. The excretory duct of this gland perforates the buccinator muscle, and opens into the mouth opposite to the space between the second and third molar tooth of the upper jaw.

PARO'TIS. (*is, idis.* f.; from παρα, near, and ους, the ear.) 1. The parotid gland.

2. An inflammatory swelling of the parotid gland.

PAROTI'TIS. (*is, idis.* f.; from *parotis*, the parotid gland, the seat of the complaint, and *itis*, which imports inflammation.) The mumps. An inflammation of the parotid gland. As the inflammation takes place, the cheeks become swollen and painful, there is difficulty in opening the mouth, and in swallowing. Very little constitutional derangement attends this disease, which is mostly produced by a miasm in low and swampy situations. It is believed to be contagious; for when it makes its appearance in a school, and youths are the subjects of it, it generally goes through it. It seldom attacks the more aged and infants. It declines about the fourth or sixth day.

The disease is subject to a metastasis occasionally, in females to the mammæ, in males to the testes; and in a few instances, repelled from these parts, it has affected the brain, and even proved fatal. In general, however, the disease is without danger, and scarcely calls for medical aid. Keeping a flannel over the part, and the antiphlogistic regimen, with mild laxatives, will be sufficient. Should the mammæ or the testes be affected, more active evacuations may be necessary to prevent the destruction of those organs, bleeding general and topical, &c., but avoiding cold applications, lest it should be driven elsewhere.

PA'ROXYSM. (*Paroxysmus, i.* m.; from παροξυνω, to aggravate.) 1. An obvious increase of the symptoms of a disease which lasts a certain time and then declines.

2. A periodical attack or fit of a disease, as that of an ague.

Parsley. See *Apium petroselium.*

Parsley, black mountain. See *Athamanta.*

Parsley, Macedonian. See *Bubon.*

Parsley, stone. See *Amomum verum.*

Parsnip. See *Pastinaca sativa.*

Parsnip, water. See *Sium nodiflorum.*

PARTHENIA'STRUM. (Diminutive of *parthenium*, tansy.) See *Matricaria.*

Parthenis. The same as *parthenium.*

PARTHE'NIUM. (*um, ii.* n.; from παρθενος, a virgin: so called because of its uses in diseases of young women.) See *Matricaria parthenium.*

Parthenium mas. See *Tanacetum.*

PARTI'TUS. Partite: cut, as it were, almost to the base; and, according to the number of incisions, *bipartite* when two, *tripartite* when three, *quadripartite* when four, *quinque-partite* when five, &c.

PARTURI'TION. (*Parturitio, onis*, f.; from *pario*, to bring forth young.) The expulsion of the fœtus from the uterus.

After seven months of pregnancy, the fœtus has all the conditions for breathing, and exercising its digestion; it may then be separated from its mother, and change its mode of existence: childbirth rarely, however, happens at this period: the fœtus remains two months longer in the uterus, and it does not pass out

of this organ till after the completion of nine months.

Examples are related of children being born after ten full months of gestation; but these cases are very doubtful, for it is very difficult to know exactly the period of conception. The legislation, in France, however, has fixed the principle, that childbirth may take place the 299th day of pregnancy.

Nothing is more curious than the mechanism by which the fœtus is expelled: every thing happens with wonderful precision: all seems to have been foreseen, and calculated to favour its passage through the pelvis, and the genital parts.

The physical causes that determine the exit of the fœtus are the contraction of the uterus, and that of the abdominal muscles: by their force the liquor amnii flows out, the head of the fœtus is engaged in the pelvis, it goes through it, and soon passes out by the vulva, the folds of which disappear. These different phænomena take place in succession, and continue a certain time: they are accompanied with pains more or less severe, with swelling and softening of the soft parts of the pelvis, and external genital parts, and with an abundant mucous secretion in the cavity of the vagina. All these circumstances, each in its own way, favour the passage of the fœtus.

To facilitate the study of this complicated action, it must be divided into several periods.

The first period of childbirth. — It is constituted by the precursory signs. Two or three days before childbirth, a flow of mucus takes place from the vagina, the external genital parts swell, and become softer: it is the same with the ligaments that unite the bones of the pelvis; the *cervix uteri* flattens, its opening is enlarged, its edges become thinner; slight pains, known by the name of *flying pains*, are felt in the loins and abdomen.

Second period. — Pains of a peculiar kind come on: they begin in the lumbar region, and seem to be propagated towards the *cervix uteri*, or the *rectum*; they are renewed only after considerable intervals, as a quarter, or half an hour. Each of them is accompanied with an evident contraction of the body of the uterus, with tension of its neck, and dilatation of the opening: the finger, directed into the vagina, discovers that the envelopes of the fœtus are pushed outward, and that there is a considerable tumour, which is called *the waters*: the pains very soon become stronger, and the contractions of the uterus more powerful; the membranes break, and a part of the liquid escapes; the uterus contracts on itself, and is applied to the surface of the fœtus.

Third period. — The pains and contractions of the uterus increase considerably; they are instinctively accompanied by the contraction of the abdominal muscles. The woman who is aware of their effect is inclined to favour them, in making all the muscular efforts of which she is capable: her pulse then becomes stronger and more frequent, her face is animated, her eyes shine, her whole body is in extreme agitation, and perspiration flows in abundance. The head is then engaged in the pelvis: the occiput, placed at first above the left acetabulum, is directed inward and downward, and comes below and behind the arch of the pubis.

Fourth period. — After some instants of repose, the pains and expulsive contractions resume all their activity: the head presents itself at the vulva, makes an effort to pass, and succeeds when there happens to be a contraction sufficiently strong to produce this effect. The head being once disengaged, the remaining parts of the body easily follow, on account of their smaller volume. The section of the umbilical cord is then made, and a ligature is put round it at a short distance from the umbilicus.

Fifth period. — If the accoucheur has not proceeded immediately to the extraction of the placenta after the birth of the child, slight pains are felt in a short time, the uterus contracts freely, but with force enough to throw off the placenta, and the membranes of the ovum: this expulsion bears the name of *delivery*. During the twelve or fifteen days that follow childbirth, the uterus contracts by degrees upon itself, the woman suffers abundant perspirations, her mammæ are distended by the milk that they secrete; a flow of matter, which takes place from the vagina, called *lochia*, first sanguiferous, then whitish, indicates that the organs of the woman resume, by degrees, the disposition that they had before conception.

Such is the course of a natural labour, the accomplishment of which implies the completion of the natural term of gestation — a proper confirmation on the part of the mother — and a natural development and normal position on the part of the fœtus. Various deviations from these conditions give rise to different irregularities in the process of parturition, attended with greater or less danger to the mother and child. The subdivision of labours has been carried by many writers to a frivolous degree of minuteness, especially by some French authors. The classification adopted by Dr. Burns is perhaps the most practically useful. It is as follows: —

Class I. *Natural labour.* Labour taking place at the end of the ninth month of pregnancy, the child presenting the central portion of the sagittal suture, and the forehead being directed at first toward the sacro-iliac symphysis; a due proportion existing betwixt the size of the head, and the capacity of the pelvis: the pains being regular and effective, the process not continuing beyond twenty-four hours, seldom above twelve, and very often not for six. No morbid affection supervening, capable of preventing delivery, or endangering the life of the woman.

This comprehends only one order.

Class II. *Premature labour*, or labour taking place considerably before the completion of the usual period of utero-gestation, but yet not so early as necessarily to prevent the child from surviving.

This comprehends only one order.

Class III. *Preternatural labours*, or those in which the presentation, or position of the child is different from that which occurs

natural labour; or in which the uterus contains a plurality of children, or monsters.

This comprehends seven orders.

Order 1. Presentation of the breech.

Order 2. Presentation of the inferior extremities.

Order 3. Presentation of the superior extremities.

Order 4. Presentation of the back, belly, or sides of the child.

Order 5. Malposition of the head.

Order 6. Presentation of the funis.

Order 7. Plurality of children, or monsters.

Class IV. *Tedious labour*, or labour protracted beyond the usual duration; the delay not caused by the malposition of the child, and the process capable of being finished safely, without the use of extracting instruments.

This comprehends two orders.

Order 1. Where the delay proceeds from some imperfection or irregularity of muscular action.

Order 2. Where it is dependent principally on some mechanical impediment.

Class V. *Laborious or instrumental labour;* labour which cannot be completed without the use of extracting instruments; or altering the proportion betwixt the size of the child, and the capacity of the pelvis.

This comprehends two orders.

Order 1. This case admitting the use of such instruments as do not necessarily destroy the child.

Order 2. The obstacle to delivery being so great, as to require that the life of the child should be sacrificed for the safety of the mother.

Class VI. *Impracticable labour;* labour in which the child, even when reduced in size, cannot pass through the pelvis.

This comprehends only one order.

Class VII. *Complicated labour;* labour attended with some dangerous or troublesome accident or disease, connected in particular instances with the process of parturition.

This comprehends six orders.

Order 1. Labour complicated with uterine hemorrhage.

Order 2. Labour complicated with hemorrhage from other organs.

Order 3. Labour complicated with syncope.

Order 4. Labour complicated with convulsions.

Order 5. Labour complicated with rupture of the uterus.

Order 6. Labour complicated with suppression of urine, or rupture of the bladder.

PA'RTUS. (*us, ûs.* m.; from *pario*, to bring forth young.) 1. Labour, or the act of bringing forth young.

2. The young when brought forth.

PARU'LIS. (*is, idis.* f.; from παρα, near, and ουλον, the gum.) An inflammation, boil, or abscess in the gums. A gum-boil is often a primary disease, depending on an inflammation of the gums from accidental and common causes, in which case the lancet, or leaving it to nature, soon restores the gum to a healthy state. But sometimes it arises from a carious tooth, or from cutting the dentes sapientiæ. From the first of these, the gum-boil frequently returns, and requires the removal of the tooth; from the latter, much irritation is often produced, and the jaw and face swell considerably. If there be constitutional disturbance with it, leeches and purgatives are to be resorted to.

PARU'RIA. (*a, æ.* f.; from παρω, *perperam*, and ουρεω, to make water.) Mismicturition.

PARY'GRON. (Παρυγρον; from παρα, and ὑγρος, humid.) A liquid or moist preparation for allaying a slight topical inflammation. — *Galen.*

PASI'PHILUS. (Πασιφιλος; from πας, all, and φιλος, grateful; from its general usefulness.) The name of a desiccative plaster, composed of equal parts of vitriol, sandarach, misy, and chalcitis.

PA'SMA. (From πασσω, to sprinkle over.) A dry powder to sprinkle over the body. See *Catapasma.*

PA'SSA. (*a, æ.* f.; from *pando*, to spread.) 1. A grape or raisin.

2. Paracelsus uses this word to signify a whitlow.

Passa minor. See *Uva passa minor.*

PASSAVA'NTICUS. (From πας, all, and αναινω, to dry up.) The epithet of an old purgative powder.

PASSIFLO'RA. (*a, æ.* f.; altered by Linnæus, from *flos passionis* of preceding botanists: a term applied to the beautiful genus in question, because the instruments of Christ's passion were thought to be represented in the parts of the fructification.) The name of a genus of plants in the Linnæan system. Class, *Gynandria;* Order, *Pentandria.*

PASSIFLORA LAURIFOLIA. Bay-leaved passion-flower. A native of Surinam. The fruit of this tree grows to the size of a small lemon, which it greatly resembles. It has a delicious smell and flavour, and is excellent for quenching thirst, abating heat of the stomach, increasing the appetite, recruiting the spirits, and allaying the heat in fevers.

PASSIFLORA MALIFORMIS. Apple-shaped granadilla. The fruit of this species of passion-flower is esteemed a delicacy in the West Indies, where it is served up at table in desserts. It is not unwholesome.

Passio hysterica. See *Hysteria.*

Passio ileaca. See *Ileac passion.*

PASSION. (Πάθημα. *Passio, onis.* f.; from *patior*, to suffer.) 1. By passion, is generally understood an instinctive feeling become extreme and exclusive. A man of strong passion neither hears, sees, nor exists, but through the feeling which agitates him; and as the violence of this feeling is such that it is extremely painful, it has been called *passion* or *suffering.* The passions have the same end as instinct; like them, they incline animals to act according to the general laws of animated nature. We see in man passions which he has in common

with the animals, and which consist of animal wants become excessive; but he has others which are displayed only in the social state. These are *social* wants grown to excess.

The *animal passions* have a twofold design, the preservation of the individual, and of the species. To the preservation of the individual belong fear, anger, sorrow, hatred, excessive hunger, &c. To the preservation of the species, excessive venereal desires, jealousy, the fury which is felt when the young ones are in danger, &c.

Nature has made this sort of passions very powerful, and they are equally so in a state of civilisation.

The passions which belong to the social state are only the social wants carried to an excess. Ambition is the inordinate love of power; avarice, the love of riches become excessive; hatred and revenge, the natural and impetuous desire to injure whoever hurts us; the passion of gaming, and almost all the vices, which are also passions, are violent inclinations to increase the feeling of existence; violent love is an elevation of the venereal desires, &c.

Some of the passions are allayed or extinguished by gratification; others become more irritated by it. The first sort is, therefore, often the cause of happiness, as is seen in philanthropy and love; whilst the latter sort necessarily causes misery. Misers, ambitious and envious people, are examples of the last.

If our necessities develop the intellect, the passions are the principle or the cause of every thing *great* which man performs, whether good or bad. Great poets, heroes, great criminals, and conquerors, are men of strong passions. — *Magendie.* The passions have a strong influence on the health of the individual. See *Pathemata animi.*

2. The disease named *ileus*, is called also *ileac passion*, and the paroxysm of hysteria has been called *hysteric passion.*

Passion, cœliac. See *Diarrhœa cœliaca.*

Passion, hair-brained. See *Pathemata animi.*

Passion, hysteric. See *Hysteria.*

Passion, ileac. See *Ileac passion.*

PASSU'LA. (*a*, *æ*. f.) A small raisin.

Passula major. See *Vitis vinifera.*

PASSULA'TUS. (From *passula*, a fig, or raisin.) This epithet is applied, by the old pharmacologists, to some medicines in which raisins are the chief ingredient; as the *Electuarium passulatum*, &c.

PA'SSUM. (*um*, *i*. n.; from *passa*, a grape, or raisin.) Raisin wine.

PA'STA. (*a*, *æ*. f.) A cake or lozenge.

Pasta regia. See *Panis sancti marci*, in the Supplement.

PASTI'LLUM. (*um*, *i*. n.; diminutive of *pasta*, a lozenge.) *Pastillus.* A pastil or troch.

PASTINA'CA. (*a*, *æ*. f.; so called because its root resembles the *pastinum*, a forked instrument used by the Romans for planting seeds.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia.* Parsnip.

2. The pharmacopœial name of the parsnip. See *Pastinaca sativa.*

PASTINACA OPOPANAX. The plant which yields the opopanax of commerce, was formerly referred to the genus *pastinaca*, but it is now placed under a new genus *opoponax.* See *Opoponax chironium*, in the Supplement.

PASTINACA SATIVA. The systematic name of the parsnip; called also, *Banica*, and *Elaphoboscum.* The cultivated or garden parsnip is the *Pastinaca — foliolis simpliciter pinnatis*, of Linnæus. Its roots are sweet and nutritious, and in high esteem as an article of food. They possess an aromatic flavour, more especially those of the wild plant, and are exhibited in calculous complaints for their diuretic and sheathing qualities.

PÂTE ARSENICALE. Arsenical paste. This consists of seventy parts of cinnabar, twenty-two of dragons' blood, and eight of white arsenic, made into a paste with saliva at the time of its application. It is much used in France as a caustic to destroy cancerous tumours; but is justly reprobated by English surgeons. See *Arsenious acid.*

PATE'LLA. (*a*, *æ*. f.; diminutive of *patina*, a dish: so named from its shape.) *Rotula.* The knee-pan. A small flat bone, which, in some measure, resembles the common figure of the heart, with its point downwards, and is placed at the fore-part of the joint of the knee. It is thicker in its middle part than at its edge. Anteriorly it is a little convex, and rough for the insertion of muscles and ligaments; posteriorly it is smooth, covered with cartilage, and divided by a middle longitudinal ridge, into two slightly concave surfaces, of which the external one is the largest and deepest. They are both exactly adapted to the pulley of the os femoris. The edges of this posterior surface are rough and prominent where the capsular ligament is attached, and below is a roughness at the point of the bone, where the upper extremity of a strong tendinous ligament is fixed, which joins this bone to the tuberosity at the upper end of the tibia. This ligament is of considerable thickness, about an inch in breadth, and upwards of two inches in length. The patella is composed internally of a cellular substance, covered by a thin bony plate; but its cells are so extremely minute, that the strength of the bone is, upon the whole, very considerable. In new-born children it is entirely cartilaginous. The use of this bone seems to be, to defend the articulation of the joint of the knee from external injury. It likewise tends to increase the power of the muscles which act in the extension of the leg, by removing their direction farther from the centre of motion, in the manner of a pulley. When we consider the manner in which it is connected with the tibia, we find that it may very properly be considered as an appendix to the latter, which it follows in all its motions so as to be to the tibia what the olecranon is to the ulna; with this difference, however, that the patella is moveable, whereas the olecranon is a fixed process. Without this mobility, the rotatory motion of the leg would have been prevented.

PA'TENS. Patent. Expanding. Spreading. Applied in botany to leaves which form a moderately acute angle, with the stem or branch. *folia pdtentia.*

PATHE'MA. (*a, atis.* n.) Passion; emotion. See *Passion.*

Pathemata animi. Passions of the mind. These are divided into the exciting and depressing; and each of these again, in a medical point of view, into such as excite suddenly and with temporary violence, or more slowly and permanently.

Passions are either,

1. *Exciting.*

a. In a violent degree; as *rage, intense enthusiasm.*

b. More moderately; as *joy, emulation, desire, hope, benevolence, love.*

2. *Depressing.*

a. In a violent degree; as *terror, grief.*

b. More moderately; as *fear, jealousy, envy, resentment.*

3. *Calming;* as *veneration, admiration, contemplation.*

Persons of strong, active imaginations, sanguine in temperament, and eager in their pursuits and expectations, are most liable to, and suffer most from, the violently exciting passions. The effects are often apoplexy, palsy, hæmorrhage, jaundice. The depressing passions are, in different degrees, sedative. The more violent ones are sometimes fatal in a moment. The others slowly undermine the constitution, weaken every function, and produce indigestion and dropsy.

