CARDAMINE PRATENSIS. The systematic name of the common ladies' smock, or cuckoo- flower, called *cardamine* in the pharmacopœias, and *Cardamantica, Nasturtium aquaticum, Culi flos*, and *Iberis sophia*.

Cardamine — foliis pinnatis, foliolis, radica- libus subrotundis, caulinis lanceolatis of Lin- næus. The flower has a place in the materia medica, upon the authority of Sir George Baker, who has published five cases, two of chorea Sancti Viti, one of spasmodic asthma, one of hemiplegia, and a case of spasmodic affection of the lower limbs, wherein the *flores cardamines* were supposed to have been success- fully used. A variety of virtues have been ascribed to this plant, but it is now banished from practice.

CARDAMO'MUM. (*um, i.* n.; from καρδαμον, and αμωμον: because it partakes of the nature both of the cardamon and amomum, or from the Arabic *Cardumeni.*) The car- damom or cardamum. See *Matonia* and *Amo- mum*.

Cardamomum majus. See *Amomum granum paradisi*.

CARDAMOMUM MEDIUM. The seeds so called appear to be merely a variety of the lesser or common cardamom seeds; they differ only in being longer.

Cardamomum minus. See *Matonia carda- momum*.

CARDAMOMUM PIPERATUM. The common cardamom.

CA'RDAMON. (Καρδαμον.) The Greek name of the nasturtium.

Cardamum. See *Cardamomum*.

CA'RDIA. (*a, æ.* f.; Καρδια.) 1. A Greek name of the heart.

2. In modern anatomy, the superior orifice of the stomach is so called.

CA'RDIAC. (*Cardiacus*; from καρδια, the heart.) 1. Of, or belonging to, the heart.

2. Cordial. Applied to medicines supposed to strengthen the heart. See *Cordial*.

Cardiac arteries. The coronary arteries of the heart. See *Cor.*

Cardiac confection. See *Confectio aromatica.*

Cardiac herb. So named from the supposed relief it gives in faintings, and disorders of the stomach. A name given to the plant called Mother-wort. See *Leonurus cardiaca.*

Cardiac passion. *Passio cardiaca.* An old name of the heartburn.

Cardiac plexus. The plexus of nerves which supplies the heart. See *Cor.*

Cardiac veins. The coronary veins of the heart. See *Cor.*

Cardiacus morbus. The heartburn.

CARDIALGIA. (*a*, *æ*. f.; from καρδια, the cardia, and αλγος, pain.) *Cordolium.* An uneasy sensation in the stomach, with heat more or less violent, sometimes attended with anxiety and faintness, and often with an inclination to vomit, or a plentiful discharge of a clear watery fluid.

Cardialgia is frequently a symptom also of other complaints; as dyspepsia, scirrhus, chronic inflammation of the stomach, worms, retrocedent gout, suppressed menstruation, and various diseases of the heart, liver, pancreas, kidneys, and intestines; but it is likewise found, in many instances, as an idiopathic affection.

In some cases the gnawing and burning pain is felt chiefly at the cardia, or upper orifice of the stomach, whence the name of cardialgia. The cardia, indeed, has been supposed to be the immediate seat of this affection; but it is merely from the greater sensibility of the upper orifice of the stomach than any other part of it, that we are most sensible of uneasiness in that region: irritability of the whole, or of any part of the organ, and perhaps of the adjoining organs, as the pancreas, spleen, and liver, will often produce the same local pain; and, in some instances, of very long standing, it has been ascertained after death to have been occasioned by a scirrhous, or some other obstruction of the pylorus.

In other cases, the pain or uneasiness are somewhat less intense, but far more general; reaching, indeed, over the whole range of the stomach and epigastrium, accompanied with nausea and anxiety, and sympathetically affecting the general system, attended with coldness of the extremities, failure of strength, shortness of breath, and great tendency to faint.

This is distinguished, in popular language, by the name of the *heartburn.*

In another form, the disease is characterised by increased secretion, and eructation of a thin watery liquor, frequently in considerable abundance. This takes place chiefly in the morning, when the stomach contains nothing but its own fluids. Dr. Cullen has described this form of the disease as follows: — "It appears most commonly," says he, "in persons under middle age, but seldom in any persons before the age of puberty. When it has once taken place, it is ready to recur occasionally for a long time after; but it seldom appears in persons considerably advanced in life. It affects both sexes, but more frequently the female. The fits of this disease usually come on in the morning and forenoon, when the stomach is empty. The first symptom is a pain at the pit of the stomach, with a sense of constriction, as if the stomach were drawn towards the back: the pain is increased by raising the body into an erect posture, and therefore the body is bended forward. This pain is often severe; and, after continuing for some time, brings on an eructation of a thin watery fluid in considerable quantity. This fluid has sometimes an acid taste, but is very often absolutely insipid. The eructation is for some time frequently repeated, and does not immediately give relief to the pain which preceded it; but does so at length, and puts an end to the fit." This variety of cardialgia constitutes the *pyrosis* of medical writers. In England, its popular name is *black-water*; in Scotland, *water-brash* or *water-qualm.*

Most of these varieties have sometimes returned periodically, especially in the spring. Since their general causes and mode of treatment do not essentially differ, it is more convenient to consider them jointly than under detached heads.

The remote causes of cardialgia, under whatever variety it shows itself, which is chiefly regulated by the habit or idiosyncrasy of the individual, are indigestible articles of diet, especially fat, oil, butter, or cheese, taken in excess; an habitual and copious use of very cold or very hot beverages, but especially the latter; indulgence in spirituous potations; worms, drastic purges; obstructed perspiration; repelled cutaneous eruptions; and a depraved, or excessive secretion of bile.

All these causes have a direct tendency to produce debility of the stomach, and, consequently, a morbid condition of its secreted fluids, which hence become changed in their quantity or quality, are given forth too freely or too scantily, or acquire an acid or other acrimonious character.

There seems generally to be a predominance of acid in the stomach in cases of cardialgia.

The acid, according to the experiments of M. Perperes, is chiefly the acetic. The gastric fluid itself appears to be secreted in too dilute or weakly a condition for the purposes of digestion; on which account, the food, instead of being converted into chyme, passes readily into a state of fermentation, so that some persons cannot take either honey or sugar without producing this effect: in some cases also the gastric juice may contain an acid at the time of its secretion.

In applying to this disease the resources of the art of healing, it is obvious that our intention should be twofold:

1. To palliate the present distress.
2. To prevent a recurrence of the paroxysms.

The first may be obtained by small doses of opium, and sometimes by other antispasmodics, as ether, and where acidity prevails by alkalis, especially ammonia, which conjoins an antispasmodic with an antacid effect.

Oleaginous preparations have also been had recourse to, and in some habits apparently with success; and when we have full proof of acidity

as the existing cause, there are few medicines we can more fully depend upon than soap: probably because in its decomposition it lets loose the oleaginous principle, which may in some degree obtund the pain, and at the same time unites its alkali with the acid of the stomach; thus neutralising its acrimony, and forming a valuable aperient. "It is often," says Dr. Cullen, "a more convenient remedy than common absorbents or simple alkalines." If the pain be very severe, we shall much improve the beneficial operation of the soap, by combining it with opium — a very valuable medicine in all the varieties of the disease, but particularly so in pyrosis.

It is necessary, in every case, to direct our view to the second intention, that of preventing a recurrence of the paroxysm.

This can only be done effectually by restoring the stomach to its proper tone. The warmer bitters, the oxides of zinc and bismuth, and mild chalybeates bid fairest for success.

The terebinthinate balsams appear sometimes to have been highly serviceable. The balsam of Gilead, and that of Mecca, were once highly extolled; but are too dear for common use. The Turks take eight or ten drops as a dose; but the quantity may be considerably increased.

It is almost superfluous to add, that the diet should consist of articles least disposed to ferment; for which reason plain animal food is generally to be preferred. Weak brandy-and-water, toast-and-water, or soda-water may be used as the ordinary drink.

CARDIALGIA SPUTATORIA. Pyrosis. See *Cardialgia.*

CARDIANA'STROPHE. (From καρδια, the heart, and αναστροφη, *conversio.*) Malposition of the heart.

CARDIE'CTASIS. (From καρδια, the heart, and εκτασις, extension.) The name given by Brechet to dilatation of the heart.

CARDIELCO'SIS. (From καρδια, the heart, and ελκωσις, ulceration.) Ulceration of the heart.

CARDIMELECH. (From καρδια, the heart, and *meleck*, the Hebrew for a king.) A term forged by Dolæus, by which he would designate a particular active principle resident in the heart, and superintending what we call the vital functions.

CARDINALIS DE LUGO CORTEX. In the year 1653, Cardinal de Lugo administered the Peruvian bark, then a new medicine, to a great number of patients; whence the bark got the name of *Cortex Cardinalis de Lugo*, Cardinal de Lugo's bark.

Cardinalis flos. See *Lobelia.*

Cardinal flower. See *Lobelia.*

CARDINAL HUMOURS. Hippocrates, following the doctrine of the Pythagorean school, taught that the four elements, variously combined, formed four primary humours in the animal body, namely *blood*, *phlegm*, *yellow bile*, and *black bile*; and that from these all the solids and fluids of the body were derived. This doctrine was adopted by Galen and his followers, and in later times the four humours got the name of *Cardinal humours* — *humores cardinales.*

CARDINAME'NTUM. (From *cardo*, a hinge.) An articulation like a hinge. See *Ginglymus.*

CARDIOCE'LE. (From καρδια, the heart, and κηλη, a tumour.) The protrusion of the heart into the abdomen through a wound of the diaphragm has been so called.

CARDIO'GMUS. (*us*, *i.* m. Καρδιωγμος.) This term has been variously applied. With the Greek writers it is synonymous with *cardialgia*; some modern authors have applied it to *angina pectoris*; and Sauvages understands by it an incipient aneurism of the heart or its large vessels.

CARDIO'NCHUS. (*us*, *i.* m.; from καρδια, the heart, and ογκος, a tumour.) Aneurism of the heart.

CARDIOPA'LMUS. (From καρδια, the heart, and παλμος, palpitation.) Palpitation of the heart.

CARDIORRHE'XIS. (From καρδια, the heart, and ῥηξις, a rupture.) Rupture of the heart.

CARDIO'TROMUS. (From καρδια, the heart, and τρεμω, to tremble.) Tremor of the heart; that is, a slight degree of palpitation.

CARDI'TIS. (*is*, *idis.* f.; from καρδια, the heart.) Inflammation of the heart. Inflammation of the entire substance of the heart is of comparatively rare occurrence, although inflammation of particular parts of it is not very uncommon. When the muscular substance of the heart becomes inflamed, this proceeds, in a great majority of cases, from the extension of inflammation from the pericardium. See *Pericarditis.*

CA'RDIUM. (*um*, *i.* n.; from *cardo*, a hinge: so called from the hinge-like union of the two shells.) The name of a genus of bivalve mollusca. The cockle.

CARDIUM EDULE. The common cockle. It is found plentifully buried in the sands on all the arid shores of Europe. It has a very peculiar flavour, and is much esteemed by some. It is never eaten raw, but boiled or stewed, in which state it is considered as wholesome.

CA'RDO. A hinge. The articulation called *Ginglymus.*

CARDO'NIUM. A wine medicated with herbs. — *Paracelsus.*

CARDOPA'TIUM. 1. The ancient name of a plant, which was probably the *carline thistle.* See *Carlina acaulis.*

2. A genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia æqualis.*

CA'RDUUS. (*us*, *i.* m. Latin for a thistle.) A genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia æqualis.*

CARDUUS ACANTHUS. The bear's breech. See *Acanthus mollis.*

Carduus altilis. See *Cinara.*

Carduus arvensis. See *Serratula.*

Carduus benedictus. See *Centaurea.*

CARDUUS CHRYSA'NTHEMUS. The artichoke. See *Cinara.*

CARDUUS DOMESTICUS. The artichoke.

CARDUUS FULLONUM. The fuller's teasel. See *Dipsacus fullonum.*

Carduus hæmorrhoidalis. See *Serratula arvensis.*

Carduus lacteus. The milk-thistle. See *Carduus marianus.*

Carduus mariæ. An officinal name of the *Carduus marianus.*

Carduus marianus. The systematic name of the officinal *Carduus mariæ.* Common milk-thistle, or Lady's-thistle. *Carduus — foliis amplexicaulibus, hastato-pinnatifidis, spinosis; calycibus aphyllis; spinis caliculatis, duplicato-spinosis,* of Linnæus. The seeds of this plant, and the herb, have been employed medicinally. The former contain a bitter oil, and are recommended as relaxants. The juice of the latter is said to be salutary in dropsies, in the dose of four ounces; and, according to Miller, to be efficacious against pungent pains. The leaves, when young, surpass, when boiled, the finest cabbage, and in that state are diuretic.

Carduus pinea. See *Atractylis.*

Carduus sativus. See *Cinara.*

Carduus solstitialis. See *Calcitrapa officinalis.*

Carduus spinossimus. See *Carduus nutans.*

Carduus stellatus. See *Centaurea calcitrapa.*

Carduus tomentosus. See *Onopordium acanthium.*

Carduus veneris. The *Dipsacus sylvestris.*

CAREBARI'A. (*a, æ.* f. Καρηβαρια; from καρη, the head, and βαρος, weight.) Heaviness of the head. — *Hippocrates. Galen.*

Carena. The twenty-fourth part of a drop. — *Ruland.*

Ca'reum. (*eum, ei.* n.; from *Caria,* the country whence they were brought.) The caraway. See *Carum carui.*

Careum vinum. Wine boiled away to two thirds of its original quantity.

CA'REX. (*ex, icis.* fœm.) A genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Triandria.* Sedge.

Carex arenaria. Sea sedge. This plant grows plentifully on the sea-coast. The root is said to have been found serviceable in some affections of the trachea, in rheumatic pains, and gouty disorders.

Carex hirta. The roots of this and several other species, as *C. villosa, C. disticha,* and *C. intermedia,* are called *German sarsaparilla,* and are sometimes mixed with the true sarsaparilla.

Cariacou. A fermented liquor, made in Cayenne, from a mixture of cassava, potatoes, and cane syrup.

CA'RICA. (*a, æ.* f.; from *Caria,* the place where they were cultivated.) The fig. See *Ficus carica.*

Carica papaya. Papaw-tree. This is a native of both Indies and of the Guinea coast. When the roundish fruit is nearly ripe, the inhabitants of India boil and eat it with their meat, as we do turnips. They have somewhat the flavour of a pompion. Before they are boiled they are soaked for some time in salt and water, to extract the corrosive juice. This juice, diluted with water, is used to wash meat in order to make it tender. The fruit, when pickled, forms a substitute for the mango. The buds of the female flowers are made into a sweetmeat; and the inside of the fruit is eaten with sugar, like a melon. Every part of the papaw-tree, except the ripe fruit, affords a milky juice, which is considered, in the Isle of France, as an effectual remedy for the tape-worm. In Europe, however, whither it has been sent in the concrete state, it has not answered, perhaps from some change it had undergone, or not having been given in a sufficient dose.

Ca'ricum. (Καρικον.) An escharotic and detergent application used by the Greeks, consisting of black hellebore, sandarach, copper, burnt lead, sulphur, orpiment, and cantharides, made up with oil to the consistence of a liniment.

CA'RIES. (*es, ei.* f.; the Latin word for rottenness.) In medical language this word is used to designate the ulceration of a bone, or that state of a bone which is analogous to ulceration of the soft parts.

CARI'NA. (*a, æ.* f.; the keel of a ship.) 1. In *Anatomy,* a name formerly applied to the back-bone.

2. In *Botany,* the keel, or that part of a papilionaceous flower consisting of two petals united or separate, which incloses the parts of fructification.

CARINA'TUS. Keel-shaped; boat-shaped: applied to leaves and petals when the back is longitudinally prominent, like the keel of a boat; as in the leaf of *Allium carinatum,* and the petals of *Allium ampeloprasum.*

Cariosse. See *Ady.*

Carious. *Cariosus.* Affected with caries.

Ca'rium terræ. Lime. — *Ruland.*

CARLI'NA. (or *Carolina, æ.* f.; from *Carolus Magnus,* Charles the Great, or Charlemagne: because, as the story goes, an angel showed the Carline thistle to him, and, by the use of it, his army was preserved from the plague.) A genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia æqualis.*

Carlina acanthifolia. In the mountainous regions in the south of France, this species is used as a substitute for the artichoke, under the name of *artichaut sauvage.*

Carlina acaulis. The Carline thistle. Called also *Chamæleon album, Carlina, Cardopatium, Crocodilium, Heracantha,* and *Ixia. Carlina — caule unifloro, flore breviore,* of Linnæus. The root of this plant is bitter, and said to possess tonic, diaphoretic, anthelmintic, and other virtues. It was formerly extolled as a remedy for various diseases, but is now discarded.

Carlina gummifera. See *Atractylis gummifera.*

Carline thistle. See *Carlina acaulis.*

Ca'rlo sancto. St. Charles's root; so called by the Spaniards, on account of its great virtues. It is found in Mechoachan, a province in America. Its bark has an aromatic flavour, and a bitter acrid taste. It is said to be sudorific, and to strengthen the gums and stomach.

Carmelite water. See *Eau des Carmes.*

Ca'rminans. Synonymous with *carminativus.*

CARMI'NATIVE. (*Carminativus;* from *carmen,* a verse, or charm: because the medicine was thought to operate like a charm.) Applied to medicines which allay spasmodic pain of the

bowels, and dispel flatulence. The principal carminatives are ginger, cardamom, anise, and caraway seeds; several of the essential oils, as those of peppermint, anise, caraway, and juniper; ardent spirits, and especially aromatic tinctures.

CARMINE. A beautiful pigment, formed of the colouring matter of the cochineal.

CARMOT. An alchemical term for the matter which composed the philosopher's stone.

CARNABA'DIUM. Caraway-seed.

Carneæ columnæ. See *Cor.*

CA'RNEOUS. Carneous: fleshy. 1. Applied to some muscles of the heart. See *Cor.*

2. Applied generally, in *Natural History*, to designate colour: *color carneus*, flesh colour.

CARNI'CULA. (*a, æ.* f.; diminutive of *caro, carnis*, flesh.) A small fleshy substance.

CA'RNIFEX SPAGY'RICUS. A name given by the alchemists to fire when employed in the pursuit of the philosopher's stone.

CARNIFICA'TIO. (*o, onis.* f.) Carnification. The conversion of any texture of the animal body into a substance resembling flesh.

CARNIFO'RMIS. (From *caro*, flesh, and *forma*, likeness.) Having the appearance of flesh.

CARNI'VORA. An order of the class *Mammalia*. See *Animal kingdom.*

CARNIVOROUS. (*Carnivorus;* from *caro*, flesh, and *voro*, to devour.) Flesh devouring: applied to animals that live on flesh.

CARNO'SA. The name of an order of animals of the Class *Polypi.*

Carnosa cutis. See *Panniculus carnosus.*

CARNO'SUS. Fleshy: applied generally, in *Natural History*, to parts which are either fleshy, or of a consistence resembling that of flesh; thus, in botany, many leaves are styled fleshy, *folia carnosa*, as those of *sedum crassula*, &c.

Carnosus panniculus. See *Panniculus carnosus.*

CA'RO. (*Caro, carnis.* fœm.) 1. Flesh. The fibrous part of the muscles, which constitutes the greater portion of the bulk of the limbs, and affords a general covering to the bones, is called in common language the flesh.

2. The soft part of a fruit.

CARO ANSERINA. *Caro gallinacea.* The same as cutis anserina. See *Cutis anserina.*

Caro gallinacea. See *Caro anserina.*

CAROLI. A barbarous name for syphilitic sores on the penis.

Carolina. See *Carlina.*

Caros. See *Carus.*

Caro'sis. See *Carus.*

Caro'ta. (*a, æ.* f.) See *Daucus.*

CARO'TID. (*Carotis, Caroticus*, from καροω, to cause to sleep; because the arteries so called supply the head with blood, and the ancients believed sleep to be caused by an increased flow of blood to the head.) The name of an artery on each side of the neck, *Arteria carotica.* The common carotids are two considerable arteries, that ascend on the fore part of the cervical vertebræ, to the head, to supply it with blood. The right common carotid is given off from the arteria innominata. The left arises from the arch of the aorta. In its course up the neck, the common carotid artery lies by the side of the trachea, and behind the sterno-mastoid muscle, and is contained in a common cellular sheath, with the internal jugular vein, and the pneumogastric nerve. About midway between the thyroid cartilage and the os hyoides, the common carotid divides into the *external* and *internal carotids;* the point at which this division takes place, however, varies considerably in different subjects.

The external carotid usually gives off the following branches to the neck and external part of the head. The *superior thyroideal*, the *lingual*, the *facial*, the *inferior pharyngeal*, the *occipital*, the *posterior auris*, the *internal maxillary*, and the *temporal.* The internal carotid passes through the carotic canal of the temporal bone to the interior of the cranium, where it gives off the *opthalmic*, the *middle cerebral*, and the *arteria communicans.*

CARO'UM. The caraway-seed.

Carp. See *Cyprinus carpio.*

CA'RPASUS. Καρπασος. A plant mentioned by Dioscorides, Pliny, Galen, and other ancient authors. It is not known what plant it was. Its concrete juice, which was called οποκαρπασον, *opocarpasum*, bore some resemblance in appearance to myrrh, but was considered as a violent narcotic poison.

Carpathian balsam. See *Balsamum carpathicum.*

Carpa'thicum balsamum. See *Balsamum carpathicum.*

CARPENTA'RIA. (*a, æ.* f.; from *carpentarius*, a carpenter: so named because carpenters applied it to the wounds made by their tools.) The old name of a vulnerary herb, which was probably the *Achillea millefolium*, but has also been supposed to have been the *Sanicula Europæa*, or the *Nasturtium barbarea.*

CARPE'SIUM. (*um, i.* n.. Καρπησιον.) 1. An aromatic plant mentioned by the ancient writers. It is not at present known to what plant the name was applied.

2. The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia superflua.*

CARPHOLO'GIA. (*a, æ.* f.; from καρφος, chaff, and λεγω, to pluck.) *Carpologia.* A disposition to pick minute objects, which accompanies the delirium of low fever. Continual picking at the bed clothes is a frequent symptom in such cases. It is usually accompanied by a vacancy of expression in the countenance, and is indicative of great cerebral exhaustion and extreme danger.

CA'RPHOS. A Greek name of the herb *Fenugreek.*

CA'RPIA. (*a, æ.* f.; from *carpo*, to pluck, as lint is made from linen cloth.) Lint.

CARPI'SMUS. The wrist.

CARPOBA'LSAMUM. (*um, i.* n.; from καρπος, fruit, and βαλσαμον, balsam.) See *Amyris gileadensis.*

Carpologia. See *Carphologia.*

CARPO'TICA. (From καρπος, fruit.) Diseases affecting impregnation. The name given by

Mason Good to the third order of his class *Genetica*.

CA'RPUS. (*us*, *i*. m. Καρπος.) The wrist. The wrist is a very complex articulation, by means of which the hand moves on the fore arm. It consists of eight bones, viz. the *os scaphoides*, *lunare*, *cuneiforme*, *pisiforme*, *trapezium trapezoides*, *magnum*, and *unciforme*. The first four of these bones form one row, and the second form another row. These bones are connected to each other, and to the metacarpal bones, by numerous ligaments, styled *oblique*, *transverse*, *capsular*, *lateral*, &c., according to their shape and position. The three first bones of the carpus are connected with the extremities of the radius and ulna by a *capsular* and two *lateral ligaments*. A *transverse*, *anterior*, or *annular* ligament is stretched from the projecting points of the pisiform and unciform bones to the scaphoides and trapezium, binding down the tendons of the flexor muscles of the fingers, and giving firmness to the articulation of the wrist.

Carrot. See *Daucus carota*.

Carrot, *candy*. See *Athamanta cretensis*.

Carrot poultice. See *Cataplasma dauci*.

CA'RTHAMUS. (*us*, *i*. m.; from καθαιρω, to purge.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia æqualis*.

2. The pharmacopœial name of the saffron flower. See *Carthamus tinctorius*.

Carthamus tinctorius. The systematic name of the saffron flower, or bastard saffron; called also *Cnicus*, *Crocus saracenicus*, *Carthamum officinarum*, and *Carduus sativus*. *Carthamus—foliis ovatis*, *integris*, *serrato-aculeatis* of Linnæus. The seeds are strongly cathartic: they are also emetic, and are thought by some to be diuretic. They are given as food to parrots, and are thence called parrots' corn. The dried flowers are frequently mixed with saffron to adulterate it. The plant is cultivated in many places on account of its flowers, which are used as a dye. Rouge is prepared from this plant; and it is in very general use for dying silk of a poppy, cherry, rose, and bright orange red.

CA'RTILAGE. (*Cartilago*, *inis*. f.) A white, elastic, glistening substance, commonly called *gristle*. Cartilage forms the nidus in which the earthy matter of most bones is deposited; and when the earthy matter of a bone is removed by macerating it in diluted muriatic acid, a mass of cartilage remains, retaining the original figure of the bone, and permeated by its vessels. The cartilage forms about one third of the weight of the bone. (See *Os*.) Cartilage, independently of its entering into the constitution of bone, exists as a separate substance, covering articular surfaces, and forming a medium of connexion between bones. The organisation of cartilage is obscure; it is generally admitted, however, to be of a fibrous texture. In pure cartilage no blood-vessels can be demonstrated, even by the finest injections; but in those cartilages which are attached to the extremities of growing bones, blood-vessels of considerable size may often be seen with the naked eye. Neither nerves nor absorbents have hitherto been found in cartilage. That it is a vascular and living substance is nevertheless certain, from the facts that it becomes yellow in jaundice, has its colour affected by substances combined with the blood, and, when cut, exudes serous fluid. Cartilages are divided by anatomists into *obducent*, which cover the moveable articulations of bones; *inter-articular*, which are situated between the articulations, and *uniting* cartilages, which unite one bone with another.

The chemical properties of cartilage have not yet been very accurately ascertained. Nitric acid converts it into gelatine. With alkalis it forms an animal soap. According to Dr. J. Davy it consists of 44·5 parts of albumen, 55·0 water, and ·5 phosphate of lime.

CARTILA'GINOUS. *Cartilagineus*. 1. In *Anatomy*, applied to parts which naturally, or from disease, have a cartilaginous consistence.

2. In *Botany*, to the margin of leaves, when they are of a hard or horny consistence, as in several species of saxifrage. See *Leaf*.

Cartilago annularis. The ring-like cartilage. See *Cartilago cricoides*.

Cartilago arytænoidea. See *Larynx*.

Cartilago arytænoides. See *Larynx*.

Cartilago cricoi'des. The cricoid cartilage. See *Larynx*.

Cartilago ensiformis. *Cartilago xiphoides*. Xiphoid cartilage. Ensiform cartilage. A cartilage shaped somewhat like a sword, attached to the lower end of the sternum.

Cartilago gutturalis. The arytenoid cartilage.

Cartilago scutiformis. See *Thyroid cartilage*.

Cartilago thyroidea. See *Thyroid cartilage*.

Cartilago tri'quetra. The arytenoid cartilage.

Cartilago xiphoides. See *Cartilago ensiformis*.

Ca'rui. See *Carum*.

CA'RUM. (*um*, *i*. n.; Καρος; so named from *Caria*, a province of Asia where it grows abundantly.) The caraway. 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*.

2. The pharmacopœial name of the caraway plant. See *Carum carui*.

Carum carui. The caraway plant. *Carvi*, *Carus*, *Caruon*, *Cuminum pratense*. The seeds are well known to have a pleasant spicy smell, and a warm aromatic taste; and, on this account, are used for various economical purposes. They are esteemed carminative, cordial, and stomachic, and recommended in dyspepsia, flatulencies, and other symptoms attending hysterical and hypochondriacal disorders. An essential oil and distilled water are directed to be prepared from them by the London College.

CARU'NCULA. (*a*, *æ*. f.; diminutive of *caro*, flesh.) A caruncle, or little fleshy excrescence. It is variously applied. 1. To healthy and natural parts; as the caruncule myrtiformes, and caruncula lachrymalis.

2. To soft, fleshy excrescences which are the product of disease.

Caruncule cuticulares. This name has been given to the nymphæ.

Caruncula lachrymalis. The lachrymal caruncle. A little fleshy conoidal glandiform body, red externally, situated in the internal canthus of each eye. It appears to be formed of numerous sebaceous glands, from which many small hairs grow. The gum-like substance found in the inner corner of the eye in the morning, is the indurated secretion of this caruncle.

Carunculæ mamillares. The extremities of the lactiferous tubes in the nipple.

Carunculæ myrtiformes. After the laceration of the hymen there remain in its place, two, three, or four caruncles, which have received the name of myrtiform.

Carunculæ papillares. The protuberances within the pelvis of the kidney, formed by the convergence of the tubuli uriniferi.

Ca'ruon. See *Carum.*

CA'RUS. (*us, i.* m. ; Καρος.) 1. The most profound degree of coma. The word has been variously applied by different medical writers, but by all to some form of coma.

2. The caraway plant.

Ca'rva. The cassia lignea.

Carydon. See *Caryedon.*

Caryæ'don. (From καρυα, a nut.) *Carydon.* A sort of fracture, where the bone is broken into small pieces, like the shell of a cracked nut.

Caryoccs. See *Ady.*

Caryocosti'num. An electuary ; so named from two of its ingredients, the clove and costus.

CARYOPHILLA'TA. (*a, æ.* f. ; from καρυοφυλλον, the clove ; so named because its root has an odour resembling that of the clove.) See *Geum urbanum.*

Caryophy'lleæ. The name of a natural family of plants of which the genus caryophyllus is the type.

Caryophylloides cortex. See *Laurus culilawan.*

Caryophy'llum. (*um, i.* n. ; Καρυοφυλλον, from καρυον, a nut, and φυλλον, a leaf ; so named because it was supposed to be the leaf of the Indian nut.) The clove. See *Eugenia caryophyllata.*

CARYOPHY'LLUS. (*us, i.* m. Same etymology.) The clove-tree. The name of a genus of plants in the Linnæan system. Class, *Polyandria ;* Order, *Monogynia.*

Caryophyllus aromaticus. See *Eugenia caryophyllata.*

Caryophyllus aromaticus americanus. See *Myrtus pimenta.*

Caryophyllus hortensis. See *Dianthus caryophyllus.*

Caryophyllus ruber. The clove pink. See *Dianthus caryophyllus.*

Caryophyllus vulgaris. See *Geum urbanum.*

CASCARI'LLA. (*a, æ.* f. ; diminutive of *cascara*, the Spanish for bark or rind.) A name given originally to small specimens of cinchona ; but now applied to another bark. See *Croton cascarilla.*

Caschu. See *Acacia catechu.*

CASEIC ACID. The name given by Proust to an acid obtained from cheese. Braconnot denies the existence of any such acid.

Caseous oxide. See *Cheese.*

Caseum. See *Cheese.*

Cashew-nut. See *Anacardium occidentale.*

Cashow. See *Acacia catechu.*

Casia. See *Cassia.*

Casminar. See *Cassumuniar.*

Cassa'da. See *Jatropha manihot.*

Ca'ssamum. The fruit of the balsam tree.—*Turton.*

Cassava. See *Jatropha manihot.*

CA'SSIA. (*a, æ.* f. ; from the Arabic *katsia*, which is from *katsa*, to tear off : so called from the act of stripping the bark from the tree.) The name of a genus of plants in the Linnæan system. Class, *Decandria ;* Order, *Monogynia.*

Cassia absus. The systematic name of a small Egyptian lotus. The Egyptians powder the seeds with an equal quantity of sugar, and put a little of the mixture under the eyelids at the commencement of their ophthalmia.

Cassia alata. The systematic name of a plant, the leaves of which are bitter, nauseous in their taste, and supposed to be cathartic. They are said to cure herpes.

Cassia bark. See *Laurus cassia.*

Cassia caryophylla'ta. The clove-bark tree. See *Myrtus caryophyllata.*

Cassia fistula. The purging cassia. Called also, *Cassia nigra, Cassia fistularis, Cassia Alexandrina, Canna, Cassia solutiva.* This plant is now transferred to another genus. See *Cathartocarpus.*

Cassia fistularis. See *Cassia fistula.*

Cassia latinorum. See *Osyris.*

Cassia lignea. See *Laurus cassia.*

Cassia monspeliensium. See *Osyris.*

Cassia nigra. See *Cassia fistula.*

Cassia poetica. See *Osyris.*

Cassia, purging. See *Cassia fistula.*

Cassia senna. One of the plants which produce senna. See *Senna.*

Cassia solutiva. See *Cassia fistula.*

Cassiæ artamentum. The pulp of cassia.

Cassiæ flores. The cassia flowers. See *Laurus cinnamomum.*

Cassiæ pulpa. See *Cassia fistula.*

Cassina. See *Ilex cassine.*

Cassius's precipitate. The purple powder of Cassius. See *Aurum.*

Ca'ssor. An obsolete term for kali.

Cassoleta. A kind of moist fumigation described by P. Morellus.

CASSUMU'NIAR. (Of uncertain derivation ; perhaps Indian.) *Casamunar, Casmina, Risagon, Bengale Indorum.* A root which is brought from the East Indies in irregular slices of various forms, some cut transversely, others longitudinally. The cortical part is marked with circles of a dusky brown colour ; the internal part is paler, and unequally yellow. It possesses moderately warm, bitter, and aromatic qualities, and a smell like ginger. It is recommended in hysterical, epileptic, and paralytic affections.

CASTA'NEA. (*a, æ.* f. ; καστανον, from *Castana*, a city in Thessaly, where it was abundant.) The chesnut. See *Fagus castanea.*

Castanea equina. The horse-chesnut. See *Æsculus hippocastanum.*

Castjoe. See *Acacia catechu.*

Castle-leod. The name of a place in Ros-

Shire, in Scotland, where there is a sulphureous spring, celebrated for the cure of cutaneous diseases and foul ulcers.

CA'STOR. (*or, oris.* m.; καστωρ, the beaver, according to some *quasi* γαστωρ; from γαστηρ, belly: because of the largeness of its belly; the or *à castrando*, because he was said to castrate himself in order to escape the hunters. Neither of these are very probable derivations, but we have no better to offer.) 1. The name of a genus of animals.

2. The English name of the *Castoreum* of the Pharmacopœias; a peculiar concrete substance obtained from the *Castor fiber* of Linnæus. See *Castor fiber.*

Castor fiber. The systematic name of the beaver. A quadruped, inhabiting some parts of Prussia, Russia, Germany, &c.; but abounding chiefly in Canada. The name of *castoreum*, or castor, is given to two bags, situated in the inguinal regions of the beaver, which contain a very odorous substance, soft, and almost fluid when recently cut from the animal, but which dries, and assumes a resinous consistence in process of time. The best comes from Russia. It is of greyish yellow, or light brown colour. It consists of a mucilage, a bitter extract, a resin, an essential oil, in which the peculiar smell appears to reside, and a flaky crystalline matter, much resembling the adipocire of biliary calculi. Castor has an acrid, bitter, and nauseous taste; its smell is strong and aromatic, yet at the same time fœtid. It is used medicinally, as a powerful antispasmodic, in hysterical and hypochondriacal affections, and in convulsions, in doses of from 10 to 30 grains, in the form of bolus. A tincture of castor is directed in the three British Pharmacopœias. It is also said to have been successfully administered in epilepsy and tetanus. It is occasionally adulterated with dried blood, gum ammoniacum, or galbanum, mixed with a little of the powder of castor, and the fat of the beaver.

Castor oil. See *Ricinus.*

Castor, Russian. See *Castor fiber.*

Casto'reum. *um, i.* n. Castor. See *Castor fiber.*

CASTRATION. (*Castratio, onis.* f.; from *castro.*) 1. In *Surgery*, an operation, by which a testicle is removed from the body.

2. In *Botany*, the removal of the anther of a flower.

Castra'tus. One who is castrated.

Castre'nsis. (From *castra*, a camp.) Belonging to a camp: applied to those diseases with which soldiers, encamped under unhealthy circumstances, are especially liable to be affected; as *febris castrensis*, camp fever.

Cataba'ticus. (Καταβατικος; from καταβαινω, to descend.) Applied to a fever which gradually diminishes in severity till it terminates.

Catable'ma. (Καταβλημα; from καταβαλλω, to throw round.) *Epiblema. Periblema.* The outermost fillet, which secures other bandages.

Catacau'ma. (From κατακαιω, to burn.) A burn or scald.

CATACAU'SIS. (From κατακαιω, to burn.) Combustion or burning. This name is given by Dr. Young and Dr. Good to the phenomenon commonly called spontaneous combustion of the human body. See *Combustion, spontaneous.*

Cataceras'ticus. (From κατακεραννυμι, to mix; to temper.) Having the property of obtunding the acrimony of humours, by mixing with and reducing them.

Catachri'ston. (From καταχριω, to anoint.) *Catachrisma.* An ointment.

Cata'clasis. (From κατακλαω, to break.) The fracture of a bone.

Ca'tacleis. (From κατα, beneath, and κλεις, the clavicle.) 1. The first rib, which is placed immediately under the clavicle.

2. The subclavicular region of the chest.

Catacly'sma. (From κατακλυζω, to wash.) A clyster.

Catacly'smus. (From κατακλυζω, to wash.) 1. An embrocation.

2. The dashing of water upon any part.

Cata'gma. (Καταγμα; from καταγνυμι, to break.) A fracture.

Catagma'ticus. (From καταγμα, a fracture.) Catagmatic: promoting the formation of callus. Formerly applied to medicines which were supposed to possess this power.

Catale'ntia. A name given by Paracelsus to a kind of epilepsy.

CATALE'PSIA. (*æ.* f.; from καταλαμβανω, to seize, to hold.) Catalepsis. Catalepsy. Trance. This disease has also been denominated *Catoche, Catochus, Congelatio, Detentio, Encatalepsis* by Hippocrates, *Aphonia* by Antigenes, *Anaudia* by Cælius Aurelianus, *Apprehensio, Oppressio*, and *Comprehensio.* It consists in a total suspension of sensibility and voluntary motion, and generally also of mental power; the pulsation of the heart and the breathing continuing, the muscles remaining flexible, the body yielding to and retaining any given position, in which respect it differs chiefly from ecstacy.

It is very difficult to ascertain the causes of this nervous affection: the most frequent exciting cause is some mental perturbation, the state of the habit or idiosyncrasy determining the effect. The countenance is usually florid; the eyes open, and apparently fixed intently upon some object, but in most cases without perception, though occasionally it is otherwise.

In most cases the paroxysm comes on without any previous warning, and closes with sighing. Its duration is from a few hours or minutes to two or three days; and, according to well-established authorities, sometimes for a much longer period. This disease is far from common. Dr. Cullen affirms he never saw an instance of it that was not counterfeited, and asserts the same of other practitioners. On careful examination a very feeble flutter of the heart, and some movement of the involuntary organs are generally detected; and if a clear mirror be applied to the mouth and nostrils, it will in most cases be found to have a slight halitus on its surface: but even these signs of animation are not always present; the disease has been mistaken

or real death; and, in countries where the rite of sepulture takes place speedily, it is much to be feared that the unfortunate sufferer has, in a few instances, been buried alive.

The cure of this disease is to be effected by stimulants: no good has resulted from bloodletting, nor means which reduce the nervous influence. Volatile stimulants should be applied to the nostrils, and ammoniated and spirituous fluids injected into the stomach through a tube passed down the œsophagus. Electricity and voltaism are likely to be serviceable. The body should be kept warm, with a free influx of pure air, and general friction resorted to.

When the paroxysm has passed off, tonics, and medicines which strengthen the nervous system, should be persisted in for a considerable time.

CATALE'PTIC. Relating to, or of the nature of, catalepsy.

CATALO'TICUS. Sometimes improperly written for *Catuloticus*.

CATAME'NIA. (*a,orum*. neut. plur.; from κατα, according to, and μην, the month.) The monthly discharge from the uterus of females. See *Menstruation*.

CATANA'NCE. This name has been given to several plants, as the *scorpiurus sulcata*, *plantago cretica*, &c.

CATAPA'SMA. (*a, atis*. n.; from καταρασσω, to sprinkle.) *Catapastum*, *Conspersio*, *Epipaston*, *Pasma*, *Sympasma*, *Aspersio*. The ancient Greek physicians meant by this word any dry medicine reduced to powder to be sprinkled on the body. The various forms and uses of catapasmata may be seen in Paul of Egina, lib. iii. cap. xiii. Those which were valued for their grateful smell were called *diapasms; empasms* were used to restrain sweat; and *sympasms* were of an acrid quality, and used to produce heat.

CATA'PHORA. (*a, æ*. f.; from καταφερω, to sink or fall down.) A term used by some authors to designate a state of coma, and by others an unusually profound sleep.

CATAPHRA'CTA. (Καταφρακτα; from καταφρασσω, to fortify.) A bandage for the thorax, used in cases of fracture of the sternum and ribs.

CATAPLAS'MA. (*a, atis*. n.; from καταπλασσω, to spread like a plaster.) A poultice.

CATAPLASMA ACETI. Vinegar poultice. This is made by adding vinegar to crumb of bread, or any simple farinaceous matter. It is a good application to bruises and sprains.

CATAPLASMA ACETOSÆ. Sorrel poultice. The leaves are to be beaten in a mortar into a pulp. A good application to scorbutic ulcers.

Cataplasma aeratum. See *Cataplasma fermenti*.

CATAPLASMA ALUMINIS. This application was formerly used in chronic inflammation of the eyes: it is now seldom applied, a solution of alum being generally substituted.

CATAPLASMA BYNES. Malt poultice. Finely ground malt is to be mixed with thin yeast to the consistence of a poultice, and applied warm. Some surgeons prefer this to the yeast poultice against gangrene.

CATAPLASMA CARBONIS. Charcoal poultice. Made by mixing very finely powdered charcoal with linseed and warm water. Some put the charcoal only on the surface. It is used to correct the state of ill-conditioned ulcers and destroy their fetor.

CATAPLASMA CEREVISIÆ. Strong beer poultice. This is sometimes made with the grounds or dregs of strong London porter, when it can be had, or with that of other strong beer, by stirring in as much oatmeal as is necessary to make it of a proper consistence, and heating it cautiously in a pipkin or pan. It is considered a good stimulant and antiseptic for sloughing or gangrenous parts. See *Fermentum cerevisiæ*.

CATAPLASMA CONII. Hemlock poultice. R. Conii foliorum exsiccatorum ʒj. Aquæ fontanæ, Oij. Boil till only a pint remains, when as much linseed meal as necessary is to be added. This is an excellent application to many cancerous, scrophulous, and other ill-conditioned ulcers; frequently producing great diminution of the pain, and improving the appearance of the ulcers. Justamond preferred the fresh herb bruised.

CATAPLASMA CUMINI. Take of cumin seeds, one pound; bay berries, the leaves of water germander dried, Virginia snake root, of each three ounces; cloves, one ounce; with honey equal to thrice the weight of the powder formed: of these make a cataplasm. It was formerly called Theriaca Londinensis. This is a warm and stimulating poultice, and was formerly much used as an irritating antiseptic application to gangrenous ulcers, and the like. It is now seldom ordered.

CATAPLASMA DAUCI. Carrot poultice. R. Radicis dauci recentis, lbj. Bruise it in a mortar into a pulp. Some, perhaps with reason, recommend the carrots to be first boiled. The carrot poultice is employed as an application to cancerous, scrofulous, and other irritable and unhealthy ulcers. It is a most useful application.

CATAPLASMA DIGITALIS. Fox-glove poultice. Linseed-meal, oatmeal, or crumb of bread are to be made into the consistence of a poultice, by mixing them with a strong decoction of the leaves of fox-glove. This poultice is said to be more sedative than hemlock, and to allay the pain of irritable sores.

CATAPLASMA FERMENTI. Yeast cataplasm. Take of flour, a pound; yeast, half a pint. Mix and expose to a gentle heat, until the mixture begins to rise. This is a celebrated application in cases of sloughing and mortification.

CATAPLASMI FUCI. Sea-weed poultice. This is prepared by bruising a quantity of the marine plant, commonly called sea-tang, which is afterwards to be applied by way of a poultice. Its chief use is in cases of scrofula, white swellings, and glandular tumours more especially. When this vegetable cannot be obtained in its recent state, a common poultice of sea-water and oatmeal has been substituted by the late Mr. Hunter, and other surgeons of eminence.

CATAPLASMA LINI. Linseed poultice. R. Farinæ lini, lbss. Aquæ ferventis, Ojss. The linseed meal is to be gradually sprinkled into the water, while they are quickly blended toge-

ther with a spoon. This is the best and most convenient of all emollient poultices for common cases, and has, in a great measure, superseded the bread and milk one, so much in use formerly.

Cataplasma panis. Bread poultice. This is either made with milk or water. It is made by putting the crumb of stale bread into milk or water, and letting them gently simmer over a fire, in a pipkin, until they are properly softened. The mass is then to be beat and stirred about with a spoon. A small quantity of lard, or sweet oil, should be spread over it before it is applied. The linseed meal poultice is much better than this as an emollient. A cold bread and water poultice is sometimes used to allay inflammation.

Cataplasma plumbi acetatis. R. Liquoris plumbi acetatis, ʒj. Aquæ distill., Oj. Micæ panis, q. s. Misce. Practitioners, who place much confidence in the virtues of lead, often use this poultice in cases of inflammation.

Cataplasma quercus marini. See *Cataplasma fuci.*

Cataplasma sinapeos. See *Cataplasma sinapis.*

Cataplasma sinapis. Mustard cataplasm. Take of mustard-seed, linseed, of each powdered half a pound; boiling vinegar, as much as is sufficient. Mix until it acquires the consistence of a cataplasm.

Cataple'xis. (*is, is.* f.; from κατα, and πλησσω, to strike.) A sudden stupefaction, or deprivation of sensation, in any member, or organ, as the eye, &c.

Catapo'tium. (Καταποτιον. *um. ii.* n.; from καταπινω, to swallow down.) A pill. See *Pilula.*

Catapsy'xis. (From κατα, and ψυχω, to refrigerate.) A considerable degree of chilliness without shivering. — *Galen.*

Catapto'sis. (From καταπιπτω, to fall down.) A sudden falling down, as of the whole body in apoplexy or epilepsy; or of a particular limb when seized with palsy.

Catapu'tia. (*a, æ.* f.; from *catapotium*, a pill, because the seeds of the plants so called were swallowed like pills.) A name given to three plants, viz., the *Ricinus americanus*, which was called *Cataputia maxima*; the *Ricinus communis*, which was called *Cataputia media*; and the *Tithymalus latifolius* (*Euphorbia Lathyris* of Linnæus). — *Blancard.*

Cataputia major. See *Ricinus.*

Cataputia minor. See *Euphorbia Lathyris.*

CA'TARACT. (*Cataracta, a, æ.* f.; generally derived from καταρασσω, to disturb or confound, because it disturbs or destroys the sense of vision. Baratta has suggested, with more probability, that it is derived from καταρακτης, the gate of a city, because it is interposed like a gate or barrier between the light and the retina.) The following general illustration of the subject of cataract is taken from Mr. S. Cooper's First Lines of the Practice of Surgery.

Cataract is usually defined to be a weakness or interruption of sight, produced by opacity either of the crystalline lens, its capsule, or the fluid of Morgagni. Occasionally, however, the term is used in a more comprehensive sense, implying every perceptible obstacle to vision, situated between the vitreous humour and the uvea and pupil.

When the disease is seated in the lens, its capsule, or the fluid of Morgagni, it is called *a true cataract*; but, when it consists of opake matter deposited in front of the lens, it is denominated a *false cataract.* The terms, *lenticular*, *capsular*, and *capsulo-lenticular cataracts*, express some of the distinctions referred to. The *Morgagnian* may be dismissed from present consideration, its separate existence not being generally credited.

Cataracts are also distinguished into *idiopathic*, or such as arise from internal, but generally unknown causes, — and *accidental*, which originate from external violence, or active inflammation. In general, the idiopathic, sooner or later, affect both eyes; but an accidental cataract is frequently restricted to one eye.

The symptoms of a cataract are of the following description: — 1st. All objects, especially white ones, seem to the patient as if covered with a mist, a circumstance that generally precedes any visible opacity behind the pupil. 2d. The decline of vision bears an exact proportion to the degree of opacity. 3d. The opacity is almost always first noticed in the centre of the pupil, the examples in which it first presents itself at the circumference being much less frequent. 4th. When the iris is light-coloured, the more opake the cataract is, the more plainly a blackish ring is seen at the edge of the pupil; and such a ring is particularly conspicuous when the cataract is soft and large, as it then propels the margin of the uvea forwards. 5th. As a cataract generally begins at the central point behind the pupil, objects placed directly in front of the eye are most difficultly seen, even in the early stage of the disease; but those which are on one side may yet be discerned, particularly if the light be not strong, which would make the pupil too diminutive to let the rays pass through the thinner transparent edge of the lens. 6th. What has just been observed likewise explains why patients, having an opacity in the centre of the lens, are sometimes completely blind in a strong light, though they may enjoy a useful degree of vision in the shade, or in moderately dark places. 7th. The eyesight of patients affected with incipient cataract may be materially assisted by convex glasses, because objects are magnified by them. 8th. To patients in this state, the flame of a candle seems to be obscured in a white misty halo, which always becomes broader the further the patient is from the light. When the cataract is more advanced the flame cannot be discerned, but merely the situation of the light. 9th. The action of the iris is not affected.

In amaurosis, the horn-like or glaucomatous appearance is more deeply seated in the eye than the opacity of a cataract, and is somewhat concave. It is frequently of a greenish colour, while the opacity of cataract is usually greyish, white, or amber coloured. The decline of vision, also, is not in a ratio to the opacity, and the patient may be entirely blind, with little appearance of defect

in the eye. The pupil is likewise generally dilated and motionless, with its pupillary margin somewhat irregular. The temporary increase or decrease of blindness, a circumstance so common in patients with incomplete amaurosis, depends upon circumstances which depress or excite the system, and not, as in cases of cataract, upon the degree of light, and the corresponding alterations in the size of the pupil.

The misty halo, seen by amaurotic patients round the flame of a candle, is not like a whitish cloud, as in cases of cataract, but exhibits all the colours of the rainbow. To amaurotic patients spectacles are of no service; and objects situated on one side are not better seen by such persons, than those which are directly in front of the eye. Neither is there any temporary increase of the power of vision obtained by the use of belladonna, as in cataract.

Whiteness denotes either a dissolved lens or a capsular cataract; a grey colour, a lenticular cataract; an amber colour or dark grey, a firm lens; and light grey, a soft one. If the whole extent of the pupil is uniformly opake, the cataract is probably one of the lens; if the opacity is streaked or speckled, it is likely to be one of the capsule. If the opake streaks radiate from a centre, the posterior layer of the capsule is probably affected. If the form of the opacity is convex, either the anterior capsule or the lens is the seat of it; if concave, the posterior part of the capsule. With the light concentrated on the pupil by means of a double convex glass, all these particulars may be ascertained. Mr. Cooper believes that the size of a cataract is a better criterion of its consistence than its colour; and, at all events, that the smaller the lens is, and the darker its colour, the more solid its substance will generally be; while the larger and more protuberant it is against the iris, the greater is the probability of its being soft.

A cataract of the lens itself, as already explained, is termed a *lenticular cataract*, which may vary much in its consistence. Thus, such a cataract may be *hard*, as it is often found to be in elderly persons, with an amber colour, the tint being deeper in proportion as the cataract is firmer.

A lenticular cataract may be *soft*, that is to say, of a cheesy, gelatinous, or even milky consistence. Soft cataracts are more bulky than hard ones, so that they project nearly into the pupil. Hence, sight is more considerably interrupted than when the cataract is hard, and the power of distinguishing colours frequently quite abolished. The capsular cataract has a smooth and glistening surface, with streaks upon it, and it lies close to the edge of the pupil.

When the lens is present, a capsular cataract is rarely unaccompanied by a lenticular one; but an opake lens may be removed or taken away by absorption, and a capsular cataract may be left. In this case, as the opacity is merely a thin layer of the capsule, the cataract makes no projection against the iris, and the anterior chamber is not lessened by the advance of the iris towards the cornea.

In children, cataracts are never hard: but in adults, we meet with both hard and soft ones.

Cataracts may occur at any period of life, and are sometimes *congenital*. They are most frequent in elderly persons, and usually arise without any manifest cause, or anything wrong in the rest of the eye, or the constitution at large. The capsulo-lenticular cataract is alleged to form very commonly under circumstances denoting a determination of blood to the head and the eye, accompanied by uneasy sensations in those parts; but generally we cannot refer the origin of a cataract to any particular causes. There is an exception, with respect to cataracts following a wound of the lens, or its capsule. Experience proves that the slightest prick of these parts will lead to their opacity, or, to speak more accurately, the capsule inflames, and becomes opake, and the lens itself is afterwards absorbed; so that the result is, in fact, a capsular cataract.

A cataract is termed *simple* when accompanied by no other disease of the eye likely to impair its functions, or with no particular constitutional disease; *complicated*, when joined with other diseases of the eye, as adhesion of the crystalline capsule to the iris, amaurosis, glaucoma, or a gouty, rheumatic, or syphilitic state of the system. The circumstances denoting glaucoma have already been explained. If in addition to a sluggish or immovable iris, the patient is totally incapable of distinguishing the least glimpse of light, the cataract is combined with amaurosis.

When a cataract is free from every complication; when it is not attended with frequent headach, nor pains in the eye; when the pupil retains its regular circular shape; when the iris possesses its natural power of motion in the different degrees of light; and when the patient can readily discern the difference between light and darkness, and even perceive bright colours, and the outlines of objects, in shady places where the pupil naturally expands — the prognosis is favourable.

There are no medicines, nor applications, capable of dispersing an opacity of the lens, or its capsule. The cases, injudiciously blended with the subject of cataract under the name of *false cataracts*, which are only obstructions of the pupil by lymph, effused in consequence of inflammation, may indeed sometimes be benefited, or even cured, by the means recommended for the cure of iritis; but no real analogy exists between such cases and opacity of the lens and its capsule. In all examples of true cataract, it is only by an operation that sight can be restored.

Whether an operation should be performed when the cataract is single, and the other eye in the enjoyment of good vision, is a question on which some difference of opinion is entertained. Diversity in the refracting powers of the eyes after the removal of the lens from one of them, and the apprehension of confused vision, as the result, are the reasons usually urged against the practice, which has, however, to a certain extent, proved successful; while the continuance of a cataract in one eye not only gives a disposition to the origin of the same kind of opacity in the other, but permanently impairs the sensibility of the retina itself for want of exercise.

It is a general and judicious maxim, never to operate upon both eyes at the same time. In the case of extraction in particular, this rule is universally observed. It is also a maxim to let the patient have the benefit of preparatory treatment before he undergoes the operation. His diet should be lowered and his bowels emptied.

In cases of congenital cataract, ought the operation to be delayed till the patient has attained the age of docility and reason? Or ought it to be practised in early infancy? Every consideration seems to be in favour of an early performance of it. If it be postponed, the eyes, having no distinct perception of external objects, acquire such an inveterate habit of rolling, that for a long time after the pupil has been cleared by an operation no voluntary effort can control this irregular motion. The retina, too, by a law common to all structures of the animal body, for want of being exercised, becomes more or less deprived of power. From the age of eighteen months to that of two years is deemed an advantageous period for operating on congenital cataracts.

Persons blind from congenital and other cataracts of long duration, and habituated to live with four senses, are generally confused and perplexed on the restoration of vision. They have a difficulty in combining the action of the eye with that of the other senses. Hence Dupuytren has often found it necessary to deprive them, for a time, of the use of one or two of the other senses, in order to enable them to use the organ of vision. He has applied this principle to infants, by closing their ears, as it was noticed that they suffered themselves to be guided by sound, and by impressions received by the hands, which they thrust out before their bodies, like tentacula.

There are three kinds of operation for cataract. 1st. The method formerly termed *couching*, and which is simply the removal of the cataract out of the axis of vision, leaving it still in the eye. It is now frequently called *displacement*; and has two varieties, *depression* and *reclination*. 2d. Surgeons practise *extraction of the cataract*; that is, they take the opake lens completely out of the eye. 3d. Another method, often adopted, consists in the *division of the cataract into fragments*, which, being exposed to the aqueous humour, become absorbed.

By *depression* and *reclination*, we change the situation of the cataract. In *depression*, the lens is pushed directly below the level of the pupil. In *reclination*, the lens is made to turn over into the middle, and towards the bottom of the vitreous humour; so that the surface of the lens, which was previously directed forwards, is now placed upwards, and what was the upper edge is turned backwards. Over the lens, displaced in this manner, the vitreous humour will close much more completely than over the simply depressed lens, so that it will be less likely to reascend behind the pupil. Nor will the retina be so liable to be pressed upon by the cataract as after depression; yet, reclination unavoidably does more extensive injury to the hyaloid membrane of the vitreous humour.

Extraction is the complete removal of the cataract from the eye through an opening made in the cornea. The incision for this purpose must form the segment of a regular circle, be smooth, and, at the same time, of sufficient size to permit the easy passage of the cataract through it. Both in this first period of the operation, and in the subsequent one of opening the capsule, the iris should remain entirely free from injury.

One of the chief dangers of extraction is that of loss of the vitreous humour, which if due care be not taken, is apt to be suddenly forced out of the eye along with the cataract.

Another risk is that of the iris being wounded. Sometimes the operation is followed by a prolapsus of this organ, and occasionally by a closure of the pupil from the inflammation excited in the iris by injury of its texture.

The *division*, or breaking of a cataract piecemeal, may be done with a needle, either through the sclerotica or the cornea. It has the recommendation of being the most easy, but sometimes needs repetition. Opake portions of the capsule, however, frequently resist absorption, and must, after all, either be extracted or displaced. The division of a cataract, when performed by passing the needle through the cornea and pupil, is termed *keratonyxis*.

No method of operating for the cure of cataract should be exclusively preferred; each having its advantages in particular cases.

CATARACT, BLACK. 1. A very rare variety of cataract, in which the opake lens is black.

2. Some authors have designated amaurosis by this term.

CATA'RIA. (From *catus*, a cat: so called because cats are fond of it.) See *Nepeta cataria*.

CATARRHAL. Appertaining to or partaking of the nature of a catarrh; thus *catarrhal fever*, fever complicated with catarrh.

CATARRHE'CTICUS. (From καταῤῥηγνυμι, to break.) A name given by Hippocrates to medicines supposed to have a dissolvent power, as *oxymel* — καταῤῥηκτικα φαρμακα.

CATARRHEU'MA. (*a, atis.* n.; from καταῤῥέω to flow from.) Synonymous with *catarrh*.

CATARRHE'XIS. (*is, is.* f.; from καταῤῥηγνυμι, to burst out.) A sudden and violent effusion. Hippocrates applies it to a sudden and profuse diarrhœa. Schneider calls a copious and rapid discharge of blood from the bowels *catarrhexis vera*.

CATA'RRHUS. (*us, i.* m.; from καταῤῥεω, to flow from.) Catarrh. The older writers distinguished the symptoms of what is commonly called a cold by different names according to the part more immediately affected; as expressed in the old verse —

"Si fluit ad pectus dicatur rheuma *catarrhus*;
Ad fauces *branchus*, ad nares esto *coryza*."

The term catarrh is now applied to a cold in the head or on the chest. Bronchitis is called *pulmonary catarrh* by some writers, and an increased secretion of mucus from the internal coat of the urinary bladder is styled *catarrh of the bladder*. Catarrh or inflammation of the lining membrane of the air passages presents itself under two forms, *common catarrh*, called in ordinary language a cold, and *epidemic catarrh* or *influenza*. The symptoms of common catarrh

are a sense of fulness in the head, and of weight over the eyes, which are weak and watery. The nostrils are obstructed, and pour forth a fluid which is at first thin and acrid, and excoriates the skin around the nostrils, but which afterwards becomes thicker and often purulent. There is frequent sneezing, hoarseness of the voice, cough, generally attended with expectoration, and often a sense of fulness or soreness in the fauces. The common cause of catarrh is the direct exposure of the affected surfaces to a cold or damp atmosphere, or the sudden suppression of perspiration from a rapid reduction of temperature. These, however, are not the sole causes, since patients who have been long confined to their room by other diseases, frequently catch cold without any exposure whatever; some persons always get a cold in the head on quitting the town for the country; and others on quitting the country for the town; and since we know of no reason why the mucous membrane of the air passages should be exempt from the general causes, whatever these may be, which produce inflammation in other mucous membranes, what ground have we for supposing that a catarrh must always arise from cold?

Where the attack is slight, medical aid is not often sought for, or needed. A few days' confinement to the house in a warm but not a close apartment, diluent drinks, abstinence from animal food, and vinous or other fermented liquors, gentle laxatives and diaphoretics usually succeed in carrying off the complaint. But if there be a sense of oppression on the chest, or much fulness in the head, with a degree of symptomatic fever, a more decided antiphlogistic treatment is indicated; smart purgatives should be given, and venesection may sometimes be advisable. If the cough be troublesome, it is to be allayed by demulcent mixtures, with small doses of henbane, gentle expectorants, &c. Opium uncombined is not generally serviceable in catarrh, as it is apt to check the secretion from the inflamed membranes, and thus increase the inflammation: Dover's powder, however, is recommended by many practitioners.

Catarrh is a pretty constant accompaniment of measles, and is not unfrequent in fever, small-pox, worms, dentition, rheumatism, and other diseases.

In the epidemic catarrh or influenza, the attack is very sudden; there is great heaviness over the eyes; and the fever is attended with great depression.

It commences, according to Dr. J. C. Smith, who has accurately recorded its progress as it appeared in 1781 and 1782, with the usual catarrhal symptoms, in conjunction with others of a much graver character, such as great languor, lowness, and oppression at the præcordia; anxiety, with frequent sighing, sickness, and violent headach. The pulse is peculiarly quick and irregular, and at night there is often delirium. The heat of the body is seldom considerable, particularly when compared with the violence of the other symptoms; the skin is moist, with a tendency to profuse sweating; the tongue moist, but white or yellowish. Sometimes there are severe muscular pains, general or local; at other times, erysipelatous patches or efflorescences on different parts of the body. From the onset, for the first twenty-four or forty-eight hours, the symptoms are extremely violent, far beyond the danger or duration of the distemper. For the most part it attacks the healthy and robust: children, and old people either escape entirely, or are affected in a slighter manner. Pregnant women, when affected by it, are disposed to miscarry, and the flooding is in some cases fatal. Patients subject to pulmonic complaints, suffer much from the cough, difficulty of breathing, and other peripneumonic symptoms, which occasionally lead to a fatal result.

Such is the general character of influenza in most of the periods in which it has shown itself. But in every period its symptoms have considerably varied in severity in different individuals. In many instances, they have scarcely exceeded those of a common cold; in others, the pleuritic pain has been very acute, or the headach intolerable, shooting up to the vertex with a sense of splitting; the pulse has been a hundred and forty, and often considerably more, in a minute, with incoherency or delirium from the first night. Yet cases of real danger are very few; and the violence of the disease is over frequently in forty-eight hours; sometimes in twenty-four. Those who have suffered, appear to be little susceptible of a second attack during the continuance of the epidemy, though they have no indemnity against the next that may appear. In many cases, however, the general debility which has been induced does not terminate with the catarrh itself, but remains for weeks, perhaps for months afterwards, and is sometimes removed with great difficulty.

The disease has been known and described from the time of Hippocrates to the present day; and is dwelt upon at great length by Sydenham, who regarded it, in the autumn of 1675, as a general cough produced by cold and moist weather, grafted upon the autumnal epidemy, and varying its symptoms.

Influenza, however, has not only occurred in the autumn, but in every season of the year, whether hot, cold, damp, or temperate; and when there has been apparently no other constitutional distemper with which it could unite itself. That it is an epidemy, cannot be doubted: yet this is to advance but a very little way towards a knowledge of its origin or remote cause; for we have still to inquire into the nature of epidemies, their sources, diversities, and means of diffusion; often, as in the case of spasmodic cholera, in the very teeth of periodical winds and other meteorological phenomena that we might fairly conclude, if we did not know the contrary, would irresistibly oppose their progress. Sydenham freely confesses his ignorance upon the subject, though he is rather disposed to ascribe them to "some occult and inexplicable changes wrought in the bowels of the earth itself, by which the atmosphere becomes contaminated with certain effluvia, which predispose the bodies of men to some form or other of disease."

An epidemic constitution of the atmosphere,

however, or that state of the air capable of producing any general disorder, may depend either upon an intemperament, or inharmonious combination of the elementary principles of which it consists, or upon some miasm, or foreign morbific principle accidentally combined with it. It is possible that both these may be causes of different diseases.

Many writers have endeavoured to trace the malady under consideration to the first of the above causes, and particularly to the atmosphere's being in a state of negative electricity; and M. Weber, fully confiding in this cause, has recommended, somewhat whimsically, the use of socks made of the most powerful non-conductors, as oiled silk, or paper covered with sealing-wax, as a certain prophylactic. Others, without undertaking to determine in what the atmospheric intemperament consists, have regarded it as a mere exciting cause of catarrhs, or, in other words, as merely rendering the body more obnoxious to the ordinary causes of this disease, and hence converting a sporadic into a general distemper.

More commonly, however, catarrh, as well as other epidemics, have, in modern times, been contemplated as dependent upon the second of the aërial causes just adverted to, namely, the existence of a specific miasm, or morbid principle of a peculiar kind in the atmosphere, distinct from any change in the combination of its proper elements. It is, however, quite useless to speculate on a subject on which, if we are ever to know anything, such knowledge can only result from long-continued and laborious observation of the influence of external nature on the living body; nor is it a very philosophical occupation to weave hypotheses concerning the state of the *air* which causes epidemics, when, for aught we know to the contrary, the cause may just as well be in the earth, or in the waters under the earth. The sudden and simultaneous invasion of a great part of the population of a place, sufficiently demonstrates that the spread of influenza depends principally upon causes much more extensive in their operation than contagion: facts are not wanting, however, which render it highly probable that the disease is communicable from one individual to another; whilst there is nothing which at all tends to disprove its contagious character.

Cullen, in his synopsis, has followed the more striking returns of influenza from the fourteenth century down to his own times. "In all these instances," says he, "the phænomena have been much the same; and the disease has always been particularly remarkable in this, that it has been the most widely and generally spreading epidemic known. It has seldom appeared in any one country of Europe, without appearing successively in every other part of it." In some instances, the infection has passed the Atlantic, with little or no remission of its severity, and attacked Americans, who had not had the slighest intercourse with Europeans.

The track of this disease may be traced at sea as well as on land. In the epidemy of 1782, Lord Anson sailed in the month of May with a fleet for the Dutch coast; and Admiral Kempenfelt for that of France. The crews of both fleets were well on sailing; but in the same month both were attacked very generally, and the latter was obliged to return home. The previous state of the air, with respect to any of the sensible qualities of heat, cold, electricity, or damp, seems to have exercised but little appreciable influence. Influenzas have recurred at every different season, in every state of the barometer, thermometer, and hygrometer.

Thus the influenza of 1762, one of the severest on record, producing effects which continued, in many instances, for two or three years afterwards, was preceded by weather uncommonly warm; while in that of 1767, being the next in succession, which was also very severe, though productive of less durable mischief to the constitution, the weather was remarkable for being unusually cold. We know nothing of the country from which the disease has at any time taken its rise; but it has usually observed some particular track, as from north to south or from east to west. That of 1781 and 1782 is said to have originated in China, and to have travelled through Asia into Europe, thence crossing the Atlantic, and arriving the ensuing year in America; but this assertion wants confirmation.

The influenza which occurred in the spring of 1803, was prevalent in Paris and other parts of France, and in Holland, some weeks before it appeared in London; and it was again some weeks in travelling from London to Manchester. It visited Cork and Dublin before reaching the north of Ireland, and it finally crossed the Atlantic, and appeared in the United States the same spring. The epidemics of 1831–2 and 1836–7 are fresh in the memory of all practitioners, and were nearly universal throughout the civilised world. Influenza has sometimes been observed to precede the eruption of more formidable epidemics. That of 1803 was followed by an epidemic ophthalmia in France and a very severe dysentery in the United States. Of late years influenza has been the immediate precursor of malignant cholera in many places.

In the treatment of epidemic catarrh bleeding is rarely required, and, from the debility so soon induced, should be avoided, except when an inflamed state of important organs renders it necessity imperative. It was tried copiously by many practitioners in 1782, but they soon reverted to the cautionary track of Sydenham. Quiet, diluent drinks, the promotion of gentle perspiration, and a due attention to the state of the bowels, will usually be found sufficient. If the chest be much loaded, an emetic will afford the most effectual relief. If the cough be troublesome, and the breathing laborious, both which, however, are generally alleviated by an emetic, small doses of ipecacuan, with or without oxymel of squills, will promote an easy expectoration, and take off the sense of oppression. Cullen joined these with opium, and was particularly attached to the use of Dover's powder in all catarrhal affections, asserting that there is no disease in which opium has been found more

seful; but this position, doubtful with respect o common catarrh, is decidedly opposed to ecent experience in influenza, the symptoms of which have very generally been found to be ggravated by opium, exhibited in whatever orm. A more liberal diet may be allowed in nfluenza than is usual in ordinary febrile affec-ions. The subsequent debility may be removed y vegetable and mineral tonics, gentle exercise, ure air, cold bathing, and a nutritious diet. The cough which generally accompanies influ-nza sometimes remains as a sequel, long after he other symptoms have disappeared: and, in his case, opium with camphor, or the resinous alsams, often affords essential relief, and espe-ially at night. It has not generally been found hat the cough has proved any impediment to he use of bark, or even that of cold bathing. nfluenza has rarely terminated in phthisis; which, according to Dr. Carmichael Smith, is ess frequently consequent on epidemic than on ommon catarrh.

CATARRH URETHRAL. The name of urethral atarrh has been given to gleet.

CATARRH UTERINE. Leucorrhœa has been alled uterine catarrh.

CATARRHUS BELLINSULANUS. The mumps. See *Parotitis*.

CATARRHUS SUFFOCATIVUS. See *Croup*.

CATARRHUS VESICÆ. This name has been iven to a copious discharge of mucus from the bladder, which arises from chronic inflammation f its mucous coat.

CATARTI'SMUS. Καταρτισμος. The reduction f a dislocated bone. — *Paulus Ægineta*.

CATASA'RCA. (From κατα, and σαρξ, flesh.) ynonymous with *Anasarca*.

CATASTA'GMOS. (Καταστραγμος; from κατα-ταξω, to distil.) The Greek word for distil-ation. Some medical writers have used it sy-onymously with coryza.

CATASTA'LTICUS. (From κατασ-ελλω, to repress.) Catastaltic. Applied to medicines which repress evacuations, as astrin-ents and styptics.

CATA'STASIS. (Κατασταση; from καθισ-ημι, to constitute.) 1. The constitution or tate of any thing, as of the human body or of he atmosphere.

2. The restoration of a dislocated part to its roper position.

CATA'TASIS. (From κατατεινω, to extend.) Hippocrates used this term to signify the ex-ension of a fractured or dislocated limb, in rder to replace it, and also its actual reduction.

CATE. A name of catechu. See *Catechu*.

CA'TECHU. (*Catechu*, indeclinable. It is aid that, in the Japanese language, *kate* sig-ifies a tree, and *chu*, juice.) See *Acacia catechu*.

Catechu, extractum. See *Acacia catechu*.

CATEIA'DION. (Κατειαδιον; from κατα, and α, a blade of grass: so called from its shape.) a long-shaped instrument mentioned by Are-eus, which was thrust into the nostrils to pro-oke a hæmorrhage in cases of head-ach.

CATE'NÆ MUSCULUS. The anterior tibial uscle. — *Spigelius*.

CATHÆRE'TICUS. (Καθαιρετικος; from αθαιρω, to take away.) Escharotic.

CATHA'RMA. (*a, atis*. n.; from καθαιρω, to purge.) An excrement. Any thing purged from the body naturally or by art.

CATHA'RSIS. (*is, eos*. f.; from καθαιρω, to purge.) Purgation of the excrements or humours, either naturally or artificially.

CATHA'RTIC. (*Cathartícus*; from καθαιρω, to purge.) Purgative. Applied to a medicine which, taken internally, or applied externally, increases the evacuations. Purgative medicines have received many appellations: *purgantia; catocathartica; catoretica; catotetica; dejecto-ria; alviduca*. The different articles referred to this class are divided into five orders of cathartics: —

1. *Stimulating*, as jalap, aloes, bitter apple, and croton oil, which are well calculated to dis-charge accumulations of serum, and are mostly selected for indolent and phlegmatic habits, and those who are hard to purge.

2. *Refrigerating*, as sulphate of soda, super-tartrate of potash, &c. These are better adapted for plethoric habits, and those with an inflam-matory diathesis.

3. *Astringent*, as rhubarb and damask roses, which are mostly given to those whose bowels are weak and irritable, and subject to diarrhœa.

4. *Emollient*, as castor oil and olive oil, which may be given, in preference to other cathartics, to infants and very aged persons.

5. *Narcotic*, as tobacco, hyoscyamus, and digitalis. Medicines of this kind are never ex-hibited in the practice of the present day.

Murray, in his Materia Medica, considers the different cathartics under the two divisions of *laxatives* and *purgatives*; the former being mild in their operation, and merely evacuating the contents of the intestines; the latter being more powerful, and even extending their stimu-lant operation to the neighbouring parts. The following he enumerates among the principal laxatives: — Manna, Cassia fistula, Tamarindus indica, Ricinus communis, Sulphur, Magnesia. Under the head of purgatives, he names Cassia senna, Rheum palmatum, Convolvulus jalapa, Helleborus niger, Bryonia alba, Cucumis colo-cynthis, Momordica elaterium, Rhamnus ca-tharticus, Aloe perfoliata, Convolvulus scam-monia, Gambogia, Submurias hydrargyri, Sul-phas magnesiæ, Sulphas sodæ, Sulphas potassæ, Supertartras potassæ, Tartras potassæ, Tartras potassæ et sodæ, Tighlii oleum, Phosphas sodæ, Murias sodæ, Terebinthina veneta, Nicotiana tabacum.

CATHARTIC SALT. Both Epsom salt and Glauber's salt are so named. See *Magnesiæ sulphas* and *Sodæ sulphas*.

CATHA'RTINE. A substance of a reddish colour, a peculiar smell, and a bitter nauseous taste, soluble in water and alkohol, but insoluble in ether; obtained by Lassaigne and Fenuelle from the leaves of senna.

CATHARTOCA'RPUS. A genus of plants separated from the Linnæan genus *Cassia*.

CATHARTOCARPUS FISTULA. Cassia fistula of Linnæus. The plant which produces the cassia pulp. It grows in the East and West Indies and Egypt, and rises to the height of forty or

fifty feet. The fruit is a long cylindrical woody dark brown pod, about the thickness of the thumb, and two feet in length, divided into numerous transverse cells, each containing one seed, embedded in a soft black pulp. The greater part of the cassia pods imported into this country are from the West Indies, but those from the East Indies are reckoned finer; they are of smaller size, and the pulp is blacker. The pulp is the part used in medicine. According to Vauquelin, it contains sugar, gelatin, gluten, mucus, a small proportion of resin, extractive, and colouring matter. It is a gentle laxative in a small dose, but in large doses occasions nausea and griping. It is now hardly ever used except as an ingredient in compounds, as the confectio sennæ, &c. The dose of cassia pulp is from ʒiij. to ʒj.

Cathemeri'nus. (Καθημερινος; from κατα, and ἡμερα, a day.) Synonymous with quotidian.

CA'THETER. (*Catheter, teris*, m.; Καθετηρ, from καθιημι, to thrust into.) A long and hollow tube, introduced by surgeons into the urinary bladder, to draw off the urine when the patient is unable to pass it naturally. Catheters are either made of silver, or of a mixture of metals, or of elastic gum. That for the male urethra is much longer than that for the female, and so curved, if metallic, as to adapt itself to the urethra.

Catheteri'smus. (*us, i.* m.; from καθετηρ, a catheter.) The operation of introducing the catheter.

Cathi'drysis. (Καθιδρυσις; from καθιδρυω, to place together.) Hippocrates uses this term to signify reduction of a fracture.

Cathmia. A term applied by the alchemists to several things; as to a mineral vein containing gold and silver, to gold, to litharge, to the smoke arising from burnt copper, &c.

Catho'lceus. (Καθολκευς; from καθελκω, to draw over.) An oblong fillet, applied round that bandage for the head called *pericepastrum*, in order to secure it.

CATHO'LICON. (Καθολικος, universal.) *Catholicum*. An universal medicine: a medicine that was supposed to purge away all vitiated humours.

Catholicum duplex. An old purgative electuary, containing rhubarb, senna, cassia, tamarinds, &c.

Catholici humores. Humours which exist throughout the body were formerly so called.

Ca'tias. Κατιας. A knife used for cutting a dead fœtus out of the womb. — *Paulus Ægineta.*

Cati'llia. A weight of nine ounces.

Catillus. See *Capella.*

Catillus cinereus. See *Cupella.*

Cati'nus fuso'rius. A crucible.

Catkin. See *Amentum.*

CA'TLING. A long, narrow, double-edged, sharp-pointed knife, used chiefly in amputations.

Catma. Gold-filings.

Catmint. (So called, because cats are said to be fond of it.) See *Nepeta.*

Catocatha'rtic. (*Catocatharticus*; from κατω, downwards, and καθαιρω, to purge.) Applied to a purgative medicine.

Ca'toche. (From κατεχω, to detain.) See *Catalepsis.*

Catochei'lum. (*Catochellum, i.* n.; from κατω, beneath, and χειλος, the lip.) The lower lip.

CA'TOCHUS. (*us, i.* m. Κατοχη; from κατεχω, to detain.) Some writers use this term synonymously with *catalepsy*, and others with *coma-vigil*; others again distinguish catochus from catalepsy by the rigidity of the limbs, which obtains in the former, but not in the latter.

Catomi'smus. (From κατω, below, and ωμος, the shoulder.) A method of reducing a luxated humerus, practised by the Greeks. It consisted in throwing the arm of the patient over the shoulder of a strong man, so that the body was raised from the ground, and the reduction effected by the conjoined action of the patient's own weight and the shoulder of the operator.

Cato'pter. (Κατοπτηρ; from κατοπτομαι, to see clearly.) The Greek name for a speculum ani.

Catorchi'tes. (Κατορχιτης; from κατορχεομαι, properly to delight or soothe by dancing.) The name of a soothing or demulcent wine used by the Greeks, prepared with figs. It was the same with the *Sycites.*

Catore'ticus. This word appears to be merely a false reading for *catotericus*, which see.

Catote'ricus. (Κατωτερικος; from κατωτερος, inferior.) Applied to a cathartic as being a medicine which operates downwards.

Catulo'ticus. Κατουλωτικος. Catulotic. This term has been applied to medicines which promote cicatrisation; but in the fragment of the book *De Dynamidiis*, falsely attributed to Galen, we read "Catuloticæ sunt quæ cicatrices grossas comedendo æquant et limpidant." — *Ed. Venet. Ap. Junt Latin*, 1576. And this, as far as we know, is the only ancient authority for the word.

Ca'tulus. See *Amentum.*

CAU'CALIS. (*is, is* vel *idis.* f.; καυκαλις.) The name of a genus of plants. Class, *Pentandria*; Order, *Monogynia.*

Caucalis anthriscus. *Daucus annuus minor.* A common plant in the hedges, said to be diuretic, but not used in the present day.

Caucaloi'des. (From καυκαλις, and ειδος, a likeness; from its likeness to the flower of the caucalis.) Like unto the caucalis. 1. A specific name of some plants.

2. An epithet of the patella, from an alleged resemblance to the flower of the caucalis. — *Moxion.*

CAU'DA. (*a, æ.* f.; from *cado*, to fall: because it hangs down behind.) A tail. 1. The tail of animals.

2. An appendage to seeds which resembles a tail; as in the genus *clematis.*

3. A name formerly given to the os coccygis, that being, in tailed animals, the beginning of the tail.

4. The clitoris, especially when of undue magnitude. — *J. G. Walther.*

Cauda equina. 1. The spinal marrow, at its termination about the second lumbar vertebra, gives off a large number of nerves, which,

hen unravelled, resemble the horse's tail; ence the name. See *Medulla spinalis.*

2. See *Hippuris vulgaris.*

Cauda muris. See *Myosotis.*

Cauda porcina. See *Peucedanum.*

CAUDA VULPIS RUBICUNDI. An alchemical ame of red lead.

CAUDA SEMINIS. The tail, or elongated, and enerally feathery appendage to a seed, formed of e persistent style. It is simple, in *Geranium onale;* hairy, in *Clematis* and *Pulsatilla;* and eniculate, in *Tormentilla.*

CAUDAL. Relative to the tail. Thus we peak of the *caudal vertebræ* of a quadruped, nd the *caudal fin* of a fish.

CAUDA'TIO. (From *cauda*, a tail.) An elonation of the clitoris. — *Blasius.*

CAUDA'TUS. (From *cauda*, a tail.) Cauate; tailed: applied generally in natural hisory. In botany, to seeds which have a tail-like ppendage; as those of the *Clematis vitalba*, and *nemone sulphurea.*

CAU'DEX. (*ex, icis.* m.) A name aplied by some botanists to that part, both of e root and stem of a plant, which is not rami-ed: the former is called *caudex descendens*, and e latter *caudex ascendens.*

CAUL. 1. The English name for the omenum. See *Omentum.*

2. A detached portion of the membrane is ometimes found covering the face of a newborn child: this is named, in popular language, caul. The superstitious believe that this piece f membrane, borne about the person, will preent an individual from ever being drowned.

CAULE'DON. (Καυληδον; from καυλις, a em.) This word has been introduced into ome lexicons as a substantive signifying a ransverse fracture, or a fracture resembling at of the stem of a tree; but it is in reality an dverb, signifying "in the manner of a stem." -το καυληδον καταγμα, the kind of fracture which esembles that of a stem; namely, a transverse acture.

Caulescens. Having a stem.

Cauliflower. See *Brassica oleracea.*

CAULINE. (*Caulinus*, from *caulis*, the em.) Of or belonging to the stem. Leaves nd peduncles are so called, which grow on, or ome immediately from, the stem.

CAU'LIS. (*is, is.* m. Καυλος.) A stem hich bears the leaves as well as the flowers. plant is said to be

Caulescent, when furnished with a stem.

Acauline, when destitute of a stem; as in *arlina acaulis.*

From its *duration*, the caulis, or stem, is disnguished into,

1. *Herbaceous*, which perishes every year; as *Melissa officinalis.*

2. *Suffruticose*, which perishes halfway down very year; as in *Cheiranthus incanus.*

3. *Fruticose*, shrubby, having many stems, hich do not perish in the winter; as in *Melissa uticosa.*

4. *Arboreal;* as the trunk of trees.