PATHE'TICUS. (*Pathetic;* from παθος, an affection.) Appertaining to the passions.

Pathetici. The fourth pair of nerves are so called, because they are distributed to the *musculus patheticus,* or superior oblique muscle of the eye.

Patheticus musculus. The superior oblique muscle of the eye is so called, on account of its instrumentality in expressing certain passions.

PATHOGNOMO'NIC. (*Pathognomonicus;* from παθος, a disease, and γινωσκω, to know.) A term given to those symptoms which are peculiar to a disease. They are also termed proper or characteristic symptoms.

PATHO'LOGY. (*Pathalogia, æ.* f.; from παθος, a disease, and λογος, a discourse.) The doctrine of diseases. That branch of medicine which treats of the nature of diseases. It is divided into *general pathology,* which regards what is common to a number of diseases taken as a class; and *special pathology,* which treats of individual diseases: thus, the consideration of fever, in a wide sense of the term, is a matter of general pathology; but the consideration of typhus, and the morbid states on which it more particularly depends, is a matter of special pathology. Pathology is subdivided into *medical* and *surgical.*

Patie'ntia. (*a. æ.* f.; from *patior,* to bear, or suffer.) A name of the herb monks' rhubarb. Why it is so called we know not. See *Rumex patientia.*

Patience. See *Rumex patientia.*

Pa'tor na'rium. (From *pateo,* to be open.) The sinus, cavity, or chasm of the nose.

Patrum cortex. (So called from the Jesuits, who first spread its use in Europe.) See *Cinchona.*

PA'TULUS. Open: a term frequently used in botany.

Patu'rsa. A barbarous name of the venereal disease.

Paul's betony. See *Veronica.*

Paulina confectio. See *Aristarchi antidotus paulina.*

Pavana. See *Croton tiglium.*

PA'VO. (*o, onis.* m. and f.) The name of a genus of birds, of the order *Gallinæ.* The peacock.

Pavo cristatus. The pea-fowl. The flesh of this bird is delicate when young; but it is more esteemed for its beauty than as an aliment.

PA'VOR. (*or, oris.* m.) 1. Fear. See *Pathemata animi.*

2. The itch, from the fear there is of catching it.

Pea. See *Pisum sativum.*

Pea-fowl. See *Pavo cristatus.*

Peach. See *Amygdalus persica.*

Peagle. See *Primula veris.*

Pear. See *Pyrus communis.*

Pearl. See *Margarita.*

Pearl-ash. An impure potash, obtained by lixiviation from the ashes of plants. See *Potassa.*

Pearl barley. See *Hordeum.*

Pearl white. The subnitrate of bismuth.

Peche'dion. Πηχεδιον. The perinæum.

Pechu'rim cortex. An highly aromatic bark, the produce of a species of *Laurus.* The odour is extremely fragrant, like unto that of cinnamon, which it greatly resembles in its properties. In Lisbon it is much esteemed in the cure of dysenteries, and for allaying obstinate vomitings.

Pechurim faba. See *Faba pechurim.*

Pechuris. See *Faba pechurim.*

Pechy'agra. (From πηχυς, the cubit, and αγρα, a seizure.) The gout in the elbow. The term is an incorrect one.

Pe'chys. Πηχυς. The cubit, or elbow.

Pechyty'rbe. An incomprehensible name for the scurvy. It is used by Forest.

Pecquet's duct. See *Thoracic duct.*

PE'CTEN. (*en, inis.* m.) The pubes.

PE'CTIC ACID. (*Acidum pecticum;* so called from πηκτις, a coagulum.) The name given by Braconnot to an acid, which he conceives to be universally diffused through vegetables, and analogous to, if not identical with, jelly. Eighty-five parts of this acid seem to neutralise 15 of potash, and afford a compound like gum arabic.

PECTINA'LIS. (So named from its arising at the *pecten,* or pubes.) *Pectinæus,* of authors. A small flat muscle, situated obliquely between the pubes and the little trochanter, at the upper and anterior part of the thigh. It arises broad and fleshy from the anterior edge of the os pectinis, or pubis, as it is more commonly called, as far as its spine; and, descending obliquely backwards and outwards, is inserted by a short and broad tendon, into the upper and anterior part of the linea aspera of the os femoris, a little below the lesser trochanter. This muscle serves to bend the thigh, by drawing it upwards and

inwards, and likewise assists in rolling it outwards.

PECTINA'TUS. (From *pecten*, a comb.) Pectinate: comb-like. 1. A term applied to a pinnatifid leaf, the segments of which are remarkably narrow and parallel, like the teeth of a comb; as the lower leaves of the *Hottonia palustris*, and *Meriophyllum verticillatum*.

2. The fasciculated muscular fibres of the right auricle of the heart are called *musculi pectinati*.

Pectinæus. See *Pectinalis.*

PE'CTORAL. (*Pectoralis*; from *pectus*, the breast.) Appertaining to the breast. Pectoral medicines are those which relieve diseases of the chest.

Pectoral moss. See *Lichin pulmonarius.*

PECTORALIS MAJOR. A broad, thick, fleshy, and radiated muscle, situated immediately under the integuments, and covering almost the whole anterior part of the breast. *Pectoralis*, of authors. Winslow calls it *pectoralis major*, to distinguish it from the serratus minor anticus, which he has named *pectoralis minor*. It arises from the cartilaginous extremities of the fifth and sixth ribs, from the last of which its tendinous fibres descend over the upper part of the obliquus externus and rectus abdominis, helping to form a part of the sheath in which the latter is included. It likewise springs from almost the whole length of the sternum by short tendinous fibres, which evidently decussate those on the other side; and tendinous and fleshy from more than a third of the anterior part of the clavicle. From these origins the fibres run in a folding manner towards the axilla, and are inserted by a broad tendon into the os humeri, above the insertion of the deltoid muscle, and at the outer side of the groove which lodges the tendon of the long head of the biceps. Some of its fibres likewise extend into that groove; and, from the lower part of this tendon, which is spread near two inches along the os humeri, we find it sending off other fibres, which help to form the fascia that covers the muscles of the arm. It often happens that that part of the pectoralis, which arises from the clavicle, is separated from the inferior portion, so as to appear like a distinct muscle. This has induced Winslow to divide it into parts, one of which he calls the *clavicular*, and the other the *thoracic* portion. Sometimes these two portions are inserted by separate tendons, which cross one another at the upper and inner part of the os humeri, the tendon of the thoracic portion being inserted at the outer edge of the bicipital groove, immediately behind the other. This muscle, and the latissimus dorsi, form the cavity of the axilla, or arm-pit. The use of the pectoralis is to move the arm forwards, or to raise it obliquely towards the sternum. It likewise occasionally assists in moving the trunk upon the arm; thus, when we exert any efforts with the hand, as in raising ourselves from an arm-chair, or in sealing a letter, the contraction of this muscle is particularly observable. To these uses Haller adds that of assisting in respiration, by raising the sternum and ribs. He tells us he well remembers, that when this muscle was affected by rheumatism, his breathing was incommoded; and that, when troubled with difficulty of respiration, he had often found himself greatly relieved by raising and drawing back his shoulders, keeping his arms at the same time firmly fixed. Winslow, however, has denied this use, and Albinus has omitted it, probably because it does not take place in a natural state.

PECTORALIS MINOR. *Serratus anticus*, of Albinus. A small fleshy and digitated muscle, situated at the anterior and lateral part of the thorax, immediately under the pectoralis major. Douglas and Cowper call this muscle *Serratus minor anticus*; and Winslow gives it the name of *Pectoralis minor*. It arises from the upper edges of the third, fourth, and fifth ribs, near where they join with their cartilages, by an equal number of tendinous and fleshy digitations, which have been compared to the teeth of a saw, whence this and some other muscles, from their having a similar origin, or insertion, have got the name of *serratus*. From these origins it becomes thicker and narrower as it ascends, and is inserted by a flat tendon into the upper part of the coracoid process of the scapula. The principal use of this muscle is to draw the scapula forwards and downwards; and when that is fixed, it may likewise serve to elevate the ribs.

PECTORI'LOQUY. (*Pectorilóquium*; from *pectus*, the chest, and *loquor*, to speak: so called because the voice seems as if it proceeded directly from the chest of the patient.) When the stethoscope is applied over an excavation of the lungs which communicates with the bronchiæ, the voice appears to come direct through the tube of the instrument from the chest of the patient to the ear of the auscultator. This phenomenon is called *pectoriloquy*. It is distinguished into *perfect*, *imperfect*, and *doubtful*. The two latter are with difficulty distinguishable from bronchophony, and are not at all to be depended on unless in conjunction with the symptoms. Pectoriloquy is most frequently heard in the subclavicular and axillary regions because vomicæ are most frequently formed in the upper part of the lungs. Pectoriloquy may be suspended if the bronchial tubes, which communicate with the excavation, be obstructed. If the morbid cavity communicate with a great number of bronchia, or with the cavity of the pleura, the pectoriloquy is much diminished, or ceases altogether.

Pectoris os. See *Sternum.*

PE'CTUS. (*us*, *oris*. n.) The breast.

PECTU'SCULUM. (Diminutive of *pectus*, the breast: so named from its shape.) The metatarsus. — *Turton.*

PEDA'TUS. (From *pes*, a foot.) Pedate: bird-foot-like.) Applied to a particular kind of leaf, which is ternate, with its lateral leaflets compounded in their fore-part; as in *Helleborus niger* and *fœtidus*, and *Arum dracunculus*.

PEDE'THMUS. (*us*, *i*. m. Πηδηθμος; from πηδαω, to leap.) The pulsation of blood-vessels.

PEDICELLATE. *Pedicellatus.* (From *pedicellus*, a partial flower stalk.) Having a partial stalk. Applied to flowers which are

supported by partial stalks; also to glands, nectaries, &c., when placed at the top of a stalk.

PEDICE'LLUS. A partial flower-stalk. See *Pedunculus.*

PEDICULA'RIA. (*a*, *æ.* f.; from *pediculus*, a louse: so called from its use in destroying lice.) See *Delphinium stavisagria.*

PEDICULA'RIS. (From *pediculus*, a louse.) The name of a genus of plants of the Class, *Didynamia;* and Order, *Angiospermia.* Louse-wort. The *Pedicularis palustris*, Marsh louse-wort, is said to kill lice. It is somewhat acrid, and has been used in decoction as an application to indolent ulcers.

PEDICULA'TIO. *Morbus pedicularis.* That disease of the body in which lice are continually bred on the skin.

PEDI'CULUS. (*us*, *i.* m.; diminutive of *pes*, a foot: so named from its many small feet.) 1. A louse. The name of a genus of insects, of the order *Aptera.* Two species are found on the human body, the *pediculus humanus*, the common louse, infesting the head; and the *P. pubis*, or crab-louse, found chiefly on the pubes.

2. A pedicle or footstalk of a flower, or leaf. See *Pedunculus.*

Pedicus. See *Extensor brevis digitorum pedis.*

PEDILU'VIUM. (From *pes*, the foot, and *lavo*, to wash.) A bath for the feet.

PE'DION. (Πεδιον; from *πους*, the foot.) The sole of the foot.

PE'DORA. The sordes of the eyes, ears, and feet.

PEDUNCULA'TUS. Pedunculate: growing on a fruit-stalk: opposed to sitting.

PEDU'NCULUS. A peduncle, or a flower-stalk, or that which springs from the stem, and bears the flowers and fruit, and not the leaves.

Pedicellus, is a partial flower-stalk, the ultimate subdivision of a general one; as in the cowslip.

The pedunculus is,

1. *Cauline*, when it grows immediately out of the main stem, especially of a tree; as in *Averrhoa bilimbi.*

2. *Rameus*, growing out of the main branch; as in *Eugenia malaccensis.*

3. *Axillary*, growing either from the bosom of a leaf, that is, between it and the stem, as in *Anchusa sempervirens;* or between a branch and a stem; as in *Ruppia maritima.*

4. *Oppositifolius*, opposite to a leaf; as in *Geranium pyrenaicum.*

5. *Internodis*, proceeding from the intermediate part of a branch between two leaves; as in *Ehretia internodis.*

6. *Gemmaceous*, growing out of a leaf-bud; as in *Berberis vulgaris.*

7. *Terminal*, when it terminates a stem or branch; as in *Centaurea scabiosa.*

8. *Lateral*, when situated on the side of a term or branch; as in *Erica vagans.*

9. *Solitary*, either single on a plant, as in *Rubus chamæmorus;* or only one in the same place, as in *Antirrhinum spurium.*

10. *Aggregate*, clustered, when several grow together; as in *Verbascum nigrum.*

11. *Sparsus*, dispersed irregularly over the plant or branches; as in *Ranunculus sceleratus.*

12. *Uniflorus, biflorus, triflorus*, &c. bearing one, two, three, or more flowers.

13. *Multiflorus*, many-flowered; as in *Daphne laureola.*

When there is no flower-stalk, the flowers are said to be *sessile;* as in *Centaurea calcitrapa*, and the dodders.

PEGANELÆ'UM. (*um*, *i.* n.; Πηγανελαιον; from *πηγανον*, rue, and *ελαιον*, oil.) Oil of rue.

PEGANE'RUM. (*um*, *i.* n.; Πηγανηρον; from *πηγανον*, rue.) A plaster composed of rue and other ingredients.

PE'GANUM. (*um*, *i.* n. *πεγανον*, rue; from *πηγνυμι*, to compress: so called, because, by its dryness, it condenses the seed.) The name of a genus of plants. Class, *Dodecandria;* Order, *Monogynia.*

PEGANUM HA'RMALA. The Assyrian wild rue: much the same in its properties with the common rue, and as generally used in that part of the world as the latter with us.

PE'GE. (Πηγη, a fountain.) The internal angles of the eye were called *pegæ.*

PELADA. A species of baldness; a shedding of the hair from a venereal cause.

PELA'RIUM. (From *πηλος*, mud: so called from its muddy consistence.) A collyrium.

PELECA'NUS. (*us*, *i.* m.; from *πελεκαω*, to perforate.) 1. The bird called the pelican.

2. An instrument to draw teeth: so named from its curvature at the end resembling the beak of a pelican.

PELECI'NUM. (From *πελεκυς*, a hatchet: so called because its seeds are shaped like a two-edged hatchet.) The hatchet-vetch.

PELIO'MA. (Πελιωμα; from *πελος*, black.) An extravasation of blood of a livid colour.

PELLA'GRA. (*a*, *æ.* f.) *Pelagra.* This disease has been little noticed by nosologists. Dr. Good, however, has admitted it under the name of *Elephantiasis Italica;* and M. Alibert under that of *Ichthyosis pellagra.* The earliest description of it is that by Francesa Trapolli, a Milenese physician. Indeed, few accounts of it have hitherto been published, although the peculiar symptoms with which it is attended, and the fatal consequences which generally ensue from it, render it equally curious and important. In certain districts, as Milan and Padua, in Italy, where it is peculiarly prevalent, it is computed to attack five inhabitants out of every hundred.

About the month of March or April, when the season invites the farmers to cultivate their fields, a shining red spot suddenly arises on the back of the hand, or some part of the body, resembling the common erysipelas, but without much itching or pain, or indeed any other particular inconvenience. Both men and women, girls and boys, are equally subject to it. This red spot elevates the skin a little, producing numerous small tubercles of different colours; the skin becomes dry and cracks, and the epidermis sometimes assumes a fibrous appearance. At length it falls off in white furfuraceous scales; but the shining redness underneath still

continues, and, in some instances, remains through the following winter. In the mean time, excepting this mere local affection, the health is not the least impaired, the patient performs all his rural labours, as before, enjoys a good appetite, eats heartily, and digests well. And what is most surprising is, that in the month of September, when the heat of the summer is over, in some cases sooner, in others later, the disorder generally altogether disappears, and the skin resumes its natural healthy appearance. The patients, however, are not now to be considered as well: the disease hides itself, but is not eradicated: for no sooner does the following spring set in, but it quickly reappears, and generally is accompanied with severer symptoms. The spot grows larger, the skin becomes more unequal and hard, with deeper cracks. The patient now begins to feel uneasiness in the head, becomes fearful, dull, and less capable of labour; even when the pelagra has arrived at this stage, the returning winter, nevertheless, commonly restores the patient to apparent health: but the more severe the symptoms have been, and the deeper root the disease has taken, the more certainly does the return of spring produce it with additional violence. Sometimes the disease in the skin disappears, but the other symptoms remain notwithstanding. The powers both of the mind and body now become daily more enfeebled; peevishness, watchings, vertigo, and, at length, complete melancholy, supervene. Nor is there a more distressing kind of melancholy any where to be seen, than takes place in this disease. The patients now begin to grow emaciated, and delirious. A colliquative diarrhœa comes on, which no remedy can stop. Sometimes, in the pellagra, the diarrhœa comes on before the delirium, and the patient is alternately affected with delirium and stupor. The appetite often suddenly fails, so that the sick will sometimes go for near a week without tasting food. Not uncommonly it returns as suddenly, so that they eagerly devour whatever is offered them, and this even at times when they are horribly convulsed. The convulsions with which they are attacked are most shocking to see, and are of almost every kind, catalepsy excepted, which has been described by writers. The first stage of the pellagra, in which the local affection only takes place, continues in some instances for a great length of time; persons being occasionally met with in whom it has lasted six or eight, or even fifteen years, disappearing regularly every winter, and returning again in the spring. This occasions some of the inhabitants to pay little attention to it; although, in other cases, it reaches its greatest height after the second or third attack. It appears that this disease is not infectious, and that the causes producing it are yet unascertained. It has been supposed, by some, to arise from the heat of the sun's rays; and hence it is now and then called *mal de sol*; but this does not produce any similar disease in other parts of the world, where it is in an equal or even much greater degree than at Milan; no disease in any respect resembling it having hitherto been noticed in such regions, except the lepra asturiensis described by Thiery, and after him by Sauvages. Pure air, habitual cleanliness, warm bathing, and a nutritious diet, with such tonics as best agree with the constitution, have proved most useful in removing this disease, when not advanced beyond the reach of recovery.

Dr. Holland has lately published a valuable paper on pellagra, containing the results of his own observation, and to this we refer the reader for more ample information. See *London Medico-chirurgical Transactions*, vol. vii.

PELLI'CULA. (*a*, *æ*. f.; from *pellis*, the skin.) A pellicle, or slender skin. In *Medicine*, it is applied to such an appearance of the surface of urine, and to very delicate membraneous productions. In *Botany*, to the delicate skin which covers some seeds and other parts.

Pellitory. See *Parietaria*.

Pellitory, bastard. See *Achillea ptarmica*.

Pellitory of Spain. See *Anthemis*.

PE'LMA. (Πελμα; from πελω, to move forwards.) The sole of the foot, or a sock adapted to the sole of the foot.

PE'LTA. (*a*, *æ*. f.; a shield, buckler, or target.) A variety of the calyculus, called the shield, which is the fruit, of an oblong, flat, and obtuse form, observed in the lichen tribe.

PELTA'LIS CARTILA'GO. (From *pelta*, a buckler: so called from its shape.) The scutiform cartilage of the larynx.

PELTA'TUS. (From *pelta*, a shield.) Peltate, or target-shaped: applied to leaves which have the stalk inserted into their middle, like the arm of a man holding a shield; as in *Tropæolum majus*, and *Hydrocotyle vulgaris*.

PE'LVIC. (*Pelvicus*; from *pelvis*, the lower part of the trunk of the body.) Pertaining to the pelvis.

PE'LVIS. (*is*, *is*. f.; from πελυς, a basin: because it is shaped like a basin used in former times.) The cavity below the belly. It is composed of the two ossa innominata, the os sacrum, and os coccygis. It contains the rectum and urinary bladder, the internal organs of generation, and is lined and covered by muscles and common integuments.

It is wide and expanded at its upper part, and contracted at its inferior aperture. The upper part of the pelvis, properly so called, is bounded by an oval ring, which parts the cavity of the pelvis from the cavity of the abdomen. This circle is denominated the brim of the pelvis: it is formed by a continued and prominent line along the upper part of the sacrum, the middle of the ilium, and the upper part, or crest, of the os pubis. The circle of the brim supports the intestines and impregnated womb. The lower part of the pelvis is denominated the outlet. It is composed by the arch of the oss pubis, and by the sciatic ligaments.

The office of the pelvis is to give a steady bearing to the trunk, and to connect it with the lower extremities, by a sure and firm joining, to form the centre of all the great motions of the body, to contain the internal organs of generation, the urinary bladder, the rectum, and

occasionally part of the small intestines, and to give support to the gravid uterus.

There is a considerable difference in the relative dimensions of the male and female pelvis. In the male, the antero-posterior diameter is greater than the transverse, and the brim of the pelvis is nearly circular. In the female, the transverse is the greater, and the brim of the pelvis is of an oval shape. The female pelvis is larger in all its dimensions than the male, except in height: the ossa ilia are more expanded, the sacrum and coccyx more curved, and broader, and the latter more movable. The ischiatic notch and the thyroid foramen are larger in the female, and the angle formed by the rami of the ossa pubis is more obtuse.

In a female pelvis of ordinary dimensions, the distance between the os sacrum and os pubis, at the *brim*, is found to be between four and five inches, that between the two ossa ilia between five and six inches; and the oblique diameter about four inches and five eighths. At the outlet the proportions are reversed, the distance between the symphysis pubis and os coccygis being longer than that between the ossa ilia. The depth of the fore-part of the pelvis, at the symphysis of the pubis, measures about an inch and a half, behind it is six inches, and at the sides three inches and a half. The pelvis may vary from the above dimensions according to the size and proportions of the body, which may differ somewhat in the different nations, yet be well formed; or it may vary from disease, either of the bones or viscera, and then it is considered as distorted.

The pelvis has two *axes*, the direction of which must be carefully attended to by the obstetrician. The *axis of the brim* is indicated by a straight line drawn from the umbilicus to the point of the coccyx; *the axis of the outlet* by a straight line drawn from the first bone of the sacrum to the orifice of the vagina.

Pelvis auris. The cochlea of the ear.

Pelvis cerebri. The infundibulum.

Pemphigoi'des. (From πεμφιξ, a vesicle, and ειδος, likeness.) The epithet of a fever accompanied with an eruption of vesicles.

PE'MPHIGUS. (*us*, *i.* m.; from πεμφιξ, a bubble, or vesicle.) An eruption, consisting of vesicles of various sizes, from a pea to a walnut, and mostly attended by fever. The disease has been described as *Febris bullosa*, *Exanthemata serosa*, *Morta*, *Pemphigus helveticus*, *Pemphigus major*, and *Pemphigus minor*. The eruption is transparent, like small bladders filled with a pellucid or slightly coloured fluid. The vesicle is mostly almond-shaped, and has an inflamed base, and when it breaks the part is disposed to ulcerate. The fever may be either synocha or typhus. The latest writers on this disease contend, that it is sometimes acute, and sometimes a chronic affection; that the former is constantly attended with fever, and the latter constantly without; that in neither case is an acrimonious or contagious matter thrown out by the constitution, but pure serum, secreted by the cutaneous exhalent arteries. So rare was the disease when Dr. Cullen wrote, that he never saw it but once, in a case which was shown to him by Dr. Home. Dr. David Stuart, then physician to the hospital of Aberdeen, published an account of it in the Edinburgh Medical Commentaries. It is ushered in by sickness at stomach, great oppression about the præcordia, headach, lassitude, and weariness on the least exertion, with stiffness and rigidity of the joints. The eruption comes out as very small, distinct, red spots, a little elevated above the surface of the skin, and much resembling the first appearance of the small-pox. The eruption gradually spreads itself over the whole body, and the vesicles daily increase in size. The patient complains of headach, sickness, oppression about the præcordia, thirst, sore throat, with difficulty of swallowing; the tongue is foul; the skin hot and feverish; the pulse from 100 to 120, rather depressed; the belly costive; the eyes dull and languid, but without delirium. The whole surface of the skin is now interspersed with vesicles of various sizes, many of them large, especially on the arms and breast. In the interstices, between the vesicles, the appearance of the skin is natural, nor is there any redness round their base; the distance from one to another is from half an inch to a handbreath, or more. In some places two or three are joined together, like the pustules in the confluent small-pox. If the vesicles burst of themselves, they form a whitish scab or crust. They are mostly on the neck and face; by far the greatest number are perfectly entire, turgid, and of a bluish colour. Upon opening them it is evident that the cuticle elevated above the cutis, and distended with a thin, yellowish, semipellucid serum, forms this appearance. Nor is the surface of the cutis ulcerated, or livid; but of a red florid colour, as when the cuticle is separated by a blister, or superficial burning.

Since the description of this disease by Dr. Stuart, observations on it have been published by Dr. Dickson of Dublin, by Mr. Gaitskell and Mr. Upton, in the Memoirs of the Medical Society of London. Some subsequent observations on pemphigus were published in the London Medical Journal, by Mr. Thomas Christie. From a case which Mr. Christie describes, he is disposed to agree with Dr. Dickson, in thinking that sometimes, at least, pemphigus is not contagious. He remarks, however, that the pemphigus described by some foreign writers was extremely infectious; circumstances which, he thinks, may lead to a division of the disease into two species, the pemphigus simplex, and complicatus, both of which, but especially the last, seem to vary much with respect to mildness and malignity. The fever in pemphigus is mostly a mild or malignant typhus, and requires the same remedies — port wine and bark, with mineral acids. The best application to the eruption, when the vesicles break, is finely powdered starch.

Pemphigus major. See *Pemphigus.*

Pemphigus minor. See *Pemphigus.*

PE'MPHIX. (*ix*, *igis.* f.; Πεμφιξ, a vesicle, or bubble.) See *Pemphigus.*

Pemptæ'us. (Πεμπταιος; from πεμπτος, the

fifth.) An ague, the paroxysm of which returns every fifth day.

PENÆ'A. (*a*, *æ*. f.; a name given by Linnæus in memory of the learned Peter Pena, a native of France, and an excellent botanist.) 1. A genus of plants in the Class *Tetrandria*; Order, *Monogynia*.

2. The name of a species of polygala.

PENÆA MUCRONATA. The systematic name of the plant which is said to afford the sarcocolla. This is brought from Persia and Arabia in small grains of a pale yellow colour, having also sometimes mixed with them a few of a deep red colour. Its taste is bitter, but followed with some degree of sweetness. It has been chiefly used for external purposes, and, as its name imports, has been thought to agglutinate wounds and ulcers; but this opinion now no longer exists.

PE'NDULUS. Pendant; pendulous; hanging: applied to roots, leaves, flowers, seeds, &c.; as the root of the *Spiræa filipendula*, and *Pæonia officinalis*, which consists of knobs connected by filaments; and the seeds of the *Magnolia grandiflora*, which are suspended by their filaments.

PE'NETRANS. (From *penetro*, to pierce through.) Penetrating. Applied to a medicine supposed to pass through the pores and stimulate.

PENICI'LLIFORM. (*Penicilliformis*; from *penicillus*, a pencil-brush, and *forma*, likeness.) Pencil-shaped: applied to the stigma of the *Milium paspalium*, and to the extremities of the arteries which secrete the bile.

PENICI'LLUS. (*us*, *i*. m.; diminutive of *peniculum*, a brush.) *Penicillum*. 1. A tent, or pledget.

2. The secreting extremities of the vena portæ are called *penicilli*. See *Liver*.

PENI'DIUM. A kind of clarified sugar, with a mixture of starch, made up into small rolls. The confectioners call it white barley-sugar.

PE'NIS. (*is*, *is*. m.; *à pendendo*, from its hanging down.) *Membrum virile*. The cylindrical part that hangs down, under the mons veneris, before the scrotum of males. It is divided by anatomists into the root, body, and head, or *glans penis*. It is composed of common integuments, two *corpora cavernosa*, and one *corpus spongiosum*, which surrounds a canal, the *urethra*, that proceeds from the bladder to the apex of the penis, where it opens by the *meatus urinarius*. See *Urethra*. The fold of the skin that covers the glans penis, is termed the prepuce, and the band which ties the prepuce to the under surface of the glans, is called the *frænum præputii*. The arteries of the penis are from the hypogastric and ischiatic. The veins of the penis form the *vena magna penis*, which empties itself into the hypogastric vein. The absorbents of this organ are very numerous, and run under the common integuments to the inguinal glands: absorbents also are found in great plenty in the urethra. The glands of the penis are, Cowper's glands, the prostate, muciparous, and odoriferous glands. The nerves of the penis are branches of the sacral and ischiatic.

PENIS CE'REBRI. The pineal gland.

Penis erector. See *Erector penis*.

PENIS MULIE'BRIS. The clitoris.

Pennyroyal. See *Mentha*.

Pennyroyal, hart's. See *Mentha cervina*.

PENTADA'CTYLON. (*um*, *i*. n.; from πεντε, five, and δακτυλος, a finger: so called because it has five leaves upon each stalk, like the fingers upon the hand.) 1. The herb cinquefoil.

2. A name for the ricinus, the leaf of which resembles a hand.

PENTA'GONUS. (From πεντε, five, and γωνια, an angle.) Pentagonal: five-sided. Applied to leaves synonymously with quinqueangular; as in *Geranium peltatum*.

PENTA'MYRUM. (Πενταμυρον; from πεντε, five, and μυρον, ointment.) An ointment composed of five ingredients.

PENTA'NDRIA. (*a*, *æ*. f.; from πεντε, five, and ανηρ, a husband.) The name of a class of plants in the sexual system of Linnæus, embracing those which have hermaphrodite flowers and five stamens.

PENTANEU'RON. (From πεντε, five, and νευρον, a string: so called because it has five-ribbed leaves.) A species of plantain. See *Plantago lanceolata*.

PENTAPHA'RMACON. (From πεντε, five, and φαρμακον, *remedium*, remedy.) Any medicine consisting of five ingredients.

PENTAPHYLLOI'DES. (From πενταφυλλον, cinquefoil, and ειδος, likeness: so called from its resemblance to cinquefoil.) Resembling the cinquefoil, or five-leaved plant. See *Fragaria sterilis*.

PENTAPHY'LLUM. (*um*, *i*. n.; from πεντε, five, and φυλλον, a leaf: so named because it has five leaves on each stalk.) Five-leaved. See *Potentilla reptans*.

PENTAPHY'LLUS. (From πεντε, five, and φυλλον, a leaf.) Pentaphyllous, or five-leaved: applied to leaves, calyces, &c.; as the flower-cup of the *Ranunculus bulbosus*.

PENTAPLEU'RUM. Five-ribbed wort. See *Plantago lanceolata*.

PENTASPE'RMOUS. (*Pentaspermus*. From πεντε, five, and σπερμα, a seed.) Having five seeds. Applied to the capsules, &c., of plants.

PENTA'TOMUM. (From πεντε, five, and τεμνω, to cut: so called because its leaves are divided into five segments.) Cinquefoil. The *Potentilla reptans*.

PENTO'ROBUS. (From πεντε, five, and οροβος, the wood-pea: so called because it has five seeds resembling the wood-pea.) The herb peony. See *Pæonia officinalis*.

Peony. See *Pæonia*.

PEPA'NSIS. (Πεπανσις. From πεπαινω, to concoct.) *Pepasmus*. Maturation or concoction. Applied by the humoral pathologists to the humours of the living body.

PEPA'SMUS. The same as *pepansis*.

PEPA'STICUS. (From πεπαινω, to concoct.) Applied formerly to medicines supposed to promote concoction.

PE'PITA NUX. St. Ignatius's bean.

PE'PLION. The same as *peplus*.

Peplos. See *Peplus*.

PE'PLUS. (Erom πεπλος, the herb devil's-milk.) A species of euphorbia. See *Euphorbia peplus.*

PE'PO. (From πεπτο, to ripen.) I. In botanical definitions, a fleshy, succulent seed-vessel, or pericarpium, the seeds of which are inserted into the sides of the fruit. — *Gærtner* and *Willdenow.*

From its figure, the pepo is said to be, —

1. *Globose;* as in *Cucumis colocynthis.*
2. *Oblong;* as in *Cucumis sativus.*
3. *Lagenæform;* as in *Cucurbita lagenaria.*
4. *Curvate;* as in *Cucumis flexuosus.*
5. *Nodose;* as in *Cucumis melopepo.*
6. *Fusiform;* as in *Cucumis chale.*
7. *Echinate;* as in *Cucumis anguria.*
8. *Verrucose;* as in *Cucurbita verrucosa.*
9. *Scabious;* as in *Cucumis sativus.*

II. The gourd. See *Cucurbita pepo.*

Pepper. See *Piper.*

Pepper, black. See *Piper nigrum.*

Pepper, dulce. See *Fucus pinnatifidus.*

Pepper, Guinea. See *Capsicum annuum.*

Pepper, Jamaica. See *Myrtus pimenta.*

Pepper, long. See *Piper longum.*

Pepper, poor man's. See *Polygonum.*

Pepper, wall. See *Sedum acre.*

Pepper, water. See *Polygonum.*

Pepperidge bush. See *Berberis.*

Peppermint, See *Mentha piperita.*

Pepperwort. See *Lepidium iberis.*

PE'PTIC. (*Pepticus;* πεπτικος, from πεπτω, to digest.) Digestive.

PERACU'TE. *Peracutus;* Very sharp: applied to diseases when very severe, or aggravated beyond measure; as subacute is applied to such as are not very acute, or so severe as they generally are.

PE'RCA. (*a, æ.* f.) The name of a genus of fishes, of the Order *Acanthopterygii.* The perch.

Perca fluvia'tilis. This species is common in the rivers of Europe. Its flesh is wholesome and well flavoured.

Perception. See *Mind.*

PERCHLO'RIC ACID. *Acidum perchloricum.* Oxychloric acid. An acid discovered by Count Stadion. It is obtained by distilling the perchlorate of potash with an equal weight of sulphuric acid, diluted with a fourth part of water. At the temperature of about 280 white fumes come over, which condense into a colourless liquid. Its specific gravity is 1·6. It is a very fixed compound, not boiling under 392°. By distillation with concentrated sulphuric acid, it may be obtained in the solid form, and crystallised. It consists of one equivalent of chlorine and seven of oxygen.

PERCOLA'TION. (*Percolatio, onis.* f.; strained through: from *percolo,* to strain or filter.) A term generally applied to animal secretion, from the office of the glands being thought to resemble that of a strainer in transmitting the liquors that pass through them.

PERCU'SSION. In medical language this term signifies the striking of any part of the surface of the body with the hand, in order to ascertain by the sound the healthy or diseased condition of the subjacent parts. This mode of exploration is applied principally to the chest, and affords very important indications with respect to the diseases of the thoracic viscera. This method of diagnosis was discovered by Dr. Leopold Avenbrugger, and published by him at Vienna in 1761. His work was translated into French by Corvisart, in 1808; and the great utility of percussion derived further illustration from the celebrated work of Laennec, on Auscultation, published eight years after.

In order for the proper performance of percussion, the patient should, if possible, be in a sitting posture, and the chest covered with a light linen garment, which prevents the clacking sound produced by the stroke of the hand upon the naked chest. In striking the chest, the fingers of the operator should be held with their extremities in one line, and kept firm in this position by the opposition of the thumb. The stroke should be made with the points of the fingers, and directed perpendicularly on the part; it should also be made with equal force in the different parts of the chest examined. Percussion is sometimes performed with the intervention of a piece of wood, ivory, or other sonorous body: it is then termed *mediate percussion.* The ivory instrument generally used for this purpose is called a *plexímeter.* (See *Plexímeter.*)

The thorax of a healthy individual gives out a clear sound on percussion in its anterior and lateral parts. The clearness of the sound is greater or less according to the density of the parts subjacent to that which is struck, and according to the thickness and tension of the parietes of the thorax: hence it varies greatly in the different regions of the thorax. (See *Thorax.*) Whenever, in the progress of disease, any denser substance takes the place of air within the thorax, there is a corresponding diminution of sonorousness: hence, hepatisation and tubercles of the lungs, hypertrophy of the heart, effusions of serum, lymph, or other matters, all occasion a diminution of sound in the regions which they respectively occupy; while in pulmonary emphysema, pneumothorax, and large empty excavations in the substance of the lungs, the sound on percussion is greater than natural. The application of percussion in different diseases is noticed under the heads of those diseases. For more minute information respecting percussion, we must refer the reader to the various treatises on the subject, especially that of M. Piorry, which is the latest and the most elaborate.