From the *substance*, into,

1. *Fistulose*, hollow internally; as in *Anethum raveolens*, and *Allium fistulosum.*

2. *Loculamentose*, hollow and divided into cells; as in *Angelica, Archangelica*, and *Phellandrium aquaticum.*

3. *Inane*, or *medullary*, empty or pithy; as in *Sambucus nigra.*

4. *Solid;* as in *Mentha* and *Melissa.*

5. *Ligneous*, woody; as in *Prunus spinosa.*

6. *Carnose*, or fleshy; as in *Sedum arboreum*, and *Stapelia hirsuta.*

7. *Pulpous*, pulpy; as in *Mesenbryanthemum crystallinum.*

8. *Fibrose*, separable into long fibres; as *Cocos nucifera.*

9. *Succous*, full of juice; as in the *Euphorbias*, and *Chelidonium majus.*

From the difference of the *surface*, the *caulis* is said to be,

1. *Glaber*, or *lævis*, smooth, without any hairiness, or roughness, or inequality; as *Lepidium latifolium.*

2. *Scaber*, or *asper*, when it has hard inequalities; as in *Galium aparine*, and *Lithospermum arvense.*

3. *Suberose*, corky; as *Passiflora suberosa*, and *Quercus suber.*

4. *Rimose*, cracked; as in *Ulmus campestris.*

5. *Tuberculate*, with rough nobs; as in *Cissus tuberculata.*

6. *Tunicate*, the cuticle peeling off spontaneously in large portions; as in *Betula alba*, and some of the *Spiræas.*

7. *Striate*, having superficial longitudinal lines; as in *Chærophyllum sylvestre, Aster sibiricus*, and *Daphne mezereon.*

8. *Sulcate*, furrowed, fluted, when longitudinally indented with long and deep hollows; as in *Celosia coccynea, Selinum carvifolia, Pimpinella sanguisorba, Doronicum pardalianches.*

9. *Perfoliate;* as in *Bupleurum perfoliatum.*

The *figure* affords the following distinctions: —

1. *Caulis teres*, or *cylindrical*, round, without angles; as *Sinapis arvensis.*

2. *Semiteres*, half-rounded, flat on one side; as *Hyacinthus orientalis, Allium descendens.*

3. *Compressed*, which implies that two sides of the stem are flat, and approach each other; as in *Poa compressa, Lathyrus latifolius, Pancratium declinatum.*

4. *Anceps*, two-edged; as *Iris graminea, Hypericum androsæmum.*

5. *Angulate*, presenting several acute angles in its circumference.

a. *Triangulate*, three-cornered; as in *Cactus triangularis.*

b. *Quadrangulate*, four-cornered; as *Cactus tetragonus.*

c. *Quinqueangulate;* as in *Cactus pentagonus.*

d. *Hexangulate*, six-cornered; as *Cactus hexagonus.*

e. *Multangulate*, many-cornered; as *Cactus cereus.*

6. *Obtusangulate*, obtuse-angled; as in *Scrophularia nodosa.*

7. *Acutangulate*, acute-angled; as in *Scrophularia aquatica.*

8. *Triquetral*, three-sided, when there are three flat sides, forming acute angles; as *Hedysarum triquetrum, Viola mirabilis, Carex acuta.*

9. *Tetraquetral*, four-sided; as in *Hypericum quadrangulare*, *Monarda fistulosa*, *Mentha officinalis*.

10. *Membranaceous*, leaf-like; as in *Cactus phyllanthus*.

11. *Alate*, when the edges or angles expand into leaf-like borders; as in *Onopordium acanthium*, and *Lathyrus latifolius*.

12. *Articulate*, jointed; as *Cactus flagelliformis*, and *Lathyrus sylvestris*.

13. *Nodose*, knotty, divided at intervals by swellings; as in *Scandix nodosa*, *Geranium nodosum*.

14. *Enodus*, without knot.

From the *direction*, the caulis is,

15. *Rectus*, erect, when it ascends almost perpendicularly; as in the firs, *Chenopodium scoparium*, &c.

16. *Strictus*, straight, perpendicular; as in *Alcea rosea*.

17. *Obliquus*, oblique; as in *Solidago mexicana*.

18. *Adscendens*, ascending, when its lower portion forms a curve, the convexity of which is towards the earth, or rests upon it, and the summit rises; as exemplified in many grasses, *Trifolium pratense*, *Hedysarum onobrychis*.

19. *Descendens*, or *Declinatus*, the reverse of the former, forming an arch, towards the ground; as in *Pancratium declinatum*, *Ficus carica*.

20. *Nutans*, or *cernuus*, nodding, when bent towards the summit; as in *Convallaria polygonatum*.

21. *Procumbens*, or *Prostatus*, lying on the earth; as *Veronica officinalis*.

22. *Decumbens*, rising a little, and then turning towards the ground; as *Thymus serphyllum*.

23. *Repens*, creeping and sending radicles into the ground; as *Trifolium repens*, and *Gnaphalium repens*.

24. *Flexuosus*, zigzag; as in *Celastrus buxifolius*, and *Solidago flexicaulis*.

25. *Radicans*, sending fibres which take root in the earth; as in *Ficus indica*.

26. *Sarmentosus*, trailing, or sending off a runner, which fixes on neighbouring bodies; as in *Hedera helix*.

27. *Stoloniferus*, sending off radicating stolos; as in *Agrostis stolonifera*, and *Fragaria vesca*.

28. *Scandens*, climbing, furnished with tendrils; as in *Solanum dulcamara*, and *Cobæa scandens*.

29. *Volubilis*, twining, winding itself spirally round any other plant or body.

a. *Dextrorsum*, when from right to left; as in *Phaseolus multiflorus*, and *Convolvulus*.

b. *Sinistrorsum*, in the opposite direction, or following the apparent motion of the sun; as in *Lonicera periclimenum*, and *Humulus lupulus*.

30. *Laxus*, bent by the lightest wind; as in *Secale cereale*, and *Juncus bufonius*.

31. *Rigidus*, breaking when lightly bent; as in *Boerhaavia scandens*.

When *clothed* with any kind of appendage, the stem is designated by a term expressive of this; thus,

1. *Caulis foliosus*, when leafy; as in *Melissa officinalis*.

2. *Aphyllus*, when without leaves; as in *Asphodelus fistulosus*.

3. *Squamosus*, scaly; as in *Orobanche major*.

4. *Stipulatus*, when furnished with stipulæ; as in *Cystus helianthemum*, and *Geranium terebinthinaceum*.

5. *Imbricatus*, tiled or covered with little scales; as in *Crassula imbricata*, and *Aloe viscosa*.

6. *Vaginatus*, sheathed, embraced by the base of a leaf as by a sheath; as in *Canna indica*, and *Arundo donax*.

7. *Bulbiferus*, bulb-bearing, when studded with bulbs in the axilla of the leaves; as in *Lilium bulbiferum*.

8. *Nudus*, naked, without leaf, scale, or other covering; as in *Cuscuta europea*.

From its mode of *branching*, the stem is distinguished into,

1. *Simplex*, having few branches; as in *Campanula perfoliata*, and *Verbascum thapsus*.

2. *Simplicissimus*, without branches; as in *Orobanche americana*, and *Campanula barbata*.

3. *Prolifer*, shooting off new branches from the tops of the former ones; as in *Dracena draco*.

4. *Dichotomus*, forked, always divided into pairs; as in *Horanthus europæus*, and *Valeriana locusta*.

5. *Ramosus*, branched; as in *Rosmarinus officinalis*.

6. *Ramosissimus*, having many branches; as *Chenopodium scoparia*, *Ulmus*, *Grossularia*, &c.

7. *Paniculatus*, paniculate; as in *Crambe tataria*.

From the *pubescence* and *armature*, or defences, into,

1. *Spinosus*, when furnished with sharp spines; as in *Prunus spinosa*, and *Mespilus oxyacantha*.

2. *Aculeatus*, prickly, when covered with sharp-pointed bodies; as in *Rosa centifolia*.

3. *Cetaceus*, bristly, when the armature consists of brushes of minute bristles; as in *Cactus flagelliformis*.

4. *Ramentaceus*, ramentaceous; as in *Erica ramentacea*.

5. *Pilosus*, hairy, the pubescence consisting of long hairs; as in *Hieraceum pilocella*, *Salvia pratensis*.

6. *Muricatus*, or *hispidus*, when the hairs are stiff or bristly; as in *Borago officinalis*, and *Echium vulgare*.

7. *Tomentosus*, downy; as in *Verbascum thapsus*, and *Geranium rotundifolium*.

8. *Villosus*, shaggy; as in *Stachys germanica*, and *Veronica villosa*.

9. *Lanatus*, woolly, when the hairs are long and matted; as in *Stachys lanata*, and *Ballote lanata*.

10. *Sericus*, silky, when the hairs are shining and silky.

Instead of pubescence, the covering is in some instances either a dry powdery, or a moist, excretion; and hence, the stem is denominated either,

1. *Incanus*, or *pruinosus*, when covered with a fine white dust; as the *Atriplex portulacoides*.

2. *Farinosus*, mealy; as the *Primula farinosa*.

3. *Glaucus*, of a sea-green colour; as *Ricinus ficinalis*.

4. *Viscidus*, viscid, covered with a resinous exudation; as in *Lychnis viscaria*.

5. *Glutinosus*, glutinous, when the exudation is adhesive and soluble in water; as in *Primula utinosa*.

The primary division of a stem is into *lateral ems* or *branches*. These are variously distinguished,

From their *situation*, into,

1. *Opposite*, when one branch stands on the opposite side of the stem to another, and their bases are nearly on the same plane; as in *Mentha arvensis*.

2. *Alternate*, one opposite to another, alternately; as in *Althæa officinalis*.

3. *Verticillate*, when more than two proceed from a centre, like the spokes of a wheel; as *Pinus abies*.

4. *Scattered*, when given off from the stem in any indeterminate manner.

From their *direction*, the branches, or rami, are termed,

1. *Patentes*, spreading, when the angle formed by the branch and the upper part of the stem is obtuse; as in *Galium mollugo*.

2. *Patentissimi*, proceeding at a right angle from the stem, or horizontally; as in *Asparagus officinalis*.

3. *Brachiati*, brachiate, spread in four directions, crossing each other alternately in pairs; as *Syringa vulgaris*.

4. *Deflexi*, bending downward from the stem, in an arched or curved direction; as in *Pinus larix*.

5. *Reflexi*, hanging almost perpendicularly from the stem; as in *Salix babylonica*.

6. *Retroflexi*, turned backward; as in *Solanum dulcamara*.

7. *Introflexi*, bent inward, when the tops tend towards the stem; as in *Populus dilatata*.

8. *Fastigiati*, when the tops of the branches, from whatever part of the stem they spring, rise nearly to the same height; as in *Chrysanthemum corymbosum*, and *Dianthus barbatus*.

9. *Virgati*, weak and long; as in *Salix viminalis*.

10. *Appressi*, approximated, when nearly parallel and close to the stem; as in *Genista tinctoria*.

11. *Fulcrati*, supported or propped, when they project nearly horizontally, and give out root-like shoots from the under side, which, extending until they reach the ground, take root, and serve as props to the branches; as in *Ficus religiosus*.

CAULIS FLORIDA. Cauliflower.

CAULO'DES. (From *caulis*, a stem.) The name given by Pliny to cabbage.

CAU'MA. (*a*, *atis*. n. Καυμα, heat; from καιω, to burn.) Burning heat; febrile heat.

Cause. See *Ætiology*.

CAUSO'DES. (From καιω, to burn.) Ardent — καυσωδης πυρετος, an ardent fever; the same with *causus*.

Caustic. See *Causticum*.

CAUSTIC ALKALI. A pure alkali. See *Alkali*.

Caustic barley. See *Cevadilla*.

Caustic, lunar. See *Argenti nitras*.

Caustic volatile alkali. See *Ammonia*.

CAUSTICITY. A body which has the properties of a caustic is said to possess causticity.

CAU'STICUM. (*um*, *i*. n.; from καιω, to burn: because it produces effects on the animal body analogous to those of fire.) A caustic. 1. A substance which has so strong a tendency to combine with organised substances, as to destroy their texture. The caustics in most common use are the lunar caustic, or nitrate of silver, and the caustic potash.

2. An hypothetical body, imagined by Mayer as the cause of causticity.

Causticum americanum. See *Veratrum sabadilla*.

CAUSTICUM ANTIMONIALE. Muriate of antimony.

Causticum arsenicale. See *Arsenical caustic*.

Causticum commune fortius. See *Potassa cum calce*.

Causticum lunare. See *Argenti nitras*.

CAU'SUS. (*us*, *i*. m. Καυσος; from καιω, to burn.) An ardent fever. The opinions of medical critics have been divided as to the precise nature of the fever called καυσος by the Greeks. The Greek writers, from Hippocrates downwards, give nearly a similar account of it. Aretæus has left a very distinct description of it. The principal symptoms, as stated by that elegant writer, are a pungent and subtile heat, especially in the internal parts; great heat of the breath; desire of cold air; dryness of the tongue, lips, and skin; coldness of the extremities; the urine loaded with bile; watchfulness; quick, small, and weak pulse; eyes clear, splendid, and reddish; good complexion of the countenance. If the disease go on increasing, delirium supervenes, with oblivion of every thing; the respiration is hurried; the hands are cold, except the palms, but these are burning hot; the nails are livid, and there is a moisture on the neck and forehead. The last stage is that of complete collapse; the body is covered with a cold sweat, which is uncontrollably profuse; the breath is cold: but, amid this exhaustion of all the corporeal powers, the mind recovers its energy; the faculties become subtle and the senses acute; and the dying man appears as if endowed with the spirit of prophecy. (*De Causis et Signis acutorum Morborum*, lib. ii. c. 4. ed. Wigan.)

According to Alexander of Tralles there are two kinds of *causus*— the true, which is marked by intense thirst, bilious stools, and a rough and black tongue; and the *spurious*, in which the thirst is moderate, the tongue not black, and the stools not bilious: the former was ascribed to the predominance of a bilious, and the latter of a pituitous, humour. The Arabian writers describe the causus as bearing considerable resemblance to a tertian, but with more intense paroxysms, and no complete intermission, but a remission merely of the symptoms. According to Albucasis, the disease is caused by heated bile, accumulated in the veins near the heart, stomach, or liver. On the whole, the most probable conjecture seems to be, that the *causus* is identical with that variety of the malignant remittent of warm climates, which is called

ardent, or *burning remittent*; and which, though essentially of the remittent type, undergoes little actual remission on account of the intense visceral inflammation with which it is complicated. (See *Febris remittens.*) It must be acknowledged, however, that the προσωπου ευχροια — the good complexion of the countenance mentioned by Aretæus — is not very favourable to this conjecture. Some writers, who have supposed that the *causus* of the Greeks was *synocha*, or inflammatory fever, are evidently quite wide of the mark, and indeed have probably been deceived by the name of the disease without referring to the descriptions of the ancients.

Cauterets. A village in the department of the Hautes Pyrenées, celebrated for its warm sulphureous springs.

CAUTERIZATION. (*Cauterizatio*; from *cauterium*, a cautery.) The application of a cautery.

CAUTERY. (*Cauterium, ii.* n.; from καιω, to burn.) Cauteries were divided, by the older surgeons, into *actual* and *potential*: the former name was applied to a red hot iron; the latter, to what is now called a caustic. See *Causticum.*

Cava vena. See *Vena cava.*

Cave'rna. (*a, æ.* f.; from *cavus*, hollow.) A cavern: the pudendum muliebre is so called by some writers.

Caverno'sus. (From *caverna.*) Formed of large cells. See *Corpus cavernosum*, and *Sinus cavernosus.*

Caviare. See *Acipenser.*

Cavi'cula. (Diminutive of *cavilla.*) See *Cavilla.*

Cavi'lla. (From *cavus*, hollow.) 1. The malleolus, or protuberance of the ankle. — *Forestus.*

2. A name given by Haly Abbas to the cuneiform bone. — *Schneider.*

CAVITY. (*Cavitas, atis.* f.; from *cavus*, hollow.) A term applied generally to the hollow parts of the body; thus we speak of the *abdominal cavity*, the *thoracic cavity*, the *articular cavities*, &c. The cavities of bones are usually named according to some real or fancied resemblance; thus we have *glenoid cavities*, *cotyloid cavities*, *fossæ*, *sinuses*, &c.

Cayenne pepper. See *Capsicum.*

CEANO'THUS. (*us, i.* m.; from κεανωθος, quia κεει ανωθεν, because it pricks at the extreme part.) 1. A genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.*

2. An ancient name of the *Serratula arvensis.*

Ceanothus americanus. The leaves of this plant are called *New Jersey tea*, and are used in some parts of North America as a substitute for the Chinese leaf. The root is said to be astringent, and yields a cinnamon-coloured dye.

Ceber. (Arabic.) The Lignum aloes.

Cebi gallinæ. A hen's liver roasted.

Cebipira. A large Brazilian tree, decoctions of the bark of which are used in baths and fomentations, to relieve rheumatic pains in the limbs, and cutaneous diseases.

Cecryphalon. Κεκρυφαλον. The same as *cecryphalos.*

Cecryphalos. (Κεκρυφαλος, the net with which women confined their hair.) The name given by the Greek anatomists to the *reticulum*, or second stomach of ruminating animals.

Cedar. See *Pinus cedrus.*

Ce'dma. (Κεδμα; from κεδαζω, or κεδαω, for σκεδαζω, to disperse.) A name given by the Greeks to chronic rheumatism of the joints, especially the hip.

Cedrinum lignum. Cedar wood. See *Pinus cedrus.*

Ce'drinus. Appertaining to the cedar, as *oleum cedrinum*, oil of cedar, &c.

Cedrinum oleum. See *Oleum cedrinum.*

Cedrinum vinum. See *Vinum cedrinum.*

Cedri'tes. (From κεδρος, the cedar-tree.) Wine in which the resin which distils from the cedar-tree has been steeped. It was formerly employed as a vermifuge.

Cedria. *Cedrium. Cedreleum.* This term seems to have been applied to several substances, but most generally to the resin of the cedar.

Cedrome'lla. The citron.

Cedrone'lla. Turkey balsam.

Cedro'stis. (*is, is.* f. κεδρωστις.) A Greek name of the white bryony.

Ce'drula. A name of the *Juniperus oxycedrus*, or berry-bearing cedar.

Ce'drus. (*us, i.* f. κεδρος; from the Hebrew *keder.* See *Pinus cedrus.*

Cedrus americana. The arbor vitæ.

Cedrus bacci'fera. The *Juniperus oxycedrus.*

Ceiria. (Κειρια; from κειρω, to abrade.) The tape-worm: so called from its abrading the intestines. — *Galen.*

Cellandine. See *Chelidonium.*

Cela'strus. Κελαστρος. 1. The Greek name of a plant supposed to be the *Rhamnus alaternus.*

2. The name of a genus of plants of the Class *Pentandria*, and Order *Monogynia.*

Cela'stus. See *Celastrus.*

Celauritis. An alchemical name of litharge.

CE'LE. (From κηλη.) A tumour caused by the protrusion of any soft part: a hernia. Hence the compound terms *enterocele*, *epiplocele*, &c.

Celery. See *Apium graveolens.*

Cell. *Cella.* See *Cellula*, and *Loculamentum.*

Cells, bronchial. See *Pulmo.*

Cells, mastoid. See *Auris.*

Ce'llula. (*a, æ.* f.; diminutive of *cella*, a cell.) A little cell, or cavity.

Cellulæ mastoideæ. See *Temporal bones.*

Ce'llular. *Cellularis.* Composed of little cells.

Cellular membrane. See *Membrana.*

Cellular texture. See *Membrana.*

Cellular tissue. See *Membrana.*

Cellular web. See *Membrana.*

Celoto'mia. (*a, æ.* f.; from κηλη, hernia, and τεμνω, to cut.) The operation for a strangulated hernia, by cutting.

Ce'lsa. A barbarous term in use among the Paracelsists. Ruland defines it "musculus vitæ, pulsus per singulas partes corporis oberrans," or what is called in common language

the "life blood." Paracelsus denotes by it some cutaneous disease supposed to depend on a morbid vapour striving to escape from the body.

Cembra. See *Pinus cembra.*

CEMENT. Chemists call by this name any substance employed to unite things together by adhesion, as lutes, glues, solders, &c.

CEMENTATION. A chemical process, which consists in surrounding a body in the solid state with the powder of some other bodies, and exposing the whole for a time, in a close vessel, to a degree of heat not sufficient to fuse the contents. Thus iron is converted into steel by cementation with charcoal; green bottle glass is converted into porcelain by cementation with sand, &c.

CEMENTE'RIUM. An aludel.

CE'NCHRIAS. *Cenchris. Cenchrites.* (From κεγχρος, a millet seed, so called from its resemblance to that seed.) A species of herpes.

CENEANGEI'A. (From κενος, empty, and αγγος, a vessel.) Emptiness of the vessels of the body.

CE'NEON. (Κενεων; from κενος, hollow.) 1. The hollow of the flank between the false ribs and the ilium. — *Hippocrates.* — *Galen.*

2. According to the editors of the Castelli, Moschion uses this word to designate the hollow of the navel in children.

CENIFICATUM. *Cenificatum.* A calx. — *Ruland.*

CENIOTE'MIUM. A purging remedy, formerly used in the venereal disease, supposed to be mercurial.

CENIPLAM. *Cenipotam. Cenigdam cenigoam.* An instrument used to open the head in epilepsy! — *Ruland.*

CENOBIUM. (Κοινοβιον, a society, especially of monks.) This name is given by Mirbel to a fruit consisting of several pericarps, without valves or sutures, styles or stigmata, united at the base; as in the labiated plants. Each of the pericarps is called *eremus*, a solitary.

CENO'SIS. (From κενοω, to empty.) Synonymous with evacuation.

CENO'TICUS. (Same etymon.) Cenotic, evacuant.

CENTAU'REA. (*ea, æ.* f.; Κενταυριον, so called from *Chiron*, the centaur, who is said to have employed one of its species to cure himself of a wound accidentally received, by letting one of the arrows of Hercules fall upon his foot.) The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia frustanea.*

CENTAUREA BEHEN. The *Behmen abiad* of the Arabians. The officinal *behen album. Jacea orientalis patula. Raphonticoides lutea.* White behen. This plant grows on Mount Libanus. The root is regarded in the east as a tonic. This is not the same with the *behen blanc* of the French, which is the root of the *cucubalus behen.*

CENTAUREA BENEDICTA. The systematic name of the blessed or holy thistle: called also, *Carduus benedictus* and *Cnicus sylvestris.*

Centaurea benedicta — calycibus duplicato-spinosis lanatis involucratis, foliis semi-decurrentibus denticulato-spinosis of Linnæus. This plant, a native of Spain, and some of the Archipelago islands, obtained the name of Benedictus, from its being supposed to possess extraordinary medicinal virtues. In loss of appetite, where the stomach has been injured by irregularities, its good effects have been frequently experienced. It is a strong bitter, and is tonic and astringent. Bergius considers it as antacid, corroborant, stomachic, sudorific, diuretic, and eccoprotic. Camomile flowers, are now generally substituted for the *carduus benedictus*, and are thought to be of at least equal value.

CENTAUREA CALCITRA'PA. The systematic name of the common star-thistle, or star-knapweed. Called also, *Calcitrapa, Carduus stellatus*, and *Jacea ramosissima, stellata*, and *rupina.* This plant, the *Centaurea — calycibus subduplicato-spinosis, sessilibus, foliis pinnatifidis, linearibus dentatis, caule piloso,* of Linnæus, is a strong bitter. The juice, extract, or infusion, is said to cure intermittents; and the bark of the root, and the seeds, have been recommended in nephritic disorders, and in suppression of urine. It is now little used.

CENTAUREA CENTAURIUM. The greater centaury; also named, *Rhaponticum vulgare, Centaurium magnum*, and *Centaurium majus.* The root of this plant was formerly used as an aperient and corroborant, in alvine fluxes. It is now discarded from the Materia Medica of this country.

CENTAUREA CYANUS. The systematic name of the blue-bottle, or corn-flower plant. *Cyanus* of the Pharmacopœias. The flowers of this plant, *Centaurea — calycibus serratis; foliis linearibus, integerrimis, infimis dentatis,* of Linnæus, were formerly in frequent use; but their antiphlogistic, antispasmodic, cordial, aperient, diuretic, and other alleged properties, are now disregarded.

CENTAUREA SOLSTITIALIS. St. Barnaby's thistle: also named, *Calcitrapa officinalis, Carduus stellatus luteus, Carduus solstitialis, Jacea stellata, Jacea lutea capite spinoso minori*, and *Leucanthe veterum.* It has been recommended as an anticteric, anticachectic, and lithontriptic; but is, in reality, only a weak tonic.

Centaurii cacumina. See *Chironia centaurium.*

CENTAURIOI'DES. (From κενταυριον, and ειδος, resemblance.) See *Gratiola officinalis.*

CENTAURIS. Κενταυρις. The lesser centaury. — *Theophrastus.*

CENTAURIUM. Κενταυριον. The herb centaury. See *Centaurea.*

Centaurium magnum. See *Centaurea centaurium.*

Centaurium majus. See *Centaurea centaurium.*

Centaurium minus. See *Chironia centaurium.*

Centaurium parvum. See *Chironia centaurium.*

Centaury. See *Chironia.*

CENTE'RIA. Κεντερια. The name given by Theophrastus to the *Hypericum androsæmum.*

CENTIGRAMME. A French weight; the 100th part of a *gramme.*

CENTILITRUM. An old liquid measure, equal to the 100th part of the Greek Λιτρα or pound.

Centimo'rbia. (*a*, *æ*. f.; from *centum*, a hundred, and *morbus*, a disease: so named, from its supposed efficacy in the cure of a multitude of disorders.) The *Lysimachia nummularia*, or moneywort.

Centine'rvia. (From *centum*, and *nervus*, a nerve or sinew; so called from the many ribs upon its leaf.) See *Plantago*.

Centinodia. See *Centumnodia.*

Centra'tio. (From *centrum*, a centre.) Paracelsus expresses by this term the degeneration of a saline principle, which thereby contracts a corrosive and ulcerating quality. Hence he calls *centrum salis* the principle and cause of ulcers.

Centres, nervous. The brain, spinal cord, and sympathetic ganglia are so called.

Ce'ntrium. (Κεντριον; from κεντεω, to prick.) The epithet of a plaster recommended by Galen against stitches in the side.

Centrum commune. The solar plexus. See *Nervous system.*

Centrum nerveum. The middle tendinous portion of the diaphragm. See *Diaphragm.*

Centrum ovale. This name was given by Vieussens to the oval expanse of white matter displayed when the hemispheres are removed down to the level of the corpus callosum; and this is generally called *Centrum ovale Vieussenii*. It has been said that this is not the part of the brain to which Vieussens gave the name of *centrum ovale*; but it unquestionably is so, and is figured as such in the plates accompanying the work of Vieussens entitled *Neurologia Universalis*. Again, if the upper part of the brain be removed by an horizontal section, at a level a little above that just mentioned, there appears in each hemisphere a smaller oval expanse of white matter, which has been described by Vicq D'Azyr, and is called the small, or lateral centrum ovale, or *centrum ovale of Vicq D'Azyr.*

Centrum tendinosum. See *Diaphragm.*

Centumno'dia. (*a*, *æ*. f.; from *centum*, a hundred, and *nodus*, a knot: so called from its many knots or joints.) *Centinodia.* See *Polygonum aviculare.*

Centu'nculus. (From *cento* a patched garment on account of its woolly ragged appearance.) The cud-weed. See *Gnaphalium.*

CE'PA. (*a*, *æ*. f.) An onion. See *Allium cepa.*

Cepa ascalonica. The chalot.

Cepæ'a. The *Sedum cepæa* of Linnæus.

Cephaëlis. See *Ipecacuanha.*

CEPHALÆ'A. (From κεφαλη, the head.) Violent and inveterate pain in the head.

CEPHALALGIA. (*a*, *æ*. f.; from κεφαλη, the head, and αλγος, pain.) This term has been generally applied to a common headach, while the term *cephalæa*, has been used to designate that obstinate and inveterate kind of headach, which in some cases resists all means of cure.

Cephala'rticus. (From κεφαλη, the head, and αρτιζω, to make perfect.) Having the property of purging the head as errhines, &c. Kraus says it is a corruption of *Cephalo-cathartica.*

CEPHALIC. (*Cephalicus*. From κεφαλη, the head.) Pertaining to the head. 1. In *Pharmacy*, a variety of medicines are so called, as being adapted for the cure of disorders of the head. Of this class are the snuffs, which produce a discharge from the mucous membrane of the nose, &c.

2. In *Anatomy*, applied to a vein of the arm which the ancients supposed to have some particular connexion with the head. Chaussier calls the internal jugular vein the *cephalic vein*; and the common carotid artery, the *cephalic artery.*

Cephalic vein. (*Vena cephalica*; so called because the head was supposed to be relieved by opening it.) The anterior or outermost vein of the arm, which receives the cephalic of the thumb.

Cephalic powder. See *Pulvis cephalicus.*

Cephalic snuff. An errhine powder, the active ingredient of which is asarabacca.

Cephali'tis. (From κεφαλη, the head.) A term that has been applied to inflammation of the brain; but improperly, for it would signify inflammation of the whole head, not of the brain in particular. See *Encepalitis.*

Cephalo'dium. (*um*, *i*. n.; from κεφαλη, a head, and ειδος, resemblance.) The orbicular and convex conceptaculum of some lichens is so called; as in the genus *stereocaulon.*

Cephaloi'des. (Same etymon.) Cephaloid. Applied in botany synonymously with *capitate.*

Cephalo'meter. (*Cephalometrum*; from κεφαλη, a head, and μετρον, a measure.) An instrument formerly used to estimate the size of the fœtal head during parturition.) It is now laid aside; the fingers are the best cephalometer.

Cephalo'nosus. (From κεφαλη, the head, and νοσος, a disease.) This name has been given to cephalic fever, or that kind of fever in which the brain is particularly affected.

Ce'phalo-pharynge'us. (From κεφαλη, the head, and φαρυγξ, the pharynx.) See *Constrictor pharyngis inferior.*

CEPHALO'PODA. (From κεφαλη, a head, and πους, a foot.) An order of molluscous animals, in which the mouth is surrounded with locomotive tentacula. See *Animal Kingdom.*

CEPHALOPO'NIA. (*a*, *æ*. f.; from κεφαλη, the head, and πονος, pain.) Pain or heaviness in the head.

Cepini. Vinegar.

Cepula. Large myrobalans. — *Nicolaus Myrepsus.*

CE'RA. (*a*, *æ*. f. Κηρος.) Wax. A fatty substance which, when pure, is white, pellucid, destitute of taste, but possessing often a slight smell, which, however, is not essential to it. Its specific gravity is from ·960 to ·966. At 32° it is brittle; but becomes soft and flexible when heated to 86°, and melts at 155°. It is insoluble in cold alkohol and ether, but partly soluble in hot alkohol, and boiling alkohol dissolves a twentieth part of its weight. It is soluble, to a considerable extent, in the volatile and fixed oils. It is capable of being made into a soap, which, however, is always very hard and not easily soluble in water, and which is decomposed by acids

eaving the wax almost unaltered. It is soluble n liquid ammonia, but separates from it on the ddition of water. It is converted into oxalic cid, though with some difficulty, by the action f nitric acid, and is dissolved by the aid of heat n concentrated sulphuric acid, from which it is leposited on cooling.

Wax has been found, like the oils and fats, to e composed of two substances which differ rom each other only in their fusibility and heir solubility in alkohol, and which are called Cerine and Myricine.

The *Cerine* may be separated from the *Myricine* in the same way as the elaine of unctuous odies is separated from the stearine. Cerine is nalogous to elaine, and myricine corresponds o stearine.

The properties of *Cerine* are almost exactly the same as those of wax. Its specific gravity is ·969. According to John, it melts at 109°; but, according to Boudet and Boissenot, at 145°, a result which certainly does not agree very well with the other. It is soluble in sixteen times its weight of boiling alkohol, in twenty-four times its weight of cold ether, and in a smaller quantity of hot ether, from which it separates in part as it cools. When subjected to dry distillation, it yields margaric acid and empyreumatic oil, but no sebacic (benzoic) acid. By its saponification, we obtain from it margarate of potash, and a substance resembling wax, which Boudet and Boissenot named *Cerüine*. This substance does not melt till heated above 158°, and may be distilled almost without alteration. It is insoluble in cold alkohol, and very slightly so in hot alkohol, forming a solution which, as it cools, becomes gelatinous. It cannot be converted into soap.

Myricine is not soluble in less than 200 times its weight of boiling alkohol of specific gravity ·833, and 123 times its weight of pure alkohol. It is soluble in 99 times its weight of cold ether. Its specific gravity is 1·000. It fuses, according to John, at from 95° to 100°, but according to Boudet and Boissenot at 149°; and, after being melted, it is softer than wax, although before it was much harder. When subjected to dry distillation, it passes over into the receiver almost unaltered. It does not form a soap with pure potash.

It is with wax that bees construct the cells intended to receive their honey or protect their larvæ. It was formerly thought that the wax was kneaded with the pollen of plants which the bees bring home attached to the brushes of their feet; but this is a mistake, for even crude wax does not show any thing by the microscope similar to the grains of pollen, and on analysis we do not detect in it the presence of either resin, or gluten, or water, all of which are abundant in pollen.

Huber and some observers following in his steps have gone yet farther. They have established as the result of direct observation, that the only purpose of the pollen which bees collect is, to form the paste with which they nourish their larvæ; for, having fed bees with sugar alone, and prevented them from quitting the hive, they, nevertheless, continued to construct cells. According to this experiment, it would follow that wax and honey are the produce of two different elaborations of sugar. M. Raspail objects to this experiment, that the pollen may be subjected in the digestive organs of the bees to an action by which, without changing its essential nature, the wax which it contains is extracted, and that, they may preserve this substance in their glands or viscera for a longer or shorter time after its extraction, until they require it for the purposes of their admirable architecture; and that it was with materials thus reserved that they continued to build during the whole of the short time that they were confined.

However this may be, the honey is separated from the wax of the combs by compression. The honey runs out, and the wax is left in cakes, which are afterwards thrown into boiling water. The impurities are skimmed off, and the wax is removed from the surface after the water has cooled. In this state wax possesses a smell and a colour which are owing to its still containing a portion of honey. It may be bleached by exposing it in thin plates to the dew and the sun, or by the action of chlorine; but it has been remarked, that candles made of wax bleached by chlorine, are of inferior quality. — *Raspail.*

Bees' wax is the only kind which has been subjected to chemical analysis. It consists, according to

	Carbon.	Oxygen.	Hydrogen.
Gay Lussac and Thenard, of	81·784	5·544	12·672
Saussure	81·587	4·554	13·859
Ure	80·69	7·94	11·37

Thus it appears to contain less oxygen than any other of the fatty substances except cholesterine; and, accordingly, it is very solid and very little soluble in alkohol.

Vegetable Wax. — Wax is also found as an exclusively vegetable product. Proust asserts, that the bloom on fruit, as well as the varnish on leaves, consists of wax; but this needs confirmation. It is certain, however, that some vegetables contain it, as the *Myrica cerifera*, *Ceroxylum andicola*, *Palma carnauba*, and *Galactodendron utile*. From these the wax may be extracted by boiling in water.

Wax is employed for various economical purposes. In medicine it is used for making plasters, cerates, and bougies.

Cera alba. White wax; bees' wax bleached. See *Cera*.

Cera flava. Yellow wax. See *Cera*.

Ceræ'æ. (Καραῖαι; from κερας, a horn.) The cornea of the uterus. — *Rufus Ephesius.*

Cera'mium. A Greek measure of about nine gallons.

Cerani'tes. (Κερανιτης; from κερανυμι, to temper together.) A pastil mentioned by Galen, consisting of orpiment, birth-wort, iris, galls, alum, chalcitis, oxide of copper, scales and flowers of brass, resin, and vinegar. It was, according to Galen, of manifold use.

Ce'ras. (From κερας, a horn; so named from its shape.) The wild parsnep.

Cerasa nigra. See *Prunus avium.*

Cerasa rubra. See *Prunus cerasus.*

CERASIA'TUM. (From *cerasus*, a cherry.) The name of a purging medicine mentioned by Libavius: so called because cherries are an ingredient in it.

CE'RASIN. The name given by Dr. John, of Berlin, to those gummy substances which swell in cold water, but do not readily dissolve in it. Cerasin is soluble in boiling water, but separates as a jelly when the water cools. Water, acidulated with sulphuric, nitric, or muriatic acid, by the aid of a gentle heat, forms a permanent solution of cerasin. Gum tragacanth is the best example of this species of vegetable product.

CERA'SIOS. (From *cerasus*, a cherry.) The name of an ointment mentioned by Mesue; there was a greater and a lesser cerasios.

CE'RASUS. (*us*, *i.* f. Κερασος; from Κερασουντη, a town in Pontus, whence Lucullus first brought them to Rome: or from κηρ, the heart; from the fruit having a resemblance to it in shape and colour.) The cherry-tree. See *Prunus cerasus*.

Cerate. See *Ceratum*.

CERA'TIA. This name has been given to the *Ceratonia siliqua*, and several other plants.

CERATIA DIPHYLLUS. A name of the plant from which the gum anime exudes.

Ceraticum. See *Ceratonia siliqua*.

CERA'TIO. A term used by the alchemists to designate the covering of a body with wax; or the reduction of a body to a state in which it might be melted like wax; or the fixation of mercury.

CERATI'TES. The fossil unicorn. See *Unicornu*.

CERA'TIUM. Κερατιον. 1. The pod of a tree. 2. An ancient weight equal to four grains.

CE'RATOCE'LE. (From κερας, a horn, and κηλη, a hernia.) When the outer layer of the cornea is destroyed by ulceration, and the inner layer, still entire, is protruded by the pressure of the aqueous humour, it forms what is called a *ceratocele*, or hernia of the cornea.

CE'RATO-GLO'SSUS. (From κερας, a horn, and γλωσσα, a tongue.) A muscle, so named from its shape, and insertion into the tongue. See *Hyoglossus*.

Cerato hyoideus. See *Stylo-hyoideus*.

CERATOI'DES. (From κερας, horn, and ειδος, appearance.) Horn-like. The Greek epithet of that part of the eye which we call the cornea.

CE'RATOMALA'GMA. (From κηρος, wax, and μαλαγμα, a poultice.) A cerate. See *Ceratum*.

CERATO'NIA. (*a*, *æ.* f. Probably the Κερατωνια of Galen and Paulus Ægineta: so called from its horn-like pod.) The name of a genus of plants. Class, *Polygamia*; Order, *Triœcia*.

CERATONIA SI'LIQUA. The systematic name of the plant which affords the sweet pod. Called also *Ceratium*, *Ceratia*, and *Siliqua dulcis*. *Caroba*. The carob tree. St. John's Bread. This plant is a native of Europe and Asia. The pods are about four inches in length, and as thick as one's finger, compressed and unequal, and mostly bent; they are used as food both for man and beast; and the sweet brown pulp which they contain, is given, in the form of decoction, as a pectoral in asthmatic complaints and coughs.

CE'RATOTOME. (*Ceratotomus*, *i.* m.; from κερας, a horn, and τεμνω, to cut.) Baron Wenzel gave this name to the knife with which he divided the cornea of the eye.

CERA'TUM. (*um*, *i.* n.; from *cera*, wax, because its principal ingredient is wax.) Cerate.

1. A composition of wax, oil, or lard, with or without other ingredients. The obsolete synonyms are *cerelæum*, *ceroma*, *ceronium*, *cerotum*, *ceratomalagma*. The wax which enters into the composition of cerates is the ingredient to which they owe their consistence, which is intermediate between that of plasters and that of ointments; though no very definite rule for this consistence is, in fact, either given or observed.

2. Common cerate. See *Ceratum simplex*.

Ceratum album. See *Ceratum cetacei*.

CERATUM CALAMI'NÆ. *Ceratum lapidis calaminaris*, *Ceratum epuloticum*. Calamine cerate. Take of prepared calamine, yellow wax, of each half a pound; olive oil, a pint. Mix the oil with the melted wax; then remove it from the fire; and, as soon as it begins to thicken, add the calamine, and stir it constantly until the mixture becomes cold. A composition of this kind was first introduced under the name of Turner's cerate. It is well calculated to promote the cicatrisation of ulcers.

CERATUM CANTHA'RIDIS. Cerate of blistering fly. Take of spermaceti cerate, six drachms; blistering flies, in very fine powder, a drachm. Having softened the cerate by heat, add the flies, and mix them together.

CERATUM CETA'CEI. *Ceratum spermatis ceti*. *Ceratum album*. Spermaceti cerate. Take of spermaceti, half an ounce; white wax, two ounces; olive oil, four fluid ounces. Add the oil to the spermaceti and wax, previously melted together, and stir them until the mixture becomes cold. This cerate is cooling and emollient; and, applied to excoriations, &c., it may be used with advantage in ulcers, where no stimulating application is required.

CERATUM CI'TRINUM. See *Ceratum resinæ*.

CERATUM CONI'I. Hemlock cerate. R. Unguenti conii, ℔ j. Spermatis ceti, ℥ ij. Ceræ albæ, ℥ iij. Misce. One of the formulæ of St. Bartholomew's hospital, occasionally applied to cancerous, scrofulous, phagedenic, herpetic, and other inveterate sores.

Ceratum epuloticum. See *Ceratum calaminæ*.

Ceratum lapidis calaminaris. See *Ceratum calaminæ*.

Ceratum lithargyri acetati compositum. See *Ceratum plumbi compositum*.

CERATUM PLUMBI ACETA'TIS. *Unguentum cerussæ acetatæ*. Cerate of acetate of lead. Take of acetate of lead, powdered, two drachms; white wax, two ounces; olive oil, half a pint. Dissolve the wax in seven fluid ounces of oil; then gradually add thereto the acetate of lead, separately rubbed down with the remaining oil, and stir the mixture with a wooden slice, until

e whole has united. This cerate is cooling
id desiccative.

CERATUM PLUMBI COMPOSITUM. *Ceratum hargyri acetati compositum.* Compound cerate f lead. Take of solution of acetate of lead, vo fluid ounces and a half; yellow wax, four unces; olive oil, nine fluid ounces; camphire, alf a drachm. Mix the wax, previously melted, ith eight fluid ounces of oil; then remove it om the fire, and, when it begins to thicken, dd gradually the solution of acetate of lead, nd constantly stir the mixture with a wooden ice, until it gets cold. Lastly, mix in the mphire, previously dissolved in the remainder f the oil. Its virtues are cooling, desiccative, nd resolvent. It is an application to superial ulcers, which are inflamed.

CERATUM RESINÆ. *Ceratum resinæ flavæ; eratum citrinum.* Resin cerate. Take of llow resin, yellow wax, of each a pound; ive oil, a pint. Melt the resin and wax togeer, over a slow fire: then add the oil, and rain the cerate, while hot, through a linen oth. Digestive.

CERATUM SABINÆ. Savine cerate. Take of esh leaves of savine, bruised, a pound; yellow ax, half a pound; prepared lard, two pounds. aving melted together the wax and lard, boil erein the savine leaves, and strain through a nen cloth. This article is of late introduction, r the purpose of keeping up a discharge from istered surfaces. It was first introduced by fr. Crowther, and has since been received into tensive use, because it does not produce the conveniences that follow the constant applition of the common blistering cerate. A ick white layer forms daily upon the part, hich requires to be removed, that the cerate ay be applied immediately to the surface from hich the discharge is to be made.

CERATUM SAPONIS. Soap cerate. Take of rd soap, eight ounces; yellow wax, ten unces; semi-vitreous oxide of lead, powdered, pound; olive oil, a pint; vinegar, a gallon. oil the vinegar, with the oxide of lead, over a ow fire, constantly stirring, until the union is mplete; then add the soap, and boil it again a similar manner, until the moisture is enely evaporated; then mix in the wax, previsly melted with the oil. Resolvent; against rofulous tumours, &c. It is a convenient plication in fractures, and may be used as an ternal dressing for ulcers.

CERATUM SIMPLEX. *Ceratum.* Simple cerate. ake of olive oil, four fluid ounces; yellow ax, four ounces: having melted the wax, mix e oil with it.

Ceratum spermatis ceti. See *Ceratum cei.*

CE'RBERUS. (Κερβερος; because, like the g Cerberus, it has three heads, or principal gredients, each of which is eminently active.) fanciful name that has been given to the comund powder of scammony.

CE'RCIS. (Κερκις, the spoke of a wheel; radius of a circle; a weaver's shuttle.) 1. he radial bone of the forearm was anciently called, from its shape, like a spoke.

2. A pestle, from its shape.

CERCO'SIS. (*is, is.* f.; from κερκος, a tail.) 1. A polypus of the uterus.

2. An enlargement of the clitoris.

CE'REA. (*a, æ.* f.; from *cera*, wax.) The *cerumen aurium*, or wax of the ear.

CEREA'LIA. (*Cerealis*, pertaining to corn; from *Ceres*, the goddess of corn and tillage.) All sorts of corn, of which bread or any nutritious substance is made, come under the head of *cerealia.*

CEREBE'LLA URI'NA. Paracelsus thus distinguishes urine which is whitish, of the colour of the brain, and from which he pretended to judge of some of the disorders of that organ.

CERE'BELLUM. (*um, i.* n.; diminutive of *cerebrum.*) The little brain. See *Encephalos.*

CEREBRUM ELONGATUM. The medulla oblongata, and medulla spinalis.

CEREFO'LIUM. (*um, i.* n.; most probably a corruption, of *chærophyllum.*) See *Chærophyllum.*

Cerefolium hispanicum. See *Scandix odorata.*

Cerefolium sylvestre. See *Chærophyllum sylvestre.*

CERELÆ'UM. (*um, i.* n.; from κηρος, wax, and ελαιον, oil.) A cerate, or liniment, composed of wax and oil.

CERE'OLUS. (*us, i.* m.; diminutive of *cereus.*) A wax bougie.

CE'REUS. (*us, i.* m.; from *cera*, wax, because it is made of wax.) A wax bougie.

CEREUS MEDICATUS. A medicated bougie.

CEREVI'SIA. (*a, æ.* f.; *quasi cererisia*, i. e. *cerealis liquor*, from *ceres*, corn, of which it is made.) Any liquor made from corn, especially ale and strong beer.

For the preparation of beer and ale, the grain is malted and boiled, and hops are then added, and the whole fermented. The grain is first steeped for two or three days in water, until it swells, becomes somewhat tender, and tinges the water of a bright reddish brown colour. The water being then drained away, the barley is spread about two feet thick upon a floor, where it heats spontaneously, and begins to grow, by first shooting out the radicle. In this state the germination is stopped by spreading it thinner, and turning it over for two days; after which it is again made into a heap, and suffered to become sensibly hot, which usually happens in little more than a day. Lastly, it is conveyed to the kiln, where, by a gradual and low heat, it is rendered dry and crisp. This is malt; and its qualities differ according as it is more or less soaked, drained, germinated, dried, and baked. In this, as in other manufactories, the intelligent operators often make a mystery of their processes from views of profit; and others pretend to peculiar secrets who really possess none.

Indian corn, and probably all large grain, requires to be suffered to grow into the blade, as well as root, before it is fit to be made into malt. For this purpose it is buried about two or three inches deep in the ground, and covered with loose earth; and in ten or twelve days it springs up. In this state it is taken up and washed, or fanned, to clear it from its dirt; and then dried in the kiln for use.

Barley, by being converted into malt, becomes one fifth lighter, or 20 per cent.; 12 of which are owing to kiln drying, 1·5 are carried off by the steep-water, 3 dissipated on the floor, 3 lost in cleaning the roots, and 0·5 waste or loss.

The degree of heat to which the malt is exposed in this process, gradually changes its colour from very pale to actual blackness, as it simply dries it, or converts it to charcoal.

The colour of the malt not only affects the colour of the liquor brewed from it; but, in consequence of the chemical operation of the heat applied, on the principles that are developed in the grain during the process of malting, materially alters the quality of the beer, especially with regard to the properties of becoming fit for drinking and growing fine.

Beer is made from malt previously ground or cut to pieces by a mill. This is placed in a tun, or tub, with a false bottom; hot water is poured upon it, and the whole stirred about with a proper instrument. The temperature of the water in this operation, called Mashing, must not be equal to boiling; for, in that case, the malt would be converted into a paste, from which the impregnated water could not be separated. This is called Setting. After the infusion has remained for some time upon the malt, it is drawn off, and is then distinguished by the name of Sweet Wort. By one or more subsequent infusions of water, a quantity of weaker wort is made, which is either added to the foregoing, or kept apart, according to the intention of the operator. The wort is then boiled with hops, which gives it an aromatic, bitter taste, and is supposed to render it less liable to be spoiled in keeping; after which it is cooled in shallow vessels, and suffered to ferment, with the addition of a proper quantity of yest. The fermented liquor is beer; and differs greatly in its quality, according to the nature of the grain, the malting, the mashing, the quantity and kind of the hops and the yest, the purity or admixtures of the water made use of, the temperature and vicissitudes of the weather, &c.

Beer well prepared should be limpid and clear, possess a due quantity of spirit, and excite no disagreeable sweet taste, and contain no disengaged acid. By these properties it is a species of vinous beverage, and is distinguished from wine in the strict sense, and other liquors of that kind, by the much greater quantity of mucilaginous matter which it has received by extraction from the malted grains, but which also makes it more nourishing. Brown beer derives its colour from malt strongly roasted in the kiln, and its bitterish taste from the hops. Pale beer is brewed from malt dried in the air, or but slightly roasted, with but little or no hops at all.

Besides the various qualities of malt liquors of a similar kind, there are certain leading features by which they are distinguished, and classed under different names, and to produce which, different modes of management must be pursued. The principal distinctions are into beer, properly so called; ale; table or small beer; and porter, which is termed beer in London. Beer is a strong, fine, and thin liquor; the greater part of the mucilage having been separated by boiling the wort longer than for ale, and carrying the fermentation farther, so as to convert the saccharine matter into alkohol. Ale is of a more syrupy consistence, and sweeter taste; more of the mucilage being retained in it, and the fermentation not having been carried so far as to decompose all the sugar. Small beer, as its name implies, is a weaker liquor; and is made, either by adding a large portion of water to the malt, or by mashing with a fresh quantity of water what is left after the beer or ale wort is drawn off. Porter was probably made originally from very high-dried malt; but it is said that its peculiar flavour cannot be imparted by malt and hops alone.

Mr. Brande obtained the following quantities of alkohol from 100 parts of different species of beer. Burton ale 8·88; Edinburgh ale, 6·2; Dorchester ale, 5·56; the average being = 6·87. Brown stout, 6·8; London porter (average) 4·2; London small beer (average) 1·28.

As long ago as the reign of Queen Anne, brewers were forbid to mix sugar, honey, Guinea pepper, essentia bina, coculus indicus, or any other unwholesome ingredient, in beer, under a certain penalty; from which we may infer that such, at least, was the practice of some; and writers, who profess to discuss the secrets of the trade, mention most of these, and some other articles, as essentially necessary. The essentia bina is sugar boiled down to a dark colour, and empyreumatic flavour. Broom-tops, wormwood, and other bitter plants were formerly used to render beer fit for keeping, before hops were introduced into this country; but are now prohibited to be used in beer made for sale.

By the present law of this country, nothing is allowed to enter into the composition of beer, except malt and hops. Quassia and wormwood are often fraudulently introduced; both of which are easily discoverable by their nauseous bitter taste. They form a beer which does not preserve so well as hop beer. Sulphate of iron, alum, and salt, are often added by the publicans, under the name of *beer heading*, to impart a frothing property to beer, when it is poured out of one vessel into another. Molasses, and extract of gentian root, are added with the same view. Capsicum, grains of paradise, ginger root, coriander seed, and orange peel, are also employed to give pungency and flavour to weak or bad beer. The following is a list of some of the unlawful substances seized at different breweries, and brewers' druggists' laboratories in London, as copied from the minutes of the committee of the House of Commons: — Coculus indicus multum (an extract of the coculus), colouring, honey, hartshorn shavings, Spanish juice, orange powder, ginger, grains of paradise, quassia, liquorice, caraway seeds, copperas, capsicum, mixed drugs. Sulphuric acid is very frequently added to *bring beer forward*, or make it hard, giving new beer instantly the taste of what is eighteen months' old. According to Mr. Accum, the present *entire* beer of the London brewer is composed of all the waste and

poiled beer of the publicans, the bottoms of butts, the leavings of the pots, the drippings of the machines for drawing the beer, the remnants of beer that lay in the leaden pipes of the brewery, with a portion of brown stout, bottling beer, and mild beer. He says, that opium, tobacco, nux vomica, and extract of poppies, have been likewise used to adulterate beer. By evaporating a portion of beer to dryness, and igniting the residuum with chlorate of potash, the iron of the copperas will be procured in an insoluble oxide. Muriate of barytes will throw down an abundant precipitate from beer contaminated with sulphuric acid or copperas; which precipitate may be collected, dried, and ignited. It will be insoluble in nitric acid.

Beer appears to have been of ancient use, as Tacitus mentions it among the Germans, and has been usually supposed to have been peculiar to the northern nations: but the ancient Egyptians, whose country was not adapted to the culture of the grape, had also contrived this substitute for wine; and Mr. Park has found the art of making malt, and brewing from it very good beer, among the negroes in the interior parts of Africa. See *Wheat*.

Cerevisiæ fermentum. See *Fermentum cerevisiæ.*

CE'RIA. (*a. æ*, f.; from *cereus*, soft.) The flat worm generated in the intestines. — *Turton.* See *Tænia.*

Cerine. See *Cera.*

CE'RION. (From κηριον, a honeycomb.) An eruptive disorder of the head. See *Achor.*

Cerite. See *Cerium.*

CE'RIUM. (*um, ii.* n.) A metal discovered in 1803 by Hisinger and Berzelius in a mineral which occurs in the Swedish mine of Bastnäs, and which had long been known to the German mineralogists under the name of *Bastnas schwerstein, heavy stone of Bastnas.* The metal was named *Cerium* by its discoverers, after the planet Ceres, which had been discovered by Piazzi the year before. The mineral has since been called *cerite*, from the metal it contains. The properties of cerium have hitherto been little investigated. It is brittle, white, and volatile in a very intense heat. It is not acted on by nitric, but is dissolved by nitro-muriatic, acid. It combines with oxygen in two proportions. The protoxide is white, and the peroxide of a fawn-red colour. Cerium may also be made to unite with sulphur, by transmitting the vapour of sulphuret of carbon over carbonate of cerium, at a red heat, or by fusing oxide of cerium at a white heat, with a large excess of sulphuret of potassium and washing away the soluble parts with water. The first process affords a porous light substance, of a colour like red lead; the sulphuret obtained by the second method is brilliant yellow scales: these sulphurets, however, are essentially the same.

CERNIN, SAINT. St. Cernin is a parish in the diocese of St. Flour, in Upper Auvergne. It has a cold chalybeate spring, the water of which is called *Eau du Cambon.*

CER'NUUS. A Latin adjective applied to one who hangs down his head, and hence by botanists to flowers which are placed on curved peduncles and look towards the earth — *cernui flores.* Also to the peduncles which support such flowers — *pedunculi cernui.*

CERO'MA. (*a, atis.* n.; κηρωμα; from κηρος, wax.) *Ceroneum.* Cerotum, a cerate.

CEROPI'SSUS. (*us, i.* m.; κηροπισσος: from κηρος, wax, and πισσα, pitch.) A cerate or plaster, composed of pitch and wax.

Cerotum. See *Ceroma.*

CERU'MEN. (*en, inis.* n.; from *cera*, wax.) The waxy matter of the ear secreted by follicles, situated under the cuticular lining of the meatus auditorius externus. Its principal use seems to be to entangle particles of foreign matter, and prevent them from reaching the membrana tympani. It consists of an inspissated oil, albumen, soda, phosphate of lime, and colouring matter.

Ceruminous glands. See *Auris.*

CERU'SSA. (Generally derived from κηρος, wax; but what it has to do with wax is hard to tell.) Cerusse; white lead. See *Plumbi subcarbonas.*

Cerussa acetata. See *Plumbi acetas.*

Cervi spina. See *Rhamnus catharticus.*

CERVICAL. (*Cervicalis*; from *cervex* the neck.) Belonging to the neck; as, cervical nerves, cervical muscles, &c.

CERVICAL ARTERY. There are two cervical arteries, both of which generally rise from the subclavian, behind the scalenus muscle, sometimes by a common trunk, and sometimes separately. The *cervicalis profunda, vel posterior*, ascends obliquely backwards between the transverse processes of the two lowest cervical vertebræ, and continues its course directly upwards on the posterior part of the spine, supplying the adjacent muscles and inosculating with the occipital artery. The *cervicalis superficialis, vel anterior*, crosses the neck transversely, communicating with other branches of the subclavian, and with the occipital artery.

Cervicalis anterior. See *Cervical artery.*

Cervicalis posterior. See *Cervical artery.*

Cervicalis profunda. See *Cervical artery.*

Cervicalis superficialis. See *Cervical artery.*

Cervical nerves. See *Nervous system.*

CERVICAL VERTEBRÆ. The seven uppermost of the vertebræ, which form the spine. See *Vertebra.*

CERVICAL VEINS. The veins which correspond with the cervical arteries.

CERVICA'RIA. (*a, æ.* f.; from *cervix*, the neck: so named because it was supposed to be efficacious in diseases of the throat and neck.) The herb throatwort. See *Campanula trachelium.*

CE'RVIX. (*ix, icis.* f.) 1. The neck. Properly, the back part of the neck.

2. Applied also to portions of organs which somewhat resemble a neck, as *cervix uteri*, the neck of the uterus; *cervix vesicæ*, the neck of the bladder, &c.

CE'RVUS. (*us, i.* m.) The name of a genus of ruminant animals. The following are the principal species: —

1. *Cervus alces.* The elk or moose deer.
2. *C. tarandus.* The rein-deer.
3. *C. elephas.* The stag.

4. *C. dama.* The fallow deer.
5. *C. canadensis.* The Wapiti deer.
6. *C. virginianus.* The Virginian deer.
7. *C. axis.* The axis or spotted Indian deer.
8. *C. capreolus.* The European roebuck.
9. *C. muntjac.* The Indian roebuck.

The flesh of all these species is used as food. See *Venison.* The horns of several species were formerly in high esteem as an article of the Materia Medica: by distillation they yield ammonia, whence solution of ammonia, is commonly called *Spirit of hartshorn.* See *Cornu cervi* and *Spiritus cornu cervi.* The hoof of the elk, *Alcis ungula*, was formerly in vogue as antepileptic. It was believed that the animal was subject to epilepsy, and cured its fits by applying the hoof to the ear. The stag's pizzle, *Priapus cervi*, was once considered aphrodisiac. The dried powder was given in the dose of ℈j. — ʒj.

CE'SPITOSE. (*Cespitosus*, from *cespes*, a sod, or turf.) A plant is so called which produces many stems from one root, and which has all its leaves radical so as to resemble a turf.

Cestri'tes vinum. (From κεστρον, betony.) Wine impregnated with betony.

Ce'strum. (*um. i.* n.; κεστρον.) The herb betony. See *Betonica officinalis.*

CETA'CEA. An order of marine mammiferous animals, including the whale, porpoise, dolphin, and others erroneously considered by the unscientific as fish: they are in reality mammiferous animals, destitute of hind feet: they are warm blooded, and breathe air by means of lungs; and they bring forth their young alive, and suckle them.

CETA'CEUM. (*um, ii.* n.; from *cete*, a whale.) The substance otherwise called *spermaceti.* See *Physeter macrocephalus.*

Cetaceus. (From *ceta*, a whale.) Cetaceous. Appertaining to the whale as *Oleum cetaceum*, whale oil.

Ce'terach. The herb spleenwort. See *Asplenium ceterach.*

Ceterach officinalis. See *Asplenium ceterach.*

Cetic acid. *Acidum ceticum.* A name given by Chevreuil to what he supposed to be a peculiar acid resulting from the saponification of *cetine*, but which he has since found to be merely a mixture of margaric acid and cetine.

Cetine. The name given by Chevreuil to spermaceti. See *Adeps.*

Cevadate. *Cevadas.* A salt formed by the combination of the cevadic acid with a base.

Cevadic acid. *Acidum cevadicum.* By the action of potash on the fat matter of the cevadilla, a plant that comes from Senegal, an acid is obtained which is called the *cevadic.*

Cevadi'lla. (*a, æ.* f.; from *cebeda*, the Spanish for barley.) See *Veratrum sabadilla.*

Cevil. A name given by Paracelsus to a hardened substance which he also calls *Ludus.* He says, it is formed of the tartar of the earth indurated by an urinous spirit which is in the earth; that it resembles a human calculus, and is good against the calculus diathesis.

Ceyenne pepper. See *Capsicum annuum.*

Chacarilla. See *Cascarilla.*

Chærefolium. See *Scandix cerefolium.*

CHÆROPHY'LLUM. (*um, i.* n.; from χαιρω, to rejoice, and φυλλον, a leaf: so called from the luxuriance of its foliage.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia.*

2. The pharmacopœial name of the *Scandix cerefolium*, or common chervil.

Chærophyllum odoratum. *Scandix odorata. Myrrhis.* Sweet cicely. It has the flavour of anise, and is used as a savoury herb.

Chærophyllum sativum. See *Scandix cerefolium.*

Chærophyllum sylvestre. The systematic name of the bastard hemlock, called, in the pharmacopœias, *Cicutaria. Chærophyllum — caule lævi striato; geniculis tumidiusculis*, of Linnæus. It is often mistaken for the true hemlock. It may with great propriety be banished from the list of officinals, as it possesses no remarkable property.

Chæ'te. Χαιτη. Properly the mane of a quadruped, but used also to signify the human hair.

Chala'sticus. (Χαλαστικος; from χαλαω, to relax.) Applied to a medicine which obviates an undue state of tension in parts. An emollient. — *Galen.*

Chala'za. (Χαλαζα, a hail-stone.) 1. The same as *Chalazion.*

2. Two white bodies attached to the membrane which covers the yolk of an egg, are called *chalazæ*, or grandines. See *Ovum.*

3. Gærtner gives the name of chalaza to a point marked on the internal tunic of the seeds of plants, which corresponds with the insertion of their umbilical cord.

Chala'zion. (*Chalazium, ii.* n. Χαλαζιον; from χαλαζα, a hail-stone.) *Chalaza.* A small tubercle on the margin of the eye-lid, commonly called a *stye.* See *Hordeolum.*

Chalazo'sis. Χαλαζωσις. The same as *Chalazion.*

Cha'lbane. Καλβανη. Galbanum.

Chalca'nthum. (*um, i.* n. Χαλκανθον; from χαλκος, brass, and ανθος, a flower.) 1. Flowers of brass; that is, verdigris.

2. Vitriol.

Chalcha'nthe. Χαλχανθη. The same as *Chalchanthon.*

Chalcedo'nius. The epithet of a medicine used by Galen in disorders of the ears.

Chalce'tum. A herb mentioned by Pliny, probably the *Valeriana locusta* of Linnæus.

Chalcoi'deum os. The cuneiform bone of the foot. See *Tarsus.*

Chalci'tis. Χαλκιτις. See *Colcothar.*

Chalcus. Χαλκους. See *Æreolum.*

Chali'cratum. (From χαλις, wine, and κερανυμι, to mix.) Wine mixed with water.

Cha'linos. (Χαλινος, a bridle.) That part of the cheeks which is contiguous on each side to the angles of the mouth. — *Cælius Aurelianus. Julius Pollux.*

CHALK. A very common species of carbonate of lime, which forms the white cliffs of our shores, and is found abundantly in most parts of the world.

Chalk stone. See *Gout.*

CHALY'BEATE. (*Chalybeatus*; from *chalybs*, iron, or steel.) Of or belonging to

iron. Applied to a medicine containing iron, and to mineral waters which are impregnated with iron; such as the water of Tunbridge, Spa, Pyrmont, Cheltenham, Scarborough, Hartfel, and many others.

Chalybis rubigo præparata. See *Ferri subcarbonas.*

CHA'LYBS. (Χάλυψ. *Chalys, ybis.* m.; from the *Chalybes*, a people in Pontus, who used to prepare it.) Steel. See *Ferrum.* The medicinal preparations of iron are generally called in common language *steel* medicines.

Chalybs tartarizatus. See *Ferrum tartarizatum.*

CHAMÆA'CTE. (*e, es.* f.; from χαμαι, on the ground, and ακτη, the elder tree.) The dwarf elder. — *Dioscorides.*

CHAMÆBA'LANUS. (*us, i.* m.; from χαμαι, on the ground, and βαλανος, an acorn.) The Greek name of a plant, which was probably the *Lathyrus tuberosus* of Linnæus.

CHAMÆ'BATOS. (From χαμαι, on the ground, and βατος, a bramble.) Dwarf bramble. The *Rubus fruticosus*, or blackberry bush.

CHAMÆBU'XUS. (*us, i.* f.; from χαμαι, on the ground, and πυξος, the box-tree.) The dwarf box-tree. The *Polygala chamæbuxus* of Linnæus.

CHAMÆ'CEDRUS. (*us, i.* f.; from χαμαι, on the ground, and κεδρος, the cedar-tree.) *Chamæcedrys.* A species of dwarf abrotanum.

CHAMÆCI'SSUS. (*us, i.* f.; from χαμαι, on the ground, and κισσος, ivy.) Ground-ivy. The *Glechoma hederacea* of Linnæus.

CHAMÆCLE'MA. (*a, atis.* n.; from χαμαι, on the ground, and κλημα, a young shoot.) The ground-ivy.

CHAMÆCRI'STA. (*a, æ.* f.; from χαμαι, on the ground, and *crista*, a plume or tuft.) The *Cassia chamæcrista* of Linnæus, a decoction of which, drunk freely, is said to be serviceable against the poison of the night-shade.

CHAMÆCYPARI'SSUS. (Χαμαικυπαρισσος: from χαμαι, on the ground, and κυπαρισσος, the cypress.) Lavender cotton. See *Santolina chamæcyparissus.*

CHAMÆDA'PHNE. (From χαμαι, on the ground, and δαφνη, laurel.) This name appears to have been given by Dioscorides to the Alexandrian laurel, *Ruscus hypoglossum* of Linnæus, by many to the periwinkle, *Vinca minor*, and by Matthiolus and Lobel to the spurge laurel, *Daphne laureola.*

Chamædrops. See *Chamædrys.*

CHAMÆDRYI'TES. Wine impregnated with germander.

CHAMÆ'DRYS. (*ys, yos.* f.; from χαμαι, on the ground, and δρυς, the oak: so called from its being a low plant with leaves somewhat resembling those of the oak.) The germander. See *Teucrium chamædrys.*

Chamædrys incana maritima. See *Teucrium marum.*

Chamædrys palustris. See *Teucrium scordium.*

Chamædrys spuria. See *Veronica officinalis.*

Chamædrys sylvestris. See *Veronica chamædrys.*

CHAMÆGEI'RON. Χαμαιγειρον. A Greek name for the colt's foot. — *Mentzel.*

CHAMÆLE'A. (*a, æ.* f.; from χαμαι, on the ground, and ελαια, the olive-tree.) See *Daphne alpina.*

CHAMÆLÆA'GNUS. (From χαμαι, on the ground, and ελαιαγνος, the Bohemian olive.) See *Myrica gale.*

CHAMÆLAI'TES. Wine impregnated with the chamælea.

CHAMÆ'LEON. (*on, ontis*, and *onis.* m.; from χαμαι, on the ground, and λεων, a lion, *i. e.* dwarf lion.) 1. A genus of lizards, containing several species, all inhabitants of hot climates. These animals are remarkable for the great size of their lungs, which, when fully dilated, make their body almost transparent. From this peculiarity arises the frequent change of colour which has rendered the chamæleon an object of curiosity in all ages. According to the degree in which the lungs are dilated, the animal is more or less transparent; a greater or less quantity of blood is thrown upon the surface of the body; and perhaps also the colour of the blood may vary somewhat according to its degree of aeration: thus the hue of the animal changes with its passions, temperature, and every other circumstance that can affect the circulation; and since the play of the lungs is under voluntary control, it is no fable that the chamæleon can change its colour at will. The blood and gall of the chamæleon were formerly supposed to possess divers medicinal virtues.

2. A name given to some thistles, from the variety and uncertainty of their colours.

Chamæleon album. See *Carlina acaulis.*

CHAMÆLEON MINERALIS. Mineral chamæleon. When peroxide of manganese is mixed with an equal weight of nitre or carbonate of potash, and the mixture fused at a red heat, a green-coloured mass is obtained called *mineral chamæleon.* When this substance is dissolved in water the solution is at first green; it then becomes successively blue, purple, and red, and finally throws down a brown precipitate, and becomes colourless: from these phenomena it derives its name. See *Manganese.*

Chamæleon verum. See *Cnicus.*

CHAMÆLEU'CE. (*e, es.* f.; from χαμαι, on the ground, and λευκη, the herb colt's-foot.) See *Tussilago farfara.*

CHAMÆLI'NUM. (*um, i.* n.; from χαμαι, on the ground, in allusion to its slow growth, and λινον, flax.) Purging flax. See *Linum catharticum.*

Chamæmelon. See *Chamæmelum.*

CHAMÆME'LUM. (*um, i.* n.; from χαμαι, on the ground, and μηλον, an apple; because it is of low growth, and is said to have the smell of an apple, which, however, is by no means true.) See *Anthemis nobilis.*

CHAMÆMELUM CANARIE'NSE. The *Chrysanthemum frutescens* of Linnæus.

CHAMÆMELUM CHRYSA'NTHEMUM. The *Buphthalmum germanicum* of Linnæus.

CHAMÆMELUM FŒTIDUM. The *Anthemis cotula* of Linnæus.

Chamæmelum nobile. See *Anthemis nobilis.*

Chamæmelum vulgare. See *Matricaria.*

CHAMÆ'MORUS. (*us, i.* f. Χαμαιμορεα; from χαμαι, on the ground, and μορεα, the mulberry-tree.) The cloud-berry. See *Rubus chamæmorus.*

CHAMÆMY'RTUS. (From χαμαι, on the ground, and μυρτος, myrtle.) Dwarf myrtle. The *Ruscus aculeatus.*

CHAMÆPEU'CE. (*e, is.* f.; from χαμαι, on the ground, and πευκη, the pine-tree.) See *Camphorosma Monspeliensis.*

CHAMÆ'PITYS. (*ys, yos.* f.; from χαμαι, on the ground, and πιτυς, the pine-tree.) See *Teucrium chamæpitys.*

Chamæpitys moschata. See *Teucrium iva.*

CHAMÆ'PLION. Χαμαιπλιον. See *Erysimum.*

CHAMÆRA'PHANUS. (From χαμαι, on the ground, and ραφανος, the radish.) 1. The upper part of the root of apium, according to P. Ægineta.

2. The dwarf radish. — *Turton.*

CHAMÆRODODE'NDRON. (*um, i.* n.; from χαμαι, on the ground, and ροδοδενδρον, the rose laurel.) The *Azalæa pontica* of Linnæus.

CHAMÆ'ROPS. (*ops, opis.* f.; from χαμαι, on the ground, and ρωψ, a young shoot.) A species of germander. See *Teucrium.*

CHAMÆ'RUBUS. (*us, i.* m. and f.; from χαμαι, on the ground, and *rubus*, the bramble.) See *Rubus chamæmorus.*

CHAMÆSPA'RTIUM. (*um, ii.* n.; from χαμαι, on the ground, and σπαρτιον, Spanish broom.) See *Genista tinctoria.*

Chamber. See *Camara.*

CHAMBERLAIN'S RESTORATIVE PILLS. A quack medicine, consisting of cinnabar, sulphur, sulphate of lime, and a little gum, or other vegetable matter.

Chamomile. See *Anthemis nobilis.*

CHAMOMILE DROPS. Alkoholic spirit, flavoured with essential oil of chamomile.

Chamomile, stinking. See *Anthemis cotula.*

CHAMOMI'LLA. (*a, æ.* f.; from χαμαι, on the ground, and μηλον, an apple.) See *Anthemis nobilis.*

Chamomilla nostras. See *Matricaria.*

Chamomilla romana. See *Anthemis.*

Champignon. See *Agaricus pratensis.*

CHA'NCRE. (A word borrowed from the French.) A primary venereal ulcer. Such ulcers, of course, are found most frequently on the genitals; but they may occur on any part of the body to which the venereal poison has been immediately applied. See *Syphilis.*

Channelled. See *Canaliculatus.*

CHAOSDA. Paracelsus uses this word as an epithet for the plague.

Charabe. See *Carabe.*

CHARACTERS, CHEMICAL. Various systems of characters or symbols have at different times been introduced into the science of chemistry, for the purposes of concealment or of brevity of expression: they are now generally disused. See *Abbreviation.*

Charantia. See *Momordica elaterium.*

Charcoal. See *Carbon.*

CHA'RDONE. The artichoke.

CHARISTOLOCHIA. (*a, æ.* f.; from χαρις, joy, and λοχια, parturition: so named from its supposed usefulness to women, in childbirth.) See *Artemisia vulgaris.*

CHA'RME. (From χαιρω, to rejoice.) *Charmis.* A cordial mentioned by Galen.

CHARPIE. The French for scraped linen, or lint.

Charr. See *Salmo alpinus.*

CHA'RTA. (*a, æ.* f. Χαρτης.) 1. Paper.

2. The amnio has been called the *charta virginea*, from its likeness to a piece of fine paper.

CHARTREUX, POUDRE DE. (So called because it was said to have been invented by some friars of the Carthusian order.) A hydrosulphuret of antimony.

Chaste tree. See *Agnus castus.*

Chate. See *Cucumis ægyptia.*

Chay. See *Oldenlandia umbellata.*

Chaya. See *Oldenlandia umbellata.*

Cheek bone. See *Jugale os.*

Cheese. See *Milk.*

CHEILOCA'CE. (*e, es.* f.; from χειλος, a lip, and κακον, an evil.) Canker of the mouth.

CHEIME'THLON. (Χειμεθλον; from χειμα, winter.) A chilblain. See *Pernio.*

CHEIMETLON. Χειμετλον. The same as *Cheimethlon.*

CHEIRA'NTHUS. (*us, i.* m.; probably from χειρ, the hand, and ανθος, a flower; a flower to be borne in the hand.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia;* Order, *Siliquosa.*

CHEIRANTHUS CHEIRI. The systematic name of the wall-flower; called also *Leucoium luteum*, and *Viola lutea.* The flowers of this plant, *Cheiranthus—foliis lanceolatis, acutis, glabris; ramis angulatis; caule fruticoso*, of Linnæus, are recommended as possessing nervine and deobstruent virtues. They have a moderately strong, pleasant, smell, and a nauseous, bitter, somewhat pungent taste.

CHEI'RI. 1. The wall-flower. See *Cheiranthus Cheiri.*

2. An alchemistical term by which some writers seem to have meant *quicksilver*, others *aurum potabile*, others *antimony*, &c.

CHEIRI FLORES. The flowers of the *Cheiranthus cheiri.*

CHEIRIA'TER. (From χειρ, the hand, and ιατρος, a physician.) A surgeon, whose office it is to remove maladies by manual operations.

CHEIRI'XIS. (*is, is.* f.; from χειριζομαι, to labour with the hand.) The art of surgery.

CHEIRO'PTERA. (From χειρ, the hand, and πτερονα, wing.) A family of mammiferous animals, which have the fingers of the hand greatly elongated, and a production of the skin extended between the fingers, and between the hands and the feet, so as to supply the place of wings, and enable the animals to fly small distances. Bats are an example.

CHE'LA. (*a, æ.* f. Χηλη, *forceps;* from χεω, to take.) 1. The claw of a crab.

2. A forked probe, used by the ancients for extracting polypi from the nose.

3. Fissures or chops, such as occur on the hands, feet, parts of generation, &c. were called *Chelæ.* — *Julius Pollux.*

4. The extremities of the eye-lashes were called χηλαι. — *Rufus Ephesius.*

CHELÆ CANCRORUM. Crabs' claws. The large claws of the *cancer pagurus* or black-clawed crab were formerly used medicinally as an ab-

orbent. They consist of carbonate of lime, with a little phosphate of lime and animal matter. They possess no virtues but those of chalk, which is the form in which carbonate of lime is now always prescribed.

CHELI'DON. (Χελιδων.) The Greek for swallow. Applied also to the bend of the arm.

CHELIDO'NIUM. (*um, ii.* n.; from χελιδων, the swallow: so named from an opinion, that it was pointed out as useful for the eyes by swallows, who are said to open the eyes of their young by it; or because it blossoms about the time when swallows appear.) 1. A genus of plants in the Linnæan system. Class, *Polyandria;* Order, *Monogynia.*

2. The herb celandine.

CHELIDONIUM MAJUS. Tetterwort, and great celandine; called, in some Pharmacopœias, *Papaver corniculatum luteum; Curcum.* The herb and root of this plant, *Chelidonium — pedunculis umbellatis,* of Linnæus, have a faint unpleasant smell, and a bitter, acrid, durable taste, which is stronger in the roots than the leaves. They are aperient and diuretic, and recommended in icterus, when not accompanied with inflammatory symptoms. The chelidonium should be administered with caution, as it is liable to irritate the stomach and bowels. Of the dried root, from ℈ss. to ℈j. is a dose; of the fresh root, infused in water, or wine, the dose may be about ℈ss. The decoction of the fresh root is used in dropsy, cachexy, and cutaneous complaints. The fresh juice is used to destroy warts, and films in the eyes; but, for the latter purpose, it is diluted with milk.

CHELIDONIUM MINUS. See *Ranunculus ficaria.*

CHELIDO'NIUS LAPIS. A name formerly given to a stone, alleged to be found in the stomach of young swallows, and believed to possess antiepileptic virtues.

CHELOI'DES. (From χελυς, a tortoise, and ειδος, resemblance.) A new form of cutaneous disease described by Alibert, consisting of raised patches of integument of a bluish red colour, traversed by white lines, accompanied with increased heat, intolerable itching, and sometimes severe and pungent pain.

CHELO'NE. (*e, es.* f. Χελωνη.) 1. The tortoise.

2. An instrument for extending a limb, and so called, because, in its slow motions, it represents a tortoise. This instrument is mentioned by Oribasius.

CHELO'NIA. An order of reptiles including the various species of tortoise and turtle. See *Reptilia.* The most remarkable characteristic of the chelonia is their external skeleton which envelops the whole body like a suit of armour, leaving only the head, neck, feet, and tail uncovered. The superior covering, called *carapace,* is formed of the ribs, eight in number on each side, broadened out, and united by sutures to each other, and to plates proceeding from the dorsal vertebræ. The inferior covering, or breastplate, is an expansion of the sternum, consisting generally of nine pieces. Some of the chelonia inhabit the sea, and these are called in common language *turtles;* others are terrestrial, and these are called *tortoises.* All these animals are used as the food of man. See *Testudo.*

CHELO'NION. (From χελωνη, the tortoise; and so called from its resemblance to the shell of a tortoise.) A hump, or gibbosity in the back.

CHELSEA PENSIONER. The name of a nostrum for rheumatism. It consists of gum guaiac ℥j. rhubarb ℥ij. cream of tartar ℥j., flowers of sulphur ℥j., one nutmeg, and a pound of clarified honey. It is said to have derived its name from the circumstance of a Chelsea pensioner having cured Lord Amherst with it.

CHELTENHAM. A large and populous town, in Gloucestershire, celebrated for its purging waters, which are both saline and chalybeate. The water, when first drawn, is clear and colourless, but somewhat brisk; and has a saline, bitterish, chalybeate taste. It does not keep, nor bear transporting to any distance; the chalybeate part being lost by precipitation of the iron, and in the open air it even turns fetid. The salts, however, remain. Its heat in summer is from 50° to 55° or 59°, when the medium heat of the atmosphere is nearly 15° higher. On evaporation, it is found to contain a calcareous earth, mixed with ochre and a purging salt. There are a number of wells dug at different periods, the waters of which contain different proportions of saline matters, and if there has not been some mistake in the analyses, the waters of the same wells have in a few years undergone considerable changes in this particular. The general analyses of these waters give muriate of soda, sulphate of soda, sulphate of magnesia, muriate of magnesia, muriate of lime, sulphuretted hydrogen, carbonic acid, and oxide of iron. The two first of these ingredients are the most abundant and constant; and are those on which the cathartic power of the water chiefly depends. The oxide of iron, though in minute quantity, is sufficient to give a decidedly chalybeate character to the water. The Cheltenham water when first taken, generally produces a degree of drowsiness, or even headach, which however soon subsides. A moderate dose acts powerfully, and speedily, as a cathartic, without occasioning griping, or leaving that faintness and languor which often follow the action of the rougher cathartics. It is principally on this account, but partly too from the salutary operation of the iron, and perhaps the carbonic acid, that the Cheltenham water may be, in most cases, persevered in without interruption for a considerable length of time; and that, during its use, the appetite is improved, the digestive organs strengthened, and the whole constitution invigorated. A dose of this water, too small to operate directly on the bowels, will generally determine pretty powerfully to the kidneys. As a purge, this water is drunk from one to three pints; in general, from half a pint to a quart is sufficient. Cheltenham water is used, with considerable benefit, in a number of chronic diseases, and especially those in which the functions of the liver are deranged. Persons whose biliary organs have been injured by excess in the pleasures of the table, or by a long

residence in hot climates, and who are suffering under the symptoms, either of excess or deficiency of bile, and an irregularity in its secretion, receive remarkable benefit from a course of this water, judiciously exhibited. Its use may be here continued, even during a considerable degree of debility; and, from the great determination to the bowels, it may be employed with advantage to check the incipient symptoms of dropsy, and general anasarca, which so often proceed from an obstruction of the liver. In scrofulous affections, the sea has the decided preference; in painful affections of the skin, called scorbutic eruptions, which make their appearance at stated intervals, producing a copious discharge of lymph, and an abundant desquamation, this, in common with other saline purgative springs, is found to bring relief; but it requires to be persevered in for a considerable time, keeping up a constant determination to the bowels, and making use of warm bathing. The season for drinking the Cheltenham water is during the whole of the summer months.

CHELY'SCION. (Χελυσκιον; from χελυς, the breast.) A dry short cough. — *Hippocrates.*

CHE'MIA. An ancient measure containing two small spoonfuls.

CHE'MIA. (*a, æ.* f.) See *Chemistry.*

CHE'MICAL. Of or belonging to chemistry.

CHEMISTRY. (*Chemia, æ.* f. Χυμεια, and sometimes χημεια. Some derive this word from χεω, or χυω, to pour; but as we learn from Plutarch, that Egypt was called *Chemia* in the sacred language of the priests, and since the art is doubtless of Egyptian origin, it is probable that the word *chimia*, or chemistry, is also derived from the Egyptian language.) *Chimia, Chymia.* The learned are not yet agreed as to the most proper definition of chemistry. Boerhaave seems to have ranked it among the arts. According to Macquer, it is a science, the object of which is to discover the nature and properties of all bodies by their analysis and combinations. Dr. Black and Fourcroy define it a science which teaches the mutual actions of all natural bodies on each other. "Chemistry," says Jacquin, "is that branch of natural philosophy which unfolds the nature of all material bodies, determines the number and properties of their component parts, and teaches us how those parts are united, and by what means they may be separated and recombined." Mr. Heron defines it, "that science which investigates and explains the laws of that attraction which takes place between the minute component particles of natural bodies." Dr. Ure's definition is, "the science which investigates the composition of material substances, and the permanent changes of constitution which their mutual actions produce." According to Dr. Thomson, "The object of chemistry is to determine the constituents of bodies, and the laws which regulate the combinations and separations of the elementary particles of matter." The objects to which the attention of chemists is directed, comprehend the whole of the substances that compose the globe.