Perde'tum. In Paracelsus it means the root of skirret, or *Sium sisarum.*

Perdi'cium. (From περδιξ, a partridge: so called because partridges were said to feed upon it.) See *Parietaria officinalis.*

PERE'NNIAL. *Perennis.* Lasting naturally more than two years. Applied to plants, in opposition to those which live only one or two years; thus the elm, oak, fir, &c., are perennial.

Perennial worm-grass. See *Spigelia.*

Perete'rion. (Περητηριον; from περαω, to dig through.) The trepan.

PERFECT. A flower is said to be perfect

or complete that has both calyx and corols, and one or more stamens and pistils.

PERFOLIA'TA. (*a, æ.* f.; from *per*, and *folium*: so called because the leaves surround the stem, like those of a cabbage.) See *Bupleurum perfoliatum.*

PERFO'LIATE. (*Perfoliatus*; from *per*, through, and *folium*, a leaf.) Applied to plants the leaves of which surround the stem at their base, as in *Chlora perfoliata.*

Perforans. See *Flexor profundus forans.*

Perforans, seu flexor profundus. See *Flexor longus digitorum pedis profundus perforans.*

Perforans, seu flexor tertii internodii digitorum pedis. See *Flexor longus digitorum pedis profundus perforans.*

Perforans, vulgo profundus. See *Flexor profundus perforans.*

PERFORA'TA. (*a, æ.* f.; from *perforo*, to pierce through: so called because its leaves are full of holes.) See *Hypericum perforatum.*

PERFORA'TUS. 1. In *Anatomy*, applied to muscles. See *Flexor brevis digitorum pedis*, and *Flexor sublimis perforatus.*

2. In *Botany*, applied to leaves through which the stems pass, and to leaves or other parts which are penetrated with small holes.

Perforatus, seu flexor secundi internodii digitorum pedis. See *Flexor brevis digitorum pedis perforatus sublimis.*

PERIA'MMA. (From περιαπτω, to hang round.) An amulet. See *Amulet.*

PERIA'NTHIUM. (*um, ii.* n.; from περι, and ανθος, a flower.) The calyx properly and commonly so called, when it is contiguous to, and makes a part of, the flower; as the five green leaves which encompass a rose, including their urn-shaped base; the tubular part comprehending the scales in the pinks, or the globular scaly cup in *Centaurea.* The tulip is a naked flower, having no calyx at all. The perianth is of infinite variety of forms.

From its number of leaves, it is, —

1. *Monophyllous*, formed of one only; as in *Datura stramonium.*

2. *Diphyllous*; as in *Papaver rhœas.*

3. *Triphyllous*; as in *Canna Indica.*

4. *Tetraphyllous*; as *Lunaria annua.*

5. *Pentaphyllous*; as *Ranunculus.*

From the division of its edge, —

1. *Undivided*, without any irregularity; as in the female of the *Quercus robur.*

2. *Partite*, or divided almost to the base: hence *bipartite*, or *bilabiate*, in *Salvia officinalis*; *tripartite*, in *Stratiotes aloides*; *quadripartite*, in *Œnothera biennis*; *quinquepartite*, in *Nereum oleander*; *duodecempartite*, in *Sempervivum tectorum.*

3. *Cloven*, cut as it were to the middle only: hence, *bifid*, in *Adoxa moschatellina*; *trifid*, in *Asarum canadense*; *quinquefid*, in *Æsculus hippocastanum.*

4. *Dentate*, in *Marrubium vulgare*; *quinque dentate*, in *Cucumis* and *Cucurbita*, the female flowers.

5. *Serrate*, in *Centauria cyanus.*

From its *figure*, —

1. *Tubulosum*; as in *Datura stramonium.*

2. *Patens*, with spreading leaflets; as in *Borago officinalis.*

3. *Reflexum*, its laciniated portions turned backward; as in *Œnothera biennis.*

4. *Inflatum*, pouched and hollow; as in *Cucubalus behen*, and *Physalis alkekengi*, in fruit.

From its colour, —

Coloratum, when of any other than green; as in *Gomphrena globosa.*

From the disposition of the germen, —

1. *Superum*, when the perianth and corols are above. Hence the remains are visible on the fruit; as in roses, pears, &c.

2. *Inferum*, when below the germen; as in the poppy and water-lily.

From the number on each flower, —

1. *Simplex*, when one; as in *Nicotiana tabacum.*

2. *Duplex*, double; as in *Malva*, *Althæa*, *Hibiscus*, &c.

3. *Calyculatum*, or *auctum*, having a lesser one, or scales down to the base; as in *Dianthus caryophyllus.*

Nullum, when wanting; as in tulips.

From its situation with respect to the fructification, —

1. *Perianthium floris*, when belonging to the male.

2. *P. fructus*, when with the pistils.

3. *P. fructificationis*, containing both stamina and pistils in the flower.

From its duration, —

1. *Caducous*, falling off early; as in *Papaver.*

2. *Deciduous*, very late; as in *Tilia europæa.*

3. *Peristent*; as in *Hyosciamus.*

4. *Marcescent*, withered, but yet conspicuous on the fruit; as in *Pyrus*, *Mespilus*, &c.

PERIBLE'PSIS. (*is, is.* f.; from περιβλεπω, to stare about.) That kind of wild look which is observed in delirious persons.

PERI'BOLE. (From περιβαλλω, to surround.) A word used frequently by Hippocrates in different senses. Sometimes it signifies the dress of a person; at others, a translation of the morbific humours from the centre to the surface of the body.

PERIBRO'SIS. An ulceration or erosion at the corners or uniting parts of the eyelids. It most frequently affects the internal commissure. It arises from the acrimony of the tears or from ægylops, which sometimes extends to the corners of the eyelids.

PERICARDI'TIS. (*is, idis.* f.; from περικαρδιον, the pericardium.) Inflammation of the pericardium. See *Heart, diseases of the.*

PERICA'RDIUM. (*um, ii.* n.; from περι about, and καρδια, the heart.) The membranous bag that surrounds the heart, and the arterial and venous trunks connected with it. The pericardium consists of two layers, an external or fibrous, and an internal or serous. The serous membrane lines the fibrous one, and is reflected over the heart after the manner of serous membranes in general. Its use is to secrete and contain the vapour of the pericardium which lubricates the heart, and thus prevents it from concreting with the pericardium.

PERICARPIA'LIS. Pericarpial. Belonging

the pericarpium of plants: thus the spines of the *Datura stramonium* on the fruit, are called pericarpial.

PERICA'RPIUM. I. (From περι, about, and *carpus*, the wrist.) This name was formerly given to medicines and plasters which were applied to the wrist.

II. In *Botany*, (from περι, about, and καρπος, a seed.) The seed-vessel or covering of the seed of plants which is mostly membraneous, leathery, woody, pulpy, or succulent. The membraneous are, —

1. *Capsula.*
2. *Siliqua.*
3. *Silicula.*
4. *Legumen.*
5. *Lomentum.*
6. *Folliculus.*
7. *Samara*

The woody seed-vessels are, —

8. *Strobilus.*
9. *Nux.*

The fleshy ones, —

10. *Pomum.*
11. *Pepo.*
12. *Drupa.*

The succulent, —

13. *Bacca.*

The seed-vessel is extremely various in different plants, and is formed of the germen enlarged. It is not an essential part of a plant, the seeds being frequently naked, and guarded only by the calyx, as is the case with the plants of the order *Gymnospermia*, also in the great class of compound flowers, *Syngenesia*.

The use of the seed-vessel is to protect the seeds till ripe, and then in some way or other to promote their dispersion, either scattering them by its elastic power, or serving for the food of animals, in the dung of which the seeds vegetate, or promoting the same end by various other means. The same organ which remains closed so long as it is juicy or moist, splits or flies asunder when dry, thus scattering the seeds in weather most favourable for their success. By an extraordinary provision of nature, however, in some annual species of Mesembryanthemum, natives of sandy deserts in Africa, the seed-vessels open only in rainy weather; otherwise the seeds might, in that country, lie long exposed before they met with sufficient moisture to vegetate.

PERICHÆ'TIUM. (*um, ii.* n.; from περι, about, and χαιτη, a hair, or bristle.) A scaly sheath, investing the fertile flower, and consequently the base of the fruit-stalk, of some mosses. In the genus *Hypnum* it is of great consequence, not only by its presence, constituting a part of the generic character, but by its differences in shape, proportion, and structure, serving frequently to discriminate species. Linnæus appears by his manuscripts, Sir James Smith informs us, to have intended adding this to the different kinds of calyx, though it is not one of the seven enumerated in his printed works.

PERICHO'NDRIUM. (*um, ii.* n.; from περι, about, and χονδρος, a cartilage.) The membrane that covers a cartilage.

PERICHRI'SIS. (From περι, about, and χριω, to anoint.) A liniment.

PERI'CLASIS. (From περι, about, and κλαω, to break.) It is a term used by Galen for such a fracture of the bone as quite divides it, and forces it through the flesh into sight. Or a fracture with a great wound, wherein the bone is laid bare.

PERICLY'MENUM. (*um, i.* n.; from περικλυζω, to roll round: so called because it twists itself round whatever is near it.) See *Lonicera periclimenum*.

PERICNE'MIA. (*a, æ.* f.; from περι, about, and κνημη, the tibia.) The parts about the tibia.

PERICRA'NIUM. (*um, ii.* n.; from περι, about, and κρανιον, the cranium.) The membrane that is closely connected to the bones of the cranium. It corresponds with what is called the *periosteum* of other bones.

PERI'DIUM. (*um, ii.* n.) The name given by Persoon to the round membraneous dry case of the seeds of some of the angiospermous mushrooms.

PERI'DROMOS. (Περιδρομος; from περι, about, and δρομος, a course.) The extreme circumference of the hairs of the head. — *Gorrhæus.*

PERI'GRAPHE. (From περιγραφω, to circumscribe.) Vesalius applies this term to the *lineæ transversæ* of the *rectus abdominis* muscle.

PE'RIN. Πηριν. A testicle. Some explain it the *perinæum*; others say it means the *anus*.

PERINÆOCE'LE. (*e, es.* f.; from περιναιον, the perinæum, and κηλη, a rupture.) A rupture in the perinæum.

PERINÆ'UM. (*um, i.* n.; from περινεω, to flow round, because that part is generally moist.) The space between the anus and organs of generation.

Perinæus transversus. See *Transversus perinæi*.

PERINY'CTIS. (*is, idis.* f.; from περι, and νυξ, the night.) The same as *epinyctis*. See *Epinyctides*.

PERIOD. (*Periodus, i.* m. περιοδος; from περι, about, and οδος, a way.) A stated time. 1. In medical language there are said to be five periods of a disease: the *invasion*, the *augment*, the *state* or full development of the disease, the *decline*, and the *termination*. With respect to intermittent diseases, the term *period* is sometimes applied synonymously with *interval*, that is, it means the time that elapses from the commencement of one paroxysm to the commencement of the next.

2. In *Physiology*, it has been applied to the circulation of the blood — *Periodus sanguinis.*

PERIODS OF LIFE. The living organism is not destined to be stationary or permanent; it passes rapidly through several stages of development to perfection, which it has scarcely reached when it begins to decline, and passes as rapidly towards dissolution. The most remarkable periods in the life of man after birth, are *Infancy*, *Dentition*, *Puberty*, the *Climacteric period*, and that of *Decay*.

PERIODICAL DISEASES. Diseases of which the symptoms recur at stated intervals.

PERIODI'CITY. The disposition of certain phenomena of living bodies to recur at stated times. Thus, the flow of the menses, the return of an ague, the budding of trees, and the fall of the leaf, are referable to what is called *periodicity*.

Periodus lunaris. The menstrual period.

Periodus sanguinis. The circulation of the blood.

PERIO'STEUM. (*um, i.* n.; from περι, about, and οστεον, a bone.) The membrane which invests the external surface of all the bones, except the crowns of the teeth. It is of a fibrous texture, and well supplied with arteries, veins, nerves, and absorbents. It is called *pericranium*, on the cranium; *periorbita*, on the orbits; *perichondrium*, when it covers cartilage; and *peridesmium*, when it covers ligament. Its use appears to be to distribute the vessels on the external surfaces of bones.

Periphimosis. See *Phimosis.*

Peripleumo'nia. See *Pneumonia.*

PERIPNEUMO'NIA. (*a, æ.* f.; from περι, and πνευμων, the lung.) Peripneumony, or inflammation of the lungs. See *Pneumonitis.*

Peripneumonia notha. Bastard or spurious peripneumony. See *Bronchitis.*

PERIPYE'MA. (*a, atis.* n.; from περι, about, and πυον, pus.) *Peripyesis.* A collection of matter about any part, as round a tooth, in the gums.

Perirrhœ'a. (From περιῤῥεω, to flow about.) A reflux of humours in a dropsical case to any of the larger emunctories for its excretion.

Periscyphismus. A false reading for *periscythismus.*

Periscythi'smus. (Περισκυθισμος; from περισκυθιζω, to scalp, as the Scythians (Σκυθαι) did their enemies.) A surgical operation, which consisted in making transverse incisions in the forehead, and triangular ones above the temples. — *Galen*, Isagoge, C. xix.

PERISTA'LTIC. (*Peristalticus;* from περιστελλω, to contract.) The vermicular motion of the intestines, by which they contract and propel their contents, is called the *peristaltic motion.*

PERISTAPHYLI'NUS. (From περι, about, and σταφυλη, the uvula.) Applied to two muscles connected with the uvula.

Peristaphylinus externus. The *Circumflexus palati.*

Peristaphylinus internus. The *Levator palati.*

Periste'rium. (From περιστερος, a pigeon: so called because pigeons covet it.) See *Verbena officinalis.*

Peristoma. See *Peristomium.*

PERISTO'MIUM. (*um, ii.* n.; from περι, around, and στομα, the mouth or opening of the capsule.) *Peristoma.* The fringe-like membraneous margin which, in many mosses, borders the orifice of the theca or capsule. It is either simple or double, and consists either of separate teeth, or of a plated or jagged membrane. The external fringe is mostly of the former kind; the inner, when present, of the latter. The number of teeth remarkably constant in each genus and species, is either four, eight, sixteen, thirty-two, or sixty-four. On these, Hedwig and his followers have placed great dependence.

PERISY'STOLE. (*e, es.* f.; from περιστελλω, to compress.) The pause or time between a contraction and dilatation of the heart.

Peritonæore'xis. (From περιτοναιον, the peritonæum, and ρησσω, to break.) A bursting of the peritonæum.

PERITONÆ'UM. (*um, i.* n.; from περιτεινω, to extend round.) A strong simple membrane, by which all the viscera of the abdomen are surrounded. It has an exceedingly smooth, exhaling, and moist internal surface. Outwardly, it is every where surrounded by cellular substance, which, towards the kidneys, is very loose and very fat, but is very short at the lower tendon of the transverse muscles. It begins from the diaphragm, which it completely lines, and at the last fleshy fibres of the ribs, and the external lumbar fibres, it completes the septum, in conjunction with the pleura, with which it is continuous through the various intervals of the diaphragm. Posteriorly, it descends before the kidneys; anteriorly, behind the abdominal muscles. It dips into the pelvis from the bones of the pubes, passes over the bladder, and descends behind; and being again carried backwards at the entrance of the ureters, in two lunar folds, it rejoins upon the intestinum rectum that part of itself which invests the loins, and in this situation lies before the rectum. The cellular texture, which covers the peritonæum on the outside, is continued into sheaths in very many places; of which, one receives the testicle on each side, another the iliac vessels of the pelvis, viz. the obturatoria, those of the penis and bladder, and the aorta, and, ascending to the breast, accompanies the œsophagus and vertebræ; by means of which there is a communication between the whole body and the peritonæum, well known in dropsical people. It has various prolongations for covering the viscera. The shorter productions of this membrane are called ligaments, and are formed by a continuous reduplication of the peritonæum receding from its inner surface, enclosing cellular substance, and extending to some viscus where its plates separate, and, having diverged, embrace the viscus; but the intermediate cellular substance always accompanies this membranaceous coat, and joins it with the true substance of the viscus. Of this short kind of production, three belong to the liver, one or two to the spleen, and others to the kidneys, and to the sides of the uterus and vagina. By these means the tender substance of the viscera is defended from injury by any motion or concussion, and their whole mass is prevented from being misplaced by their own weight, and from injuring themselves, being securely connected with the firm sides of the peritonæum.

PERITONI'TIS. (*is, idis.* f.; from περιτοναιον, the peritonæum.) This term is applied to inflammation of the peritonæum, which covers the parietes of the abdomen. When inflammation takes place in the peritoneal covering of the viscera, the symptoms are similar to those which inflammation of the viscera produce, and the disease takes the name of the viscus in which the disease is: thus, inflammation of the peritoneal covering of the liver produces symptoms of hepatitis; that of the stomach, sym-

oms of gastritis; and so on. The symptoms
f peritonitis, when the viscera are not affected,
re, tenderness in the part when pressed, and
xed pain, accompanied by fever, and, generally,
onsiderable disturbance of the system. It may
e produced by any of the causes of inflamma-
on, and requires the free use of the lancet,
eeches, blisters, the warm bath, and foment-
ions, and the same internal remedies as reduce
nflammatory fever, and inflammation in other
arts.

There is a particular form of peritonitis in-
dent to lying-in women, which is sometimes
idemic, and which is very violent and fatal.
ee *Puerperal fever*.

There is a chronic form of peritonitis, which
ay either be primary or consecutive on the
cute. Its course is usually protracted, and
s symptoms obscure. It is generally fatal.

PERIZO'MA. (From *περιζωννυμι*, to gird
ound.) 1. This term strictly signifies a girdle.
2. Hildanus, and some other chirurgical wri-
rs, applied it to those instruments for support-
g ruptures which we commonly call trusses.
3. Some express by it the diaphragm.

Perkinism. See *Metallic tractors*.

PE'RLA. (Ital. and Span.; *perl*, Welch;
erl, Germ.) See *Margarita*.

PERLATE ACID. A name given by Bergman
to the acidulous phosphate of soda.

Permanent. See *Persistens*.