CHEMO'SIS. (*is, eos.* f.; from χαινω, to gape: because it gives the appearance of a gap, or aperture.) Inflammation of the tunica conjunctiva of the eye, in which the white of the eye is distended with blood, and elevated above the margin of the transparent cornea. See *Ophthalmia.*

CHENO'CORUS. (From χην, a goose, and κοπρος, dung.) Goose-dung; which was formerly given, when dried, in the dose of half a drachm to a drachm, as a powerful resolvent and diuretic, and particularly against jaundice.

CHENOPODIO-MO'RUS. (From *chenopodium*, and *morus*, the mulberry; so called, because it resembles a chenopodium, and has leaves like a mulberry.) The herb mulberry-blight. The *Blitum capitatum* of Linnæus.

CHENOPO'DIUM. (*um, ii.* n.; from χην, a goose, and πους, a foot: so called from its supposed resemblance to a goose's foot.) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.* The herb chenopody: goosefoot.

CHENOPODIUM AMBROSIOIDES. The systematic name of the Mexican tea-plant. Mexico tea, Spanish tea, and Artemisian botrys. *Botrys Mexicana, Botrys ambrosioides Mexicana, Chenopodium Mexicanum, Botrys Americana.*

Chenopodium — foliis lanceolatis dentatis, racemis foliatis simplicibus, of Linnæus. A decoction of this plant has been recommended in paralytic cases. Formerly the infusion was drunk instead of Chinese tea.

CHENOPODIUM ANTHELMINTICUM. The seeds of this plant, *Chenopodium — foliis ovato-oblongis dentatis, racemis aphyllis,* of Linnæus, though in great esteem in America, for the cure of worms, are seldom exhibited in this country. They are powdered and made into an electuary, with any proper syrup or conserve.

CHENOPODIUM BONUS HENRICUS. The systematic name of the English mercury. Called also, *Tota bona,* and *Lapathum unctuosum.*

Chenopodium — foliis triangulari-sagittatis, integerrimis, spicis compositis aphyllis axillaribus, of Linnæus. This is an indigenous plant very abundant in waste grounds. It differs little from spinach when cultivated; and in many places the young shoots are eaten in spring like asparagus. The leaves are accounted emollient, and have been made an ingredient in decoctions for glysters. They have also been popular as a vulnerary.

CHENOPODIUM BOTRYS. The systematic name of the Jerusalem oak; called also, *Botrys, Botrys vulgaris, Ambrosia, Artemisia chenopodium, Atriplex odorata,* and *suaveolens. Chenopodium — foliis oblongis sinuatis, racemis nudis multifidis,* of Linnæus. This plant was formerly administered in form of decoction in some diseases of the chest; as humoral asthma, coughs, and catarrhs. It is now fallen into disuse.

Chenopodium fœtidum. See *Chenopodium vulvaria.*

CHENOPODIUM VULVARIA. The systematic name for the stinking orach; called, in some Pharmacopœias, *Atriplex fœtida, Atriplex olida, Vulvaria, Garosmum, Raphex, Chenopodium fœtidum,* and *Blitum fœtidum.* The very fetid

smell of this plant, *Chenopodium — foliis integerrimis rhombeo-ovatis, floribus conglomeratis axillaribus*, of Linnæus, induced physicians to exhibit it in hysterical diseases; and it is recommended by some even in the present day as an emmenagogue. Messrs. Chevalier and Lassaigne have detected ammonia in this plant in an uncombined state, which is probably the vehicle of the remarkably nauseous odour which it exhales, strongly resembling that of putrid fish. When the plant is bruised with water, and the liquor expressed, and afterwards distilled, we procure a fluid which contains the subcarbonate of ammonia, and an oily matter, which gives the fluid a milky appearance. If the expressed juice of the chenopodium be evaporated to the consistence of an extract, it is found to be alkaline; there seems to be acetic acid in it. Its basis is said to be of an albuminous nature. It is stated also to contain a small quantity of the substance which the French call osmazome, a little of an aromatic resin, and a bitter matter, soluble both in alkohol and water, as well as several saline bodies.

CHE'NOPUS. The same as chenopodium.

Cherefo'lium. See *Chærophyllum.*

Chermes. See *Kermes.*

Cheronia. See *Chironia.*

Cherry. See *Prunus cerasus.*

Cherry, bay. See *Prunus.*

Cherry-laurel. See *Prunus.*

Cherry, winter. See *Physalis.*

Chervil. See *Scandix cerefolium.*

Chervillum. See *Scandix cerefolium.*

Chesnut. See *Æsculus* and *Fagus.*

Chesnut, horse. See *Æsculus hippocastanum.*

Chesnut, sweet. See *Fagus castanea.*

CHEVA'STER. *Chevastre.* A double-headed roller, which is applied by its middle below the chin; then running on each side, is crossed on the top of the head; then passing to the nape of the neck, is there crossed; it then passes under the chin, where crossing again, it is carried to the top of the head, &c. until it is all taken up.

CHEZANA'NCE. (From χεζω, to go to stool, and αναγκη, necessity.) The name given by Paulus to an ointment which was rubbed on the anus to promote stools, and by Aëtius, to a plaster applied to the navel with the same intention.

CHIA TERRÆ. An earth brought from the isle of Chio. It is in grayish white masses: it was formerly used as an application to burns.

CHI'ACUS. (From Χιος, the island of Scio.) The epithet of a collyrium, the chief ingredient of which was wine of Chios.

CHI'ADUS. Paracelsus uses this word to signify a boil.

Chian turpentine. See *Pistachiæ terebinthus.*

Chiasmus. See *Chiastre.*

Chiastos. See *Chiastre.*

CHI'ASTRE. (*Chiasmus, i.* m.; from χιαζω, to form the Greek letter χ, chi.) *Chiastos.* The name of a bandage for the temporal artery. It is a double-headed roller, the middle of which is applied to the side of the head, opposite to that in which the artery is opened, and, when brought round to the part affected, it is crossed upon the compress that is laid upon the wound, and is then continued over the coronal suture, and under the chin; then crossing on the compress, it is carried as at first, round the head, &c. till the whole roller is taken up.

CHIBOU. The French name of a spurious species of gum elemi. It is not known in England.

CHIBUR. Sulphur.

CHICA. A fermented liquor used by the Peruvians. It is made from Indian meal and water.

CHICHI'NA. Contracted from China chinæ. See *Cinchona.*

Chicken-pox. See *Varicella.*

Chick-weed. See *Alsine media.*

Chilblain. See *Pernio.*

Child-bed Fever. See *Puerperal fever.*

CHILI, BALSAMUM DE. Salmon speaks, but without any proof, of a peculiar balsam brought from Chili. The Barbadoes tar, in which are mixed a few drops of the oil of aniseed, is usually sold for it.

CHILIODY'NAMON. (From χιλιοι, a thousand, and δυναμις, virtue.) The name in Dioscorides for an herb, given on account of its many virtues. It is supposed to be the same with the white behen.

CHILIOPHY'LLON. (From χιλιοι, a thousand, and φυλλον, a leaf, because of the great number of leaflets.) See *Achillea millefolium.*

CHI'LON. (From χειλος, the lip.) An inflamed and swelled lip. — *Vogel.*

Chimethlon. See *Cheimethlon.*

CHI'MIA. Chemistry.

Chimiater. See *Chymiater.*

CHIMO'LEA LAXA. The powder which is separated from the flowers of saline minerals. — *Paracelsus.*

CHI'NA. (*a, æ.* f.; so named because it comes from China.) See *Smilax China.*

CHINA CHINÆ. The Peruvian bark.

CHINA OCCIDENTALIS. American or West Indian China. *China spuria nodosa. Smilax pseudo-China. Smilax Indica spinosa.* This root is chiefly brought from Jamaica, in large round pieces full of knots. In scrofulous disorders, it has been preferred to the Oriental kind. In other cases it is of similar but inferior virtue.

China supposita. See *Senecio pseudo-China.*

Chinchi na. See *Cinchona.*

Chinchi'na Caribæa. See *Cinchona caribæa.*

CHINCHINA DE SANTA FÉ. There are several species of bark sent from Santa Fé; but neither their particular natures, nor the trees which afford them, are yet accurately determined.

Chinchina de St. Lucia. See *Cinchona floribunda.*

Chinchina Jamaicensis. See *Cinchona caribæa.*

Chinchina rubra. See *Cinchona oblongifolia.*

Chincough. See *Pertussis.*

Chio turpentine. See *Pistacia terebinthus.*

CHIOLI. In the writings of Paracelsus it is synonymous with furunculus.

CHIRAGRA. (*a, æ.* f.; from χειρ, the hand, and αγρα, a seizure.) The gout in the joints of the hands. See *Gout.*

Chiro'nes. (Χειρωνες; from χειρ, the hand.) Small pustules on the hand and feet, enclosed in which is a troublesome worm. — *Turton.*

CHIRO'NIA. (*a, æ.* f.; from *Chiron*, the centaur, who discovered its use.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.*

2. (From χειρ, the hand.) An affection of the hand, where it is troubled with *chirones.*

Chironia centaurium. The systematic name of the officinal centaury: called also, *Centaurium minus vulgare*, *Centaurium parvum*, *Centaurium minus*, and *Libadium.*

Chironia — corollis quinquefidis infundibuliformibus, caule dichotomo, pistillo simplici, of Linnæus. This plant is justly esteemed to be the most efficacious bitter of all the medicinal plants indigenous to this country. It has been recommended, by Cullen, as a substitute for gentian; and by several is thought to be a more useful medicine. The tops of the centaury plant are directed for use by the colleges of London and Edinburgh, and are most commonly given in infusion; but they may also be taken in powder, or prepared into an extract.

Chiro'nius. (From *Chiron*, the centaur, who is said to have been the first who healed it.) The epithet given by Galen. A malignant ulcer, callous on its edges, and difficult to cure.

CHIROTHE'CA. (*a, æ.* f.; from χειρ, the hand, and τιθημι, to put.) A glove of the scarfskin, with the nails, which is brought off from the dead subject, after the cuticle is loosened, by putrefaction, from the parts under it.

CHIRU'RGIA. (*a, æ.* f.; from χειρ, the hand, and εργον, a work: because surgical operations are performed by the hand.) Chirurgery, or surgery. See *Medicine.*

CHIRU'RGICE. (*e, es.* f.; from χειρ, the hand, and εργον, a work.) Surgery.

CHIRU'RGICUS. Surgical: appertaining to surgery.

CHIRU'RGUS. (*us, i.* m.; from χειρ, the hand, and εργον, a work, or performance.) A surgeon.

Chi'um vinum. (From Χιος, the island where it was produced.) A wine used by the Greeks and Romans.

Chive. See *Stamen.*

Chliaros. (Χλιαρος, tepid.) Applied by Galen to a fever which is not very intense.

Chlia'sma. (From χλιαινω, to make warm.) A warm fomentation.

Chloral. A compound of chlorine, carbon and oxygen. See *Chlorine.*

Chlora'sma. (From χλωρος, green.) See *Chlorosis.*

CHLO'RATE. (*Chloras, atis.* f.) A compound of chloric acid with a salifiable base. The chlorates of soda and potash, are used in medicine.

Chlorate of lime. *Calcis chloras.* This is best obtained by dissolving carbonate of lime in chloric acid. It has a sharp bitterish taste, and is very soluble and deliquescent.

Chlorate of potash. *Potassæ chloras.* This salt has been long known, and may be procured by receiving chlorine, as it is formed, into a solution of potash. When the solution is saturated, it may be evaporated gently, and the first crystals produced will be the salt desired, this crystallising before the simple muriate, which is produced at the same time with it. Its crystals are in shining hexaëdral laminæ, or rhomboidal plates.

The effects of this salt on inflammable bodies are very powerful. Rub two grains into powder in a mortar, add a grain of sulphur, mix them well by gentle trituration, then collect the powder into a heap, and press upon it suddenly and forcibly with the pestle, a loud detonation will ensue. If the mixture be wrapped in strong paper, and struck with a hammer, the report will be still louder. Five grains of the salt, mixed in the same manner with two and a half of charcoal, will be inflamed by strong trituration, especially if a grain or two of sulphur be added, but without much noise. If a little sugar be mixed with half its weight of the chlorate, and a little strong sulphuric acid poured on it, a sudden and vehement inflammation will ensue; but this experiment requires caution, as well as the following: — To one grain of the powdered salt in a mortar, add half a grain of phosphorus; it will detonate, with a loud report, on the gentlest trituration. In this experiment the hand should be defended by a glove, and great care should be taken that none of the phosphorus get into the eyes. Phosphorus may be inflamed by it under water, putting into a wine-glass one part of phosphorus and two of the chlorate, nearly filling the glass with water, and then pouring in, through a glass tube reaching to the bottom, three or four parts of sulphuric acid. This experiment, too, is very hazardous to the eyes. If olive or linseed oil be taken instead of phosphorus, it may be inflamed by similar means on the surface of the water. This salt should not be kept mixed with sulphur, or perhaps any inflammable substance, as in this state it has been known to detonate spontaneously. As it is the common effect of mixtures of this salt with inflammable substances of every kind, to take fire on being projected into the stronger acids, Chenevix tried the experiment with it, mixed with diamond powder in various proportions, but without success.

Chlorate of soda. *Sodæ chloras.* This may be prepared in the same manner as the chlorate of potash, by substituting soda for potash; but it is not easy to obtain it separate, as it is nearly as soluble as the muriate of soda, requiring only 3 parts of cold water. In its other properties it resembles the chlorate of potash.

CHLO'RIC ACID. *Acidum chloricum.* This acid, formerly called the *hyperoxymuriatic*, was observed by Chenevix, but first obtained in a separate state by Gay-Lussac. It may be obtained by adding to a dilute solution of chlorate of baryta a quantity of weak sulphuric acid, exactly sufficient to saturate the baryta. The insoluble sulphate of baryta is precipitated, and pure chloric acid remains in the liquid. This acid is without colour and smell; its taste is very

acid, and it reddens litmus without destroying the colour. M. Vauquelin says, its taste is not only acid, but astringent; and its odour, when concentrated, is somewhat pungent. It differs from chlorine, in not precipitating gelatine, and in possessing no bleaching qualities.

Chloric acid combines with the bases, and forms the *chlorates*, a set of salts formerly called *hyperoxymuriates*. They may be formed either directly, by saturating the alkali or earth with the chloric acid, or by the old process of transmitting chlorine through the solutions of the bases, in Woolf's bottles. In this case the water is decomposed. Its oxygen unites to one portion of the chlorine, forming chloric acid, while its hydrogen unites to another portion of chlorine, forming muriatic acid; and hence, chlorates and muriates must be contemporaneously generated, and must be afterwards separated by crystallisation, or peculiar methods.

CHLORIC OXIDE. The peroxide of chlorine.

CHLO'RIDE. A compound of chlorine with a base.

Chloride of azote. See *Nitrogen*.

Chloride of lime. See *Calcis chloridum*.

CHLORIDE OF SODA. *Chlorite of soda.* A compound of chlorine and soda, formed by passing chlorine into a cold dilute solution of pure soda, or by decomposing chloride of lime by carbonate of soda. It smells like chlorine, and has similar bleaching properties. When exposed to the air it absorbs carbonic acid and evolves chlorine.

CHLO'RINE. (From χλωρος, green, on account of its colour.) A substance discovered in the year 1770 by Scheele, while investigating the nature of manganese; and he described it under the name of *dephlogisticated marine acid*. The French chemists called it *oxygenised muriatic acid*, a term which was afterwards contracted to *oxy-muriatic acid*, from an opinion proposed by Berthollet, that it is a compound of muriatic acid and oxygen. In 1809, Gay-Lussac and Thenard published an abstract of some experiments upon this substance, which subsequently appeared at length in their *Recherches Physico-Chimiques*, wherein they stated, that oxymuriatic acid might be regarded as a simple body, though they gave the preference to the doctrine advanced by Berthollet. Sir H. Davy engaged in the inquiry about the same time; and after having exposed oxymuriatic acid to the most powerful decomposing agents which chemists possess, without being able to effect its decomposition, he communicated to the Royal Society an essay, in which he denied its compound nature; and he maintained that, according to the true logic of chemistry, it is entitled to rank with simple bodies. This view, which is commonly termed the *new theory of chlorine*, though strongly objected to at the time it was first proposed, is supported by the most powerful analogies, and adequate to the explanation of all chemical phenomena in which chlorine is concerned. It is now therefore almost universally received by chemists.

Chlorine gas is obtained by the action of muriatic acid on peroxide of manganese. The most convenient method of preparing it is by mixing concentrated muriatic acid, contained in a glass flask, with half its weight of finely powdered peroxide of manganese. Effervescence, owing to the escape of chlorine, takes place even in the cold; but the gas is evolved much more freely by the application of a moderate heat. It should be collected in inverted glass bottles, filled with warm water; and when the water is wholly displaced by the gas, the bottles should be closed with a well-ground glass stopper. As some muriatic acid gas commonly passes over with it, the chlorine should not be considered quite pure, till after being transmitted through water.

Before explaining the theory of this process, it may be premised that muriatic acid consists of 35·45 parts or one equivalent of chlorine, and 1 part or one equivalent of hydrogen. Peroxide of manganese is composed of 27·7 parts or one equivalent of manganese, and 16 or two equivalents of oxygen. When these compounds react on each other, one equivalent of each is decomposed. The peroxide of manganese gives one equivalent of oxygen to the hydrogen of the muriatic acid, in consequence of which one equivalent of water is generated, and one equivalent of chlorine disengaged; while the protoxide of manganese unites with an equivalent of undecomposed muriatic acid, and forms an equivalent of muriate of the protoxide of manganese. Consequently, for every 43·7 grains of peroxide of manganese, 72·9 (36·45 × 2) grains of real muriatic acid disappear; and 35·45 parts of chlorine, 9 of water, and 72·15 of protomuriate of manganese, are the products of the decomposition. The affinities which determine these changes are the attraction of oxygen for hydrogen, and of protoxide of manganese for muriatic acid.

When it is an object to prepare chlorine at the cheapest rate, as for the purposes of manufacture, the preceding process is modified in the following manner: — Three parts of sea-salt are intimately mixed with one of peroxide of manganese, and to this mixture two parts of sulphuric acid, diluted with an equal weight of water, are added. By the action of sulphuric acid on sea-salt, muriatic acid is disengaged, which, reacts as in the former case, upon the peroxide of manganese; so that, instead of adding muriatic acid directly to the manganese, the materials for forming it are employed. In this process, however, the protoxide of manganese unites with sulphuric instead of muriatic acid, and the residue is sulphate of manganese and sulphate of soda.

Chlorine (from χλωρος, green) is a yellowish-green coloured gas, which has an astringent taste, and a disagreeable odour. It is one of the most suffocating of the gases, exciting spasm and great irritation of the glottis, even when considerably diluted with air. When strongly and suddenly compressed, it emits both heat and light, — a character which it possesses in common with air and oxygen gas; but Thenard has shown, that though all gases are heated by sudden compression, the temperature in our experiments is never so great as to render the gas

luminous. The light emitted by oxygen and chlorine arises from the heat due to compression, causing the gases to act chemically on the oil with which the compressing vessel is lubricated: when no organic matter is present, no light whatever appears. (*An. de Ch. et Ph.* xliv. 181.) According to Davy 100 cubic inches of dry chlorine, at 30 B. and 60 F. weigh between 76 and 77 grains. Gay-Lussac and Thenard found the density of pure and dry chlorine to be 2·47, which gives 76·599 grains as the weight of 100 cubic inches at 60° F. and 30° B. The estimate of Dr. Thomson, namely 2·5, which gives 77·529 as the weight of 100 cubic inches, differs widely from that of the other observers, and is, it is believed, erroneous. Under the pressure of about four atmospheres it is a limpid liquor, of a bright yellow colour, which does not freeze at the temperature of zero, and which assumes the gaseous form with the appearance of ebullition when the pressure is removed. Mr. Kemp finds that this liquid is a non-conductor of electricity.

In consequence of the extensive range of affinity possessed by chlorine, it is important that its combining proportion should be determined with precision. Recent observations satisfied Dr. Turner that 35·45, inferred from the experiments of Berzelius, is very nearly correct; and that 36, the equivalent which had been formerly adopted by him on the authority of Dr. Thomson, was inexact.

Cold recently boiled water, at the common pressure, absorbs twice its volume of chlorine, and yields it again when heated. The solution, which is made by transmitting a current of chlorine gas through cold water, has the colour, taste, and most of the other properties of the gas itself. When moist chlorine gas is exposed to a cold of 32° F. yellow crystals are formed, which consist of water and chlorine in definite proportions. They are composed, according to Mr. Faraday, of 35·45 parts or one equivalent of chlorine, and 90 or ten equivalents of water.

Chlorine experiences no chemical change from the action of the imponderables. Thus it is not effected chemically by intense heat, by strong shocks of electricity, or by a powerful galvanic battery. Sir H. Davy exposed it also to the action of charcoal heated to whiteness by galvanic electricity, without separating oxygen from it, or in any way affecting its nature. Light does not act on dry chlorine; but if water be present, the chlorine decomposes that liquid, unites with the hydrogen to form muriatic acid, and oxygen gas is set at liberty. This change takes place quickly in sunshine, more slowly in diffused day-light, and not at all when light is wholly excluded. Hence the necessity of keeping moist chlorine gas, or its solution, in a dark place, if it is wished to preserve it for any time.

Chlorine unites with some substances with evolution of heat and light, and is hence termed a supporter of combustion. If a lighted taper be plunged into chlorine gas, it burns for a short time with a small red flame, and emits a large quantity of smoke. Phosphorus takes fire in it spontaneously, and burns with a pale white light. Several of the metals, such as tin, copper, arsenic, antimony, and zinc, when introduced into chlorine in the state of powder or in fine leaves, are suddenly inflamed. In all these cases the combustible substances unite with chlorine.

Chlorine has a very powerful attraction for hydrogen; and many of the chemical phenomena, to which chlorine gives rise, are owing to this property. A striking example is its power of decomposing water by the action of light, or at a red heat; and most compound substances, of which hydrogen is an element, are deprived of that principle, and therefore decomposed in like manner. For the same reason, when chlorine, water, and some other body which has a strong affinity for oxygen, are presented to one another, water is usually resolved into its elements, its hydrogen attaching itself to the chlorine, and its oxygen to the other body. Hence it happens that chlorine is, indirectly, one of the most powerful oxidising agents which we possess.

When any compound of chlorine and an inflammable is exposed to the influence of galvanism, the inflammable body goes over to the negative, and chlorine to the positive pole of the battery. This establishes a close analogy between oxygen and chlorine, both of them being supporters of combustion, and both negative electrics.

Chlorine, though formerly called an acid, possesses no acid properties. It has not a sour taste, does not redden the blue colour of plants, and shows comparatively little disposition to unite with alkalis. Its strong affinity for the metals is sufficient to prove that it is not an acid; for chemists are not acquainted with any instance of an acid combining directly in definite proportion with a metal.

The mutual action of chlorine and the pure alkalis leads to complicated changes. If chlorine gas be passed into a solution of potash till all alkaline reaction cease, a liquid is obtained which has the odour of a solution of chlorine in water. But on applying heat, the chlorine disappears entirely, and the solution is found to contain two neutral salts, chlorate and muriate of potash. The production of the two acids is owing to decomposition of water, the elements of which unite with separate portions of chlorine and form chloric and muriatic acids. The affinities which give rise to this change are the attraction of chlorine for hydrogen, of chlorine for oxygen, and of the two resulting acids for the alkali.

One of the most important properties of chlorine is its bleaching power. All animal and vegetable colours are speedily removed by chlorine; and when the colour is once discharged, it can never be restored. Sir H. Davy proved that chlorine cannot bleach unless water is present. Thus, dry litmus paper suffers no change in dry chlorine; but when water is admitted, the colour speedily disappears. It is well known also that muriatic acid is always generated when chlorine bleaches. From these facts it is inferred that water is decomposed during the process; that its hydrogen unites

with chlorine; and that decomposition of the colouring matter is occasioned by the oxygen which is liberated. The bleaching property of binoxide of hydrogen and of chromic and permanganic acids, of which oxygen is certainly the decolorising principle, leaves little doubt of the accuracy of the foregoing explanation.

Chlorine is useful, likewise, for the purposes of fumigation. The experience of Guyton Morveau is sufficient evidence of its power in destroying the volatile principles given off by putrefying animal matter; and it probably acts in a similar way on contagious effluvia. A peculiar compound of chlorine and soda, the nature of which will be considered in the section on Sodium, has been lately introduced for this purpose by M. Labarraque.

Chlorine is in general easily recognised by its colour and odour. Chemically it may be detected by its bleaching property, added to the circumstance that a solution of nitrate of silver occasions in it a dense white precipitate (a compound of chlorine and metallic silver), which becomes dark on exposure to light, is insoluble in acids, and dissolves completely in pure ammonia. The whole of the chlorine, however, is not thrown down by nitrate of silver; for the oxygen of the oxide of silver unites with a portion of chlorine, and converts it into chloric acid.

Those compounds of chlorine, which are not acid, are termed *chlorides*, or *chlorurets*. The former expression, from the analogy between chlorine and oxygen, is perhaps the more appropriate.

Chlorine unites with hydrogen, forming hydrochloric, or muriatic acid. See *Hydrochloric acid*.

Chlorine forms several compounds with oxygen. The leading character of these compounds is derived from the circumstance, that chlorine and oxygen, the attraction of which for most elementary substances is so energetic, have but a feeble affinity for each other. These principles, consequently, are never met with in nature in a state of combination. Indeed, they cannot be made to combine directly; and when they do unite, very slight causes effect their separation. Chemists are not agreed as to the exact number of the compounds of chlorine and oxygen. The subjoined list contains those which hitherto have been generally admitted; but the existence of the first is very problematical, while some enumerate a fifth under the name of *chlorous acid* : —

	By Weight.		By Volume.	
	Chl.	Oxy.	Chl.	Oxy.
Protoxide of chlorine	35·45	8	2	1
Peroxide of chlorine...	35·45	32	2	4
Chloric acid.....	35·45	40	2	5
Perchloric acid.....	35·45	56	2	7

According to the practice of most British chemists two volumes of chlorine, as also two volumes of hydrogen and of nitrogen, are considered as respectively corresponding to one equivalent or one atom; whereas one volume of oxygen corresponds to one equivalent. Berzelius, with many continental chemists, considering the atoms of all elements to possess the same volume, regard the four preceding compounds as composed of 2 atoms or 1 equivalent of chlorine combined with 1, 4, 5, and 7, atoms or equivalents of oxygen.

Protoxide of Chlorine. — This gas was discovered in 1811 by Davy; and was described by him, in the *Philosophical Transactions* for that year, under the name of *Euchlorine*. It is made by the action of muriatic acid on chlorate of potash; and its production is explicable by the fact, that muriatic and chloric acids mutually decompose each other. When muriatic acid and chlorate of potash are mixed together, part of the muriatic acid unites with the potash of the salt, and thus sets chloric acid free, which instantly reacts on the free muriatic acid. The result of the reaction depends on the relative quantity of the substances. If chlorate of potash be mixed with excess of concentrated muriatic acid, the chloric acid undergoes complete decomposition. For each equivalent of chloric, five equivalents of muriatic acid are decomposed: the five equivalents of oxygen, contained in the former, unite with the hydrogen of the latter, producing five equivalents of water; while the chlorine of both acids is disengaged. If, on the contrary, chlorate of potash is in excess, and the muriatic acid diluted, the chloric acid is deprived of part of its oxygen only; and the products are water, protoxide of chlorine, and chlorine; the two latter escaping in the gaseous form. The best proportion of the ingredients is two parts of chlorate of potash, one of strong muriatic acid, and one of water; and the reaction of the materials should be promoted by heat sufficient to produce moderate effervescence. The gases should be collected over mercury, which combines with the chlorine, and leaves the protoxide of chlorine in a pure state.

Protoxide of chlorine has a yellowish green colour similar to that of chlorine, but considerably more brilliant; which induced Davy to give it the name of *Euchlorine*. Its odour is like that of burned sugar. Water dissolves eight or ten times its volume of the gas, and acquires a colour approaching to orange. It bleaches vegetable substances, but gives the blue colours a tint of red before destroying them. It does not unite with alkalis, and therefore is not an acid.

Protoxide of chlorine is explosive in a high degree. The heat of the hand, or the pressure occasioned in transferring it from one vessel to another, sometimes causes an explosion. This effect is also occasioned by phosphorus, which bursts into flame at the moment of immersion. All burning bodies, by their heat, occasion an explosion, and then burn vividly in the decomposed gas. With hydrogen it forms a mixture which explodes by flame or the electric spark, with production of water and muriatic acid. The best proportion is fifty measures of protoxide of chlorine to eighty of hydrogen.

Protoxide of chlorine is easily analysed by heating a known quantity of it in a strong tube over mercury. An explosion takes place; and 50 measures of the gas expand to 60 measures, of which 20 are oxygen, and 40 chlorine. From this it was considered to contain an equivalent of chlorine and oxygen. But most chemists

have regarded the existence of euchlorine as problematical, suspecting it to be a mere mixture of chlorine with the peroxide of chlorine; and M. Soubeiran, supposing his experiments correct, has lately proved this suspicion to be well-founded. He finds that euclorine itself acts on mercury, and therefore cannot be purified by its means. He effected its purification by transmitting the gas through a tube nearly full of calomel, which absorbed the free chlorine only; and on subsequently exploding the oxide of chlorine thus purified, he obtained one volume of chlorine to two volumes of oxygen, being the precise composition of the peroxide. The confirmation of these results will cause the removal of euchlorine from the list of definite compounds. (*An. de Ch. et Ph.* xlviii. 113.)

Peroxide of Chlorine. — This compound was discovered in 1815 by Sir H. Davy (*Phil. Trans. for* 1815), and soon after by Count Stadion of Vienna. It is formed by the action of sulphuric acid on chlorate of potash. A quantity of this salt, not exceeding 50 or 60 grains, is reduced to powder, and made into a paste by the addition of strong sulphuric acid. The mixture, which acquires a deep yellow colour, is placed in a glass retort, and heated by warm water, the temperature of which is kept under 212° F. A bright yellowish green gas, of a still richer colour than protoxide of chlorine, is disengaged, which has an aromatic odour without any smell of chlorine, is absorbed rapidly by water, to which it communicates its tint, and has no sensible action on mercury. This gas is peroxide of chlorine.

The chemical changes which take place in the process are explained in the following manner: — The sulphuric acid decomposes some of the chlorate of potash, and sets chloric acid at liberty. The chloric acid, at the moment of separation, resolves itself into peroxide of chlorine and oxygen; the last of which, instead of escaping as free oxygen gas, goes over to the acid of some undecomposed chlorate of potash, and converts it into perchloric acid. The whole products are bi-sulphate and perchlorate of potash, and peroxide of chlorine. It is most probable, from the data contained in the preceding table, that every 3 equivalents of chloric acid yield 1 equivalent of perchloric acid and 2 equivalents of peroxide of chlorine.

Peroxide of chlorine does not unite with alkalis. It destroys most vegetable blue colours, without previously reddening them. Phosphorus takes fire when introduced into it, and occasions an explosion. It explodes violently when heated to a temperature of 212° F., emits a strong light, and undergoes a greater expansion than protoxide of chlorine. According to Sir H. Davy, whose result is confirmed by Gay-Lussac, 40 measures of the gas occupy after explosion the space of 60 measures; and of these, 20 are chlorine and 40 oxygen. The peroxide is therefore composed of 35·45 parts or one equivalent of chlorine, united with 32 or four equivalents of oxygen; and its specific gravity must be 2·346. Count Stadion considers the chlorine to be united with 3 instead of 4 equivalents of oxygen; but the late researches of Soubeiran confirm the statement of Davy. For the acid compounds of chlorine and oxygen, see *Chloric acid*, *Perchloric acid*, and *Chlorous acid*.

Chloride of Nitrogen. — The mutual affinity of chlorine and nitrogen is very slight: they do not combine at all if presented to each other in their gaseous form; and when combined, they are easily separated. Chloride of nitrogen is formed by the action of chlorine on some salt of ammonia. Its formation is owing to the decomposition of ammonia (a compound of hydrogen and nitrogen) by chlorine. The hydrogen of the ammonia unites with chlorine, and forms muriatic acid; while the nitrogen of the ammonia, being presented in its nascent state to chlorine dissolved in the solution, enters into combination with it.

A convenient method of preparing chloride of nitrogen is the following: — An ounce of muriate of ammonia is dissolved in twelve or sixteen ounces of hot water; and when the solution has cooled to the temperature of 90° F., a glass bottle with a wide mouth, full of chlorine is inverted in it. The solution gradually absorbs the chlorine, and acquires a yellow colour; and in about twenty minutes or half an hour, minute globules of a yellow fluid are seen floating like oil upon its surface, which, after acquiring the size of a small pea, sink to the bottom of the liquid. The drops of chloride of nitrogen, as they descend, should be collected in a small saucer of lead, placed for that purpose under the mouth of the bottle.

Chloride of nitrogen, discovered in 1811 by Dulong, (*An. de Ch.* lxxxvi.) is one of the most explosive compounds yet known, having been the cause of serious accidents both to its discoverer and to Sir H. Davy. (*Phil. Trans.* 1813.) Its specific gravity is 1·653. It does not congeal in the intense cold produced by a mixture of snow and salt. It may be distilled at 160° F.; but at a temperature between 200° and 212° it explodes. It appears, from the investigation of Messrs. Porrett, Wilson, and Kirk, that its mere contact with some substances of a combustible nature causes detonation even at common temperatures. This result ensues particularly with oils, both volatile and fixed. Dr. Turner has never found olive oil to fail in producing the effect. The products of the explosion are chlorine and nitrogen. (*Nicholson's Journal*, xxxiv.)

Sir H. Davy analysed chloride of nitrogen by means of mercury, which unites with chlorine, and liberates the nitrogen. He inferred from his analysis, that its elements are united in the proportion of four measures of chlorine to one of nitrogen; and it hence follows that, by weight, it consists of 4 equivalents of chlorine, and 1 equivalent of nitrogen.

Compounds of Chlorine and Carbon. — For the knowledge of the compounds of chlorine and carbon, chemists are indebted to the ingenuity of Mr. Faraday. When olefiant gas (a compound of carbon and hydrogen) is mixed with chlorine, combination takes place between them, and an oil-like liquid is generated, which consists of chlorine, carbon, and hydrogen. On

exposing this liquid in a vessel full of chlorine gas to the direct solar rays, the chlorine acts upon and decomposes the liquid; muriatic acid is set free, and the carbon, at the moment of separation, unites with the chlorine. (*Phil. Trans.* 1821.)

Perchloride of Carbon, as this compound is named by Mr. Faraday, is solid at common temperatures, has an aromatic odour approaching to that of camphor, is a non-conductor of electricity, and refracts light very powerfully. Its specific gravity is exactly double that of water. It fuses at 320° F., and after fusion it is colourless and very transparent. It boils at 360°, and may be distilled without change, assuming a crystalline arrangement as it condenses. It is sparingly soluble in water, but dissolves in alkohol and ether, especially by the aid of heat. It is soluble also in fixed and volatile oils.

Perchloride of carbon burns with a red light when held in the flame of a spirit-lamp, giving out acid vapours and smoke; but the combustion ceases as soon as it is withdrawn. It burns vividly in oxygen gas. Alkalis do not act upon it: nor is it changed by the stronger acids, such as the muriatic, nitric, or sulphuric acids, even with the aid of heat. When its vapour, mixed with hydrogen, is transmitted through a red-hot tube, charcoal is separated, and muriatic acid gas evolved. On passing its vapour over the peroxides of metals, such as that of mercury and copper, heated to redness, a chloride of the metal and carbonic acid are generated. Protoxides, under the same treatment, yield carbonic oxide gas and metallic chlorides. Most of the metals decompose it also at the temperature of ignition, uniting with its chlorine, and causing deposition of charcoal.

From the proportions of chlorine and olefiant gas employed in forming perchloride of carbon, and from its analysis, made by passing it over oxide of copper at the temperature of ignition, Mr. Faraday infers, that this compound consists of 106·35 parts or 3 equivalents of chlorine, and 12 parts or 2 equivalents of carbon.

New Chloride of Liebig. — This active chemist has lately described a new substance under the name of *Chloral*, which consists of chlorine, carbon, and oxygen, as will be more fully stated in the latter part of this section. On boiling this substance in a solution of potash, lime, or baryta, a muriate and formate are generated, and the new chloride of carbon passes over in vapour. It is then washed repeatedly with pure water, and obtained quite dry by admixture with strong sulphuric acid, and distillation at 212° F. It may also be more conveniently prepared by distilling, from a capacious retort, a mixture of 1 pound of chloride of lime, 3 pounds of water, and 2 or 3 ounces either of alkohol or pyroacetic spirit.

The new chloride of carbon is a limpid colourless liquid, similar in odour and appearance to the oily fluid which chlorine forms with olefiant gas; though in density, volatility, and composition, it is quite different. Its density is 1·48; and it boils at 141° F. It is but feebly combustible, and is not changed at moderate temperatures either by acids or alkalis.

It is freely dissolved by alkohol and ether, and is precipitated from them by water, in which it is quite insoluble. It may be distilled in contact with potassium, without change. When its vapour is transmitted over metallic copper, charcoal is deposited, no gas whatever appears, and a metallic chloride is formed. From an analysis made by transmitting its vapour over oxide of copper at a red oxide, when chloride of copper and carbonic acid were the sole products, Leibig infers that his new chloride consists of 2 equivalents of carbon and $2\frac{1}{2}$ of chlorine, or of 4 atoms of the former to 5 of the latter. (*An. de Ch. et Ph.* xlix. 146.)

Protochloride of Carbon. — When the vapour of perchloride of carbon is passed through a red-hot glass or porcelain tube, containing fragments of rock crystal to increase the extent of heated surface, partial decomposition takes place; chlorine gas escapes, and a fluid passes over, which Mr. Faraday calls the *protochloride of carbon*.

Protochloride of carbon is a limpid colourless fluid, which does not congeal at zero of Fahrenheit, and at 160° or 170° F. is converted into vapour. It may be distilled repeatedly without change; but when exposed to a red heat, some of it is resolved into its elements. Its specific gravity is 1·5526. In its chemical relations it is very analogous to perchloride of carbon. Mr. Faraday analysed it by transmitting its vapour over ignited oxide of copper; and he infers from the products of its decomposition — carbonic acid and chloride of copper — that it is composed of 35·45 parts or 1 equivalent of chlorine, and 6 parts or 1 equivalent of carbon.

A fourth compound of chlorine and carbon is described in volume xvii. of the *Annals of Philosophy*. It was brought from Sweden by M. Julin; and is said to have been formed, during the distillation of nitric acid, from crude nitre and sulphate of iron. It occurs in small, soft, adhesive fibres of a white colour, which have a peculiar odour, somewhat resembling spermaceti. It fuses on the application of heat; and boils at a temperature between 350° and 450° F. At 250° F. it sublimes slowly, and condenses again in the form of long needles. It is insoluble in water, acids, and alkalis; but is dissolved by hot oil of turpentine or by alkohol, and forms acicular crystals as the solution cools. It burns with a red flame, emitting much smoke and fumes of muriatic acid gas.

The nature of this substance is shown by the following circumstances: — When its vapour is exposed to a red heat, evolution of chlorine gas ensues, and charcoal is deposited. A similar deposition of charcoal is produced by heating it with phosphorus, iron, or tin; and a chloride is formed at the same time. Potassium burns vividly in its vapour with formation of chloride of potassium and separation of charcoal. On detonating a mixture of its vapour with oxygen gas over mercury, a chloride of that metal and carbonic acid are generated. From these facts, the greater part of which were ascertained by Messrs. Phillips and Faraday, it follows that

the substance brought from Sweden by M. Julin is a compound of chlorine and carbon; and the same able chemists conclude, from their analysis, that its elements are united in the ratio of 1 equivalent of chlorine to 2 equivalents of carbon. (*An. of Phil.* xviii. 150.)

Chloride of Sulphur was discovered in the year 1804 by Dr. Thomson, and was afterwards examined by Berthollet. It is most conveniently prepared by passing a current of chlorine gas over flowers of sulphur gently heated, until nearly all the sulphur disappears. Direct combination ensues, and the product, distilled off from uncombined sulphur, is obtained under the form of a liquid which appears red by reflected, and yellowish-green by transmitted light. Its density is 1·687. It is volatile below 200° F., boils at 280°, yielding vapour which has a density of 4·70, and condenses again without change in cooling. When exposed to the air it emits acrid fumes, which irritate the eyes powerfully, and have an odour somewhat resembling sea-weed, but much stronger. Dry litmus paper is not reddened by it, nor does it unite with alkalis. It acts with energy on water: — mutual decomposition ensues, with formation of muriatic and hyposulphurous acids; but as the latter quickly begins to be resolved into sulphur and sulphurous acid, the water is rendered cloudy by a deposit of sulphur. From a recent analysis by Rose, it consists of 35·45 parts or 1 equivalent of chlorine and 16 parts or 1 equivalent of sulphur. (*Pog. Annalen*, xxi. 431.)

Rose maintains, that the preceding is the only chloride of sulphur, arguing that the bi-chloride analysed by Davy was merely chloride of sulphur holding chlorine in solution. Dumas, on the other hand, contends, that when sulphur is acted on by access of chlorine, a bi-chloride of sulphur is really obtained, which is apt to retain traces of the protochloride, and can only be purified by repeated distillation, at about 140° F. This bi-chloride is a liquid of a deep reddish brown tint, and has a density of 1·62. It boils at 147° F.; and the density of its vapour is between 3·67 and 3·70. By decomposition in water it should yield muriatic and sulphurous acids. (*An. de Ch. et Ph.* xlix. 205.)

Compounds of Chlorine and Phosphorus. — There are two definite compounds of chlorine and phosphorus, the nature of which was first satisfactorily explained by Sir H. Davy. (*Elements*, p. 290.) When phosphorus is introduced into a jar of dry chlorine, it inflames; and on the inside of the vessel a white matter collects, which is *Perchloride of Phosphorus*. It is very volatile; a temperature much below 212° F. being sufficient to convert it into vapour. Under pressure it may be fused; and it yields transparent prismatic crystals in cooling.

Water and perchloride of phosphorus mutually decompose each other; and the sole products are muriatic and phosphoric acids. Now in order that these products should be formed, consistently with the constitution of phosphoric acid, the perchloride must consist of 15·7 parts or 1 equivalent of phosphorus, and 88·62 parts or $2\frac{1}{2}$ equivalents of chlorine. One equivalent of the chloride and two and a half of water will then mutually decompose each other without any element being in excess, and yield 1 equivalent of phosphoric, and $2\frac{1}{2}$ equivalents of muriatic acid. This proportion is not far from the truth; for, according to Davy, one grain of phosphorus is united in the perchloride with six of chlorine.

Protochloride of Phosphorus may be made either by heating the perchloride with phosphorus, or by passing the vapour of phosphorus over corrosive sublimate contained in a glass tube. It is a clear liquid like water, of specific gravity 1·45; emits acid fumes when exposed to the air, owing to the decomposition of watery vapour; but when pure it does not redden dry litmus paper. On mixing it with water, mutual decomposition ensues, heat is evolved, and a solution of muriatic and phosphorous acids is obtained. It hence appears to consist of 15·7 parts or 1 equivalent of phosphorus, and 53·17 parts or $1\frac{1}{2}$ equivalent of chlorine.

When sulphuretted hydrogen gas is transmitted through a vessel containing perchloride of phosphorus, muriatic acid is disengaged, and a liquid produced, which Serullas states to be a compound of 3 equivalents of chlorine, 1 of phosphorus, and 1 of sulphur. (*An. de Ch. et Ph.* xlii. 25.)

Chlorocarbonic acid Gas. — This compound was discovered in 1812, by Dr. John Davy, who described it, in the *Philosophical Transactions* for that year, under the name of *Phosgene Gas.* (From φως, light, and γενναω, to produce.) It is made by exposing a mixture of equal measures of dry chlorine and carbonic oxide gases to sunshine, when rapid but silent combination ensues, and they contract to one half their volume. Diffused day-light also effects their union slowly; but they do not combine at all when the mixture is wholly excluded from light.

Chlorocarbonic acid Gas is colourless, has a strong odour, and reddens dry litmus paper. It combines with four times its volume of ammoniacal gas, forming a white solid salt; so that it possesses the characteristic property of acids. It is decomposed by contact with water. One equivalent of each compound undergoes decomposition; and as the hydrogen of the water unites with chlorine, and its oxygen with carbonic oxide, the products are carbonic and muriatic acids. When tin is heated in chlorocarbonic acid gas, chloride of tin is generated, and carbonic oxide gas set free, which occupies exactly the same space as the chlorocarbonic acid which was employed. A similar change occurs when it is heated in contact with antimony, zinc, or arsenic.

As chlorocarbonic acid gas contains its own volume of each of its constituents, it follows that 100 cubic inches of that gas, at the standard temperature and pressure, must weigh 106·749 grains; namely, 76·599 of chlorine added to 30·15 of carbonic oxide. Its specific gravity is therefore 3·4421; and it consists of 55·45 parts or 1 equivalent of chlorine, and 14 parts or 1 equivalent of carbonic oxide.

Chloral. — This name, derived from the first

syllable of the words *Chlorine* and *Alkohol*, has been applied by Liebig to a new compound of chlorine, carbon, and oxygen, prepared by the mutual action of alkohol and chlorine. The production of the new substance more immediately depends on the union of one portion of chlorine with the hydrogen both of the olefiant gas and some of the water which constitute alkohol, while the corresponding carbon and oxygen unite with another portion of chlorine. A very large quantity of chlorine is therefore required for its production, and a large quantity of muriatic acid is generated. When chlorine is transmitted through common alkohol, the chloral at first formed is retained in solution by the water of the alkohol; but when the liquid becomes charged with muriatic acid, the chloral insoluble in that solution subsides as a liquid of an oily aspect. The method recommended by Liebig is to transmit dry chlorine gas into absolute alkohol. At first the alkohol should be artificially cooled, since otherwise the action is attended with flame; but as soon as muriatic acid begins to accumulate, it is necessary to expel it by a continued gentle heat, since its presence protects the alkohol from decomposition, and thereby prevents the absorption of the chlorine. By acting in this manner for several successive days, Liebig succeeded in decomposing eight ounces of absolute alkohol, and obtained a liquid of syrupy consistence, which after a few days became a soft white crystalline solid. In this state the chloral is united with water as a hydrate of unknown composition, and also contains traces of undecomposed alkohol and muriatic acid. On agitation with strong sulphuric acid it is rendered anhydrous, and rises as a liquid to the surface; and by distillation from unslacked lime or baryta, muriatic acid is entirely separated.

Pure chloral is a colourless transparent liquid, of a penetrating pungent odour; is oily to the touch, and has a density of 1·502. It is nearly tasteless, or at most oily. It boils at 201° F., and may be distilled without change. In water, with the aid of gentle heat, it is freely dissolved without decomposition. Agitated with a few drops of water, it forms a white crystalline mass, which appears to be a hydrate, though its composition is unknown; for when put into water, the chloral appears oily as usual, and by heat a solution having the characteristic odour and character of chloral is obtained. On keeping this crystalline hydrate for a few days, it becomes a very white flocculent matter, which is quite insoluble in water. From the ratio of its ingredients Liebig regards it also as a hydrate, formed of two equivalents, one of water to one of chloral.

Chloral unites with iodine, bromine, and sulphur. It may be distilled from the anhydrous metallic oxides without change; but when its vapour is transmitted over anhydrous baryta, strontia, or lime heated to 212° F., instant decomposition ensues, and the earth becomes incandescent. Carbonic oxide gas escapes at the same time, and a metallic chloride, intermixed with a light charcoal, is generated. Similar products are obtained; but of course more charcoal, when the vapour of chloral is transmitted over iron or copper at a red heat. Chloral is readily decomposed by the alkalies or alkaline earths, in the state of hydrates, or when dissolved in water. During this action the new chloride of carbon, already described, is deposited; and the solution is found to contain muriatic and formic acids; united, of course, with the alkali. To understand the source of these three products, a knowledge of the composition of chloral is necessary. By transmitting its vapour over ignited oxide of copper, Liebig converted it into chloride of copper and carbonic acid; and from the quantities thus obtained, he considers chloral to consist of 9 equivalents of carbon, 6 of chlorine, and four of oxygen. By the action of an alkali, 4 equivalents of carbon take 3 of chlorine, and constitute chloride of carbon; the remaining one equivalent of chlorine, with one equivalent of hydrogen from decomposed water, forms muriatic acid; and the 4 equivalents of oxygen from the chloral with one from decomposed water unite with 5 equivalents of carbon, giving rise to 5 equivalents of carbonic oxide, which, with $2\frac{1}{2}$ equivalents of water, yield $2\frac{1}{2}$ equivalents of formic acid. (*An. de Ch. et Ph.* xlix. 146.)

Chloride of Boron. — Sir H. Davy noticed, that recently prepared boron takes fire spontaneously in an atmosphere of chlorine, and emits a vivid light; but he did not examine the product. Berzelius remarked, that if the boron has been previously heated, whereby it is rendered more compact, the combustion does not take place till heat is applied. This observation led him to expose boron, thus rendered dense, in a glass tube, to a current of dry chlorine; and to heat it gently, as soon as the atmospheric air was completely expelled, in order to commence the combustion. The resulting compound proved to be a colourless gas; and on collecting it over mercury, which absorbed free chlorine, he procured the chloride of boron in a state of purity. This gas is rapidly absorbed by water; but double decomposition takes place at the same instant, giving rise to the production of muriatic and boracic acids. The watery vapour of the atmosphere occasions a similar change, so that when the gas is mixed with air containing hygrometric moisture, a dense white cloud is produced. The specific gravity of the gas, according to Dumas, is 3·942. It is soluble in alkohol, and communicates to it an etherial odour, apparently by the action of muriatic acid. It unites with ammoniacal gas, forming a fluid volatile substance, the nature of which is unknown. — (*Annals of Phil.* xxvi. 129.)

Dumas finds that chloride of boron may be generated by the action of dry chlorine on a mixture of charcoal and boracic acid, heated to redness in a porcelain tube. Despretz also appears to have invented a similar process. — (*Philos. Magazine and Annals*, i. 469.)

The composition of the chloride of boron may be inferred from its action on water. If the constitution of boracic acid, as estimated by Dr. Thomson, is correct, the chloride of boron should consist of 70·9 parts or two equivalents

of chlorine, and 8 parts or one equivalent of boron; for 1 equivalent of such a compound, with 2 of water, will yield 1 of boracic and 2 equivalents of muriatic acid.

Chloro-nitrous Gas. — When fused chloride of sodium, potassium, or calcium, in powder, is treated with as much strong nitric acid as is sufficient to wet it, mutual decomposition ensues, and a new gas, composed of chlorine and binoxide of nitrogen, is generated. Its discoverer, Mr. E. Davy, describes it as a gas of a pale reddish yellow colour, of an odour similar to that of chlorine, though less pungent, and possessed of bleaching properties. It fumes on exposure to the air, and is freely absorbed by water. It is decomposed by sulphur, phosphorus, mercury, and most metals, and by substances in general which have an affinity for chlorine. It consists, according to Mr. Davy, of equal volumes of chlorine and binoxide of nitrogen, united without any condensation.

In the mutual decomposition of chloride of sodium and nitric acid, the products appear to be chloro-nitrous and chlorine gases, and nitrate of soda. Their formation must obviously depend on sodium being oxidised at the expense of nitric acid, while part of the chlorine unites, at the moment of separation from the sodium, with binoxide of nitrogen. (*Phil. Mag.* ix. 355.) Theoretically, it should be mixed with twice its volume of chlorine, the presence of which must materially obscure the properties of the new gas. — *Turner.*

CHLORI'ODATE. (*Chloriodas, atis.* f.) A compound of the chloriodic acid, with a salifiable base.

Chloriodic acid. See *Chlorine.*

Chlo'rium. See *Chlorine.*

Chlorocarbonic acid. See *Chlorine.*

CHLOROCYANIC ACID. (*Acidum chlorocyanicum.*) An acid composed of hydrocyanic acid and chlorine.

CHLOROPHYLLE. (*Chlorophyllum*; from χλωρος, green, and φυλλον, a leaf.) The green matter of the leaves of plants. Supposed by Pelletier and Caventou to be a peculiar proximate principle.

Chloroprussic acid. See *Chlorocyanic acid.*

CHLORO'SIS. (*is, is.* f.; from χλωρος, green.) The green sickness. A disease which principally affects young unmarried females. It is characterised by languor, listlessness, fatigue on the least exercise, palpitations of the heart, pains in the back, loins, and hips, flatulency and acidities in the stomach and bowels, constipation, a preternatural appetite for chalk, lime, and various other absorbents, and other symptoms indicative of loss of tone in the digestive organs, and universal debility. As it advances in its progress, the face becomes pale, and assumes a peculiar greenish hue; the whole body is flaccid, and likewise pale; the feet are affected with œdematous swellings; the breathing is much hurried by any considerable exertion of the body; the pulse is quick, but small; and the patient is apt to be affected with many of the symptoms of hysteria. From the commencement of the disorder, the catamenia are usually pale and scanty, and at length disappear altogether. If the disease be inveterate, various organic affections of the viscera are induced, which bring the case to a fatal termination. On dissection of those who have died of chlorosis, various lesions of the abdominal viscera are frequently detected; but as no one of these seems to have a more particular relation to the symptoms than another, they must be considered merely as the effects or accompaniments of the general morbid state. From the researches of M. Andral, it would appear that chlorosis is attended with a degree of anæmia, or a diminished proportion of the crassamentum to the serum of the blood, a circumstance which sufficiently explains the characteristic change of complexion, and the pale colour of the catamenia. From the circumstance of the menses being deficient in chlorosis, it has been supposed that the symptoms all arise from some peculiar derangement of the generative system incident to females about the age of puberty; that this idea, however, is erroneous, is sufficiently proved by the facts, that great debility of the uterine system and total defect of menstruation are frequently observed in young females who present no symptoms of chlorosis; that chlorosis sometimes occurs in girls before the age of puberty, and in adult and married women, as a consequence of abortion, fever, and other debilitating causes; and, lastly, that the disease is not in reality peculiar to the female sex, but is occasionally met with in young men of a very weakly habit.

The cure of chlorosis is to be attempted by increasing the tone of the system, and exciting the action of the uterine vessels. The first may be effected by a generous diet, with the moderate use of wine; by gentle and daily exercise, particularly on horseback; by agreeable company, to amuse and quiet the mind; and by tonic medicines, especially the preparations of iron, joined with myrrh, &c. Griffith's chalybeate, which is a compound of these, is very generally used, and with great success. See *Mistura ferri composita*, and the *Pillulæ ferri compositæ*. Cold bathing will be found a powerful corroborant, if the temperature of the bath be made gradually lower, as the patient bears it; and sometimes drinking the mineral chalybeate waters may assist. The bowels must be kept regular, and occasionally a gentle emetic will prepare for the tonic plan. The other object of stimulating the uterine vessels may be attained by the exercises of walking and dancing; by frequent friction of the lower extremities; by the pediluvium, hip-bath, &c.; by electric shocks, passed through the region of the uterus; by active purgatives, especially those containing aloes, which act particularly on the rectum, and thence sympathetically on the uterus. These means may be resorted to with more probability of success, when there appear efforts of the system to produce the discharge, the general health having been previously improved. Various remedies have been dignified with the title of emmenagogues, though mostly little to be depended on, as madder, &c. In obstinate cases, the tinctura cantharidis, or savine, may be tried, but with proper caution, as the most likely to avail.

CHLO'ROUS. (*Chlorosus*, from *chlorium*.) Of or belonging to chlorine.

CHLOROUS ACID. *Acidum chlorosum*. The name given by Berzelius to the *peroxide of chlorine*, which, from its being readily absorbed by water, from the strongly acrid taste of the solution, approaching to sour, and its giving a red tint to vegetable blues, is considered as approaching to an acid in its nature.

CHLOROUS OXIDE. Protoxide of chlorine. See *Chlorine*.

CHO'ANA. (Χοανα, a funnel; from χεω, to pour out.) The part of the brain called *infundibulum*.

CHO'ANUS. A furnace made like a funnel, for melting metals.

CHOCOLATE. (Dr. Alston says this word is compounded of two Indian words, *choco*, sound, and *atte*, water; because of the noise made in its preparation.) An article of diet prepared from the cacao-nut. See *Theobroma cacao*.

Chocolate-tree. See *Theobroma cacao*.

CHŒ'NICIS. (From χοινικις, the nave of a wheel.) The trepan: so called by Galen and P. Ægineta. Obsolete.

CHŒRAS. p. *Chœrades*. (From χοιρος, a swine.) A Greek name of scrofula.

CHŒRADO'LETHRON. (From χοιρος, a swine, and ολεθρος, destruction: so named from its being poisonous to hogs.) Hogbane. A name in Aëtius for the *Xanthium*, or lousebur.

CHOKE-DAMP. (*Damp*, from the German *dampff*, a vapour or exhalation.) The name given by miners, in Cornwall and other mining regions, to all irrespirable gases or vapours.

CHO'LADES. (From χολη, bile; or from κοιλος, hollow.) The smaller intestines were so called, because they contain bile, or because they are hollow.

Cholago. See *Cholas*.

CHO'LAGOGUE. (*Cholagogus*, *i*. m.; from χολη, bile, and αγω, to drive away.) Applied by the ancients to purgative medicines which brought away a great quantity of bile.

CHO'LAS. (From χολη, bile, or from κοιλος, hollow.) *Cholago*. 1. All the cavity of the hypochondria was so called by the Greeks.

2. The intestine. See *Cholades*.

CHO'LE. (Χολη. *Chole*, *es*. f.) The bile.

CHOLE'DOCHUS. (From χολη, bile, and δεχομαι, to receive.) Receiving or retaining the gall. That which receives the bile: applied to a duct.

CHOLEDOCHUS DUCTUS. *Ductus communis choledochus*. The common biliary duct, which conveys both the cystic and hepatic bile into the duodenum.

CHOLE'GON. See *Cholagogue*.

CHOLERA. (*a*, *æ*. f. According to Celsus, this word is derived from χολη, bile, and ρεω, to flow, thus signifying a flow of bile. According to Alexander of Tralles, it is derived from χολη, the intestine, and ρεω, to flow, signifying intestinal fluid. Others again derive it simply from χολη, bile— χολερα νοσος δια χολης. Vide Zonaræ Lexic. *in voce*. Donnegan derives it from χολερα, a gutter for carrying off the rain from the roof of a house: the conjecture is a very probable one, although most of the Greek lexicographers derive χολερα, a gutter, from χολη, bile.) *Felliflua passio*. *Cholera morbus*. This name is now applied to two diseases utterly dissimilar; to a common bilious disease long known in this and most other countries, and to a malignant disease of recent origin, which commenced in Hindustan, and has since diffused itself epidemically in various directions. It were much to be wished that some more appropriate designation should be agreed upon for the latter. To avoid confusion, we shall call the first common cholera, and the second malignant cholera.

1. *Common Cholera*. This consists in copious vomiting and purging of bilious matter, with violent griping, cramps of the muscles of the abdomen and lower extremities, and great depression of strength. Cullen makes two species of this genus: 1. *Cholera spontanea*, which happens, in hot seasons, without any manifest cause. 2. *Cholera accidentalis*, which occurs after the use of food that digests slowly, and irritates. In warm climates it is met with at all seasons of the year, and its occurrence is very frequent; but in England, and other cold climates, it is apt to be most prevalent in the middle of summer, particularly in the month of August; and the violence of the disease has usually been observed to be greater in proportion to the intenseness of the heat. The spontaneous species is produced by causes which influence the liver, so as to cause a superabundant secretion of bile, mostly of an acrimonious quality, such as suppressed perspiration in very hot weather, from cold or damp incautiously applied to the feet, and by taking cold drinks, especially when the body is considerably heated by exercise. This species is mostly epidemic at the close of summer, or the beginning of autumn. Sydenham says, as certainly as the appearance of swallows in the spring, or cuckoos about the dog-days. At this time the heat of the sun stimulates the liver to an inordinate secretion of bile, so that the alimentary canal becomes overloaded with it, the blood somewhat impregnated, while the liver itself is debilitated by undue action. The accidental species is generally caused by cold and indigestible fruits, as unripe apples and pears, cucumbers, melons, mushrooms; drastic purges, sudden fright, &c. It usually comes on with soreness, pain, distension, and flatulency in the stomach and intestines, succeeded quickly by a severe and frequent vomiting and purging of bilious matter, heat, thirst, a hurried respiration, and frequent but weak and fluttering pulse. When the disease is not violent, these symptoms, after continuing for a day or two, cease gradually, leaving the patient in a debilitated and exhausted state; but where the disease proceeds with much violence, there arises great depression of strength, with cold clammy sweats, considerable anxiety, a hurried and short respiration, and hiccoughs, with a sinking and irregularity of the pulse, which quickly terminate in death; an event that not unfrequently happens within the space of twenty-four hours.

On dissection the bowels are found loaded with bilious matter, and the ducts of the liver relaxed and distended. In the early period of the disease, when the strength is not much exhausted, the object is to lessen the irritation, and facilitate the discharge of the bile, by tepid demulcent liquids, frequently exhibited. It will likewise be useful to foment the abdomen, and to procure a determination to the surface by the pediluvium, or even the warm bath. But where the symptoms are urgent, and the patient appears rapidly sinking from the continued vomiting, violent pain, &c., it is necessary to give opium freely, but in a small bulk; from one to two grains should be given in the solid form, and repeated at intervals of an hour or two till relief be obtained. Sometimes where the stomach could not be got to retain the opium, it has answered in the form of clyster; or a liniment containing it may be rubbed into the abdomen; or a blister, applied over the stomach, may lessen the irritability of that organ. Afterwards the bile may be allowed to evacuate itself downwards; or mild aperients, or clysters given, if necessary, to promote its discharge. When the urgent symptoms are relieved, the strength must be restored by gentle tonics, as the aromatic bitters, calumba, and the like, with a light nutritious diet: strong toast and water is the best drink, or a little burnt brandy may be added if there is much languor. Exposure to cold must be carefully avoided, and the abdomen and feet in particular must be kept warm; and great attention is necessary to regulate the bowels, and procure a regular discharge of bile, lest a relapse should happen. It will also be proper to examine the state of the abdomen, whether pressure give pain at any part, because inflammation in the primæ viæ is very liable to supervene, often in an insidious manner: should that be the case, leeches, blistering the part, and other suitable means, must be promptly resorted to.

2. *Malignant Cholera. Asiatic Cholera. Blue Cholera. Pestilential Cholera. Spasmodic Cholera.* This disease, which is in many respects one of the most remarkable that has ever afflicted mankind, is decidedly of modern origin. Very severe and fatal visitation of epidemic cholera seem to have been known in the East Indies from time immemorial, but the earlier epidemies of this kind, although different from and much more intense than the ordinary bilious cholera, did not, as far as we can judge from the descriptions given of them, possess the peculiar characteristics of the disease now known under the name of malignant cholera. This pestilence is generally supposed to have originated at Jessore in the year 1817. There is reason to believe, however, that partial eruptions of the same malady had occurred before this period; and we have, in particular, one account, by Mr. Curtis, of a disease prevalent in Sir Edward Hughes's squadron in 1782, which was evidently in all respects identical with that which has since occasioned such devastation over the greater part of the globe: this was believed to have arisen from communication with an infected port in Ceylon. It is stated also by Mr. Barnes, who was medical superintendent at Jessore from the year 1810, that the disease had twice made its appearance at this place to a formidable extent previously to 1817; it would likewise appear, from the testimony of Dr. Christie, that it existed in the South of Bengal several months prior to its violent eruption at Jessore in the month of August of that year.

The epidemy, which commenced at Jessore, spread with frightful rapidity over Asia, sweeping away millions of human beings. In 1823 it appeared at Astracan; but did not at that time invade Russia any further. In 1828 it broke out at Orenburg; and raged with great violence in different parts of the Russian dominions in the spring of the ensuing year. In September, 1830, it reached Moscow. It now accompanied the Russian army into Poland. In the following year it diffused itself through various parts of Europe, and reached our own shores. The following account, taken from the papers published by the London Board of Health a short time before its appearance here, gives a good general idea of the malignant cholera as it presented itself in India:

The attack of the disease in extreme cases is so sudden, that, from a state of apparent good health, or with the feeling only of trifling ailment, an individual sustains as rapid a loss of bodily power as if he were suddenly struck down, or placed under the immediate effects of some poison; the countenance assuming a death-like appearance, the skin becoming cold, and giving to the hand (as expressed by some observers) the sensation of coldness and moisture which is perceived on touching a frog; by others represented as the coldness of the skin of a person already dead. The pulse is either feeble, intermitting, fluttering, or lost; a livid circle is observed round the eyelids; the eyes are sunk in their sockets; the tongue is cold, and either clean or covered with a slight white fur; and, in many instances, even the breath is cold. In cases of this severity, the vomiting and purging characteristic of the disease do not commonly take place so early as in milder attacks, but seem to be delayed until the almost overpowered functions of the body make a slight effort at reaction. It is worthy of remark, that, unless death takes place in these extreme cases within a few hours, some effort of the animal power is made to rally the constitution; and this point is insisted upon here, because it will direct the mind of practitioners to the particular moment when bleeding, and certain other parts of practice, recommended in the Indian reports, can be enforced in this country with probable success. Vomiting soon succeeds; first of some of the usual contents of the stomach, next of a turbid fluid, like whey, white of egg, water-gruel, or rice-water; described, perhaps, more accurately as a serous fluid, containing flocculi of coagulated albumen. The lower bowels seem to let go their contents; what happens to be lodged in the rectum is passed more or less in its natural state; the next discharges are similar to those thrown up from the stomach, and are passed with violence, as if squirted with a syringe.

The same similitude may be applied to the vomiting. Spasms, beginning at the toes and fingers, soon follow, and extend, by degrees, to the larger muscles of the legs and arms, and to those of the abdomen. These vary in intensity, but are sometimes so violent as to put on the appearance of tetanus.

In some severe cases the vomiting is slight, in others considerable; and the purging and vomiting precede each other without any known rule: but whichever may be the precursor, a severe burning heat is early felt at the præcordia; there is an invincible desire for cold liquids, particularly water; and, although the skin and tongue are cold to the touch, and the pulse nearly lost, or altogether imperceptible, the patient complains of intense heat, and has an almost insuperable aversion to any application of it to the skin. The spasms increase, sometimes spreading gradually, sometimes suddenly, to the abdomen, as high as the scrobiculus cordis. The next severe symptoms are, an intolerable sense of weight and constriction felt upon the chest, accompanied with anxious breathing, the spasms continuing at the same time; a leaden or bluish appearance of the countenance, the tongue, fingers, and toes, assuming the same colour; the palms of the hands and soles of the feet becoming shrivelled; the fingers and toes giving the appearance of having been corrugated by long immersion in hot water. There is, throughout, a suppression of the secretion of urine, of the secretions of the mouth and nose: no bile is seen in the evacuations; and it may be generally observed, that all the functions employed in carrying on life are suspended, or alarmingly weakened, except that of the brain, — which appears, in these extreme cases, to suffer little, the intellectual powers usually remaining perfect to the last moment of existence. At length a calm succeeds, — and death. The last period is commonly marked by a subsidence of the severe symptoms, without improvement of the pulse or return of natural heat; but, occasionally, it terminates in convulsive spasm. Within an hour or two from the commencement of such a seizure, and sometimes sooner, the pulse may be imperceptible at the wrist, or in the temporal arteries. If it be discoverable, it will usually be found beating from eighty to a hundred strokes in a minute; this, however, is not invariable, the pulse being not unfrequently quicker. The powers of the constitution often yield to such an attack at the end of four hours; and seldom sustain it longer than eight.

We have described the symptoms of the extreme case, in the usual order of their occurrence; but it will be obvious, that in a disease which proceeds so quickly to a fatal termination, medical practitioners will seldom see their patient until the greater number of these symptoms have taken place.

In the less rapid and more ordinary form, sickness at the stomach, slight vomiting, or perhaps two or three loose evacuations of the bowels, which do not attract much attention, mark the commencement of the attack; a sense of burning heat soon felt at the præcordia excites suspicion of the disease; an increased purging and vomiting of the peculiar liquid gives certain indication of its presence if this have not been previously declared by the prostration of strength, and an expression of the countenance not often exhibited, except when death is to be expected within a few hours. The symptoms before described follow each other in similar but slower succession: the spasms of the extremities increase with the vomiting and purging, and particularly in proportion to the constriction of the thorax; and this form of the disease, which creeps on at first insidiously, and is in its progress more slow, by giving a greater opportunity for assistance, is, if treated early, more tractable; but if neglected, equally fatal with the more sudden seizures. Such cases last from twelve to thirty-six hours.

The principal difference consists in the diffusion of the symptoms through a greater space of time; a misfortune, it is true, to the patient, if the disease prove ultimately fatal, but advantageous, by affording an interval for the natural powers of the constitution to rally themselves, and for the employment of the resources of medical art. But there is another remarkable distinction well worthy of attention. It has been observed before, that in the more rapid cases, the intellectual faculties suffer but little; and it may be added here, that the disturbance of them is not delirium, but rather a confusion and hesitation of mind resembling slight intoxication. In those of longer duration, if the individuals, either by the natural vigour of their constitution or medical assistance, sustain the shock beyond the period of twenty-four hours, suffusion of the *tunica conjunctiva* often takes place, not unfrequently delirium, and even coma.

It is remarked, that those who survive seventy-two hours, generally recover — but there are exceptions to this: for although, according to the Reports of the Medical Practitioners in the Presidencies of Bombay and Madras, the recovery from this seizure commonly terminates the disease; or, as is stated in the latter, the sequelæ are those dependent upon some previous ailment of the individual: yet the Bengal Report details a series of subsequent symptoms resembling those of low nervous fever, which, when they proved fatal, usually terminated within eleven days from the commencement of the seizure called Cholera. To complete the outline, an account of these symptoms, extracted from the Bengal Report, will be presently given; and we may observe, that they correspond accurately with the description given by Dr. Keir of the second stage of the disease, as it appeared at Moscow from the beginning of the month of October to the earlier part of the month of March. But we will previously point out the manner in which the recovery from this seizure commonly takes place. The first symptoms are, the abatement of the spasms and difficulty of breathing, a return of heat to the surface of the body, and a restoration of the pulse; these, however, are equivocal, from being often only temporary; and the prognostic from them is very uncertain unless they follow a progressive march of amendment: sleep and warm

perspiration attending it are of more importance and more certain signs of recovery. The return of the secretion and evacuation of urine is reckoned one of the most favourable signs: the next is, the passage of bile by the bowels; and if this be freely established, and accompanied with an improvement of the pulse and of the temperature of the skin, the patient is soon placed in a state of security from the attack: but it will appear, from the following extract from the Bengal Report, that upon this recovery he has often a serious stage of disease to encounter; the description of which is given in the words of the author. Before, however, we proceed to this, we must remark, that the seizure, when not fatal, has three modes of termination; one in immediate convalescence, accompanied only with great weakness; — a second, in which large evacuations of vitiated bile are passed for several days, sometimes attended with blood, and with peculiar pains in the bowels, particularly in the rectum. The third is of a febrile nature, of which the following account is supplied from the information given in the Bengal Report, viz.: —

"The fever, which almost invariably attended this second stage of the disease, * * * partook much of the nature of the common bilious attacks of these latitudes. There was a hot, dry skin, a foul, deeply-furred tongue, parched mouth, thirst, sick stomach, restlessness, watchfulness, and quick variable pulse, sometimes with delirium and stupor, and other marked affections of the brain. Generally, when the disorder proved fatal in this stage, the tongue, from being cream-coloured, became brown, and sometimes black, hard, and more deeply furred; the teeth and lips were covered with sordes, the state of the skin varied, chills alternating with heats, the pulse became extremely quick, weak, and tremulous, hiccough, catching of the breath, great restlessness and deep moaning succeeded, and the patient soon sunk incoherent and insensible under the debilitating effects of low nervous fever, and frequent dark, tarry alvine discharges." It is to be observed, that the able author of the Bengal Report doubts whether these symptoms can be considered as 'forming any integrant or necessary part of the disorder itself,' or whether they belonged to the bilious seizures of the climate. Subsequent experience of the disease has removed this doubt by showing that the febrile stage of cholera has been much more frequent in other climates than in India.

The third report of Drs. Russell and Barry to the Board of Health, describing the disease in Petersburg, may be compared with the above account as illustrative of the modifications which the disease has undergone in its progress westward: —

"The cholera morbus of the north of Europe, to which the Russian peasants have given the name of 'chornaia bolezn,' or *black illness*, like most other diseases, is accompanied by a set of symptoms which may be termed preliminary; by another set which strongly mark the disease in its first, cold, or collapsed stage; and by a third set, which characterise the second stage, that of reaction, heat, and, fever.

"*Preliminary Symptoms.* — We have had but few opportunities of witnessing the presence of all these symptoms, some of which precede the complete seizure by so short an interval, that the utmost diligence is scarcely sufficient to bring the patient and the physician together, after their occurrence, before the disease is fully formed. Diarrhœa, at first feculent, with slight cramps in the legs, nausea, pain or heat about the pit of the stomach, *malaise*, give the longest warning. Indeed, purging, or ordinary diarrhœa, has been frequently known to continue for one, two, or more days, unaccompanied by any other remarkable symptom, until the patient is suddenly struck blue, and nearly lifeless. Often the symptoms just mentioned are arrested by timely judicious treatment, and the disease completely averted. When violent vertigo, sick stomach, nervous agitation, intermittent, slow, or small pulse, cramps beginning at the tips of the fingers and toes, and rapidly approaching the trunk, give the first warning, then there is scarcely an interval.

"*First Stage.* — Vomiting or purging, or both these evacuations, of a liquid like rice-water, or whey, or barley-water, come on; the features become sharp and contracted; the eye sinks; the look is expressive of terror, wildness, and, as it were, a consciousness on the part of the sufferer, that the hand of death is upon him. The lips, the face, the neck, the hands, feet, and even the thighs, arms, and whole surface assume a leaden, blue, purple, black, or deep brown tint, according to the complexion of the individual, varying in shade with the intensity of the attack. The fingers and toes are reduced at least a third in thickness; the skin and soft parts covering them are wrinkled, shrivelled, and folded; the nails put on a bluish pearl white. The larger superficial veins are marked by flat lines of a deeper black; the pulse is either small as a thread, and scarcely vibrating, or else totally extinct. The skin is deadly cold, and often damp; the tongue *always moist*, often white and loaded, but flabby and chilled like a bit of dead flesh. The voice is gone; the respiration quick, irregular, and imperfectly performed. Inspiration appears to be effected by an immense effort of the chest, whilst the *alæ nasi* (in the most hopeless cases and towards the close), instead of expanding, collapse, and stop the ingress of the air. Expiration is quick and convulsive. The patient asks only for water, speaks in a plaintive whisper (the 'vox cholerica,') and only by a word at a time, from not being able to retain air enough in his lungs for a sentence. He tosses incessantly from side to side, and complains of intolerable weight and anguish around his heart. He struggles for breath; and often lays his hand on his stomach and chest, to point out the seat of his agony. The integuments of the belly are sometimes raised into high irregular folds, whilst the belly itself is violently drawn in, the diaphragm upwards, and inwards towards the chest. Sometimes there are tetanic spasms of the legs, thighs, and loins; but we have not seen general tetanus, nor even trismus. There is occasionally a low suffering whine. The secretion of urine

is *always* totally suspended; nor have we observed tears shed under these circumstances. Vomiting and purging, which are far from being the most important or dangerous symptoms, and which in a very great number of cases of the present epidemic have not been profuse, generally cease, or are arrested by medicine early in the attack. Frictions remove the blue colour for a time from the part rubbed, but in other parts, particularly the face, the livor becomes every moment more intense and more general. The lips and cheeks sometimes puff out and flap in expiration, with white froth between them, as in apoplexy. If blood be obtained in this state, it is black, flows by drops, is thick, and feels to the finger colder than natural. Towards the close of this scene the respiration becomes very slow; there is a quivering among the tendons of the wrist. The mind remains entire. The patient is first unable to swallow, then becomes insensible; there never is, however, any rattle in the throat, and he dies quietly, after a long convulsive sob or two.

"The above is a faint description of the very worst kind of case dying in the cold stage, in from six to twenty-four hours after the setting in of the bad symptoms. We have seen many such cases just carried to the hospital from their homes or their barracks. In by far the greater number vomiting had ceased; in some, however, it was still going, and invariably of the true, serous kind. Many confessed that they had concealed a diarrhœa for a day or two. Others had been suddenly seized, generally very early in the morning.

"From the aggravated state which we have just described, but very few indeed recover; particularly if that state have been present even *for four hours* before treatment has commenced. A thread of pulse, however small, is almost always felt at the wrist, where recovery from the blue or cold stage is to be expected. Singular enough to say, hiccup, coming on in the intermediate moments between the threatening of death and the beginning of reaction, is a favourable sign; and generally announces the return of the circulation.

"In less severe cases, the pulse is not wholly extinguished, though much reduced in volume; the respiration is less embarrassed; the oppression and anguish at the chest are not so overwhelming, although the vomiting, the purging, and the cramps, may have been more intense. The coldness and change of colour of the surface; the peculiar alteration of the voice; a greater or less degree of coldness of the tongue; the character of the liquids evacuated, have been invariably well marked in all the degrees of violence of attack which we have hitherto witnessed, in this epidemic. In no case or stage of this disease have we observed shivering, nor have we heard, after inquiry, of more than one case in which this febrile symptom took place.

"*Fever, or Hot Stage.* — After the blue, cold period has lasted from twelve to twenty-four, seldom to forty-eight hours or upwards, the pulse and external heat begin gradually to return; headache is complained of, with noise in the ears; the tongue becomes more loaded, redder at the top and edges, and also dryer. High coloured urine is passed with pain, and in small quantities; the pupil is often dilated; soreness is felt on pressure over the liver, stomach, and belly; bleeding by the lancet or leeches is required; ice to the head gives great relief. In short, the patient is now labouring under a continued fever, not to be distinguished from ordinary fever. A profuse, critical perspiration may come on, from the second or third day, and leave the sufferer convalescent, but much more frequently the quickness of pulse and heat of skin continue; the tongue becomes brown and parched; the eyes are suffused and drowsy; there is a dull flush, with stupor and heaviness, about the countenance much resembling typhus; dark sordes collect about the lips and teeth; sometimes the patient is pale, squalid, and low, with the pulse and heat below natural: but with the typhous stupor delirium supervenes; and death takes place from the fourth to the eighth day, or even later, in the very individual, too, whom the most assiduous attention had barely saved in the first or cold stage. To give a notion of the importance and danger of the cholera fever, a most intelligent physician, Dr. Reimer, of the Merchants' Hospital, informs us, that of twenty cases treated under his own eye, who fell victims to the disease, seven died in the cold stage, and thirteen in the consecutive fever.

"This singular malady is only cognizable, *with certainty*, during its blue, or cold period. After reaction has been established, it cannot be distinguished from an ordinary continued fever, except by the shortness and fatality of its course. The greenish, or dark, and highly bilious discharges produced, in the hot stage, by calomel, are not sufficiently diagnostic; and it is curious, that the persons employed about these typhoid cases, when they are attacked, are never seized with ordinary fever, but with the genuine, cold, blue, cholera. Nothing therefore, is more certain, than that persons may come to the coast of England, apparently labouring under common, feverish indisposition, who really and truly are cases of cholera in the second stage.

The points of difference between the present epidemic and the cholera of India, when the two diseases are closely compared, appear to us to be the following: —

"1st. The evacuations, both upwards and downwards, seem to have been much more profuse and ungovernable in the Indian, than in the present cholera; though the characters of the evacuations are precisely the same.

"2dly. Restoration to health, from the cold stage, without passing through consecutive fever of any kind, was by far more frequent in India than here; nor did the consecutive fever there assume the typhoid, type.

"3dly. The proportion of deaths in the cold stage, compared with those in the hot, was far greater in India, according to Dr. Russell's experience, than here.

"4thly. The number of medical men and hospital attendants attacked with cholera, during the present epidemic, in proportion to the whole employed and to the other classes of society, has

been, beyond all comparison, greater here than in India under similar circumstances. Twenty-five medical men have been already seized; and nine have died out of 264. Four others have died at Cronstadt, out of a very small number residing in that fortress at the time the disease broke out there. Six attendants have been taken ill at a small temporary hospital, behind the Aboucoff, since we wrote last. It is certain, however, that in some cholera hospitals, favourably circumstanced as to site, ventilation, and space, very few of the attendants have suffered."

The phenomena of the disease as since witnessed in other European countries, have not varied in a degree sufficient to render the above inapplicable as a general description. The appearances, observed on dissection by practitioners in the East Indies, varied much in different individuals, and apparently according to the duration of the disease. In those who died within eight or ten hours, the stomach was generally found in a relaxed, dilated state, loaded with the same fluids as had been thrown up during life: sometimes containing food, which had been swallowed and not returned, although the vomiting had been excessive. The internal and peritoneal coats of the stomach were, in these instances, pale and bloodless; the small and great intestines bore the same appearance; the arch of the colon, when the spasms had reached the abdomen before death, was generally so much contracted as to be less in diameter than the duodenum. The same was occasionally observed with respect to the sigmoid flexure. No appearance of bile or feces was found in the intestines. The bladder was generally empty and contracted. The liver, and vessels which pass to the vena cava inferior, were turgid with blood; this turgescence extended to the vena cava superior, to the right side of the heart, and in some instances to the left ventricle: blood was in the same manner stagnant in the lungs, marking a congestion in the whole venous circulation of the larger vessels: the blood in the vessels was unusually *black*, resembling tar in colour and consistence. It is worthy of remark, that this local accumulation of blood was uniformly found in all fatal cases, whether they were of rapid or slower termination; and was particularly evident, as might be expected, in those in which the oppression of the breathing had prevailed with most violence. The gall-bladder was turgid with bile; the gall-duct commonly pervious, but bearing no marks of bile having recently passed.

In cases of longer duration, the same leading appearances were observed; but often with great addition. The vessels of the stomach, in these instances, were found loaded with blood, presenting a surface sometimes of a pale pink hue, sometimes of a deep blue, at others of so dark a tint as to resemble sphacelus of the membrane, from which it could only be distinguished by the firmness of texture, and the appearance of vascular congestion on holding up the stomach between the eye and the light: in other instances the arteries of the stomach presented the appearance of having been penetrated by a vermilion injection; the same was observed in the smaller intestines, very rarely in the larger. In those cases in which coma had existed, serum was found effused, sometimes between the membranes of the brain, sometimes into the ventricles, and in some there was merely congestion of the blood in the vessels. Those who died of the consecutive fever showed no appearances after death different from such as are usually observed in other cases of febrile disease, attended with corresponding symptoms.

Subsequent observations in other parts of the world have not added anything of the least importance to the morbid anatomy of cholera.