PE'RNIO. (*o*, *onis*. m.) A kibe or chil-
ain. A chilblain is a painful inflammatory
velling, of a deep purple or leaden colour, to
hich the fingers, toes, heels, and other extreme
arts of the body are subject, on being exposed
a severe degree of cold. The pain is not
onstant, but rather pungent and shooting at
rticular times, and an insupportable itching
tends it. In some instances, the skin remains
ntire, but in others it breaks and discharges a
in fluid. When the degree of cold has been
ry great, or the application long continued,
e parts affected are apt to mortify and slough
F, leaving a foul ill-conditioned ulcer behind.
hildren and old people are more apt to be
oubled with chilblains than those of a middle
ge; and such as are of a scrofulous habit are
marked to suffer severely from them. Local
imulants are the best applications against
hilblains, and particularly those which serve at
e same time to defend the weakened parts
om the severity of the external air: hence,
arm socks and gloves, worn day and night,
e useful, and warm diachylon and burgundy
tch plaster, spread upon leather, still more so.
or the same reason, embrocations of oil of tur-
entine, opodeldoc, equal parts of vinegar and
pirits of wine, the liquor ammoniæ acetatis,
ith dilute spirit, will be found serviceable.
innæus recommends bathing the part with
ry dilute muriatic acid: it should be so pro-
ortioned as just to be felt. The weakened
essels should never be too much distended;
nd hence, though gentle warmth and stimu-
nts are indispensable, great heat, and espe-
ally a near approach to the fire, and more
rticularly still when very cold, will always be
ound very injurious. When the inflamed part becomes ulcerated, it is called a *kibe*. Warm and stimulating dressings will alone succeed in effecting a cure, as the unguentum resinæ, elemi, and the like, so reduced with simple cerate as not to irritate; and, if fungous granulations should appear, which they are very apt to do, they must be removed by some mild escharotic, as a solution of nitrate of silver, or of sulphate of copper.

PE'RONE. (From *πειρω*, to fasten: so called because it fastens together the tibia and the muscles.) The fibula.

PERONE'US. (*Περοναιος*; from *περονη*, the fibula.) Belonging to the fibula.

Peroneus anticus. See *Peroneus brevis*.

PERONEUS BREVIS. This muscle is the *peroneus secundus, seu anticus*, of Douglas; the *peroneus medius, seu anticus*, of Winslow; and the *peronæus secundus*, of Cowper. It arises by an acute, thin, and fleshy origin, from the anterior and outer part of the fibula, its fibres continuing to adhere to the lower half of that bone. Its round tendon passes through the groove in the malleolus externus, along with that of the peroneus longus, after which it runs in a separate groove to be inserted into the upper and posterior part of the tubercle at the basis of the metatarsal bone that supports the little toe. Its use is to assist the peroneus longus.

PERONEUS LONGUS. This muscle, which is the *peroneus primus, seu posticus*, of Douglas; *peroneus maximus, seu posterior*, of Winslow; and *peronæus primus*, of Cowper; is situated somewhat anteriorly along the outer side of the leg. It arises tendinous and fleshy from the external lateral part of the head of the tibia, and likewise from the upper anterior surface, and outer side of the *perone* or fibula; its fibres continuing to adhere to the outer surface of the latter, to within three or four inches of the malleolus externus. It terminates in a long round tendon, which runs obliquely behind the malleolus internus, where it passes through a cartilaginous groove in common with the peroneus brevis, being bound down by an annular ligament. When it has reached the os calcis, it quits the tendon of the peroneus brevis, and runs obliquely inwards along a groove in the os cuboides, under the muscles on the sole of the foot, to be inserted into the outside of the posterior extremity of the metatarsal bone that supports the great toe. Near the insertion of this muscle we find a small *bursa mucosa*. This muscle draws the foot outwards, and likewise assists in extending it.

Peroneus maximus. See *Peroneus longus*.

Peroneus medius. See *Peroneus brevis*.

Peroneus posticus. See *Peroneus longus*.

Peroneus primus. See *Peroneus longus*.

Peroneus secundus. See *Peroneus brevis*.

PERONEUS TERTIUS. This is the name given by Albinus to a muscle, which by some writers is called *nonus Vesalii*, or Vesalius's ninth muscle of the foot; but by most considered in the present day as a portion of the extensor longus digitorum pedis. It is situated at the anterior, inferior, and outer part of the leg, along the outer edge of the last described muscle, to which it is intimately united. It arises

fleshy from the anterior surface of the lower half of the fibula, and from the adjacent part of the interosseus ligament. Its fibres run obliquely downwards, towards a tendon which passes under the annular ligament, and then running obliquely outwards, it is inserted into the root of the metatarsal bone that supports the little toe. This muscle assists in bending the foot.

PERPENDICULAR. *Perpendicularis.* Applied to parts of plants; as the root of the *Daucus carota*, which goes straight down into the earth.

Perry.' A vinous liquor made from pears in the same manner as cyder from apples.

Pe'rsica. (*a*, *æ*. f.; from *Persia*, its native soil.) The peach. See *Amygdalus.*

Persica'ria. (*a*, *æ*. f.; from *Persica*, the peach-tree: so called, because its blossoms are like those of the peach.) See *Polygonum.*

Persicaria mitis. See *Polygonum.*

Persicaria urens. See *Polygonum.*

PERSI'STENS. Permanent: applied to flower-cups remaining a long time after the flower; as that of the *Hyosciamus niger.*

Persistens febris. A regular intermitting fever, the paroxysms of which return at constant and stated periods.

Persona'ta. (*a*, *æ*. f.; from *persona*, a mask: because, says Pliny, the ancient actors used to mask themselves with the leaves of this plant.) See *Arctium lappa.*

PERSONA'TUS. Personate. A term applied to a gaping blossom, or monopetalous corolla, when irregular, and closed by a kind of palate; as in *Antirrhinum.*

PERSPIRA'TION. (*Perspiratio, onis.* f.) The vapour that is secreted by the extremities of the cutaneous arteries from the external surface of the body. It is distinguished into *sensible* and *insensible*: the former is separated in the form of an invisible vapour; the latter so as to be visible in the form of very little drops adhering to the epidermis. The *secretory organ* is composed of the extremities of the cutaneous arteries. The *smell* of the perspirable fluid, in a healthy man, is oleaginous and animal; its *taste* manifestly salt and ammoniacal. In *consistence* it is vaporous or aqueous; and its *specific gravity* in the latter state is greater than that of water. For the most part it is yellowish, from the passage of the subcutaneous oil, and sebaceous matter of the subcutaneous glands.

Whatever form it takes, the liquid that escapes from the skin is composed, according to Thénard, of a great deal of water, a small quantity of acetic acid, of muriate of soda and potash, a small quantity of earthy phosphate, an atom of oxide of iron, and a trace of animal matter. Berzelius considers the acid of sweat not the same as acetic acid, but like the lactic acid of Scheele. The skin exhales, besides, an oily matter, and some carbonic acid.

Many experiments have been made to determine the quantity of transpiration which is formed in a given time, and the variations that this quantity undergoes according to circumstances. The first attempts are due to Sanctorius, who, during thirty years, weighed every day, with extreme care and indefatigable patience, his food and his drink, his solid and liquid excretions, and even himself. Sanctorius, in spite of his zeal and perseverance, arrived at results that were not very exact. Since his time, several philosophers and physicians have been employed on the same subject, with more success; but the most remarkable labour in this way is that of Lavoisier and Seguin. These philosophers were the first who distinguished the loss that takes place by pulmonary transpiration from that of the skin. Seguin shut himself up in a bag of *gummed silk*, tied above his head, and presenting an opening, the edges of which were fixed round his mouth by a mixture of turpentine and pitch. In this manner only, the humour of the pulmonary transpiration passed into the air. In order to know the quantity, it was sufficient to weigh himself, with the bag, at the beginning and end of the experiment, in a very fine balance. By repeating the experiment out of the bag, he determined the whole quantity of humour transpired; so that by deducting from this the quantity he knew had passed out from the lungs, he had the quantity of humour exhaled by the skin. Besides, he took into account the food that he had used, his excretions, solid and liquid, and generally all the causes that could have any influence upon the transpiration. By following this plan, the results of Lavoisier and Seguin are these: —

1st, The greatest quantity of insensible transpiration (the pulmonary included) is 25·6 grains troy per minute; consequently, 3 ounces, 1 drachm, 36 grains per hour; and 6 pounds, 4 ounces, 6 drachms, 24 grains, in 24 hours.

2d, The least considerable loss is 8·8 grains per minute; consequently, 2 pounds, 2 ounces, 3 drachms, in 24 hours.

3d, It is during the digestion that the loss of weight occasioned by insensible transpiration is at its minimum.

4th, The transpiration is at its maximum immediately after dinner.

5th, The mean of the insensible transpiration is 14·4 grains per minute; in the mean 14·4 grains, 8·8 depend on cutaneous transpiration and 5·6 upon the pulmonary.

6th, The cutaneous transpiration alone varies during and after repasts.

7th, Whatever quantity of food is taken, or whatever are the variations of the atmosphere, the same individual, after having augmented its weight by all the food that he has taken, returns, in 24 hours, to the same weight nearly that he was the day before, provided he is not growing, or has not eaten to excess.

It is much to be wished that this interesting labour had been continued, and that authors had not limited their studies to insensible transpiration, but had extended their observations to the sweat.

Whenever the humour of transpiration is not evaporated, as soon as it is in contact with the air, it appears at the surface of the skin in the form of a layer of liquid, of variable thickness. Now, this effect may happen because the transpiration is too copious, or because of the dim

nution of the dissolvent force of the air. We perspire in an air hot and humid, by the influence of the two causes joined: we should perspire with more difficulty in an air of the same heat, but dry. Certain parts of the body transpire more copiously, and sweat with more facility than others; such are the hands and the feet, the arm-pits, the groins, the brow, &c. Generally the skin of these parts receives a greater proportional quantity of blood; and in some people, the arm-pit, the sole of the foot, and the intervals between the toes, do not come so easily in contact with the air.

The sweat does not appear to have every where the same composition: every one knows that its odour is variable, according to the different parts of the body. It is the same with its acidity, which appears much stronger in the arm-pits and feet than elsewhere.

The cutaneous transpiration has numerous uses in the animal economy, keeps up the suppleness of the epidermis, and thus favours the exercise of the tact and the touch. It is by evaporation along with that of the lungs, the principal means of cooling, by which the body maintains itself within certain limits of temperature; also its expulsion from the economy appears very important, for every time that it is diminished or suspended, derangements of more or less consequence follow, and many diseases are not arrested until a considerable quantity of sweat is expelled.

Besides water, it cannot be doubted that *carbon* is also emitted from the skin; but in what state, the experiments hitherto made do not enable us to decide. Cruickshanks found, that the air of the glass vessel in which his hand and foot had been confined for an hour, contained carbonic acid gas; for a candle burned dimly in it, and it rendered lime-water turbid. And Jurine found, that air which had remained for some time in contact with the skin, consisted almost entirely of carbonic acid gas. The same conclusion may be drawn from the experiments of Ingenhouz and Milly. Trousset has lately observed, that air was separated copiously from a patient of his, while bathing.

Besides water and carbon, or carbonic acid gas, the skin emits also a particular odorous substance. That every animal has a peculiar smell, is well known: the dog can discover his master, and even trace him to a distance, by the scent. A dog, chained up several hours after his master had set out a journey of some hundred miles, followed his footsteps by the smell. But it is needless to multiply instances of this fact; they are too well known to every one. Now, this smell must be owing to some peculiar matter which is constantly emitted; and this matter must differ somewhat, either in quantity or some other property, as we see that the dog easily distinguishes the individual by means of it. Cruickshanks has made it probable, that this matter is an oily substance, or at least that there is an oily substance emitted by the skin. He wore repeatedly, night and day, for a month, the same under waistcoat of fleecy hosiery, during the hottest part of the summer. At the end of this time he always found an oily substance accumulated in considerable masses on the nap of the inner surface of the waistcoat, in the form of black tears. When rubbed on paper, it rendered it transparent, and hardened on it like grease. It burned with a white flame, and left behind it a charry residuum.

Berthollet has observed the perspiration acid; and he has concluded that the acid which is present is the phosphoric: but this has not been proved. Fourcroy and Vauquelin have ascertained, that the scurf which collects upon the skins of horses consists chiefly of phosphate of lime, and urea is even sometimes mixed with it.

According to Thénard, however, who has endeavoured more particularly to ascertain this point, the acid contained in sweat is the acetous; which, he likewise observes, is the only free acid contained in urine and in milk, this acid existing in both of them when quite fresh. His account of his examination of it is as follows: —

The sweat is more or less copious in different individuals; and its quantity is perceptibly in the inverse ratio of that of the urine. All other circumstances being similar, much more is produced during digestion, than during repose. The maximum of its production appears to be twenty-six grains and two thirds in a minute; the minimum, nine grains, troy weight. It is much inferior, however, to the pulmonary transpiration; and there is likewise great difference between their nature and manner of formation. The one is the product of a particular secretion, similar in some sort to that of the urine; the other, composed of a great deal of water and carbonic acid, is the product of a combustion gradually effected by the atmospheric air.

The sweat, in a healthy state, very sensibly reddens litmus paper or infusion. In certain diseases, and particularly in putrid fevers, it is alkaline; yet its taste is always rather saline, and more similar to that of salt, than acid. Though colourless, it stains linen. Its smell is peculiar, and insupportable when it is concentrated, which is the case in particular during distillation. But before he speaks of the trials to which he subjected it, and of which he had occasion for a great quantity, he describes the method he adopted for procuring it, which was similar to that of Cruickshanks.

Human sweat, according to Thénard, is formed of a great deal of water, free acetous acid, muriate of soda, an atom of phosphate of lime and oxide of iron, and an inappreciable quantity of animal matter, which approaches much nearer to gelatine than to any other substance.

Perspiration varies in respect to, 1. The *temperature of the atmosphere*. Thus men have a more copious, viscid, and higher-coloured sweat in summer than in winter, and in warm countries than in colder regions. 2. *Sex*. The sweat of a man is said to smell more acrid than that of a woman. 3. *Age*. The young are more subject to sweat than the aged, who, during the excessive heat of the summer, scarcely

sweat at all. 4. *Ingesta.* An alliacious sweat is perceived from eating garlick; a leguminous, from peas; an acid, from acids; a fœtid, from animal food only; and a rancid sweat from fat foods, as is observed in Greenland. A long abstinence from drink causes a more acrid and coloured sweat; and the drinking a great quantity of cold water in summer, a limpid and thin sweat. 5. *Medicines.* The sweat of those who have taken musk, even moderately, and assa-fœtida, or sulphur, has the odour of these substances. 6. *Region of the body.* The sweat of the head is greasy; on the forehead it is more aqueous; under the axillæ, very unguinous; and in the interstices of the toes, it is very fœtid. 7. *Diseases.* In this respect it varies very much in regard to quantity, smell, and colour; for the sweat of gouty persons is said to turn blue vegetable juices to a red colour. Some men also have a lucid sweat, others a sweat tinging their linen of a cærulean colour.

The uses of the insensible perspiration are, 1. To *liberate* the blood from superfluous animal gas, azote, and water. 2. To eliminate the noxious and heterogeneous excrements: hence the acrid, rancid, or putrid perspiration of some men. 3. To *moisten* the external surface of the body, lest the epidermis, cutis, and its nervous papillæ, be dried up by the atmospheric air. 4. To *counter-balance* the suppressed pulmonary transpiration; for when this is suppressed, the cutaneous transpiration is increased.

The use of the sensible perspiration, or sweat, in a healthy man, is scarcely observable, unless from an error of the non-naturals. Its effects in the removal of disease are very important, and various inflammatory and febrile affections are often resolved by a copious sweat, which appears to relieve the vascular system, both by depletion and by a transfer of action from the deep seated to the superficial vessels. In some instances, however, it is believed that morbid matter may be excreted with the sweat. Where fluids are accumulated in a preternatural quantity, or the system is suffering from the retention of the natural excretions, a copious perspiration then affords relief.

Thus, dropsy is sometimes carried off by perspiration, and the bad effects of a suppression of urine are occasionally obviated by a copious sweat of an urinous smell.

PERTU'SSIS. (*is, is.* f.; from *per*, much, and *tussis*, cough.) The hooping-cough. A disease known by a convulsive strangulating cough, accompanied with a peculiar sonorous inspiration, returning by fits, that are usually terminated by vomiting; and by its being contagious. It is vulgarly called also *chin-cough* or *kin-cough.*

Children are most commonly the subjects of this disease; and it seems to depend on a specific contagion, which affects them but once in their life. The disease being once established, the fits of coughing are often repeated without any evident cause; but, in many cases, the contagion may be considered as only giving the predisposition, and the frequency of the fits may depend upon various exciting causes, such as violent exercise, a full meal, the having taken food of difficult digestion, and irritation of the lungs by dust, smoke, or disagreeable odours. Emotions of the mind may likewise prove an exciting cause. Very different opinions have been entertained as to the nature of hooping-cough: some contend that it is essentially a spasmodic disease, the seat of which is in the brain or some part of the nervous system; others maintain, that it is an inflammatory affection of the bronchial membrane; and others, that it is compounded of a primary bronchial inflammation, and a secondary irritation of the brain. The greater part of practitioners, however, regard hooping-cough as a spasmodic disease, extremely liable to become complicated with bronchial inflammation and frequently producing irritation of the brain and hydrocephalus, as a consequence of the disturbance of the cerebral circulation.

The hooping-cough usually comes on with a difficulty of breathing, some degree of thirst, a quick pulse, and other slight febrile symptoms, which are succeeded by a hoarseness, cough, and difficulty of expectoration. These symptoms continue perhaps for a fortnight or more, at the end of which time the disease puts on its peculiar and characteristic form, and is now evident, as the cough becomes convulsive, and is attended with a sound which has been called a hoop.

When the sonorous inspiration has happened, the coughing is again renewed, and continues in the same manner as before, till either a quantity of mucus is thrown up from the lungs, or the contents of the stomach are evacuated by vomiting. The fit is then terminated, and the patient remains free from any other for some time, and shortly afterwards returns to the amusements he was employed in before the fit, expresses a desire for food, and when it is given to him takes it greedily. In those cases however, where the attack has been severe, he often seems much fatigued, makes quick inspirations, and falls into a faint.

On the first coming on of the disease, there is little or no expectoration; or, if any, it consists only of thin mucus; and as long as this is the case the fits of coughing are frequent and of considerable duration; but on the expectoration becoming free and copious, the fits of coughing are less frequent, as well as of shorter duration.

By the violence of coughing, the free transmission of blood through the lungs is somewhat interrupted, as likewise the free return of the blood from the head, which produces that turgescence and suffusion of the face which commonly attend the attack, and in some cases brings on a bleeding either from the nose or ears. If the fits are put an end to by vomiting it may be regarded as a favourable symptom, as may likewise the taking place of a moderate and free expectoration, or a slight hæmorrhage from the nose.

The disease having arrived at its height usually continues for some weeks longer, and at length goes off gradually. In some cases it is, however, protracted for several months, even a year.

Although the hooping-cough often proves tedious, and is liable to return with violence on any fresh exposure to cold, when not entirely removed, it nevertheless is seldom fatal in its simple form. The dangerous cases are those in which bronchitis supervenes, or irritation is set up in the head. When inflammation extends through the minute ramifications of the bronchial tubes, there is a similar danger to that in other cases of bronchitis similarly situated, namely, of the effects on the brain and the whole system, arising from the circulation of imperfectly arterialised blood, and accordingly, a large proportion of fatal cases of hooping-cough really terminate in asphyxia. Where tubercles pre-exist in the lungs, they are sometimes rapidly developed in the course of hooping cough, and the child dies of phthisis. In a few cases, a profuse suppuration takes place throughout the bronchial membrane, a state accompanied with great debility and emaciation, and liable to be confounded with phthisis. From this state, however, the child may recover if the strength be properly supported.

Where the disease is long protracted, the recovery is often imperfect. A disposition to chronic bronchitis may remain for many years or for life; a portion of the substance of the lungs may be hepatized, or a foundation laid for asthma or consumption.

In the treatment of this disease it must be borne in mind that, in the early period, palliative measures can only be employed; but when it continues merely from habit, a variety of means will often at once put a stop to it. In the first stage, in mild cases, very little is required, except obviating occasional irritation, keeping the bowels regular, &c. But where it puts on a more serious character, the plan will differ accordingly as it is attended with inflammatory symptoms, or exhibits a purely spasmodic form. In the former case, it may be sometimes proper, in plethoric habits, to begin by a full bleeding, or leeches to the chest if the patient be very young; then clear the bowels effectually, apply a blister, and exhibit ipecacuan, antimonials, or squill, in nauseating doses, to promote diaphoresis and expectoration. An occasional emetic, where the breathing is much oppressed with wheezing, in young children particularly, may afford material relief. When the disorder is more of the spasmodic character, some of these means may still be useful, as blisters, and nauseating medicines, so far as the strength will admit; but the remedies of greatest efficacy are the narcotics, as opium, conium, &c. exhibited in adequate doses. In the chronic or habitual stage of the disease, almost any thing which produces a considerable impression on the constitution, will occasionally succeed; but we chiefly rely on sedative and antispasmodic, or on tonic remedies, according as there are marks of irritability, or of mere debility in the system. Of the former description opium is perhaps the best, especially in conjunction with squill, given in a full dose at night, and in small quantities swallowed slowly from time to time during the day. Conium, assafœtida, &c. may, however, occasionally answer better in particular constitutions. Among the tonics the cinchona is often highly efficacious, where no appearances of local disease attend: some of the metallic preparations also, particularly sulphate of zinc, may be much relied upon. Sometimes stimulant applications to the chest, but still more certainly opiate frictions, will be found to cure this disorder. When hooping cough is tedious and protracted without the presence of any formidable complication, the great remedy is change of air, which will frequently do more in a few days than medicine in as many months. The cold bath also, where there is no local disease, may have an excellent effect; assisted by warm clothing, especially wearing some kind of fur over the chest.

Peruvian balsam. See *Myroxylon.*

Peruvian bark. See *Cinchona.*

Peruvianus cortex. See *Cinchona.*

Peruvianus cortex flavus. See *Cinchona cordifolia.*

Peruvianus cortex ruber. See *Cinchona oblongifolia.*

PERVIGI'LIUM. (*um, ii.* n.; from *per*, much, and *vigilo*, to watch.) Watching, or a want of sleep. See *Vigilance.*

PERVI'NCA. (*a, æ.* f.; from *per* and *vincio*, to bind.) So called because its stringy roots were used for binding substances together. See *Vinca minor.*

PES. (*es, edis.* m.; a foot.) The foot. It consists of the tarsus, metatarsus, and toes. It has its proper muscles and tendons, arteries, veins, and nerves.

Pes alexandrinus. See *Anthemis.*

PES ANSERI'NUS. A whimsical name given to the radiated expansion of the portio dura on the side of the face.

PES CAPRÆ. Goat's-foot, a species of *Oxalis;* also a species of *Convolvulus.*

Pes cati. See *Gnaphalium dioicum.*

Pes colombi'nus. See *Geranium.*

PES HIPPOCAMPI. The name of two columns at the end of the fornix of the brain, which diverge posteriorly. See *Encephalos.*

Pes leonis. See *Alchemilla.*

PES TIGRIDIS. A species of *Ipomœa.*

PE'SSARY. (*Pessarium, ii.* n.; from πεσσω, to soften.) An instrument made of wood, ivory, or other materials introduced into the vagina to support the uterus. Pessaries are of various forms; as the *globe pessary*, the *ring pessary*, the *conical pessary*, &c.

PESTILENCE. A plague.

PESTILENTIAL. (*Pestilentialis;* from *pestis*, the plague.) A disease which is epidemic and malignant, partaking of the nature of a plague, is called a pestilential disease.

Pestilentwort. See *Tussilago.*

Pestilochia. See *Aristolochia virginiana.*

PE'STIS. The plague: a disease characterised by typhoid fever, which is contagious in the extreme; prostration of strength, buboes, and carbuncles; petechiæ, hæmorrhage, and colliquative diarrhœa. The epidemic violence of the plague is restrained within certain limits of atmospheric temperature. When the thermometer rises above 80°, or sinks much below 60°,

the epidemy ceases, and the disease becomes sporadic and much more tractable.

By some writers the disease has been divided into three species: that attended with buboes; that attended with carbuncles; and that accompanied with petechiæ. This division appears wholly superfluous. Dr. Russel, in his elaborate treatise on the plague, makes mention of many varieties; but when these have arisen, they seem to have depended in a great measure on the temperament and constitution of the air at the time the disease became epidemical, as likewise on the patient's habit of body at the time of his being attacked.

The plague is by most writers considered as the consequence of a pestilential contagion, which is propagated from one person to another almost solely by *contact* with a diseased person, or with fomites embued with the specific poison.

It has been observed that it generally appears as early as the fourth or fifth day after infection; but it has not yet been ascertained how long a person who has laboured under the disease is capable of infecting others, nor how long the contagion may lurk in an insusceptible habit without producing the disease, and may yet be communicated, and the disease excited, in habits more susceptible of the infection. It has generally been supposed, however, that a quarantine of forty days is much longer than is necessary for persons, and probably for goods also. Experience has not yet determined how much of this term may be abated.

It sometimes happens, that after the application of the contagious miasm, the patient experiences only a considerable degree of languor and slight headach for many days previous to a perfect attack of the disease: but it more usually comes to pass, that he is very soon seized with great depression of strength, anxiety, palpitations, syncope, stupor, giddiness, violent headach, and delirium, the pulse becoming at the same time very weak and irregular.

These symptoms are shortly succeeded by nausea, and a vomiting of a dark bilious matter; and, in the further progress of the disease, carbuncles make their appearance; buboes arise in different glands, such as the parotid, maxillary, cervical, axillary, and inguinal; or petechiæ, hæmorrhages, and a colliquative diarrhœa, ensue, which denote a putrid tendency prevailing to a great degree in the mass of the blood.

Such are the characteristic symptoms of this malignant disease; but it seldom happens that they are all to be met with in the same person. Some, in the advanced state of the disease, labour under buboes, others under carbuncles, and others again are covered with petechiæ.

The plague in its severe form is always to be considered as attended with imminent danger, and when it prevailed in this country about 200 years ago, proved fatal to most of those who were attacked with it. It is probable, however, that many of them died from want of care and proper nourishment, as the infected were forsaken by their nearest friends; because in Turkey and other countries, where attention is paid to the sick, a great many recover. Much depends, however upon the particular epidemy, and the period of the epidemy: at the commencement of the more formidable visitations of this pestilence, almost all the cases are fatal.

When the disease is unattended by buboes, it runs its course more rapidly, and is more generally fatal, than when accompanied by such inflammations. The earlier they appear, the milder usually is the disease. When they proceed kindly to suppuration, they always prove critical, and ensure the patient's recovery. A gentle diaphoresis, arising spontaneously, has been known in many instances likewise to prove critical. When carbuncles show a disposition to gangrene, the event will be fatal. Petechiæ, hæmorrhages, and colliquative diarrhœa, denote the same termination.

There is a particular mild form of plague, cases of which are met with more frequently towards the end of an epidemic than at any other period. In this form the symptoms are similar to those of the severe, but infinitely less in degree — indeed, cases are observed in which the individual is scarcely ill, and can follow his usual occupations. This form is always attended with buboes, but never with carbuncles or petechiæ. In some cases the buboes only occur, without any constitutional affection.

Dissections of the plague have discovered the gall bladder full of black bile, the liver very considerably enlarged, the heart much increased in size, and the lungs, kidneys, and intestines beset with carbuncles. They have likewise discovered all the other appearances observed in typhus fever. The plague may be communicated by inoculation with the matter of the buboes. In 1801, Dr. Whyte tried the experiment on himself, and died on the fourth day of the disease; and in 1817, Mr. Van Rosenfeldt fell a victim to a similar rashness — he died on the second day. We need not here speak of the treatment of the plague which is of comparatively little interest to practitioners in this country. It appears moreover to be a disease very little under the control of medicine, and where recovery takes place it generally appears to be owing much more to the efforts of nature than to those of art.

PE'TAL. (*Petalum*, *i.* n.) The name of the coloured leaflets of the corolla of a flower. The great variety of form, duration, &c., of the petals, give rise to the following names: —

From their duration, —

1. *Patent*; as in *Rosa canina.*
2. *Patentissima*, very spreading.
3. *Erect*; as in *Allium nigrum.*
4. *Connivent*; as in *Rumex.*
5. *Distant*; as in *Cucubalus bacciferus.*

From the figure of the border, —

6. *Acuminate*; as in *Saxifraga stellaris.*
7. *Setaceous*; as in *Tropæolum minus.*
8. *Apice cohærentia*; as in *Vitis.*
9. *Apice reflexa*; as in *Anemone.*
10. *Aristate*; as in *Galium aristatum.*
11. *Bifid*; as in *Silene nocturna.*
12. *Bipartite*; as in *Alsine media.*
13. *Bilobe*; as in *Geranium striatum.*
14. *Carinate*; as in *Carum carui.*
15. *Concave*; as in *Ruta graveolens.*

16. *Cordate;* as in *Sium selinum.*
17. *Hirsute;* as in *Menyanthes.*
18. *Ciliate;* as in *Asclepias undulata.*
19. *Crenate;* as in *Linum usitatissimum.*
20. *Dentate;* as in *Silene Lusitanica.*
21. *Serrate;* as in *Dianthus arboreus.*
22. *Cuneiform;* as in *Epidendrum cordatum.*
23. *Emarginate;* as in *Allium roseum.*
24. *Inflex;* as in *Pimpinella.*
25. *Reflex;* as in *Pancratium Zelanicum.*
26. *Involute;* as in *Anethum.*
27. *Integer;* as in *Nigella arvensis.*
28. *Laciniate;* as in *Reseda.*
29. *Lanceolate;* as in *Narcissus minor.*
30. *Linear;* as in *Tussilago farfara.*
31. *Lineate;* as in *Scilla Lusitanica.*
32. *Punctate;* as in *Melanthium.*
33. *Maculate;* as in *Digitalis.*
34. *Oblong;* as in *Citrus* and *Hedera.*
35. *Obtuse;* as in *Tropæolum majus.*
36. *Ovate;* as in *Allium flavum.*
37. *Plane;* as in *Pancratium.*
38. *Subrotund;* as in *Rosa centifolia.*
39. *Truncate;* as in *Hura crepitans.*
40. *Coronate;* as in *Nerium oleander.*

The claw of the petal is very long in *Dianthus* and *Saponaria;* and *connate,* in *Malva sylvestris* and *Oxalis.*

PETA'LIFORM. *Petali'formis.* Like a petal: applied to the stigma of the *Iris germanica.*

PETALO'DES. (From πεταλον, a leaf, or thin scale.) This term is by Hippocrates applied to urine which has in it flaky substances resembling leaves.

PETASI'TES. (*es, is.* f.; from πετασος, a hat: so named because its leaves are large, and spread like a hat.) See *Tussilago petasites.*

PETE'CHIA. (*a, æ.* f.; a low Latin word.) *Peticula.* A red or purple spot, which resembles a flea-bite. It arises from a small extravasation of blood under the skin. When the extravasation is larger, so as to resemble a bruise, it is called a *vibex.* Petechiæ and vibices are common in malignant fevers.

PETECHIÆ SINE FEBRE. The simple form of purpura has been so called. See *Purpura simplex.*

PETI'OLAR. *Petiola'ris.* Fixed to the petiole or leafstalk.

PETI'OLATE. *Petiola'tus.* Applied to leaves which are formed with a stalk, whether long or short, simple or compound, as most leaves are; as in *Verbascum nigrum,* &c.

PETI'OLUS. (*us, i.* m.; from *petalum,* a leaf.) A petiole. The footstalk or leafstalk of a plant. The term is applied exclusively to the stalk of the leaf.

It is distinguished into the *apex,* which is inserted into the leaf, and the *base,* which comes from the stem.

From its figure it is called, —

1. *Linear,* equal in breadth throughout; as in *Citrus medica.*
2. *Alate;* as in *Citrus aurantium.*
3. *Appendiculate,* when furnished with leaflets at its base; as in *Dipsacus pilosus.*
4. *Round,* throughout; as in *Pisum sativum.*
5. *Half-round,* round on one side, and flat on the other.
6. *Triquetral,* three-sided.
7. *Angulate,* having angles.
8. *Cuniliculate,* channelled to its very base, where it is sometimes greatly dilated and concave; as in *Angelica sylvestris.*
9. *Compressed,* compressed towards its base; as in *Populus tremula.*
10. *Clavate,* thicker towards the apex; as in *Cacalia suaveolens.*
11. *Spinescent,* becoming a spine after the fall of the leaf; as in *Rhamnus catharticus.*

From its insertion the petiolus is said to be, —

12. *Insertus;* as in the *Pyrus communis,* and most trees.
13. *Articulate;* as in *Oxalis acetosella.*
14. *Adnate,* adhering so to the stem, that it cannot be displaced without injuring the bark.
15. *Decurrent,* adhering at its base, and going some little way down the stem; as in *Pisum ochrus.*
16. *Amplexicaulis,* surrounding the stem at its base; as in *Senecio hastatus.*
17. *Vaginans,* surrounding the stem with a perfect tube; as in *Canna Indica.*

From its length with respect to the leaf, it is said to be *brevissimus* when much shorter, and *longissimus,* when longer; as in *Anemone hepatica,* and *Geranium terebinthinatum.*

It is distinguished also into *simple,* when not divided; as in most leaves: and *compound,* when divided into lateral branches; as in all compound leaves.

PETRA'PIUM. (From *petra,* a rock, and *apium,* parsley: so called because it grows in stony places.) See *Bubon macedonicum.*

PETRELÆ'UM. (From πετρα, a rock, and ελαιον, oil.) The liquid bitumen which distils from rocks.

PETRO'LEUM. (*um, i.* n.; from *petra,* a rock, and *oleum,* oil.) A liquid, bituminous substance which flows from the clefts of rocks, or in different places at the surface of the earth. See *Bitumen.*

PETROLEUM BARBADENSE. Barbadoes tar. A very dark coloured liquid bitumen brought from Trinidad and other places.

PETROLEUM RUBRUM. A species of rock-oil which abounds about the village of Gabian in Languedoc. See *Bitumen.*

Petroleum sulphuratum. See *Balsamum sulphuris Barbadense.*

PETROMYZON. (*on, i.* m.; from πετρον, a stone, and μυζαω, to suck: so called from being found adhering to the stones by sucking, and so keeping its place.) The name of a genus of fishes of the chondropterygious order. The lamprey.

PETROMYZON FLUVIATILIS. The lesser lamprey. This and the *bronchialis,* or lampern, are of easy digestion, equally well flavoured with the larger, but are seldom eaten.

PETROMIZON MARINUS. The true lamprey. This is an exquisite dainty when in season and well dressed. The death of King Henry I. was attributed to a too luxurious indulgence in this his favourite dish.

Petrous. See *Petrosus.*

Petropharyngæus. See *Constrictor pharyngis superior.*

Petro-salpingo staphylinus. See *Levator palati.*

PETROSELI'NUM. (*um*, *i.* n.; from πετρα, a rock, and σελινον, parsley.) See *Apium petroselinum.*

Petroselinum macedonicum. See *Bubon.*

Petroselinum vulgare. See *Apium.*

PETRO-SPHENOIDAL SUTURE. The small suture situated between the anterior margin of the os petrosum and the posterior margin of the sphenoid bone.

PETROSTAPHYLINUS. (Πετρον, and σταφυλη, the uvula.) The *levator palati mollis* muscle. — *Chaussier.*

PETRO'SUS. (From *petra*, a rock.) Petrous. A portion of the temporal bone is the *os petrosum*, or petrous portion, on account of its great hardness. See *Temporis os.*

PEUCE'DANUM. (*um*, *i.* n.; from πευκη, the pine-tree: so called from its leaves resembling those of the pine-tree.) 1. The name of a genus of plants. Class, *Pentandria*; Order, *Digynia.*

2. The pharmacopœial name of the hog's fennel. See *Peucedanum officinale.*

PEUCEDANUM OFFICINALE. The systematic name of the hog's fennel; called also, *Marathrum sylvestre*, *Marathrophyllum*, *Pinastellum*, and *Fœniculum porcinum.* The plant which bears these names in the pharmacopœias is the *Peucedanum — foliis quinquepartitis, filiformibus linearibus*, of Linnæus. The root is the officinal part: it has a strong fœtid smell, somewhat resembling that of sulphureous solutions, and an acrid, unctuous, bitterish taste. Wounded when fresh, in the spring or autumn, particularly in the former season, in which the root is most vigorous, it yields a considerable quantity of yellow juice, which soon dries into a solid gummy resin, which retains the taste and strong smell of the root. This, as well as the root, is recommended as a nervine and anti-hysteric remedy.