The attention of chemists has been directed to the changes which take place in the blood in this disease, and to the nature of the peculiar matter discharged from the stomach and intestines. Nothing very satisfactory, however, appears to have resulted from these investigations. According to Dr. Thomson the blood becomes entirely insusceptible of the ordinary influence of the air; but Dr. O'Shaugnessy found, that when agitated with air it became florid and gave out carbonic acid gas. Dr. Stevens ascribes the state of the blood to deficiency of saline matter; and, on this view, has founded a peculiar mode of treatment. The white fluid which is discharged from the bowels, consists of a large quantity of serum, some fibrin, and the salts of the blood; its composition, therefore, is similar to that of the blood deprived of its colouring matter, and with a larger proportion of serum.

It is scarcely necessary to do more than mention the principal opinions that have been held with respect to the pathology of malignant cholera. Kennedy and Orton suppose, that the morbid cause operates on the nervous system generally; Bell that it operates on the ganglionic system exclusively. Roche and other French writers attribute the disease to inflammation or congestion in the gastro-enteric mucous membrane; and Christie, to inflammation of the mucous surfaces throughout the body. Caspar believes, that a loss of elasticity in the skin is the essential part of the disorder. Dr. Stevens maintains, that the symptoms arise from a deficiency of saline matter in the blood. Those opinions which refer the symptoms of malignant cholera to inflammation or other disease of the mucous membranes, are by no means countenanced by morbid anatomy, which has generally failed to detect any such condition. Dr. Stevens's theory is at first sight plausible, but the experiments of Dr. Christie go to prove that at the commencement of cholera there is no alteration in the blood; and again, the remarkable suddenness with which cholera makes its attack, and the equal suddenness with which the patient sometimes recovers from it, appear highly unfavourable to the notion, that the disease depends on disordered processes of animal chemistry, which can hardly be conceived to be instantaneously effected. If indeed the disease were always ushered in by profuse diarrhœa, it might be reasonably maintained that the salts of the blood being thus purged away along with the serum, a deficiency of saline matter was

produced, but since, in the very worst and most concentrated cases, there is often no diarrhœa at all, the abolition of the salts remains in these cases unaccounted for. Of the opinions offered, that which supposes the nervous system to be in some way primarily affected, has greatly the advantage over the others, inasmuch as it does not come into violent collision with any known facts; it derives support moreover from the striking analogy between pestilential cholera and some of the congestive forms of fever, — which latter disease, notwithstanding the occasional prevalence of hypotheses referring it to local inflammation, has always been regarded by the greater number of pathologists as essentially a disease of the nervous centres. On the whole it is best to acknowledge, that all hitherto advanced as to the proximate cause of cholera is mere conjecture, and that we are in a state of entire ignorance on the subject.

An important question with respect to the disease under consideration is, whether it be contagious or not? It is not deemed necessary to enter upon this question here. Notwithstanding the pertinacity and even acrimony with which the champions of conflicting opinions have maintained the dispute, we conceive that there are hitherto not sufficient data for a philosophical conclusion, at the same time it is but justice to the contagionists to say, that, after the recent experience we have had of the disease in our own country, their doctrine appears to be gaining ground. The analogy between cholera and malignant fever is also favourable to the opinion that the former is contagious.

Such being the obscurity which hangs over the causes and the pathology of this affection, it is not to be expected that there should be much accordance among practitioners as to its treatment, or much success from the use of remedies. The following are the means which have been principally employed: —

1. *Blood-letting.* — This seems to have been more successful than any other remedy in the cholera of the East Indies; and was generally supposed to operate mechanically by unloading the large veins, and thus freeing the circulation. It was found, that where a large quantity of blood could be obtained great benefit resulted, but that where only a few ounces were withdrawn, the debility was increased without alleviation of the symptoms. The general result of experience in Europe has been adverse to blood-letting. In few instances has any striking benefit resulted from it. During the symptoms which precede the stage of collapse, while the pulse yet retains some force, moderate blood-letting has seldom done harm, and has often succeeded in arresting the diarrhœa; in the stage of collapse, the abstraction of blood, where any could be obtained, has almost invariably appeared to hasten the death of the patient.

2. *Emetics.* — These have been found to have a very marked effect in rousing the system from the state of collapse, and restoring the circulation. Unfortunately such beneficial results are often merely temporary, and the patient again sinks; still they have been permanent in a sufficient number of cases to warrant us in considering emetics as among the most valuable remedial means used in the treatment of cholera. The choice of the emetic does not seem to be of much importance, provided it be one which excites immediate and full vomiting. The mustard emetic has been much extolled, and perhaps with reason; although the sulphate of zinc or copper, from their vehement emetic action and astringent qualities appear *à priori* to deserve the preference. Antimony is decidedly objectionable. In mild cases, where the vomiting is frequent and violent, it has been found a very useful practice to keep up this action of the stomach by copious draughts of cold water; for under this simple treatment the patient frequently recovers.

3. *Stimulants.* — The various forms of alkohol, the essential oils, especially those of turpentine and cajeput, volatile alkali, mustard, and other medicines of this class, have been used with unequivocal advantage in many cases. It is necessary, however, to set proper limits to the use of alkohol in the stage of collapse, lest its effects be injuriously felt in the succeeding stage of febrile reaction.

4. *Purgatives.* — These have sometimes been found useful in the early stage; but those of the saline class, or those of an irritating kind, are by no means admissible; a full dose of calomel, from its ordinary effect on the secretions, and rhubarb, on account of its astringent and tonic qualities, appear to be the most eligible. We have said, that irritating purgatives are not admissible, yet, if we are to believe some accounts, croton oil, one of the most violent of this class of medicines, has been used in cholera with great benefit; an anomaly which we pretend not to explain.

5. *Calomel.* — This powerful agent has been given, with a view to its specific effect on the system, in large and in small doses. It has sometimes produced a good effect, but more generally produces no effect of any kind; patients also have been known to die in the collapsed state of cholera while their mouths were actually sore with mercury.

6. *Opium.* — This is very useful in the early stage, but is to be avoided in that of collapse, as tending to increase cerebral congestion. It should be given in full doses, and is best combined with calomel.

7. *Saline medicines.* — These were introduced by Dr. Stevens, in consequence of his peculiar views as to the cause of the disease. The solutions of muriate and carbonate of soda, recommended by that gentleman to be given by the mouth, have altogether failed to realise the expectations at first excited with respect to them; and, in the majority of cases, are found to produce no effect of one kind or another. The injection of saline fluids into the veins, has, however, been productive of much more striking results. In some cases the system has been thus roused from a state of collapse, as if by magic; and the good effect has in several instances been permanent, while in others it has been only temporary. It must be admitted also, that, in some instances, the saline injection has

accelerated the fatal termination, instead of ameliorating the symptoms; and that in others, even where it has rescued the patient from cholera, it has been itself the efficient cause of death, by producing effusion into the ventricles of the brain. It may be reasonably doubted, whether the benefit observed from the use of the saline injection be in reality attributable to its chemical action on the blood; it seems quite as probable that it may act simply as a stimulus applied to the internal membrane of the heart and blood-vessels, rousing them to their wonted action and diluting their inspissated contents. This however is all matter of mere conjecture.

8. *External remedies.* — These are not among the least important of the means used for the cure of cholera. A bath of hot water or heated air, friction on the surface of the body, with stimulating substances, and the application of hot oil of turpentine to the abdomen, have been found powerful auxiliaries.

9. The *Tobacco clyster* has been strongly recommended, on what principle we do not understand; but everything alleged on respectable authority to be useful, should be tried, where it is acknowledged that the means of which we have been hitherto in possession, are altogether inadequate.

Such are some of the principal remedies which have been employed for the cure of cholera, and many more might be added were this at all profitable. It is evident, that of those above alluded to, some are better adapted to one case and some to another; and that, consequently, the treatment most advisable in any individual case must be determined by the judgment of the practitioner. Much need not to be said on the treatment of the fever which is consecutive on the cold stage of cholera. It is a typhoid fever, accompanied with inflammatory affections of the brain, bowels, or lungs. The inflammatory action is usually of the insidious kind which accompanies low fever; and the general character of the affection is that of feeble and irregular arterial action, and venous congestion. In a few cases, however, more decided reaction takes place, and the resulting affection does not differ, in any essential particular, from ordinary continued fever, although there is invariably something in its general physiognomy which marks it as being *sui generis*. In the treatment of these consecutive febrile affections, there is nothing materially different from that of ordinary fevers of a similar character. There is one remark, however, which may be made with respect to the *prognosis* of the choleric fever, namely, that very often when the patient appears to be doing extremely well, he dies from some cause which nobody can understand.

Cholera morbus. See *Cholera.*

Cholera sicca. Flatulent colic. See *Colica.*

CHOLE'RICUS. 1. Appertaining to cholera; as *febris cholerica,* a fever accompanied with symptoms of cholera, or the fever which succeeds to cholera.

2. Bilious; as the choleric or bilious temperament. See *Temperament.*

Cholesteric acid. *Acidum cholestericum.* When cholesterine, or the fat matter of human biliary calculi is treated with nitric acid, a peculiar acid is formed, which is called the cholesteric. It is in crystals of a yellowish white colour; little soluble in water, but abundantly so in boiling alkohol.

CHOLESTERINE. (*Cholesterina, æ.* f.; from χολη, bile, and στερεος, solid.) A pearly substance, found abundantly in human biliary calculi. It consists of 72 carbon, 6·66 oxygen, and 21·33 hydrogen. See *Calculus biliary.*

CHOLOLI'THUS. (*us, i.* m.; from χολη, bile, and λιθος, a stone.) A gall-stone. See *Calculus.*

Cholo'ma. (From χωλος, lame, or maimed.) Any kind of lameness or distortion of a limb. — *Galen.*

CHONDRI'LLA. (*a, æ.* f.; from χονδρον, a grain of any corn: and so called because it emits small particles of gum which resemble grains.) A genus of plants. Class, *Syngenesia;* Order, *Polygamia æqualis.*

Chondroglo'ssus. (From χονδρον, a cartilage, and γλωσση, the tongue.) A muscle so named from its insertion, which is in the basis or cartilaginous part of the tongue. See *Hyoglossus.*

CHONDRO'LOGY. (*Chondrologia. æ.* f.; from χονδρος, a cartilage, and λογος, a discourse.) A discourse on cartilages.

CHONDRO-PHARYNGÆUS. (From χονδρος, a cartilage, and φαρυγξ, the upper part of the fauces.) A muscle so named because it rises in the cartilaginous part of the tongue, and is inserted in the pharynx.

CHO'NDROS. (Χονδρος. *us, i.* m.)

1. A cartilage.
2. A food of the ancients. See *Alica.*
3. A grumous concretion.

CHONDROSYNDE'SMUS. (*us, i.* m.; from χονδρος, a cartilage, and συνδεω, to tie together.) The union of bones by fibro-cartilage. — *Galen.*

Cho'ne. Χωνη. See *Choana.*

Cho'ra. Χωρα. A region. Galen uses this word particularly to signify the cavities of the eyes; but also applies it to any void space.

CHO'RDA. (*a, æ.* f.: from χορδη, which properly signifies an intestine, or gut, and hence also the string of a musical instrument.) 1. A cord, or assemblage of fibres.

2. The tendon of a muscle.

3. A painful erection of the penis in gonorrhœa. See *Chordee.*

Chorda magna. See *Tendo Achillis.*

Chordæ tendineæ. The tendons which connect the *carneæ columnæ* of the ventricles of the heart to the auricular valves.

Chorda tympani. A branch of the seventh pair of nerves. See *Auris.*

Chorda willisii. The small fibres which cross the sinuses of the dura mater. They are so termed, because Willis first described them.

Chordæ. The genitals. — *Paracelsus.*

CHORDA'PSUS. (From χορδη, a cord, and απτω, to knit.) A painful colic, where the intestines appear to be twisted into knots. See *Ileus.*

CHORDEE'. (*Chordé.* French.) A spasmodic erection of the penis, which is a common accompaniment of gonorrhœa. See *Furethritis.*

CHORE'A. (*a*, *æ*. f. Χορεια, from χορος, a dance.) *Chorea Sancti Viti. Convulsio habitualis.* St. Vitus's dance. Convulsive motions of the limbs occasioning strange and involuntary gesticulations. During the middle ages some extraordinary epidemic diseases occurred in Germany and the Netherlands, consisting in maniacal dancing and raving. The accounts of these are mixed up with the superstitions of the times, and with wonderful stories invented by the priests to serve their own ends. It is related, that in the year 1027 some peasants disturbed the service of the convent church at Kölbig, by dancing and making a noise in the church-yard, whereupon they were cursed by a priest, and doomed to dance and scream for a year without ceasing; which, accordingly, they did. In 1237 upwards of a hundred children were seized with the dancing mania at Erfurt; and in 1278 two hundred fanatics danced upon the bridge at Utrecht till the bridge gave way, and they were all drowned. But the grand eruption of the dancing plague occurred in 1374. In this year "assemblages of men and women were seen at Aix-la-Chapelle who had come out of Germany, and who, united by one common delusion, exhibited to the public both in the streets and in the churches the following strange spectacle: — They formed circles hand in hand, and appearing to have lost all control over their senses, continued dancing, regardless of the bystanders, for hours together, in wild delirium, until at length they fell to the ground in a state of exhaustion. They then complained of extreme oppression, and groaned as if in the agonies of death, until they were swathed in cloths bound tightly round their waists, on which they again recovered, and remained free from complaint until the next attack. This practice of swathing was resorted to on account of the tympany which followed these spasmodic ravings; but patients were frequently relieved in a less artificial manner, by thumping and trampling upon the parts affected. While dancing they neither saw nor heard, being insensible to external impressions through the senses, but were haunted by visions, their fancies conjuring up spirits whose names they shrieked out; and some of them afterwards asserted that they felt as if they had been immersed in a stream of blood, which obliged them to leap so high. Others, during the paroxysm saw the heavens open and the Saviour enthroned with the Virgin Mary, as indeed the religious notions of the age were strangely and variously reflected in their imaginations.

"Where the disease was completely developed, the attack commenced with epileptic convulsions. Those affected fell to the ground senseless, panting and labouring for breath. They foamed at the mouth, and suddenly springing up began their dance amidst strange contortions. Yet the malady doubtless made its appearance very variously, and was modified by temporary, or local circumstances, whereof non-medical contemporaries but imperfectly noted the essential particulars, accustomed as they were to confound their observation of natural events with their notions of the world of spirits.

"It was but a few months ere this demoniacal disease had spread over the neighbouring Netherlands from Aix-la-Chapelle, where it appeared in July."—(*Hecker on the Epidemics of the Middle Ages. Babington's Translation.*) These singular affections were called *St. John's dance* and *St. Vitus's dance.* It is probable that the former name was derived from the mania originating amid the revels of St. John's day; the latter was derived from the cures effected at the chapels of St Vitus, near Nabern and Rotestein; where the priests, working upon the imagination of the patients, dispossessed them of their infatuations by religious ceremonies. This extraordinary malady continued its visitations at intervals for more than two centuries. At the beginning of the sixteenth century, it diminished greatly; and soon after the close of that century, disappeared altogether. Such is the origin of the name St. Vitus's dance, which is now transferred to a disease very different from that just described, but which may nevertheless be its degenerate descendant.

One of the best general descriptions of chorea, as known in the present day, is the following of Dr. Hamilton, contained in his Treatise on the Utility of Purgatives: — "Chorea Sancti Viti attacks boys and girls indiscriminately; and those chiefly who are of a weak constitution, or whose natural good health and vigour have been impaired by confinement, or by the use of scanty or improper nourishment. It appears most commonly from the eighth to the fourteenth year. I saw it in two young women who were from sixteen to eighteen years of age. The approaches of chorea are slow. A variable and often a ravenous appetite, loss of usual vivacity and playfulness, a swelling and hardness of the lower belly, and, in general, a constipated state of the bowels, aggravated as the disease advances, and slight, irregular, involuntary motions of different muscles, particularly those of the face, which are thought to be the effect of irritation, precede the more violent convulsive motions, which now attract the attention of the friends of the patient.

"These convulsive motions vary. The muscles of the extremities and of the face, those moving the lower jaw, the head, and the trunk of the body, are, at different times, and in different instances, affected by it. In this state, the patient does not walk steadily; his gait resembles a jumping or starting; he sometimes cannot walk at all, and seems palsied; he cannot perform the common and necessary motions with the affected arms. This convulsive motion is more or less violent; and is constant, except during sleep, when, in most instances, it ceases altogether. Although different muscles are sometimes successively convulsed, yet, in general, the muscles affected in the early part of the disease remain so during the course of it. Articulation is now impeded, and is frequently completely suspended. Deglutition is also occasionally performed with difficulty. The eye loses its lustre and intelligence; the countenance is pale, and expressive of vacancy and languor. These circumstances give the patient a fatuous appearance. When the complaint has subsisted

for some time, fatuity to a certain extent interrupts the exercise of the mental faculties."

In some instances, the disease has continued with considerable violence from an early period to old age, without making any inroad whatever on the mind, or even spreading to any other muscles than those at first affected.

There is a singular form of this disease, which has been called by some writers *Malleatio*, consisting in a convulsive action of one or both hands, which strike the knee like a hammer.

The predisponent cause of this disease is an irritability of the nervous system, chiefly dependent upon debility, and particularly a debility of the stomach and its collatitious organs; the ordinary occasional causes being bad nursing, innutritious diet, accumulated feces, worms, or some other intestinal irritant.

About the age of puberty there is another kind of general irritation that pervades the system; and where this change does not take place kindly in females, which is frequently the case in weakly habits, the irritation assumes a morbid character, and is exacerbated by a congestive state of the vessels that constitute its more immediate seat: and chorea takes its rise from this cause.

In effect, where the predisponent cause of an irritable state of the nervous system is very active and predominant, a local or temporary excitement of any organ, and almost at any period of life, producing increased irregularity in the distribution of the nervous energy, will give rise to the convulsive movements of chorea.

From this view of the general nature and origin of the disease, we can be at no loss to account for the great benefit which has been derived from a steady course of brisk purging in recent cases, or those of early life: for this, while it carries off the causal acrimony, or unloads the infarcted viscera, seems at the same time to act the part of a revellent, and to prohibit the return of the paroxysm by a new excitement. It may, perhaps, appear strange to those who have not thought upon the subject, that where the disease has proceeded from intestinal irritation, it should be carried off by intestinal irritation also. But the irritations are of very different kinds: and it is so far from following of necessity that, because one kind of irritation applied to a particular organ excites a particular effect in a remote part, another will do the same; that the converse is more commonly true, and that any other kind of irritation applied to the same organ, by exciting a new action, will be the most effectual way of taking off or preventing such effect.

The principle being a general one, it does not seem of much consequence what purgative is employed, provided it be sufficiently powerful.

There is no malady whatever, perhaps, that calls so peremptorily for stimulating the abdominal viscera into increased action; and as chorea often precedes puberty, or occurs about this period of life, we have another reason for directing an augmented stimulus to the lower regions of the living frame, and rousing into energy the tardy development of the sexual organs.

But it is necessary to attend to the state of the system generally as well as locally; to take off the constitutional weakness and irritability, as well as the topical acrimony, and especially where the disorder has acquired a chronic character. And hence other remedies must be had recourse to as well as purgatives. The use of antispasmodics and sedatives, and especially musk, belladonna, and foxglove, have been strongly recommended with a view of allaying the irregular action. But these, in most cases, will be found merely palliative; and the stimulant tonics and alterants promise a better success.

The metallic salts and oxides have been tried in every form, with apparent benefit in a few individual cases, but without any decided or general success. The most popular of these were at one time the flowers of zinc. When the stomach has reached its full dose of this medicine, it will still bear a full dose of ammoniated copper in conjunction with it, by which means the metallic power may be very much increased. Thus a delicate stomach will rarely bear more than two grains of either of these without nausea; yet it has been found that the same stomach will continue at ease under a mixed powder of two grains of the former, and two and a half of the latter, at a dose.

The preparations of iron have, for the most part, been found too stimulating: but silver, in the form of nitrate, seems to have been radically successful in various well-established cases. It has commonly been given in the form of pills, from one to two grains or more at a dose. But the metal that seems most entitled to credit, according to recent experience, is arsenic; for it is difficult to resist the evidence from various quarters in which it seems not only to have produced benefit, but to have established a perfect cure. It is commonly given in the form of the arsenical solution in doses of six minims to a youth of twelve or fourteen years of age, three times a day, increasing the dose as there may be occasion.

In this disease, however, as in various others, it will often be found, and the remark is well worth attending to, that different remedies are required for different individuals, even where the cause is obviously the same; and that what produces no benefit in one case, is highly advantageous in another. Camphor, in large doses, has succeeded, where the nitrate of silver has completely failed; and a brisk purgative plan has sometimes answered, where all the preceding have proved of no use whatever.

Cold bathing, and sponging the body with cold salt or sea water, is of great service, especially when the disease has become chronic. Electricity has also been recommended.

CHO'RION. (Probably from χωρεω, to separate, depart: because it always escapes from the uterus with the fœtus; but possibly from χωριον, a castle or fortified place, because it forms the exterior covering or *protection* of the fœtus.) The second or external membrane, or involving membrane of the fœtus. On

the inside it is smooth, and between it and the amnion a gelatinous fluid is interposed. In the earlier months it is much stronger than the amnion, but in an advanced stage it is in contact with it, no fluid being betwixt them: and in proportion as the amnion gains strength to be of essential service in dilating the orifice of the womb during labour, the chorion becomes relatively very thin and weak. On the outside the chorion has a shaggy surface called the *spongy chorion*, consisting of those minute extremities of the vascular system of the ovum which attach to the surface of the womb, or rather to the flocculent membrane which it throws out. The use of this membrane seems to be to convey the maternal supply of blood to the umbilical chord of the fœtus.

CHO'ROID. (*Choroides*: from χοριον, the chorion, and ειδος, resemblance.) Resembling the chorion: applied to a membrane of the eye.

CHOROID MEMBRANE. *Membrana choroides.* The second tunic of the eye, lying immediately under the sclerotica, to which it is connected by vessels. The true knowledge of this membrane is necessary to a perfect idea of the iris and uvea. The tunica choroides commences at the optic nerve, and passes forwards, with the sclerotic coat, to the beginning of the transparent cornea, where it adheres very firmly to the sclerotic membrane, by means of a whitish circular band, called the *ciliary ligament*. It then recedes from the sclerotica and ciliary circle, directly downwards and inwards, and is drawn into a number of delicate folds, forming a circle round the margin of the crystalline lens and the anterior surface of the vitreous humour. This circle is termed *corpus ciliare*, and the folds of which it is composed are called the *ciliary processes*. The choroid membrane is highly vascular, and its external vessels are disposed like stars, and termed *vasa vorticosa*. The internal surface of this membrane is covered with a black pigment, called the *pigmentum nigrum*.

CHOROID PLEXUS. *Plexus choroides.* A plexus of blood vessels, situated in the lateral ventricles of the brain.

Choroid tunic. See *Choroid membrane.*

CHRI'SIS. (From χριω, to anoint.) An unction, or anointing of any part.

Christmas-rose. See *Helleborus niger.*

CHRO'MAS. (*as, atis.* f.) A chromate, or salt, formed by the union of chromic acid with a salifiable base; as chromate of lead, &c.

CHROMIC ACID. *Acidum chromicum.* This acid is extracted from the red lead ore of Siberia, by treating it with carbonate of potash, and separating the alkali by means of a more powerful acid. In this state it is a red or orange-coloured powder, of a peculiar rough metallic taste, which is more sensible in it than in any other metallic acid. Neither this acid, its oxide, nor any of its combinations, are used medicinally.

CHROMIUM. (*um, i.* n.; from χρωμα, colour: because it is remarkable for giving colour to its combinations.) The name of a metal, which may be extracted either from the native chromate of lead or of iron. It combines with several of the acids, forming insoluble salts, which are of little interest. There are two compounds of chromium and oxygen, besides the acid: a *protoxide* and a *deutoxide*.

CHRO'NIC. (*Chronicus*; from χρονος, time.) Of long continuance: applied to diseases, and used in opposition to the term acute. See *Acute.*

CHRU'PSIA. (*a, æ.* f.; from χρoα, colour, and οψις, sight.) *Visus coloratus.* A disease of the eyes, in which the person perceives objects of a different colour from their natural one. This term is used by Beer, but is ill derived.

CHRYSALIS. (*is, is.* f. Χρυσαλις.) The middle state in which all lepidopterous and most other insects remain for some time, between the caterpillar form and their appearance as perfect insects.

CHRYSA'NTHEMUM. (*um, i.* n.; from χρυσος, gold, and ανθεμον, a flower.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia.* Sun-flower, or marigold.

2. Many herbs are so called, the flowers of which are of a bright yellow colour.

CHRYSANTHEMUM LEUCANTHEMUM. The systematic name of the great ox-eye daisy, or Maudlin-wort; called also, *Bellis-major*, *Buphthalmum majus*, *Leucanthemum vulgare*, *Bellidioides*, *Consolida media*, and *Oculus bovis*. The *Chrysanthemum — foliis amplexicaulibus, oblongis, supernè serratis, infernè dentatis*, of Linnæus. The flowers and herb were formerly esteemed in asthmatic and phthisical complaints, but have now deservedly fallen into disuse.

CHRY'SE. (From χρυσος, gold.) A yellow vulnerary plaster, mentioned by Paulus.

CHRYSELE'CTRUM. (From χρυσος, gold, and ηλεκτρον, amber.) Amber, of a golden yellow colour. — *Turton.*

CHRYSI'PPEA. (From *Chrysippus*, its discoverer.) An herb enumerated by Pliny.

CHRYSI'TIS. (From χρυσος, gold.) 1. Litharge of gold.

2. An herb mentioned by Pliny, supposed to be the *gnaphalium orientale.*

CHRYSOBA'LANUS. (*us, i.* m.; from χρυσος, gold, and βαλανος, a nut. 1. A fruit mentioned by Galen, which some have supposed to be the nutmeg.

2. The name of a genus of plants in the Linnæan system.

CHRYSOCO'LLA. (*a, æ.* f.; from χρυσος, gold, and κολλη, cement.) Borax. So called because it is used to solder gold.

CHRYSO'COMA. (*a, æ.* f.; from χρυσος, gold, and κομη, hair: so called from its golden, hair-like appearance.) See *Achillea millefolium.*

CHRYSOGO'NIA. (From χρυσος, gold, and γινομαι, to become.) A tincture of gold.

CHRYSOLA'CHANON. (From χρυσος, gold, and λαχανον, a pot-herb: so named from its having a yellow leaf.) A species of atriplex, or orach.

CHRYSOSPLE'NIUM. (*um, ii.* n.; from χρυσος, gold, and ασπλενιον, spleenwort.) The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Digynia.* Golden saxifrage.

CHRYSU'LCA. (From χρυσος, gold, and ελκω, to draw.) The aqua regia was so called, because it has the property of dissolving gold.

CHYAZIC ACID. (*Acidum chyazicum.* So called from the initial letters of carbon, hydrogen, and azote.) A name of prussic acid.

CHYLA'RIA. (From χυλος, chyle.) A discharge of a whitish mucous urine, of the colour and consistence of chyle.

CHYLE. (*Chylus, i.* m. ; from χυλὸς, the juice.) The milk-like liquor observed, some hours after eating, in the lacteal vessels of the mesentery, and in the thoracic duct. It is separated by digestion from the chyme, and is that fluid substance from which the blood is formed. See *Digestion.*

The chyle may be studied under two different forms : —

1st. When it is mixed with chyme in the small intestines.

2. Under the liquid form, circulating in the chyliferous vessels, and the thoracic duct.

No person having particularly engaged in the examination of the chyle during its stay in the small intestine, our knowledge on this point is little. The liquid chyle contained in the chyliferous vessels has been examined with great care.

In order to procure it, the best manner consists in giving food to an animal, and, when the digestion is supposed to be in full activity, to strangle it, or cut the spinal marrow behind the occipital bone. The whole length of the breast is cut open ; the hand is thrust in so as to pass a ligature which embraces the aorta, the œsophagus, and the thoracic duct, the nearest to the neck possible ; the ribs of the left side are then twisted or broken, and the thoracic duct is seen, closely adhering to the œsophagus. The upper part is detached, and carefully wiped to absorb the blood ; it is cut, and the chyle flows into the vessel intended to receive it.

The ancients were acquainted with the existence of the chyle, but their ideas of it were very inexact: it was observed anew at the beginning of the seventeenth century ; and being, in certain conditions, of an opake white, it was compared to milk ; the vessels that contain it were even named *lacteal vessels,* a very improper expression, since there is very little other similarity between chyle and milk except the colour.

It is only in modern times, and by the labours of Dupuytren, Vauquelin, Emmert, and Marcet, that positive notions concerning the chyle have been acquired.

If the animal, from which the chyle is extracted, has eaten animal or vegetable substances of a fatty nature, the liquid drawn from the thoracic duct is of a milky white, a little heavier than distilled water, of a strong spermatic odour, of a salt taste, slightly adhering to the tongue, and sensibly alkaline.

Chyle, very soon after it has passed out of the vessel that contained it, becomes firm, and almost solid: after some time it separates into three parts; the one solid that remains at the bottom, another liquid at the top, and a third that forms a very thin layer at the surface of the liquids. The chyle, at the same time, assumes a vivid rose colour.

When the chyle proceeds from food that contains no fat substance, it presents the same sort of properties, but instead of being opake white, it is opaline, and almost transparent; the layer which forms at the top is less marked than in the former sort of chyle.

Chyle never takes the hue of the colouring substances mixed in the food, as many authors have pretended.

Animals that were made to eat indigo, saffron, and madder, furnished a chyle the colour of which had no relation to that of the substances.

Of the three substances into which the chyle separates when abandoned to itself, that of the surface of an opake white colour, is a fatty body ; the solid part is formed of fibrin and a little colouring matter ; the liquid is like the serum of the blood.

The proportion of these three parts is variable, according to the nature of the food. There are species of chyle, such as that of sugar, which contain very little fibrin ; others, such as that of flesh. contain more. The same thing happens with the fat matter, which is very abundant when the food contains grease or oil, whilst there is scarcely any seen when the food is nearly deprived of fatty bodies.

The absorption of the chyle has been attributed to the capillarity of the lacteal radicles, to the compression of the chyle by the sides of the small intestine, &c. Latterly, it has been pretended that it takes place by virtue of the proper sensibility of the absorbing mouths, and of the insensible organic contractility that they are supposed to possess. It first enters the threads of the lacteal vessels, it then traverses the mesenteric glands, it arrives at the thoracic duct, and at last enters the subclavian vein.

The causes that determine its motion are, the contractility proper to the chyliferous vessels, the unknown cause of its absorption, the pressure of the abdominal muscles, particularly in the motions of respiration. and, perhaps, the pulsation of the arteries of the abdomen.

If we wish to have a correct idea of the velocity with which the chyle flows into the thoracic duct, we must open this canal in a living animal, at the place where it opens into the subclavian vein. We find that this rapidity is not very great, and that it increases every time that the animal compresses the viscera of the abdomen by the abdominal muscles: a similar effect is produced by compressing the belly with the hand.

However, the rapidity of the circulation of the chyle appears to be in proportion to the quantity formed in the small intestine : this last is in proportion to the quantity of the chyme; so that if the food is in great abundance, and of easy digestion, the chyle will flow quickly : if, on the contrary, the food is in small quantity, or, which is the same thing, if it is of difficult digestion, as less chyle will be formed, so its progress will be more slow.

It would be difficult to appreciate the quantity of chyle that would be formed during a

given digestion, though it ought to be considerable. In a dog of ordinary size that had eaten animal food at discretion, an incision into the thoracic duct of the neck (the dog being alive) gave about half an ounce of liquid in five minutes, and the running was not suspended during the whole continuance of the formation of the chyle, that is, during several hours.

It is not known whether there is any variation in the rapidity of the motion of the chyle during the same digestion; but supposing it uniform, there would enter six ounces of chyle per hour into the venous system. We may presume that the proportion of chyle is more considerable in man, whose chyliferous organs are more voluminous, and in whom the digestion is, in general, more rapid than in the dog. — *Magendie.*

The chyle is mixed with the lymph in the thoracic duct, which receives it from the lymphatics.

The use of the chyle is to supply the matter from which the blood is formed, and the waste of the living organs repaired. Certain hypothetical notions have also been entertained with respect to it. It has been said, that, by its acescent nature, it restrains a putrescent tendency in the blood; whence the dreadful putridity of the humours from starving; and the utility of milk as a remedy against scurvy. It has also been supposed that by aqueous latex, it prevents the thickening of the fluids, and thus renders them fit for the various secretions. The milk secreted in the female breast has been imagined to be entirely analogous to chyle, to which, however, it bears no sort of resemblance, except in colour.

CHYLIFICA'TION. (*Chylificatio, onis,* f.; from *chylus*, and *fio*, to become.) The process carried on in the small intestines, and principally in the duodenum, by which the chyle is separated from the chyme. See *Digestion.*

CHYLI'SMA. (From χυλος, juice.) An expressed juice.

CHYLOPOIE'TIC. (*Chylopoieticus;* from χυλος, chyle, and ποιεω, to make.) Concerned in the formation of chyle; thus chylopoietic viscera, chylopoietic vessels, &c.

CHYLO'SIS. (*is, is,* f.; from χυλος, juice.) Chylification, or the changing the food into chyle.

CHYLOSTA'GMA. (From χυλος, juice, and σαζω, to distil.) The distillation or expression of any juice, or humid part, from the rest.

CHYLOSTAGMA DIAPHORETICUM. A name given by Mindererus to a distillation of Venice treacle, mithridate, and other alexipharmics with the addition of tormentil, ash bark, and a variety of other ingredients.

Chylus. See *Chyle.*

CHYME. (*Chymus, i.* m.; from χυμος, which signifies humour, or juice.) The infested mass of food that passes from the stomach into the duodenum, and from which the chyle is prepared in the small intestines by the admixture of bile, &c. See *Digestion.*

CHY'MIA. (*a, æ.* f. Χυμια.) *Chimia.* Chemistry.

CHYMIA'TER. (*er, ri.* m.; from χυμια, chemistry, and ιατρος, a physician.) *Chimiater.* A chemical physician. See *Paracelsists.*

CHYMIA'TRIA. (*a, æ.* f.; from χυμια, chemistry, and ιαομαι, to heal.) The art of curing diseases by the application of chemistry to the uses of medicine.

Chymosis. See *Chemosis.*

CHY'NLEN RADIX. A cylindrical root, of the thickness of a goose-quill, brought from China. It has a bitterish taste, and imparts a yellow tinge to the saliva. The Chinese hold it in great estimation as a stomachic, infused in wine.

CHY'TLON. (Χυτλον; from χυω, to pour.) An anointing with oil and water. — *Erotian.*

CIBA'TIO. (*o, onis.* f.; from *cibus*, food.) The taking of food. The term is also used by alchemical writers; but what they understand by it is not very clear. Ruland says it means "*corporatio;*" Ripley "*nutritio materiæ siccæ nostræ;*" and J. Quercetanus "*subtilis ingrossatio et crassi subtiliatio.*"

CI'BUR. *Chybur.* An obsolete term for sulphur.

CICATRISANT. (*Cicatrisans;* from *cicatrizo*, to skin over.) That which disposes wounds and ulcers to dry up and heal, and to be covered with a skin.

CICATRISA'TUS. *Cicatrised.* 1. In *Surgery*, applied to parts formerly ulcerated, on which the skin has formed.

2. In *Botany*, it means scarred.

CICA'TRIX. (*ix, icis.* f.; from *cicatrizo*, to heal up or skin over.) A scar upon the skin after the healing of a wound or ulcer.

CICATRIZATION. (*Cicatrizatio, onis.* f.; from *cicatrizo*, to heal.) That process by which ulcers and sores are healed. See *Abscess.*

Cicely, sweet. See *Scandix odorata.*

CI'CER. (*er, eris.* n.; a plant so called. The *Cicerones* had their name from this pulse, as the *Pisones* had from the pisum or pea, and the *Lentuli* from the lens or lentil.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia;* Order, *Decandria.* The vetch.

2. The pharmacopœial name of the common cich or ciches.

CICER ARIETINUM. The systematic name of the cicer plant, which is called *Erebinthus* in some pharmacopœias.

Cicer — foliis serratis, of Linnæus. The seeds have been employed medicinally, but are now fallen into disuse. In some places they are toasted, and used as coffee; and in others ground into a flour for bread. The colour of the arillus of the seed is sometimes white, red, or black; hence the distinction into *cicer album, rubrum*, and *nigrum.*

CI'CERA. (From *cicer*, the vetch.) A small pill of the size of a vetch.

CICERA TARTARI. A small pill, composed of turpentine and cream of tartar, of the size of a vetch.

CICHO'RIUM. (*um, i.* n.; originally, according to Pliny, an Egyptian name, and adopted by the Greeks. It is written sometimes Κιχορεων: whence Horace has *cichoreæ, levesque malvæ:* sometimes Κιχοριον, or Κι-

χωριον. It is supposed by some to have this name, παρα το δια των χωριων κιειν, from its creeping through the fields. Others derive it from κιχεω, *invenio*; on account of its being so readily found, or so common.) Succory. 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia æqualis*.

2. The pharmacopœial name of the wild cichory. See *Cichorium intybus*.

Cichorium endivia. The systematic name of the endive.

Cichorium — floribus solitariis, pedunculatis, foliis integris; crenatis, of Linnæus. It is an extremely wholesome salad, possessing bitter and anodyne qualities.

Cichorium intybus. The systematic name of the wild succory; called also, *Pancratium Cichorium*, *Cichoreum*, *Cichorium sylvestre*, *Cichorium officinarum*.

Cichorium — floribus geminis, sessilibus; foliis runcinatis, of Linnæus. It belongs to the same family with the garden endive, and by some botanists has been supposed to be the same plant in its uncultivated state; but the endive commonly used as salad, is an annual, or at most a biennial plant, and its parent is now known to be the *cichorium endivia*. Wild succory, or cichory, abounds with a milky juice, of a penetrating bitterish taste, but no remarkable smell, or flavour: the roots are more bitter than the leaves or stalks, and these much more so than the flowers. By culture in gardens, and by blanching, it loses its bitterness, and may be eaten early in the spring in salads. The roots, if gathered before the stem shoots up, are also eatable, and when dried may be made into bread. The roots and leaves of this plant are stated by Lewis to be very useful aperients, acting mildly and without irritation, tending rather to abate than to increase heat, and which may therefore be given with safety in hectic and inflammatory cases. Taken freely, they keep the bowels open, or produce a gentle diarrhœa; and when thus continued for some time, they have often proved salutary in the commencement of visceral obstruction, in jaundices, cachexies, hypochondriacal and other chronic disorders. A decoction of this herb, with others of the like kind, in whey, and rendered purgative by a suitable addition of polychrest salt, was formerly esteemed as a remedy in cases of biliary calculi, and believed to be useful in many complaints requiring what have been termed attenuants and resolvents. The virtues of succory, like those of dandelion, reside in its milky juice; and we are warranted, says Dr. Woodville, in asserting, that the expressed juice of both these plants, taken in large doses frequently repeated, has been found an efficacious remedy in phthisis pulmonalis, as well as the various other affections above mentioned. The milky juice may be extracted by boiling in water, or by pressure. The wild and the garden sorts are used indifferently. If the root is cut into small pieces, dried and roasted, it resembles coffee; and is sometimes a good substitute for it.

Cichory. See *Cichorium intybus*.

Cichory, wild. See *Cichorium intybus*.

CICINDE'LA. (A diminutive of *candela*, a candle: so called from its light.) The glow-worm. *Lampyris noctilulca*. Formerly thought by some to be anodyne, and lithonthriptic, though probably neither. It is not used in the present day.

Cici'num oleum. (From κικι, the ricinus.) An oil, obtained by boiling the bruised seeds of the *Jatropha curcas* of Linnæus. It is somewhat similar in its properties to castor oil.

Ci'cla. A name for the white-beet.

CICU'TA. *a*, *æ*. f. The Latin word for hemlock and also for a shepherd's pipe made of the hollow stalks of hemlock. Some confusion has arisen among modern writers from the name cicuta having been sometimes applied to the common hemlock, or *conium maculatum*, and at others to the water hemlock or *cicuta virosa*. 1. Hemlock. See *Conium*.

2. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia*.

Cicuta aquatica. See *Cicuta virosa*.

Cicuta virosa. The systematic name of the long-leaved water hemlock and cow-bane: called also, *Cicuta aquatica*, *Cicutaria virosa*, *Sium majus alterum angustifolium*, and *Sium erucæ folio*. This plant — *Cicuta, umbellis oppositifoliis; petiolis marginatis obtusis*, of Linnæus — is seldom employed medicinally in the present day. It is an active poison, and has occasionally been eaten by mistake for the *Apium graveolens*, of Linnæus; when it produces tremors, vertigo, a violent burning at the stomach, epilepsy, convulsions, spasms of the jaw, a flowing of blood from the ears, tumefaction of the abdomen, and death.

Cicuta'ria. (*a*, *æ*, f.; from *cicuta*, hemlock.) See *Chærophyllum sylvestre*.

Cicutaria aquatica. See *Phellandrium aquaticum*.

Cicutaria virosa. See *Cicuta virosa*.

Cido'nium. See *Pyrus cydonia*.

CILIA (plural of *cilium*). 1. The edges of the eyelids, or the eyelashes growing from them.

2. A species of pubescence of plants which consists of hairs on the margin of a leaf or petal, giving it a fringed appearance.

CI'LIARY. (*Ciliaris*; from *cilium*, the eyelid.) Belonging to the eyelid.

Ciliary ligament. *Ligamentum ciliare*. The circular band that united the iris and sclerotic membrane to the choroid coat. See *Oculus*.

Ciliaris musculus. That part of the musculus orbicularis palpebrarum which lies nearest the cilia, considered by Riolan as a distinct muscle.

Ciliary processes. The folds into which the choroid coat is gathered around the margin of the crystalline lens.

CILIATUS. Fringed, bordered: applied to leaves, corollæ, petals, &c.: *folium ciliatum*, *petala ciliata*, &c. See *Leaf*, *Corolla*, *Petalum*. Fimbriated is synonymous with this term.

CI'LIUM. (*um*, *ii*. n.; from *cilleo*, to move about.) The eyelid or eyelash.

Ci'llo. (From *cilium*, the eyelid.) One who is affected with a spasm or trembling of the eyelids.

CILLO'SIS. (From *cilium*, the eyelid.) A spasmodic trembling of the eyelids.

Cimeter-shaped. See *Leaf.*

CIMEX. (*ex*, *icis*. m.; from κειμαι, to inhabit: so called because it infests houses.) The name of a genus of insects in the Linnæan system. The wall-louse, or bug.

CIMEX DOMESTICUS. Of this small insect six or seven have been given inwardly to cure the ague, just before the fits come on, and are sometimes effectual, like other things which excite disgust.

CIMO'LIA. (*a*, *æ*. f.; from Κιμωλος, Cimolus, an island in the Cretan sea, where it is procured.) See *Cimolite.*

CIMOLIA ALBA. See *Cimolite.*

CIMOLIA PURPURESCENS. Fullers' earth.

CIMOLITE. *Cimolia.* Cimolian earth, Fuller's earth, of a greyish white colour, which consists of silex, alumina, oxide of iron, and water. It was formerly used in medicine as an astringent.

CI'NA CINÆ. See *Cinchona.*

CIN'Æ SEMEN. See *Artemisia santonica.*

CI'NARA. (*a*, *æ*. f.; from κινεω, to move; *quasi movet ad venerem vel urinam.*) Artichoke.

1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia æqualis.*

2. The pharmacopœial name for the common artichoke. See *Cinara scolymus.*

CINARA SCO'LYMUS. The systematic name of the artichoke: called, in the pharmacopœias, *Alcocalum*, *Agriocinara*, *Articocalus*, *Artischocas lævis*, *Costus nigra*, *Carduus sativus non spinosus*, *Cinara hortensis*, *Scolymus sativus*, *Carduus domesticus capite majore*, and *Carduus altilis.*

Cinara — foliis subspinosis pinnatis indivisisque, calycinis squamis ovatis, of Linnæus. A native of the southern parts of Europe, but cultivated here for culinary purposes. The leaves are bitter, and afford, by expression, a considerable quantity of juice, which, when strained, and mixed with an equal quantity of white wine, is said to have been given successfully in dropsies, in the dose of three or four table-spoonfuls night and morning; but it is very uncertain in its operation.

CINAROCEPHA'LIÆ. (From κιναρα, the artichoke, and κεφαλη, a head: having a head like the artichoke.) A natural family of plants so called from the shape of their inflorescence; as the thistle, globe thistle, burdock, blue-bottle, &c.

CINCHO'NA. *a*, *æ*. f. A well-known medicinal bark, the use of which, according to Geoffroy, was first learned from the following circumstance: — Some of the trees being thrown by the winds into a pool of water, lay there till the water became so bitter that every body refused to drink it. However, one of the neighbouring inhabitants being seized with a violent paroxysm of fever, and finding no other water to quench his thirst, was forced to drink of this, by which he was perfectly cured. He afterwards related the circumstance to others, and prevailed upon some of his friends, who were ill of fevers, to make use of the same remedy, with whom it proved equally successful. The use of this excellent remedy, however, was very little known till about the year 1638, when a signal cure having been performed by it on the Spanish viceroy's lady, the Countess del Cinchon, at Lima, it came into general use, and hence it was distinguished by the appellation of *cortex cinchonæ*, and *pulvis comitissæ*, or the Countess's powder. On the recovery of the Countess, she distributed a large quantity of the bark to the Jesuits, in whose hands it acquired still greater reputation, and by them it was first introduced into Europe, and thence called *cortex*, or *pulvis jesuiticus*, *pulvis patrum;* and also Cardinal de Lugo's powder, because that charitable prelate bought a large quantity of it, at a great expense, for the use of the religious poor at Rome.

I. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.* Cinchona, or Peruvian bark-tree.

II. The pharmacopœial name of several kinds of Peruvian barks; which have been called, *Cortex; Cortex Chinæ; Chinchina*, *Kina kina*, *Kinkina*, *Quina quina*, and *Quinquina.* The trees which afford these barks grow wild in the hilly parts of Peru; the bark is stripped from the branches, trunk, and root, and dried. Three kinds of bark are now in use: —

1. *Cortex cinchonæ cordifoliæ.* The plant which affords this species is the *Cinchona cordifolia*, of Zea; the *Cinchona officinalis*, of Linnæus; the *Cinchona macrocarpa*, of Willdenow. Heart-leaved cinchona. The bark of this tree is called *yellow bark*, because it approaches more to that colour than either of the others does. It is in flat pieces, not convoluted like the pale, nor dark-coloured like the red; externally smooth, internally of a light cinnamon colour, friable and fibrous; has no peculiar odour different from the others, but a taste incomparably more bitter, with some degree of astringency. It is from this species of cinchona that a new alkali, called *quina*, has been obtained; which, in combination with sulphuric acid, forms the sulphate of quinine. See *Quinine.*

2. *Cortex cinchonæ lancifoliæ.* This species is obtained from the *Cinchona lancifolia* of Zea. Lance-leaved cinchona. This is the *quilled bark*, which comes in small quilled twigs, breaking close and smooth, friable between the teeth, covered with a rough coat of a brownish colour, internally smooth, and of a light brown; its taste is bitter, and slightly astringent; flavour slightly aromatic, with some degree of mustiness.

3. *Cortex cinchonæ oblongifoliæ.* This kind is procured from *Cinchona oblongifolia* of Zea. Oblong-leaved cinchona. This is the *red bark:* it is in large thick pieces, externally covered with a brown rugged coat, internally more smooth and compact, but fibrous, of a dark red colour; taste and smell similar to that of the *cinchonæ lancifoliæ cortex*, but the taste rather stronger.

From the general analysis of bark, it appears to consist, besides the woody matter which composes the greater part of it, of gum, resin, gallic acid, of very small portions of tannin and essential oil, of a peculiar acid, called the *kinic*, and several salts. Seguin also supposed the

existence of gelatine in it, but without sufficient proof. Cold water infused on pale bark for some hours, acquires a bitter taste, with some share of its odour; when assisted by a moderate heat, the water takes up more of the active matter; by decoction, a fluid, deep coloured, of a bitter styptic taste, is obtained, which, when cold, deposits a precipitate of resinous matter and gallic acid. By long decoction, the virtues of the bark are nearly destroyed, owing to the oxygenation of its active matter. Magnesia enables water to dissolve a larger portion of the principles of bark, as does lime, though in an inferior degree. Alkohol is the most powerful solvent of its active matter. Brandy and other spirits and wines, afford also strong solutions, in proportion to the quantity of alkohol they contain. A saturated solution of ammonia is also a powerful solvent; vinegar is less so even than water. By distillation, water is slightly impregnated with the flavour of bark: it is doubtful whether any essential oil can be obtained.

The action of menstrua on the red bark is nearly the same, the solutions only being considerably stronger, or containing a larger quantity of resinous matter, and of the astringent principle.

The analysis of the yellow bark, shows that its active principles are more concentrated than in either of the others, affording to water, alkohol, &c. tinctures much stronger, both in bitterness and astringency; especially in the former principle.

Vauquelin made infusions of all the varieties of cinchona he could procure, using the same quantities of the barks and water, and leaving the powders infused for the same time. He observed, 1. That certain infusions were precipitated abundantly by infusion of galls, by solution of glue and tartar emetic. 2. That some were precipitated by glue, but not by the two other re-agents; and, 3. That others were, on the contrary, by nut-galls, and tartar emetic, without being affected by glue. 4. And that there were some which yielded no precipitate by nut-galls, tannin, or emetic tartar. The cinchonas that furnished the first infusion were of excellent quality; those that afforded the fourth were not febrifuge; while those that gave the second and third were febrifuge, but in a smaller degree than the first. Besides mucilage, kinate of lime, and woody fibre, he obtained in his analysis a resinous substance, which appears not to be identic in all the species of bark. It is very bitter, very soluble in alkohol, in acids, and alkalies; scarcely soluble in cold water, but more soluble in hot. It is this body which gives to infusions of cinchona the property of yielding precipitates by emetic tartar, galls, gelatine; and in it the febrifuge virtue seems to reside. It is this substance in part which falls down on cooling decoctions of cinchona, and from concentrated infusions. A table of precipitations by glue, tannin, and tartar emetic, from infusions of different barks, has been given by Vauquelin.

Pelletier and Caventou analysed the *Cinchona condaminæa*, gray bark, and found it composed of, 1. cinchonina, united to kinic acid; 2. green fatty matter; 3. red colouring matter, slightly soluble; 4. tannin; 5. yellow colouring matter; 6. kinate of lime; 7. gum; 8. starch; 9. lignine.

The red bark has been considered as superior to the pale; the yellow is represented, apparently with justice, as being more active than either of the others.

The effects of Peruvian bark are those of a powerful and permanent tonic, so slow in its operation that its stimulating property is scarcely perceptible by any alteration in the state of the pulse, or of the temperature of the body. In a large dose, it occasions nausea and headach; in some habits it operates as a laxative; in others it occasions costiveness. It is one of those medicines, the efficacy of which, in removing disease, is much greater than could be expected, *à priori*, from its effects on the system in a healthy state.

Intermittent fever is the disease for the cure of which bark was introduced into practice; and there is still no remedy which equals it in power. The disputes respecting the mode of administering it are now settled. It is given as early as possible, after clearing the stomach and bowels, in the dose of from one scruple to a drachm every second or third hour, during the interval of the paroxysm; some have continued to give it during the hot fit, but this is a very dangerous practice. See *Ague*.

In remittent fever it is given with due caution, even though the remission of the fever may be obscure.

In some forms of continued fever which are connected with debility, as in typhus, cynanche maligna, confluent small-pox, &c., it is regarded as one of the most valuable remedies. It may be prejudicial, however, in those diseases where the brain, or its membranes are inflamed, or where there is much irritation, marked by subsultus tendinum, and convulsive motions of the extremities; and in pure typhus it appears to be less useful in the beginning of the disease, than in the convalescent stage.

Even in fevers of an opposite type, where there are marks of inflammatory action, particularly in acute rheumatism, bark has been found useful after blood-letting. In erysipelas, in gangrene, in extensive suppuration and venereal ulceration, the free use of bark is of the greatest advantage.

In the various forms of passive hæmorrhagy, in many other diseases of chronic debility, dyspepsia, hypochondriasis, paralysis, rickets, scrofula, dropsy, and in a variety of spasmodic affections, epilepsy, chorea, and hysteria, it is administered as a powerful and permanent tonic, either alone, or combined with other remedies suited to the particular case.

The officinal preparations of bark are an infusion, decoction, an extract, a resinous extract, a simple tincture, an ammoniated and a compound tincture, and the sulphate of quinine. The usual dose is half a drachm of the powder. The only inconvenience of a larger dose is its sitting uneasy on the stomach. It may therefore, if necessary, be frequently repeated; and, in

urgent cases, may be taken to the extent of an ounce, or even two ounces, in twenty-four hours.

The sulphate of quinine has the greatest febrifuge power of all the preparations of bark; and next to it the powder, which may be given in wine, in any spirituous liquor, or, if it excite nausea, combined with an aromatic. The cold infusion is the least powerful, but most grateful: the decoction contains much more of the active matter of the bark, and is the preparation generally used when the powder is rejected; its dose is from two to four ounces. The spirituous tincture, though containing still more of the bark, cannot be extensively used on account of the menstruum; but is principally employed, occasionally, and in small doses of two or three drachms, as a stomachic. The extract is a preparation of considerable power, when properly prepared, and is adapted to those cases where the remedy requires to be continued for some time. It is then given in the form of pill, in doses of from five to fifteen grains.

Bark is likewise sometimes given in the form of enema; one scruple of the extract, or two drachms of the powder, being diffused in four ounces of starch mucilage. The decoction is also sometimes applied as a fomentation to ulcers.

CINCHONA CARIBÆA. The systematic name of the Caribæan bark-tree. It grows in Jamaica, where it is called the sea-side beech. According to Dr. Wright, the bark of this tree is not less efficacious than that of the cinchona of Peru, for which it will prove an useful substitute; but by the experiments of Dr. Skeete, it appears to have less astringent power.

Cinchona condaminæa. See *Cinchona.*

Cinchona cordifolia. See *Cinchona.*

Cinchona flava. See *Cinchona.*

CINCHONA FLORIBUNDA. The systematic name of the plant which affords the Saint Lucia bark. *Cinchona — floribus paniculatis glabris, capsulis turbinatis lævibus, foliis ellipticis acuminatis glabris* of Linnæus. It has an astringent, bitter taste, somewhat like gentian. It is recommended in intermittents, typhoid dysentery, and dyspepsia: it should always be joined with some aromatic. Dr. Withering considers this bark as greatly inferior to that of the other species of this genus. In its recent state it is considerably emetic and cathartic, properties which it retains in some degree on being dried; so that the stomach does not bear this bark in large doses, and in small ones, its effects are not such as to give it any peculiar recommendation.

Cinchona lancifolia. See *Cinchona.*

Cinchona oblongifolia. See *Cinchona.*

Cinchona officinalis. See *Cinchona.*

Cinchona rubra. See *Cinchona.*

CINCHONA SANCTA FE'. Several species of cinchona have been lately discovered at Sancta Fé, yielding barks both of the pale and red kind; and which, from their sensible qualities, are likely, upon trial, to become equally useful with those produced in the kingdom of Peru.

Cinchonia. See *Cinchonine.*

Cinchonic acid. See *Kinic acid.*

CINCHONINE. (*Cinchonina, æ.* f.; so called, because obtained from the *cinchona* bark.) Cinchonine is the salifiable base, or alkali, discovered in the *Cinchona condaminæa*, by Pelletier and Caventou. The person, however, who first recognised its existence, though he did not ascertain its alkaline nature, or its combinations with acids, was Gornis of Lisbon. It is obtained from the bark in which it exists, in the same manner as the quinine is obtained from the yellow bark. See *Quinine.*

Cinchonine crystallises in the form of a rhomboidal prism, of 108° and 72°, terminated by a bevelment. It has but little taste, requiring 7000 parts of water for its solution; but when dissolved in alkohol, or an acid, it has the bitter taste of bark. When heated, it does not fuse before decomposition. It consists of oxygene, hydrogene, and carbon; the latter being predominant. It dissolves in only very small quantities in the oils, and in sulphuric ether.

The sulphate is composed of cinchonine, 100; sulphuric acid, 13: whence the prime equivalent would appear to be 38·5.

The muriate is more soluble. It consists of cinchonine, 100; muriatic acid, 7·9.

Gallic, oxalic, and tartaric acids, form neutral salts with cinchonine, which are soluble only with excess of acid. Hence infusion of nut-galls gives, with a decoction of good cinchona, an abundant precipitate of gallate of cinchonine.

Robiquet gives as the composition of a subsulphate of cinchonine of the first crystallisation, sulphuric acid, 11·3; cinchonina, 79·0.

Cinchonine possesses the same medicinal properties as quinine, but in a less powerful degree.

Cinchoninæ sulphas. See *Cinchonine.*

CINCI'NNUS. The hair on the temples.

CINCLE'SIS. (From κιγκλιζω, to move.) *Cinclismus.* An involuntary winking. — *Vogel.*

CINERA'RIUM. (*um, ii.* n.; from *cinis*, ashes.) The ash-hole of a furnace.

Cineres clavellatæ. See *Clavellatæ cineres.*

Cineres russici. See *Potassa impura.*

CINERI'TIOUS. (*Cineritius*; from *cinis*, ashes.) Of the colour of ashes. The cortical substance of the brain is so called from its ash colour. — See *Encephalon.*

CINERI'TIUM. (From *cinis*, ashes: so named from its containing the ashes of vegetables or bones.) A cupel.

CINE'RULA. A name for spodium.

CINE'TICA. (From κινεω, to move.) Diseases affecting the organs of motion, that is the muscles. The third order in the Class *Neurotica* of Mason Good.

CINE'TICUS. (Κινητικος, having the power of motion.) Appertaining to the powers of motion, and consequently the muscles.

CINE'TUS. The diaphragm.

CINGULA'RIA. (From *cingulum*, a girdle; because it grows in that shape.) Most probably the *lycopodium selago* of Linnæus.

CINGULUM MERCURIALE. A mercurial girdle; called also *cingulum sapientiæ*, and *cingulum stultitiæ.* It was an invention of Rulandus's: different directions are given for making it; but the following is one of the neatest: — "Take three drachms of quicksilver;

shake it with two ounces of lemon-juice until the globules disappear; then separate the juice, and mix with the extinguished quicksilver, half the white of an egg; gum-dragon, finely powdered, a scruple; and spread the whole on a belt of flannel." It was used to excite salivation.

Cingulum Sancti Johannis. A name of the *artemisia vulgaris*.

Cinifica'tum. The same as calcinatum.

CI'NNABAR. (*Cinnabaris, is.* f.) Pliny says the Indians call by this name a mixture of the blood of the dragon and elephant, and also many substances which resemble it in colour, particularly the minium; but it now denotes the red sulphuret of mercury. An ore of mercury, consisting of that mineral united to sulphur. A native sulphuret of mercury. See *Hydrargyri sulphuretum rubrum*.

2. An artificial compound of mercury and sulphur, called factitious cinnabar, red sulphuret of mercury, and vermilion. See *Hydrargyri sulphuretum rubrum*.

Cinnabarine. *Cinnabarinus.* Of a red lead or cinnabar colour: applied generally in natural history.

Cinnabaris factitia. Factitious cinnabar. See *Hydrargyri sulphuretum rubrum*.

Cinnabaris græcorum. The sanguis draconis and cinnabar.

Cinnabaris nativa. Native cinnabar. See *Hydrargyri sulphuretum rubrum*.

CINNAMO'MUM. (*um, i.* n.; from *kinamon*, Arabian.) Cinnamon. See *Laurus cinnamomum*.

CINNAMON. The name of an aromatic bark. See *Laurus cinnamomum*.

Cinquefoil. See *Potentilla reptans*.

CI'ON. (Κιων, a column.) 1. The uvula was formerly so named, from its pyramidal shape.

2. An enlargement of the uvula.

Cio'nis. (From κιων, the uvula.) An enlargement and painful swelling of the uvula.

CIRCÆ'A. (*a, æ.* f.; from *Circe*, the enchantress: so named from the opinion that it was used by Circe in her magical operations.) 1. The name of a genus of plants in the Linnæan system. Class, *Diandria*; Order, *Monogynia*. Enchanter's nightshade.

2. The name, in some pharmacopœias, for the *Circæa lutetiana*, which is now fallen entirely into disuse.

Circium arvense. The *Serratula arvensis*.

Circocele. See *Cirsocele*.

Ci'rcus. (From κιρκος, a circle.) A circular bandage. — *Turton*.

CIRCULATION. (*Circulatio, onis.* f.; from *circulo*, to compass about.) The blood, propelled by the heart and arteries, visits every part of the living system, from the nearest to the most remote, nourishing all the organs and textures, and sustaining their vital activity; it then returns by the veins to the heart. This course is called the *circulation of the blood*, the discovery of which by Harvey formed so important an epoch in the history of physiology and medicine. Attempts have been made to prove that the circulation was known to Galen; this, however, is quite an erroneous idea: he appears, as happens so often in the progress of science, to have stood on the very verge of the discovery without having the smallest notion of the truth. Servetus, who fell a victim to the intolerance and cruelty of Calvin in the year 1553, was the first who made any approach to a knowledge of the circulation. He had evidently a correct idea of the passage of the blood through the lungs, or what may be called the minor circulation. Cæsalpinus and Realdus Columbus, the former of whom died in 1571, and the latter in 1577, both entertained the same ideas; and by their examination of the mechanism of the heart, more immediately prepared the way for the discovery of the general circulation, — the knowledge of which, however, was not in any degree attained by either of them. This greatest of physiological discoveries was made by William Harvey in 1620, after many years of laborious observation and experiment. He delayed the publication of his discovery for eight years, in order to mature it the more perfectly; and finally gave it to the world in a treatise, entitled *Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus*, published at Frankfort in 1628. For the following very neat summary of what is at present known on the subject of the circulation, we are indebted to Dr. Alison's Outlines of Physiology and Pathology: —

A regular supply of a nutritious fluid, recently exposed to the air, is a condition essential to the maintenance of the vital phenomena, not only in the moving solids, but in all other parts of living bodies, whether belonging to the organic or animal life, and in all classes of animals. But it is important to bear in mind, that it is only in the higher classes of animals that this essential condition of all vital action is fulfilled by means of a Circulating System; — the nourishment even of complex structures, in the radiated class of animals, being effected, as is believed, simply by imbibition and transudation through porous solids.

The circumstance in the animal economy, which appears chiefly to impose the necessity of a distinct circulating system, is the appropriation of a separate organ to the office of regularly exposing the fluids to the air; and this again is demanded by such occasion for strength and solidity in certain parts of the frame, as precludes the possibility of free admission of air to the fluids in all parts of the body, such as takes place in some of the lower classes. A complex frame, capable of exertions of strength, and of resistance to injury, a separate respiratory organ, and a regular circulating system, are therefore very generally, if not necessarily, combined throughout the animal creation. And in all warm-blooded animals, the circulating system is to be regarded as merely the channel of communication between the capillaries of the lungs, where the blood is prepared by the action of the air, for the maintenance of the different functions of life, and the capillaries of the rest of the body, where it is applied to the support of these different functions. The collection and concentration of the blood at the heart are manifestly intended to subject it to the action of a

strong muscle, and thereby secure its transmission, with adequate force and precision, through the different sets of capillary vessels; and the juxta-position of the two portions of the heart, which move the blood to and from the lungs, appears to be merely a matter of convenience.

In treating of the circulation, we first state the course followed by the blood in the living body, with the evidence by which this course is demonstrated; and then we consider the nature and efficacy of the agents, by which this movement of the blood is produced.

During the living state, all the blood which is contained in very minute and capillary vessels, in every part and in almost every texture of the body, gradually makes its way into veins, and along them, passing from those that are more numerous and smaller, into those that are less numerous and larger, till it reaches the anterior or right auricle of the heart, by the venæ cavæ and coronary vein, and distends that cavity. By the contraction of this auricle it is driven into the right ventricle, and by the contraction of this, into the pulmonary artery, by the numerous branches of which it is distributed among the minute capillaries of the lungs, to be exposed to the air. From these, it again passes along an ascending series of vessels contained in the lungs, until it emerges from them to enter the four pulmonary veins, which lead to the cavity of the posterior or left auricle of the heart. By the contraction of this auricle, simultaneous with that of the right auricle, it is forced into the left ventricle; and by the contraction of this, simultaneous with that of the right ventricle, it is forced into the aorta, by the numerous branches of which it is gradually conveyed into the capillaries, that pervade the various organs and textures of the body.

That this is the real course of the blood, is proved by various facts, but especially by the following: —

1. By the observation of the successive distension of the venæ cavæ near the heart, of the auricles, and of the ventricles, in living and warm-blooded animals, taking place in the order above stated, — and by the observed passage of the blood through these cavities, in those lower animals that have hearts similarly formed (although single) and translucent.

2. By the observed passage of the blood from the minute capillary arteries into the beginnings of the veins, in the translucent textures of different fishes and reptiles, which have a circulating system similarly formed to that of the higher classes, although single.

3. By the structure of the valves, at the heart and in the veins, necessarily prohibiting, or greatly impeding, movement along the vascular system in the opposite direction from that above stated.

4. By the effect of ligatures, and of punctures made above and below ligatures, in the larger arteries and veins; the former swelling out and giving a free jet of blood within the ligatures, and the latter beyond them.

5. By the quantity of blood which may be rapidly discharged from a wound below a ligature on the vein of a limb; which is so great as to demonstrate that the vein must have a continual supply of blood from the arteries of the limb.

6. By the effect of injections into living arteries and veins, making their way readily, and easily filling the vessels, when thrown in the direction of the circulation as described, but strongly resisted when forced in the opposite direction.

The structure and actions of the heart, the chief muscular agent in this process, and the *first* of the powers, by which the movement of the circulating fluids in the adult state are effected, first demand our attention. Its oblique position within the pericardium, in the fore part and left side of the thorax, — its irregular conical form, flattened posteriorly, — its division into two parts by the septum, and the form, size, and relative position of the right or anterior, and of the left or posterior, auricle and ventricle, — the termination of the great veins in the auricles, and origin of the great arteries from the ventricles, — the investment of the muscular texture of the heart by two serous membranes, the external reflected from the inner layer of the pericardium, and the internal continuous with that which lines the bloodvessels, — are all supposed to be made known by the study of anatomy.

The muscular fibres of the auricles of the heart are quite distinct, and easily separable (after long-continued boiling) from those of the ventricles; and the part of the heart which may be regarded as the fixed point or pivot of its movements, is the point between the posterior groove on its surface and the origin of the aorta, where the muscular fibres, constituting the septum of the auricles, are set upon those which form the septum of the ventricles. The contractions, both of auricles and ventricles, tend to bring all other parts of the heart nearer to this fixed point. The texture found at this point is tendinous; and in immediate connection with it, are the tendinous rings (partly bony in some animals) which surround the origin of the aorta and pulmonary artery, and the openings between the auricles and the ventricles. From these tendinous parts most of the fibres, constituting the muscular parietes of the heart, take their origin. Those which go to the parietes of the auricles ascend, form loops around these cavities, of various form and size, and then descend to be inserted into other points of the same tendinous rings, and are encompassed at their lower part by more superficial horizontal layers of fibres. Those which go to the parietes of the ventricles have an oblique course downwards, and appear to be reinforced by others which originate in the muscular texture itself, especially along the anterior and posterior grooves, which lodge some of the coronary vessels. The outermost of them converge towards the apex, and, after making a spiral turn round it, pass inwards and ascend along the interior of the ventricles, forming the columnæ carneæ and part of the septum, and arranging themselves in the reticulated form, which is obvious on opening the heart. Others of the

fibres descending from the tendinous rings merely form loops around the ventricles, and re-ascend to the rings. The obliquity of the direction of the fibres is gradually altered towards the interior of the muscular substance, so that about the centre of the thickness of the parietes, the fibres are wrapped round the ventricles nearly transversely; some surrounding both ventricles, while others detach themselves at the septum, and surround the left ventricle only, making its parietes thicker and stronger than those of the right.

This is a general outline of the disposition of the greater part of the muscular fibres of the heart. At its base the arrangement is more complex, but it is always regular and uniform; and evidently such, that a general contraction of the fibres of the heart shall bring all parts of the heart towards the central point above mentioned, and compress the contents of all the cavities, so as to secure their forcible ejection by the openings there situated.

The valves placed at these openings effectually prevent any reflux of the blood that has been ejected. The structure of the membranous folds, forming the semilunar valves, at the mouths of the great arteries, sufficiently indicates their use; for they are attached to the interior of the vessels by curved edges, the concavity of which is turned from the heart, and they must therefore be raised and stretched across the opening by any fluid passing towards the heart, but are laid down along the sides of the arteries by any fluid passing out of it. The precise object of the structure of the tricuspid and mitral valves, which descend from the tendinous rings surrounding the auriculo-ventricular orifices, into the ventricles, and are attached by tendinous cords to the ends of the columnæ carneæ, is not so perfectly ascertained; it being doubtful whether the membranous parts of the valves always project into the cavities of the ventricles, and are merely pulled together by the contraction of the columnæ carneæ to close the orifices, or whether they are raised and stretched across the orifices by the blood at the time when the ventricles are full, and contract on their contents. In order to decide this question, it would be necessary to ascertain more precisely than has been yet done, whether the contraction of the columnæ carneæ takes place precisely at the same time as that of the other fibres of the ventricles. But either in the one way or the other, these valves are certainly fitted, and intended, to prevent any reflux of blood from the ventricles into the auricles, at the time when the ventricles contract.

When the heart of a living warm-blooded animal is exposed, the simultaneous contractions, first of the two auricles, and then of the two ventricles, may be distinguished; but, in the natural and vigorous state of the circulation, the former movement (always a comparatively slight one), is hardly over before the latter begins; and the longest pause in the visible contractions of the heart is that which succeeds the systole of the ventricles, and precedes that of the auricles.

The successive contractions of the auricles and ventricles are often observed to go on, for a short time, nearly in the usual way, after the heart of a living animal is emptied of its blood, or even removed from the body; so that there is obviously a tendency to the regular succession of these movements, independently of the successive applications of the stimulus of the blood to these parts.

When the ventricles contract, the apex of the heart is not only pulled upwards, but somewhat raised or tilted forwards; hence it is generally, and no doubt justly supposed, that it is during this systole of the ventricles, that the apex of the heart gives the impulse against the parietes of the chest, which is felt, in the natural state, between the fifth and sixth ribs, and which, just perceptibly, precedes the pulse at the wrist. The projection of the apex of the heart on the contraction of the ventricles, is seen even when the heart is removed from the body of a warm-blooded animal before its actions have ceased, and is, perhaps, sufficiently explained by the disposition of its muscular fibres, and particularly by the irregular cone which they form, being *flattened posteriorly*.

When the ear is applied to the human chest, over the situation of the heart, a dull and somewhat prolonged sound is observed to precede and accompany the impulse of the heart against the parietes above mentioned; and this is immediately succeeded by a shorter and sharper sound; after which there is a short pause, before the dull sound and impulse are renewed. A slighter impulse or succession is sometimes observed to accompany the sharper sound likewise. The duller sound, and stronger impulse, are generally ascribed to the contraction of the ventricles, and movement of their fluid contents; and Laennec and others have ascribed the sharper sound and feebler impulse to that of the auricles; but this last opinion is probably erroneous; because the sharper sound certainly immediately *precedes* the longest pause in the sounds of the heart; whereas the contraction of the auricles immediately *succeeds* the longest pause in the visible contractions of the heart; as appears not only from experiments on animals, but also from cases occurring occasionally in the human body, both in health and disease, where the contractions of the right auricle are made obvious by a retrograde impulse, communicated to the blood in the jugular veins.

It is also doubtful, whether the contraction of the columnæ carneæ, in the inside of the ventricles, takes place at the same instant with that of the mass of muscular fibres constituting their parietes. It is obvious, that the contraction of these columnæ cannot aid in lessening, but must elongate and enlarge, the cavities of the ventricles. It has therefore been conjectured, that their contraction may precede, and alternate with the general systole of the ventricles, and pull down and stretch the tricuspid and mitral valves during the diastole of these, and so prepare them for the entrance of the blood from the auricles; and that the second or sharper sounds of the heart is caused by this action of the columnæ and valves, or rather by

the sudden entrance of the blood from the auricles, for which preparation is thus made. Perhaps it may also be supposed, that one stimulus which excites the columnæ to act, is the pressure made on them during the previous contraction of the mass of muscular fibres lying exterior to them, in the systole of the ventricles; and that the contraction thus beginning in those internal columns, is afterwards propagated to that surrounding mass of fibres, many of which are continuous with those in the columnæ themselves. In this manner it seems possible, that the peculiar convoluted form of the muscular fibres of the heart may be concerned in giving the tendency above noticed, to a regular succession of their own contractions.

The contractions of the muscular fibres of the different parts of the heart are clearly sufficient to agitate the blood powerfully, and ultimately to eject it by the arteries with great force. The quantity ejected at each systole of the left ventricle seems to be nearly two ounces in an average-sized man, and the space it must occupy in the aorta nearly eight inches. The calculations of Hales, who states the force exerted by the left ventricle of a human heart as equivalent to 51½ pounds, the velocity of the blood leaving the heart as 149·2 feet per minute, and the quantity of blood passing through the heart every hour as 20 times the whole weight of the blood in the body, — although only approximations to the truth, do not appear to be founded on exaggerated data. The velocity of the circulation is also illustrated by the fact, that in the horse, a fluid injected into one jugular vein has been detected in the opposite vein, and even in the vena saphena, within half a minute.

The diastole, as well as the systole, of the different parts of the heart, especially of the ventricles, is performed with force; the muscular fibres not merely relaxing as the cavities are distended with blood, but springing back directly after their own contraction is over. The tendency thus given to the formation of a vacuum in the auricles, is one cause of motion of the blood towards the heart along the great veins, where it is subject to pressure from various causes.

Although the different parts of the heart have obviously a tendency to regular and successive movements, independently of the stimulus of the blood, yet experiments prove, that the blood, which is in contact with the inner surface of the heart, acts as a powerful stimulus upon it; and we cannot doubt that it is by the constant succession of fresh applications of this stimulus, that the nearly uniform succession of the heart's movements, throughout the whole of life, is maintained.

We can go no farther, in assigning a cause for the natural movements of the heart, than to refer them to the application of this stimulus, and to the property of irritability, in a high and peculiar degree of intensity, resident in its fibres. We cannot ascribe to the heart any feeling or sensation, in the performance of these actions, without altering the meaning of these words; we cannot liken these actions to any voluntary movements, without overlooking the most essential peculiarities of both; and we cannot suppose any action of nerves to be essentially concerned in them, without ascribing to the nerves of the heart endowments, which no experiments or observations show that they possess.

The blood is conveyed from the heart to the capillary vessels all over the body by the arteries; and the properties of these constitute the *second* great agent, by which its motion is effected.

These are flexible and elastic tubes, consisting of three coats, of which the exterior, composed of dense cellular texture, is the most distensible and the toughest: the middle, composed of transverse fibres, denser and lighter coloured than those of muscles, is the thickest, strongest, and most elastic; and the internal, on which the blood moves, is very thin and smooth. The arteries are all to a considerable degree extensible, especially in the longitudinal direction; and are of great strength, the smaller branches even more so than the larger.

Every small portion of artery, by reason of its elasticity, has nearly a cylindrical form, and the blood therefore passes along a series of descending cylinders, on its way from the heart to the capillaries. But the sum of the areas of the whole of the smallest branches into which any artery divides itself, is considerably greater than the area of the artery itself; although the ratio of this difference has been very variously stated.

The arteries are subdivided into small branches to a great but very various degree of minuteness in the different textures. In some parts the smallest branches are so minute as not to admit the red globules of the blood; but various textures appear to be nourished, without so minute a subdivision of their vessels.

The smaller arteries communicate or anastomose freely with one another in all parts of the body; the smallest capillaries the most freely of all; and on this account the characteristic effect of ligatures formerly observed, in emptying the portions of artery beyond them, and distending the portions within them, is only distinctly seen in the larger branches.

The arteries in the living body (with the exception of the smallest branches, in which a greater variety is observed) are always filled, and even somewhat distended with blood, which is moving towards the capillaries. This blood receives a sudden *increase of velocity* from the impulse of each successive jet of blood from the ventricles of the heart; and from the same cause the arteries are slightly *distended*, — and in many parts of the body even somewhat *displaced*. These effects of the systole of the ventricles, constitute what is called the *pulsation* of the arteries; but the two last of these effects, in the healthy and tranquil state of the circulation, are scarcely perceived at any single points; and therefore the pulse in an artery is not distinctly felt, unless the artery is somewhat compressed by the finger, to make the impulse, which its contents receive from the heart, perceptible.

The slight distension which the whole arteries experience, from the impetus of each suc-

cessive jet of blood from the heart, is sufficient to call into action their elasticity, which enables them to react on the blood, in each interval of the heart's pulsation, and gradually to equalise its motion, until it becomes quite uniform and continuous in the capillaries.

There are many and great obstacles to the free motion of the blood along the arteries, — from the friction of their sides, — from their angular and tortuous course and minute subdivisions, — and from their constant tendency to contraction. The effect of these is not, as some have taught, to make the velocity of the blood in the smaller arteries less than in the larger, but to make its velocity, in all the arteries, less than it otherwise would be. As we know that no part of the circulating system in the healthy state is continually becoming fuller of blood, we are sure that the quantity of blood delivered into all the veins in a given time from all the arteries, is equal to that received by them from the heart; and this proves, that the velocity of the blood in the capillaries, on the whole, must be less than that in the aorta, just in the same proportion as the area of the aorta is less than the sum of the areas of all the capillaries.

But although this proportion must hold on the whole, yet many facts inform us, that the velocity of the blood, even in vessels of the same size, in different parts of the system, is habitually different; and that the quantity of blood received into, and its velocity in, the smaller arteries and capillaries of all parts of the body, are liable to much temporary variation. In particular, the blood which enters the brain, as it meets with more of the obstacles above mentioned than that which is sent to most other parts, must have an habitually slower motion. For these varieties in the flow of blood in different parts, and at different times, there is ample provision, in the distensibility of the vessels, and in the possibility of increased velocity in one part compensating for diminished velocity in another, without the general law above stated being perceptibly violated.

Although the ordinary velocity of the blood in different arteries must be very different, it would appear from the experiments of Poiseuille, that the pressure exerted on the blood in different parts of the body (as measured by the column of mercury which the blood in different arteries will sustain), is almost exactly the same.

In attempting to form a judgment on the difficult subject of the efficiency of any action of arteries, in causing, or regulating, the movement of the blood, it is first necessary to consider how far the action of the heart extends, and is efficient as a cause of that movement, throughout the vascular system.

It appears from experiments of different physiologists, and especially of Magendie and Poiseuille, that when the circulation of a limb, in a warm-blooded animal, is confined to the branches of a single artery and corresponding vein, the blood stagnates in the vein, whenever the artery is emptied by ligature; but flows freely along the vein, when the ligature on the artery is removed; and that its flow along the vein is varied by any cause that affects its movement in the artery; which shows, that the action of the capillaries and veins of a limb is insufficient to propel the blood, without the impulse *a tergo*, given by the heart and large arteries. Indeed a little management gives nearly similar results in a common bloodletting.

Farther, the movement of the blood in all the small vessels of a warm-blooded animal, is always speedily arrested when the heart's action ceases; and although there are various examples on record, in which the human fœtus (always imperfect, however, in other respects), has attained a considerable size without a heart, yet every such fœtus has been contained in the same womb, and probably nourished through the same placenta, as another fœtus of the natural structure; and in every such case the heart of the perfect fœtus would, in all probability, be instrumental in maintaining the circulation of the monster. It would appear, therefore, that in warm-blooded animals at least, the heart's action is essential to the support of the circulation in every part of the vascular system.

On the other hand, that the pressure of the coats of arteries may act as a powerful cause of motion in the blood, appears from the effects of an opening made in an artery, in which case a current of blood is established towards the opening, from the artery and anastomosing branches beyond it, as well as from those nearer the heart; and the same is shown by the rapidity with which the portion of an artery beyond a ligature is emptied of its blood.

Dr. Marshall Hall has ascertained, that in some cold-blooded animals, there are arteries which pulsate nearly as a heart does, after the heart has been cut out; and Poiseuille and Guillot have described, in some of the lowest class of animals, which have vessels, but not hearts, movements of these vessels resembling the peristaltic movements of the bowels, and manifestly propelling their contents; but in the arteries of warm-blooded animals, no such unequivocal indications of vital action have ever been observed. In all these animals, the action of arteries on their contents seems to be always of the same *kind* as that which results from the physical property of elasticity called into action by a distending force; but the following facts appear sufficient to prove that they possess the vital power of tonicity, as formerly defined, which will determine a *greater degree* of reaction on their contents, than mere elasticity would occasion: —

1. In experiments made by many physiologists, particularly by Verschuir, Thomson, Giulio and Rossi, Parry, Hastings, and Wedemeyer, it appeared, that by various stimuli applied to arteries, chiefly small arteries, which could not affect their mechanical properties, constriction of those arteries, at the points irritated, lasting some time, and then gradually relaxing, were induced.

2. In experiments made by Wedemeyer, it was found, that when stimulating fluids (such as alkohol or vinegar of a certain strength), are injected into the arteries of living animals, there is great difficulty in pushing them forward into

the veins; whereas mild fluids in the living body, and these irritating fluids in the dead, pass forward readily.

3. In experiments made by Mr. Hunter and Dr. Parry, it appeared distinctly that the arteries of dying animals, especially those dying from hæmorrhage, when emptied of their blood, contract immediately after death, and in some instances before death, to a calibre considerably less than that which they afterwards gradually assume, and then maintain till putrefaction begins: which proves, that the tendency of living arteries to contraction is greater than their merely physical properties can occasion.

4. In experiments made by Poiseuille, where an artery from an animal just killed was distended by water urged by the pressure of a given column of mercury, and then the force of its re-action measured by the height of a column of mercury which the water expelled from it could support, it appeared that the force of re-action, excited by the distention of the recent artery, was greater than the force used to distend it; and greater than an artery could exert some time after death, but before any decomposition of its texture had commenced.

These facts leave no room for doubt that arteries possess, and must occasionally, if not habitually, exert on their contents a truly vital power of contraction.

This being ascertained, we next observe, that various facts show the course of the blood to be variously modified, and probably much promoted on the whole, by causes acting at a distance from the heart; — in modes which the merely physical properties of arteries cannot possibly explain. The most instructive of these facts are the following: —

1. The great amount of the obstacles which oppose the free flow of the blood into and through the small capillaries of the system; and the force therefore found requisite in the dead body to imitate the flow of blood by injection, especially when injection is attempted in an animal just killed, when, as it would appear, the property of tonicity remains in the blood-vessels.

2. The small amount of force found sufficient to stop the flow of blood along the chief artery of a limb, when compared with those obstacles, which the blood, moving along that artery, must encounter in its passage through the smaller vessels.

3. The immediate diminution produced in the flow of blood through the arteries of a limb, by some attacks of palsy, in which the heart's action is unaffected.