PEUCEDANUM SI'LAUS. The systematic name of the English meadow saxifrage: called also, *Agrion*, *Agriophyllon*, *Saxifraga vulgaris*, *Saxifraga angelica*, *Hippomarathrum*, *Fœniculum erraticum*, and *Pinastellum.* The roots, leaves, and seeds of this plant have been commended as aperients, diuretics, and carminatives; and appear, from their aromatic smell, and moderately warm, pungent, bitterish taste, to have some claim to these virtues. They are rarely used.

PEWTER. A compound metal, the basis of which is tin. The best sort consists of tin alloyed with about a twentieth or less of copper or other metallic bodies which the experience of the workmen has shown to be the most conducive to the improvement of its hardness and colour, such as lead, zinc, bismuth, and antimony. There are three sorts of pewter, distinguished by the names of plate, trifle, and ley pewter. The first was formerly much used for plates and dishes; of the second are made the pints, quarts, and other measures of beer: and of the ley-pewter, wine measures and large vessels.

The best sort of pewter consists of 17 parts of antimony to 100 parts of tin; but the French add a little copper to this kind of pewter. A very fine silver-looking metal is composed of 100 parts of tin, eight of antimony, one of bismuth, and four of copper. On the contrary, the ley-pewter, by comparing its specific gravity with those of the mixtures of tin and lead, must contain more than a fifth part of its weight of lead.

PEYER'S GLANDS. *Peyeri glandulæ.* The clustered mucous glands of the small intestines are so called after Peyer, a Swiss anatomist who described them. See *Brunner's glands*, and *Intestines.*

PEZI'ZA. (*a*, *æ.* f.; somewhat altered from the Greek πεζικη, which is derived from πεζα, the sole of the foot. Piny speaks of the *peziæ*, as the Greek appellation of such fungi as grow without any stalk or apparent root.) The name of a genus of plants. Class, *Cryptogamia*; Order, *Fungi.*

PEZIZA AURI'CULA. Jew's ears. Called also, *Auricula Judæ*, *Fungus sambucinus*, and *Agaricus auriculæ forma.* A membranaceous fungus, *Peziza — concava rugosa auriformis*, of Linnæus, which resembles the human ear. Its virtues are astringent, and when employed (by some its internal use is not thought safe), it is made into a decoction, as a gargle, for relaxed sore throats.

PHA'CIA. (Φακια, a lentil.) A cutaneous spot or blemish, called by the Latins *lentigo*, and *lenticula.*

PHAGEDÆ'NA. (*a*, *æ.* f.; from φαγω, to eat.) A species of ulcer that spreads very rapidly.

PHAGEDÆNA GANGRENOSA. Hospital gangrene. See *Mortification.*

PHAGEDÆ'NIC. (*Phagedænicus*; from φαγω, to eat.) 1. Applied to an ulceration which spreads very rapidly.

2. To escharotics.

PHALACRO'SIS. (Φαλακρωσις; from φαλακρος, bald.) Baldness.

PHA'LACRUM. (From φαλακρος, bald.) A surgical instrument, with a blunt, smooth top, as a probe. — *Turton.*

PHALA'NGES. The plural of *phalanx.*

PHALANGO'SIS. (From φαλαγξ, a row of soldiers.) 1. An affection of the eyelids, when there are two or more rows of hairs upon them.

2. A prolapsus of the upper eyelid. See *Ptosis.*

PHA'LANX. (*x*, *gis.* f.; from φαλαγξ, a battalion.) The small bones of the fingers and toes, are distinguished into the first, second and third *phalanges.*

PHA'LARIS. (*is*, *idis.* f.; from φαλ, white, shining: so named from its white shining seed, supposed to be the φαλαρος of Dioscorides.) The name of a genus of plants. Class *Triandria*; Order, *Digynia.* Canary grass.

PHALARIS CANARIENSIS. Canary grass. The seed of this plant is well known to be the common food of the canary-birds. In the Canary islands, the inhabitants grind it into meal, and make a coarse sort of bread with it.

PHA'LLUS. (*us*, *i.* m.; after the φαλλος of the Greeks, to which it bears a great resemblance.) The name of a genus of the Order *Fungi*; Class, *Cryptogamia.*

PHALLUS ESCULENTUS. The systematic name of the morel fungus. It grows on moist ba

and wet pastures, and springs up in May. It is used in the same manner as the truffle, for gravies and stewed dishes, but gives an inferior flavour.

PHALLUS IMPUDICUS. The stinkhorns. *Fungus phalloides*. A fungus which is, at a distance, intolerably fœtid, so that it is oftener smelt than seen, being supposed to be some carrion, and therefore avoided: when near, it has only the pungency of volatile alkali. It is applied to allay pain in the limbs.

PHANTA'SMA. (*a, atis.* n.; from φανταζω, to make appear.) The imaginary perception of some object which is not really present. It may arise from disease of the eye or of the sensorium.

PHA'RICUM. Φαρικον. The name of a substance which was violently poisonous. What it was is now unknown.

PHARMACEU'TIC. (*Pharmaceuticus*; from φαρμακευω, to exhibit medicines.) Belonging to pharmacy. See *Pharmacy*.

PHARMACIEN. The French for an apothecary. The French pharmacien, however, does not correspond with our apothecary; he is an educated druggist, who passes an examination, whose sole business is to dispense, not to prescribe, medicines. The regular medical practitioner never dispenses medicines, and the profession is thus judiciously kept apart from trade, while the practice of pharmacy is conducted by well informed, and often highly scientific, persons.

PHARMACOCHY'MIA. (*a, æ.* f.; from φαρμακον, a medicine, and χυμια, chemistry.) Pharmaceutic chemistry, or that part of chemistry which respects the preparation of medicines.

PHARMACOLOGY. (*Pharmacologia, a, æ.* f.; from φαρμακον, a medicine, and λογος, a discourse.) The study of *pharmacy*.

PHARMACOPŒ'IA. (*a, æ.* f.; from φαρμακον, a medicine, and ποιεω, to make.) 1. The art of preparing medicines.

2. A dispensatory, or book of directions for the composition of medicines approved of by medical practitioners, or published by authority.

PHARMACOPO'LA. (*a, æ.* f.; from φαρμακον, a medicine, and πωλεω, to sell.) An apothecary, or vender of medicines.

PHARMACOPO'LIUM. (*um, ii.* n.; from φαρμακον, a medicine, and πωλεω, to sell.) A druggist's or apothecary's shop.

PHARMACOPO'SIA. (From φαρμακον, a medicine, and ποσις, a potion.) A liquid medicine.

PHARMACOTHE'CA. (*a, æ.* f.; from φαρμακον, a medicine, and τιθημι, to place.) A medicine chest.

PHA'RMACY. (*Pharmacia, æ.* f.; from φαρμακον, a medicine.) The art of preparing remedies for the treatment of diseases.

The articles of the Materia Medica, being generally unfit for administration in their original state, are subjected to various operations, mechanical or chemical, by which they become adapted to this purpose. Herein consists the practice of pharmacy, which therefore requires a previous knowledge of the sensible and chemical properties of the substances operated on. The qualities of many bodies are materially changed by heat, especially in conjunction with air and other chemical agents; the virtues of others reside chiefly in certain parts, which may be separated by the action of various menstrua, particularly with the assistance of heat; and the joint operation of remedies on the human body is often very different from what would be anticipated, from that which they exert separately: hence, in the preparations and compositions of the pharmacopœias, we are furnished with many powerful as well as elegant forms of medicine.

PHARYNGE'THRON. Φαρυγγεθρον. The pharynx, or fauces.

PHARYNGE'AL. (*Pharyngeus*; from φαρυγξ, the pharynx.) Belonging to, or affecting the pharynx.

PHARYNGI'TIS, (*is, idis.* f.; from *pharynx*, the seat of the disease, and *itis*, which imports inflammation.) An inflammation of the membrane which forms the pharynx: it is usually described under the genus cynanche, and is the cynanche pharyngea of Cullen's arrangement. It is known by the unnatural florid colour of the pharynx, especially about the lower part of the fauces; and this is accompanied by feverishness of the inflammatory kind, which is seldom considerable. In most cases of phlegmonous tonsillitis the pharynx is also affected; and so when phlegmonoid inflammation of the pharynx takes place, the disease mostly extends to the tonsils; so that what has been said of tonsillitis, of both its species, the malignant as well as the phlegmonoid, will apply to pharyngitis, the pharynx being as often the seat of the malignant disease as the tonsils. Dr. Cullen declares, indeed, that he never saw a case of true cynanche pharyngea; that is, a case in which the inflammation was confined to the pharynx: it constantly spreads in a greater or less degree to the tonsils and neighbouring parts. Besides, the mode of treatment is, in almost every instance, the same in both.

PHARYNGOSTAPHYLI'NUS. A muscle originating in the pharynx, and terminating in the uvula. More commonly called *palato-pharyngæus*.

PHARYNGOTO'MIA. (*a, æ.* f.; from φαρυγξ, the pharynx, and τεμνω, to cut.) The operation of cutting into the pharynx.

PHA'RYNX. (*x, gis.* f. Απο του φερω, because it conveys the food into the stomach.) The muscular bag at the back part of the mouth. It is shaped like a funnel, adheres to the fauces behind the larynx, and terminates in the œsophagus. Its use is to receive the masticated food, and to convey it into the œsophagus.

PHASE'OLUS. (*us, i.* m.; from φασηλος, a little ship, or galliot, which its pods were supposed to resemble.) The name of a genus of plants. Class, *Diadelphia*; Order, *Decandria*.

PHASEOLUS CRE'TICUS. A decoction of the leaves of this plant, called by the Americans Cajan, and Cayan, is said to restrain the bleeding from piles when excessive.

PHASEOLUS VULGARIS. The systematic name of the kidney-bean. This is often called the

French bean: when young and well boiled it is easy of digestion, and delicately flavoured, and less liable to produce flatulency than the pea.

PHASGA'NIUM. (From φασγανον, a sword, so called because its leaves are shaped like a sword.) The herb sword grass.

PHASIA'NUS. (*us*, *i.* m.) 1. The name of a genus of birds, of the order *Gallinæ*.

2. The pheasant.

PHASIANUS COLCHICUS. The common pheasant. The flesh of this bird is easy of digestion, and a great delicacy.

PHASIANUS GALLUS. The common or domestic fowl, of which there are many varieties, all highly useful to man.

PHA'TNIUM. (From φατνη, a stall.) The socket of a tooth.

PHELLA'NDRIUM. (*um*, *ii.* n.; from φελλος, the cork-tree, and ανδριος, male: so called because it floats upon the water like cork.) The name of a genus of plants. Class, *Pentandria*; Order, *Digynia*.

PHELLANDRIUM AQUATICUM. The systematic name of the water-fennel, or fine-leaved water-hemlock. *Fœniculum aquaticum. Cicutaria aquatica.* The plant which bears this name in the pharmacopœias is the *Phellandrium —foliorum ramificationibus divaricatis*, of Linnæus. It possesses narcotic and poisonous qualities, which are best counteracted by acids, after clearing the primæ viæ. The seeds have been recommended in conjunction with Peruvian bark, in the cure of pulmonary phthisis.

PHE'MOS. (Φημος.) A medicine used by the Greeks against a dysentery.

PHENECIN. A purple substance obtained by Mr. Crum, from indigo.

PHILADEL'PHUS. (*us*, *i.* m.; from φιλεω, to love, and αδελφος, a brother; so called because, by its roughness, it attaches itself to whatever is near it.) See *Galium aparine*.

PHILANTHRO'PUS. (*us*, *i.* m.; from φιλεω, to love, and ανθρωπος, a man: so called from its uses.) 1. A medicine employed by the Greeks in nephritic complaints.

2. (*us*, *i.* f.) The herb goose-grass, because it sticks to the garments of those who touch it. See *Galium aparine*.

PHILO'NIUM. (*um*, *i.* n.; from *Philo*, its inventor. The ancient name of an aromatic opiate invented by Philo; also the name of a collyrium which contained numerous ingredients.

PHILONIUM LONDINENSE. An old name of the *Confectii opii*.

Philosopher's stone. See *Lapis philosophorum*.

PHILLY'RIA. (*a*, *æ.* f. Φιλλυρια, of Dioscorides: supposed to be so called from *Philyra*, the mother of Chiron, who first applied it medicinally.) The name of a genus of plants. Class, *Diandria*; Order, *Monogynia*. Mock privet.

PHI'LTRUM. (*um*, *i.* n. from φιλεω, to love.) 1. A philtre, or medicine to excite love. The ancients had great faith in such medicines.

2. The groove between the nose and the upper lip.

PHIMO'SIS. (*is*, *is.* f.; from φιμοω, to tie or bind up.) A constriction or straightness of the extremity of the prepuce, which, preventing the glans from being uncovered, is often the occasion of many troublesome complaints. It may arise from different causes, both in children and grown persons. Children have naturally the prepuce very long; and as it exceeds the extremity of the glans, and is not liable to be distended, it is apt to contract its orifice. This often occasions a lodgment of a small quantity of urine between that and the glans, which, if it grows corrosive, may irritate the parts so as to produce an inflammation. In this case, the extremity of the prepuce becomes more contracted, and consequently the urine more confined. Hence the whole inside of the prepuce excoriates and suppurates; the end of it grows thick and swells, and in some months becomes callous. At other times it does not grow thick, but becomes so straight and contracted as hardly to allow the introduction of a probe. The only way to remove this disorder is by the operation of slitting it open. A phimosis may affect grown persons from the same cause as little children, though there are some grown persons who cannot uncover their glans, or at least not without pain, and yet have not the extremity of the prepuce so contracted as to confine the urine from passing, we notwithstanding find them sometimes troubled with a phimosis, which might be suspected to arise from a venereal taint, but has, in reality, a much more innocent cause. There are, we know, sebaceous glands situated in the prepuce round the corona, which secrete an unctuous humour, which sometimes becomes acrimonious irritates the skin that covers the glans, and the irritation extending to the internal membrane of the prepuce, they both become inflamed, and yield a purulent serum, which cannot be discharged, because the glans is swelled, and the orifice of the prepuce contracted. We find also some grown persons, who, though they never uncovered the glans, have been subject to phimosis from a venereal cause. In some, it is owing to gonorrhœa, where the matter lodged between the prepuce and the glans occasioned the same excoriation as the discharge before mentioned from the sebaceous glans. In others it proceeds from venereal chancres on the prepuce, the glans, or the frænum; which producing an inflammation either on the prepuce or glans, or both, the extremity of the for skin contracts, and prevents the discharge of the matter. The parts, in a very little time, are greatly tumefied, and sometimes a gangrene comes on in less than two days. Lastly, it occasionally is produced by common inflammation, which causes a swelling and an imprisonment of the glans.

The cure of the primary disease requires leeches, cold lotions, and cataplasms. If the prepuce continues contracted, after the inflammation is subdued, it should be slit open with a knife. And so, also, if after the removal of the disease which may have given rise to the phimosis, it still remains, recourse must be had to the same operation.

PHLEBES AËTIOI. Eagle veins. The veins of the temples. — *Rufus Ephesius.*

PHLEBI'TIS. Inflammation of a vein.

Phlebitis uterine. See *Puerperal fever.*

PHLEBORRHA'GIA. (*a, æ.* f.; from φλεψ, a vein, and ρηγνυμι, to break out.) A rupture of a vein.

PHLEBO'TOMY. (*Phlebotomia, æ.* f.; from φλεψ, a vein, and τεμνω, to cut.) The opening of a vein. See *Venesection.*

PHLEGM. (*Phlegma, atis.* n.; πλεγμα, from φλεγω, to burn, or to excite.) 1. One of the primary humours of the body according to the Greek physiologists. See *Cardinal humours.*

2. Inflammation. — *Hippocrates.*

3. The viscid mucus expectorated.

4. Aqueous matter obtained by distillation from the lungs.

PHLEGMAGO'GUS. (From φλεγμα, phlegm, and αγω, to drive out.) Applied to a medicine which promotes the discharge of phlegm.