4. The greatly increased determination of blood to various organs at particular times, without corresponding alteration of the heart's action; *e. g.* in many cases of partial inflammation or hæmorrhages, — in the case of blushing, and other effects of mental emotion, — in the case of occasional or periodic secretion or nutrition at individual parts, whether natural or morbid, often observed without increase of the heart's action, and contrasting strongly with other instances, where, from mental emotion, exercise, febrile disease, &c., the heart's action is strongly excited, while secretion and nutrition are every where diminished.

5. The alteration which is gradually produced on the arteries of any part of the body, when any cause is applied, which greatly and permanently augments the action going on at *their extremities only*; the influence of which cause is manifestly *retrograde* along the vessels; — *e. g.* the increased size given to the anastomosing branches of a limb, of which the principal artery has been tied, — when contrasted with the shrunk condition of all the arteries of the stump of a limb which has been amputated; — the increased size and tortuous course of the arteries of the uterus during gestation, and of the arteries of any part of the body, where the growth of a tumour has been excited; and again the deficient circulation in, and nourishment of, a limb of which the sensitive nerves are palsied, or which is long kept completely at rest (as by disease of a joint) without palsy.

These facts show, that the flow of blood in the arteries, and especially in the capillaries, of different parts, is in a great measure determined by causes acting at the extremities of the circulation, and bears no fixed relation to the state of the heart's action.

The question that next presents itself is, how far the additional power, which plainly affects the motion of the blood, at a distance from the heart, is referable to the vital contractions of the coats of arteries?

The influence exerted on the circulation by any such action of the *largest* arteries is certainly of no great amount; because the circulation has often been observed to be well maintained, when those arteries had become rigid and inflexible, and lost both their elasticity and vital power. But the vital properties of arteries probably reside chiefly in their *smaller branches*, as would appear from the following facts: —

1. From the coats of the smaller arteries bearing a much larger proportion, on the whole, to their fluid contents than those of the larger.

2. From the fibrous coat of the smaller arteries more nearly resembling muscular texture.

3. From experiments of Mr. Hunter, which show that the smaller arteries contract more at the moment of death than the larger.

4. From many experiments of Bichat, Buniva, Parry, &c., which show that an injection thrown into the arteries immediately after death, while tonicity remains in them, passes by the largest of the arteries that communicate with veins, but does not fill the smaller capillaries; and from the observation of Hunter, that an injection forced into the arteries of an animal just killed, which retain their tonic power, is apt, after a time, to be forced back into the larger.

5. From the observation of Haller and others, that in animals just killed, and of which the hearts have been cut out, the blood in the arteries, as well as the veins, is apt to move chiefly from the smaller to the larger branches.

It cannot, therefore, be doubted, that this vital power of the arteries must, to a certain degree, modify the motion of the blood; but it is more difficult to understand how *an increase* of

this tonic power can, in any case, promote the flow of the blood; and it has therefore been supposed, that it is by a *relaxation* of this kind of contraction, giving additional effect to the impetus from the heart, that local determinations and congestions of blood are effected.

To this opinion there are the following objections: —

1. The amount of the obstacles already noticed to the flow of blood in the arteries, renders it probable, that whatever vital powers affect the motion of the blood at a distance from the heart, must on the whole assist, instead of opposing, the effect of its contractions.

2. If local and occasional congestions of blood resulted simply from diminution of the vital action of the arteries, allowing a fuller effect to the impulses given from the heart, the blood in the capillary arteries of parts where congestion has taken place, might be expected to have always an intermitting motion; which is not the case.

3. The causes which usually excite local congestions of blood, are very generally causes, which, in all other instances, *excite*, instead of depressing or weakening, vital action.

These statements render it probable that vital contractions, chiefly of the smaller arteries, do come in aid of the actions of the heart in maintaining and regulating the circulation; but it must be added, that in the warm-blooded animals, we have no evidence of any powerful action of this kind being habitually exercised; and the following reasons may be given for thinking that causes distinct from any vital contractions of vessels, are concerned in producing the flow of blood in the extreme branches of the arteries; *i. e.* that there is a *third* power concerned in producing and regulating the movement of the blood, besides any mechanical action of the heart and arteries: —

1. The smallest arteries, or true capillaries, in which the greatest variety as to the quantity and velocity of the blood is observed, do not show any fibrous structure; and when the circulation in them is examined with the microscope, in ordinary circumstances, no contractions of their coats are perceptible.

2. Haller and others have described varying movements of globules of blood in living animals, such as do not appear to be explicable by mechanical laws, seen under the microscope, especially when these globules had escaped from the blood-vessels into surrounding textures.

3. Movements of other fluids contained within living textures, and even currents in fluids placed in contact with living textures, have been observed, which cannot be traced to the influence of any contractions of solids.

4. On minute examination of the progressive development of parts in the fœtal state of different animals, it appears that various parts are in progress of organisation (implying regulated movements in the fluids) before the heart acts, or the arteries are distinctly formed.

5. When the blood has been delivered into the capillary vessels of any living part, although still influenced by the contractions of the heart and arteries, it must be supposed to come likewise under the dominion of the laws, whatever these be, by which the movements of the nourishing fluid are effected, in those animals that have no circulating system, and in vegetables. In particular, it may fairly be presumed, that the *vital affinities*, which regulate the chemical changes that are wrought on the blood in the capillaries, must likewise be a cause of its movement there. To this we should probably refer the striking fact (to be afterwards more fully considered), that when the chemical changes at the lungs are arrested, by obstruction to the access of air thither, the contractions of the right ventricle and pulmonary artery, although continuing vigorous for a time, fail of their wonted effect; and the blood stagnates in the capillaries of the lungs and right side of the heart; but its motion is instantly resumed, if, within a short interval of time, the access of air to the blood be again permitted.

It must, however, be observed, that the experiments of Magendie and of Poiseuille, already noticed, as they prove that the flow of blood along veins is dependent on, and continually modified by, the flow along the arteries communicating with these veins, sufficiently demonstrate that the powers residing in the capillaries, although they may promote the movement, and determine the distribution, of the blood in them, are inadequate to the propulsion of masses of blood along the larger veins.

Since it has been ascertained that galvanism, transmitted through a fluid, is a cause, not only of its decomposition, but of its movement, through any porous substance, from the positive towards the negative side of the apparatus, it has been conjectured that the electrical relations of arterial and venous blood (the first of which is, in a slight degree, positively, and the last negatively, electrified), may be an important cause of the motion of the blood in the capillaries. But if this be a cause which promotes, as has been stated, the flow of blood in the capillaries throughout the body, where the arterial blood becomes venous, it ought to retard its motion in the capillaries of the lungs, where the venous blood becomes arterial. Yet we know, from the fact above stated, that the change of the blood from venous to arterial at the lungs, is a very powerful cause of its motion there.

The power or property, by which various fluids attract others with unequal force, through the intervention of any porous substance, lately described by Dutrochet and others under the names of endosmose and exosmose (in whatever way it is to be explained), must certainly operate as a cause of motion in the fluids in different parts of the animal system. But neither this, nor any other principle, which is found to apply equally to dead matter, can suffice for the explanation of the *variations*, especially of the sudden and partial variations observed in the motion of the blood in the capillaries in different parts, and in different circumstances of the body; for example, of those which result from mental acts or feelings. Whether the auxiliary powers, residing in the

small arteries, consist merely in contractions of solids, or partly (as is more probable) in *peculiar attractions* of solids and fluids, we cannot doubt that they are in a great measure truly *vital*.

No termination of arteries has ever been distinctly demonstrated, except that in veins. This is seen on microscopical examination, in the translucent parts of various living animals, and may be traced, after injection, in different textures of the human body. The capillary arteries, which are turned backwards and form veins, vary considerably in size, some admitting three or four globules of blood abreast, and others probably not admitting one. It appears, however, from the microscopical observations of Dr. M. Hall, that in most parts of animals there is a numerous set of minute vessels, of nearly equal calibre and anastomosing freely, in which most of the smaller arteries terminate abruptly, in which the motion of the blood is much slower than in the gradually tapering arteries, and from which nearly all the veins originate. These are strictly the capillary vessels.

The veins become gradually, though not uniformly, larger when traced towards the heart, and terminate ultimately in the venæ cavæ and coronary vein. Those which are of sufficient size to be examined, are found to consist only of two coats, corresponding to the outermost and innermost of the coats of arteries, but possessed of greater strength. Hence they are thinner and less elastic, but more distensible and tougher, than the arteries. Near the heart, and in various other parts of the larger veins, thin irregular layers of fibres, more or less resembling those of muscles, are interposed between their coats.

The veins in the extremities, and generally in muscular parts of the body, are provided with valves, constructed nearly in the same manner as those at the mouth of the aorta, with their free edges towards the heart.

There are two important singularities in the venous system; *first*, the sinuses within the cranium, formed by separation of the laminæ of the dura mater, into which the veins of the pia mater open obliquely in a direction opposite to the current of the blood, the effect of which is to lessen the effect on the vessels of the brain, of any stagnation and congestion of blood in the great veins near the heart; *secondly*, the distribution of vena portæ, (which is of great size and strength, and collects the blood from the stomach, intestines, pancreas, and spleen), through the substance of the liver, after the manner of an artery. In many of the lower animals, the venous blood from the lower extremities is, in like manner, diffused through the kidneys.

Besides being more distensible, the veins are considerably more numerous and more capacious than the arteries, and their larger branches anastomose much more freely. Hence the quantity of blood in the veins is always much greater, and is liable to greater variations, both locally and generally, than that in the arteries.

From the smaller capacity of the arteries, and from the pretty uniform distention, on the whole, of all parts of the vascular system, it follows, that the velocity of the blood in the veins must, on the whole, and in the same proportion, be less than that in the arteries. And from the sum of the smallest veins of the body having a much larger capacity than the venæ cavæ, it follows, that the velocity of the blood in these smallest veins must, on the whole, and in the same proportion, be less than that in the venæ cavæ. But the circumstances stated as to the structure of veins, admit of greater local and temporary variations of the velocity of the blood in them, without perceptible deviation from these generel laws, than can occur in the case of the arteries. Absolute stagnation, and even retrograde movement, for a time, of blood in individual veins, have often been observed in experiments on animals.

The ordinary motion of the blood in the veins is continuous, with these exceptions; *first*, that, in a state of great weakness, when the arteries are very little distended by the stroke of the heart, the blood in the smallest of the veins retains somewhat of the intermitting motion; *secondly*, that the flow of blood in the great veins, even independently of disease, is slightly retarded at each systole of the auricles, and accelerated on their diastole; *thirdly*, that the flow of blood in the great veins is somewhat retarded by each act of expiration, and accelerated by each inspiration; the natural effect of the enlargement of the shut cavity of the chest, in inspiration, being to draw towards it, (*i. e.* to cause the pressure of the atmosphere to urge towards it,) not only air by the trachea, but also blood by the great veins. This last is the respiratory pulse of Haller and others, which is distinctly seen to communicate a movement to the brain and spinal cord, when they are exposed.

The motion of the blood in the veins is manifestly determined by various causes: —

1. Probably the most efficacious is the impulse *a tergo* communicated by the heart and arteries, the effect of which is unequivocally shown by the experiments previously mentioned. But when we consider the great distensibility of the veins, and the very moderate degree of distension observed in them in the healthy state, we cannot doubt, that the motion of the blood along them must be much aided by causes acting in this part of the circulation itself.

2. The experiments of several physiologists, particularly Verschuir, Hastings, and Beclard, seem sufficiently to indicate a vital power of tonicity in the veins, similar to that which we ascribed to the arteries. But in several parts of the body, as in the interior of bones, and in the substance of the liver, where the coats of the veins form the internal lining of unyielding canals, it is obvious that this power cannot be exerted; and in any individual part, it is probably a feeble power.

3. Gravitation manifestly affects the flow of blood in the veins, especially of the extremities; but cannot materially, on the whole, promote the flow towards the heart.

4. The action of neighbouring muscles, and probably the pressure of other adjacent and especially elastic textures, such as the skin, aided

by the effect of the valves, frequently and greatly promote the flow of blood in many veins, chiefly of the extremities.

5. It appears that the "suction influence" of the diastole of the auricles of the heart, promotes the flow of blood along the veins somewhat more than their systole retards it. But the rapid distention of a vein below a ligature, where this cause cannot act, shows that the other causes of the motion in the veins are much more powerful.

6. It appears from the experiments of Dr. Barry, that the motion of the blood along the veins is promoted also, in animals of which the respiration is similar to the human, by the 'suction influence' of the acts of inspiration above mentioned. But, besides what was observed in the last paragraph, the facility with which circulation is carried on in the fœtus, which does not breathe; in animals, of which the pericardium has been opened, and the heart exposed to the air (so that no influence of this kind can affect the motion of the blood); and even in cases of artificial respiration, where no such influence can be exerted by the chest — sufficiently demonstrates that this cause likewise is of comparatively inconsiderable amount.

The effect of the more violent respiratory actions on the flow of blood in the veins, and particularly the retardation of the blood's motion, and congestion in the great veins, from forced or prolonged expiration, accompanied by muscular effort, are very important in pathology. Muscular exertion, especially of the respiratory muscles, has the additional effect of accelerating the flow of blood in the arteries, which will be considered afterwards.

The pulmonary artery and its branches are similar to the other arteries of the body, and the pulmonary veins to other internal veins. The termination of the smallest branches of the artery in the capillary veins of the lungs, has been ascertained as distinctly, and in the same manner, as in other textures; and the smallest branches of the bronchial arteries, which bring arterial blood from the aorta, have been found to inosculate with those of the pulmonary artery.

As the whole of the pulmonary circulation is carried on within the cavity of the chest, it cannot derive any aid, on the principle of suction, from the movements of the chest. But the motion of the lungs in inspiration and expiration promotes the flow of blood through their substance, for reasons which will appear afterwards.

The fibrous middle coat found in the pulmonary artery and its branches, as well as in the aorta, is probably chiefly useful by resisting the strong and variable impulse given by the heart's contractions, and thus preventing morbid dilatation of the arteries. And it is with the same intention, no doubt, that the great veins are strengthened by muscular fibres near their termination, where they are exposed to the retrograde impulse from the stroke of the auricles.

According to the most probable estimates, the whole quantity of blood in the body may be in general about one-fifth of the weight of the whole body; and of this, it is generally thought that about one-fourth may be in the arterial, and three-fourths in the venous system.

Circula'tor. (From *circulo*, to compass about.) An itinerant practitioner of medicine. A mountebank.

Circulato'rium. (From *circulo*, to move round.) A chemical digesting vessel, so contrived that the fluid within it is made to perform a circulatory motion.

Ci'rculus. (Diminutive of *circus*, a circle.) A circle or ring. 1. Applied in *Anatomy* to circular parts; as the *circulus osseus* of the temporal bone of the fœtus, or any part of the body which is of an annular shape, as *circulus oculi, iridis*, &c.

2. To an iron instrument used by the old chemists for dividing glass. See *Ruland, Lexicon Alchemiæ.*

3. To several circular instruments used by the older surgeons.

Circulus arteriosus i'ridis. The artery which runs round the iris, and forms a circle, is so termed. See *Oculus.*

Circulus ciliaris. See *Ciliary circle.*

Circulus osseus. *Annulus osseus.* A ring-like bone in the ear of the fœtus. It is placed at the bottom of the cartilaginous meatus externus, and supports the membrana tympani. In the adult it is united with the meatus.

Circulus qua'druplex. A kind of bandage used by the old surgeons.

Circumcalua'lis. A name that has been given to the tunica conjunctiva of the eye. See *Oculus.*

CIRCUMCI'SION. (*Circumcisio, onis.* f.; from *circumcido*, to cut about.) The removal of the prepuce from the glans penis. This is a religious rite among the Jews and Mahommedans. It is also practised by surgeons in some cases of phymosis.

Circumductionis opifex. An epithet applied by Vesalius to the superior oblique muscle of the eye.

Circumflexa anterior. *Articularis anterior.* The name of a branch of the humeral artery dispersed upon the muscles covering the anterior part of the shoulder joint.

Circumflexa externa. An artery usually arising from the *profunda femoris*, but sometimes from the common femoral. It is distributed to the muscles of the hip and thigh.

Circumflexa ili'aca. *Circumflexa ossis ilii. Iliaca anterior.* An artery which rises nearly opposite the epigastric, from the external iliac artery immediately before it passes under Poupart's ligament. It runs along the crest of the ilium between the transversalis and internal oblique muscles to the loins. It gives blood to the abdominal psoas iliac and sartorial muscles and inosculates with the epigastric inferior intercostal and lumbar arteries.

Circumflexa interna. An artery of the thigh, given off from the profunda or femoral opposite the external circumflex. It turns round the inner part of the neck of the thigh bone, and supplies the hip joint and muscles surrounding it.

Circumflexa posterior. *Articularis posterior.* A branch of the humeral artery, larg

than the circumflexa anterior, passing to the back of the shoulder joint, and dispersed chiefly on the deltoid muscle.

CIRCUMFLE'XUS. *Circumflex.* An epithet given by anatomists to objects which wind round others. Thus there is an anterior and posterior circumflex artery around the shoulder joint, a circumflex muscle of the palate, &c.

CIRCUMFLEXUS PALATI. A muscle of the palate. *Tensor palati*, of Innes. *Circumflexus palati mollis*, of Albinus. *Spheno-salpingo-staphilinus, seu staphilinus externus*, of Winslow. *Musculus tubæ novæ*, of Valsalva. *Palato-salpingeus*, of Douglas. *Pterigo-staphilinus*, of Cowper. It arises from the spinous process of the sphenoid bone, behind the foramen ovale, and from the Eustachian tube, not far from its osseous part; it then runs down along the pterygoideus internus, passes over the hook of the internal plate of the pterygoid process by a round tendon, which soon spreads into a broad membrane. It is inserted into the velum pendulum palati, and the semilunar edge of the os palati, and extends as far as the suture which joins the two bones. Generally some of its posterior fibres join with the constrictor pharyngis superior, and palato-pharyngæus. Its use is to stretch the velum, to draw it downwards, and to the side towards the hook. It has little effect upon the tube, being chiefly connected to its osseous part.

CIRCUMFORA'NEUS. Wandering. A Latin adjective, applied to an itinerant quack or mountebank. It has been made into a substantive.

CIRCUMLI'TIO. (From *circumlino*, to anoint around.) A liniment; especially one applied to the eyelids.

CIRCUMOSSA'LIS MEMBRANA. The periosteum.

CIRCUMSCI'SUS. (From *circumscindo*, to cut round about.) Circumcised. Applied to a membraneous capsule, separating into two parts by a complete circular fissure.

CIRRO'SUS. Cirrose: having a cirrus or tendril. Applied to a leaf tipped with a tendril; as in *Gloriosa* and *Hagellaria*.

CIR'RUS. (*us*, *i.* m.; from κερας, a horn, because it is twisted like a horn.) *Cirrhus. Clavicula.* A clasper or tendril. One of the *fulcra* or props of plants. A long, cylindrical, slender, spiral body, issuing from various parts of plants.

From its origin, a cirrus is distinguished into,

1. *Foliar*, when a continuation of the midrib of a simple leaf; as in *Fumaria claviculata*, *Mimosa scandens*, and *Gloriosa superba*.

2. *Petiolar*, when terminating the common petiole of a compound leaf; as in *Pisum sativum*. This is sometimes distinguished by the number of leaflets which grow under it: hence *cirri diphylli — tetraphylli*, and *polyphylli*.

3. *Peduncular*, when it proceeds from the peduncle; as in *Vitis vinifera*.

4. *Axillary*, when it arises from the stem or branches in the axillæ of the leaves; as in *Passiflora incarnata*.

5. *Subaxillary*, when it originates below the leaf.

6. *Lateral*, when at the side of it; as in *Bryonia*.

From the division of its apex, a *cirrus* is,

1. *Simple*, consisting of one undivided piece; as in *Momordica balsaminea*, *Passiflora quadrangularis*, and *Bryonia dioica*.

2. *Compound*, consisting of a stalk, variously branched or divided.

3. *Bifid*, when it has two divisions; as in *Vitis vinifera*, *Lathyrus palustris*, *Ervum tetraspermum*, &c.

4. *Trifid*, when there are three; as in *Bignonia unguis*, and *Lathyrus hirsutus*.

5. *Multifid*, or *branched*, when the divisions are more numerous; as in *Lathyrus latifolius*, and *Cobea scandens*.

From its *convolution* into,

1. *Convolute*, when all the gyrations are regular in the same direction; as in *Hedera quinquefolia*.

2. *Revolute*, winding itself irregularly, sometimes on one side, sometimes on the other; as in *Passiflora incarnata*.

CI'RSIUM. (From κιρσος, a varix, which this herb was supposed to cure.) The herb sawwort. See *Serratula*.

CIRSOCE'LE. (*e*, *es.* f. Κιρσοκηλη; from κιρσος, *varix*, or a dilatation of a vein, and κηλη, a tumour.) A varicose enlargement of the spermatic veins: it is most frequently confined to that part of the spermatic cord which is below the opening in the abdominal tendon; and the vessels generally become rather larger as they approach the testes. It bears some resemblance to a number of earthworms coiled up. It occasions pain from the distension of the vessels, and is attended also with pain, or a sense of weight in the loins. Cirsocele may be mistaken for an omental hernia, but they are easily distinguished in the following manner: place the patient in an horizontal posture, and empty the swelling by pressure upon the scrotum; then put the fingers firmly upon the upper part of the abdominal ring, and desire the patient to rise: if it be a hernia, the tumour cannot re-appear, as long as the pressure is continued at the ring; but if a cirsocele, the swelling returns with increased size, on account of the return of blood into the abdomen being prevented by the pressure. This affection can seldom be entirely cured. When the vessels are more than usually tumid, leeches should be applied, and followed by saturnine lotions to the cord and testicle. The bowels should be kept free; the testicle supported by a bag-truss, and the patient confined to the horizontal posture.

CIRSOI'DES. (From κιρσος, a varix, and ειδος, likeness.) Resembling a varix: an epithet applied by Rufus Ephesius to the upper part of the brain, and also to the spermatic veins.

CIRSO'MPHALOS. (From κιρσος, a varix, and ομφαλος, the navel.) A varicose state of the veins, or an aneurismal varix around the navel.

CIRSOPHTHA'LMIA. (*a*, *æ.* f.; from κιρσος, *varix*, and οφθαλμος, the eye.) A varicose state of the vessels of the eye.

CIRCOS. Κιρσος. The Greek for a *varix*.

CI'SSA. *Citta.* Κισσα. Κιττα. The Greek word for a magpie, and also for the disease called *pica*. See *Pica*.

CISSA'MPELOS. (*Cissampelos*, *i.* f.;

from κισσος, ivy, and αμπελος, the vine.) 1. The Greek name of a species of convolvulus.

2. The name of a genus of plants in the Linnæan system. Class, *Diœcia*; Order, *Monodelphia*. Wild vine. Velvet leaf.

Cissampelos caapeba. This species is held by the Brazilians to be a specific against the bite of serpents. The root was formerly esteemed as a linthontriptic.

Cissampelos pareira. The systematic name of the *Pareira brava*; called also, *Pareyra*, *Abuta*, *Ambutua*, *Butua*, and *Overo butua*. The root of this plant — *Cissampelos, foliis peltatis cordatis emarginatis*, of Linnæus — a native of South America and the West Indies; has no remarkable smell, but a sweet bitter, and somewhat austere taste. It has been extolled in nephritic and calculous complaints; but is not used in this country. The dose is from ℈j. to ℈ij. of the powder; or an infusion may be made with ℥iij. of the root to ℔j. of water, the third part of this being taken at once.

Cissarus. See *Cistus creticus.*

Cissinum. Κισσινον. The name of a plaster prescribed by Paulus Ægineta for wounds of the tendons. Its name is derived from κισσος, ivy; but ivy is not mentioned as an ingredient in it.

CISTERNA. (*a*, *æ*. f.; a cistern.) The fourth ventricle of the brain has been so called.

Cisterna chyli. *Cisterna lumbaris.* The receptaculum chyli.

Cisterna lumbaris. See *Cisterna chyli.*

Cisthorus. See *Cistus creticus.*

Cistic. See *Cystic.*

CISTUS. (*us*, *i*. m. Κιστος.) The name of a genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Monogynia*. The Cistus.

Cistus creticus. The systematic name of the plant from which the ladanum of the shops is obtained. It has also been named *Cisthorus*, *Cissarus*, and *Dorycinium*.

Cistus — arborescens extipulatus, foliis spatulato-ovatis petiolatis enerviis scabris, calycinis lanceolatis, of Linnæus. This plant is a native of Syria, and the islands of the Archipelago. The gum resin, called ladanum, exudes upon the leaves of this plant. It is collected by lightly rubbing the leaves with leather, and afterwards scraping it off, and forming it into irregular masses for exportation. Three sorts of ladanum have been described by authors, but only two are to be met with in the shops. The best, which is very rare, is in dark-coloured masses, of the consistence of a soft plaster, and growing still softer on being handled; the other is in long rolls, coiled up, much harder than the preceding, and not so dark. The first has commonly a small, and the last a large admixture of fine sand; the dust blown on the plant by winds, from the loose sands among which it grows, being retained by the tenacious juice. The soft kind has an agreeable smell, and a lightly pungent bitterish taste: the hard is much weaker. Ladanum was formerly much employed internally as a pectoral and astringent in catarrhal affections, dysenteries, and several other diseases; at present, however, it is never used, except as an ingredient in the stomachic plaster, *emplastrum ladani.*

Cistus ladaniferus. This species grows in Spain, Portugal, and Provence. Its young branches afford, by boiling in water, a substance analogous to the ladanum of Crete.

Cistus laurifolius. This grows in the South of France, and also affords a kind of ladanum.

Cistus ledon. See *Ledum palustre.*

Citharus. (From κιθαρα, a harp.) The breast is sometimes so named from its shape. — *Turton.*

Citrago. (From *citrus*, a citron; so called from its citron-like smell.) Baum. See *Melissa.*

CITRATE. (*Citras*, *atis*. f.; from *citrus*, the lemon.) A salt formed by the union of the citric acid, or acid of lemons, with the salifiable bases.

Citrate of potash. This salt is used medicinally, in the form of the common effervescing saline draught. A scruple of carbonate of potash, dissolved in a little water, is neutralised with the juice of one common-sized lemon, or with fifteen grains of crystallised citric acid. It is extremely useful in allaying irritability of the stomach and vomiting; and is an excellent light diaphoretic. Its action on the skin is rendered much more certain by the addition of a few drops of antimonial wine.

Citrate of soda. A scruple of carbonate of soda, neutralised by a sufficient quantity of lemon-juice or ten grains of citric acid, forms an effervescing draught, which has nearly the same effects as that made with citrate of potash.

Citrea. See *Citrus medica.*

Citreum. (From *citrus*.) The citron-tree. See *Citrus medica.*

CITRIC. (*Citricus*, from *citrus*, the lemon.) Of or belonging to the lemon.

Citric acid. *Acidum citricum.* On account of the mucilaginous matter with which lemon-juice is mixed, it is very soon altered by spontaneous decomposition. Various methods have been contrived to prevent this effect from taking place, in order that this wholesome and agreeable acid might be preserved for use in long voyages, or for domestic purposes. The juice may be kept in bottles under a thin stratum of oil, which indeed prevents, or greatly retards, its total decomposition; though the original fresh taste soon gives place to one which is much less grateful. In the East Indies, it is evaporated to the consistence of a thick extract. If this operation be carefully performed by a very gentle heat, it is found to be very effectual. When the juice is thus heated the mucilage thickens, and separates in the form of flocks, part of which subside, and part rise to the surface: these must be taken out. The vapours which arise are not acid. If the evaporation be not carried so far as to deprive the liquid of its fluidity, it may be long preserved in well-closed bottles; in which, after some weeks' standing, a farther portion of mucilage is separated, without any perceptible change in the acid.

Of all the methods of preserving lemon-juice, that of concentrating it by frost appears to be the best, though in the warmer climates it cannot conveniently be practised. Lemon-juice,

exposed to the air in a temperature between 50° and 60°, deposits in a few hours a white semi-transparent mucilaginous matter, which leaves the fluid, after decantation and filtration, much less alterable than before. This mucilage is not of a gummy nature, but resembles the gluten of wheat in its properties: it is not soluble in water when dried. More mucilage is separated from lemon-juice by standing in closed vessels. If this depurated lemon-juice be exposed to a degree of cold of about seven or eight degrees below the freezing point, the aqueous part will freeze, and the ice may be taken away as it forms; and if the process be continued until the ice begins to exhibit signs of acidity, the remaining acid will be found to be reduced to about one eighth of its original quantity, at the same time that its acidity will be eight times as intense, as is proved by its requiring eight times the quantity of alkali to saturate an equal portion of it. This concentrated acid may be kept for use, or, if preferred, it may be made into a dry lemonade, by adding six times its weight of fine loaf sugar, in powder.

The above processes may be used when the acid of lemons is wanted for domestic purposes, because they leave it in possession of the oils, or other principles, on which its flavour peculiarly depends; but in chemical researches, and where the acid itself is required to be had in the utmost purity, a more elaborate process must be used. Boiling lemon-juice is to be saturated with powdered chalk, the weight of which is to be noted, and the powder must be stirred up from the bottom, or the vessel shaken from time to time. The neutral saline compound is scarcely soluble in water; it therefore falls to the bottom, while the mucilage remains suspended in the watery fluid, which must be decanted off; the remaining precipitate must then be washed with warm water, until it comes off clear. To the powder, thus edulcorated, a quantity of sulphuric acid, equal to the chalk in weight, and diluted with ten parts of water, must be added, and the mixture boiled a few minutes. The sulphuric acid combines with the earth, and forms sulphate of lime, which remains behind when the cold liquor is filtered, while the disengaged acid of lemons remains dissolved in the fluid. This last must be evaporated to the consistence of a thin syrup, which yields the pure citric acid in little needle-like crystals. It is necessary that the sulphuric acid should be rather in excess, because the presence of a small quantity of lime will prevent the crystallisation. This excess is allowed for above.

Its taste is extremely sharp, so as to appear caustic. It is, of the vegetable acids, the one which most powerfully resists decomposition by fire. In a dry and warm air it effloresces; but it absorbs moisture when the air is damp, and at length loses its crystalline form. A hundred parts of this acid are soluble in seventy-five of water, at 60°. Though it is less alterable than most other solutions of vegetable acids, it will undergo decomposition when long kept.

Crystallised citric acid contains, according to Berzelius, 21 *per cent.* of water. This may be expelled by heat. The anhydrous acid, as analysed by the same chemist, consists of oxygen 54·831, carbon 41·369, hydrogen 3·800. The crystallised acid deposited from its saturated solution, consists of

	Dumas.	Brout.	Ure.
Carbon	36·28	34·28	33·00
Hydrogen	4·45	4·76	4·63
Oxygen	59·27	60·96	62·37
	100·00	100·00	100·00

The crystals, obtained by spontaneous evaporation at common temperatures, differ from the above in containing more water.

The saline compounds are called *citrates*. Those used medicinally are,

1. *C. of potash.* See *Citrate of potash.*
2. *C. of soda.* See *Citrate of soda.*
3. *C. of Ammonia.* See *Citrate of Ammonia* in the Supplement.
4. *C. of morphia.* See *Morphia.*

All the citrates are decomposed by the powerful acids, which do not form a precipitate with them, as with the oxalates and tartrates. The oxalic and tartaric acids decompose them, and form crystallised or insoluble precipitates in their solutions. All afford traces of acetic acid, or a product of the same nature, on being exposed to distillation: this character exists particularly in the metallic citrates. Placed on burning coals, they melt, swell up, emit an empyreumatic smell of acetic acid, and leave a light coal. All of them, if dissolved in water, and left to stand for a time, undergo decomposition, deposit a flocculent mucus, which grows black, and leaves their bases combined with carbonic acid; one of the products of the decomposition. Before they are completely decomposed, they appear to pass to the state of acetates.

The citric acid is found in many fruits united with the malic acid.

Citric acid being more costly than tartaric, may be occasionally adulterated with it. This fraud is discovered by adding slowly to the acid, dissolved in water, a solution of subcarbonate of potash, which will give a white pulverulent precipitate of tartar, if the citrate be contaminated with the tartaric acid. When one part of citric acid is dissolved in 19 of water, the solution may be used as a substitute for lemon-juice. If before solution the crystals be triturated with a little sugar and a few drops of the oil of lemons, the resemblance to the native juice will be complete. It is an antidote against sea-scurvy; but the admixture of mucilage and other vegetable matter in the recent fruit of the lemon, has been supposed to render it preferable to the pure acid of the chemist.

Citrina'tio. An alchemical term, signifying *complete digestion*, or, according to Ruland, *resuscitation.*

Citri'nula. (*a*, *æ*. f.; a diminutive of *citrus.*) A small citron or lemon.

Citri'nulus. *Citrinolus. Citrinus.* A kind of crystal, which Paracelsus called saxifragus; and believed to be lithontriptic.

Ci'trinus. Citrine. Lemon-coloured.

Citrinum unguentum. See *Unguentum citrinum.*

Citron. See *Citrus medica.*

Citrul, Sicilian. See *Cucurbita citrullus.*

Citrul'lus. (*us, i.* f.) See *Cucurbita citrullus.*

CI'TRUS. (*us, i.* f. Κιτρος.) 1. The name of a genus of plants in the Linnæan system. Class, *Polyadelphia;* Order, *Icosandria.*

2. The name of the lemon. See *Citrus medica.*

CITRUS AURANTIUM. The systematic name of the orange-tree and fruit; called also, *Aurantium, Aurantium Hispalense, Aurantium Chinense, Malus aurantia major, Malus aurantia, Aurantium vulgare, Malus aurantia vulgaris, Mala aurea, Chrysomelia, Nerantia, Martianum pomum,* and *Poma aurantia.* The China and Seville orange are both only varieties of the same species: *Citrus — petiolis alatis foliis acuminatis,* of Linnæus. The latter is specified in our pharmacopœias; and the *flowers, leaves, yellow rind,* and *juice,* are made use of for different medical purposes.

The flowers, *flores naphæ,* are highly odoriferous, and are used as a perfume; they are bitter to the taste; they give their taste and smell both to water and to spirit, but most perfectly to rectified spirit of wine. The water which is distilled from these flowers is called *aqua florum naphæ.* In distillation, they yield a small quantity of essential oil, which is called *oleum* vel *essentia neroli:* they are brought from Italy and France. Orange flowers were once thought to possess considerable antispasmodic powers; and the water distilled from them is still prescribed on the continent. See *Aqua florum aurantii.*

The *leaves* have a bitterish taste; and yield, by distillation, an essential oil: when rubbed between the fingers, they give out a fragrant odour. They have been applied for the same purposes as the flowers, but without success.

The *yellow rind* of the fruit, freed from the white pithy part, has a grateful aromatic flavour, and a warm, bitterish taste. Infused in boiling water, it gives out nearly all its smell and taste: cold water extracts the bitter, but very little of the flavour. In distillation, a light, fragrant, essential oil rises, without the bitter. Its qualities are those of an aromatic and bitter. It has been employed to restore the tone of the stomach, and is a very common addition to combinations of bitters, used in dyspepsia. It has been given in intermittents, in doses of a drachm, twice or thrice a day, and has also been much celebrated as a remedy in menorrhagia, and immoderate uterine evacuations.

The *juice* of Seville oranges is a grateful acid, which, by allaying heat, quenching thirst, promoting various excretions, and diminishing the action of the sanguiferous system, proves extremely useful in both ardent and putrid fevers: though the China orange-juice, as impregnated with a larger proportion of sugar, becomes more agreeable, and may be taken in larger quantities. The Seville orange-juice is particularly serviceable as an antiscorbutic, and alone will prevent or cure scurvy in the most apparently desperate circumstances. In dyspepsia, from putrid bile in the stomach, both lemon and orange-juice are highly useful.

CITRUS MEDICA. The systematic name of the lemon-tree; called also, *Limon, Limonia mala, Malus medica, Malus limonia acida, Citrea malus,* and *Citrus.* The tree which affords the lemon is the *Citrus — petiolis lineariibus,* of Linnæus; a native of the upper part of Asia, but cultivated in Spain, Portugal, and France. The juice, which is much more acid than that of the orange, possesses similar virtues. It is always preferred where a strong vegetable acid is required. As an antiscorbutic, lemon-juice has been often taken on board ships destined for long voyages; but even when well depurated of its mucilaginous parts, it is found to spoil by long keeping. To preserve it in purity for a considerable length of time, it is necessary that it should be brought to a highly concentrated state; and, for this purpose, it has been recommended to expose the juice to a degree of cold sufficient to congeal the aqueous and mucilaginous parts. After a crust of ice is formed, the juice is poured into another vessel: and, by repeating this process several times, the remaining juice, it is said, has been concentrated to eight times its original strength, and kept, without suffering any material change, for several years. See *Citric acid.*

Whytt found the juice of lemon to allay hysterical palpitations of the heart, after various other medicines had been experienced ineffectual; and this juice, or that of oranges, taken to the quantity of four or six ounces in a day, has sometimes been found a remedy in the jaundice. The exterior rind of the lemon is a very grateful aromatic bitter, not so hot as orange-peel, and yielding in distillation a less quantity of oil, which is extremely light, almost colourless, and generally brought from the southern parts of Europe, under the name of Essence of Lemons. The lemon-peel, though less warm, is similar in its qualities to that of the orange, and is employed with the same intentions. The pharmacopœias direct a syrup of the juice *syrupus limonis,* and the peel enters into some vinous and aqueous bitter infusions; it is also ordered to be candied; and the essential oil is an ingredient in some formulæ.

The citron-tree is also considered as belonging to the same species, — the *Citrus medica* of Linnæus. Its fruit is called *Cedromela,* which is larger and less succulent than the lemon; but in all other respects the citron and lemon-trees agree. The citron-juice, when sweetened with sugar, is called by the Italians *Agro di cedro.*

The *Citrus mella rosa* of Lamarck, is another variety of the *Citrus medica* of Linnæus. It was produced, at first, casually, by an Italian's grafting a citron on a stock of a bergamot pear-tree; whence the fruit produced by this union participated both of the citron-tree and the pear-tree. The essence prepared from this fruit is called essence of bergamotte, and *Essentia de cedra.*

Ci'tta. See *Cissa.*

CITTARA. A place in the Isle of Ischia, where there are thermal waters, of 100° Fahr. They contain carbonate and sulphate of lime, and muriate of soda.

Civet-cat. See *Viverra.*

CIVE'TTA. (*a*, *æ*. f.; from *sebet*, Arabic.) *Zibethum*. Civet; an unctuous odoriferous drug, derived from more than one species of viverra. See *Viverra*.

Cladonia islandica. See *Cetraria islandica*, in the Supplement.

CLAP. (So called from the old French word *clapises*, which were public shops, kept and inhabited by single prostitutes; and generally confined to a particular quarter of the town.) See *Urethritis*.

CLA'RET. *Claretum*. A light French wine, drunk in this country chiefly in summer. Claret is an excellent drink in typhoid fevers.

CLARE'TUM. (*um*, *i*. n.; from *clareo*, to be clear.) 1. The wine called *claret*. See *Claret*.

2. A name formerly given to several factitious wines.

CLARETUM LAXATIVUM. *Vinum Hippocraticum*. Wine impregnated with senna, mechoacanna, turbith, and aromatics. It was given to purge melancholy and pituitous humours.

CLARETUM PURGATORIUM. *Vinum Hippocraticum antimoniale*. A vinous solution of glass of antimony with cinnamon-water and sugar. It was emetic and purgative.

CLARIFICA'TION. (*Clarificatio*, *onis*. f.; from *clarus*, clear, pure, and *facio*, to make.) The depuration of any thing, or process of freeing a fluid from heterogeneous matter, or fecuencies.

Clary. See *Salvia*.

Clasper. See *Cirrus*.

CLASSY. A place near Laon, in Picardy, where there are chalybeate waters.

CLAUDI'ACON. Κλαυδιακον. The epithet of a collyrium described by Paulus Ægineta.

CLAUDICATION. Lameness.

CLAU'STRUM. (*um*, *i*. n.; a barrier, from *claudo*, to shut.) Formerly applied in anatomy, as *claustrum gutturis*, the opening of the pharynx; *claustrum virginitatis*, the hymen.

CLAUSU'RA. (*a*, *æ*. f.; from *claudo*, to shut.) An imperforation of any canal or cavity of the body. Thus *clausura uteri* is a preternatural imperforation of the uterus; *clausura tubarum Fallopiarum*, a morbid imperforation of the Fallopian tubes, mentioned by Ruysch as one cause of infecundity.

Clava rugosa. See *Acorus calamus*.

CLAVA'RIA. (*a*, *æ*. f.; from *clava*, a club.) The name of a genus of plants. Class, *Cryptogamia*; Order, *Fungi*. Club-shaped fungus.

CLAVARIA CINEREA. Grey goat's beard. This and the *clavaria coralloides* are sometimes eaten. Their flesh is cottony; and they have little flavour.

CLAVARIA COROLLOI'DES. The systematic name of the *Fungus corolloides* of old writers; called also *crotelus*. It is sometimes eaten. See *Clavaria cinerea*. It was once used as a corroborant and astringent.

CLAVA'TIO. (From *clavus*, a nail.) A sort of articulation without motion, where one bone is driven into another like a nail. It is synonymous with *Gomphosis*, which see.

CLAVA'TUS. Clubbed; club-shaped; applied to parts of plants; as the stigma of the *Genipi*.

CLAVELLA'TI CINERES. The wood ashes from which potash is prepared have been so called, because the wood, previously to burning, is cut into slips, *clavæ*.

Clavicle. See *Clavicula*.

CLAVI'CULA. (*a*, *æ*. f.; from *clavis*, a key, on account of some resemblance to the keys used by the ancients.) I. In *Anatomy*, the clavicle, or collar-bone. The clavicle is placed at the root of the neck, and at the upper part of the breast. It extends across, from the tip of the shoulder to the upper part of the sternum; it is a round bone, a little flattened towards the end, which joins the scapula; it is curved like an Italic *f*, having one curve turned out towards the breast: it is useful as an arch, supporting the shoulders, preventing them from falling forwards upon the breast, and making the hands strong antagonists to each other; which, without this steadying, they could not have been.

The thoracic end, that next the sternum, or what may be called the inner head of the clavicle, is round and flat, or button-like; and it is received into a suitable hollow on the upper piece of the sternum. It is not only like other joints surrounded by a capsule or purse; it is further provided with a small moveable cartilage, which, like a friction-wheel in machinery, saves the parts and facilitates the motions, and moves continually as the clavicle moves.

The outward end of the clavicle is flattened, as it approaches the scapula, and the edge of that flatness is turned to the edge of the flattened acromion, so that they touch but in one single point. This outer end of the clavicle, and the corresponding point of the acromion, are flattened and covered with a layer of cartilage; but the motion here is very slight, and quite insensible: they are tied firmly by strong ligaments; and we may consider this as almost a fixed point, for there is little motion of the scapula upon the clavicle: but there is much motion of the clavicle upon the breast, for the clavicle serves as a shaft, or axis, firmly tied to the scapula, upon which the scapula moves and turns, being connected with the trunk only by this single point, viz. the articulation of the clavicle with the breast-bone.

II. A tendril. See *Cirrus*.

CLAVI'CULUS. The clavicle.

CLA'VIS. (*is*, *is*. f.; a key. The clavicle.

CLA'VUS. (*us*, *i*. m.; a nail.) 1. A corn, so called from its resemblance to the head of a nail. It is a roundish, horny, cutaneous extuberance, with a central nucleus, sensible at its base; found chiefly on the toes, from the pressure of tight shoes.

2. An intense pain in some part of the head, limited to a very small space, and causing a sensation as if a nail were being driven into the head. It is most frequently connected with hysteria; and is then called *clavus hystericus*.

3. A tubercle on the white of the eye; so called from its shape. — *Celsus*.

4. Condylomata of the uterus have been called *clavi*.

CLAVUS HYSTERICUS. See *Clavus*.

Clavus oculi. This name has been given by some to staphyloma.

Clavus secali'nus. A name of the *Secale cornutum*.

Clay. See *Alumina*.

CLEAVAGE. This term is applied to the mechanical division of crystals; by showing the direction in which their *laminæ* can separate, it enables us to determine the mutual inclination of these *laminæ*. The cleavage affords an important character of many minerals. In the interior of some minerals, the direction of the cleavage may be frequently seen, without using any mechanical violence.

Cleavers. See *Galium aparine*.

Clei'dion. Κλειδιον. Clidion. The name of an astringent pastil described by Galen and Paulus; also the name of an astringent epithem described by Aëtius.

Cleidomastoide'us. (From κλεις, the clavicle, and μαστοειδης, the mastoid process.) Albinus gives this name to the posterior part of the *sternocleido-mastoideus*, which he makes a separate muscle.

CLEI'SAGRA. (α, æ. f.; from κλεις, the clavicle, and αγρα, a prey.) A name given by Ambroise Paré to gout affecting the articulation of the clavicle.

Clei'thron. (Κλειθρον; from κλειω, to shut.) See *Claustrum*.

CLE'MATIS. (*tis, idis.* f.; from κλημα, a tendril: so named from its climbing up trees, or any thing it can fasten upon with its tendrils.) The name of a genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Polygynia*.

Clematis daphnoi'des. The name given by Bauhin to the herb perwinkle. — *Vinca minor* of Linnæus.

Clematis passiflo'ra. The passion-flower. See *Passiflora*.

Clematis recta. The name of the upright virgin's bower: called also, *Flammula Jovis*. *Clematis — foliis pinnatis, foliolis ovato lanceolatis integerrimis, caule erecto, floribus pentapetalis tetrapetalisque*, of Linnæus. The same virtues are attributed to this plant as to the *clematis vitalba*.

Clematis vitalba. The systematic name of the traveller's joy: called also, *Vitalba, Atragene, Viorna*. The *Clematis arthragene* of Theophrastus. This plant is common in our hedges, and is the *Clematis — foliis pinnatis, foliolis cordatis scandentibus*, of Linnæus. Its leaves, when fresh, produce a warmth on the tongue, and if the chewing is continued, blisters arise. They also vesicate and ulcerate the skin when rubbed in it. The plant has been administered internally to cure lues venerea, scrofula, and rheumatism. An infusion of two or three drachms of the leaves in a pound of boiling water, may be taken in the course of the four and twenty hours. In France, the young sprouts are eaten, when boiled, as hoptops are in this country.

Clemati'tis. The same as clematis.

Cleo'nis collyrium. The name of a collyrium, of which Celsus describes several forms.

Clepsy'dra, or Cle'psydra. (From κλεπτω, to conceal, and ὑδωρ, water.) The name of an instrument used by the ancients to measure time by the dropping of water through a hole, from one vessel to another; also a chemical vessel, perforated in the same manner; and an instrument mentioned by Paracelsus, contrived to convey fumigations to the uterus in hysterical cases.

Clermont ferrand. A town in the department of Puy de Dôme. It has acidulous springs.

Cle'ves. A city of Westphalia. It has mineral waters, containing carbonate and sulphate of iron.

Cli'banus. A portable furnace, made of iron, copper, or earthen-ware.

CLIMACTERIC. (*Climactericus*, from κλιμαξ, a gradation.) A term applied to certain years in the life of man, which have been supposed to mark a certain degree in the scale of his existence; and to a particular disease observed in persons advanced in life. See *Climacteric disease*.

Climacteric disease. The ordinary duration of life seems to have undergone little or no change from the Mosaic age, in which, as in the present day, it varied from threescore and ten to fourscore years. In passing through this term, however, we meet with particular epochs at which the body is peculiarly affected, and suffers a considerable alteration. These epochs the Greek physiologists contemplated as five; and, from the word climax, which signifies a gradation, they denominated them climacterics. They begin with the seventh year, which forms the first climacteric; and are afterwards regulated by a multiplication of the figures three, seven, and nine, into each other; as, the twenty-first year being the result of three times seven; the forty-ninth, produced by seven times seven; the sixty-third, or nine times seven; and the eighty-first, or nine times nine. A more perfect scale might, perhaps, have been laid down; but there is some truth in the general principle, and as we do not possess sufficient knowledge to improve on its application, it is not worth while to attempt it. The two last were called grand climacterics, or climacterics emphatically so denominated, as being those in which the life of man was supposed to have consummated itself, and beyond which there is no prospect but that of dissolution.

The change which frequently strikes our attention as taking place about the fourth, or in the interval between the fourth and fifth, is of two distinct and opposite kinds; and it is necessary to notice each.

We sometimes find the system, at the period before us, exhibiting unexpectedly a very extraordinary renovation of powers. Persons who have been deaf for twenty years, suddenly recover their hearing, so as in some cases to hear very acutely: others as suddenly recover their sight, and throw away their spectacles, which had been in habitual employment for as long a period; others return to the process of dentition, and reproduce a smaller or larger number of teeth to supply vacuities progressively produced in earlier life; and examples are given of entire sets of teeth cut at this period. That the hair should evince a similar regeneration, of which instances are also adduced, is

perhaps, less surprising; since this has been known to grow again, and even to change its colour after death.

On the other hand, instead of a renovation of powers at the period before us, we sometimes perceive as sudden and extraordinary a decline. We behold a man apparently in good health, without any perceptible cause, abruptly sinking into a general decay. His strength, his spirits, his appetite, his sleep fail equally; his flesh falls away; and his constitution appears to be breaking up. In many instances this is, perhaps, the real fact; and no human wisdom or vigilance can save him from the tomb. But in many instances, also, it is an actual disease, in which medical aid and kindly attention may be of essential service; and upon an application of which we behold the powers of life, as in other diseases, rally; the general strength return; the flesh grow fuller and firmer, the complexion brighten; the muscles become once more broad and elastic; and the whole occasionally succeeded by some of those extraordinary renovations of lost powers, or even lost organs.

The subject is obscure; and it is as difficult, perhaps, to account for either of these extremes — for the sudden and unexpected decline, as for the sudden and singular restoration. That the decline, however, is a real malady, and not a natural or constitutional decay, is perfectly obvious from the recovery. And hence, in reference to the period in which it occurs, and by which, no doubt, it is influenced, it is emphatically denominated the *Climacteric disease*.

The patient falls away in flesh and strength before he complains of any loss of appetite, or has any dyspeptic symptoms; which only appear to take place afterwards by sympathy. And that the mesentery and lacteals are not paralysed and obliterated, as in the atrophy of old age, is incontrovertible from the renovation of power and reproduction of bulk that form an occasional termination of the disease.

In watching carefully the symptoms of this malady, when totally unconnected with any concomitant source of irritation, either mental or bodily, we shall often perceive that it creeps on so gradually and insensibly, that the patient himself is hardly aware of its commencement. "He perceives," to adopt the language of Sir Henry Halford, "that he is tired sooner than usual, and that he is thinner than he was; but yet he has nothing material to complain of. In process of time his appetite becomes seriously impaired; his nights are sleepless, or, if he get sleep, he is not refreshed by it. His face becomes visibly extenuated, or perhaps acquires a bloated look. His tongue is white, and he suspects that he has fever. If he ask advice, his pulse is found quicker than it should be, and he acknowledges that he has felt pains in his head and chest, and that his legs are disposed to swell; yet there is no deficiency in the quantity of his urine, nor any other sensible failure in the action of the abdominal viscera, except that the bowels are more sluggish than they used to be."

Sometimes he feels pains shooting over different parts of the body, conceived to be rheumatic, but without the proper character of rheumatism: and sometimes the headache is accompanied with vertigo. Towards the close of the disease, when it terminates fatally, the stomach seems to lose all its powers; the frame becomes more and more emaciated; the cellular membrane in the lower limbs is laden with fluid; there is an insurmountable restlessness by day, and a total want of sleep at night; the mind grows torpid and indifferent to what formerly interested it; and the patient sinks at last; seeming rather to cease to live than to die of a mortal distemper.

In the progress of this disease, medicine will generally be found to accomplish but little. The constitutional debility must be met by tonics, cordials, and a generous diet; and a scrupulous attention should be paid to such contingencies of body or mind as may form an exciting cause, or aggravate the morbid diathesis if already in a state of activity. Congestions must be removed where they exist, and every organ have room for the little play that the rigidity of advanced life allows to it: and where aperients are necessary, they should consist principally of the warm and bitter roots or resins, as rhubarb, guaiacum, and aloes. In many instances the Bath water, and in a few that of Cheltenham, will be also found of collateral use; and especially where there is reason to hope that a beneficial impression has been made on the disease, and that the system is about to recover it.

Climacteric years. See *Annus climactericus*, and *Climacteric disease*.

CLIMATE. (From κλιμα, a region.) The prevailing constitution of the atmosphere of any region with respect to heat, cold, moisture, winds, and impregnation with extraneous matters, is called the *climate* of that region. The climate of any place depends on some causes, the operation of which is sufficiently manifest; as latitude elevation above the level of the sea, insular or continental position, presence or absence of mountains, forests, rivers, lakes, marshes, &c.: there are other causes which may have their influence on climate, although we are less able to estimate the degree or nature of that influence; such are electricity, subterranean fire, peculiar states of the earth's surface which may be supposed to obtain in volcanic regions, and various astronomical causes. Under the influence of these causes, remarkable changes of climate are continually taking place. There is little doubt that the climates of European countries were more severe in ancient times than they are at present. Cæsar says, that the vine could not be cultivated in Gaul, on account of its winter-cold. The rein-deer, now found only in the frozen zone, was then an inhabitant of the Pyrenees. The Tiber was frequently frozen over, and the ground about Rome covered with snow for several weeks together, which hardly ever happens in our times. The Rhine and the Danube, in the reign of Augustus, were generally frozen over for several months of winter. The barbarians who overran the Roman empire, a few centuries afterwards, transported

their armies and waggons across the ice of these rivers. The improvement that is continually taking place in the climate of America, proves that the power of man extends to phænomena, which, from the magnitude and variety of their causes, seemed entirely beyond his controul. At Guiana, in South America, within five degrees of the line, the inhabitants living amid immense forests, a century ago, were obliged to alleviate the severity of the cold by evening fires. Even the duration of the rainy season has been shortened by the clearing of the country, and the warmth is so increased, that a fire now would be deemed an annoyance. It thunders continually in the woods, rarely in the cultivated parts.

Drainage of the ground, and removal of forests, however, cannot be reckoned among the sources of the increased warmth of the Italian winters; and in this, as in many other instances, we must acknowledge our incompetency to explain the causes by which even the most considerable changes of climate are brought about.

The subject of climate is one of the highest interest to the naturalist, the physiologist, and the physician. Climate exerts a very sensible influence on the animal and vegetable kingdoms in different parts of the globe: it is one of the causes which determine the physical and moral peculiarities of different races of mankind; and it has a marked influence in modifying the characters of disease, the operation of remedies, and the whole practice of medicine. The following sketch of the principal climates in the world, and their respective adaptation to the preservation or restoration of health, is taken from the excellent work of Dr. James Clark; to which we refer the reader for fuller information: —

English climates. — The great desideratum in this country is to find a mild climate and sheltered residence for our pulmonary and other delicate invalids during the winter and spring.

Our warmest winter residences in England are mostly found on the southern and south-western shores; indeed it is their vicinity to the sea which in a great degree renders them warmer than the inland parts in their respective vicinities.

The mild region of England admits of a natural division into four districts or groups, each having some peculiar features in its climate which characterise it and distinguish it from the others, both as regards its physical and medical qualities. These are —

1. The south coast, comprehending the tract of coast between Hastings and Portland Island, including the Isle of Wight.

The superiority of the climate of this district exists chiefly during the months of December, January, and February. In March the temperature of this coast, and that of the interior, is nearly the same. In April and May, the temperature of the interior rises above that of the coast and continues higher, though in a less ratio, through the summer months. In October the mean temperatures are again equal, and in November that of the coast begins to exceed the interior. The only places on the south coast which we consider deserving of particular notice, are, Undercliff in the Isle of Wight, and Hastings and Brighton, on the coast of Sussex.

Undercliff is decidedly the most sheltered and warmest of these places, and it has moreover this convenience over most of our other winter residences, that it also affords a good summer climate.

Hastings follows Undercliff in point of shelter and warmth during the winter and spring months. Its situation at the base of a range of steep hills, which protect it in a considerable degree from the north and north-east winds, render it a milder and more sheltered residence during this season than the other parts of the coast of Sussex.

Brighton differs materially in the character of its climate from both these places. It is more exposed to northerly winds, but the atmosphere is drier and more bracing. While inferior to Undercliff and Hastings as a residence in diseases of the respiratory organs accompanied with much irritation, it offers advantages over both to invalids of a relaxed and nervous habit who are not very excitable. Autumn is the season during which the climate of this place possesses the greatest advantages; and even to the end of December it is one of the mildest climates in our island, and most favourable for a large class of invalids; more especially for cases in which a relaxed state of the system is a leading feature.

Invalids who select the coast of Sussex as their winter residence, might find it advantageous to pass the autumn at Brighton and the winter at Hastings.

2. South-west coast. — The winter climate of the south coast of Devon has long been noted for its mildness. The temperature of its more sheltered spots during the months of November, December, and January (when the difference is greatest), is, in the average, about five degrees higher than that of London during the same period; whereas, on the south coast, the difference scarcely exceeds two degrees. This superiority of temperature over London at both places, occurs chiefly during the night; though the days are proportionally warmer, and the temperature more steady on the south-west than on the south coast.

Various places on the coast of Devonshire are held in repute on account of the beneficial effects of their climate, more especially in pulmonary diseases. The principal of these are *Torquay*, *Dawlish*, *Sidmouth*, and *Exmouth*. Salcombe, the Montpellier of Huxham, is unquestionably one of the warmest spots in our island during the winter. At Torquay the invalid has the advantage of a considerable tract of sheltered country, some part or other of which will afford a protected ride or walk, in whatever direction the wind blows. Torquay is superior in this respect to every place in our island. Its position also on the southern declivity of a range of pretty steep hills, composed chiefly of calcareous rocks, renders it comparatively dry. Hence, while Torquay possesses all the advantages of the climate of this coast,

its chief disadvantage (humidity) is felt in a less degree than elsewhere.

3. Land's-End. — The only place in this district deserving particular notice is *Penzance*, which has long been frequented by invalids on account of the mildness of its winters. Penzance has a very peculiar climate, which depends on its almost peninsular situation at the south-western extremity of the island. A remarkable equality in the distribution of the temperature throughout the year, and throughout the day and night, is a striking character of this place. In this respect, indeed, the climate of Penzance is superior to that of the south of Europe; and the only climate which we have examined that excels it is that of Madeira. This peculiarity of the climate of Penzance will be shown at once by comparing it with that of London, where the difference between the warmest and coldest months is 26°, while at Penzance it is only 18°.

In other respects the climate of the Land's-End does not stand so high in a medical point of view. It is very humid; the quantity of rain which falls annually at Penzance being nearly double that which falls in London, and the number of rainy days much greater. This district is also proverbial for the frequency and violence of its gales; and Penzance, owing to its total want of shelter from the northerly and easterly winds, is colder during the spring than either Torquay or Undercliff. Hence it is, that although Penzance possesses a decided superiority over all the other situations in our island, in the mildness and equability of its winter climate, its humidity, exposed situation, and liability to winds, render it inferior to several other places as a residence for invalids.

Flushing, a small village in the vicinity of Falmouth, is the only other place in this district deserving notice. The position of Flushing differs from that of Penzance only in being somewhat protected from the north and east winds by a low range of hills which rises immediately behind it.

Before quitting the south-west coast and Land's-End, it is proper to remark, that, though varying somewhat in degree at different places, the predominant character of the climate is that of softness and humidity; on the system generally, it has a soothing but relaxing influence.

From this character of the climate of the whole south-western coast of our island, it will be at once understood that it is most suitable for the irritable and inflammatory habit, and least so for the relaxed nervous constitution; that in the dry, irritated conditions of the mucous membranes, with a parched state of the skin, it will prove beneficial; while in the morbid states of the same membranes, accompanied with copious secretion, or when there exists a disposition to profuse discharges of any kind, it will prove injurious. Even many of those cases which are benefited by a temporary sojourn, would be injured by a permanent residence in this district. The climate, indeed, possesses qualities of so marked a kind, that when it ceases to do good, it generally begins to do harm; hence it will seldom be prudent, much less advantageous, for the invalid who has passed the winter and spring on this coast, to prolong his residence through the summer; he will in general do well to betake himself to a drier and more bracing air, especially if he intends to return the succeeding winter.

4. West of England. — *Clifton*, the only place in the western district which we deem it necessary to notice, has several local advantages, and possesses the best climate in the part of the country where it is situated. Compared with that of the south-west coast, it is more exciting, more bracing, and drier, but not so mild. It is therefore less suited for pulmonary and other diseases, accompanied with much irritation, and with a tendency to inflammation. On the other hand, it is better adapted to invalids of a relaxed, languid habit; and it is also very beneficial in many cases of dyspepsia, in affections of the mucous membranes with much secretion, and in the scrofulous affections of young persons.

Before commencing our review of foreign climates, the islands of *Guernsey* and *Jersey* require some notice, as they are occasionally resorted to by invalids from this country. The climate of these islands resembles in its general characters that of the coast of Devonshire; it is somewhat warmer, but not more steady; and is more exposed to high winds. Those from the south-west prevail during the autumn and winter, while those from the north-east often continue for weeks together during the spring, producing the same unpleasant effects on invalids which arise from them in this country. The climate is found by experience to be beneficial in the same diseases, and in constitutions of a similar character, as that of our south-west coast; the observations therefore formerly made relative to the class of invalids that may expect to derive advantage from the latter, apply equally to persons who may be sent to Jersey, which, of the two islands, is in all respects the best suited for invalids. The summer climate of these islands is delightful.

Foreign Climates. — The climate of the *South of France* has long been held in repute, but all the southern provinces of that country are far from possessing the same climate; those situated on the eastern frontier being very different in this respect from those on the western. It is highly important, as we shall presently show, to attend to this distinction in recommending the south of France as a place of residence for invalids.

South-west of France. — We comprehend under this division the tract of country which extends from Bourdeaux and Bayonne to Toulouse.

The transition from the climate of the south-western shores of our own island to that of the south-west of France is easy and natural, inasmuch as they exhibit a striking similarity in their general characters. Taking the south-west of France generally, the mean annual temperature is only about 4° higher than that of the south-west of England. Both climates are soft and rather humid, and agree and disagree, generally speaking, with diseases of the same character.

Pau is the only place in this district of France which we deem it necessary to notice particularly. This little town, which has been a good deal frequented of late years by invalids from this country, is pleasantly situated at the base of the Pyrenees; and when its close vicinity to that range of lofty mountains is considered, it certainly possesses a far milder winter and spring climate, and is much less subject to high winds and extensive transitions of temperature, than might be expected. One remarkable circumstance in the character of its climate is the mildness of the spring, and its comparative exemption from sharp cold winds during that season. In this respect it bears a very favourable comparison with the climates of the south of Italy. While Pau is 6° colder than Rome during the winter, it is only 2½° colder in the spring. Compared with the warmest parts of England, the same superiority of its spring climate holds good. Penzance during the winter months is 3° *higher* than Pau, but 5° *lower* in the spring. This mild character of the spring constitutes the great advantage of the climate. Pau is also very free from fogs, and possesses a dry soil. Its chief fault is the unsteadiness of its temperature. It may however be considered, upon the whole, the most favourable residence for invalids in the south-west of France, as far as we have had the means of judging. The difference between the climate of Pau and that of the best situations in England is not great. It is drier and warmer in the spring; and the northerly winds are much less trying to invalids than in this country. One advantage possessed by it, is its vicinity to the delightful watering-places among the higher Pyrenees, which offer to the invalid who has passed the winter at Pau a healthy summer climate, without the inconvenience of a long journey.

South-east of France. — Under this division we include that extensive tract of country which stretches along the shores of the Mediterranean, from Montepllier to the banks of the Var, the boundary stream between France and Piedmont. The climate of this district is warmer and drier, but more irritating and exciting than that of the south-west. It is also subject to sudden vicissitudes of temperature, and to frequent harsh, cold winds. This great liability to cold piercing winds, more especially the north-west *(mistral)*, which often continues to blow with considerable force for many days together, renders the whole of this country an improper residence for patients suffering under, or peculiarly disposed to inflammation or irritation of the respiratory organs. We consider the custom, therefore, which has long prevailed, of sending consumptive patients to the south of France, a grievous error; an error which the obvious character of the climate, and the result of ample experience of its effects, should have long since corrected. There may be constitutions, having a tendency to tuberculous disease, which might even derive some benefit from a temporary residence in this climate; but when tubercles already exist in the lungs, it will certainly prove injurious.

After this account of the climate and its effects on phthisical patients (the cases which have been chiefly sent thither), it will be unnecessary to say much of the different places in this district which have been most frequented by invalids. We shall, however, notice the principal of these briefly.

Montpellier. — This place has now so completely lost the character which it once possessed as a mild climate, that it may suffice to remark here, that a more improper residence could scarcely be selected for a person disposed to pulmonary disease. Its high, exposed situation, renders it liable to all the evils of this climate in a remarkable degree; and it is, moreover, well ascertained that pulmonary inflammation and phthisis are among the most prevailing diseases of the place.

Marseilles. — Although less exposed than Montpellier, this is an equally improper residence for consumptive invalids. From the manner in which the environs of Marseilles are divided into small properties, surrounded with high walls, the invalid has no means of taking proper exercise, or of breathing country air; and without these, consumptive invalids can derive little advantage from any climate. For cases likely to benefit by a dry sharp air, Marseilles forms a good winter residence. It is said to prove particularly favourable to persons who have suffered from intermittent fever.

Hyères possesses the mildest climate in the whole of this district, and this advantage it owes chiefly to its sheltered situation at the base of a range of hills which protect it, in a considerable degree, from northerly winds. The country also around this little town differs in its character from that of Provence generally, (which comprehends the larger portion of the district now under consideration.) The hills here present the appearance of verdure, being covered with shrubs, many of them evergreens, affording a pleasing contrast to the bare and rugged mountain masses which form so striking a feature, and compose so large a portion of Provence. The extensive orange gardens which flourish under the immediate shelter of Hyères, and the verdure of its hills, afford evident proofs of the amenity of its climate; while, by experience, it is known to be one of the most favourable residences for invalids in this part of France, — certainly the best with which we are acquainted.

Nice. — This place has long been celebrated for the mildness of its climate; and continues to form the favourite resort of a numerous class of invalids, both from this and other northern countries. Although situated in the same line of coast as Provence, Nice is superior to it in several respects. In the general qualities of its climate it certainly resembles that of the south-east of France; but it has some important local advantages over the best parts of that country. By its steep and lofty range of mountains it is protected from the northerly winds, and especially from the mistral, which we have stated to be so prevalent, and which experience proves to be so injurious to delicate invalids, in Provence. This circumstance

gives a comparative degree of softness to the climate; but it is still rather exciting. Nice is not exempt from cold winds, especially during the spring; indeed, the prevalence of these constitutes one of the principal objections to the climate of this place in pulmonary diseases generally. For consumption, even in its earlier stages, we consider Nice an unfavourable situation, in a very large proportion of cases. In bronchial diseases of the dry irritable character, it is also prejudicial; and in dyspepsia, depending on an irritated or inflammatory condition of the mucous membrane of the stomach, it is equally so. So decidedly, indeed, is this the case, that when such a state of the digestive organs exists, the invalid will derive little benefit from a residence at Nice, whatever may be his disease. Though warm and dry, the climate is ill suited to irritable habits. With languid, torpid constitutions, on the other hand, it agrees well. In the scrofulous affections of young persons possessing this character of constitution, it produces the best effects; as it does in chronic bronchial disease, accompanied with copious expectoration, and in what has been termed humoral asthma. In chronic rheumatism it is found very beneficial; and in deranged health from various causes, in which a dry, warm, and rather exciting climate is indicated, advantage will be derived from a winter spent at Nice; provided always that the state of the digestive organs which we have adverted to does not exist. In consequence of the tendency of the climate to aggravate and even excite gastric irritation, a more abstemious diet is requisite for invalids than in England. The summer at Nice is too hot for any class of invalids.

Italy. — The climate of the south of Italy differs little in actual temperature from that of Provence and Nice, but it is softer, more humid, and less exciting. On the other hand the sirocco, which is scarcely felt at the latter places, forms an objection to the Italian climate, though this objection is not of much weight during the winter.

The only places which we consider deserving of notice as winter climates in Italy, are *Pisa*, *Rome*, and *Naples*.

The climates of Pisa and Rome resemble each other in their general qualities. Rome is somewhat warmer in the winter. It is also drier than Pisa, though more humid than Nice and the parching climate of Provence. About one-third more rain falls at Rome than in the latter country; and the number of rainy days is considerably greater. Taking into account all the qualities of the climate of Rome, we consider it one of the best of Italy: to the invalid capable of taking exercise in the open air, it affords advantages over both Naples and Pisa. Patients, on the other hand, who can bear little exposure to the air, and who must therefore confine themselves to the most sheltered situations, will find in the Lung'Arno in Pisa a residence possessing advantages, perhaps, over every other place in Italy.

Naples differs somewhat in the character of its climate from both the last named places. Independently of the effect which its immediate vicinity to the sea may have in modifying the climate, it is more subject to winds; and the air is more exciting than that of Pisa or Rome. As a residence for invalids labouring under pulmonary irritation, or chronic rheumatism, it is inferior to both; nor are we aware of any cases in which it ought to be considered a more favourable climate. The beauty of the scenery around Naples, however, and the gaiety and excitement of the place and climate altogether, prove very attractive to strangers generally; and render it a very agreeable winter residence for persons who visit Italy rather as a recreation than for the removal of actual disease.

The diseases in which the climate of Italy proves most beneficial, are chronic bronchitis and rheumatism. We have, in particular, observed many decided examples of the beneficial effects of a residence at Rome in both these diseases. But it is still more in the numerous cases of deranged health which scarcely admit of being defined, though well known to the medical practitioner, that a tour and winter spent in Italy will prove beneficial. Such persons need not be limited to any particular situation, but may, with proper caution, visit the different places frequented by strangers in the south of Italy, and that even with greater advantage to their health than if they had remained stationary at any one of them.

These observations have reference to the climate of Italy during the winter and spring, that is, from October till May or June. To such as are under the necessity of remaining in that country through the summer, the baths of Lucca, Sienna, and the vicinity of Naples, afford the coolest residences.

There may be several situations on the shores of the Mediterranean which have climates equal, and perhaps superior, to those which have been mentioned. Malaga has been particularly mentioned to us as possessing a very mild winter climate; but our information respecting the south of Spain is too imperfect to enable us to speak positively on this subject: and the want of proper accommodations forms an insuperable objection to it as a residence for invalids.

The Mediterranean islands do not merit much notice. Some parts of the coast of Sicily afford a pretty good winter climate; but here again the difficulty of obtaining the necessary comforts, and even conveniences of life, renders them almost useless to English invalids.

This objection, however, cannot be made to *Malta*, the only island in the Mediterranean belonging to this country. All the wants of the invalid may be supplied here, and the packets which are established between this place and England afford the means of reaching it conveniently. But, unfortunately, the climate of Malta has little to recommend it to any class of invalids, and least of all to such as suffer from pulmonary affections. The arid nature of the soil, the quantity of impalpable dust which is suspended in the atmosphere

whenever the weather is dry, the currents of cold air to which the capital (the residence of invalids) is subject during the winter, and the frequent and heavy rains which prevail during the same season, render it an unsuitable residence for patients of this class. It may not be irrelevant to mention also that phthisis carries off a large proportion of the inhabitants of Malta, constituting nearly one-tenth of the whole mortality, according to Dr. Hennen. Indeed, the full and satisfactory information respecting the medical topography of Malta, supplied by this gentleman, affords more than sufficient grounds for excluding it from the list of climates which promise any advantage to phthisical patients. We are not, indeed, aware of any class of invalids likely to derive much advantage from the winter climate of Malta, and we are not acquainted with any to whom its summer climate would not prove injurious.

Atlantic climate. — The climate of the Northern Atlantic in the temperate latitudes is more steady than that of the Mediterranean, and imparts a similar character to the climate of its islands. Various groups of islands scattered over this ocean, between the 28th and 38th degrees of latitude, having been praised for the excellence of their climate, and occasionally frequented by invalids in consequence, deserve some notice in this place. The Azores, the Madeiras, and the Canary Islands in the Eastern, and the Bermudas and the Bahamas in the Western Atlantic, have all been recommended as suitable residences for persons requiring a mild and equable climate, and more especially for consumptive invalids.

Madeira. — The minute and careful observations of the late Dr. Heineken and of Dr. Renton, for a series of years, have afforded us sufficient data to form an accurate estimate of the climate of this island; and although our materials for enabling us to judge of the other Atlantic islands are much less complete, they leave little doubt in our minds that Madeira is superior to any of them; while it affords conveniences in other respects as a residence for invalids possessed by none of them. The height of the central ridge of mountains which compose the greater part of this island, although it may detract somewhat from its warmth during the winter, contributes greatly to temper the heat of its summer. It gives Madeira the advantage of a cool land-breeze during the night, which, alternating with a refreshing sea-breeze in the day, moderates the summer heat in a very material degree; while the trade-winds which prevail at this season in the latitude of Madeira, contribute also to its coolness and salubrity. The invalid, moreover, by choosing for his summer residence an elevated situation in the interior, finds a climate considerably cooler than that of Funchal, which is situated on the sea-shore and affords the best winter residence.

Comparing Madeira with the south-east of France and Italy, we find that, although its mean annual temperature is only about six degrees higher than that of these places, this temperature is very differently distributed throughout the year, the range being far less at Madeira than in the most favoured spots in the south of Europe. Thus, while the winter is twelve degrees warmer than in Italy and France, the summer is five degrees *cooler*; and while the mean annual range at Madeira is only fourteen degrees, it is nearly double this at Pisa, Rome, Naples, and Nice. In the equable distribution of heat throughout the year, it possesses a similar superiority over the same places; for example, while the mean difference of temperature of successive months at Madeira is only two degrees, at Rome and Nice it is four, and at Pisa and Naples five degrees.

In the progression of temperature during the day, it maintains the same superiority; the mean range for twenty-four hours being ten degrees by the *register* thermometer, while at Nice it is nine degrees, at Rome ten degrees, and at Naples thirteen degrees, by the *common* thermometer. In steadiness of temperature from day to day (a very important quality in a climate), Madeira excels all those places greatly. There is also a considerable difference in respect to the dryness of the two climates. Nearly the same quantity of rain falls at Madeira as at Rome; but there are only seventy-three days on which any rain falls, while at Rome there are one hundred and seventeen days. The rain at Madeira also falls at more regular seasons, chiefly in the autumn, the atmosphere being generally dry and clear for the remainder of the year.

The annual range of atmospheric pressure is very small, which is the case also at Rome and Naples.

From this comparison, the superiority of the climate of Madeira over that of the south of Europe will be at once seen.

Canary Islands. — These rank next to Madeira in point of climate. They are somewhat warmer; the mean annual temperature of Funchal, the capital of Madeira, being 65°, while that of Santa Cruz, the capital of Teneriffe, is nearly 71°. This excess of temperature, however, is not equally distributed over the whole year, the difference between the winter temperatures at these two places being considerably less than between their summer temperatures; while Santa Cruz is 7° warmer than Funchal in summer, it is only 5° warmer in winter. The temperature is also more equable throughout the year at Madeira than at Teneriffe; the difference between the mean temperature of summer and winter being 9° at the former place, while it is 12° at the latter. The want of sufficient materials prevents us from comparing the climate of Teneriffe more minutely with that of Madeira. It seems probable, however, that when we are better acquainted with the climate and topography of Teneriffe, we may find it a favourable winter residence. But whatever may be the merits of its climate, it is at present very deficient in the other requisites necessary to render it a suitable abode for delicate invalids.

The Azores, or Western Islands, as they are sometimes called, lie about 5° north of Madeira, and considerably more to the west-

ward. In their external characters these islands resemble Madeira and the Canaries. We have not had the means of making ourselves sufficiently acquainted with the temperature of the Azores to speak very positively on the subject. The climate appears to be mild and somewhat humid; less warm than Madeira during the winter, and more oppressive during the summer. They certainly possess no advantages in point of climate over Madeira, while they afford few of the conveniences which that island offers to invalids.

Bermudas. — This numerous cluster of small islands is in the same latitude as Madeira, and differs little from it in the mildness of its winter climate. From the stormy character of the Western Atlantic, however, these islands are much more liable to high winds in the winter than Madeira, while their low character and arid rocky soil render them extremely hot during the summer, and quite improper at this season for the residence of such invalids as are likely to be sent from this country.

Bahamas. — This is another and much more extensive group of low islands, further south than any of those which have been mentioned, being only just beyond the limit of the tropics. The climate of the Bahamas has not much to recommend it. The winter and spring are considerably cooler than the same seasons in the West Indies, while the temperature of the summer and autumn is nearly the same as in those islands. During the winter the temperature is subject to rapid and considerable vicissitudes; and cold, harsh, northerly winds are not unfrequent. The close vicinity of the Bahamas to the North American continent no doubt has the effect of rendering the climate less equable than it otherwise would be, judging from what we know of insular climates generally in the same latitudes.

West Indies. — The mean annual temperature of the West India Islands, near the level of the sea, is about 80°, and during the six months which include the winter season the temperature is only 2° lower. Now it will be readily admitted that few invalids are likely to be benefited by so high a temperature, more particularly when continued, almost without sensible variation, night and day. The extreme annual range in the West Indies does not exceed 20°, while the mean daily range throughout the year is only 6°. But it is not so much the actual degree of temperature of a tropical climate, as its unceasing and unvarying character, which oppresses and exhausts the invalid, more especially in cases where there exists a disposition to symptomatic fever.

From this brief account of the climate of the West Indies, it is evidently an improper one, generally speaking, for consumptive invalids, who, nevertheless, are frequently sent thither. The uniformly high temperature, and almost cloudless skies, which afford no shelter from the direct rays of a tropical sun, preclude invalids from taking exercise in the open air, the principal object for which they are generally sent abroad. There is no twilight to compensate for the heat and glare of the day, and the nights are too hot to admit of refreshing repose. When we add to the foregoing evils of climate the many privations, discomforts, and annoyances, which are almost inseparable from a temporary residence in these islands, and the still more weighty objection derived from the experience of medical men who have resided there, we may consider the question of the propriety of sending patients labouring under consumption to the West Indies as finally set at rest. The concurrent testimony of all the medical men whom we have consulted on the subject, and whose opportunities of judging were ample, establishes the fact, that consumptive cases, sent thither from this country, proceed much more rapidly to a fatal termination than in temperate climates.

Calculous disorders are extremely rare in the West Indies, a circumstance which probably depends, in a great degree, on the abundance of the cutaneous secretion, by which the largest proportion of fluid is discharged from the system, and along with it some of those saline principles which constitute the chief ingredients of which urinary calculi are composed. A well known case has been recorded of an officer who was about to undergo the operation of lithotomy in this country: he was suddenly ordered to Jamaica, and after some time no calculus could be discovered in the bladder, nor were there any symptoms of the existence of one. Aneurisms and diseases of the heart and large vessels are also rare, and the osseous deposits, which are so generally found in the coats of the larger arteries in persons who die at an advanced age in cold climates, are said to be rarely met with in those who die at a similar age in the West Indies. Gout is not common, and rheumatism neither frequent nor severe.

Scrofula is a very rare disease in the West India islands; and there are many cases of scrofula in this country which we have little doubt would be greatly benefited, if not cured, by a temporary residence in that climate. The cases in which we should expect the greatest benefit are those in which the disease exists chiefly in the lymphatic glands in torpid constitutions.

The diseases on which Dr. Clark comments, as chiefly benefited by a change of climate, are,

1. *Pulmonary Consumption.* — Concerning this Dr. Clark observes, with great justice, that, if change of climate is to be productive of any real benefit, it must be tried at a much earlier period of the disease than it generally is, and before the actual development of tubercles in the lungs. The climates best adapted to consumptive patients are those of Madeira, Rome, Pisa, Torquay, and Undercliff. It is chiefly in winter, however, that a residence in these places is useful. Italy, during the summer, is decidedly injurious to the phthisical invalid; and those who have passed the winter in the milder climates of England, should in general seek a more bracing air in summer; and during the course of this season they may advantageously change the air frequently, taking care not to visit any place the climate of which is hostile to their particular state of health.

2. *Chronic bronchitis.* — The morbid conditions

of the mucous lining of the larynx, trachea, and bronchi are greatly influenced by climate; and the change from a cold and moist to a mild and dry air seldom fails to relieve, and occasionally removes them. The situations which have been mentioned as most favourable in phthisis are best suited also to bronchial diseases generally. Of the continental climates, those of Rome and Pisa are the most beneficial in cases attended with an irritable state of the affected parts, without much secretion; and that of Nice in cases attended with less sensibility, a more copious expectoration, and a relaxed state of the system generally. Madeira, as far as our experience goes, has proved more beneficial in the former class of cases than in the latter. In England, Torquay and Undercliff afford the best climates in the first class of cases, and Clifton in the latter, in which Brighton also is a very favourable residence during the autumn.

3. *Asthma* is often greatly relieved, and occasionally ceases, under the influence of a mild climate, more especially when complicated with disease of the bronchial membrane, as it almost always is when of some duration. In what has been termed humoral asthma, Nice is the best residence; but Rome is preferable when this disease is accompanied with an irritated state of the digestive organs, a complication which is exceedingly common.

4. *Chronic rheumatism.*—Climate produces the most decidedly beneficial effects in this disease, and that often with surprising rapidity, even in cases of long standing, which have resisted the best directed medical treatment. We would particularise Rome and Nice as the best residences for invalids suffering from this complaint. The preference to be accorded to the one or the other place will depend upon the character of the patient's constitution, and the state of his digestive organs. When there exists an irritable state of these, we have already remarked that the climate of Nice will generally disagree, whatever may be the more prominent disease.

5. *Gout* is remarkably alleviated by a warm climate. In the selection of a residence for the gouty invalid, we must be guided by the particular state of his constitution, and the effects of the different climates which have been already pointed out. Genoa is rather remarkable for the rare occurrence of the disease among its inhabitants. But a warmer climate than any part of Italy would in many cases, we have no doubt, prove still more effectual in removing gout. We have already remarked the effects of the West Indian climate in this disease.

6. *Scrofula.* — Strumous affections, especially when seated in the skin and lymphatic glands, are frequently cured, and the general health is greatly improved, by a mild climate. In such cases Nice and Rome have appeared to us the most favourable residences; but in giving a preference to either, in this and all other complaints in which a residence in these places is useful, the practitioner must always keep in view the characteristic peculiarities of these climates formerly pointed out. There are cases of this disease in which the climate of the West Indies, as already remarked, would prove more effectual than any European climate; those, namely, of an indolent character, with little disposition to febrile excitement.

7. *Dyspepsia.* — Different forms of dyspepsia, hypochondriasis, and other nervous affections, intimately connected with a disordered state of the digestive organs, all of which are aggravated by a cold and humid atmosphere, are much mitigated by a winter's residence in the south of Europe, if aided by proper regimen. Attention to the diet is particularly necessary in changing from a cold to a warm climate, and in no class of cases is this more requisite than in those of which we are now treating. (See Dyspepsia.)

Besides the above mentioned, there are several other morbid states of the system which are remarkably benefited by change of climate. Such are irritable states of the mucous membranes generally, and irritable cutaneous affections. At those periods of life, also, which are attended with rapid development or critical changes in the constitution, the influence of change of climate is very beneficial. In weakly childhood, and puberty, and in climacteric decay, a new climate, if well adapted to the individual, has frequently succeeded in improving, and permanently establishing, the health.

CLI'MAX. (κλιμαξ, a gradation.) A name of some medicines, which, in regular proportion, increased or diminished the ingredients of which they were composed; e. g. R. *Chamædryos* ℥iij. *Centaurii* ℥ij. *Hyperici* ʒj.

Climbing. See *Scandens.*

Climbing bithwort. See *Aristolochia.*

CLINAN'THUS. (*us, i.* m.; from κλινη, a bed, and ανθος, a flower.) *Clinanthium.* The enlarged and flattened top of a common peduncle which supports several sessile flowers, as in *scabiosa* and *dorstenia.*

2. Mirbel gives this name to the part which supports the perichetium, vaginula, and pedicel of mosses.

CLI'NICAL. (*Clinicus;* from κλινη, a bed.) Relating to a bed: thus clinical lectures, lectures delivered at the bedside of the patient,—clinical notes, notes taken at the bedside, &c.

CLI'NOID. (*Clinoides*; from κλινη, a bed, and ειδος, resemblance.) Resembling a bed. The four processes surrounding the sella turcica of the sphenoid bone are so called, of which two are anterior and two posterior.

Clinomastoide'us. A corruption of cleidomastoideus. See *Sterno-cleido-mastoideus.*

CLINOPO'DIUM. (*um. i.* n.; from κλινη, a bed, and πους, a foot, because its leaves are said to resemble the feet of a bed.)

Clinopo'dium vulgare. Wild basil. This plant, which is indigenous in this country, was formerly in esteem against the bite of serpents, and to facilitate labour; it was also given in strangury, and as an astringent in diarrhœa. It is now disused.

Cliseo'meter. (*Cliscometrum, i.* n.; from κλισις, inclination, and μετρον, a measure.) An instrument invented by Stein, and described by Osiander, for measuring the degree of inclination of the female pelvis, or, in other words,

the angle which the axis of the pelvis makes with that of the body.

Cli'ssus. See *Clyssus.*

Clito'ridis musculus. See *Erector clitoridis.*

CLITORIS. (*is, idis.* f. κλειτορις; from κλειω, to inclose, or hide: because it is hidden by the labia pudendorum.) *Columella.* A small glandiform body, like a penis in miniature, and, like it, covered with a prepuce, or foreskin. It is situated above the nymphæ, and before the opening of the urinary passage of women. Anatomy has discovered, that the clitoris is composed, like the penis, of a cavernous substance, and of a glans, which has no perforation, but is, like that of the penis, exquisitely sensible. The clitoris is the principal seat of sexual pleasure: during coition it is distended with blood, and after the venereal orgasm it becomes flaccid and falls. Instances have occurred, where the clitoris was so enlarged as to enable the female to have venereal commerce with other women; and, in Paris, this fact was made a public exhibition of to the faculty. Women thus formed, appear to partake, in their general form, less of the female character, and have been called hermaphrodites. The clitoris in children is larger, in proportion, than after the age of puberty: it often projects beyond the external labia at birth.

CLOA'CA. (*a, æ.* f.; Latin for a common sewer.) A cavity formed by the extremity of the intestinal canal in birds, fish, reptiles, and the monotrematous animals. It forms a common cavity in which the intestines and ureters terminate in both sexes, and the vagina also in the female.

CLO'NIC. (*Clonicus;* from κλονος, agitation, commotion.) A spasm which is not of long duration, though it may be repeated in rapid succession; such are the spasms which affect the muscles in epilepsy. *Clonic* is opposed to *tonic* spasm. See *Tonic* and *Spasmus.*

CLONO'DES. (Κλονωδες; from κλονεω, to agitate.) A term applied by Galen to that kind of pulse which we call a *vibratory pulse.* See *Pulsus.*

CLOPORTE ORDINAIRE. The French name of the *oniscus asellus.* See *Oniscus asellus.*

Cloporte preparé. See *Armadillo.*

Clove. See *Eugenia caryophyllata.*

Clove bark. See *Myrtus caryophyllata.*

Clove gilliflower. See *Dianthus.*

Clove pink. See *Dianthus caryophyllus.*

Cloven. See *Fissus.*

CLUB-FOOT. A name given to different kinds of congenital distortion of the feet. See *Feet, distortion of the.*

Club-shaped. See *Clavatus.*

CLUNE'SIA. (*a, æ.* f.; from *clunes,* the buttocks.) An inflammation of the buttocks. — *Vogel.*

CLU'PEA. (*a, æ.* f. Latin for a shad.) The name of a genus of fishes.

CLUPEA ALO'SA. The shad or chad, the flesh of which has been recommended as a restorative.

CLUPEA ENCRASI'COLUS. The anchovy, a little fish, found in great abundance about the island of Gorgona, near Leghorn. It is prepared for sale, by salting and pickling. It is supposed the ancient Greeks and Romans prepared a kind of garum for the table from this fish. It has a very fine and peculiar flavour, and is eaten as a delicacy all over Europe; but its principal use is for making the sauce called anchovy sauce.

CLUPEA HARENGUS. The common herring; a fish of great importance to a large proportion of the population of Europe. When broiled or boiled, they are an agreeable article of food, but they do not generally agree well with delicate stomachs. When salted, either wet or dry, they are still difficult of digestion. Dry salted, and smoked, they constitute what are called *red herrings.* The Dutch prepare the herring by salting or pickling in a way peculiar to themselves. The fish thus prepared are called *Dutch herrings,* and are by many esteemed as a great delicacy.

CLUPEA LA'TULUS. Whitebait. A very small fish, extremely abundant in the river Thames. When fried it is esteemed a great delicacy.

CLUPEA PILCHARDUS. The pilchard. This is smaller than our herring. It is found on the coast of Cornwall, and in the Mediterranean, and is eaten like the common herring. The young fish are substituted for anchovies.

CLUPEA SINENSIS. This very much resembles our herring. It is found on the China coast, and eaten in the same way.

CLUPEA SPRATTUS. The sprat. These little fish come to our shores in vast abundance in the winter, and are a great delicacy to the poorer classes, who broil them, and eat plentifully of them. They are too strong for weak stomachs. Sprats are pickled in the northern parts of Europe, and exported as a delicacy: they are also fraudulently substituted for the anchovy.

CLUSIA. (*a, æ.* f.; so called in memory of Charles Clusius, an eminent botanist.) The name of a genus of plants in the Linnæan system. Class, *Polygamia;* Order, *Monœcia.* The species composing it, which are nearly confined to South America, exude several kinds of gum-resins, used for different purposes by the natives.

Cluster. See *Racemus,* and *Thyrsus.*

CLU'TIA. (*a, æ.* f.; named after Cluyt, and sometimes spelt *cluytia.*) The name of a genus of plants in the Linnæan system. Class, *Diœcia;* Order, *Gynandria. Clutia collina* is a poisonous species; and *C. Spinosa* (now referred to the genus *Brodelia*) is astringent, and used in India as an anthelmintic for cattle.

Cluytia. See *Clutia.*

CLY'DON. (Κλυδων, a wave.) Fluctuation of the contents of the abdomen; flatulence. — *Galen.*

CLYPEA'LIS CARTILAGO. (*Clypealis,* from *clypeus* a shield.) The thyroid cartilage.

CLYSMA. (Κλυσμα; from κλυζω, to wash.) In medical language, a clyster.

CLY'SSUS. An old chemical term that was very variously applied. Sometimes it meant a compound of various chemical products of the same substance; sometimes the quintessence of any thing; but most generally the product of the detonation of nitre with any other substance: thus nitre, deflagrated with charcoal, formed the *Clyssus nitri;* with antimony, the *Clyssus antimonii;* and with sulphur, the *Clyssus sulphuris.*

CLYSTER. (*er, eris.* m.; from κλυζω, to wash.) See *Enema.*

CNEMODACTYLÆ'US. (From κνημη, the tibia, and δακτυλος, a finger, or toe.) See *Extensor longus digitorum pedis.*

CNEORUM TRICOCCUM. Mezereon. See *Daphne mezereum.*

CNICILÆ'ON. (From κνικος, *cnicus*, and ελαιον, oil.) Oil made of the seeds of the *cnicus* or carthamus tinctorius.

CNI'CUS. (*us, i.* f. κνικος.) 1. The ancient name of the *carthamus tinctorius.*

2. The name of a genus of plants, Class, *Syngenesia;* Order, *Polygamia æqualis.*

CNICUS CERNUUS. The nodding cnicus, the tender stalks of which, boiled and peeled, are eaten by the Siberians.

CNICUS LANATUS. *Chamæleon verum.* The distaff thistle. Formerly used as a depurator, but now forgotten.

CNICUS OLERACEUS. Round-leaved meadow thistle. The leaves of this plant are boiled in the northern parts of Europe, and eaten like cabbage.

Cnicus sylvestris. See *Centaurea.*

Cnidii grana. See *Daphne mezereum.*

CNIDO'SIS. (Κνιδωσις; from κνιδη, the nettle.) A pungent itching, such as that produced by the sting of a nettle. — *Hippocrates.*

CNI'POTES. (Κνιποτης. A dry itching.) Some consider this word, as used by Hippocrates, to be synonymous with *Xerophthalmia*, or dry ophthalmia. — *Galen.*

COADUNA'TÆ. The name given by Linnæus to a natural family of plants, which have a number of flowers clustered together so as to resemble a single flower.

COA'GULABLE. *Coagulabilis.* Susceptible of coagulation.

Coagulable lymph. See *Sanguis.*

Coagulating lymph. See *Sanguis.*

COA'GULANT. (*Coagulans;* from *coagulo*, to incrassate, or curdle.) Having the power of coagulating. Formerly applied to medicines which were supposed to render the blood more coagulable.

COAGULA'TION. (*Coagulatio;* from *coagulo*, to curdle.) The sudden conversion of a liquid into a soft solid mass, as when the white of an egg is consolidated by heat; or the separation of the denser particles from a fluid, as in the coagulation of the blood.

COA'GULUM (*um, i.* n.) The tenacious substance formed from a fluid by coagulation.

COAGULUM ALU'MINIS. This is made by beating the white of eggs with a little alum, until a coagulum is formed. It has been recommended as an efficacious application in a relaxed state of the conjuctive membrane of the eye.

Coal-fish. See *Gadus carbonarius.*

COALTE'RNA FEBRIS. (From *con*, and *alternus*, alternate.) The name given by Bellini to a double intermittent.

COAPTA'TIO. (*o, onis.* f.; from *con*, and *apto*, to fit.) Coaptation. An old surgical term for what is now called the *reduction* of a dislocation or fracture.

COARCTA'TION. (*Coarctatio;* from *coarcto*, to straiten.) Applied in medical language to the contraction or lessening of the diameter of a canal, as the intestinal canal, or the urethra.

COARCTA'TUS. Crowded: applied, in *botany*, to a panicle which is dense, compact, or crowded; as in *Phleum paniculatum*, the inflorescence of which looks, at first sight, like a cylindrical spike; but when bent to either side, separates into branched lobes, constituting a real panicle.

COARTICULA'TIO. (From *con*, and *articulatio*, an articulation.) Synonymous with *diarthrosis*, which see.

CO'BALT. (*Cobaltum, i.* n.) The name of a metal. A mineral called *cobalt* was used to tinge glass blue, long before the peculiar metal now designated by that name was known to chemists. The name is derived from an old German superstition. The mines of that country were believed to be haunted by certain mischievous demons called *kobolden*, and those ores which appeared rich to the eye, but afforded nothing of any value, were believed by the miners to be manufactured by these spirits, and were called after them *kobold;* the ores of the metal in question were supposed to be of this useless kind, and hence got the name of *cobalt.*

Cobalt is met with in the earth chiefly in combination with arsenic, constituting an ore from which all the cobalt of commerce is derived. It is a constant ingredient of meteoric iron; at least Professor Stromeyer states that he has analysed several varieties, in every one of which he has detected the presence of cobalt.

When native arseniuret of cobalt is broken into small pieces, and exposed in a reverberatory furnace to the united action of heat and air, its elements are oxidised, most of the arsenious acid is expelled in the form of vapour, and an impure oxide of cobalt, called *zaffre*, remains. On heating this substance with a mixture of sand and potash, a beautiful blue coloured glass is obtained, which, when reduced to powder, is known by the name of *smalt.*

Metallic cobalt may be obtained by dissolving zaffre in muriatic acid, and transmitting through the solution a current of sulphuretted hydrogen gas, until the arsenious acid is completely separated in the form of sulphuret of arsenic. The filtered liquid is then boiled with a little nitric acid, in order to convert the protoxide into peroxide of iron, and an excess of carbonate of potash is added. The precipitate, consisting of peroxide of iron and carbonate of cobalt, after being well washed with water, is digested in a solution of oxalic acid, which dissolves the iron, and leaves the cobalt in the form of an insoluble oxalate. (Laugier.) On heating the oxalate of cobalt in a retort from which atmospheric air is excluded, a large quantity of carbonic acid is evolved, and a black powder, metallic cobalt, is left. (Thomson, in *Annals of Philosophy*, N. S. i.) The pure metal is easily procured, also, by passing a current of dry hydrogen gas over oxide of cobalt, heated to redness in a tube of porcelain. In this state it is porous, and if formed at a low temperature it inflames spontaneously.

A solution of cobalt may also be made by

acting on the native arseniuret with sulphuric, mixed with a fourth part of nitric acid, separating as much arsenious acid as possible by evaporation, and conducting the remainder of the process as above described. The arseniuret from Tünaberg should be preferred for this purpose, as it is in general free from nickel, which always accompanies the cobalt ores of Germany.

Cobalt is a brittle metal, of a reddish-gray colour, and weak metallic lustre. Its density, according to Dr. Turner, is 7·834. It fuses at about 130° of Wedgwood, and when slowly cooled it crystallises. It is attracted by the magnet, and is susceptible of being rendered permanently magnetic. It undergoes little change in the air, but absorbs oxygen when heated in open vessels. It is not easily acted on by sulphuric or muriatic acid, but is readily oxidised by means of nitric acid. Like iron, and the other metals of this order, it decomposes water at a red heat, with disengagement of hydrogen gas. — *Despretz.*

Oxides of Cobalt. — Chemists are acquainted with two oxides of cobalt, the oxygen of which is in the ratio of 1 to 1·5. According to the experiments of Rothoff (*Ann. of Phil.* iii. 356.), the protoxide is composed of 29·5 parts or one equivalent of cobalt, and eight parts of oxygen. Dr. Thomson infers, from his analysis of sulphate of cobalt, that twenty-six is the equivalent of this metal; but the inference from this and various other analyses of Dr. Thomson is vitiated by his error in the equivalent of barium. The estimate of Rothoff is, therefore, to be preferred, and the equivalents of the oxides of cobalt may be considered respectively as 37·5 and 41·5.

The protoxide is of an ash-gray colour, and is the basis of the salts of cobalt, most of which are of a pink hue. When heated to redness in open vessels it absorbs oxygen, and is converted into the peroxide. It may be prepared by decomposing carbonate of cobalt by heat, in a vessel from which atmospheric air is excluded. It is easily recognised by giving a blue tint to borax when melted with it; and is employed in the arts, in the form of smalt, for communicating a similar colour to glass, earthenware, and porcelain.

Protoxide of cobalt is precipitated from its salts by pure potash as a blue hydrate, which absorbs oxygen from the air, and gradually becomes black. Pure ammonia likewise causes a blue precipitate, which is redissolved by the alkali if in excess. It is thrown down as a pale pink carbonate by carbonate of potash, soda, or ammonia; but an excess of the last redissolves it with facility. Sulphuretted hydrogen produces no change, unless the solution is quite neutral, or the oxide is combined with a weak acid. Alkaline hydrosulphurets always precipitate it as black sulphuret of cobalt.

Muriate of cobalt is celebrated as a sympathetic ink. When diluted with water so as to form a pale pink solution, and then employed as ink, the letters, which are invisible in the cold, become blue if gently heated.

Peroxide of cobalt is of a black colour, and is easily formed from the protoxide in the way already mentioned. It does not unite with acids; and when digested in muriatic acid, the protomuriate of cobalt is generated, with disengagement of chlorine. When strongly heated in close vessels, it gives off oxygen, and is converted into the protoxide.

When a salt of cobalt is treated with pure ammonia in close vessels, part of the cobalt is dissolved, and part subsides in form of a blue powder. On admitting atmospheric air, this substance passes to a higher state of oxidation, and is gradually dissolved. If nitrate of cobalt is used, a double salt may be obtained in crystals, which L. Gmelin, to whom we are indebted for these remarks, believes to consist of nitrate and *cobaltate* of ammonia. The existence of this acid, however, has not yet been satisfactorily established.

Cobalt appears to unite with sulphur in three proportions; the first being a protosulphuret, the second a sesquisulphuret, and the third a bisulphuret. The protosulphuret has a gray colour, a metallic lustre, and a crystalline texture. It may be formed in the dry way, either by throwing fragments of sulphur on red-hot cobalt, or by igniting oxide of cobalt with sulphur; and it is thrown down as a black precipitate from the salts of cobalt by alkaline hydrosulphurets, or even by sulphuretted hydrogen gas, if the salt is quite neutral, or the oxide united with any of the feebler acids.

Arfwedson has observed, that when hydrogen gas is transmitted over sulphate of cobalt, heated to redness, water and sulphurous acid are evolved, and a compound remains, called an *oxysulphuret*, consisting of oxide of cobalt united with sulphuret of cobalt. When this substance is exposed to sulphuretted hydrogen gas, at a red heat, the oxide is decomposed, and a sesquisulphuret is formed.

The bisulphuret is prepared, according to Setterberg, by heating carbonate of cobalt in a state of intimate mixture with one and a half of its weight of sulphur. The process is conducted in a glass retort, and the heat continued as long as sulphur is expelled; but the temperature should not be suffered to reach that of redness.

The compounds of cobalt with the other non-metallic bodies have hitherto been little examined. — *Turner.*

Cobham. The name of a town in Surrey, in the neighbourhood of which is weak, saline, purging, water.

Co'bra de cape'llo. The Portuguese name of the hooded snake. See *Naja.*

Cobweb. See *Aranea.*

Cocoa-nut. See *Cocos nucifera.*

Cocca cnidia. See *Daphne mezereum.*

Cocca'rium. A very small pill.

Coccine'lla. (*a, æ.* f.; diminutive of *coccus*, a berry: from its resemblance to a berry.)

1. The cochineal insect. See *Coccus cacti.*

2. The name of a numerous genus of coleopterous insects. The lady-bird. *Cocinella bipunctata*, and *septem-punctata*, have been in vogue as remedies for the toothach, the insect being bruised, and applied to the affected tooth.

Co'cco-ba'lsamum. The fruit of the *Amyris gileadensis*.

Coccogni'dia. See *Daphne mezereum*.

CO'CCULUS. (*us*, *i*. m.; diminutive of κοκκος, a berry.) 1. A little berry.

2. The name of a genus of plants constituted by Decandolle. Natural order *Menispermiæ*. Class, *Diœcia*; Order, *Dodecandria* of the Linnæan system.

Cocculus Indi aromaticus. Jamaica pepper. See *Myrtus pimenta*.

Cocculus indicus. See *Menispermum cocculus*.

Cocculus palma'tus. *Menispermum palmatum*. The plant which produces the calumba root.

This species of cocculus is a native of the eastern part of Southern Africa, growing in great abundance in the forests of Mozambique, between Oibo and Mozambo. The roots are dug up by the natives in the month of March, and transported to Tranquebar, where it is a staple article of export with the Portuguese. The root was formerly erroneously supposed to be named from the principal town in the island of Ceylon, which was regarded as its place of export. An entire root was taken to Madras by Mons. Fortin, in 1805, and a plant raised from it there by Dr. Anderson, from a drawing of which it was ascertained to belong to the natural order Menispermeæ; but, as it was a male plant only, the genus and species were undetermined until they were fixed by De Candolle. In 1825, both male and female plants were obtained by Captain Fitzwilliam Owen, from Oibo, and carried to the Mauritius, Bombay, and the Seychilles Archipelago. Dr. Berry drew up the following character of the male plant, which has been adopted by De Candolle; but the female plant is yet undescribed. The root is perennial, ramose, and bears fusiform tubers. The stems are annual, withering at the end of seven months, voluble, simple, round, hairy, about the thickness of a goosequill, bearing distant, alternate, five-lobed, five-nerved, leaves, with entire acuminate lobes; and supported on round hairy petioles, shorter than the leaves. The male flowers are in axillary, solitary, compound, racemes, hairy, and shorter than the leaves, bearing partial, alternate, peduncles, with sessile flowers, and lanceolate, ciliated, deciduous bractes. The calyx is hexaphyllous, with three exterior leaflets, and three interior, equal, oblong, obtuse, and glabrous. The corolla consists of six minute, oblong, wedge-shaped, concave, fleshy, obtuse, petals. The stamens are six, a little longer than the corolla; the anthers four-lobed and four-celled: there is no pistillum. The roots are dug up in March; but the offsets only are taken; each offset being a sessile tuber. In the female plant, the racemes are solitary, axillary, patent, and shorter than those of the male. The calyx and petals resemble those of the male. The pistils are three, free, of which two are abortive: they are ovate, accuminate, glanduloso-pilose, and contain one ovule. The style is short, the stigmas patent, the fruit drupaceous, the seed subreniform, black, striated.

The dried root is brought to this country packed in bags, and sometimes in cases. It is in transverse sections, generally about one third of an inch in thickness, and one or two inches in diameter. The bark is thick, and easily detached, internally bright yellow, and covered with a wrinkled olive-brown cuticle. The interior part of the root is of a pale brownish colour, and has a spongy texture, with darker converging rays, which are the remains of sap-vessels. The pieces are frequently much perforated, evidently by worms, and not, as has been supposed, by stringing to facilitate its drying. Those pieces which have the fewest wormholes, the brightest colour, and are solid and heavy, are the best. It is said that the root of white bryony, tinged yellow with the tincture of calumba, has been fraudulently substituted for this root.

Calumba root has a very slight aromatic odour, and a bitter taste. It breaks with a starchy fracture, and is easily pulverised. Water at 212° takes up one third of its weight; and the infusion has all the sensible qualities of the root. These are also extracted by alkohol; but proof spirit is its best menstruum. The infusion is not altered by solutions of sulphate of iron, nitrate of silver, muriate of mercury, and tartarized antimony; but a copious precipitate is produced by the infusion of galls and yellow cinchona bark, by acetate and superacetate of lead, oxymuriate of mercury, and limewater. Hence calumba root was erroneously supposed to contain cinchonia. M. Planche found it to contain a large proportion of a peculiar animal substance; a yellow, bitter, resinous matter, and one third of its weight of starch. By repeated distillation, he also obtained a volatile oil; and, from the residue, malate of lime and sulphate of lime. By treating calumba root with alkohol of 0·835, then reducing the tincture by distillation to one third, allowing the residue to stand until crystals form in it, and afterwards purifying these, Mr. Wittstock of Berlin procured a new salt, to which he gave the name of *colombin*, and which he supposes to be the active principle of calumba root. It is inodorous, extremely bitter, neither acid nor alkaline, forms in quadrilateral, transparent, acicular, crystals, scarcely soluble in water or in cold alkohol. The acetic acid is its proper menstruum; but it is also taken up by alkaline solutions.

Medical properties and uses. — Calumba root is a useful antiseptic and tonic. It was first brought into notice by Fr. Rede, in 1685. It is frequently employed with much advantage in diarrhœas arising from a redundant secretion of bile, and in bilious remittent fever, and cholera, in which it generally checks the vomiting. It also allays the nausea and vomiting which accompany pregnancy; and, according to Percival, it is equally serviceable in stopping the severe diarrhœa and vomiting which sometimes attend dentition. Denman found it more useful than the cinchona in the low stage of puerperal fever. As a tonic, unaccompanied with astringency, and possessing little stimulus, it has been recommended in phthisis and hectic fever, to allay irritability and strengthen the digestive organs; and in dys-

pepsia. It may be given combined with aromatics, orange-peel, opiates, and alkaline or neutral salts, as circumstances require. We have found the powder, in combination with rhubarb and sulphate of potassa, exceedingly serviceable in mesenteric fever.

The dose of the powdered root is from grs. xv. to ʒss., repeated three or four times a day. — *A. T. Thomson.*

Officinal preparations. — *Infusum calumbæ*, L. E. *Infusum Columbæ*, D. *Tinctura Calumbæ*, L. E. D.

CO'CCUM. (*um*, *i.* n.) A species of seed-vessel, which Gœrtner distinguishes from a capsule: he defines it to be a dry seed-vessel, more or less aggregate, not solitary, the sides of which are elastic, projecting the seeds with great force, as in the *Euphorbia*.

Co'ccum ba'phicum. A name of the kermes berry. See *Coccus infectorius*.

CO'CCUS. (Κοκκος. *us. i.* m.) 1. In *Botany*, a cell or capsule: when two are joined together, it is termed *dicoccous*; and where there are three, *tricoccous*, &c. See *Capsula*.

2. In *Entomology*, the name of an order of hemipterous insects.

Coccus cacti. The systematic name of the cochineal insect; which has also been called, *Coccinella*, *Coccinilla*, *Ficus Indiæ grana*, *Scarabæolus hemisphæricus*, *Cochinelifera cochinilla*, *Coccus Americanus*, *Cochinella*, and *Coccus Indicus tinctorius*. Cochineal, so highly prized for its valuable properties in producing the dye which bears its name, is a native of South America. It comes to us in the form of a reddish grain, covered with a white powder or bloom, and feeds on various species of Cactus or Indian fig. In Mexico, where the insect is domesticated, and reared with the greatest care, the plant is called Nopal, and has been generally supposed to be the *Cactus cochinilifer*, but, according to Humboldt, is unquestionably a distinct species, to which he has given the name of C. *Bonplandii*. The female, which alone is valuable for its dye, is about one eighth of an inch in length; the body is depressed, downy, transversely rugose, of a purplish red colour, flat below and convex above; the head is furnished with a rostrum rising from the breast, with a vagina and setæ; the legs are six in number, short and black. The male is a very small fly, with long filiform antennæ, and two erect wings; the body is of a deep red colour, with two very long setæ proceeding from the apex of the abdomen. No good figure and description of this interesting species has yet been published.

Cochineal is chiefly cultivated in the intendency of Oaxaca; and some plantations contain 50 or 60,000 nopals in lines, each being kept about four feet high, for more easy access in collecting the dye. The cultivators prefer the most prickly varieties of the plant, as affording protection to the cochineal from insects; to prevent which from depositing their eggs in the flower or fruit, both are carefully cut off. The greatest quantity, however, of cochineal employed in commerce, is produced in small nopaleries belonging to Indians of extreme poverty, called *Nopaleros*. They plant their nopaleries in cleared ground, on the slopes of mountains or ravines, two or three leagues distant from the villages; and, when properly cleaned, the plants are in a condition to maintain the cochineal in the third year. As a stock, the proprietor in April or May purchases branches or joints of the *Tuna de Castilla*, laden with small cochineal insects recently hatched (*Semilla*). These branches, which may be bought in the market of Oaxaca for about three francs (2*s.* 6*d.*) the hundred, are kept for twenty days in the interior of their huts, and then exposed to the open air under a shed, where, from their succulency, they continue to live for several months. In August and September the mother cochineal insects, now big with young, are placed in nests made of a species of *Tillandsia* called *Paxtle*, which are distributed upon the nopals. In about four months, the first gathering, yielding twelve for one, may be made, which in the course of the year is succeeded by two more profitable harvests. This period of sowing and harvest refers chiefly to the districts of Sola and Zimatlin. In colder climates, the semilla is not placed upon the nopals until October or even December, when it is necessary to shelter the young insects by covering the nopals with rush mats; and the harvests are proportionably later and unproductive. In the immediate vicinity of the town of Oaxaca, the Nopaleros feed their cochineal insects in the plains from October to April, and at the beginning of the remaining months, during which it rains in the plains, transport them to their plantations of nopals in the neighbouring mountains, where the weather is more favourable.

Much care is necessary in the tedious operation of gathering the cochineal from the nopals, which is performed with a squirrel's or stag's tail by the Indian women, who for this purpose squat down for hours together beside one plant; and, notwithstanding the high price of the cochineal, it is to be doubted if the cultivation would be profitable were the value of the labour more considerable.

The cochineal insects are killed either by throwing them into boiling water, by exposing them in heaps to the sun, or by placing them in ovens (*Temazcalli*), used for vapour baths. The last of these methods, though least in use, preserves the whitish powder on the body of the cochineal, which, being then less subject to the adulterations so often practised by the Indians, bears a higher price both in America and Europe.

The quantity at present annually exported from South America is said by Humboldt to be 32,000 arrobas, estimated at 2,400,000 piastres, about 500,000*l.* sterling.

Cochineal has a faint, disagreeable, bitter, and austere taste. According to MM. Pelletier and Caventou, the colouring matter, which composes the principal part of the cochineal, is mixed with a peculiar animal matter, a fatty matter, phosphate and carbonate of lime, and muriate and phosphate of potass. The colouring matter, which they have named *carminium*, is soluble in water, alkohol, and solutions of

pure alkalis. Carmine is prepared by precipitating the colouring matter from its solution in water, by means of alum or oxide of tin.

Cochineal has been recommended as an antispasmodic and anodyne in hooping cough; but its principal use is to impart a fine colour to tinctures and other preparations. It is sometimes adulterated with an admixture of a manufactured imitation, composed of coloured dough. The fraud may be very easily detected by the action of boiling water, which dissolves the spurious grains, while it has little action upon the genuine insect. — *Stephenson.*

Coccus infecto'rius. *Coccus baphicus. Coccus ilicis. Coccus quercus cocciferæ.* The insect which produces the kermes grains, or kermes berries. The tree which these insects inhabit (*Quercus coccifera*) grows in the South of France, in Spain, and in the islands of the Archipelago. The insect has the appearance of a little reddish-brown berry, covered with a grayish powder: it used to be esteemed aphrodisiac, analeptic, &c.; but is now only used to colour syrups red.

Coccus lacca. Lac is the produce of an insect formerly supposed to be a kind of ant or bee, but now ascertained to be a species of coccus; and is collected from various trees in the East Indies, where it is found so abundantly, that, were the consumption ten times greater than it is, it could be readily supplied. This substance is made use of in that country in the manufacture of beads, rings, and other female ornaments. Mixed with sand, it forms grindstones; and added to lamp or ivory-black, being first dissolved in water, with the addition of a little borax, it composes an ink, not easily acted upon when dry by damp or water. In this country, where it is distinguished by the names *stick-lac* when in its native state, unseparated from the twigs to which it adheres; *seed-lac* when separated, pounded, and the greater part of the colouring matter extracted by water; *lump-lac* when melted and made into cakes; and *shell-lac* when strained and formed into transparent laminæ; it has hitherto been chiefly employed in the composition of varnishes, japanned ware, and sealing wax: but within these few years it has been applied to a still more important purpose, originally suggested by Dr. Roxburgh, that of a substitute for cochineal in dying scarlet. — *Stephenson.*

Coccus polo'nicus. This is found on the roots of the *Polygonum cocciferum* and other plants. It is used as a red dye.

COCCYGE'US. (*Coccygeus*; from κοκκυξ: because it is inserted into the coccyx.) A muscle of the os coccygis, situated within the pelvis. It arises, tendinous and fleshy, from the spinous process of the ischium, and covers the inside of the sacro-ischiatic ligament; from this narrow beginning it gradually increases to form a thin fleshy belly, interspersed with tendinous fibres. It is inserted into the extremity of the os sacrum, and nearly the whole length of the os coccygis, laterally. Its use is to support and move the os coccygis forwards.

COCCY'GIS OS. (*Coccyx, ygis*, f.; from κοκκυξ, the cuckoo, the bill of which bird it is said to represent.) *Cauda. Ossis sacri acumen.* This bone is a small appendage to the end of the sacrum, terminating in a point. It is found in very different conditions in the several stages of life. In the child, it is merely cartilage, and we can find no point of bone: during youth, it is ossifying into distinct bones, which continue moveable upon each other till manhood: then the separate bones gradually unite with each other, so as to form one conical bone, with bulgings and marks of the pieces of which it was originally composed; but still the last bone continues to move upon the joint of the sacrum, till, in advanced life, it becomes firmly united: this takes place later in women than in men. The coccyx is of a roundish form, convex without, and concave inwards; forming, with the sacrum, the lowest part of the pelvis behind. It has no holes, like the sacrum; has no communication with the spinal canal, and transmits no nerves; but points forward to support the lower part of the rectum: thus it contracts the lower opening of the pelvis, so as to support effectually the rectum, bladder, and womb; and yet continues so moveable in women, as to recede in time of labour, allowing the head of the child to pass.

CO'CCYX. (Κοκκυξ, the cuckoo.) The *Os coccygis.* See *Coccygis os.*

Coccinellin. *Carminium.* The colouring principle of cochineal. See *Coccus cacti.*

Co'chia. (Κοκκια; from κοκκος, a berry.) *Coccia.* An ancient name of some officinal pills. The pill of cochia of the shops, in the present day, is the compound colocynth pill.

Cochineal. See *Coccus cacti.*

Cochinella Germanica. See *Coccus Polonica.*

CO'CHLEA. (*Cochlea*, a snail's shell.) A cavity of the internal ear, so called from its shape. See *Auris.*

Cochlea terrestris. See *Limax.*

COCHLE'ARE. (*Cochleare, is.* n.; from *cochlea*, a cockle, the shell of which its bowl resembles.) A spoon. *Cochleare amplum*, or *magnum*, is a table-spoon, calculated to hold half a fluid ounce; *cochleare medium*, is a dessert or pap-spoon, supposed to hold two tea-spoonsful; and *cochleare minimum*, a tea-spoon, which holds about one fluid drachm.

COCHLEA'RIA. (*a, æ.* f.; from *cochleare*, a spoon: so called from the shape of its leaves.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia*; Order, *Siliculosa.*

Cochlearia armoracia. The systematic name of the horseradish; called also, *Raphanus rusticanus, Armoracia, Raphanus marinus*, and *Raphanus sylvestris.*

Cochlearia foliis radicalibus lanceolatis crenatis caulinis incisis, of Linnæus. The root of this plant has long been received into the materia medica, and is also well known at our tables. "It affects the organs both of taste and smell with a quick penetrating pungency; nevertheless it contains in certain vessels a sweet juice which sometimes exudes in little drops upon the surface. Its pungent matter is of a very volatile kind, being totally dissipated in drying

and carried of in evaporation, or distillation by water; as the pungency exhales, the sweet matter of the root becomes more sensible, though this, also, is, in a great measure, dissipated or destroyed. It impregnates both water and spirit by infusion, or by distillation, very richly with its active matters. In distillation with water, it yields a small quantity of essential oil, exceedingly penetrating and pungent."

Dr. Cullen has mentioned every thing necessary to be known respecting the medicinal virtues of horseradish; we shall, therefore, transcribe all that the ingenious professor has written on this subject: — "The root of this plant only is employed; and it affords one of the most acrid substances of this order (*Siliculosa*), and therefore proves a powerful stimulant, whether externally or internally employed. Externally, it readily inflames the skin, and proves a rubefacient that may be employed with advantage in palsy and rheumatism; and, if its application be long continued, it produces blisters. Taken internally, it may be so managed as to relieve hoarseness, by acting on the fauces. Received into the stomach, it stimulates this, and promotes digestion; and therefore is properly employed as a condiment with our animal food. If it be infused in water, and a portion of this infusion be taken with a large draught of warm water, it readily proves emetic, and may either be employed by itself to excite vomiting, or to assist the operation of other emetics. Infused in water, and taken into the stomach, it proves stimulant to the nervous system, and is thereby useful in palsy, and, if employed in large quantity, it proves heating to the whole body; and thereby it proves often useful in chronic rheumatism, whether arising from scurvy or other causes. Bergius has given us a particular method of exhibiting this root, which is, by cutting it down, without bruising, into small pieces; and these, if swallowed without chewing, may be taken down in large quantities, so that of a table-spoonful. And the author alleges, that, in this way, taken in the morning for a month together, this root has been extremely useful in arthritic cases; which, however, I suppose to have been of the rheumatic kind. It would seem, in this manner employed, analogous to the use of unbruised mustard-seed; it gives out in the stomach its subtile volatile parts, that stimulate considerably, without inflaming. The matter of horseradish, like the same matter of the other siliquose plants, carried into the blood-vessels, passes readily into the kidneys, and proves a powerful diuretic, and is therefore useful in dropsy; and we need not say, that, in this manner, by promoting both urine and perspiration, it has been long known as one of the most powerful antiscorbutics."

Cochlearia hortensis. See *Cochlearia officinalis.*

Cochlearia officinalis. The systematic name of the lemon scurvy-grass. *Cochlearia hortensis; Cochlearia — foliis radicalibus cordato subrotundis; caulinis oblongis subsinuatis,* of Linnæus. This indigenous plant is cultivated in gardens for its medicinal qualities. Its expressed juice has been held in great estimation as an antiscorbutic.

COCHLEA'TUS. Spiral, like the winding of a shell. Applied, in *Botany*, to leaves, pods, seeds, &c.; as *legumen cochleatum*, seen in *Medicago polymorpha*, and the seeds of the *Salsola*.

Cocho'ne. (Κοχωνη. Κοχωνον.) Galen explains this to be the juncture of the ischium, near the seat or breech; whence, says he, all the adjacent parts about the seat are called by the same name. Hesychius says, that *cochone* is the part of the spine which is adjacent to the os sacrum.

Cocilio. A weight of eleven ounces. — *Ruland.*

Cockle. See *Cardium edule.*

Cocoa. See *Theobroma cacao.*

Cocola'ta. Chocolate. See *Theobroma cacao.*

CO'COS. (*os, i.* f. Contracted from the Portuguese *macoco*, or *macaco*, a monkey; the three holes at the end of the cocoa-nut shell giving it some resemblance to a monkey's head.) The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Hexandria.*

Cocos butyra'cea. The systematic name of the plant which affords the palm oil; *Cocos — inermis, frondibus pinnatis; foliolis simplicibus,* of Linnæus. The *oleum palmæ* is produced chiefly by bruising and dissolving the kernels of the fruit in water, without the aid of heat, by which the oil is separated, and rises to the surface, and, on being washed two or three times, is rendered fit for use. When brought into this country, it is of the consistence of an ointment, and of an orange-yellow colour, with little taste, and a strong, though not disagreeable, smell. It is used as an emollient in emulsions, and externally as a liniment for sprains, &c. It seems to possess no advantage over any other bland oil.

Cocos maldi'vicus. *Coccus de Maldiva. Nux Medica. Maldiva Nut.* The fruit of a species of palm which grows in the Maldive Islands. It was formerly in esteem as an alexipharmic, but is not now used.

Cocos nuci'fera. The systematic name of the plant, the fruit of which is the cocoa-nut. Within the nut is found a hollow kernel of a sweet and very agreeable flavour, and within this a large quantity of liquor resembling milk, which the Indians drink greedily before the fruit is ripe, it being then pleasant; but, when the nut is mature, the liquor becomes sour. Some full-grown nuts contain a pint or more of this milk, the frequent drinking of which seems to have no bad effects upon the Indians; yet Europeans should be cautious of making too free with it at first; for when Lionel Wafer was at a small island in the South Sea, where the tree grew in plenty, some of his men were so delighted with it, that, at parting, they were resolved to drink their fill, which they did; but their appetites had like to have cost them their lives; for, though they were not drunk, yet they were so chilled and benumbed that they could not stand, and were obliged to be carried aboard by those who had more prudence than themselves; and it was many days before they recovered. The milk of the cocoa-nut, when fermented, affords a kind of wine. The shells

of these nuts being hard, and capable of receiving a polish, they are often cut transversely, when, being mounted on stands, and having their edges silvered, or gilt, or otherwise ornamented, they serve the purpose of drinking-cups. The leaves of the tree are used for thatching, for brooms, baskets, and other utensils; and of the reticular web, growing at their base, the Indian women, make nets for the hair, and aprons.

CO'CTION. (*Coctio, onis.* f.; from *coquo*, to boil.) Concoction. 1. The digestion of the food in the stomach. See *Digestion.*

2. A boiling or decoction. See *Decoction.*

3. In medical language it was formerly used to signify that alteration, whatever it might be, which was supposed to take place in the crude matter of a distemper, whereby it was either fitted for a discharge, or rendered harmless to the body. This was conceived to be brought about by nature; that is, by the vis vitæ, or the disposition or natural tendency of the matter itself; or else by proper remedies, which so altered its bulk, figure, and cohesion, or gave it such a particular determination, as to prevent any farther ill effects, or drive it quite out of the body. That period of a disease wherein this action was imagined to be going on was called its state of coction.

Cod. See *Gadus morhua.*

Codaga-pala. See *Nerium antidysentericum.*

Codeia. An alkaline substance which exists in opium. See *Papaver somniferum.*

Codese'lla. An Italian name of the pestilential carbuncle. See *Anthrax and Pestis.*

Co'dia. Κωδια. A poppy head.

Codoce'le. (From κωδια, a bulb, and κηλη, a tumour.) A bubo.

Cœca'lis. (From *cæcum*, the blind gut.) Cœcal: of or belonging to the cœcum.

CŒ'CUM. From *cæcus*, blind. The blind gut. See *Intestines.*

CŒ'LIA. (Κοιλια, or κοιλιη; from κοιλος, hollow.) A cavity in any part of the body; especially the lower belly.

CŒ'LIAC. (*Celiacus*, belonging to the belly; from κοιλια, the belly.) Appertaining to the belly.

Cœliac artery. *Arteria celiaca.* The first branch given off from the aorta in the cavity of the abdomen. It arises from the aorta immediately after the emergence of the latter from between the crura of the diaphragm, or nearly opposite the eleventh dorsal vertebra. The cœliac artery is a very thick short trunk, and runs little more than an inch and a half before it divides into the great branches, viz. the *Hepatic*, the *Coronaria ventriculi*, and the *Splenic.*

Cœliac passion. (*Passio cœliaca*, from κοιλια, the belly.) This term has been variously understood by different writers. Sauvages says it is a chronic flux, in which the aliment is discharged half digested. Dr. Cullen considers it as a species of diarrhœa, under the name of *diarrhœa cœliaca.* See *Diarrhœa.*

Cœli'aca urina'lis. The name given by some writers to a disease in which chyle is passed along with the urine, or instead of urine. No such disease, however, exists.

Cœliac plexus. The solar plexus.

CŒLI'ACA. The first class of diseases in Dr. Good's Nosology, embracing diseases of the digestive organs.

Cœliaca chylosa. A name of the cœliac passion.

Cœliaca lactea. A name of the cœliac passion.

Cœliacus. See *Cœliac.*

Cœliacus fluxus. The cœliac passion.

Cœliacus morbus. The cœliac passion.

Cœlo'ma. (From κοιλος, hollow.) A large, round, and not very deep ulcer in the cornea of the eye.

CŒNOLO'GIA. (*a, æ.* f.; from κοινος, common, and λογος, discourse.) A consultation.

Cœruleus lapis. The sulphate of copper. See *Cupri sulphas.*

Cœruleus Morbus. See *Morbus Cœruleus.*

CO'FFEA. (*a, æ.* f.). The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.* The coffee-tree.

Coffea arabica. The plant which affords coffee; called also *Jasminum Arabicum, Choava, Bon*, and *Ban. Coffea Arabica — floribus quinquefidis, dispermis*, of Linnæus.

The coffee, properly so called, is the seed of this tree, which is cultivated in Arabia, Persia, the East Indies, the Isle of Bourbon, and several parts of America. Good Turkey coffee, when not too strong, is a nutritious and sufficiently wholesome beverage: it is too heating, however, for many constitutions, and, when habitually taken too strong, it produces bad effects in all, impairing the digestion, and inducing nervous irritability. It possesses nervine and astringent qualities, and may be drunk with advantage at all times, except when there is a redundance of bile. It is said to be a good antidote against an overdose of opium, and to relieve obstinate spasmodic asthmas. For the latter purpose, the coffee ought to be of the best Mocha, newly burnt, and made very strong, immediately after grinding it. Sir John Pringle commonly ordered one ounce for a dose; which is to be repeated fresh after the interval of a quarter or half an hour; and which he directed to be taken without milk or sugar.

Besides the peculiar bitter principle which is described under the head *Caffein*, coffee contains several other vegetable products. According to Cadet, 64 parts of raw coffee consist of 8 gum, 1 resin, 1 extractive and bitter principle, 3·5 gallic acid, 0·14 albumen, 43·5 fibrous insoluble matter, and 6·86 loss. Hermann found in 1920 grains of

	Levant Coffee.	Mart. Coffee.
Resin,	74	68
Extractive matter,	320	310
Gum,	130	144
Fibrous matter,	1335	1386
Loss,	61	12
	1920	1920

The nature of the volatile fragrant principle, developed in coffee by roasting, has not been ascertained. The Dutch, in Surinam, improve the flavour of their coffee by suspending bags of it, for two years, in a dry atmosphere. They never use new coffee.

Various farinaceous substances are prepared as substitutes for coffee; but none of them bear much resemblance to it, either in flavour or effects.

Cohabitation. The habit of dwelling together. Writers on legal medicine use this word in the sense of copulation, or coition.

COHE'SION. (*Cohæsio, onis.*; from *con*, and *hæreo*, to stick together.) That power by which the particles of bodies are held together. See *Attraction*.

Cohob. *Cohoph.* A barbarous term, forged by Paracelsus, the general meaning of which appears to be *iteration*: thus, to pour a fluid again and again on the same substance from which it has been abstracted, he calls *cohobare*, or *affundere per cohob*; the same terms are also applied by this eccentric author to the repetition of any medicine in the course of a disease.

Cohoba'tio. A term invented by Paracelsus to signify the redistillation of a fluid, poured afresh upon a substance of the same kind as that from which it has been before distilled, this process being repeated again and again.

Co'hol. *Kohol.* An Arabic name of antimony, with the powder of which the Eastern women pencil the inside of their eyelids, to give lustre to their eyes.

Col'lima. (From κοιλια, the bowels.) A sudden swelling of the belly from flatulence. — *Turton.*

Col'ndicans. (From *con*, and *indico*, to indicate.) Coindicant. A symptom is called coindicant, when it is accompanied by others indicating the same thing.

CO'ITUS. (*us, ûs.* m.; from *coeo*, to go together.) 1. The conjunction of the male and female in the act of procreation.

2. *Coitus humoris* means a conflux of fluids, or gathering of humours.

Coke. Charred coal.

Colato'ria la'ctea. Certain vesiculo-vascular bodies in the internal tunic of the uterus described by Astruc. He says they were formerly considered as glands.

Colato'rium. (*um, i.* n.; from *colo*, to strain.) A strainer of any kind.

Colatu'ra. (*a, æ.* f.; from *colo*, to strain.) A filtered or strained liquor.

Colchester. A seaport town of Essex, near which is a purging mineral water. *Aqua Colcestrencis*, resembling that of Epsom, but less powerful.

CO'LCHICUM. (*um. i.* n.; from *Colchis*, a country of Asia, where this plant is supposed to have been common.) 1. The name of a genus of plants in the Linnæan system. Class, *Hexandria*; Order, *Trigynia*. Meadow-saffron.

2. The pharmacopœial name of the meadow-saffron. See *Colchicum autumnale*.

Colchicum autumnale. The systematic name of the common meadow-saffron. *Colchicum — foliis planis lanceolatis erectis*, of Linnæus. This is an indigenous perennial plant, generally found, in many parts of Europe, growing in moist rich meadow grounds, and flowering in September. The bulb is solid, egg-shaped, and covered with a brown membranous coat. The leaves, which appear in spring, are radical and spear-shaped, about five inches long, and half an inch broad at the base. They wither away entirely before the end of summer, and are, nevertheless, preceded by the flower, which appears in autumn without any leaves. It is, however, proper to state, that the bulb from which the flowers spring is the offset of that from which the leaves have decayed. There is no calyx. The corolla, which is of a pale, pinkish, lilac colour, springs directly from the bulb, and consists of a tube about five inches long, two thirds of which are sunk in the ground, and a limb divided into six lanceolate keeled segments. The filaments are half the length of the segments of the corolla, subulate, united to the upper part of the tube, and supporting yellow erect anthers. The stigmas are revolute. The fruit is a three-lobed, three-celled, capsule, on a thick, short, peduncle. The impregnated germen remains under ground, close to the bulb, till the following spring, when it rises in its capsular form above the surface, accompanied by the leaves. The seeds are ripe about the end of June.

The thick old bulb begins to decay after the flower is perfectly expanded; and the new bulbs, of which there are always two on each old bulb, are perfected in the following June, from which time until the middle of August they may be taken up for medicinal use. The bulbs, when mature, on being cut transversely, yield a milky-looking acrid juice, which produces a beautiful cerulean blue colour, if rubbed with the alcoholic solution of guaiacum. To preserve the virtues of the plant, the bulb, as soon as possible after it is dug up, should be cut into transverse slices, not thicker than one eighth of an inch, and dried by placing the slices on clean, white, bibulous paper, distinct from one another, without heat, or at a very low temperature. The test of the drug being good and properly dried is the appearance of the blue colour, on rubbing it with a little distilled vinegar and the alkoholic solution of guaiacum. The slices also should not appear deeply notched or panduriform, as this is the mark of the bulb having begun to empty itself for the nourishment of the young bulbs; and, consequently, to suffer in its medicinal powers, from the chemical change which, at this period, its contents must necessarily undergo for the nourishment of the offsets. The slices should be preserved in well stopped bottles.

The *seeds* of colchicum should be collected in July and August. They are nearly round, in size about one eighth of an inch, and of a reddish-brown colour. Their active properties reside in the testa; they do not spoil by being kept.

Qualities. — The recent bulb of this plant has scarcely any odour, but the little it has is *hircine*. When it is dug up at a proper season of the year, the taste is bitter, hot, and acrid, occasioning a warm sensation in the stomach, even when taken in a small quantity. At other seasons, however, and in some soils and situations, it possesses very little acrimony, and thence the contradictory opinions which authors

have given of it. Its acrimony is said to reside in veratria, which can be separated from the other principles: this is the opinion of MM. Pelletier and Caventou, who discovered it in 1819; but Hesse and Geiger assert that it is a different alkaloid, which they have named *colchicia*. It is procured in slender acicular crystals, is inodorous, has a bitter biting taste, but is less acrid than veratria, from which it differs in being soluble in water, and forming crystallisable salts with acids. The other components of the bulb are the following: a fatty matter, malic acid, a yellow colouring matter, gum, starch, inulin in great abundance, and lignin. Vinegar and wine are the best menstrua for extracting the active qualities of the bulb. A deposit forms in the wine, which Sir E. Home says is extremely acrid, exciting nausea and griping, and ought to be removed, as its removal does not alter the virtues of the medicine. The seeds contain *colchicia*, and yield it up to wine, vinegar, and alkohol.

Medical properties and uses. — Meadow-saffron possesses diuretic, purgative, and narcotic properties. It is supposed by some to be the *hermo dactylon* of the ancients. On the Continent, where it was recommended to notice by Baron Stoerck, it is a favourite remedy in dropsy, particularly hydrothorax, and in humoral asthma. But as it does not differ in its mode of action from squill, and is more uncertain in its operation, it has not been much used in that complaint in this country. In gout, rheumatism, and other diseases of excitement, however, its efficacy has been fully ascertained; and, in allaying the pain of gout, it may be almost said to possess a specific property. It operates on the bowels chiefly, stimulating the orifice of the common gall-duct in the duodenum, so as to produce copious bilious evacuations; and acting on the nerves, it diminishes the action of the arterial system. The petals of the flower, and the seed, possess the same medicinal properties as the bulb. In the seed the veratria exists in the testa or husk, and, consequently, the seeds should not be bruised in preparing the wine or tincture with them. When colchicum is overdosed it operates as a powerful poison; causing severe diarrhœa, and the most dangerous collapse.

The dose in substance is from grs. iij. to grs. ix. of the dried bulb; and of the saturated vinous infusions, made by macerating ℥ jss. of the dried bulb, or ℥ j. of the dried petals, or of the seed, in f ℥ xij. of white wine, from ♏ xx. to ♏ lx. may be taken whenever the patient is in pain. — *A. T. Thomson.*

Officinal preparations. — *Acetum Colchici*, L. *Oxymel Colchici*, D. *Syrupus Colchici autumnalis*, E. *Vinum Colchici*, L. *Tinctura Seminum Colchici*, D.

Colchicum illyricum. The plant supposed by some to afford the root called hermodactyl. See *Hermodactylus.*

Colchicum zeylanicum. See *Zedoaria.*

COLCO'THAR. *Chalcitis; Colcothar vitrioli.* The brown-red oxide of iron, which remains after the distillation of the acid from sulphate of iron.

Colcothar vitrioli. See *Colcothar.*

Cold. 1. See *Frigus.*

2. A popular name for a catarrh. See *Catarrh.*

Cold Affusion. See *Affusion.*

COLEO'PTERA. (From κολεος, a sheath, and πτερον, a wing.) An order of insects furnished with elytra, or sheaths to their wings, as beetles, &c.

Co'les. *Colis.* The penis.

Colewort. See *Brassica.*

Colic. See *Colica.*

Colic of Poitou. See *Colica.*

Colic, lead. See *Colica.*

Colic, painter's. See *Colica.*

CO'LICA. (*a*, *æ*. f.; from κωλον, colon, the name of a portion of the intestines.) The colic or bellyache. The appellation colic is commonly given to all severe griping pains in the abdomen, not primarily dependent on inflammation; but, from the different causes and circumstances of this disorder, it is variously denominated, and several species have been distinguished by nosologists. When its principal symptoms are sharp and spasmodic pains, it is called *spasmodic colic;* and when with the pain there is constipation, and accumulation of fæcal matter, *stercoraceous colic;* when from indigestible food, *accidental colic.* When the pain is accompanied with vomiting of bile, it is called *bilious colic:* if flatus causes the pain, that is, if there be temporary distension, relieved by the discharge of wind, it takes the name of *flatulent* or *windy colic;* when accompanied with heat and a degree of inflammation, it takes the name of *inflammatory colic.* When colic arises to a violent height, and is attended with obstinate costiveness, and an evacuation of fæces by the mouth, it is called *passio iliaca*, or iliac passion.

1. *Of the spasmodic colic.*

This species is attended with pain about the navel, and a retraction of the parietes of the belly. The pain goes and returns, and moves about as in other kinds of colic, but there are more perfect periods of ease. When the belly is soft, the intestines are often felt in lumps, which move about under the hand, or wholly vanish for a time. These are its essential characters, and establish the purely spasmodic affection when there is no flatulency, nor any of the distinctive symptoms of the other species.

Spasmodic colic occurs in highly nervous and hysterical constitutions, and is relieved by stimulating fomentations, warm glysters, and carminatives, especially the compound spirit of sulphuric ether with camphire. If these do not remove the spasms, opium is an almost infallible remedy.

2. *Of the stercoraceous colic.*

The griping pains are severe, and the bowels are constipated, and there is often nausea and vomiting. When this happens, as it sometimes does, to infants very soon after birth, before the *meconium* has passed away from the intestines, the disease is called *colica meconialis.* Both the colica stercorea, or fæcosa, as it has been termed, and the meconialis, are the result of a superabundant action of the absorbents, or of a deficiency in the peristaltic power of the intestina

tube: in consequence of which, from the length of time the confined materials occupy in completing their descent, the meconium, in infants, becomes so viscid as not to be urged downward, and remains in the intestines till it grows acrid from acidity or putrescency; and, in older subjects, the fæces, deprived of moisture, harden into one solid mass, possessing the figure of the intestine; or formed in the sacculi of the colon, or separating into smaller pieces, appear, when discharged, in the shape of balls or buttons, like sheeps' dung, often as hard as sun-burnt clay, and have been called scybala. Great quantities of such indurated fæces are eliminated in some cases. There is a variety or form of stercoraceous colic, in which the quantity of fæcal matter that is discharged is enormous; apparently far beyond the quantity that is taken into the stomach. These evacuations are in weight very light, and are probably formed into the large masses that are eliminated by an intestinal fermentation peculiar to the disease.

This species of colic requires powerful cathartics, as submuriate of mercury, colocynth, aloes, camboge, senna, and jalap; and these often in conjunction with purgative salts, as sulphate of soda and magnesia.

3. *Of the bilious colic.*

The pain is seldom continued, or so severe as in the purely spasmodic species; it is more transient, and is accompanied by constipation, nausea, and vomiting; and great relief is obtained by pressure on the belly. That which passes from the stomach is bilious; and, when the bowels are opened, the fæcal discharge is very bilious, and the fæces often very dark coloured and offensive.

The remedies for this kind of colic are submuriate of mercury, with colocynth, aloetic and saline purges in active doses, and the use of fomentations.

4. *Of the flatulent colic.*

The colic pains are here accompanied by costiveness and collections of gas, which distend the bowels irregularly, and cause a rumbling noise. It is often produced by crude and flatulent fruits, by depressing passions of the mind, and long fasting. Those who are subject to it, as many women are as they advance in life, have it easily produced by flatulent vegetables and slops, as spinach, and all the oleraceous tribe, weak tea, gruels, and the like. It is often accompanied by great costiveness, from the spasmodic actions, which extend irregularly, and in a greater or less degree, through the whole of the intestinal canal, and considerably add to the torture, and produce tumefaction and tenderness of the belly.

In attending to the means of cure, we may here proceed with some degree of boldness, since, notwithstanding the degree of pain, it is not often that inflammation is to be apprehended, at least in the commencement; and hence the warmest carminates, and even brandy, may be had recourse to; for whatever will carry off the flatulency will carry off the pain and costiveness. A full dose of pure tincture of rhubarb is here an excellent medicine; and, if the bowels do not operate, the extractum colocynthidis compositum, with essential oil of cloves, cinnamon, cassia, peppermint, or carraway, are best calculated to answer the intention. Fomentations, the warm bath, and warm embrocations will assist, and also a carminative glyster of fennel, rue, and cumin: thus, —

R. Confectionis rutæ, ℥j.; aquæ carui, f. ℥x. Solve pro enemate tepide injiciendo.

R. Seminum fœniculi contusorum, ℥j.
Seminum carui contusorum, ʒij.
Aquæ ferventis, Oj.
Macera per horam deni cola, et adde
Spiritûs carui, f. ℥j. Fiat enema, tepide utatur.

5. *Of the accidental colic.*

This is produced by indigestible foods and poisons. It is characterised by pains about the navel, costiveness, perhaps vomiting, which cease when the bowels are unloaded of their undigested contents, which are mostly salted meats, pork, salmon, and high gravies.

6. *Of the colica pictonum.*

This is called from the place where it is endemial, the Poictou, the Surinam, the Devonshire colic; from its victims, the plumber's and the painter's colic; from its symptoms, the dry bellyache. It has been attributed to the poison of lead; and this is undoubtedly the cause when it occurs to glaziers, painters, and those employed in lead-works, but, though this is one, it is by no means the only cause. In Devonshire, it certainly arises more frequently from the early cider, made of harsh unripe fruit, and in the West Indies from new rum. The characteristics of this disease are obstinate costiveness, with a vomiting of an acrid or porraceous bile, pains about the region of the navel, shooting from thence to each side with excessive violence, strong convulsive spasms in the intestines, and a tendency to a paralysis of the extremities. Its accessory causes are long continued costiveness; an accumulation of acrid bile; cold applied either to the extremities, or to the belly itself; a free use of unripe fruits, and great irregularity in the mode of living. From its occurring frequently in Devonshire, and other cider countries, it has been supposed to arise from an impregnation of lead, received into the stomach along with that beverage; but it is also a very prevalent disease in the West Indies, where no cider is made, and where there is only a very small quantity of lead in the mills employed to extract the juice from the sugar-canes. The truth is, the cause of the endemic prevalence of this disease in certain districts is entirely unknown.

The disease comes on gradually, with a pain at the pit of the stomach, extending downwards to the intestines, accompanied with eructations, slight sickness at the stomach, thirst, anxiety, obstinate costiveness, and a quick contracted pulse. After a short time, the pains increase considerably in violence; the whole region of the belly is highly painful to the touch; the muscles of the abdomen are contracted into hard irregular knots or lumps; the intestines themselves exhibit symptoms of violent spasm, insomuch that a glyster can hardly be injected, from the powerful contraction of the sphincter

ani; and there is constant restlessness, with a frequent vomiting of an acrid or porraceous matter, but more particularly after taking either food or medicine.

Upon a farther increase of the symptoms, or their not being quickly alleviated, the spasms become more frequent, as well as violent; the costiveness proves invincible, and an inflammation of the intestines ensues, which soon destroys the patient by gangrene. In an advanced stage of the disease, it is no uncommon occurrence for dysuria to take place, in a very high degree.

The dry bellyache is always attended with some degree of danger; but which is ever in proportion to the violence of the symptoms, and the duration of the disease. Even when it does not prove fatal, it is too apt to terminate in palsy, and to leave behind it contractions of the hands and feet, with an inability in their muscles to perform their office; and in this miserable state of existence the patient lingers out many wretched years.

The medical treatment of this species is nearly the same with that of spasmodic colic; but the narcotics should always be combined with castor oil, purgatives, fomentations, and soothing clysters. After the free evacuation of the bowels, there is nothing better than oleaginous aperients, in combination with small doses of opium, if the pain has not vanished and assumes a spasmodic character.

Peritoneal inflammation is more apt to accompany this than the other species; and when this is apprehended, from the continued pain in the abdomen and general tenderness, the lancet and baths must be resorted to.

A very common effect of colic from lead, whether taken into the stomach by painters, plumbers, or lead manufacturers, in the way of their business, from improper attention to cleanliness, or taken by others in cider, white wines, or other ways, is a subparalytic state of the fingers and hands. This remains for a long time, but often yields at last to the internal treatment, and topical stimulants, applicable to local palsy.

Colic is frequently a symptomatic affection, occurring in most organic diseases of the abdominal viscera, especially strictures, and when abscesses, or cysts, expel their contents into the bowels. It arises also from the irritation of worms, and biliary calculi.

The colic is distinguished from inflammation of the intestines by the pain being *wringing*, and not of a burning kind; by the *spasmodic contraction* of the abdominal muscles; by the *absence* or *trifling* degree of fever; by the *state* of the pulse; and by the pain being relieved by pressure, which increases it in enteritis. Inflammation, however, is not unfrequently superadded to colic, and this is known by the pain becoming fixed and permanent, the abdomen tender on pressure, and the pulse quick and feverish.

The colic should be distinguished from a fit of the gravel; stones passing through the ureters; rheumatic pains in the muscles of the belly; a beginning dysentery; the blind piles; and from a stone passing through the gall-duct. Gravel in the kidneys often produces pains, not easily distinguishable from colic; but when stones pass through the ureters, the testicle on that side is often retracted, the leg is benumbed, a pain shoots down the inside of the thigh; symptoms occasioned by the stone passing through the ureter over the spermatic chord, or the sacro-sciatic nerve. Rheumatic pains in the muscles of the belly, rarely affect so accurately the umbilical region, but dart in various directions to the chest, or to the pelvis, and are attended with soreness, not confined to the abdomen. A beginning dysentery differs little from colic. The pain from the blind piles is confined to the rectum; and that from a stone in the gall-duct is felt in the pit of the stomach, occasionally shooting through the body to the back.

The great liability of this complaint to return, renders it necessary, for some time after, carefully to regulate the diet, to attend to the state of the bowels, as well as of the liver, to avoid the several causes, especially cold, maintaining the functions of the skin by suitable clothing, exercise, &c.

Colica dextra. A branch of the superior mesenteric artery, distributed to the ascending portion of the colon — *arteria colica dextra;* there is a corresponding vein called *vena colica dextra.*

Colica media. A branch of the superior mesenteric artery which supplies the transverse arch of the colon — *arteria colica media.*

Colica pictonum. See *Colica.*

Colica sinistra. A branch of the inferior mesenteric artery distributed to the left side and sigmoid flexure of the colon — *arteria colica sinistra;* the corresponding vein is called vena colica sinistra.

Co'lice. The colic.

Colifo'rmis. (From *cola*, a strainer, and *forma*, resemblance; so called from its having many perforations, like a strainer.) Strainer-like, or resembling a strainer. The ethmoid bone has been called *os coliforme.*

Coli'phium. *Colliphium.* A kind of fine wheaten bread, given to wrestlers.

Collis. See *Coles.*

Coli'tis. Inflammation of the mucous membrane of the colon. — *Broussais.*

Colla piscium. See *Ichthiocolla.*

COLLA'PSUS. (From *collabor*, to shrink down.) Collapse. An entire prostration of the vital powers, such as occurs in adynamic fever, pestilential cholera, &c.

Colla're miserico'rdiæ. A kind of bandage, formerly used to assist in securing the patient during the operation of lithotomy.

Collate'nna. A vulnerary specific, mentioned by Paracelsus.

Collati'tium. The flesh of a chicken, or a capon, boiled or roasted, pounded in a mortar, mixed with broth made of wether mutton, and flavoured with verjuice or lemon juice. It was used as a diet for the sick. — *Blancard.*

Colle'ticus. (From κολλα, glue.) Conglutinating.

Colli'ciæ. (From *colligo*, to collect.) The union of the ducts, which convey the tears from the puncta lachrymalia to the cavity of the nose.

COLLI'CULUS. (Diminutive of *collis*, a hill.) A term applied in anatomy to several small eminences.

COLLICULUS NERVI ÆTHMOIDALIS. The *corpus striatum*.

COLLICULUS NERVI OPTICI. The *optic thalamus*.

COLLIGA'MEN. (*en, inis.* n.; from *colligo*, to tie together.) A ligament.

COLLIQUAME'NTUM. (*um, i.* n.; from *colliqueo*, to melt.) The pellucid fluid in which the first rudiments of the embryo are formed. — *Harvey.*

COLLI'QUATIVE. (*Colliquativus*; from *colliqueo*, to melt.) A term applied to any excessive evacuation, which rapidly wastes the frame: thus we speak of *colliquative perspiration*, *colliquative diarrhœa*, &c.

COLLI'SUS. (From *collido*, to knock together.) Contused; *collisa vulnera*, contused wounds. See *Vulnus.*

COLLI'SIO. (*o, onis.* f.; from *collido*, to knock together.) In medical language, a contusion.

CO'LLIX. Κολλιξ. A pastil, troch, or lozenge. Also a kind of bread.

CO'LLUM. (*um, i.* n.) The neck, or properly its anterior part, as opposed to *cervix*, the back part of the neck.

COLLU'TIO. (*o, onis.* f.) A washing; applied especially to gargling the mouth.

COLLUTO'RIUM. (*um, i.* n.; from *colluo*, to wash.) A gargarism, or a wash for the mouth.

CO'LLYRA. (*a, æ.* f.; from κολλυρα, a little round cake: so called from its likeness to a cake.) *Collyris.* A bump, or knob, which rises after a blow.

COLLY'RIUM. (*um, ii.* n.; from κωλυω, to check, and ῥεω, to flow, because it stops defluxions.) The more ancient Greek writers, as Hippocrates and Galen, used this term to designate a kind of balanus, or suppository, of whatever composition, which was introduced into the anus, uterus, nose, ear, &c.; they also applied it to a solid or liquid medicament for the eyes. The later Greek and Roman writers use it in the latter sense only: in the modern language of medicine it is restricted to liquid applications for the eyes, or *eye-waters.*

COLOBO'MA. Κολοβωμα. 1. A deficiency of any part of the body. — *Galen.*

2. The term has been particularly applied by some modern authors to congenital fissures of the upper eyelids, iris, choroid coat, or retina.

COLOCA'SIA. Κολοκασια. See *Nymphæa nelumbo.*

COLOCY'NTHIS. (*is, idis.* f.; κολοκυνθις; from κολοκυνθα, a gourd.) See *Cucumis colocynthis.*

Colombo. See *Calumba.*

CO'LON. (*on, i* n. Κωλον, quasi κοιλον; from κοιλος, hollow: so named, from its capacity.) The greater portion of the large intestine so called. See *Intestine.*

COLOPHO'NIA. (*a, æ.* f. Κολοφωνια; from Κολοφων, the city whence it was first brought.) *Pix Græca. Resina nigra.* Colophony. The dark-coloured resin which remains in the retort after distilling rough turpentine without water.

Galen mentions another kind of colophony, from Chio, which was a soft kind of mastiche — most likely the same substance with our Chian turpentine.

Coloquintida. See *Cucumis colocynthis.*

COLORA'TUS. Coloured: applied to a leaf, calyx, seed, &c., to express any colour besides green, as in *Arum bicolor*; or to any part thereof when of another colour than green, as in *Amaranthus tricolor.*

COLO'STRUM. (*um, i.* n.) 1. A name given by the Romans to the first milk secreted in the breasts after childbirth. The word was also used as an expression of endearment, in which sense it occurs in Plautus. The derivation is not known: some derive it from κολον, food, but this is not likely, because the Greek word for the colostrum is τροφαλις, from τρεφω, to nourish; and, if the Latins had borrowed their word from the Greek, they would probably have adopted the Greek word, or taken it from the same root. Others derive colostrum from κολλᾶμαι, to glue together; the only objection to which is, that the fluid in question is not in the least glutinous, but quite thin and serous. It was thought by the Romans to be unwholesome, for Pliny speaks of a disease called *collostratio*, arising from sucking this milk, and children suffering under this affection were called *collostrati infantes.* It has been a general belief, and is so at the present time, that this early milk is purgative, and destined to carry off the meconium; an opinion which rests on no sufficient evidence, and is probably erroneous.

2. An emulsion prepared with turpentine and yolk of egg.

COLOUR. (*Color* vel *colos, oris.* m.) A correct nomenclature of colours, one which would express all their compound tints and shades, has been long wanted. Some naturalists have proposed to ground one on the colours of minerals, which change less than other substances do; and others have formed one from the colours of the most familiar plants.

The primary colours were considered by Sir Isaac Newton as seven; *red*, *orange*, *yellow*, *green*, *blue*, *indigo*, and *violet.* Dr. Wollaston reduces them to four; *red*, *green*, *blue*, and *violet.* The following is the nomenclature of colours generally adopted by modern naturalists: —

1. *Æruginosus.* Æruginous: a bluish green, like verdigris, or the leaves of some pine trees.
2. *Albidus.* A stone colour.
3. *Albus.* White.
4. *Atrovirens.* Dark green.
5. *Ater.* Deepest black.
6. *Atropurpureus.* Very dark reddish purple; as in the *Scabiosa atropurpurea.*
7. *Atrorubens.* Dark red; as in the *Amaranthus hypochondriacus.*
8. *Aurantiacus.* Orange colour; as the flowers of the marigold and nasturtium.
9. *Aureus.* Golden yellow; as that of the dandelion and sunflower.
10. *Azureus.* Azure blue; like ultramarine. This colour is brighter than *cæruleus.* The

pure light blue flowers of the *Cynoglossum omphalodes* are a good example.

11. *Badius.* Nearly the same as liver colour, but browner.

12. *Brunneus.* A deep dark brown.

13. *Cæsius.* A dull, light, blue grey.

14. *Castaneus.* Chesnut; a sort of orange brown.

15. *Carneus.* A flesh colour; as the pale blossom of the *Hesperis matronalis.*

16. *Cinereus.* Ash colour.

17. *Cinnabarinus.* Like red lead, or cinnabar, and the gay light red of the *Papaver orientalis.*

18. *Coccineus.* High crimson, or bright scarlet; as the flower of the *Salvia coccinea.*

19. *Cæruleus.* Sky blue; like the flower of borage, and the *Veronica chamædrys.*

20. *Croceus.* Deep yellow.

21. *Cyaneus.* Deep blue, like Prussian blue; as the flower of the *Gentiana acaulis.*

22. *Flavovirens.* Yellowish green.

23. *Flavus.* Yellow; as in the early daffodil.

24. *Flavescens.* Yellowish, or pale whitish yellow.

25. *Ferrugineus.* Yellowish brown; as the rust of iron.

26. *Fuscus.* Greyish brown.

27. *Glaucus.* Sea-green, bordering on grey.

28. *Griseus* Lively grey, and, when hoary, *canus.*

29. *Hepaticus.* Liver coloured.

30. *Hyalinus.* Transparent, and like glass.

31. *Lacteus.* Milk white.

32. *Liliacinus.* Lilac; as in the *Syringa vulgaris.*

33. *Lividus.* Dark greyish violet.

34. *Luteus.* A deep yellow; as the outside of the petals of saffron, and the flower of the *Cystus helianthemum.*

35. *Miniatus.* Dull red.

36. *Niger.* Black.

37. *Ochraceous.* Yellow, striped with brown; like yellow ochre, or the feathers on the upper parts of the *Strix flammula,* or white owl.

38. *Olivaceus.* Olive colour.

39. *Phœniceus.* Crimson; as the flower of the *Pæony.*

40. *Puniceus.* Fine bright red or carmine; as in *Lobelia fulgens.*

41. *Purpureus.* Purple.

42. *Prasinus.* Grass green; like the colour of the fresh meadows, before there is any mixture of yellow or other colours.

43. *Ruber.* Red.

44. *Rufus.* Carrot colour, or brownish-red orange.

45. *Roseus.* Rose colour, or red pink: *pallide roseus,* pale pink.

46. *Sanguineus.* Blood colour.

47. *Smaragdus.* Pure green.

48. *Sulphureus.* Bright but pale yellow, without the slightest orange tinge.

49. *Violaceus.* Violet, or deep bluish purple; as in *Viola odorata.*

50. *Vitellinus.* Yellow, verging to orange; as in pale marigold.

Coloured leaf. See *Leaf.*

Colpoce'le. (*e, es.* f.; from κολπος, the vagina, and κηλη, a tumour.) A hernia, o tumour, situated in the vagina. See *Hernia vaginalis.*

Colpopto'sis. (*is, is.* f.; from κολπος, the vagina, and πιπτω, to fall down.) A prolapsus, or falling down, of the vagina.

Colt's-foot. See *Tussilago.*

Co'luber. See *Vipera.*

Colubrina virginiana. See *Aristolochia serpentaria.*

Colubri'num lignum. This name has been given to a variety of woods, supposed, in the countries which produce them, to be specific against the bite of serpents. See *Dracontium pertusum, Rhamnus colubrinus,* and *Strychnos colubria.*

Co'lum. (*um, i.* n.; a filter, or strainer.) The secretory organs of the living body have been called *cola,* or strainers.

COLU'MBA. 1. The name of a plant. See *Calumba.*

2. The name of a genus of birds, the dove, the flesh of which is eaten indifferently with the common pigeon.

Colu'mbate. (*Columbas, atis.* f.) A salt, formed by the union of the columbic acid with a base.

Colu'mbic acid. *Acidum columbicum.* An acid obtained from the ore of *columbium.* Neither the acid nor its salts are used in medicine.

Columbine. See *Aquilegia.*

COLU'MBIUM. (*um, i.* n.) A metal, so called, because it was found by Mr. Hatchett in a mineral brought from North America. The mineral discovered by M. Ekeberg in the ores of tantalum, and called by him *tantalite,* has been ascertained by Dr. Wollaston to be identical with columbium.

COLUME'LLA. (*a, æ.* f.; diminutive of *columna,* a column.) 1. A column or little pillar.

2. The central column, or filament, which unites the partitions of the capsule of plants. The seeds are usually attached to it.

Columella'res dentes. The canine teeth: so called from their shape. — *Varro.*

COLU'MNA. (*a, æ.* f.) A column, or pillar. Many parts of the body, which in their shape or office resemble columns, are so named; as *columnæ carneæ* of the heart.

Columnæ carneæ. See *Heart.*

Columna nasi. The fleshy part of the nose, which forms the termination of the septum.

Columna oris. The uvula.

Columnæ rectæ morgagni. The longitudinal plicæ of the rectum.

Columna vertebralis. The vertebral column. See *Vertebræ.*

COLUMNI'FERÆ. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of plants, the stamina and pistil of which have the appearance of a pillar in the centre of the flower.

Columni'lla. See *Columnula.*

COLU'MNULA. (*a, æ.* f.) A little column. The name given by botanists to the filament which passes through the middle of the capsule of frondose mosses, to which the seeds are connected; also called *Sphrongidium.*

COLU'TEA. The name of a genus of plants of the Class *Diadelphia*, and Order *Decandria*.

COLUTEA ARBORESCENS. The bladder senna, or bastard senna, the leaves of which are laxative, and sometimes fraudulently mixed with those of true senna.

Colytea. See *Colutea.*

COLY'MBADES. Κολυμβαδες. A kind of olive mentioned by Dioscorides. It was bruised, and applied to burns to prevent vesication.

CO'MA. (*a, atis.* n.; from κω, for κειμαι, to lie down.) A morbid state resembling sound sleep, produced by compression of the brain and various other causes. Some authors make *carus* the most profound degree of morbid sleep, and *coma* a minor; but the term *coma* is now generally used to designate any state of morbid sleep from which the patient cannot be roused, or not without difficulty.

CO'MA. (*a, æ.* f.; a mane.) In *Botany*, 1. A comb or fasciculus of leaves on the top of a stem or stipe. It is said to be,

a. *Foliose*, when formed of leaves; as in *Bromelia ananas.*

b. *Frondose*, when proceeding from the frond at the apex of the stipe; as in *Palms.*

c. *Bracteal*, formed of floral leaves; as in *Lavendula stæchas.*

2. Gærtner applies this term to the feathery crown of seeds furnished with a capsule.

COMA SOMNOLENTUM. A state of profound and morbid sleep, when awakened from which the patient immediately relapses. See *Lethargus.*

Coma vigil. See *Agrypnocoma.*

Coma aurea. See *Chrysocoma.*

CO'MATA. (The plural of *coma.*) An order of the class *Neuroses* of Cullen's Nosology, embracing diseases that are characterised by a diminution of the powers of voluntary motion, with sleep, and torpor of the senses.

CO'MATOSE. *Comatosus.* Affected with coma.

COMBINATION, CHEMICAL. Chemical combination is the result of that kind of attraction which is usually denominated chemical affinity. The general laws of chemical combination have been explained in the article *Attraction.* It is there stated that some substances can combine with each other in all proportions; others in all proportions up to a certain mark, but no further; others again in only one proportion; and lastly, others in several proportions, but these proportions fixed and definite, so that the substances concerned cannot combine except in some one of them. From the observation of the two last mentioned modes of combination, have arisen the *doctrine of definite proportions*; the *doctrine of chemical equivalents*; and the *atomic theory.* Considerable difficulties have arisen to the student of chemistry from the atomic theory having been mixed up with, and considered inseparable from, the two former doctrines. Another source of perplexity has been the employment of the same term in several different acceptations. In order to divest the subject of these sources of obscurity we may observe — 1. That the doctrine of definite proportions is merely the general expression of certain facts concerning which there is no doubt; and the doctrine of chemical equivalents merely a practical inference from those facts: and that the validity of either is in no degree dependent on the truth of the atomic theory.

2. That the terms *atom, equivalent, proportion, atomic weight, combining weight, chemical equivalent, prime equivalent,* and *proportional,* are all used by different writers to signify *the same thing.*

We proceed to consider, —

I. The *Doctrine of Definite Proportions.* Sometimes, as observed above, two bodies can only combine in one proportion: thus one measure of chlorine gas, and one of hydrogen gas, unite to form hydrochloric acid; but they cannot, under any circumstances, be made to combine in any other proportion, or to form any other product.

In other instances two bodies can combine in several proportions: thus, 100 parts of manganese is known to unite with fourteen parts of oxygen, to form *protoxide of manganese;* with twenty-eight parts of oxygen, to form *sesquioxide of manganese;* with forty-two parts of oxygen, to form *peroxide of manganese;* with fifty-six parts of oxygen, to form *manganesic acid:* but these substances can only combine in some one of these four proportions, and can only constitute by their union some one of the substances above enumerated. Now, with respect to these instances in which two bodies combine in several proportions, a very important law has been observed, namely, that *whatever be the smallest quantity of one of the bodies which combines with a given quantity of the other, all the rest of the proportions in which it combines with it will be simple multiples of that smallest quantity:* thus, in the instance just cited, 14 being the number denoting the smallest quantity, 28 is a multiple of it by 2, 42 by 3, and 64 by 4. It sometimes happens that the several proportions are multiples of the smallest quantity by $1\frac{1}{2}$, $2\frac{1}{2}$, &c.: thus, twenty-eight parts of iron with eight of oxygen, form *protoxide of iron;* and with twelve of oxygen *peroxide of iron;* that is, the proportion of iron in the peroxide is a multiple by $1\frac{1}{2}$ of that in the protoxide, or in other words bears to it the ratio of 2 to 3.

The above law has been called the *law of multiples*, or of *multiple proportions.*

II. The *Doctrine of Chemical Equivalents.* The general law on which this doctrine rests is, that *whatever be the proportion by weight in which any one body combines with another, it preserves the same relative proportion in its combinations with all other bodies.* In order to illustrate this law it is necessary to fix on some substance as the standard. British chemists are generally agreed in adopting *hydrogen* as the standard, and making it represent *unity.* If we take the instance of water as one of the compounds of hydrogen, we find that this fluid consists of 11·1 hydrogen and 88·9 oxygen; then, taking hydrogen as unity 11·1 : 88·9 :: 1 : 8·009; or the hydrogen is to the oxygen very nearly as 1 to 8. We therefore set down 1 as the prime

equivalent of hydrogen, and 8 as that of oxygen. From these data we may easily arrive, by a series of comparisons, at the equivalent of any substance of which we have a known compound. Thus hydrochloric acid consists by weight of 1 hydrogen and 36 chlorine; 36, therefore, is the equivalent of chlorine. Again, soda consists of 25 oxygen and 75 sodium, but we have already the equivalent of oxygen as 8: now 25 : 75 :: 8 : 24; hence 24 is the equivalent of sodium. We have thus the equivalents of four substances; and, since these combine with other substances always in the same proportion, we can hence deduce the equivalents of those other substances, and so on without limit.

The great advantage of assuming hydrogen as an unit of comparison, arises from its being the lightest of known substances, whence the numbers representing the equivalents of other bodies are multiples of its equivalent, and may, for all ordinary purposes, be represented by whole numbers. Wollaston, Thomson, and Berzelius, however, have adopted *oxygen;* the first making it 10, the second 1, and the third 100. This discrepancy is much to be regretted. Dr. Wollaston has invented a scale of chemical equivalents on the principle of Gunter's scale, by which the equivalents of substances, the relative proportion of the ingredients of compound bodies, and other matters of interest to the theoretical and practical chemist, are immediately ascertained without the trouble of calculation. This instrument needs not to be described here, as it is in every body's hands, and will be much better understood by inspection. Before quitting the subject of chemical equivalents, it is proper to state that the term *equivalent* has been used in three senses. The most common, and that to which it ought to be entirely restricted, is that in which we have just considered it, namely, as meaning *that weight of a body which enters into combination with any other body, referred to a common standard.* Another sense in which it has been used, is to designate the comparative quantity of two bodies which are necessary to produce the same effect, as of two alkalis, to neutralise an acid. Lastly, the term equivalent has been used to signify the quantity of any body necessary for the complete decomposition of a compound.