PHLEGMA'SIA. (*a, æ.* f.; from φλεγω, to burn.) Inflammation. See *Inflammation.*

PHLEGMASIA DOLENS. A disease which mostly occurs to women soon after delivery: and hence it has been called the puerperal tumid leg. Dr. Hull gave it the name of *phlegmasia dolens;* and it has been described as *phlegmasia lactea, ecchymoma lymphatica;* and by Dr. Cullen, as *anasarca serosa;* and Dr. Good calls it *bucknemia sparganosis.* The swelling has been ascribed to a redundancy of milk, and a morbid deposition in consequence of such redundancy; whence the French call it *dépôt laiteux,* and *lait répandu;* and the Germans, *milch-streichen.* A minuter attention, however, will sufficiently prove that it has seldom any thing to do with the milk, perhaps never. It has occurred where the breasts have been long destitute of milk, and where they have overflowed; when suckling has been relinquished, and where it has been continued; and several instances have occurred in virgins and in men. It principally, however, affects women in the puerperal state; in a few instances it has been observed to attack pregnant women; and, in one or two cases, nurses, on losing their children, have been affected by it. Women of all descriptions are liable to be attacked by it during and soon after childbed; but those whose limbs have been pained or anasarcous during pregnancy, and who do not suckle their offspring, are more especially subject to it. It has rarely occurred oftener than once in the same female. It supervenes to easy and natural, as well as to difficult and preternatural births. It sometimes makes its appearance in twenty-four or forty-eight hours after delivery, and at other times, not till a month or six weeks after; but, in general, the attack takes place from the tenth to the sixteenth day of the lying-in. It has, in many instances, attacked women who were recovering from puerperal fever; and, in some cases, has supervened, or succeeded, to thoracic inflammation. It not uncommonly begins with coldness and rigors: these are succeeded by heat, thirst, and other symptoms of pyrexia; and then pain, stiffness, and other symptoms of topical inflammation, supervene. Sometimes the local affection is from the first accompanied with, but is not preceded by, febrile symptoms. Upon other occasions, the topical affection is not at first attended with feverish symptoms; but soon after it has taken place, the pulse becomes more frequent, the heat of the body is increased, and the patient is affected with thirst, head-ache, &c. The pyrexia is very various in degree in different patients, and sometimes assumes an irregular remittent or intermittent type. The complaint generally takes place on one side only at first, and the part where it commences is various; but it most commonly begins in the lumbar, hypogastric, or inguinal region, on one side, or in the hip, or top of the thigh, and corresponding labium pudendi. In this case, the patient first perceives a sense of pain, weight, and stiffness in some of the above-mentioned parts, which are increased by every attempt to move the pelvis or lower limb. If the part be carefully examined, it generally is found rather fuller or hotter than natural, and tender to the touch, but not discoloured. The pain increases, always becomes very severe, and, in some cases, is of the most excruciating kind. It extends along the thigh; and when it has subsisted for some time, longer or shorter in different patients, the top of the thigh and the labium pudendi become greatly swelled, and the pain is then sometimes alleviated, but accompanied with a greater sense of distension. The pain next extends down the thigh towards the ham in the direction of the crural blood-vessels, the course of which may generally be traced by an indurated cord which is perceptible to the touch; when it has continued for some time, the whole of the thigh becomes swelled, and the pain is somewhat relieved. The pain then extends down the leg to the foot, and is commonly the most severe in the direction of the posterior tibial vessels; after some time, the parts last attacked begin to swell, and the pain abates in violence, but is still very considerable, especially on any attempt to move the limb. The extremity being now swelled throughout its whole extent, appears perfectly or nearly uniform, and it is not perceptibly lessened by an horizontal position, like an œdematose limb. It is of the natural colour, or even whiter, is hotter than usual, excessively tense, and exquisitely tender when touched. When pressed by the finger in different parts, it is found to be elastic, little, if any, impression remaining, and that only for a very short time. If a puncture or incision be made into the limb, in some instances no fluid is discharged; in others, a small quantity only issues out, which coagulates soon after; and in others, a large quantity of fluid escapes, which does not coagulate; but the whole of the effused matter cannot be drawn off in this way. The swelling of the limb varies both in degree and in the space of time requisite for its full formation. In most instances it arrives at double the natural size, and in some cases at a much greater. In lax habits, and in patients whose legs have been very much affected with anasarca during pregnancy, the swelling takes place more rapidly than in those who are differently circumstanced; it sometimes arrives, in the former class of patients, at its greatest extent in twenty-four hours, or less, from the first attack.

Instead of beginning invariably at the upper part of the limb, and descending to the lower, this complaint has been known to begin in the foot, the middle of the leg, the ham, and the knee. In whichsoever of these parts it happens to begin, it is generally soon diffused over the whole of the limb; and when this has taken place, the limb presents the same phenomena exactly that have been stated above as observable when the groin, &c. are first affected.

After some days, generally from two to eight, the febrile symptoms diminish, and the swelling, heat, tension, weight, and tenderness of the lower extremity begin to abate, first about the upper part of the thigh, or about the knee, and afterwards in the leg and foot. Some inequalities are found in the limb, which, at first, feel like indurated glands; but, upon being more nicely examined, their edges are not so well defined as those of conglobate glands; and they appear to be occasioned by the effused matter being of different degrees of consistence in different points. The conglobate glands of the thigh and leg are sometimes felt distinctly, and are tender to the touch, but are seldom materially enlarged: and, as the swelling subsides, it has happened that an enlargement of the lymphatic vessels, in some part of the limb, has been felt, or been supposed to be felt.

The febrile symptoms having gradually disappeared, the pain and tenderness of the limb being much relieved, and the swelling and tension being considerably diminished, the patient is debilitated and much reduced, and the limb feels stiff, heavy, benumbed, and weak. When the finger is pressed strongly against it for some time, in different points, it is found to be less elastic than at first, in some places retaining the impression of the finger for a longer, in other places for a shorter time, or scarcely at all; and, if the limb be suffered to hang down, or if the patient walk much, it is found to be more swelled in the evening, and assumes more of an œdematose appearance. In this state the limb continues for a longer or shorter time, and is commonly at length reduced wholly, or nearly, to the natural size.

Hitherto the disease has been described as affecting only one of the inferior extremities, and as terminating by resolution, or the effusion of a fluid that is removed by the absorbents; but, unfortunately, it sometimes happens, that after it abates in one limb, the other is attacked in a similar way. It also happens, in some cases, that the swelling is not terminated by resolution; for sometimes a *suppuration* takes place in one or both legs, and ulcers are formed which are difficult to heal. In a few cases a gangrene has supervened. In some instances, the patient has been destroyed by the violence of the disease, before either suppuration or gangrene have happened.

The *predisposing causes* of this disease, when it occurs during the pregnant or puerperal state, or in a short time afterwards, appear to be, 1st, The increased irritability and disposition to inflammation which prevail during pregnancy, and in a still higher degree for some time after parturition. 2dly, The over-distended or relaxed state of the blood-vessels of the inferior part of the trunk, and of the lower extremities, produced during the latter months of utero-gestation.

Amongst the *exciting causes* of this disease may be enumerated, 1st, *Contusions*, or violent exertions of the lower portions of the abdominal and other muscles inserted in the pelvis or thighs, or other muscles of the inferior extremities, and contusions of the cellular texture connected with these muscles, during a tedious labour. 2dly, The *application of cold and moisture*, which are known to act very powerfully upon every system in changing the natural distribution of the circulating fluids, and consequently, in a system predisposed by parturition, may assist in producing the disease, by occasioning the fluids to be impelled, in unusual quantity, into the weakened vessels of the lumbar, hypogastric, and inguinal regions, and of the inferior extremities. 3dly, *Suppression* or diminution of the lochia, and of the secretion of milk, which, by inducing a plethoric state of the sanguiferous system, may occasion an inflammatory diathesis, may favour congestion, and the determination of an unusual quantity of blood to the vessels of the parts just mentioned, and thus contribute to the production of an inflammation of these parts. 4thly, *Food taken in too large quantity, and of a too stimulating quality*, especially when the patient does not give suck. This cause both favours the production of plethora, and stimulates the heart and arteries to more frequent and violent action; the effects of which may be expected to be particularly felt in the lumbar, hypogastric, or inguinal regions, and in the lower extremities, from the state of their blood-vessels. 5thly, *Standing or walking too much*, before the arteries and veins of the lower half of the body have recovered sufficiently from the effects of the distention which existed during the latter months of pregnancy. This must necessarily occasion too great a determination of blood to these parts, and consequently too great a congestion in them; whence they will be more stimulated than the upper parts of the body, and inflammation will sometimes be excited in them.

The opinions of authors as to the proximate cause of this affection have been very various. The first approach to what is generally believed to be the true pathology of it, was made some years since by Dr. D. Davis, who was led by his dissections to attribute it to inflammation of the iliac and crural veins. More recently, Dr. Robert Lee's investigations go to prove that the real origin of the inflammation is in the veins of the uterus. If the views of these pathologists are well founded, and they are generally thought to be so, the proper name of the disease under consideration is *crural phlebitis*.

The cure is to be attempted first by leeches applied down the course of the limb, poppy-head fomentations, and alvine evacuants; and afterwards, as soon as the inflammatory symptoms have abated, by local stimulants, so as to excite the torpid absorbents to increased action, of which the volatile liniment, with laudan-

may be advantageously used. Laudanum tends to take off the pain and irritation that still remains, and thus enables the tranquillised vessels the more easily to recover their tone. Yet, whatever application of this kind is employed, it should be accompanied with gentle friction, continued for half an hour or more, as the limb is able to bear it: for the friction itself is of essential service, and tends, perhaps, even more than any other local stimulant, to restore the limb to a healthy action. Mercurial liniment is occasionally beneficial. The chronic weakness is to be removed by a continuation of the friction, bathing with sea-water, or, which is much better, bathing in the sea itself; an elastic bandage round the limb; pure air; and, if necessary, bark, cascarilla, and a generous diet.

PHLEGMASIÆ. Inflammations. The name of the second order in the class *Pyrexiæ* of Cullen's nosological arrangement, characterised by pyrexia, with topical pain and inflammation, the blood, after venesection, exhibiting a buffy coat.

PHLEGMATORRHA'GIA. (*a, æ.* f.; from φλεγμα, mucus, and ῥηγνυμι, to break out.) An increased discharge of mucus from the nostrils.

PHLE'GMON. (*on, onis.* m.; from φλεγω, to burn.) *Phlegmone.* An inflammation of that kind which is otherwise called *healthy inflammation.* See *Inflammation.*

PHLE'GMONOID. Resembling phlegmon.

Phlegmonoid erysipelas. See *Erysipelas.*

PHLE'GMONOUS. Of the nature of phlegmon.

Phlegmonous inflammation. See *Inflammation.*

PHLOGI'STIC. (*Phlogisticus*; from φλογιζω, to burn.) 1. Appertaining to the imaginary principle called *phlogiston.*

2. Inflammatory. Thus we speak of phlogistic diathesis, meaning thereby the inflammatory diathesis.

PHLOGI'STON. (From φλογιζω, to burn.) The supposed general inflammable principle of Stahl, who imagined it was pure fire, or the matter of fire fixed in combustible bodies, as distinguished from fire in action, or in a state of liberty. See *Caloric.*

Phlogisticated air. See *Nitrogen.*

Phlogisticated alkali. See *Alkali, phlogisticated.*

Phlogisticated gas. See *Nitrogen.*

PHLOGO'SIS. (From φλογοω, to inflame.) Inflammation. See *Inflammation.*

PHLOGO'TIC. (*Phlogoticus*; from φλεγω, to burn.) Inflammatory: relating to inflammation.

PHLYCTÆ'NA. (*a, æ.* f. Φλυκταιναι, small bladders; from φλυζω, to boil.) A small pellucid vesicle, that contains a serous fluid.

PHLY'CTIS. (*is, idis.* f.; from φλυζω, to be hot.) A tumour with great heat.

PHLY'SIS. (*is, idis.* f.; from φλυζω, to boil.) 1. Synonymous with *phlytæna.*

2. A whitlow. — *Mason Good.*

PHLYZA'CIUM. (*um, ii.* n.; from φλυζω, to be hot.) A pustule. The term is limited by Willan to a particular kind of pustule. See *Pustule.*

PHOBODI'TSIA. (*a, æ.* f.; from φοβεω, to fear, and διψη, thirst.) Fear of drinking. This accompanies many diseases of the throat and stomach. It is used by some synonymously with hydrophobia. It is an ill-devised term, which does not express the meaning.

PHOCE'NIC. (*Phocenicus*; from *phocæna*, the dolphin.) Appertaining to the dolphin.

PHOCENIC ACID. *Acidum phocenicum.* See *Phocenine.*

PHOCE'NINE. M. Chevreuil found in the oil of the porpoise (*delphinium phocæna*) a peculiar fatty matter mixed with eläine. This he named *phocenine.* When saponified it yields a volatile odoriferous acid, called the *phocenic acid.*

PHŒNI'CEUS. (Φοινικιος; from φοινιξ, red.) Crimson: applied to designate colour. See *Colour.*

PHŒNICI'SMUS. (Same etymon.) Plouquet gives this name to the measles.

PHŒNICI'TES LAPIS. The *Lapis judaicus.* See this title in the Supplement.

PHŒNI'CIUS. Phenician. Appertaining to the country named *Phœnicia.*

PHŒNICIUM EMPLASTRUM. The plaster otherwise named *diachalciteos.*

PHŒNICIUS MORBUS. The tubercular elephantiasis: so called either from its being prevalent in Phœnicia, or from the discolouration of the skin.

PHŒNI'GMUS. (From φοινιξ, red.) 1. A red eruption on the skin, without fever.

2. That which reddens the skin when applied to it; a rubefacient.

PHŒ'NIX. (*ix, icis.* f.; Φοινιξ of the ancient Greeks, the date palm-tree; from which, as a *primitive* word, *Phœnicia*, the land of palm-trees, seems to have derived its name, as likewise *the red colour* phœniceus.) The name of a genus of plants. Class, *Diœcia*; Order, *Triandria.* The date palm-tree.

PHŒNIX DACTYLI'FERA. The systematic name of the date-tree. *Phœnix — frondibus pinnatis; foliolis ensiformibus complicatis*, of Linnæus. The fruit is called dactylus or date. It is fleshy, of an oblong round form; about an inch and a half long, and one in diameter, and has in its centre a hard stone. Dates, before they are ripe, are rather rough and astringent; but when perfectly matured, they are much of the nature of the fig. Senegal dates are much esteemed, they having a more sugary agreeable flavour than those of Egypt and other places.

PHO'NICUS. (From φωνη, the voice.) Relating to the voice.

PHO'SGENE GAS. (From φως, light and γενναω, to produce.) So called by its discoverer, Dr. John Davy, from its mode of production, by the agency of the sun-beam. See *Chlorocarbonic acid.*

PHO'SPHATE. (*Phosphas, atis.* f.) A salt formed by the union of phosphoric acid with a salifiable base; thus, *phosphate of ammonia, phosphate of lime*, &c.

PHOSPHA'TIC ACID. *Acidum phosphaticum.*

When phosphorus is slowly oxydated in atmospheric air, an oily acid liquor results. This was supposed by M. Dulong to contain a distinct acid, but Sir H. Davy regarded it merely as a mixture of phosphoric and phosphorous acids, and this opinion is believed to be correct.

PHO'SPHITE. *Phosphis.* A salt formed by the combination of phosphorous acid with salifiable bases; thus, *phosphite of ammonia*, &c.

Phosphorated hydrogen. See *Phosphorus.*

PHOSPHORE'SCENCE. *Phosphorescentia.* The luminous appearance which is presented by phosphorescent bodies. See *Light.*

PHOSPHORE'SCENT. Resembling phosphorus in the property of being luminous in the dark.

PHOSPHO'RIC. (*Phosphoricus;* from *phosphorus.*) Appertaining to phosphorus.

Phosphoric acid. *Acidum phosphoricum.* The base of this acid, or the acid itself, abounds in the mineral, vegetable, and animal kingdoms. In the mineral kingdom it is found in combination with lead, iron, copper, manganese, and still more abundantly with lime.

The vegetable kingdom also abounds with phosphorus, or its acid.

In the animal kingdom it is found in almost every part of the bodies of animals which are not considerably volatile. There is not, in all probability, any part of these organised beings which is free from it. It has been obtained from blood, flesh, both of land and water animals; from cheese; and it exists in large quantities in bones, combined with calcareous earth. Urine contains it, not only in a free state, but also combined with ammonia, soda, and lime. It was by the evaporation and distillation of this fluid with charcoal that phosphorus was first obtained; the charcoal decomposing the disengaged acid and the ammoniacal salt. But it is more cheaply procured by the process of Scheele, from bones, by the application of an acid to their earthy residue after calcination.

For this purpose the sulphuric acid is to be the most convenient, because it forms a nearly insoluble compound with the lime of the bones. Bones of beef, mutton, or veal, being calcined to whiteness in an open fire, lose almost half of their weight. This must be pounded and sifted; or the trouble may be spared by buying the powder that is sold to make cupels for the assayers, and is, in fact, the powder of burned bones ready sifted. To three pounds of the powder there may be added about two pounds of concentrated sulphuric acid. Four or five pounds of water must be afterwards added to assist the action of the acid; and during the whole process the operator must remember to place himself and his vessels so that the fumes may be blown from him. The whole may be then left on a gentle sand-bath for twelve hours or more, taking care to supply the loss of water which happens by evaporation. The next day a large quantity of water must be added, the whole strained through a sieve, and the residual matter, which is sulphate of lime, must be edulcorated by repeated affusions of hot-water, till it passes tasteless. The waters contain phosphoric acid nearly free from lime; and by evaporation, first in glazed earthen, and then in glass vessels, or rather in vessels of platina or silver, for the hot acid acts upon glass, afford the acid in a concentrated state, which, by the force of a strong heat in a crucible, may be made to acquire the form of a transparent consistent glass, though indeed it is usually of a milky opake appearance.

For making phosphorus, it is not necessary to evaporate the water further than to bring it to the consistence of syrup; and the small portion of lime it contains is not an impediment worth the trouble of removing, as it affects the produce very little. But when the acid is required in a purer state, it is proper to add a quantity of carbonate of ammonia, which, by double elective attraction, precipitates the lime that was held in solution by the phosphoric acid. The fluid, being then evaporated, affords a crystallised ammoniacal salt, which may be melted in a silver vessel, as the acid acts upon glass or earthen vessels. The ammonia is driven off by the heat, and the acid acquires the form of a compact glass, as transparent as rock crystal, acid to the taste, soluble in water, and deliquescent in the air.

This acid is commonly pure, but nevertheless may contain a small quantity of soda, originally existing in the bones, and not capable of being taken away by this process, ingenious as it is. The only unequivocal method of obtaining a pure acid appears to consist in first converting it into phosphorus by distillation of the materials with charcoal, and then converting it again into acid by rapid combustion, at a high temperature, either in oxygen or atmospheric air, or some other equivalent process.

Phosphorus may also be converted into the acid state by treating it with nitric acid. In this operation, a tubulated retort with a ground stopper must be half filled with nitric acid, and a gentle heat applied. A small piece of phosphorus being then introduced through the tube, will be dissolved with effervescence, produced by the escape of a large quantity of nitric oxide. The addition of phosphorus must be continued until the last piece remains undissolved. The fire being then raised to drive over the remainder of the nitric acid, the phosphoric acid will be found in the retort, partly in the concrete and partly in the liquid form.

Sulphuric acid produces nearly the same effect as the nitric; a large quantity of sulphurous acid flying off. But as it requires a stronger heat to drive off the last portions of this acid, it is not so well adapted to the purpose. The liquid chlorine likewise acidifies it.

When phosphorus is burned by a strong heat, sufficient to cause it to flame rapidly, it is almost perfectly converted into dry acid, some of which is thrown up by the force of the combustion, and the rest remains upon the supporter.

This substance has also been acidified by the direct application of oxygen gas passed through hot water, in which the phosphorus was liquefied or fused.

The general characters of phosphoric acid are: 1. It is soluble in water in all proportions,