III. *The Atomic Theory.* The law of definite proportions appears to have first suggested itself to Richter, of Berlin, about the year 1792. The law of multiple proportions was first announced by Mr. Higgins, in his "Comparative View of the Phlogistic and Antiphlogistic Theories" in 1789; in the same work, the general principle of the atomic theory is maintained. The merit of the full development and extensive application of this theory is, however, universally conceded to Mr. Dalton. The atomic theory is briefly this: — Combination is supposed to take place only between the *atoms* of bodies. When bodies combine only in one definite proportion, it is conceived that there are an equal number of atoms of each body; thus, when one part by weight of hydrogen combines with eight of oxygen, the *one* part of hydrogen contains exactly the same number of atoms as the *eight* parts of oxygen, and they combine atom to atom. When bodies unite in more than one definite proportion, *one* atom of the one body is united to *one* of the other in the first proportion, and to *two*, *three*, *four*, or more atoms, in the succeeding proportions. The atoms of different bodies differ in weight: thus, if a quantity of hydrogen weighing 1, contains as many atoms as a quantity of oxygen weighing 8, then each atom of oxygen must weigh eight times as much as an atom of hydrogen; and hence, also, if the relative weights of the atoms of bodies be referred to the same standard as those of their chemical equivalents, they will be represented by the same numbers, and the expression, *atomic weight,* becomes merely a theoretical synonyme of *equivalent*, or *combining proportion.*

The definite combinations of the atoms of bodies are called by Dalton, *binary*, when the bodies combine *one* atom to *one; ternary*, when they combine *one* atom to *two; quaternary*, when they combine one atom to *three*, and so on. In those cases in which *one* equivalent of one body unites with *one and a half, two and a half,* &c. of another, we have to get rid of the absurdity of *half an atom*, an atom being in its nature indivisible; in such cases, therefore, we multiply the proportionals by two, and it is presumed that we have *two* atoms combined with *three* or with *five*. Such are the principles of Dalton's atomic theory. Many arguments have been advanced for and against its truth, but into these it is not incumbent upon us to enter. The theory affords a happy illustration of the doctrine of definite proportions, and that of chemical equivalents: still, however, it is merely a theory; and, as before observed, the practical doctrines would stand, though the atomic theory were overthrown.

Comb-like. See *Pectinatus.*

COMBUSTIBLE. Susceptible of combustion. See *Combustion.*

COMBUSTION. (*Combustio;* from *comburo*, to burn.) 1. A burn, or scald. See *Burn.*

2. Burning. The process of decomposition by fire. Among the various operations of chemistry, none is of greater importance than combustion; and in proportion to its utility in the art, the necessity of thoroughly investigating its nature and mode of action becomes more obvious to the philosophical chemist.

Lavoisier's Theory is founded upon the absorbtion of oxygen by a combustible body.

Taking this for granted, it follows that combustion is only the play of affinity between oxygen, the matter of heat, and a combustible body.

When an *incombustible* body (a brick for instance) is heated, it undergoes no change, except an augmentation of bulk and temperature; and when left to itself, it soon regains its former state. But when a *combustible* body is heated to a certain degree, in the open air, it becomes on a sudden intensely hot, and at last emits a copious stream of caloric and light to the surrounding bodies. During this emission, the burning body gradually wastes away. It either disappears entirely, or its physical pro-

perties become totally altered. The principal change it suffers, is that of being no longer capable of combustion. If either of these phenomena, namely, the emission of heat and light, and the waste of substance, be wanting, we do not say that a body is undergoing combustion, or that it is burning. It follows, therefore, that every theory of combustion ought to explain the following facts: —

1. Why a burning body is consumed, and its individuality destroyed.

2. Why, during the progress of this alteration, heat and light are emitted.

For the elucidation of these objects, Lavoisier's theory has laid down the following laws: —

1. Combustion cannot take place without the presence of oxygen, and is more rapid in proportion to the quantity of this agent in contact with the inflamed body.

2. In every act of combustion, the oxygen present is consumed.

3. The weight of the products of every body after combustion corresponds with the weight of the body before combustion, *plus* that of the oxygen consumed.

4. The oxygen absorbed by the combustible body may be recovered from the compound formed, and the weight regained will be equal to the weight which disappeared during the combustion.

5. In every instance of combustion, light and heat, or fire, are liberated.

6. In a limited quantity of air, only a certain quantity of the combustible body can be burnt.

7. The air, wherein a body has been burnt, is rendered unfit for continuing combustion, or supporting animal life.

Though every case of combustion requires that light and heat should be evolved, yet this process is variously modified under different circumstances: hence the terms *ignition*, or glowing heat; *inflammation*, or accension; and *detonation*, or explosion.

Ignition takes place when the combustible body does not readily assume the aëriform state. Charcoal, pyrophorus, &c. furnish instances of this kind.

It seems as if the phenomenon of glowing was peculiar to those bodies which require a considerable quantity of caloric to become converted into the gaseous state.

The disengagement of caloric and light is rendered more evident to the senses in the act of *Inflammation*, or accension. Here the combustible substances are more easily converted into an elastic or aëriform state. Flame, therefore, consists of the inflammable matter in the act of combustion in the gaseous state. When all circumstances are favourable to the complete combustion of the products, the flame is perfect; if this is not the case, part of the combustible body, capable of being converted into the gaseous state, passes through the luminous flame unburnt, and exhibits the appearance of smoke. Soot, therefore, always indicates an imperfect combustion. Hence a common lamp smokes, an Argand's lamp yields no smoke.

This degree of combustion is very accurately exemplified in the

Flame of candles. — When a candle is first lighted, which must be done by the application of actual flame, a degree of heat is given to the wick, sufficient to destroy the affinity of its constituent parts; part of the tallow is instantly melted, volatilised, and burnt. As this is destroyed by combustion, another portion melts, rises, and supplies its place, and undergoes a like change. In this way combustion is maintained. The tallow is liquefied as it comes into the vicinity of the flame, and is, by the capillary attraction of the wick, drawn up to supply the place of what is burnt; the unmelted tallow, by this means, forms a kind of cup.

The congeries of capillary tubes which form the wick is black, because the charcoal of the cotton becomes predominant, the circumambient air is defended by the flame from oxydising it; it therefore remains, for a considerable time, in its natural state; but when the wick, by the continual consumption of tallow, becomes too long to support itself in a perpendicular position, its upper extremity projects nearly out of the cone of the flame, and there forms a support for an accumulation of soot, which is produced by the imperfect combustion. A candle, in this situation, affords scarcely one tenth of the light it can otherwise give; and tallow candles, on this account, require continual snuffing.

But if the candle be made of wax, the wick does not long occupy its place in the middle of the flame; its thinness makes it bend on one side, when its length is too great for its vertical position; its extremity comes then into contact with the air, and is completely burnt, or decomposed, except so much of it as is defended by the continual afflux of the melted wax. This small wick, therefore, performs the office of snuffing itself. The difficult fusibility of wax enables us to use a thinner wick for it than can be used for tallow, which is more fusible. But wax being a substance which contains much more oxygen than tallow or oil, the light it affords is not so luminous.

Detonation is an instantaneous combustion, accompanied with a loud report; it takes place in general when the compounds resulting from the union of two or more bodies occupy much more or less space than the substances did before their union; a great impulse is therefore given to the surrounding air, or else a vacuum is formed, and the air rushing in from all sides to fill it up is the cause of the report.

A mixture of oxygen and hydrogen gases detonates very loud. Gunpowder, fulminating gold, silver, and mercury; oxygenated muriate of potash; and various other explosive compounds, are capable of producing very loud detonations.

With respect to the disengagement of light and caloric. —

By the older chemists, it was universally supposed that the light and heat emitted during combustion, proceeded from the inflammable body; and this opinion would indeed appear unquestionable, while the composition of the atmosphere was imperfectly known. The burning body appeared luminous, and felt hot, and no other agent was supposed to be concerned;

the conclusion that the light and heat were evolved from the burning substance, was, therefore, unavoidable. But when the nature of the atmosphere was ascertained, and when it became evident that part of the air was absorbed during combustion, the former conclusion fell to the ground: for when two bodies exert a mutual action on each other, it becomes *à priori* equally probable that the products may be derived from either of them; consequently, the light and heat evolved might proceed either from the one or the other. Whether they proceed from the atmosphere, or from the combustible body, they must be separated at the part where the combination takes place; that is, upon the surface of the burning body itself; and consequently it appeared luminous and heated, while the air, being invisible, escaped observation.

When the laws of heat became known, at least when it was ascertained that bodies contain at the same temperature, and in equal quantities, either of mass or bulk, unequal quantities of heat, the conclusion became probable, that the caloric evolved in combustion proceeded rather from the oxygen gas of the atmosphere, than from the combustible body; since the former contains a much larger quantity than the latter. The caloric evolved was therefore supposed to be derived from the *condensation* of the oxygen gas in the new combination into which it entered.

Though *approaching* to the truth, this explanation is not strictly true. It is not merely from the oxygen gas being *condensed* that the caloric is evolved, because, in many cases of combustion, the product still exists in the gaseous state; and in others, the quantity of caloric evolved bears no proportion to the degree of condensation. Philosophers ascribed this to a change of capacity; for, in different bodies, the difference in the proportion of the capacities before and after combustion is by no means uniform; and hence the difference in the quantities of caloric extricated in various cases of combustion.

This being premised, it remains to explain the origin of the light emitted during combustion; for, although we take it for granted that the caloric is evolved from the oxygen gas, we cannot infer that the light has the same origin.

It is very probable that light is a constituent part of inflammable bodies; for it is frequently evolved in combinations when the oxygen is merely *transferred* from one inflammable substance to another. In those cases it must proceed from the inflammable body. The accension of oils by the affusion of acids, the combustion of metals in the same way, furnish instances of the kind.

It seems, therefore, probable that the light is derived from the inflammable substance; and that the oxygen, combining with the bases of these substances, disengages the light.

It may be concluded, then, that light enters into the composition of all combustible bodies; but as we are unable to separate the light, so as to obtain these bodies pure, we treat of them as simple bodies.

According to this theory, the combustion of phosphorus in oxygen gas, is, therefore, the effect of a double affinity. The basis of the oxygen gas unites with the phosphorus, to form phosphoric acid; and the light disengaged from the phosphorus, together with the heat of the oxygen gas, produces the vivid flame.

The quantity of light emitted by different bodies is supposed to depend on the quantity contained in them, and on the proportion in which it is united to caloric.

Such is the theory of combustion of Lavoisier, modified by Gren, Leonardi, and Richter.

Thomson's Theory. Though the preceding theory of combustion is simple and beautiful, it appears, from what we are now going to state, to be by no means completely satisfactory.

It has misled chemists, by confining the term combustion to the act of oxygenation, and considering that all bodies, during their combustion, combine with oxygen, without at the same time recollecting that this latter effect may take place without any of the phenomena usually attendant on combustion; and that, though certainly all combustion presupposes the combination of oxygen with a base, yet this combination may be, and repeatedly is, effected where no combustion can possibly take place. Nothing can be more evident than the difference which, in numberless instances, prevails between the act of oxygenation in bodies and that of combustion, inasmuch as neither the phenomena attending on, nor the results arising from them are the same. That a distinction, therefore, should be made between these processes is obvious; and it is on this account that Dr. Thomson has offered a theory, which considers this subject in a new point of view, and which bids fair to enable us to estimate the phenomena of combustion much better than has hitherto been done.

According to Dr. Thomson's theory, all the bodies concerned in combustion are either, — 1. *Combustibles.* — 2. *Supporters of Combustion.* — 3. *Incombustibles.*

1. Combustible bodies are those substances which are said, in common language, to *burn*. During the combustion, they appear to emit light and heat, and, at the same time, gradually waste away. When this change has reached its *maximum*, the process of combustion is at an end.

The class of combustibles is very numerous; but all the bodies belonging to it may be subdivided into three sets: namely, —

1. Simple combustibles. 2. Compound combustibles. 3. Combustible oxides, &c.

Simple Combustibles.

1. Sulphur.
2. Phosphorus.
3. Carbon.
4. Hydrogen gas.
5. All the metals.
6. Boron.

Compound Combustibles.

The *compound combustibles* consist of compounds, formed by the simple combustibles uniting together, and are of course much more numerous than the simple combustibles. They may be arranged under the five following heads: —

1. Sulphurets. 3. Carburets.
2. Phosphurets. 4. Alloys.
5. Sulphuretted, phosphuretted, and carburetted hydrogen.

The *combustible oxides* are either simple, having a single base, or compound, having more than one base. All the simple combustible oxides are, by combustion, converted into acids.

The compound combustible oxides are by far the most numerous.

II. The SUPPORTERS OF COMBUSTION are bodies which are not of themselves, strictly speaking, capable of undergoing combustion, but which are absolutely necessary for the process; for no combustible body can burn unless some one or other of them be present. Whenever they are excluded, combustion ceases. All the supporters of combustion known at present are oxygen, chlorine, iodine, and the compounds which these form with each other, and with azote.

There are, indeed, certain substances besides these, which possess nearly the same properties; these shall be afterwards enumerated under the title of *partial supporters*.

III. The INCOMBUSTIBLE BODIES are neither capable of undergoing combustion themselves, nor of supporting the combustion of those bodies that are: they are, therefore, not immediately connected with combustion; though most of them appear to be the results of that process. Azote, the alkalis, earths, &c. come under this division.

Some of the alkalis and earths possess certain properties in common with combustibles, and are capable of exhibiting phenomena somewhat analogous to combustion; which will be described afterwards, under the title of *semi-combustion*.

In every case of combustion there must, therefore, be present a *combustible* body, and a *supporter* of combustion. During combustion, the combustible always unites with the supporter. *It is this combination which occasions the apparent waste and alteration of the combustible.* The new compound thus formed is a *product of combustion*. Every product of combustion is either, 1. *an acid*, or, 2. *an oxide*, &c. It is true, indeed, that other bodies sometimes make their appearance during combustion, but these will be found, upon examination, not to be products, nor to have undergone combustion.

Thus one of the two characteristic marks which distinguish combustion, namely, the apparent *waste and alteration of the combustible body*, has been fully explained. For the explanation of it we are indebted to Lavoisier, as stated before.

But though the combination of the combustible with oxygen, or other supporter, be a constant part of combustion, yet the facility with which combustibles burn is not proportional to their apparent affinity for oxygen.

Phosphorus, for instance, burns more readily than charcoal; yet charcoal is capable of abstracting oxygen from phosphorus, and of course has a greater affinity for it. Some of the combustible oxides take fire more readily than some of the simple combustibles; alkohol, ether, and oils are exceedingly combustible, whereas all the metals require very high temperatures when the supporter is air.

This great combustibility of combustible oxides is probably owing to the weaker affinity by which their particles are united. Hence they are more easily separated than homogeneous particles, and of course combine more readily with oxygen; those simple combustibles which melt easily, or which are in the state of elastic fluids, are also very combustible, because the cohesion between their particles is easily overcome.

It is owing to the same inferiority in the cohesion of heterogeneous particles, that some of the compound supporters occasion combustion in circumstances when the combustibles would not be acted on by simple supporters.

Thus phosphorus burns in air at the common temperature; but it does not burn in oxygen gas, unless its temperature be raised. Thus, also, oils burn rapidly when mixed with nitric acid. Nitrous gas and nitrous oxide constitute exceptions to this rule.

None of the *products* of combustion are combustible, according to the definition of combustion here given. This want of combustibility is not owing to their being saturated with oxygen; for several of them are capable of combining with an *additional dose* of it. But, during this combination, no caloric or light is ever emitted; and the compound formed differs essentially from a *product* of combustion; for by this additional dose of oxygen, the *product* is converted into a *supporter*. *Hence we see that combustion ought not to be confounded with the combination of a body with oxygen*, as was done formerly.

Combustion, indeed, cannot take place without the combination of oxygen or other supporter; but oxygen may combine with bodies in different proportions without the phenomena of combustion; and the *product obtained* by combustion is capable of becoming converted into a *supporter* of *combustion*: for instance, if lead be melted, and kept so for some time, it becomes covered with a grey pellicle, or *oxide of lead*, a product consisting of oxygen and lead; but if this oxide is suffered to be heated longer, it absorbs an additional quantity of oxygen, and becomes converted into a yellow powder, called *yellow oxide of lead*. If this yellow oxide be again exposed to heat, it absorbs still more oxygen, and becomes converted into *red oxide of lead*. When the *supporters* thus formed by the combination of oxygen with *products*, are made to support combustion, they do not lose all their oxygen, but only the additional dose which constituted them supporters. Of course they are again reduced to their original state of products of combustion. Hence it follows, that they owe their properties as supporters, not to the *whole* of the oxygen which they contain, but to the *additional dose* which constituted them supporters. We may, therefore, call them *partial supporters*, indicating by the term that part only of their oxygen is capable of supporting combustion, and not the whole.

All the partial supporters with which we are acquainted, contain a metallic basis; for metallic

oxides are the only products at present known, capable of combining with an additional dose of oxygen. It is a circumstance highly deserving attention, that when metals are capable of combining with several doses of oxygen, the product, or oxide formed by combustion, is seldom or never that which contains a *maximum* of oxygen.

Thus it is evident that several of the products of combustion are capable of combining with oxygen. *The incombustibility of products, therefore, is not owing to their want of affinity for oxygen*, but to some other cause.

No product of combustion is capable of *supporting* combustion. This is not occasioned by any want of affinity to combustible bodies; for several of them are capable of combining with an additional dose of their basis. But by this combination, they *lose* their properties as products, and are converted into *combustibles*. The process, therefore, differs essentially from combustion. Thus phosphoric acid, a product of combustion, is capable of combining with an additional dose of phosphorus, and forming *phosphorous* acid, a combustible body. When this last acid is heated in contact with a supporter, it undergoes combustion; but it is only the additional dose of the combustible which burns, and the whole is converted into phosphoric acid. Hence we see that it is not the whole basis of these compounds which is combustible, but merely the additional dose. The compounds, therefore, formed by the union of a product and combustible, may be termed *partial combustibles*; indicating, by the name, that a part only of the base is capable of undergoing combustion. Since the products of combustion are capable of combining with oxygen, but never exhibit the phenomena of combustion, except when they are in the state of partial combustibles, combustible bodies must contain a substance which they lose in burning, and to which they owe their combustibility; for after they have lost it, they unite to oxygen *without* exhibiting the phenomena of combustion.

Though the products of combustion are not capable of supporting combustion, they not unfrequently part with their oxygen, just as supporters do, give it out to combustibles, and convert them into products; but, during this process, no heat nor light is ever evolved. Water, for instance, gives out its oxygen to iron, and converts it into the *black oxide*, a product. Thus we see that the oxygen of products is capable of converting combustibles into products, just as the oxygen of supporters; but during the combination of the last only, are heat and light emitted. The oxygen of supporters then contains something which the oxygen of products wants.

Whenever the whole of the oxygen is abstracted from products, the combustibility of their base is restored as completely as before combustion; but no substance is capable of abstracting the whole of the oxygene, except a *combustible*, or a *partial combustible*. Water, for instance, is a product of combustion, whose base is hydrogen. To restore the combustibility of the hydrogen, we have only to mix water with iron or zinc filings, and an acid: the metal is oxidised, and the hydrogen gas is evolved as combustible as ever. But no substance, except a combustible, is capable of separating hydrogen gas from water, by combining with its oxygen. Thus we see that combustibles are capable of restoring the combustibility of the bases of products; but they themselves lose their combustibility by the process, and are converted into products. Combustibility, therefore, may be thrown at pleasure from one body to another.

From these facts it is obvious, that the products of combustion may be formed without combustion; but in these cases a new combustible is always evolved. The process is merely an interchange of combustibility; for the combustible is converted into a product only by means of a product. Both the oxygen and the base of the product, having undergone combustion, have lost something which is essential to combustion. The process is merely a double decomposition. The product yields its oxygen to the combustible, while at the same time the combustible gives out something to the base of the product; the combustibility of that base then is restored by the loss of its oxygen, and by the restoration of something which it receives from the other combustible thus converted into a product.

There is, indeed, another method of forming the products of combustion without actual combustion in certain cases; but the phenomena are much more complicated. This method is to expose them to the action of some of the supporters dissolved in water; especially nitric acid. Thus most of the metallic oxides may be formed without combustion by the action of that acid on the metals. But, in that case, a new supporter is always evolved, namely, nitrous gas; ammonia, a new combustible, is also usually formed; and, not unfrequently, the *product* is converted into a *partial supporter*.

No *supporter* can be produced by combustion, or by any equivalent process. As several of the supporters consist of oxygen combined with a base, it follows, as a consequence, that oxygen may combine with a base without losing that ingredient which occasions combustion. The act of combination of oxygen with a base, therefore, is by no means the same with combustion. If we take a view of the different supporters, we shall find that all of them which can be obtained artificially are procured either from other supporters, or by the agency of electricity.

I. *Oxygen gas* may be procured from nitric acid, and from several of the partial supporters as the black oxide of manganese, the red oxide of lead and of mercury. The action of heat is always necessary; but the process is very different from combustion.

II. *Air*, as far as is known at present, cannot be formed artificially. The gas, indeed, which comes over during part of the usual distillation of nitrate of potash and sulphuric acid to obtain nitric acid resembles air very closely. But it is obtained from a supporter.

III. *Nitrous oxide* has hitherto been only procured from nitrous gas and nitric acid (i

nitrate of ammonia), both of which are supporters.

IV. *Nitrous gas* can only be procured by the decomposition of nitric acid, a supporter.

V. *Chlorine gas* can be formed by the action of muriatic acid on the black oxide of manganese, the red oxides of lead, iron, or mercury; all of which are partial supporters.

VI. *Nitric acid* is formed spontaneously upon the surface of the earth, by processes with which we are but imperfectly acquainted, but which certainly have no resemblance to combustion. Its oxygen is probably furnished by the *air*, which is a supporter; at least, it has been observed, that nitrogen and oxygen, at high temperatures, are capable of forming nitric acid.

This formation of nitric acid by means of electricity, has been considered as a combustion, but for what reason it is not easy to say: the substance acted upon is not a combustible with a supporter, but a supporter alone. Electricity is so far from being equivalent to combustion, that it sometimes acts in a manner diametrically opposite; *unburning*, if we may use the expression, a substance which has already undergone combustion, and converting a *product* into a *combustible* and a *supporter*. Thus it decomposes water, and converts it into oxygen and hydrogen gas; therefore it must be capable of supplying the substances which the oxygen and combustible lose when they combine by combustion, and form a product.

Several of the supporters and partial supporters are capable of combining with combustibles without undergoing decomposition, or exhibiting the phenomena of combustion. In this manner, the yellow oxide of gold combines with ammonia; the red oxide of mercury with oxalic acid; and oxymuriatic acid with ammonia. Thus also nitrate of potash may be combined, or, at least, intimately mixed with several combustible bodies, as in gunpowder, fulminating powder, &c. In all these compounds, the oxygen of the supporter and the combustible retain the ingredients which render them susceptible of combustion: hence the compound is still combustible. And in consequence of the intimate combination of the component parts, the least alteration is apt to destroy the equilibrium which subsists between them; the consequence is combustion, and the formation of a new compound. Hence these compounds burn with amazing facility, not only when heated, but when triturated, or struck smartly with a hammer. They have, therefore, received the name of *detonating* or *fulminating* bodies. Thus we have fulminating gold, fulminating mercury, fulminating powder, &c.

Such are the properties of the combustibles, the supporters, and the products; and such the phenomena which they exhibit when made to act upon each other.

If we compare together the *supporters* and the *products*, we shall find that they resemble each other in many respects. Both of them contain oxygen, or other supporter, as an essential constituent part: both are capable of converting combustibles into products; and several of both combine with combustibles and with additional doses of oxygen. But they differ from each other in their effects on combustibles. The former only produce combustion; whereas the products convert combustibles into products without combustion. Now, as the ultimate change produced upon combustibles by both these sets of bodies is the same, and as the substance which combines with the combustibles is in both cases the same, oxygen, for instance, we must conclude that this oxygen in the supporters contains something which the oxygen of the products wants, something which separates during the passage of the oxygen from the product to the combustible, and occasions the combustion, or emission of fire, which accompanies this passage. The oxygen of supporters then contains some ingredient which the oxygen of products wants. Many circumstances concur to render it probable that this ingredient is *caloric*.

The *combustibles* and the *products* also resemble each other. Both of them contain the same or a similar base; both frequently combine with combustibles, and likewise with oxygen; but they differ essentially in the phænomena which accompany their combination with oxygen. In the one case, *fire is emitted;* in the other, not. If we recollect that no substance but a combustible is capable of restoring combustibility to the base of a product, and that at its doing so it always loses its own combustibility; and, if we recollect farther, that the base of a product does not exhibit the phenomena of combustion, even when it combines with oxygen, we cannot avoid concluding, that all combustibles contain an ingredient which they lose when converted into products, and that this loss contributes to the fire which makes its appearance during the conversion. Many circumstances contribute to render it probable that this ingredient is *light*.

If we suppose that the oxygen of supporters contains caloric as an essential ingredient, and that light is a component part of all combustibles, the phenomena of combustion above enumerated, numerous and intricate as they are, admit of an easy and obvious explanation. The component parts of the oxygen of supporters are two; namely, 1. a base; 2. caloric. The component parts of combustibles are likewise two; namely, 1. a base; 2. light. During combustion, the base of the oxygen combines with the base of the combustible, and forms the product; while, at the same time, the caloric of the oxygen combines with the light of the combustible, and the compound flies off in the form of fire. Thus combustion is a double decomposition; the oxygen and combustible divide themselves each into two portions, which combine in pairs; the one compound is the *product*, and the other the *fire*, which escapes.

Hence the reason that the oxygen of products is unfit for combustion. It wants its caloric. Hence the reason that combustion does not take place when oxygen combines with products, or with the base or supporters. These bodies contain no light. The caloric of the oxygen of course is not separated, and no fire appears. And this oxygen, still retaining its caloric, is capable of producing combustion whenever a body is presented which contains light, and whose base

has an affinity for oxygen. Hence also the reason why a combustible alone can restore combustibility to the base of a product. In all such cases, a double decomposition takes place. The oxygen of the product combines with the base of the combustible, while the light of the combustible combines with the base of the product.

But the application of this theory to all the different phenomena described above, is so obvious, that it is needless to give any more examples. Let us rather inquire, with the author, into the evidences which can be brought forward in its support.

As caloric and light are always emitted during combustion, it follows that they must have previously existed in the combustible, the supporter, or in both.

That the oxygen of the supporters contains either one or both of these substances, follows incontrovertibly from a fact already mentioned, namely, that the oxygen of products will not support combustion, while that of supporters will. Hence the oxygen of supporters must contain something which the oxygen of the products wants, and this something must be caloric, or light, or both.

That the oxygen of some of the supporters at least contains caloric, as an ingredient, has been proved, in a satisfactory manner, by the experiments of Crawford, Lavoisier, and La Place. Thus the temperature of hot-blooded animals is maintained by the decomposition of *air*. Now if the oxygen of one supporter contains caloric, the same ingredient must exist in the oxygen of every supporter, because all of them are obviously in the same state. Hence we conclude that the oxygen of every supporter contains caloric as an essential ingredient.

The light emitted during combustion must either proceed from the combustible or the supporter. That it proceeds from the combustible must appear pretty obvious, if we recollect that the colour of the light emitted during combustion varies, and that this variation usually depends, not upon the supporter, but upon the combustible. Thus charcoal burns with a red flame, sulphur with a blue or violet, zinc with a greenish white, &c.

The formation of combustibles in plants obviously requires the presence and agency of light. The leaves of plants emit oxygen gas, when exposed to the sun's rays, but never in the shade, or in the dark.

Besides vegetation, we are acquainted with two other methods of *unburning* products, or of converting them into products and combustibles, by exposing them, in certain circumstances, to the agency of *fire*, or of *electricity*. The oxides of gold, mercury, &c. when heated to redness, are decomposed, oxygen gas is emitted, and the pure metal remains behind. In this case the necessary caloric and light must be furnished by the fire; a circumstance which explains why such reductions always require a red heat. When carbonic acid is made to pass repeatedly over red-hot charcoal, it combines with a portion of charcoal, and is converted into gaseous oxide of carbon. If this gas be a combustible oxide, the base of the carbonic acid and its oxygen must have been supplied with light and caloric from the fire; but if it be a *partial combustible*, it is merely a compound of carbonic acid and charcoal: which of the two it is, remains still to be ascertained.

Electricity decomposes water, and converts it into oxygen gas and hydrogen gas; it must, therefore, supply the heat and the light which these bodies lost when converted into a product.

These facts, together with the exact correspondence of the theory given above with the phenomena of combustion, render it so probable, that Dr. Thomson has ventured to propose it as an additional step towards a full explanation of the theory of combustion. Every additional experiment has served to confirm it more and more. It even throws light upon the curious experiments of the accension of metals with sulphur, which succeed *in vacuo*, under mercury, in nitrogen gas, &c.

Dr. Thomson has noticed, that the same emission of caloric and light, or of *fire*, takes place when melted sulphur is made to combine with potash, or with lime, in a crucible or glass tube, and likewise when melted phosphorus is made to combine with lime heated to redness. He supposes that, in all probability, barytes and strontia exhibit the same phenomenon when combined with melted sulphur or phosphorus; and perhaps some of the metals when combined with phosphorus.

The phenomena Dr. Thomson explains thus: — The sulphur and phosphorus are in the melted state, and therefore contain caloric as an ingredient; the alkalies, earths, and metals which produce the phenomenon in question, contain light as an essential ingredient. The sulphur, or phosphorus, combines with the base of the metal, earth, or alkali; while, at the same time, the *caloric*, to which the sulphur or phosphorus owed its fluidity, combines with the *light* of the metal, earth, or alkali; and the compound flies off under the form of *fire*.

Thus the process is exactly the same with combustion, excepting as far as regards the product. The melted sulphur, or phosphorus, acts the part of the *supporter*, while the metal, earth, or alkali, occupies the place of the *combustible*. The first furnishes caloric, the second light, while the base of each combines together. Hence we see that the base of sulphurets and phosphurets resembles the base of products in being destitute of light; the formation of these bodies exhibiting the separation of fire like *combustion*, but the product differing from a product of combustion in being destitute of oxygen, Dr. Thomson distinguishes the process by the title of *semi-combustion*; indicating by the term, that it possesses one half of the characteristic marks of combustion, but is destitute of the other half.

The only part of this theory which requires proof is, that light is a component part of the earths, and alkalis. But as potash and lime are the only bodies of that nature, which we are certain to be capable of exhibiting the phenomena of semi-combustion, the proofs must of necessity be confined to them. That *lime* contains light as a component part, has been long known. Meyer and Pelletier observed long ago, that

when water is poured upon lime, not only heat but light is emitted. Light is emitted also abundantly, when sulphuric acid is poured upon magnesia, or upon lime, potash, or soda, freed from the water of crystallisation. In all these cases, a *semi-combustion* takes place. The water and the acid being solidified, give out *caloric*, while the lime or potash gives out *light*.

That lime, during its burning, combines with light, and that light is a component part of lime, is demonstrated by the following experiment, for which we are indebted to Scheele: —

Fluor spar (fluate of lime) has the property of phosphorescing strongly when heated, but the experiment does not succeed twice with the same specimen. After it has been once heated sufficiently, no subsequent heat will cause it to phosphoresce. Now phosphorescence is merely the emission of light; light of course is a component part of fluor spar, and heat has the property of separating it. But the phosphorescing quality of the spar may be again recovered to it, or, which is the same thing, the light which the spar had lost may be restored by the following process: —

Decompose the fluate of lime by sulphuric acid, and preserve the fluoric acid separate. Boil the sulphate of lime thus formed with a sufficient quantity of carbonate of soda; a double decomposition takes place; sulphate of soda remains in solution, and carbonate of lime precipitates. Ignite this precipitate in a crucible, till it is reduced to lime, and combine it with the fluoric acid to which it was formerly united. The fluor spar, thus regenerated, phosphoresces as at first. Hence the lime, during its ignition, must have combined with light.

That potash contains light, may be proved in the same manner as the existence of that body in lime. Now as potash is deprived of its carbonic acid by lime, the doctor supposes that the process must be a double decomposition; namely, that the base of the lime combines with carbonic acid, while its light combines with the potash.

These remarks on semi-combustion might easily be much enlarged upon; for it is obvious, that whenever a liquid combines with a solid containing light, and the product is a solid body, something analogous to semi-combustion must take place.

Combustion, spontaneous. Every case in which combustion ensues from the chemical action of bodies on each other, without the direct application of fire, may be called an instance of spontaneous combustion; but the term is generally applied to the destruction of the human body by a process altogether peculiar in its phenomena and products, and which has been supposed, though in all probability erroneously, to arise without any extraneous cause of ignition. For some time the accounts given of this spontaneous combustion of the body were regarded with much incredulity. The number of cases now on record is, however, so considerable as to leave no doubt of the reality of some process of igneous decomposition commencing during life, under circumstances quite different from those of ordinary combustion from the application of fire. Little is distinctly known concerning these mysterious cases; for it is a remarkable fact, that, in no instance, has any witness been present at the precise moment when the patient took fire — the remains of the body only having been generally found after the fatal mischief had occurred: in one instance, indeed, quoted by Foderé and other writers from an Italian Journal, the individual, a priest named Bertholi, was found alive, and survived several days; but the account given by him throws no further light on the origin of the disaster than to render it probable that it was connected with some electrical cause.

What gives credibility to the accounts of this peculiar kind of combustion, is the fact that there are certain remarkable circumstances in which such of them as are respectably authenticated agree. It would appear from the observations hitherto made on this subject, — 1. That the individuals who have been consumed were habitually addicted to the use of alkoholic liquors. 2. That they have been generally advanced in years. 3. That they have most frequently been females. 4. That some burning substance has been found to have come in contact with the body, or to have been in the apartment at the time; or that there has been some reason to attribute the origin of the combustion to an electrical cause. 5. That the extremities have generally escaped the combustion. 6. That the clothes, or other combustible bodies about the person, have been little injured, and sometimes not at all; it has also been observed that, in some instances, the affusion of water, instead of extinguishing the flame, has increased its activity. 7. That the product of the combustion is peculiar, consisting of greasy, and very fetid ashes, the quantity of which is small compared with that of the animal matter decomposed.

The phenomenon in question is evidently quite distinct from common combustion. The flame does not seize upon ordinary combustible matters; it is not always extinguished by water; and it speedily reduces the body to ashes; whereas, it is well known, that to effect the incineration of a human body by ordinary combustion, is an exceedingly long and difficult process. The term *spontaneous combustion* does not appear to be properly applicable, since we have no evidence that the source of ignition has originated, in any instance, in the body itself: the case appears rather to be one of preternatural combustibility. We are entirely in the dark as to the real nature of the chemical changes which give rise to this state; but it seems reasonable to infer that they are, in some way or other, connected with the long continued use of alkohol.

Spontaneous combustion has been named *Catacausis* by Dr. Young; and Dr. Good has adopted the generic name, adding a specific one referring to its cause, and calling the disease, or rather catastrophe, *Catacausis ebriosa*.

Comedo'nes. (*Comedo*, a glutton.) A sort of worms which eat into the skin and devour the flesh. — *Turton*.

Comet. Half a drop. — *Ruland*.

Comfrey. See *Symphytum*.

Comisdi. The gum-arabic. — *James*.

COMITIA'LIS MORBUS. Epilepsy. So called because if any one were seized with this disease in the *comitia* or great assemblies of the people, the assembly was dissolved.

COMITISSÆ PULVIS. (*Comitissa, æ.* f.; a countess.) 1. The Peruvian bark was called *Pulvis comitissæ.* See *Cinchona.*

2. An old alexipharmic medicine, was called *Pulvis comitissæ de Cantia,* or *Pulvis Cantianus.* See *Cantianus pulvis.*

COMMAGE'NUM. (From *Comagena,* a district of Syria, whence it was brought.) A name given by Galen to a calefacient and relaxing ointment; called also Syriac ointment.

COMMANDUCA'TIO. (From *commanduco,* to eat.) The act of mastication, or chewing.

COMMA'NSUM. (From *con* and *mando,* to chew.) A masticatory. A medicine put into the mouth and chewed, to promote a discharge of saliva.

COMMELI'NEÆ. A natural family of plants, of which the genus *Commelina* is the type.

COMMI. Κομμι. The Greek for gum.

COMMINUTED. (*Comminutus,* from *comminuo,* to break down.) Broken into pieces: applied to fractures.

COMMISSU'RA. (*a, æ.* f.; from *committo,* to join together.) A juncture, or point of union. Applied, in *Anatomy,* to the corners of the lips, where they meet together; and also to certain parts of the brain, where its fibres cross and join one hemisphere to the other.

COMMISSURA ANTERIOR CEREBRI. The anterior commissure of the brain. See *Encephalos.*

COMMISSURA MAGNA CEREBRI. The *corpus callosum* of the brain. See *Encephalos.*

COMMISSURA POSTERIOR CEREBRI. The posterior commissure of the brain. See *Encephalos.*

COMMOTION. *Commotio.* Synonymous with concussion.

COMMU'NICANS. (From *communico,* to communicate.) A term applied by Bellini to intermittent fevers, wherein the paroxysms succeed each other so rapidly that one has no sooner ceased than another commences.

COMMUNICANS ARTERIA. The branch by which the posterior cerebral artery is connected on each of the bases of the brain with the internal carotid, is called the *arteria communicans.* The short transverse branch which connects the two anterior cerebral arteries, is sometimes called *arteria communicans anterior.*

COMPARATIVE ANATOMY. The anatomy of all organised bodies, whether animal or vegetable, compared with a view to illustrate the general principles of organisation. Comparative anatomy is the only true basis of physiology.

CO'MPEBA. Κομπεβα. Cubebs. — *Actuarius.*

CO'MPEPER. Κομπεπερ. Cubebs. — *Nic. Myrepsus.*

Complete. See *Perfect.*

COMPLEXION. In common language this term is applied merely to the colour of the face. See *Physiognomy.* But it is used by some writers to signify all the external and sensible peculiarities of an individual.

COMPLE'XUS. (From *complector,* to embrace.) *Complexus seu biventer cervicis* of Albinus. A muscle situated on each side of the back part of the neck. When one of the muscles only acts, it draws the head backwards and to one side. When both act, they draw the head directly backwards. It arises from the transverse processes of the seven superior vertebræ of the back, and four inferior of the neck, by as many distinct tendinous origins; in its ascent, it receives a fleshy slip from the spinous process of the first vertebra of the back; from these different origins it runs upwards, and is every where intermixed with tendinous fibres. It is inserted, tendinous and fleshy, into the inferior edge of the protuberance in the middle of the os occipitis, and into a part of the curved line that runs forward from that protuberance. It draws the head backwards.

Complexus minor. See *Trachelo-mastoideus.*

COMPLICATION. In medical language any disease which is co-existent with and modifies another without being in its nature inseparable from it, is called a complication.

COMPO'SITUS. Compound. Applied to that which is made up of two or more different things. It stands opposed to simple. In *Botany,* applied to leaves and flowers. See *Flos* and *Folium.*

Compound. See *Compositus.*

Compound affinity. See *Attraction.*

CO'MPRESS. (*Compressa, æ.* f.; from *comprimo,* to press together.) Soft linen, lint, or other substances, folded together into a sort of pad, for the purpose of being placed over parts which require pressure.

COMPRE'SSION. (*Compressio, onis.* f.; from *comprimo,* to press together.) A diseased state of the body, or of a part, the effect of something pressing upon it. *Compression of the brain* gives rise to symptoms which it is of great importance to distinguish from those of concussion and other morbid states. See *Concussion, Apoplexy,* and *Encephalitis.*

COMPRE'SSOR. (From *comprimo,* to press together.) A name given to those muscles which press together the parts on which they act. Also to a surgical instrument.

COMPRESSOR OF DUPUYTREN. *Compresseur de Dupuytren.* An instrument invented by M. Dupuytren for compressing the femoral artery. It consists of a semicircle of steel having a pad at each end, and which, pressing only upon the vessel and the opposite point of the thigh, has the advantage of not impeding the collateral circulation like the common tourniquet.

COMPRESSOR NARIS. *Rinæus vel nasalis* of Douglas. *Transversalis vel myrtiformis,* of Winslow. *Dilatores alarum nasi,* of Cowper. A muscle of the nose, that compresses the ala towards the septum nasi, particularly when we want to smell acutely. It also corrugates the nose, and assists in expressing certain passions. It arises, by a narrow beginning, from the root of the ala nasi externally and spreads into a number of thin separate fibres, which run up along the cartilage in an oblique manner towards the dorsum of the nose, where it joins with its fellow, and is inserted into the narrow extremity of the os nasi, and nasal process of the superior maxillary bone.

COMPRESSOR OF NUCK. *Constrictor of Nuck.*

An instrument invented by Nuck for compressing the urethra in cases of incontinence of urine.

COMPRESSOR PROSTATÆ. The anterior fibres of the levator ani, which embrace the prostate gland, are thus named by Albinus.

COMPRESSUS. Compressed; flattened laterally: applied to leaves. See *Leaf*.

COMPTO'NIA. A genus of plants. Class, *Monœcia*; Order, *Triandria*. It contains only one species, *C. Asplenifolius*, which grows in South America. Its leaves are used as an astringent against diarrhœa.

CONA'RIUM. (*um, ii.* n.; from κωνος: so named from its conical shape.) The Pineal gland.

CONCAU'SA. *Concaussa.* (From *con*, with, and *causa*, a cause.) A cause which co-operates with another in the production of a disease.

CO'NCAVUS. Concave; depressed in the middle. Applied to leaves, petals, &c. depressed in their centre, owing, as it were, to a tightness in some part of the circumference; as in *Cyanus nelumbo*, and the petals of the *Galanthus nivalis*.

CONCENTRA'NTIA. A name given by some writers to absorbents and ant-acids.

CONCENTRA'TION. (*Concentratio, onis.* f.; from *con*, and *centrum*, a centre.) The volatilisation of part of the water of fluids, in order to increase their strength. The matter to be concentrated, therefore, must be of greater fixity than water. This operation is performed on some acids, particularly the sulphuric and phosphoric, also on solutions of alkalis and neutral salts.

CONCE'NTRIC. *Concentricus.* Applied in botany to bulbs consisting of many layers one within the other: thus the bulb of the onion is a concentric bulb.

CONCEPTA'CULUM. (*um, i.* n.) The vessel which contains the reproductive corpuscles of cryptogamic plants. It is variously named in different tribes.

CONCE'PTION. (*Conceptio, onis.* f.; from *concipio*, to conceive.) Conceptus. The impregnation of the ovulum in the female ovarium, by the semen virile. See *Generation*.

CONCE'PTUS. The first rudiments of the fœtus have been so called by some writers. Others apply the term to the act of conception. See *Conceptio*.

CO'NCHA. (*a, æ.* f. Κογχη, a bivalve shell, as an oyster or scallop.) 1. A Greek measure of about half an ounce.

2. Applied in anatomy and natural history to various objects from their shape.

CONCHA AURIS. *Concha auriculæ.* The outer ear. See *Auris*.

Concha margaritifera. See *Avicula*, in the Supplement.

CONCHÆ NARIUM. The turbinated portion of the ethmoid bone, and the inferior spongy bones of the nose, which are covered by the Schneiderian membrane, have been so termed.

CONCHOI'DES. (From κογχη, a shell, and ειδος, resemblance.) Conchoid: shell-like.

CO'NCHUS. (*us, i.* m.; from κογχη, a shell: so named, from their likeness to a shell.) 1. The cranium.

2. The cavity of the eye.

CONCIDE'NTIA. (From *concido*, to fall down.) Synonymous with *Collapsus*, which see.

CONCOAGULA'TIO. (From *con*, and *coagulo*, to coagulate.) Coagulation, concretion, or crystallisation.

CONCO'CTION. (*Concoctio, onis.* f.; from *concoquo*, to digest.) Digestion. 1. The alteration which the food undergoes in the primæ viæ.

2. That operation of nature upon morbid matter which renders it fit to be separated from the healthy fluids.

CONCREMA'TIO. (From *con*, and *cremo*, to burn together.) Calcination.

CONCRE'TION. (*Concretio*; from *concresco*, to grow together.) 1. The growing together of parts which, in a natural state, are separate; as the fingers and toes.

2. The condensation of any fluid or other substance to a more solid consistence: hence bilious and urinary concretions.

Concretion, biliary. See *Calculus biliar.*

Concretion, intestinal. See *Enterolithus.*

CONCU'SSION. (*Concussio, onis.* f.; from *concutio*, to shake.) *Concussio cerebri.* Concussion of the brain. Various alarming symptoms, followed sometimes by the most fatal consequences, are found to attend great violence offered to the head; and upon the strictest examination, both of the living and the dead, neither fissure, fracture, nor extravasation of any kind can be discovered. The same symptoms, and the same events are met with, when the head has received no injury at all *ab externo*, but has only been violently shaken; nay, when only the body, or general frame, has seemed to have sustained the violence. The symptoms attending a concussion are generally in proportion to the degree of violence which the brain itself has sustained; and which, indeed, is cognisable only by the symptoms. If the concussion be very great, all sense and power of motion are immediately abolished, and death follows soon; but between this degree and that slight confusion (or stunning, as it is called,) which attends most violenses done to the head, there are many shades. The following is Abernethy's description of the symptoms of concussion, which he is of opinion may be divided into three stages: —

The *first* is that state of insensibility and derangement of the bodily powers which immediately succeeds the accident. While it lasts, the patient scarcely feels any injury that may be inflicted on him. His breathing is difficult, but in general without stertor; his pulse intermitting, and his extremities cold. But such a state cannot last long; it goes off gradually, and is succeeded by another, which is considered as the *second* stage of concussion. In this, the pulse and respiration become better; and though not regularly performed, are sufficient to maintain life, and to diffuse warmth over the extreme parts of the body. The feeling of the patient is now so far restored, that he is sensible if his skin be pinched; but he lies stupid and inattentive to slight external impressions. As the effects of concussion diminish, he becomes capable of replying to questions put to him in a loud tone of voice, especially when they refer to

his chief suffering at the time, as pain in the head, &c.; otherwise he answers incoherently, and as if his attention was occupied by something else. As long as the stupor remains, the inflammation of the brain seems to be moderate; but as the former abates, the latter seldom fails to increase; and this constitutes the *third* stage, which is the most important of the series of effects proceeding from a concussion.

These several stages vary considerably in their degree and duration; but more or less of each will be found to take place in every instance where the brain has been violently shaken. Whether they bear any certain proportion to each other or not, is not known; indeed this will depend upon such a variety of circumstances in the constitution, the injury, and the after-treatment, that it must be difficult to determine.

To distinguish between an extravasation and a concussion by the symptoms only, Mr. Pott says, is frequently a very difficult matter; sometimes an impossible one. The similarity of the effects, in some cases, and the very small space of time which may intervene between the going off of the one and accession of the other, render this a very nice exercise of the judgment. The first stunning or deprivation of sense, whether total or partial, may be from either, and no man can tell from which; but when these first symptoms have been removed, or have spontaneously disappeared, if such patient is again oppressed with drowsiness, or stupidity, or total or partial loss of sense, it then becomes probable that the first complaints were from concussion, and that the latter are from extravasation; and the greater the distance of time between the two, the greater is the probability not only that an extravasation is the cause, but that the extravasation is of the limpid kind, made gradatim, and within the brain.

Whoever seriously reflects on the nature of these two causes of evil within the cranium, and considers them as liable to frequent combination in the same subject, and at the same time considers that, in many instances, no degree of information can be obtained from the only person capable of giving it (the patient), will immediately be sensible how very difficult a part a practitioner has to act in many of these cases, and how very unjust it must be to call that ignorance which is only a just diffidence arising from the obscurity of the subject, and the absence of data on which to form a clear judgment.

Mr. Abernethy observes, that in cases of simple concussion, the insensibility is not so great as where compression exists, the pupils are more contracted, the muscles less relaxed, little or no stertor attends, but the pulse is very intermitting, and in slight cases there is often considerable sickness.

Very different modes of treating these accidents have been practised, and no doubt the same means should not be pursued indiscriminately. Much must depend on the state of the patient when he received the injury, the degree of this, the time which has elapsed since, and other circumstances. Abernethy considers, that in the first stage little should be done; that the stimulants often employed may be even injurious; but more especially so in the second stage, increasing the tendency to inflammation; and where this has come on, that the antiphlogistic plan must be actively pursued. However, a moderate abstraction of blood, general or topical, will be commonly proper at first, where the habit will allow it, as congestion may be suspected, and to obviate inflammation, especially where the person was intoxicated at the time of the accident; and the effect of this measure may influence the subsequent treatment. If the pulse rise after it, and the patient become more sensible, we should be led to pursue the evacuating plan, taking perhaps more blood, exhibiting active cathartics, as the bowels will be found very torpid, applying cold lotions to the head, &c. These means, however, will be especially called for, when marks of inflammation appear. Sometimes brisk emetics have been very beneficial, as sulphate of zinc, &c.: they are particularly recommended, where the person was under the influence of anger, or the stomach full, when the accident happened; but they are liable to objection, where there are marks of congestion, or increased action in the vessels of the head. If bleeding should lower the pulse, and render the patient worse, evacuations must not be pursued; it may be better generally to wait the gradual return of sensibility, unless the torpor be alarming, and resemble syncope; in which case, or if it continue very long, stimulants appear warrantable, as ammonia, or others of transient operation, with a blister to the head, to restore some degree of sensibility. If in the sequel marks of irritation appear, as spasms or convulsions, opium joined with antimony, or in the form of Dover's powder, will probably be useful, the necessary evacuations being premised, and the warm bath. In all cases the head should be kept quiet; as the patient is convalescent, tonics and the shower-bath may be employed with advantage; and it will be particularly necessary to avoid great bodily exertion, stimulating liquors, &c. Should paralytic symptoms remain, stimulants general or local may be required.

Condensa'ntia. Medicines were so called which were supposed to possess the power of thickening the humours of the body.

CONDENSA'TION. (*Condensatio, onis*; from *condenso*, to make thick.) The approximation of the particles of which a substance is composed, so that a given weight of it occupies less space than before. In *anatomy* and *pathology*, this term is applied to the texture of parts when it is denser or more solid than is usual in other parts: thus we speak of condensation of the cellular membrane; of the parenchyma of a viscus, &c. In chemistry the condensation of bodies gives rise to various remarkable phenomena. See *Caloric* and *Gas*.

CONDIME'NTUM. (*um*, *i.* n.; from *condio*, to season.) Condiment. A spice, pickle or other material used to season articles of food.

Co'nditum. An old name applied generally to any article of diet or medicine, rendered grateful by the addition of spices.

Conditu'ra. (*a*, *æ*. f.;) 1. The same a

ondimentum. 2. The embalming of a dead ody. See *Embalming*.

CONDU'CTIO. (From *Conduco*, to draw along.) A spasm or convulsion. *Cælius Aurelianus.*

CONDU'CTOR. (*or, oris.* m.; from *conduco*, to lead or guide.) 1. In *Surgery*, an nstrument, the use of which is to direct the nife in certain operations. It is more commonly called a director. 2. In *Electricity*. A ody which has the property of transmitting the lectric energy, as opposed to a *non-conductor*, body which has not that property. See *Electricity*.

CONDUPLICA'TUS. Folded or doubled ogether. Applied to leaves which are doubled ongitudinally so that the margins are applied atly to each other; as in *Roscæa purpurea*, nd the bases of sword-shaped leaves. See *Leaf*.

CO'NDYLE. (*Condylus.* Κονδυλος, the joint of finger, a tubercle or knot.) A process of a bone n the shape of a flattened head or eminence.

CONDYLOID PROCESS. A condyle. See *Condyle*.

CONDYLO'MA. (*a, atis*, n.; Κονδυλωμα; om κονδυλος, a tubercle or knot.) A soft, art-like excrescence, that appears about the nus and pudenda. There are several species f condylomata, which have received names om their appearance; as *ficus*, *crista*, *thymus*, om their resemblance to a fig, &c.

Cone. See *Strobilus*.

Co'NEINE. CICUTINE. The active principle f the *Conium maculatum*. It is alkaline, but s properties have yet been little investigated. Half a grain produces headach and slight vergo.

Conei'on. See *Conium*.

Cone'ssi cortex. See *Nerium*.

CONFE'CTIO. (*onis*, f.; from *conficio*, to make up.) A confection. In general it means ny thing made up with sugar. The term, in he later London Pharmacopœias, includes those rticles which were formerly called electuaries nd conserves, between which there appears to e no sufficient ground of distinction.

Confectio alkermes. See *Alkermes*.

CONFECTIO AMYGDALARUM. Confection of monds. Take of sweet almonds, eight ounces; cacia gum powdered, an ounce; refined sugar, our ounces. The almonds having been previously macerated in water, and their external oat removed, beat the whole together, until ey are thoroughly incorporated. It has been bjected to the almond mixture, which is an rticle of very general use, that it requires conderable time for its extemporaneous preparion, and that it spoils and cannot be kept when is made: this is obviated by the confection, hich will keep for a considerable length of me, and can be immediately rubbed down with ater into an almond mixture.

CONFECTIO AROMATICA. This preparation was rmerly called *Confectio cardiaca*, and *Confec- Raleighana*. Take of cinnamon bark, nutegs, of each two ounces; cloves, an ounce; rdamom seeds, half an ounce; saffron dried, vo ounces; prepared chalk, sixteen ounces; fined sugar powdered, two pounds; water, a nt. Reduce the dry substances, mixed toether, to very fine powder; then add the water gradually, and mix the whole, until it is incorporated. This preparation is now much simplified by the London college. It is an excellent medicine, possessing stimulant, antispasmodic, and astringent virtues; and is exhibited with these views to children and adults, mixed with other medicines. It may be given in doses of from 10 grs. to a drachm.

CONFECTIO AURANTII. *Confectio Aurantiorum. Conserva flavedinis aurantiorum. Conserva corticis exterioris aurantii hispalensis. Conserva flavedinis corticum aurantiorum.* Take of fresh external rind of oranges, separated by rasping, a pound; refined sugar, three pounds. Bruise the rind with a wooden pestle, in a stone mortar; then, after adding the sugar, bruise it again, until the whole is thoroughly incorporated. This is well calculated to form the basis of a tonic and stomachic confection, and may be given alone in doses of from two to five drachms, twice or three times a day.

Confectio cardiaca. See *Confectio aromatica*.

CONFECTIO CASSIÆ. *Electuarium cassiæ. Electuarium è cassiâ. Diacasia cum manna.* Confection of cassia. Take of fresh cassia pulp, half a pound; manna, two ounces; tamarind pulp, an ounce; syrup of roses, half a pint. Bruise the manna; melt it in the syrup by a water-bath; then mix in the pulps, and evaporate down to a proper consistence. This is a very elegant, pleasant, and mild aperient for the feeble, and for children. Dose from two drachms to an ounce.

CONFECTIO DE SANTALIS. An old astringent confection, made with sandal wood, red coral, bole, kermes berries, and other ingredients.

Confectio damocratis. See *Mithridatium*.

CONFECTIO HAMEC. (So named after an Arabian physician.) A confection made of the bark of the yellow myrobalan or black miforum robalans, violets, polypody of the oak absynthium, rhubarb, diagridium, canella, ginger, and other ingredients made up with honey.

CONFECTIO HYACINTHI. Hyacinth confection. The *Electuaire de safran* used in France was formerly made with the addition of hyacinth, and took its name from that ingredient.

CONFECTIO OPII. *Confectio opiata. Philonium Londinense. Philonium Romanum. Electuarium Opiatum. Electuarium Thebaicum.* Confection of opium. Take of hard opium powdered, six drachms; long pepper, an ounce; ginger root, two ounces; carraway seeds, three ounces: tragacanth, powdered, two drachms; syrup, a pint. Rub together the opium and the syrup previously heated; then add the remaining articles reduced to powder, and mix. This confection is a simplification of the Mithridate and Theriaca of the old Pharmacopœias. The effect of opium is considerably modified by combination with aromatics, and the opiate confection affords a convenient mode of exhibiting it. The confection is given in atonic gout, flatulent colic, diarrhœa unattended with inflammatory symptoms, and other cases. The dose is from grs. 10 to ʒss. The confectio aromatica of the London and Dublin Pharmacopœias contains one grain of opium in thirty-six, whereas the *Electuarium opiatum*, the corresponding preparation in the

Edinburgh pharmacopœia, contains one grain in forty-three.

Confectio piperis nigri. Confection of black pepper. Take of black pepper, elecampagne, of each a pound; fennel seeds, three pounds; honey, refined sugar, of each two pounds. Rub the dry ingredients together so as to reduce them to a very fine powder; then, having added the honey, rub them again so that the whole may incorporate. This confection is given internally in a relaxed condition of the extremity of the rectum, producing partial prolapse, and in piles occasioned by debility. A similar compound has been long celebrated under the name of Ward's paste.

Confectio Raleighana. See *Confectio aromatica.*

Confectio rosæ caninæ. *Conserva cynosbati. Conserva fructus cynosbati.* Conserve of hips. Confection of dog-rose. Take of dog-rose pulp, a pound; refined sugar, powdered, twenty ounces. Expose the pulp in a water-bath to a gentle heat; then add the sugar gradually, and rub them together until they are thoroughly incorporated. This preparation is slightly astringent; but it is only used to form other more active medicines into pills and electuaries.

Confectio rosæ gallicæ. *Conserva rosæ. Conserva rosarum rubrarum.* Conserve of red rose. Take of the petals of the red rose, before it is expanded, and without the claws, a pound; refined sugar, three pounds. Bruise the petals in a stone mortar; then, having added the sugar, beat them again together, until they are thoroughly incorporated. This is a good gentle astringent. Rubbed down with water, and acidulated with lemon juice, it forms an excellent drink, in hæmorrhagic complaints; it may also be given with vitriolated zinc, in the form of an electuary.

Confectio rutæ. *Electuarium è baccis lauri.* Confection of rue. Take of rue leaves dried, carraway seeds, bay berries, of each an ounce and a half; sagapenum, half an ounce; black pepper, two drachms; clarified honey, sixteen ounces. Rub the dry articles together, into a very fine powder; then add the honey, and mix the whole. This is an antispasmodic preparation but its use is confined to clysters.

Confectio scammoneæ. *Electuarium scammonii. Electuarium e scammonio. Electuarium caryocostinum.* Confection of scammony. Take of scammony powdered, an ounce and a half; cloves bruised, ginger root powdered, of each six drachms; oil of carraway, half a drachm; syrup of roses, as much as may be sufficient. Rub the dry articles together into very fine powder, and preserve them; then whenever the confection is to be used, the syrup being gradually poured in, rub again; lastly, the oil of carraway being added, mix them all. This is a strong stimulating cathartic, and calculated to remove worms from the primæ viæ. It is not much used. Dose from ʒ ss. to ʒ j.

Confectio sennæ. *Electuarium sennæ. Electuarium lenitivum.* Confection of senna. Lenitive electuary. Take of senna leaves, eight ounces; figs, a pound; tamarind pulp, pulp of prunes, cassia pulp, of each half a pound; coriander seeds, four ounces; liquorice root, three ounces; refined sugar, two pounds and a half; water three pints. Powder the senna leaves with the coriander seeds, and separate, by sifting, ten ounces of the mixed powder. Boil down the water with the figs and liquorice root to half, then press out the liquor and strain it. Evaporate the liquor in a water-bath, until a pint and a half only remains of the whole; then add the sugar, to make syrup. Lastly, mix the pulps gradually with the syrup, and, having added the sifted powder, mix the whole together. This is a mild and elegant aperient, but is seldom found properly prepared in the shops. Dose, ʒ ss. to ℥ ss.

Confectio Fracastorii. See *Diascordium.*

CONFERTUS. Clustered, or crowded together: applied to leaves. See *Leaf.*

CONFE'RVA. (*a, æ.* f.; from *conferveo,* to knit together or heal.) 1. Under this name Pliny mentions a plant growing near alpine rivers, which was applied to heal the wounds inflicted on trees in pruning them, and was also supposed to favour the union of broken bones.

2. The tribe of cryptogamic plants, comprehending the jointed algæ or water-weeds, are called *Confervæ.* The confervæ are chiefly fresh water plants, but many are marine. They are composed of capillary jointed tubes, the joints of which differ in length. The tubes contain granules variously arranged, and the plants grow by the addition of one tube to the end of another, and multiply by means of the granules contained in the tubes. Some genera of confervæ, especially the *oscillatoria,* have afforded matter of much interesting speculation to physiologists from the near approach which they make to the character of animals. The species of oscillatoria are well known to be endowed with a power of motion which appears spontaneous. When in an active state their tubes are seen to unite and twine together, like a bundle of worms. When burnt, they afford a very fetid charcoal, the odour of which resembles that of decomposing animal matter. Dr Priestly made some very curious observations on this subject. He found that the green matter produced in organic infusions, by exposure to light, was at first a mass of animalcules; that it was then resolved into green globules which concreted into *confervæ;* and lastly, after the solution of these, that it was again converted into infusory animals and vegetables. These observations, confirmed by those of Ingenhouz and Treviranus, have given encouragement to speculations relative to the spontaneous generation of animals, and the convertibility of animal and vegetable life. (See *Generation, equivocal.*) The recent researches of Ehrenberg, however, have thrown great doubt on the accuracy of these observations; nor is there any thing hitherto known which can warrant us in detaching the confervæ from the vegetable kingdom.

Conferva dichotoma. See *Fucus helminthocorton.*

Confervahel minthocortos. See *Fucus helminthocorton.*

Conferva rivalis. This indigenous plant

called Crow silk and Hairy river weed, — *Conferva; filamentis simplicissimus æqualibus longissimis*, of Linnæus, — is green and fibrous, and found in stagnant waters. It has a marshy smell, and is used as a vermifuge by the country people. It has also been recommended in cases of spasmodic asthma, phthisis, &c. It is very difficult to burn; and adheres firmly to glass or paper. This is supposed to be the conferva of the ancients.

CONFERVA RUPESTRIS. *Muscus marinus.* See *Fucus helminthocorton.*

CONFIRMA'NTIA. Synonymous with *Roborantia.*

CO'NFLUENT. *Confluens.* Running together. 1. In *Pathology*, applied to eruptions, especially that of smallpox. See *Variola.*

2. In *Botany*, to leaves which run together at their base.

Confluent smallpox. See *Variola.*

CONFLUE'NTIA. *Confœderatio.* A term used by Paracelsus. The consent or concord of the microcosm with the stars, or of a disease with remedies.

CONFLU'XIO. The Latin translators of Hippocrates render his ξυρροια by this word. It signifies that consent or sympathy of the different parts of the living frame, by which the actions of life are sustained.

Confœderatio. See *Confluentia.*

CONFORTA'NTIA. Cordials.

CONFORTATI'VA. The same.

CONFU'SÆ FEBRES. A name given by Bellini to irregular agues. See *Ague.*

CONFU'SIO. (From *confundo*, to mix together.) A disorder of the eyes, proceeding from a rupture of the membranes which include the humours, by which means they are all confounded together. — *Galen.*

CONGELA'TION. (*Congelatio, onis.* f. from *congelo*, to freeze.) 1. In *Chemistry*, the conversion of a liquid body into a solid.

2. In *Physiology*, it is sometimes used synonymously with coagulation.

3. In *Pathology*, it was formerly employed to designate those diseases which are attended with stupor and numbness, as *catalepsy, paralysis*, &c.

CONGELATI'VA. The same as *conglutinantia.*

CONGELA'TUS. (From *congelo*, to freeze.) *Congelaticus.* A person afflicted with ecstacy or catalepsy, was formerly so called.

CO'NGENER. (*er, eris.* adj.; from *con*, and *genus*, kind.) Applied — 1. In *Natural History*, to genera nearly allied, or to species of the same genus.

2. In *Anatomy*, to muscles which concur in the same action.

CONGE'NITAL. *Congenitus.* Applied to that which pertains to an individual from his birth: thus, a *congenital disease* is one which existed at birth; a *congenital deformity*, a deformity which existed at birth.

Congenital hernia. See *Hernia.*

CONGE'STION. (*Congestio, onis.* f.; from *congero*, to amass.) A preternatural accumulation of blood, bile, or other fluids in their proper vessels: thus we say a congestion of blood in the vessels, when they are over-distended, and the motion of the blood is slow; a congestion of bile in the biliary ducts, &c.

CONGESTIVE DISEASES. Diseases arising from congestion.

Congestive fever. See *Febris.*

CONGIA'RIUS. The same as *Congius.*

CO'NGIUS. *Congiarius.* (*us, i. m.*) An ancient measure nearly equal to a gallon. In modern latinity it signifies a gallon.

CO'NGLOBATE. (*Conglobatus;* from *conglobo*, to gather into a ball.) 1. A term applied to a gland, *Glandula conglobata*, which is formed of a contortion of lymphatic vessels, connected together by cellular structure, having neither a cavity nor an excretory duct: such are the mesenteric, inguinal, axillary glands, &c. See *Gland.*

2. A conglobate *flower* is a compound one growing in the form of a sphere or globe.

CONGLO'MERATE. (*Conglomeratus;* from *conglomero*, to heap upon.) 1. In *Anatomy*, applied to a gland, *Glandula conglomerata*, which consists of a number of smaller glomerate glands, the excretory ducts of which all unite into one common duct, as the salivary glands.

2. In *Botany*, applied to flowers which are closely compacted together on a footstalk, to which they are irregularly, but closely connected. See *Panicula.*

CONGLUTINA'NTIA. (From *conglutino*, to glue together.) The same as *agglutinantia.* See *Agglutinans.*

CONGREGA'TÆ GLA'NDULÆ. Glands which are clustered together, but each distinct from the rest, and having its own duct: the term is especially applied to the glands which are formed in clusters on the inner surface of the intestines.

Conicæ Papillæ. See *Conicus.*

CO'NICUS. Conical: applied — 1. In *Botany*, to leaves, nectaries, receptacles, &c. from their shape; as to the nectary of *Utricularia foliosa*, and the receptacle of *Anthemis arvensis*, and *Matricaria chamomilla.*

2. In *Anatomy* to the lenticular papillæ of the tongue. *Conicæ Papillæ.*

CONI'FERÆ. The cone-bearing tribe of dicotyledonous plants. It includes the pines, firs, &c.

CONIA. Κονια. A word used by the Greek writers to signify, 1. A lixivium. 2. Lime. 3. Ashes. 4. A wine prepared by fermenting must on liquid pitch previously washed with sea-water. *Dioscorides.*

Conicine. See *Coneine.*

CONIO'DES. (Κονιωδες; from κονια, a *lixivium.*) An epithet applied by Hippocrates to a certain condition of the urine — ουρα κονιωδεα.

CO'NIS. (*is, eos.* f.; Κονις.) Dust; fine powder; ashes; a nit in the hair; scurf on the head.

CONISTE'RIUM. (*um*, i. n.; Κονιστηριον; from κονιζω, to sprinkle with dust.) An apartment in the ancient gymnasia, where the athletæ were sprinkled with dust after being anointed with oil.

CONI'UM. (*um, ii.* n.: Κωνειον; Κονιον; Hemlock.

1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.*

2. The pharmacopœial name of the officinal hemlock. See *Conium maculatum.*

Conium maculatum. The systematic name for the *conium* and *cicuta* of the Pharmacopœias. Hemlock.

Cicuta major fœtida. Conium — seminibus striatis, of Linnæus. Hemlock is found in every part of England, and is distinguished from those plants which bear some resemblance to it, by the spotted stem. It is a very active poison. In a moderate dose it is apt to occasion sickness and vertigo; in a larger quantity it produces anxiety, cardialgia, vomiting, convulsions, coma, and death. Baron Stoerck was the first who brought hemlock into repute as a medicine of extraordinary efficacy: and although we have not in this country any direct facts, like those mentioned by Stoerck, proving that inveterate scirrhuses, cancers, and many other diseases hitherto deemed irremediable, are to be completely cured by the cicuta; we have, nevertheless, the testimony of several eminent physicians, showing that some complaints which had resisted other powerful remedies, yielded to hemlock; and that even some disorders, which, if not really cancerous, were at least suspected to be of that tendency, were greatly benefited by this remedy. It has, unquestionably, great efficacy in allaying the irritability and improving the appearance of ill-conditioned sores. In chronic rheumatisms, some glandular swellings, and in various fixed and periodical pains, the cicuta is now very generally employed; and from daily experience, it appears in such cases to be a very efficacious remedy. It has also been of singular use in the hooping-cough. Nor is it less efficacious when applied externally; a poultice made of oatmeal and the expressed juice, (or a decoction of the extract, when the other cannot be obtained,) allays the pain of ulcerated cancers, and gives a better aspect to irritable and unhealthy sores.

The narcotic power of hemlock resides in an alkaline principle, the properties of which require further investigation. It has been called *Conein* and *Cicutine.* See *Conein.*

The proper method of administering conium internally, is to begin with two or three grains of the powder or inspissated juice twice or thrice a day, and gradually to increase the dose. A slight giddiness and sickness, with a sensation as if the eyeballs were strained, are the first indications of an overdose. When any of these symptoms are experienced, the dose should be kept stationary for several days, until they have ceased, and then after a few days the dose may be increased; for little advantage can be expected but by a continuance of the greatest quantity the patient can bear. Occasionally, however, the effect is too powerful, and it is necessary to suspend the use of the medicine altogether. In some constitutions even small doses greatly offend, occasioning spasms, heat, and thirst; in such instances it will be of no service.

The powder of the dried leaves has been thought to act with more certainty than the extract, but the latter, if well prepared and not injured by keeping, is perfectly to be depended on. The following directions should be observed in the preparation: — Gather the plant about the end of June, when it is in flower; pick off the little leaves, and throw away the leaf-stalks: dry the small selected leaves in a hot sun, or in a tin or pewter dish before the fire. Preserve them in bags made of strong brown paper, or powder them and keep the powder in glass phials where the light is excluded; for light dissipates the beautiful green colour very soon, and thus the medicine loses its appearance, if not its efficacy: this mode is recommended by Dr. Withering. The extract should also be made of the plant gathered at this period.

CONJUGA'TUS. Conjugate or yoked; applied to a winged leaf with only one pair of leaflets; as in the *Mimosa.*

Conjunctiva membrana. See *Conjunctiva tunica.*

Conjunctiva tunica. *Membrana conjunctiva. Tunica adnata.* One of the membranes or coats of the eye. See *Oculus.*

CONJU'NCTUS. Conjoined. Applied — 1. In *Botany,* to tubera, which are in immediate contact with one another, as in many of the *orchides.*

2. In *Pathology, conjuncta causa* means a proximate cause. See *Ætiologia; conjuncta signa* mean inseparable or pathognomic symptoms; *conjuncti morbi* are diseases which are either co-existent, or consecutive one on the other.

CONNA'TUS. (From *con,* and *nascor* to grow.) 1. In *Pathology,* born with a person; the same with *congenitus.*

2. In *Botany,* applied to leaves which are united at their base; as in *Chlora perfoliata.*

Connexion. See *Articulation.*

CO'NNIVENS. (From *conniveo,* to wink.) Connivent. Applied — 1. In *Botany,* to petals of flowers, as those of the *Rumex,* and to the receptacle of the fig, which the fruit really is, being a fleshy connivent receptacle, enclosing and hiding the florets.

2. In *Anatomy,* to the folds on the mucous surface of the small intestines; which are called *valvulæ conniventes,* from their converging or approaching one another.

Connutri'tus. (From *con,* and *nutrior,* to be nourished.) Applied to a disease which is either congenital, or originates from something connected with the nutrition of the individual in early life, as sucking an unhealthy nurse. The term is obsolete.

CONQUASSA'TIO. Conquassation. In *Pharmacy,* the bruising of recent vegetables, fruits, the softer parts of animals, &c. with a pestle, till they are reduced to a soft pulp.

Consent of parts. See *Sympathy.*

CONSE'RVA. (*a, æ.* f.; from *conservo,* to keep.) A conserve. A composition of some recent vegetable and sugar, beat together into an uniform mass of the consistence of honey; as conserve of hips, orange-peel, &c. Conserves

are called confections in the later editions of the London Pharmacopœia. See *Confectio.*

Conserva absinthii maritimi. Conserve of wormwood. This was formerly celebrated for the cure of dropsies. It was given in the dose of ℥ ss. before meals.

Conserva ari. See *Arum maculatum.*

Conserva aurantii Hispalensis. See *Confectio aurantiorum.*

Conserva cynosbati. See *Confectio rosæ caninæ.*

Conserva lu'julæ. Confection of wood sorrel. It is gratefully acid to the taste, and was formerly used to allay thirst in fevers.

Conserva menthæ. Conserve of mint. This preparation of mint is given occasionally as a stomachic, in sickness and weakness of the stomach. See *Mentha viridis.*

Conserva pruni sylvestris. Conserve of sloes. Astringent virtues are ascribed to this medicine, which, however, is now seldom used. See *Prunus sylvestris.*

Conserva rosæ. Conserve of roses. This conserve, rubbed down with water, and acidulated with lemon juice, forms an excellent drink in hæmorrhagic complaints. See *Confectio rosæ Gallicæ.*

Conserva scillæ. Conserve of squill. This is an uncertain and nauseous preparation, and has been for some time expunged from the Pharmacopœias.

Consili'go. A plant mentioned by Pliny. According to Caspar Bauhin, it is the green hellebore; according to others, a species of aconite.

Consiste'ntia. (From *consisto*, to stand still.) This word has been sometimes used to designate the acme of a disease. See *Acme.*

CONSO'LIDA. (*a, æ.* f. So called, *quia consolidandi et conglutinandi vi pollet;* from its power in agglutinating and joining together things broken.) Consound. See *Symphytum.*

Consolida aurea. See *Solidago virgaurea.*

Consolida major. See *Symphytum.*

Consolida media. See *Ajuga.*

Consolida minor. See *Prunella.*

Consolida regalis. See *Delphinium.*

Consolida saracenica. See *Solidago.*

Consolida'ntia. A term formerly applied o medicines which were supposed to give firmness to parts recently healed.

Consommé. (*Consummatum*, low Latin.) The French word for a strong broth made with any gelatinous meat, so that it becomes solid on cooling.

Consound. See *Consolida.*

Consound, middle. See *Ajuga pyramidalis.*

Conspersio. See *Catapasma.*

Constella'tum ungue'ntum. An ointment omposed of the powder of dried earth worms, nd the fat of the bear or wild boar. It was ormerly used to promote the cicatrisation of wounds, aud to cure the toothach.

CONSTIPA'TION. (*Constipatio, onis.* f.; rom *constipo*, to crowd together.) *Coprostasis. opostasia. Obstipatio.* Costiveness.

Costiveness and obstipation are sometimes sed synonymously: the former, however, is enerally applied to that state in which the owels act, though tardily; and the latter, to that in which there is no alvine evacuation. Costiveness is not always a disease; for many people in robust health, and especially the poorer and hard-working classes are not accustomed to have their bowels emptied oftener than twice a week. In its simple and constitutional form, this sluggishness of the bowels is rather troublesome than dangerous. Costiveness may be caused by an undue activity of the absorbents of the bowels, whereby the fæcal matter is deprived of all moisture, and becomes indurated. This increased action of the absorbents is often produced by hard exercise, under which the skin is kept regularly perspiring; by a stimulating diet, and such as tends to constringe the bowels; and perhaps also by too small a quantity of fluids, compared with the solid substance.

As the fæces are forced forward by the peristaltic action of the intestines, it follows that whenever this action is weakened, there must be an accumulation of fæces. This sluggishness or torpitude of the bowels may be produced by various causes: for sometimes the food is not sufficiently stimulating, sometimes there is a deficiency or depraved condition of the bile, which is a natural stimulus to the bowels. In other instances there is a defect of tone in the muscular fibres of the bowels themselves, so that they are not sufficiently affected by natural and healthy stimuli.

The medical treatment of constipation consists in adopting a diet free from all astringents, taking care especially that there is no alum in the bread, and using a coarser kind, with oleraceous vegetables, and supplying proper stimulants when the peristaltic motion is enfeebled. In most cases laxative articles of diet, such as stewed fruits, and the frequent use of gentle laxatives, will be found more effectual than the stronger cathartics. Where costiveness occurs in persons of a plethoric habit, the moderate use of venesection will often prove the most effectual laxative. In all cases emollient and laxative enemata are an useful auxiliary, and in many are alone sufficient to restore the healthy action of the bowels.

In the more aggravated state, or that in which the disease is called obstipation, rather than costiveness, there is generally sluggishness of the bowels from defect of tone in their fibres, and the patients are weakly, and prone to sedentary habits: the fæces, therefore, become indurated and form into hard balls, called *scybala.* In these obstinate cases the more powerful cathartics, as the croton oil and elaterium, must be had recourse to and conjoined with stimulating clysters. It will be preferable, however, to try a number of different cathartics in succession, than to persevere in violent doses of any one of them; for owing to peculiarity of constitution, it sometimes happens that obstipation which has resisted the most drastic medicines will yield readily to a few grains of aloes, a moderate quantity of Epsom salts largely diluted, or something equally simple.

CONSTITUTION. *Constitutio.* The general condition of the body, as evinced by the peculiarities in the performance of its functions: such are, the peculiar predisposition to certain diseases, or liability of particular organs to

disease; the varieties in digestion, in muscular power and motion, in sleep, in the appetite, &c. Some marked peculiarities of constitution are observed to be accompanied with certain external characters, such as a particular colour and texture of the skin and of the hair, and also with a peculiarity of form and disposition of mind; all of which have been observed from the earliest time, and divided into classes; and which received names, during the prevalence of the humeral pathology, which they still retain. See *Temperament*.

Constricti'vus. (From *constringo*, to bind together.) Constrictive: styptic.

CONSTRI'CTOR. (*or, oris.* m.; from *constringo*, to bind together.) A name given to a muscle which contracts any opening of the body.

Constrictor alæ nasi. See *Depressor labii superioris alæque nasi.*

Constrictor ani. See *Sphincter ani.*

Constrictor isthmi faucium. *Glossostaphilinus* of Winslow, Douglas, and Cowper. A muscle situated at the side of the opening of the fauces, that draws the *velum pendulum palati* towards the root of the tongue, which it raises at the same time, and, with its fellow, contracts the passage between the two arches, by which it shuts the opening of the fauces.

Constrictor labiorum. See *Orbicularis oris.*

Constrictor oris. See *Orbicularis oris.*

Constrictor palpebrarum. See *Orbicularis palpebrarum.*

Constrictor pharyngis inferior. *Crico pharyngeus; Thyro-pharyngeus*, of Douglas and Winslow. A muscle situated on the posterior part of the pharynx. It arises from the side of the thyroid cartilage, near the attachment of the sternohyoideus and thyrohyoideus muscles; and from the cricoid cartilage, near the crico-thyroideus. It is inserted into the white line, where it joins with its fellow, the superior fibres running obliquely upwards, covering nearly one-half of the middle constrictor, and terminating in a point: the inferior fibres run more transversely, and cover the beginning of the œsophagus. Its use is to compress that part of the pharynx which it covers, and to raise it with the larynx a little upwards.

Constrictor pharyngis medius. *Hyopharyngeus* and *cephalo-pharyngeus*, of Douglas and Winslow. *Chondro-pharyngeus*, of Douglas. *Syndesmo-pharyngeus*, of Winslow. *Cephalo-pharyngeus*, of Winslow and Douglas. A muscle situated on the posterior part of the pharynx. It arises from the appendix of the os hyoides, from the cornu of that bone, and from the ligament which connects it to the thyroid cartilage; the fibres of the superior part running obliquely upwards, and covering a considerable part of the superior constrictor, terminate in a point; and it is inserted into the middle of the cuneiform process of the os occipitis, before the foramen magnum, and joined to its fellow at a white line in the middle part of the pharynx. This muscle compresses that part of the pharynx which it covers, and draws it and the os hyoides upwards.

Constrictor pharyngis superior. *Glosso-pharyngeus; Mylo-pharyngeus; Pterygo-pharyngeus*, of Douglas and Winslow. A muscle situated on the posterior part of the pharynx. It arises from the cuneiform process of the os occipitis, before the foramen magnum, from the pterygoid process of the sphenoid bone, from the upper and under jaw, near the last dentes molares, and is also connected with the buccinator muscle, with the root of the tongue, and with the palate. It is inserted in the middle of the pharynx. Its use is to compress the upper part of the pharynx, and to draw it forwards and upwards.

Constrictor vesicæ urinariæ. See *Detrusor urinæ.*

Constrin'gens. (From *constringo*, to bind together.) See *Astringent.*

Consumma'tum. A low Latin word, which, according to Blancard, properly signifies a dish made by cutting a hen into small pieces, removing the head, feet, and fat, and digesting it without any addition, in a well-covered vessel, by the heat of a water bath, so as to extract the juice. It was afterwards applied to any gelatinous broth. See *Consommé.*

CONSUMPTION. (*Consumptio*; from *consumo*, to waste away.) See *Phthisis.*

Consu'mtio. (*o, onis.* f.) Consumption. See *Phthisis.*

Contabesce'ntia. (From *contabesco*, to pine or waste away.) An atrophy; or wasting of the body.

CONTAGION. (*Contagio, onis*, f.; from *con* and *tango*, to touch.) The term contagion has been used in several acceptations. 1. It has been employed to signify the communication of a disease by personal contact with the sick. 2. It has been employed to signify the communication of a disease, either by personal contact with the sick, or by an effluvium evolved from the body of the sick. 3. It has been employed as a generic term, embracing all atmospheric and morbid poisons; all the effluvia, miasmata, infections, and poisons that cause fevers, of whatever kind; and those poisons which uniformly excite the diseases which give birth to them, as the venereal disease, the itch, tinea capitis, &c. The second of these senses is the one in which it is now generally employed. Attempts have been made to distinguish between *contagion* and *infection*, the former being restricted to the communication of disease by direct contact, and the latter to that by effluvia arising from the body of the sick, and communicated through the medium of the atmosphere; but this distinction is now properly discarded by the majority of practical writers, and the two words are considered as synonymous.

Let it be understood, then, that *contagion* or *infection* means *the communication of a disease by personal contact with the sick, or by means of an effluvium arising from the body of the sick.*

It is well known that some contagious diseases, as *typhus*, frequently originate in the animal body when subjected to the action of certain external causes, among which the more obvious are confinement in crowded and ill-ventilated places, deficient or unwholesome food, intemperance, excessive fatigue, long-continued exposure

cold and moisture, and depressing passions of the mind. Such diseases are also occasionally observed to arise sporadically, without the intervention of the causes above alluded to, and, to all appearance, independently of contagion. There is, however, a class of contagious diseases which have never yet been proved to arise sporadically, and are generally believed never to do so: the contagions which produce these are therefore called *specific contagions;* such are those of syphilis, measles, small-pox, cow-pox, hooping-cough, scarlatina, &c. Whether the majority of pathologists are in the right in denying the occasional spontaneous origin of specific contagions, is much too large a question to be entered upon here; nor have we, in truth, sufficient data for its philosophical determination. The following are the best known contagions to which the human body is subject: —

1. The contagion of *typhus.*
2. ——— of *hooping-cough.*
3. ——— of *mumps.*
4. ——— of *purulent ophthalmia.*
5. ——— of *small-pox.*
6. ——— of *cow-pox.*
7. ——— of *measles.*
8. ——— of *scarlet fever.*
9. ——— of *varicella.*
10. ——— of *erysipelas.*
11. ——— of *dysentery.*
12. ——— of *yaws.*
13. ——— of the *venereal disease.*
14. ——— of *scald head.*
15. ——— of the *itch.*
16. ——— of *hydrophobia.*

Among contagious poisons, some exist in the form of a liquid virus, by the insertion of which beneath the cuticle of a healthy individual, or its simple application to any part where the cuticle is very thin, the disease is communicated; such are the *variolous* and *syphilitic* poisons: the matter of other contagions again entirely eludes our senses; thus, the contagion of typhus is known to us only by its effects. Of liquid contagious poisons, some do not necessarily extend their action beyond the part to which they are immediately applied; thus, venereal matter may produce a chancre and nothing further; others, again, produce a local effect, the *necessary* consequence of which is a peculiar febrile excitement of the system, and the elimination of a contagious matter similar to that inserted by inoculation; such is the virus of small-pox and that of cow-pox.

The poisons of small-pox, chicken-pox, measles, and hooping-cough, produce such a change in the susceptibility of the system, when once they have influenced it, as to prevent the recurrence of the disease, except in a very small number of instances which merely form exceptions to a general rule. Other contagions again fortify the system to a considerable degree against any future infection of the same kind, but not nearly to the same degree as those above-mentioned; thus, scarlet fever generally occurs only once in a person's life-time, but still it often occurs two or three times. Lastly, many contagions confer no immunity from the future effects of the same poison; thus, having once laboured under syphilis, is no protection against a future invasion of that disease.

Further information concerning the peculiarities of the individual morbid poisons, will be found under the heads of the diseases to which they give rise.

There is an interesting fact connected with the origin of contagions, namely, that certain diseases which do not generally evince any contagious disposition, may become contagious under particular circumstances. This seems to be the case with common continued fever, which sometimes under unfavourable circumstances assumes a malignant and contagious form. Erysipelas has sometimes prevailed as a formidable epidemy, and, even when sporadic, frequently assumes a disposition to spread by contagion: nor is this confined to the idiopathic form of the disease; experience sufficiently attests that erysipelas supervening on wounds may also become contagious, especially in hospitals. Catarrh and pneumonia have frequently presented themselves in an epidemic, and probably a contagious form.

It is also worthy of remark, that a vast variety of diseases have at different times occurred as complications of contagious fever, and formed characteristic features of particular epidemies: so great indeed has been their number, that we may almost conclude, with Sennert, "nihil fere symptomatum et malorum est quod non cum peste et malignis ac pestilentibus febribus interdum conjungatur." (*De Feb.* lib. iv. c. xviii.) It would seem, therefore, that there is nothing in the nature of such affections incompatible with their communication by contagion; since, in the instances alluded to, they are so influenced by the causes of contagion as to become communicable along with the fever they accompany. These considerations point to the possibility that a contagious principle may, under certain circumstances, be superadded to many diseases, and may sometimes operate in determining their frequency, when its presence is very little suspected.

An important subject connected with contagion is that of *fomites.* It is found that the effluvia by which contagious diseases are communicated, are absorbed more or less by all porous bodies, and may, through the medium of these, be transported to distant places, and preserved in full activity for a length of time. The substances which thus convey contagion are called *fomites.* Wool, hair, cotton, feathers, woollen and cotton cloths, and other similar substances most readily imbibe and retain the contagious miasmata. (See *Pestis.*) It has been a point of discussion, whether a dead body can communicate contagion. Now, as the contagious matter of disease is the result of disordered vital actions, no further production of it can take place after death; but are there no porous substances about the dead body which may act as *fomites?* Is the hair of a dead human body, for instance, a worse fomes than any other hair? If not, we cannot perceive on what ground the capacity of the dead body to communicate contagion can be denied, unless it be supposed that the body, when dead, has an active power of neutralising the miasmata it

evolved when living, — a supposition too improbable to be maintained.

CONTI'NENS FEBRIS. A continued fever as opposed to a remittent or intermittent. See *Febris.*

CONTI'NUA FEBRIS. A continued fever. *Continued fever.* See *Febris.*

CONTORTÆ. (Twisted.) The name of an order in Linnæus's Fragments of a Natural Method, consisting of plants which have a single petal that is twisted or bent towards the side; as *Nerium*, *Vinca*, &c.

CONTO'RTUS. (From *con*, and *torqueo*, to twist.) Twisted: applied to the seed-vessels of plants; as the *legumen contortum* of the *Medicago sativa.*

CO'NTRA-APERTU'RA. (From *contra*, against, and *aperio*, to open.) A counter-opening. An opening made to give exit to matter where one, which already exists, is insufficient for that purpose.

CONTRACTILITY. *Contractilitas.* That property of the living fibre by which it contracts on the application of a stimulus. Contractility is generally said by physiologists to depend on the organic property of sensibility. On this subject the following remark of M. Broussais is worthy of attention: — "Sensibility and contractility have been attributed to the living fibre; but if the real meaning of these two words reduces itself to the affirmation, that the fibre contracts because some cause determines it to do so; it is clear, that the former of these two properties is necessarily involved in the latter. In effect, if the sensibility of the fibre is manifested only by its contractions, to say that it is sensible, is merely to say that it contracts."

CONTRACTION. (*Contractio*, *onis.* f.; from *contraho*, to draw together.) 1. In *Physiology*, the action arising from excited *contractility*; that is, the shortening of a living fibre on the application of a stimulus.

2. In *Pathology*, the shortening of a muscle from some morbid cause.

CONTRACTU'RA. (*a*, *æ.* f.; from *contraho*, to draw together.) Cullen has made *contractura* a genus of disease in his class *Locales*, and order *Dyscinesiæ.* The species are,

1. *Contractura primaria*, from a rigid contraction of the muscles, called also obstipitas; a word that, with any other annexed, distinguishes the variety of the contraction. Of this species he forms four varieties. 1. *Contractura ab inflammatione*, when it arises from inflammation. 2. *Contractura à spasmo*, called also tonic spasm and cramp, when it depends upon spasm. 3. *Contractura ob antagonistas paraliticos*, from the antagonist muscles losing their action. 4. *Contractura ab acrimoniâ irritante*, which is induced by some irritating cause.

2. *Contractura articularis*, originating from a disease in the joint.

CONTRAFISSU'RA. (*a*, *æ.* f.; from *contra*, against, and *findo*, to cleave.) Counter-fissure. *Contrecoup* of French writers. A fracture in a part distant from that in which the blow is received; as when the frontal bone is broken by a fall on the occiput, the bone in the latter region remaining sound. Counter-fissures are not confined to the cranium, but occur also in other bones.

CONTRAHE'NTIA. A term applied to medicines which produce contraction; they include *astringents* and *styptics.*

CONTRA-INDICATION. (*Contra-indicatio*, *onis.* f.; from *contra*, against, and *indico*, to show.) A symptom which forbids the use of a remedy which might otherwise be employed: for instance, it is usual to bleed in inflammation of the lungs; but if it be accompanied with highly typhoid symptoms and great sinking of the vital powers, these form *contra-indications* to the use of the lancet.

CONTRA-LUNA'RIS. (From *contra*, and *luna*, the moon.) An epithet given by Dietericus to a woman who conceives during menstruation.

CONTRAYE'RVA. (*a*, *æ.* f.; from *contra*, against, and *yerba*, an herb, Span.; because this herb was given as an antidote *against* poisons.) See *Dorstenia.*

CONTRAYERVA ALBA. *Contrayerva Germanorum.* See *Asclepias vincetoxicum.*

CONTRAYERVA NOVA. The Mexican contrayerva. See *Psoralea pentaphylla.*

Contrayerva virginiana. See *Aristolochia serpentaria.*

Contre-coup. See *contrafissura.*

CONTREXEVILLE. A village in the department of Vosges in France. It has mineral waters containing carbonates of iron and lime, muriate of lime, and a matter which appears to be bituminous. This water is used in diseases of the urinary organs, and is much esteemed as a lithontriptic. It is also used in obstructions of the glands and cutaneous diseases.

CONTUSION. (*Contusio*, *onis.* f.; from *contundo*, to knock together.) A bruise.

CO'NUS. (*us*, *i.* m.; Κωνος.) A cone. In *Botany*, a particular kind of fructification. See *Strobilus.*

CONUS FUSORIUS. *Pyramis.* A conical-shaped crucible of iron, or other metal, used by the old chemists to separate metals from the scoriæ.

CONVALESCENCE. (*Convalescentia*, *æ* f.; from *convalesco*, to get well.) The recovery of health after the cure of a disease. The period of convalescence is that space from the departure of a disease to the recovery of the strength lost by it.

CONVALESCENT. Recovering, or returning to a state of health after the cure of a disease. The word is frequently used as a substantive.

CONVALLA'RIA. (*a*, *æ.* f.; from *con vallis*, a valley: named from its abounding in valleys.) The name of a genus of plants in the Linnæan system. Class, *Hexandria*; Order *Monogynia.*

CONVALLARIA MAJALIS. The lily of the valley. May-lily. *Convallaria*, *Lilium convallium*, *Maianthemum.* The flowers of this plant *Convallaria — scapo nudo* of Linnæus, have a penetrating bitter taste. A water distilled from them is much used in Germany and the north of Europe as a nervine. When dried and powdered, they are purgative and errhine. Watery or spirituous extracts made from them

given in doses of from a scruple to a drachm, act as gentle stimulating aperients and laxatives. The root possesses the same properties as the flowers.

CONVALLARIA POLYGONATUM. The Solomon's seal. *Sigillum Salomonis; Convallaria — foliis alternis amplexicaulibus, caule ancipiti, pedunculis axillaribus subunifloris*, of Linnæus. The roots have been used externally as astringents, and internally as corroborants.

Convoluta ossa. See *Spongiosa ossa.*

Convolutions of the Brain. See *Encephalos.*

CONVOLUTIONS OF THE INTESTINES. See *Intestines.*

CONVOLU'TUS. Rolled up or folded. Applied to bones, membranes, leaves, &c.

CONVOLVULA'CEÆ. A natural tribe of plants of which the genus *Convolvulus* is the type.

CONVO'LVULUS. (*us, i.* m.; from *convolvo*, to roll together, or entwine.)

1. The ileac passion. See *Ileac passion.*

2. The name of a genus of plants in the Linnæan system, so called from their twisting round others, Class, *Pentandria*; Order, *Monogynia.*

Convolvulus americanus. See *Convolvulus jalapa.*

CONVOLVULUS BATATAS. A native of the West Indies. Its root is firm, of a pale brown outside, and white within. It is esculent, and when boiled has a sweet taste, like that of the chesnut.

CONVOLVULUS CANTABRICA. The cantabrica. Lavender-leaved bind-weed. *Convolvulus minimis spicæ foliis. Convolvulus linariæ folio.* It is anthelmintic and actively cathartic. This plant is supposed by many to be the *cantabrica* of Pliny. See *Cantabrica.*

Convolvulus colubri'nus. See *Cissampelos pareira.*

CONVOLVULUS JALAPA. The Linnæan name of the jalap plant. Called also, *Mechoacanna nigra, Convolvulus americanus, Convolvulus Syriacus.*

Convolvulus jalapa — caule volubili; foliis ovatis, subcordatis, obtusis, obsolete repandis, subtus villosis; pedunculis unifloris of Linnæus. This plant has been lately ascertained to belong to the genus *Ipomæa.* It is a native of South America. The best jalap is imported from Vera Cruz. It is in oval-pointed tubers, covered with a thin, wrinkled, brown cuticle; sometimes it is in slices. It has a heavy disagreeable smell, and a sweetish slightly pungent taste. It is hard, compact, and internally of a light brown or grayish colour with dark brown streaks. The active principle of jalap is partly imbibed both by water and alkohol, and entirely by diluted alkohol. Ether takes up three parts out of ten of jalap, and leaves on evaporation a resin and some extractive matter. Mr. Hume found a substance in jalap which he believed to be a peculiar alkali and named it *jalapine*; the nature of this substance, however, is doubtful. (See *Jalapine.*) The alkoholic extract occasions violent griping without purging; the watery extract purges without griping. The active principles appear to be resin and extractive matter; according to Cadet there are two kinds of resin, a soft and a hard. The root powdered is a very common, efficacious, and safe purgative, as daily experience evinces; but, according as it contains more or less resin, its effects must of course vary. In large doses, or when joined with calomel, it is an excellent hydragogue and anthelmintic. The operation of jalap is rendered much less irritating by the addition of a few grains of carbonate of potash. Combined with cream of tartar, it forms the compound power of jalap of the Edinburgh Pharmacopœia — an excellent hydragogue medicine. (See *Pulvis Jalapæ compositus.*) The London officinal preparations are the extract and tincture. See *Extractum Jalapæ*, and *Tinctura Jalapæ.*

Convolvulus major albus. See *Convolvulus sepium.*

Convolvulus maritimus. See *Convolvulus soldanella.*

CONVOLVULUS MECHOACAN. Mechoacan. This plant has been called *Mechoacanna, Jalapa alba, Bryonia alba Peruviana*, and *Rhabarbarum album.* The root of this species of convolvulus is brought from Mexico. It possesses aperient properties, and was long in use as a common purgative in this country, but is now entirely superseded by jalap.

CONVOLVULUS SCAMMONIA. The systematic name of the scammony plant; called also, *Convolvulus syriacus, Scammonium syriacum*, and *Diagrydium.*

Convolvulus scammonia — foliis sagittatis postice truncatis, pedunculis teretibus subtrifloris, of Linnæus. It affords the gum resin called scammony. It is a native of Asia Minor, and Cochin China. The principal supply of it is from the mountains between Aleppo and Latachea. No part of the dried plant possesses any medicinal quality, except the root, which Dr. Russell administered in decoction, and found it to be a pleasant and mild cathartic. It is from the milky juice of the root that we obtain the officinal scammony, which is procured in the following manner by the peasants, who collect it in the beginning of June: having cleared away the earth from about the root, they cut off the top in an oblique direction, about two inches below where the stalks spring from it. Under the most depending part of the slope, they fix a shell, or some other convenient receptacle, into which the milky juice gradually flows. It is left there about twelve hours, which time is sufficient for draining off the whole juice; this, however, is in small quantity, each root affording but a very few drachms. This juice from the several roots is put together, often into the leg of an old boot, for want of some more proper vessel, where, in a little time, it grows hard, and is the genuine scammony. The smell of scammony is rather unpleasant, and the taste bitterish and slightly acrid. The different proportions of gum and resin, of which it consists, have been variously stated; but, as proof spirit is the best menstruum for it, these substances are supposed to be nearly in equal parts. It is brought from Aleppo and Smyrna in masses, generally of a light shining gray colour, and friable texture; of rather an unpleasant smell, and bitterish and slightly acrid taste. The scammony of Aleppo is by far the purest. That of Smyrna is pon-

derous, black, and mixed with extraneous matters. Scammony appears to have been well known to the Greek and Arabian physicians, and was exhibited internally as a purgative, and externally for the itch, tinea, fixed pains, &c. The dose is from grs. v. to grs. xv. Its irritating qualities require to be counteracted by the addition of an aromatic. It enters into several compounds, which are administered as purgatives. See *Confectio Scammoniæ. Pulvis Scammoniæ Compositus. Extractum colocynthidis compositum.*

Convolvulus sepium. *Convolvulus major albus.* The juice of this plant, *Convolvulus — foliis sagittatis postice truncatis, pedunculis tetragonis unifloris,* of Linnæus, is violently purgative, and given in dropsical affections. A poultice of the herb, made with oil, has been recommended in white swellings of the knee joint.

Convolvulus soldanella. The systematic name of the sea convolvulus. Κραμβη θαλασσια. *Brassica marina. Convolvulus maritimus. Soldanella.* This plant, *Convolvulus — foliis reniformibus, pedunculis unifloris,* of Linnæus, is a native of our coasts. The leaves are said to be a drastic purge. The medicine has fallen into disuse.

Convolvulus syriacus. See *Convolvulus scammonia.*

Convolvulus turpe'thum. The systematic name of the turbith plant. The cortical part of the root is brought from the East Indies, in oblong pieces: it is of a brown or ash colour on the outside, and whitish within. The best is ponderous, not wrinkled, easily frangible, and of a resinous appearance. When chewed, it at first imparts a sweetish taste, which is followed by a nauseous acrimony. It is strongly purgative, but liable to much irregularity of action. Jalap therefore is now always preferred to it.

Convulsio canina. See *Risus sardonicus.*

Convulsio cerealis. See *Raphania.*

Convulsio habitualis. See *Chorea.*

CONVULSION. (*Convulsio, onis.* f.; from *convello,* to pull together.) A convulsion is an agitation of all the limbs of the body, or of a part, occasioned by violent and involuntary contractions of the muscles, with alternate relaxations, or what are called clonic spasms. Most writers on pathology assert that this state of convulsion is attended by a sound and unaffected state of the mind. It is mostly, however, otherwise; for in the generality of cases the mind is lost during the fit: but, with partial convulsions, it is unusual for the mind to be at all affected. The author has witnessed a convulsed state of one arm for more than an hour, and has conversed with the patient during the whole time: so he has frequently witnessed the one side of the body convulsed, and has found the person converse with the by-standers, until the convulsion became general, and then a state of torpor and sleep supervened. One of the most horrible instances of partial convulsion of the face and jaw that he ever witnessed, was in a noble lady, who would look stedfastly at him and talk until the convulsion prevented her, by seizing the tongue, and alternately elongating and contracting it.

Convulsions are universal or partial.

When universal, all the limbs are more or less affected, as are the muscles of the face and those of respiration. This is the case with epilepsy and hysteria, which diseases are characterised by universal convulsion. See *Epilepsy,* and *Hysteria.*

A convulsion fit varies much in the mode of attack as well as its progress. Sometimes the assault is sudden and without any warning, but more generally there are precursive indications, and especially with those who are subject to returns of it: these forerunners are, coldness of the extremities, dizziness in the head, spectra floating before the eyes, the tremors of some muscles, a cold air or *aura* creeping up a limb, or up the back. The struggle itself varies in extent, violence, and duration. The muscles are alternately rigid and relaxed; the teeth gnash, and often bite the tongue; the mouth foams; the eyelids open and shut in perpetual motion, or are stretched upon a full stare, while the protuberant balls roll rapidly in every direction: the whole face is hideously distorted. The force exerted in some cases is enormous, so as to over-power the strength of several attendants. In some instances, it has been so violent as to break a tooth, and even fracture a bone. When the lungs are much oppressed, the lips, cheeks, and, indeed, the entire surface of the face and arms, are of a dark or purple hue.

The paroxysm will sometimes cease in a few minutes, but occasionally it will last for hours, and after a short period of rest, it perhaps returns again with as much violence as before; this happens frequently in puerperal and infantile convulsion. Great languor commonly succeeds, sometimes headach and vertigo, but not unfrequently there are no secondary symptoms whatever.

Partial convulsions have received different names. 1. That kind which affects several muscles irregularly is called *chorea;* and if the arms only are affected, so that the person hammers, as it were, the knees, it is termed *malleatio.* See *Chorea.*

2. When the muscles of the face only are convulsed, it produces a kind of laughter; and this is called *risus sardonicus.*

From the period of life, a convulsion is called *infantile, juvenile,* &c.

From the particular cause, it is distinguished as being *puerperal, maniacal, dental,* &c.

The convulsion occasionally shifts about from one part to another irregularly, from the face to the arms, and from them to the feet; and in some cases the face, or the chest, or the limbs are more affected than the other parts.

The causes of convulsions are very many and very varied.

In infants, children, and youths, the common causes are irritation of the bowels from gross and indigestible food, teething, and worms. The remedies, consequently, are the appropriate purgatives, and allaying the local irritation by removing the pressure caused by the superincumbent gum. The gums should be properly lanced.

In the puerperal convulsion, the attention

must be directed to the uterus, the irritation of which is best allayed by copious, prompt, and repeated bleeding, and by the administration of opium by the mouth and rectum.

Some of the *narcotic poisons* are productive of convulsions when taken in a sufficient dose, as opium, prussic acid, the upas tienti, &c. The removal of the cause, as far as possible, is here imperiously called for, and the free exhibition of ammonia and stimulants.

Another set of causes which produce a convulsion, are affections of the mind; as excess of anger, joy, grief, and fear. The treatment during the fit must apply to the state of the constitution which gives a tendency to its recurrence.

In many cases there is an apparent congestion in the vessels of the face and head, and probably a similar state of the vascular system exists within the scull: in such cases, venesection must be had recourse to, and is a good measure of caution, more particularly if the person be of a plethoric habit; but when there are no such evidences of vascular fullness, and especially if, on the contrary, the subject is weak and nervous, bloodletting should be had recourse to with reluctance. If any medicine can be taken, it should be selected from the nervous class, as ather, ammonia, valerian, assafœtida, and camphire. I have known the following glyster remove the convulsion almost instantly in adults: —

℞. Tincturæ assafœtidæ, f. ʒ iij.
Tincturæ opii, f. ʒ jss.
Aquæ tepidæ, f. ℥ x. Misce pro enemate.

A warm bath is very generally extolled, and for children is very beneficial: but for adults, the inconvenience attending the management of the patient almost prevents its use, and often overbalances the good that might otherwise result.

Another remedy during the fit, is cold water and cold air.

The treatment after the paroxysm is over, in order to prevent a recurrence of the fit, must vary: all the exciting causes being removed, the attention should be directed to restore the healthy condition of the system by removing any vascular plethora, or nervous weakness; and the exhibition of such remedies as have been known to destroy the state of the nervous system which favoured the recurrence. These are, cold bathing, especially sea bathing; regular exercise, especially on horseback; an abstemious, but nourishing diet; aperients, so as to procure a daily and satisfactory elimination of the fæces; and a steady perseverance in antispasmodics and tonics, as cinchona, cascarilla, gentian, colomba, quassia, nux vomica, valerian, camphire, oxide of zinc, sulphate and carbonate of iron, &c.

CONY'ZA. (*a*, *æ*. f.; from κονιζω, to be dusty, because the dust adheres to its leaves.) A genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua*. Various plants have been called conyza by the older botanists: they are either of the genus conyza, inula, gnaphalium, erigeron, or chrysocoma.

Conyza squarrosa. Great fleabane. This plant has a strong disagreeable odour, which is said to be fatal to fleas and flies. It was formerly esteemed as an emmenagogue, anticteric, and antepileptic.

Conyza cærulea. See *Erigeron acre*.

Conyza major. Supposed to be the *Inula viscosa* of Linnæus.

Conyza media. See *Inula dysenterica*.

Conyza minor. *Conyza Pulicaria*. The *Inula pulicaria* of Linnæus answers to the description given of this plant in most books. Its chief use is to destroy fleas and gnats.

Coopertoria cartilago. The thyroid cartilage — *Castelli*.

Coo'strum. The centre of the diaphragm. — *Ruland*.

COPA'IBA. (*a*, *æ*. f.; from *copal*, the American name for any odoriferous gum, and *iba*, or *iva*, a tree.) See *Copaifera officinalis*.

COPAI'FERA. (*a*, *æ*. f.; from *copaiva*, and *fero*, to bear.) The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Monogynia*.

Copaifera officinalis. The systematic name of the plant from which the Copaiba balsam — *Balsamum Brasiliense* — *Balsamum copaibæ* — *Balsamum de copaiba* — *Balsamum capivi* — *Capevi*; is obtained. It is now ascertained, that nearly all the species of the genus *Copaifera* yield the balsam more or less abundantly. The *C. Multijuga*, a native of the province of Para, is said to afford the greatest quantity.

Copaiba is a yellow resinous juice, of a moderately agreeable smell, and a bitterish biting taste, very permanent on the tongue. The trees which afford it grow in the Brazils and New Spain. It is obtained by boring the trees near the bottom of the trunk, when the balsam immediately issues, and, at the proper season, flows in such abundance, that sometimes, in three hours, twelve pounds have been procured. The older trees afford the best balsam, and yield it two or three times in the same year. The balsam supplied by the young and vigorous trees, which abound with the most juice, is crude and watery, and is, therefore, accounted less valuable. While flowing from the tree, this balsam is a colourless fluid; in time, however, it acquires a yellowish tinge, and the consistence of oil; but, though by age it has been found thick, like honey, yet it never becomes solid, like other resinous fluids. By distillation in water, the oil is separated from the resin; and, in the former, the taste and smell of the balsam are concentrated. If the operation is carefully performed, about one half of the balsam rises into the receiver, in the form of oil. The balsam unites with fixed and volatile oils, and with spirit of wine. It is given in all diseases of the urinary organs, when no inflammation is present. In gonorrhœa, after the inflammatory symptoms have abated, in gleet, and in leucorrhœa, it is a medicine of great efficacy. It exerts a very stimulating effect on the kidneys, increasing their secretion, and in an overdose, causing inflammation of those organs. It often gives relief in hæmorrhoids. In irritable habits this medicine is liable to excite griping, sickness, and severe pains in the region of the kidneys, so that its use cannot

be persevered in; these effects are sometimes obviated by combining it with opium. The dose is from 20 to 30 drops, twice or thrice a day, mixed with water, by means of an egg, or any mucilage. The balsam of copaiva is occasionally adulterated with turpentine, but its virtues are not greatly injured by the fraud.

Copaiva. See *Copaiba.*

COPAL. (The American name for any odoriferous gum.) Gum copal. This substance, improperly called a gum, is imported from Guinea, and is the produce of the *Rhus copallinum*, from which it exudes spontaneously. It is a hard, shining, transparent, citron-coloured, odoriferous, concrete juice, which has neither the solubility in water common to gums, nor the solubility in alkohol common to resins, at least in any considerable degree. In these properties it resembles amber. It may be dissolved by digestion in linseed oil, rendered drying by quick lime, with a heat very little less than sufficient to boil or decompose the oil. This solution, diluted with oil of turpentine, forms a beautiful transparent varnish, which, when properly applied, and slowly dried, is very hard and very durable. This varnish is applied to snuff-boxes, tea-boards, and other utensils. It preserves and gives lustre to paintings, and greatly restores the decayed colours of old pictures, by filling up the cracks, and rendering the surfaces capable of reflecting light more uniformly.

Cope'lla. See *Cupel.*

Co'pher. A name of camphire.

COPHO'SIS. (Κωφωσις; from κωφος, deaf.) Generally synonymous with deafness, though some writers have restricted it to particular kinds of deafness.

Copi'scus. Κοπισκος. An inferior kind of incense mentioned by Dioscorides.

Co'pos. Κοπος. Weariness, lassitude.

Copparossa. See *Copperas.*

COPPER. (*Cuprum*, i. neut. *quasi æs Cyprium*; so named from the island of Cyprus, whence it was formerly brought.) A metal of a peculiar reddish brown colour; hard, sonorous, very malleable and ductile, and of considerable tenacity. Copper is found in nature in the metallic state, and in the form of oxide, sulphuret carbonate, sulphate, chloride, phosphate, and arseniate. The mineral called *copper-pyrites* is a double sulphuret of copper and iron. The native carbonate of copper constitutes the mineral called *malachite*, the blue varieties of which appear to differ from the green in containing more water. At a degree of heat far below ignition the surface of a piece of polished copper becomes covered with various ranges of prismatic colours, the red of each order being nearest the end which has been most heated; an effect which must be attributed to oxidation, the stratum of oxide being thickest where the heat is greatest, and growing gradually thinner and thinner towards the colder part. A greater degree of heat oxidises it more rapidly, so that it contracts thin powdery scales on its surface, which may be easily rubbed off; the flame of the fuel becoming at the same time of a beautiful bluish green colour. In a heat, nearly the same as is necessary to melt gold or silver, it melts, and exhibits a bluish green flame; by a violent heat it boils, and is volatilised partly in the metallic state.

Copper rusts in the air; but the corroded part is very thin, and preserves the metal beneath from farther corrosion.

There are two oxides of copper: —

1st. The *protoxide*, obtained by digesting a solution of muriate of copper with copper turnings, in a close phial. The colour passes from green to dark brown, and grey crystalline grains are deposited. The solution of these yields, by potash, a precipitate of an orange colour, which is the protoxide. It consists of 8 copper + 1 oxygen.

2d. The *deutoxide*, or black, procurable by heat, or by drying the hydratic oxide precipitated by potash from the nitrate. It consists of 8 copper + 2 oxygen.

Copper, in filings, or thin laminæ, introduced into chlorine, unites with flame into the chloride, of which there are two varieties: the protochloride, a fixed yellow substance; and the dichloride, a yellowish brown pulverulent sublimate.

1. The crystalline grains deposited from the above muriatic solution, are *protochloride.*

2. *Dichloride* is best made by slowly evaporating to dryness, at a temperature not much above 400° Fahrenheit, the deliquescent muriate of copper. It is a yellow powder.

When this substance is moistened with water, and exposed to the air, it is converted into a substance of a pale green colour called *Brunswick green*, or *submuriate of copper*; it is a compound of chloride and oxide of copper.

The *iodide*, *bromide*, and *fluoride* of copper are hitherto little known.

Of the saline compounds of this metal, the acetate, and sulphate, and ammoniated copper only are employed in the cure of diseases.

The joint agency of air and acetic acid is necessary to the production of the *acetates.* By exposing copper plates to the vapours of vinegar, the bluish-green *verdigris* is formed, which by solution in vinegar constitutes *acetate of copper.* See *Verdigris.*

The *sulphate*, or blue vitriol of commerce, is a bisulphate. See *Cupri sulphas.*

The *subsulphate of ammonia and copper* is the *cuprum ammoniatum* of the Pharmacopœias. See *Cupri ammonio-sulphas.*

With arsenious acid copper forms the pigment, known under the name of *Scheele's green.* See *Arsenious acid.*

Copper combines readily with the metals. With gold, it forms the *standard gold* used for coining. (See *Aurum.*) With zinc, it forms *brass*; with tin, *bell metal* and *bronze*; with tin and a little arsenic, the *speculum metal.* *Tombac*, *Dutch gold*, *pinchbeck*, *similor*, and *Prince Rupert's metal*, are compounds of copper and brass in various proportions. *Tutenag* is said to be an alloy of copper and zinc, with a little iron.

All the preparations of copper act as virulent poisons, when introduced in very small quantities into the stomachs of animals. A few grains are sufficient for this effect. Death is commonly preceded by very decided nervous dis-

orders, such as convulsive movements, tetanus, general insensibility, or a palsy of the lower extremities. This event happens frequently so soon, that it could not be occasioned by inflammation or erosion of the *primæ viæ*; and, indeed, where these parts are apparently sound. It is probable that the poison is absorbed, and, through the circulation, acts on the brain and nerves. The cupreous preparations are, no doubt, very acrid, and if death do not follow their immediate impression on the nervous system, they will certainly inflame the intestinal canal. The symptoms produced by a dangerous dose of copper are exactly similar to those which are enumerated under arsenic, only the taste of copper is strongly perceived. The only chemical antidote to cupreous solutions, whose operation is well understood, is water strongly impregnated with sulphuretted hydrogen. The alkaline hydrosulphurets are acrid, and ought not to be prescribed.

But we possess, in sugar, an antidote to this poison, of undoubted efficacy, though its mode of action be obscure. Duval introduced into the stomach of a dog, by means of a caoutchouc tube, a solution in acetic acid, of four French drachms of oxide of copper. Some minutes afterwards he injected into it four ounces of strong syrup. He repeated this injection every half-hour, and employed altogether 12 ounces of syrup. The animal experienced some tremblings and convulsive movements. But the last injection was followed by a perfect calm. The animal fell asleep, and awakened free from any ailment.

Orfila relates several cases of individuals who had, by accident or intention, swallowed poisonous doses of acetate of copper, and who recovered by taking large doses of sugar. He uniformly found, that a dose of verdigris which would kill a dog in the course of an hour or two, might be swallowed with impunity, provided it was mixed with a considerable quantity of sugar.

As alkohol has the power of completely neutralising, in the ethers, the strongest muriatic and hydriodic acids, so it would appear that sugar can neutralise the oxides of copper and lead. The neutral saccharite of lead, indeed, was employed by Berzelius in his experiments, to determine the prime equivalent of sugar. If we boil for half an hour, in a flask, an ounce of white sugar, an ounce of water, and 10 grains of verdigris, we obtain a green liquid, which is not affected by the nicest tests of copper, such as ferro-prussiate of potash, ammonia, and the hydro-sulphurets. An insoluble green carbonate of copper remains at the bottom of the flask.

Copper, ammoniated solution of. See *Liquor cupri ammonio-sulphatis.*

CO'PPERAS. A name given to blue, green, and white vitriol.

Copracrati'a. (From κοπρος, excrement, and ακρατεια, incontinence.) Involuntary discharge of the fæces.

COPRAGO'GUS. (From κοπρος, the excrement, and αγω, to bring away.) Purgative.

Copragogum. A laxative electuary mentioned by Ruland.

Copre'siesis. (From κοπρος, excrement, and εμεω, to vomit.) A vomiting of fæces. See *Ileac passion.*

Coprocri'ticus. (From κοπρος, excrement, and κρινω, to separate.) Synonymous with ecoprotic.

Copropho'ria. (From κοπρος, excrement, and φορεω, to bring away.) A purging.

Co'pros. (*os, i.* f. Κοπρος.) The fæces, or excrements from the bowels.

Coprosta'sia. (From κοπρος, fæces, and ἱστημι, to remain.) Costiveness.

Copro'stasis. The same.

Copta'rion. (Κοπτη, a small cake.) *Coptarium.* A lozenge.

CO'PTE. (Κοπτη, a small cake.) A medicine used by the ancients. It was generally made of vegetable substances, and applied externally over the stomach, or liver.

CO'PULA. (*a, æ.* f.; a shackle, or band.) 1. A ligament.

2. The word is used by Paulus Zacchius to signify sexual intercourse.

Copula carnalis. Sexual intercourse; coition.

COR. (*Cor, dis.* neut.) 1. The heart. See *Heart.*

2. The pith of a plant.

3. Gold. — *Ruland.*

4. An intense fire. — *Ruland.*

Cora'cine. (Κορακινη; from κοραξ, a crow: probably so named from its being of a black colour?) The name of a pastil mentioned by Galen.

Coracobo'tane. (From κοραξ, a crow, and βοτανη, a herb.) The Alexandrian laurel.

Coraco-brachiæus. See *Coraco-brachialis.*

CO'RACO-BRACHIA'LIS. *Coraco-brachiæus.* A muscle, so called from its origin and insertion. It arises, tendinous and fleshy, from the fore-part of the coracoid process of the scapula, adhering, in its descent, to the short head of the biceps; inserted, tendinous and fleshy, about the middle of the internal part of the os humeri, near the origin of the third head of the triceps, called *brachialis externus*, where it sends down a thin tendinous expansion to the internal condyle of the os humeri. Its use is to raise the arm upwards and forwards.

Coraco-hyoideus. See *Omo-hyoideus.*

CO'RACOID. (*Coracoides*; from κοραξ, a crow, and ειδος, resemblance: shaped like the beak of a crow.) Some processes of bones are so named, from a fancied resemblance to the beak of a crow; as the *coracoid process of the scapula.*

Coracoid process. See *Scapula.*

Coracoideus musculus. The *Brachialis internus.*

Coral. See *Corallium.*

Corallatum. An alchemical name of the deutoxide of mercury.

CORALLI'NA. (*a, æ.* f.; diminutive of *corallium.*) A genus of marine productions, generally supposed to be polypifers; no polypi, however, have as yet been detected in them, and hence some naturalists have regarded them as plants. They consist of a calcareous, articulated stem, rising from a kind of root, which adheres

to rocks, shells, or other bodies, and divided into articulated branches.

Corallina Corsicana. See *Fucus helminthocorton.*

Corallina melitochorton. See *Fucus helminthocorton.*

Corallina melito-corton. See *Fucus helminthocorton.*

Corallina officinalis. *Muscus maritimus; Corallina alba.* Coralline; Sea moss; White wormseed. This was administered to children as an anthelmintic, in the dose of half a drachm to a drachm, once or twice a day. What virtues it may possess are merely those of carbonate of lime, of which it chiefly consists.

Corallina rubra. See *Fucus helminthocorton.*

Coralline. See *Corallina.*

Coralline, Corsican. See *Fucus helminthocorton.*

Coralline. See *Corallina officinalis.*

Coralline, white. See *Corallina officinalis.*

CORA'LLIUM. (*um, i.* n. κοραλλιον; κουραλιον; probably from κορη, a daughter, and ἁλς, the sea, because it is the production of the sea.) Coral. A general name for those marine polypifers which have a stony or horny axis; as *Isis, Oculina, Gorgonia,* &c.

Corallium album. White coral. The produce of the several species of *Oculina* — *Madrepora oculata* of Linnæus. The powder of white coral has been administered as an absorbent.

Corallium nigrum. Black coral. *Gorgonia antipathes* — *Antipathes* of Linnæus. This was formerly used in epilepsy.

Corallium rubrum. *Acmo. Azur.* Red coral. The red coral of commerce is the hard calcareous substance of the *Isis nobilis.* When powdered, it is exhibited as an absorbent earth to children; but is in no respect preferable to common chalk.

Corallode'ndron. (From κοραλλιον, coral, and δενδρον, a tree: so named from its rich scarlet blossoms.) The coral tree of America. See *Erythrina corallodendron.*

CO'RALLOID. (*Coralloides;* from κοραλλιον, coral, and ειδος, likeness.) Coral-like: applied as a specific name to some plants. See *Clavaria coralloides.*

Corbatum. An alchemical name of copper.

CO'RCHORUS. (*us, i.* m.; from κορη, the pupil of the eye, and κορεω, to purge: so called because it was thought to purge away rheum from the eyes.) The ancient name of some kind of pot-herb, and also of a species of fish; but now applied to a genus of plants of the Class, *Polyandria;* Order, *Monogynia.* The *Corchorus olitorius* is cultivated in Egypt as a pot-herb, and the *C. trilocularis* in Barbary.

CO'RCULUM. (*um, i.* n.; a little heart: diminutive of *cor,* a heart.) An essential part of a germinating seed, called also the *embryo,* or germ. It lies between the cotyledons. It is the point from which the life and organisation of the future plant originate. In some seeds it is much more conspicuous than in others. The walnut, bean, pea, and lupine, show it in perfection. Its internal structure, before it begins to vegetate, is observed to be very simple, consisting of an uniformly medullary substance, enclosed in its appropriate bark or skin. Vessels are formed in it as soon as the vital principle is excited to action, and parts are then developed which seemed not previously to exist. There are observed in it,

1. The *rostellum,* or little beak, which penetrates into the earth, and becomes the root.

2. The *plumula,* which shoots above the ground, and becomes a tuft of young leaves, with which the young stem, if there be any, ascends. See *Cotyledon.*

Corda. See *Chorda.*

Corda tympani. See *Chorda tympani.*

Cordæ Willisii. See *Chordæ Willisii.*

CORDA'TUS. Heart-shaped: applied to leaves, petals, &c. which are ovate, and hollowed out at the base, according to the vulgar idea of a heart; as the leaves of *Arctium lappa,* and *Tamus communis,* and the petals of *Sium selinum.*

A leaf is called *obcordate,* when the apex of the heart-shaped leaf is fixed to the petiole.

CO'RDIA. (*a, æ.* f. So called by Plumier in honour of Euricius Cordius and his son Valerius, two eminent German botanists.) A genus of plants. Class, *Pentandria;* Order, *Monogynia.*

Cordia myxa. The Sebesten plant. *Sebesten, Sebestina. Cordia — foliis ovatis, supra glabris; corymbis lateralibus; calycibus decemstriatis,* of Linnæus. The black fruit of this plant is mucilaginous, and gently laxative; and is exhibited in form of decoction in various diseases of the chest, hoarseness, cough, difficult respiration, &c.

CORDIAL. *Cardiacus.* A term originally adjective; but, like most others expressive of the properties of medicines, used also as a substantive. It is applied to warm and stimulating medicines which raise the spirits, and were formerly supposed to strengthen the *heart,* whence the name.

Cordine'ma. (From καρα, the head, and δινεω, to turn round.) Heaviness of the head; vertigo. — *Erotian.*

CORDO'LIUM. (*um, i.* n.; from *cor,* the heart, and *dolor,* pain.) Synonymous with *cardialgia.*

Cordy'lea. *Crocodilea. Stercus lacerti.* The dung of a species of lizard, common in Egypt and the Levant; *Lacerta stellio* of Linnæus. It is prized in the East as a remedy for cutaneous diseases, and as a cosmetic.

CO'RE. (*e, es.* f. Κορη.) The pupil of the eye.

Corecto'mia. (From κορη, the pupil, and εκτεμνω, to cut out.) The operation of making an artificial pupil by cutting out a portion of the iris. The term is not well constructed.

Coredia'lysis. (From κορη, the pupil, and διαλυω, to loosen.) The formation of an artificial pupil by detaching the iris from the ciliary ligament. The term is ill-devised, and does not express the meaning.

Core'ma. (Κορημα; from κορεω, to cleanse.) A medicine for cleansing the skin. — *Paulus Ægineta.*

COREMORPHO'SIS. (From κορη, the pupil, and μορφωσις, formation.) The operation of forming an artificial pupil. — *Wagner.*

CORENCLEI'SIS. (From κορη, the pupil, and εγκλεισις, inclusion.) That operation for artificial pupil in which a portion of the iris is drawn through an incision in the cornea, and cut off.

CORETOMEDIA'LYSIS. (From κορη, the pupil, τεμνω, to cut, and διαλυω, to loosen.) The operation for artificial pupil, by detaching the iris from the ciliary ligament.

CORETO'MIA. (From κορη, the pupil, and τεμνω, to cut.) The operation for artificial pupil.

CORIA'CEOUS. (*Coriaceus*; from *corium*, leather.) Leathery: applied to leaves and pods that are thick and tough without being pulpy, or succulent; as in the leaves of *Magnolia grandiflora*, *Aucuba*, &c., and the pods of the lupine.

Coriander. See *Coriandrum.*

CORIAN'DRUM. (*um*, *i.* n. Κοριον. Κοριανον. Κοριαννον.) Derived, according to some, from κορη, the pupil of the eye, which the seed is said to resemble; but it does not resemble it in the least: others, with more probability, derive it from κορις, a bug, the fresh herb having a disagreeable smell resembling that of bugs. Coriander. 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia.*

2. The pharmacopœial name of the officinal coriander. See *Coriandrum sativum.*

CORIANDRUM SATIVUM. The systematic name of the coriander plant: called also *Cassibor*, and *Corianon.*

Coriandrum—*fructibus globosis*, of Linnæus. This plant is a native of the south of Europe, where, in some places, it is said to grow in such abundance, as frequently to choke the growth of wheat and other grain. From being cultivated here as a medicinal plant, it has for some time become naturalised in this country, where it is usually found in corn-fields, the sides of roads, and about dunghills. Every part of the plant, when fresh, has a very offensive odour; but the seeds, when dried, have a tolerably grateful smell, and their taste is moderately warm, and slightly pungent. They yield their virtues entirely to rectified spirit, but only partially to water. By distillation with water, they yield a small quantity of a yellowish essential oil, which smells strongly, and pretty agreeably, of the coriander.

Dioscorides asserts, that the seeds, when taken in a considerable quantity, produce deleterious effects; and in some parts of Spain and Egypt, where the fresh herb is eaten as a cordial, instances of fatuity, lethargy, &c. are observed to occur very frequently: but these qualities seem to have been unjustly ascribed to the coriander; and Dr. Withering informs us, that he has known six drachms of the seeds taken at once, without any remarkable effect. These seeds, and indeed most of those of the umbelliferous plants, possess a stomachic and carminative power. They were directed in the *infusum amarum*, the *infusum sennæ tartarizatum*, and some other compositions of the pharmacopœias; and, according to Dr. Cullen, the principal use of these seeds is, "that infused along with senna, they more powerfully correct the odour and taste of this than any other aromatic that I have employed; and are, I believe, equally powerful in obviating the griping that senna is very ready to produce."

Coriannon. See *Coriandrum.*

Corianon. See *Coriandrum.*

CO'RIS. (*is*, *is.* f.; from κειρω, to cleave or cut: so called, because it was said to heal wounds.) 1. The ancient name of the herb St. John's wort.

2. The name of a genus of plants. Class *Pentandria*; Order, *Monogynia.*

Coris cretica. See *Hypericum saxatile.*

Coris lutea. See *Hypericum coris.*

CORIS MONSPELIENSIS. Heath pine. *Symphitum petræum.* This plant is intensely bitter and nauseous, but apparently an active medicine, and employed, it is said, with success in syphilis.

CO'RIUM PHLOGI'STICUM. The buffy coat of the blood. See *Sanguis.*

Cork. See *Quercus suber.*

Corn. See *Clavus.*

Corn salad. See *Valeriana locusta.*

CORNACHI'NUS PULVIS. (So named after Cornachini, a physician of Pisa.) *Pulvis de tribus. Pulvis trium diabolorum. Pulvis comitis Warwicensis, Earl of Warwick's powder.* The preparations known under these names consist of scammony, diaphoretic antimony, and cream of tartar, in proportions varying according to different receipts. Cornachini wrote a whole book about his powder, the proportions of the ingredients of which he varied according to circumstances. Quincy tells us that the Earl of Warwick's powder is usually made in our shops, of scammony (prepared with fumes of sulphur) ʒij., diaphoretic antimony, ʒj., crystals of tartar, ʒss. The dose for an adult is from grs. xv. to ʒss.

CO'RNEA. (*a*, *æ.* f.; so called, because it is of a horny consistence.) See *Oculus.*

CORNEA OPACA. The sclerotic coat of the eye. See *Oculus.*

CORNEA TRANSPARENS. *Cornea pellucida.* See *Oculus.*

CORNESTA. A chemical retort.

Cornflower. See *Centaurea cyanus.*

CORNI'CULA. (*a*, *æ.* f.; from *cornu*, a horn.) A kind of cupping instrument in the shape of a horn, with an aperture at the narrow end, through which the air is exhausted by drawing with the mouth.

CORNICULA'RIS PROCE'SSUS. Horn-shaped process. The coracoid process of the scapula has been so called.

CORNIFO'RMIS. (From *cornu*, a horn, and *forma*, resemblance.) Horn-shaped: applied to the nectary of plants: — *nectarium corniforme*, in the orchis tribe.

CO'RNINE. An alkaline substance discovered by Mr. Carpenter, of Philadelphia, in the *Cornus florida.* It appears to resemble quinine in its properties.

CO'RNU. (*Cornu*, n. indeclinable.) 1. The horn of an animal. See *Horn.*

2. A wart. See *Verruca.*

3. A corn or horny induration of the cuticle. See *Clavus.*

4. The lateral ventricles of the brain terminate in three angular cavities, which are called their *cornua*, or horns.

Cornu ammonis. *Cornu arietis.* When the pes hippocampi of the human brain is cut transversely through, the cortical substance is so disposed as to resemble a ram's horn. This is the true cornu ammonis, though the name is often applied to the *pes hippocampi* itself.

Cornu arietis. See *Cornu ammonis.*

Cornu cervi. Hartshorn. The horns of several species of stag, as the *Cervus alces*, *Cervus dama*, *Cervus elephas*, and *Cervus tarandus*, are used medicinally. Boiled, they impart to the water a nutritious jelly, which was formerly much in esteem. Hartshorn jelly is made thus: — Boil half a pound of the shavings of hartshorn, in six pints of water, to a quart; to the strained liquor add one ounce of the juice of lemon, or of Seville orange, four ounces of mountain wine, and half a pound of sugar; then boil the whole to a proper consistence. The horns, when calcined, afford the *cornu ustum* of the pharmacopœias. By distillation they yield the *liquor volatilis cornu cervi*, or spirit of hartshorn.

Cornu cervi calcinatum. See *Cornu ustum.*

Cornu monocero'tis. Unicorn's horn. See *Unicornu.*

Cornu ustum. *Cornu cervi calcinatum.* Burn pieces of hartshorn in an open fire, until they become thoroughly white; then powder, and prepare them in the same manner as is directed for chalk. Burnt hartshorn has been supposed to possess absorbent, antacid, and astringent properties. It consists of phosphate of lime, with minute proportions of carbonate of lime and phosphate of magnesia; it has evidently, therefore, no antacid or absorbent power, and is probably altogether inert as a medicine.

Cornua uteri. The horns of the womb. See *Uterus.*

Cornumu'sa. *Cornesta.* A retort. — *Morley.*

CO'RNUS. (*us*, *i.* f.) 1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria*; Order, *Monogynia.*

2. The pharmacopœial name of the cornel tree. See *Cornus sanguinea.*

Cornus florida. A north American tree, the bark of which is recommended as a febrifuge.

Cornus mascula. An European tree, the fruit of which is of the size and form of an olive, and is edible. The bark is said to be febrifuge.

Cornus sanguinea. The fruit of this plant is moderately cooling and astringent. It yields an oil useful for burning.

Cornu'ta. A retort.

CORNU'TUS. Horn-shaped. Applied in botany to plants and parts of plants.

COROA. *Coruova. Cornova.* The name of a bark lately introduced into Europe from the East Indies. The tree which affords it is not yet known. It is said to be a powerful bitter and febrifuge. Trommsdorff has found in it a peculiar soft resin and an aromatic bitter principle.

Corocrum. Yeast. — *Ruland.*

CORO'LLA. (*a*, *æ.* f.; from *coronula*, a little crown.) That part of a flower which is within the calyx, and immediately surrounds the organs of fructification. It consists of one or more petals, which are usually of a different colour from the leaves of the plant, and of a finer texture.

When a flower has only one covering, it may be doubtful whether this should be called a *calyx* or a *corolla*, nor have botanists agreed on any absolute criterion by which they are to be distinguished: when, however, it is green, and of a coarse texture, it is generally called a *calyx*, and when of any other colour, and of a fine texture, a *corolla.* The distinction may also be aided by the natural affinities of the plant.

There are four general divisions of corollæ:

1. *Monopetalous*, which consist of one petal; as in *Nicotiana tabacum.*

2. *Polypetalous*, having many; as in *Lilium candidum.*

3. *Compound*, consisting of many corollæ, which are not calyculated, and are on a common receptacle and calyx; as in *Helianthus annuus.*

4. *Aggregate*, consisting of many calyculated corollæ placed on a common calyx; as in *Scabiosa arvensis*, and *Echinops sphærocephalus.*

A. *Monopetalous.* This is formed of one petal, which, for the most part, forms a cavity, and is divided into

a. *Limbus*, the limb, which is the margin, or horizontal spreading portion.

b. *Tubus*, the tube, which is the cylindrical and inferior part, and is enclosed in the calyx.

c. *Fauces*, or the orifice of the tube.

From the figure of a *regular* or *uniform limb* are derived the following terms: —

1. *Corolla campanulata*, bell-shaped; as in *Campanula* and *Atropa.*

2. *Globosa*, globular; as in *Hyacinthus botryoides* and *Erica ramentacea.*

3. *Tubulosa*, tubular; as in *Primula* and *Erica massoni.*

4. *Claviculata*; as in *Erica tubiflora.*

5. *Cyathiformis*, cup-shaped; as in *Symphytum officinale.*

6. *Infundibuliformis*, funnel-shaped; as in *Nicotiana tabacum*, and *Datura stramonium.*

7. *Hypocrateriformis*, salver-shaped, a flat limb upon a long tube; as in *Vinca rosea.*

8. *Rotata*, wheel-shaped, that is, salver-shaped, with scarcely any tube; as in *Borago officinalis*, and *Physalis alkekengi.*

9. *Urceolata*, saucer-like; as in *Evolvulus alcinoides.*

10. *Contorta*, obliquely bent; as in *Vinca minor*, and *Nerium oleander.*

11. *Ligulata*, the tube very short, and ending suddenly in an oblong petal; as in the corolla of the radius of the *Helianthus annuus.*

From the figure of an *unequal limb*: —

1. *Corolla ringens*, irregular and gaping like the mouth of an animal; as in *Lamium album*, and *Salvia sclarea.*

2. *Personata*, irregular and closed by a kind of palate; as in *Antirrhinum majus.*

In the ringent and personate corollæ are to be noticed the following parts: —

a. *Tubus*, the inferior part.

b. *Rictus*, the space between the two lips.
c. *Faux*, the orifice of the tube in the rictus.
d. *Galea*, the helmet or superior arched lip.
e. *Labellum*, or *barba*, the inferior lip.
f. *Palatum*, the palate, an eminence in the inferior lip which shuts the rictus of a personate corolla.
g. *Calcar*, the spur which forms an obtuse or acute bag at the side of the receptacle.

3. *Corolla bilabiata*, two-lipped, the tube divided into two irregular lips opposite each other, without any visible rictus; as in *Aristolochia bilabiata*.

In the bilabiate corolla are to be noticed
a. The *tubus*.
b. The *faux*.
c. The *superior lip*, formed of one or two lobes.
d. The *inferior lip*, mostly three-lobed.
e. *One-lipped*, the upper or lower wanting; as in *Aristolochia clematitis*, and *Teucrium*.

Corolla infera means that the corolla is below the germen, which is its most common place; and *corolla supera*, that it is above the germen, as in roses.

B. *Corolla polypetala*, formed of many petals.
In the petal of this division are noticed
a. The *unguis*, or claw, the thin inferior part.
b. The *lamina*, or border, the broader and superior part; example, *Dianthus caryophyllus*.

From the *number* of *uniform* petals the corolla of this division is named
1. *Dipetalous*; as in *Euphorbia graminea*.
2. *Tripetalous*; as in *Tradescantia virginica*.
3. *Tetrapetalous*; as in *Chieranthus incanus*.
4. *Pentapetalous*; as in *Pæonia officinalis*.
5. *Hexapetalous*; as in *Lilium candidum*.
6. *Polypetalous*; as in *Rosa centifolia*.

From the *figure* the corolla is called,
1. *Malvaceous*; pentapetalous, with its claws united lateraliy, so that it appears monopetalous; as in *Malva sylvestris*, and *Alcea*.
2. *Rosaceous*; spreading like a rose, pentapetalous, almost destitute of claws; as in *Rosa canina*, and *Pæonia officinalis*.
3. *Liliaceous*, six or sometimes three-petalled, without a calyx; as in *Lilium candidum*.
4. *Caryophyllaceous*, five-petalled, with a long claw, spreading border, and a monophyllous tubular calyx; as in *Dianthus caryophyllus*, and *Saponaria officinalis*.
5. *Cruciform*, three-petalled, like a cross; as in *Sinapis alba* and *Lunaria alba*.
6. *Manifold*; many corals lying one on another; as in *Cactus flagelliformis*.

From the *figure* of *unequal petals* the corollæ are called,
1. *Orchideal*, with five petals, three of which are bent backward, and two are lateral and in the middle of these: the labellum is bent back into the nectary.
2. *Papilionaceous*, with four petals, irregular and spreading somewhat like a butterfly; as in *Lathyrus latifolius*, and *Robinia pseudacacia*.

In a *papilionaceous* corolla observe
a. The *vexillum*, the standard or large convex petal at the back.
b. *Alæ*, the wings, or two side-petals, placed in the middle.
c. The *carina*, or keel, consisting of two petals, united or separate, embracing the internal organs.

C. *Compound corolla*; consisting of numerous florets, not calyculate, and within a common perianthium.

We here distinguish
a. The *discus*, disk, or middle.
b. The *radius*, which forms the circumference. The marginal white florets of the daisy exemplify the rays, and the central yellow ones the disk.

From the difference in the florets of a compound flower, it is said to be,
a. *Tubulate*, when all the florets are cylindrical.
b. *Ligulate*, or *semifloseulose*, shaped like a strap or riband; as in *Leontodon taraxacum*.
c. *Radiate*, if the florets in the radius are ligulate, and those in the disk tubular.
d. *Semiradiate*, the radius consisting of only a few ligulate florets on one side; as in *Bidens*.

CORO'LLULA. (*a*, *æ*. f.; diminutive of *corolla*, a little wreath or crown.) The partial floret of a compound flower.

CORO'NA. (*a*, *æ*. f.) A crown. A term used in anatomy and botany to designate certain objects supposed to resemble a crown.

Corona ciliaris. The ciliary ligament.

Corona glandis. The margin of the glans penis.

Corona imperialis. The crown imperial. See *Fritillaria*.

Corona regia. See *Trifolium melilotus officinalis*.

Corona solis. See *Helianthus annuus*.

Corona terræ. The ground ivy. See *Glechoma*.

Corona veneris. An eruption of venereal blotches or pustules on the forehead.

Co'ronal suture. *Sutura coronalis*; *Sutura arcualis*. The suture of the head that extends from one temple across to the other, uniting the two parietal bones with the frontal. It is called coronal, because it was on this part of the head that the ancients wore their *coronæ*, or garlands.

Corona'riæ. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of such as have beautiful flowers, thus forming a floral crown.

Corona'rius. See *Coronary*.

CO'RONARY. (*Coronarius*; from *corona*, a crown.) This term is applied in anatomy to several parts because they surround others, or for some less obvious reason.

Coronary arteries of the heart. Two arteries which supply the substance of the heart with blood. See *Heart*.

Coronary ligament of the radius. The ligament which surrounds the neck of the radius, and connects it with the ulna. It is called also the *annular* and the *orbicular* ligament.

Coronary ligament of the liver. See *Hepar*.

Coronatæ plantæ. The name of a class of plants in Linnæus's Fragments of a Natural Method, consisting of plants which have the seed-bud crowned by the flower cup.

CORONA'TUS. Coronate: applied to a

petal which has little crown-like eminences; as in *Nerium oleander*.

CORO'NE. (Κορωνη, a crow: so named from its supposed likeness to a crow's bill.) The acute process of the lower jaw-bone.

CO'RONOID. (*Coronoides, Coronoideus;* from κορωνη, a crow, and ειδος, likeness.) Processes of bones are so called, that have any resemblance to a crow's beak; as coronoid process of the ulna, jaw, &c.

CORO'NOPUS. (*us, odis.* m.; from κορωνη, a crow, and πους, a foot; so called from the resemblance of its leaf to a crow's foot.) See *Plantago*.

CORO'NULA. (*a, æ.* f.; diminutive of *corona.*) The hem or border which surrounds the seeds of some flowers in the form of a crown.

Corpora albicantia. Two white eminences at the base of the brain; called also *corpora albicantia Willisii*. See *Encephalos*.

Corpora Cavernosa Penis. See *Penis*.

Corpora geniculata. Two small eminences at the lower and outer part of the optic thalami. See *Encephalos*.

Corpora olivaria. Two prominences of the medulla oblongata; so named from their being shaped somewhat like an olive. See *Encephalos*.

Corpora ovata. See *Corpora olivaria*.

Corpora pyramidalia. Two eminences of the medulla oblongata; so called from their pyramidal shape. See *Encephalos*.

Corpora quadrigemina. See *Tubercula quadrigemina*.

Corpora restiformia. Two eminences situated one on each side of the upper part of the medulla oblongata. See *Encephalos*.

Corpora sesamoidea. *Corpuscula Arantii. Corpuscula Morgagni.* The small hard granules on the loose edge of the semilunar valves of the aorta and pulmonary artery. See *Heart*.

Corpora striata. See *Encephalos*.

Corpora'tio. The incorporation or blending together of substances. A term used by the old chemists and pharmaceutists.

Corpulency. (*Corpulentia, æ.* f.) See *Polysarcia*.

CORPUS. (*us, oris.* n.) A body; matter of whatever kind. See *Body*.

2. In *Pharmacy*, the basis of a formula was formerly called *corpus;* thus, oil of nutmeg was called *corpus pro balsamo*, because it was used as the basis of factitious balsams.

Corpus annulare. See *Pons varolii*.

Corpus callo'sum. *Commissura magna cerebri. Great commissure of the brain.* The white medullary part joining the two hemispheres of the brain, and coming into view under the falx of the dura mater when the hemispheres are drawn from each other.

Corpus cavernosum clitoridis. See *Clitoris*.

Corpus cavernosum penis. See *Penis*.

Corpus cinereum. See *Corpus dentatum*.

Corpus denta'tum. *Corpus cinereum. Corpus rhomboideum.* A portion of cineritious matter observed in the cerebellum. See *Encephalos*.

Corpus fimbria'tum. The flattened termination of the posterior crus of the fornix of the brain. See *Encephalos*.

Corpus glandulosum. The prostate gland. *Highmorianum*. See *Testicle*.

Corpus luteum. A yellow spot found in that part of the ovarium of females from whence an ovum has proceeded: hence their presence generally determines that the female has been impregnated. The number of the *corpora lutea* corresponds with the number of impregnations. It is, however, asserted by a modern writer, that *corpora lutea* have been detected in young virgins, where no impregnations could possibly have taken place.

Corpus mucosum. See *Cutis*.

Corpus nerveo-spongiosum. The cavernous substance of the penis.

Corpus nervosum. The cavernous substance of the clitoris.

Corpus pampiniforme. (*Pampiniforme;* from *pampinus*, the tendril of a vine.) The plexus formed by the spermatic veins around the spermatic artery.

Corpus papilla're. The nervous and vascular papillæ of the rete mucosum have been so called.

Corpus pro balsamo. See *Corpus*.

Corpus psalloides. See *Lyra*.

Corpus pyramida'le. 1. An eminence on each side of the medulla oblongata. See *Corpora pyramidalia*.

2. The plexus formed by the spermatic veins, usually called *corpus pampiniforme*.

Corpus reticulare. See *Rete mucosum*.

Corpus reticulare malpighi. See *Rete mucosum*.

Corpus rhomboideum. See *Corpus dentatum*.

Corpus spongiosum urethræ. *Substantia spongiosa urethræ. Corpus spongiosum penis.* The spongy structure around the urethra. It commences before the prostate gland, surrounds the urethra, and forms the *bulb;* then proceeds to the end of the corpora cavernosa, and terminates in the *glans penis*, which it forms.

Corpus striatum. See *Encephalos*.

Corpus varicosum. The spermatic plexus of vessels.

Corpu'scle. (*Corpusculum, i.* n.; dim. of *corpus.*) A very minute body; an atom.

Corpuscula Arantii. See *Corpora sesamoidea*.

Corrago. See *Corago*.

Correctio. In *Pharmacy*, the action of a corrigent. See *Corrigens*.

CO'RRIGENS. *Correctorius.* Corrigent. This name is given to any substance in a medical formula or prescription which is intended to modify or render milder the action of another.

Co'rrigia. (Leather thongs.) The tendons of the muscles have been so called.

Corrigiola. An old name of the *Polygonium aviculare*.

CORRO'BORANT. (*Corroborans;* from *corroboro*, to fortify or strengthen.) Possessed of the power of strengthening. See *Tonic*.

Corrosive sublimate. See *Hydrargyri bichloridum*.

CORRUGA'TOR. (*or, oris.* m.; from *corrugo*, to wrinkle.) A muscle, the office of which is to wrinkle or corrugate the part it acts on.

Corrugator supercilii. A small muscle situated on each side of the forehead. *Musculus supercilii*, of Winslow; *Musculus frontalis verus, seu corrugator Coiterii*, of Douglas. Its use is to knit the brows.

Corset de Brasdor. A bandage used by Brasdor in fracture of the clavicle.

CORTEX. (*ex, icis.* m. or f.) 1. The common integument of plants, analogous to the skin of animals. See *Bark.*

2. The Peruvian bark. See *Cinchona.*

Cortex angelinæ. See *Andira.*

Cortex angusturæ. See *Cusparia.*

Cortex antiscorbuticus. See *Wintera aromatica.*

Cortex aromaticus. See *Wintera.*

Cortex bela-aye. See *Nerium.*

Cortex canellæ malabaricæ. See *Laurus cassia.*

Cortex cardinalis de lugo. See *Cinchona.*

Cortex caryophylloides. See *Laurus culilawan.*

Cortex cerebri. The cortical substance of the brain. See *Encephalos.*

Cortex chinæ regius. See *Cinchona.*

Cortex chinchinæ. See *Cinchona.*

Cortex elutheriæ. See *Croton.*

Cortex geoffroyæ jamaicensis. See *Geoffroya jamaicensis.*

Cortex jamaicensis. See *Achras.*

Cortex la'vola. The bark bearing this name is supposed to be the produce of the tree which affords the *Anisum stellatum.* See *Illicium anisatum.*

Cortex magellanicus. See *Wintera.*

Cortex massoy. Massoy bark. The produce of an unknown tree of New Guinea, where it is beaten into a pultaceous mass with water, and rubbed upon the abdomen to allay pain of the bowels. It has the smell and flavour of cinnamon.

Cortex patrum. See *Cinchona.*

Cortex peruvianus. See *Cinchona.*

Cortex peruvianus flavus. See *Cinchona.*

Cortex peruvianus ruber. See *Cinchona.*

Cortex poggereæ. A bark sent from America; said to be serviceable in diarrhœas and dysenteries. The tree which produces it is unknown.

Cortex quassiæ. See *Quassia amara.*

Cortex winteranus. See *Wintera aromatica.*

CO'RTICAL. (*Corticalis;* from *cortex.*) Appertaining to or resembling bark. In *Anatomy*, the external portion of the brain and kidney are denominated the *cortical substance.* See *Encephalos* and *Kidney.*

CORTICO'SUS. Like bark, or rind. Applied in *Botany* to hard woody pods, as those of the *Cathartocarpus fistula.*

CORTU'SA. 1. A name of the wood sanicle. See *Sanicula europea.*

2. The name of a genus of plants. Class, *Pentandria;* Order, *Monogynia.* The *Cortusa matthioli* has been thought useful in rheumatism.

Coru. A tree mentioned by Daléchamps as growing in China, Japan, Malacca, and Bengal. The bark of its root yields a milky juice used against diarrhœa and dysentery. The bark of the stem is employed with the same intention. This tree has been thought to be the *Tabernæmontana citrifolia*, or the *Nerium antidysentericum.*

CORY'DALES. (From κορυς, a helmet.) The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of plants which have flowers somewhat resembling a helmet or hood.

Cory'daline. An alkaline substance found by Wackenroder in the *Corydalis bulbosa.*

CO'RYLUS. (*us, i.* f.; derivation unknown.) 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Polyandria.*

2. The pharmacopœial name of the hazel-tree. See *Corylus avellana.*

Corylus avella'na. The hazel-nut tree. *Corylus avellana — stipulis ovatis, obtusis,* of Linnæus. The nuts of this tree are eaten in this country. They are hard of digestion, and often pass the bowels very little altered; they contain, however, a nutritious oil. An oil is also obtained from the wood of the tree, which is said to be efficacious against the toothach, and to kill worms.

CORYMBI'FERÆ. A natural family of plants which bear corymbal flowers.

CORY'MBUS. (*us, i.* m. Κορυμβον, or κορυμβος, a branch or cluster, crowning the summit of a plant; from κορυς, a helmet.) A corymb. That species of inflorescence formed by many flowers, the partial flower-stalks of which are gradually longer, as they stand lower on the common stalk, so that all the flowers are nearly on a level; as in the *Chrysanthemum corymbosum.* It is said to be *simple*, when not divided into branches; as in *Thlaspi arvense*, and *Gnaphalium dentatum;* and *compound*, when it has branches; as in *Gnaphalium stœchas.*

CO'RYPHA. A genus of palms.

Corypha rotundifolia. This species yields a kind of sago.

Corypha umbraculi'fera. The Talipot palm. This majestic palm, a native of Ceylon and Malabar, is celebrated for the immense size of its leaves, which will cover from fifteen to thirty or forty men, and are used for making umbrellas and other purposes. The pith of the young plant is made into cakes, and used as bread. It bears fruit only in the last year of its life, and the fruit is not esculent.

Co'ryphe. Κορυφη. 1. The vertex of the head.

2. The extremities of the fingers.

3. The apex of the heart.

CORY'ZA. (*a, æ.* f. Κορυζα; from καρα, the head, and ζεω, to boil.) Dr. Good says that coryza is a very genuine and a very extensive, as well as a very ancient, oriental term, common, under some modification or other, to the Hebrew, Arabic, Chaldee, and Syriac dialects; from one of which it was undoubtedly imported into the Greek tongue. By Hippocrates it was used in a very extensive sense, so as to signify defluxion of any kind, whether from the head, nostrils, fauces, or chest. The later Greek physicians restrained coryza to a defluxion from the head and nostrils, and ap-

plied the term *catastagmus* to a defluxion from the fauces and thorax.

Cos medica. (*Cos, cotis;* a whet-stone.) A stone slab on which ointments and other medicaments are prepared.

Coscu'lia. The grains of kermes.

COSME'TIC. (*Cosmeticus;* from κοσμεω, to adorn.) An external medicine used to beautify the skin.

Co'smos. A regular series. Hippocrates applies it to the order and series of critical days.

Co'ssis. A little tubercle in the face, like the head of a worm.

Co'ssum. A malignant ulcer of the nose mentioned by Paracelsus.

CO'STA. (*a, æ.* f.) 1. In *Anatomy*, the rib of an animal. The ribs are the long curved bones which are placed in an oblique direction at the sides of the chest. Their number in man is generally twelve on each side; but in some subjects it has been found to be thirteen, and in others, though more rarely, only eleven. They are distinguished into true and false ribs. The seven upper ribs, which are articulated to the sternum, are called *true* ribs; and the five lower ones, which are not immediately attached to that bone, are called *false* ribs. At the posterior extremity of each rib we observe a small head, divided by a middle ridge into two articulating surfaces, covered with cartilage, which are received into two cavities contiguous to each other, and formed in the upper and lower part of each dorsal vertebra, as we have observed in our description of the spine. This articulation, which is secured by a capsular ligament, is a species of ginglymus, and allows only of motion upwards and downwards. The head of each rib is supported by a short neck, and immediately beyond this we find a flattened tubercle, affording an oblong and slightly convex surface, which is articulated with the transverse process of the lowest of the two dorsal vertebræ, with which its head is articulated. At some little distance from this tuberosity, the rib makes a considerable curve, which is usually called its angle. From the tubercle to the angle the ribs are of considerable thickness, and approaching to a cylindrical shape; but, from the angle to their anterior extremity, they become thinner and flatter. To this anterior extremity is fixed a long, broad, and strong cartilage, which, in each of the true ribs, reaches to the sternum, where its articulation is secured by a capsular ligament, and by other ligamentous fibres. The cartilages of the sixth and seventh ribs being longer than the rest, are extended upwards, in order to reach the sternum, the inferior portion of which is about on a level with the fifth rib. The cartilages of these two ribs are usually united into one, so as to leave no space between them. The false ribs are supported in a different manner; their cartilages terminate in an acute point before they reach the sternum, the eighth rib being attached by its cartilage to the lower edge of the cartilage of the seventh, or last of the true ribs; the ninth in the same manner to the eighth; and the tenth to the ninth; the cartilages of each rib being shorter than that of the rib above it. The eleventh and twelfth, which are the two lowermost ribs, are not fixed at their anterior extremities like the other ribs, but hang loose, and are supported only by their ligamentous fibres, and by muscles and other soft parts.

The external surface of each rib is somewhat convex, and its internal surface slightly concave. On the inferior and interior surface of these bones we observe a long fossa, for the lodgment of the intercostal vessels and nerves. This channel, however, does not extend through the whole length of the rib, being observable neither at the posterior extremity, where the vessels have not yet reached the bone, nor at the fore-end, where they are distributed to the parts between the ribs. We seldom see any marks of it in the short ribs, as in the first, second, eleventh, and twelfth.

Thus far we have given a description, which is applicable to the ribs in general; but, as we find them differing from each other in shape, length, situation, and other respects, it will be right to speak of each rib in particular.

The *first* rib, which is the shortest of any, is likewise the most curved. It is broader than the other ribs, and, instead of being placed, as they are, obliquely, and with its edges upwards and downwards, it is situated nearly in a transverse direction, one of its edges being placed inwards or nearly so. Of these edges, the inner one is sharp, and the outer one somewhat rounded. Its inner surface is smooth, and its superior surface is sometimes slightly depressed anteriorly by the clavicle. The head of this rib, instead of being angular, is flattened, and slightly convex, being received into a cavity, which is formed wholly in the first vertebra, and not by two vertebræ, as in the case with the other ribs.

The *second* rib is longer than the first, but shorter than the ribs below it. Its angle is placed at a small distance from its tuberosity, and its head is articulated with two vertebræ, like the other ribs. The other ten ribs, the two last only excepted, differ from the general description we have given, chiefly in the difference of their length, which goes on gradually increasing, from the first or uppermost, to the seventh or last of the true ribs, and as gradually diminishing from that to the twelfth. Their obliquity, in respect to the spine, likewise increases as they descend, as does the distance between the head and angle of each rib, from the first rib to the ninth. The two lowest ribs differ from all the rest in the following particulars: — Their heads, like that of the first rib, are rounded, and received into a cavity formed entirely in the body of one vetebra; they have no tubercle for their articulation with the transverse processes, to which they are only loosely fixed by ligaments, and, in this respect, the tenth rib is sometimes found to agree with them: they are much shorter than the rest of the false ribs, and the twelfth is still shorter than the eleventh. The length of the latter, however, is different in different subjects, and is not always found to be the same on both sides. Anteriorly, as we have already observed, their cartilages are short and loose, not being attached to the cartilages

of the other ribs; and this seems to be, because the most considerable motions of the trunk are not performed on the lumbar vertebræ alone, but likewise on the lower vertebræ of the back; so that if these two ribs had been confined anteriorly, like the rest, and likewise united to the bodies of two vertebræ, and to the transverse process, this disposition would have impeded the motion of the two last vertebræ of the back, and consequently would have affected the motion of the trunk in general.

The use of the ribs is to give form to the thorax, and to cover and defend its viscera; also to assist in breathing; for they are joined to the vertebræ by regular hinges, which allow of short motions, and to the sternum by cartilages, which yield to the motion of the ribs, and return again when the muscles cease to act.

2. In *Botany*, the thick nerve-like cords of a leaf, which proceed from the base to the apex, are called ribs. See *Leaf.*

Costa herba. See *Hypochæris.*

Costa pulmonaria. See *Hypochæris.*

COSTAL. (*Costalis*; from *costa*, a rib.) Belonging to a rib; applied to muscles, arteries, nerves, &c.

COSTA'TUS. Ribbed: applied to leaves which have elevated lines extending from the base to the point. See *Leaf.*

Costiveness. See *Constipation.*

COSTO-HYOIDEUS. A muscle so named from its origin and insertion. See *Omo-hyoideus.*

CO'STUS. (*us, i.* m.; from *kasta*, Arabic.) The name of a genus of plants in the Linnæan system. Class, *Monandria*; Order, *Monogynia.*

Costus amarus. See *Costus arabicus.*

COSTUS ARABICUS. The sweet and bitter costus. *Costus indicus; amarus; dulcis; orientalis.* The root of this tree possesses bitter and aromatic virtues, and is considered as a good stomachic. It is also said to be diaphoretic, diuretic, and emmenagogue. Formerly there were two species, the *bitter* and *sweet*, distinguished for use. It is generally believed, however, that they are the same, the root acquiring a bitter flavour by keeping.

Costus corticosus. See *Wintera aromatica.*

COSTUS HORTORUM MINOR. The *Achillæa ageratum.*

COSTUS NIGRA. The artichoke.

COTARONIUM. A name given by Paracelsus to an imaginary liquor, which was an universal solvent.

CO'TIS. Κοτις. The back part of the head. — *Hippocrates.*

Cotton. See *Gossipium herbaceum.*

Cotton-weed. See *Filago.*

CO'TULA. (*a, æ.* f.) Stinking chamomile.

Cotula fœtida. See *Anthemis cotula.*

CO'TULE. (*e, es.* f. Κοτυλη, the name of an ancient measure.) The socket of the hip-bone. See *Acetabulum.*

COTYLE'DON. (*on, onis.* f.; same etymon.) 1. A seed-lobe, or cotyledon. The *cotyledons* are the two halves of a seed, which, when germinating, become two pulpy leaves, called the *seminal leaves.* These leaves are often of a different *form* from those which are about to appear; as in the *Raphanus sativus*: and sometimes they are of another *colour*; as in *Cannabis sativa*, the seminal leaves of which are white.

Almost all the cotyledons wither and fall off, as the plant grows up.

These bodies are spoken of in the plural, because it is much doubted whether any plant can be said to have a solitary cotyledon. Most plants are *dicotyledonous.* Plants without any cotyledons are called *acotyledonous.* Those with more than two, *polycotyledonous.*

Between the two cotyledons of a germinating seed, is seated the *embryo*, or germ of the plant, called by Linnæus, *corculum*, or little heart. Mr. Knight denominates it the germen: but that term is appropriated to a very different part, the rudiment of the fruit. The expanding embryo, resembling a little feather, has, for that reason, been called by Linnæus, *plumula*: it soon becomes a tuft of young leaves, with which the young stem ascends. See *Corculum.*

2. The word has the same significations as *acetabulum*, which see.

COTYLOID CAVITY. (*Cotyloides*; from κοτυλη, the name of an ancient measure, and ειδος, resemblance.) The socket which receives the head of the thigh-bone.

COUCHING. A surgical operation which consists in removing the opake lens out of the axis of vision, by means of a needle constructed for the purpose.

Couch-grass. See *Triticum repens.*

COUGH. A cough is, by the Latins, called *tussis*, and by the Greeks, *bex.* It is a sonorous and violent expulsion of air from the lungs, and is well known to accompany, as a symptom, a great multiplicity of other affections; thus it occurs in pleurisy, pneumonitis, quinsy, asthma, catarrh, phthisis, hysteria, &c.: on this account some nosologists, and amongst them Dr. Cullen, have omitted cough as an idiopathic disease, and have only introduced it as synonymous with catarrh, though it belongs as much to phthisis. Cough is doubtless most frequently a symptom of some other complaint; but it is at times as truly idiopathic as any other disease, and ought to be treated as such. In the act of coughing, the lungs, like the stomach in vomiting, continue inert; and the spasmodic action by which the lungs are emptied, is performed by the muscles of respiration. "It is not necessary," observes John Hunter, "that the stomach should act violently, to produce the evacuation of its contents; nor is it even necessary that it should act at all: for the lungs themselves do not act in the least when any extraneous matter is to be thrown up; and coughing is to the lungs what vomiting is to the stomach. The muscles of respiration are the active parts in emptying the lungs, and can act naturally and preternaturally. The action of vomiting is performed entirely by the diaphragm and abdominal muscles; and we know, by the same action, that the contents of the rectum can be expelled." Generally speaking, idiopathic cough is not dangerous in itself, or while running its regular course: but it has often proved highly dangerous in its results, by superin-

ducing inflammation of some organ, an hæmoptoe, or phthisis.

A cough is in some cases attended by expectoration, and sometimes it exists without any: hence the distinction of cough into moist or *mucous*, and *dry* cough.

The *mucous cough*. — This has been named by writers, *anaptysis*, *anacatharsis*, *tex humida*, and *tussis humida*. The expectoration is chiefly mucous, and is excreted very freely. The exhalents of the mucous membrane of the bronchia are stimulated by an irritation of some kind or other, frequently by a reverse sympathy, in consequence of cold and torpid feet, to act more powerfully than in a state of ordinary health, whence the bronchial vessels become overloaded, and relieve themselves by an expectoration that takes place freely, and without the hoarseness that usually accompanies catarrh, or any considerable disturbance of the respiratory organs. This kind of cough is often a chronic disease in old age, when it takes place in long paroxysms, with a viscid and mucous discharge, excreted with some difficulty, and more or less of difficulty of breathing. Here the bronchial secretion of mucous is, perhaps, less copious than in ordinary health; but the action of the absorbents being as weak and sluggish as that of the excretories, the thinner parts of the mucus alone are imbibed and carried off: and hence what remains is necessarily small in quantity, peculiarly tenacious, and thrown up with great labour and repeated efforts. A cough of this nature, though common to persons advanced in life, occurs also to those whose lungs and bronchial vessels are rendered weak and irritable from a neglect of common mucous coughs, which have thus become habitual, and which are much increased on every change of atmosphere, and particularly during the inclemency of winter.

In some cases, the fluid that is coughed up is thin, frothy, and saline, and generally a depraved secretion: constitutions that are gouty, rheumatic, and bilious, and more especially such as have had occasional attacks of chronic hepatitis, are subject to this kind of expectoration and cough.

The *dry cough*. — There is a cough which is mostly unattended by any expectoration, and which often returns periodically. It is observed in highly irritable, nervous, and hysterical constitutions, and is obviously *nervous*.

With respect to the treatment of cough: that which is produced by cold, requires diaphoretics, demulcents, and expectorants; and laxatives, with small doses of henbane to allay the bronchial irritation, and a diet properly regulated according to circumstances. Where the symptoms assume an inflammatory character, the treatment recommended in acute bronchitis becomes applicable. Where the cough has become more habitual, and attends old age, the more stimulating expectorants are useful, as garlic, ammoniacum, benzoin, styrax; and, where the expectoration is considerable and the temperament phlegmatic, the vapour of tar inhaled twice a day for half an hour at each time, and the internal use of tar water. The nervous cough requires narcotics and antispasmodics; of the former, conium and henbane will generally be found to answer best, and of the latter, volatile alkali: there is less objection to the use of opium in the dry nervous cough, than where the secretion of the bronchial membrane is increased; and a diaphoretic opiate is often very useful in the case under consideration.

The *hooping-cough* is a specific disease, and requires separate consideration. See *Pertussis*.

Cough bronchial. See *Cough tubal*.

Cough, cavernous. The resonance of the cough, heard when the stethoscope is applied over an excavation in the lungs, is termed the *cavernous cough*.

Cough, tubal. When the lungs are hepatised, the cough, as heard through the stethoscope, applied over the trachea, root of the bronchi, and even over the subdivisions of the bronchi no larger than a goose-quill, gives, besides its natural shock, a sensation as of air passing through a tube. This is called *tubal* or *bronchial* cough.

Counter-opening. See *Contra-apertura*.

Coup de soleil. Stroke of the sun. A French term which has been used to signify any malady produced by exposure to the sun's rays, as erysipelas, apoplexy, phrenitis, &c.: it is generally restricted, however, to that form of phrenitis not uncommon in tropical climates, which arises from exposing the head uncovered to the full heat of the sun.

Courap. The vernacular name in India for cutaneous diseases attended with itching, as porrigo, scabies, &c.

Cou'rbaril. See *Hymenæa courbaril*.

Couro'ndi. An evergreen tree of India, said to be antidysenteric.

Courou moelli. A shrub of India, said to be antivenomous. It is the *Flacurtia sepiaria* of Roxburgh.

Couscous. An African food much used about the river Senegal. It is a composition of the flour of millet, with some flesh, and the bark called *lalo*. See *Adansonia digitata*.

Couvre-chef. The French name of a bandage for the head. See *Cucullus*.

Covolam. See *Crataeva marmelos*.

Cow. See *Bos taurus*.

Cowhage. See *Dolichos pruriens*.

Cow-itch. See *Dolichos pruriens*.

Cowper's glands. (*Glandulæ Cowperi*; named from Cowper, who first described them.) Two small muciparous glands, each about the size of a pea, situated at the sides of the membranous part of the urethra in the male, before the prostate gland. See *Urethra*.

COW-POX. *Vaccinia*. *Variola vaccina*. Any pustulous disease affecting the cow may be called the cow-pox: whether it arises from an over distension of the udder, in consequence of a neglect in milking the cow, or from the sting of an insect, or any other cause. But the species which claims our particular attention, is that which was recommended to the world by Dr. Jenner, in the year 1798, as a substitute for the small-pox. This was supposed by Dr. Jenner, and a number of succeeding inquirers, to originate from the disease called the *grease*

in the horse's heel, and to be accidentally communicated to the cow. This, however, is now known to be an error; and it is perfectly established that there are two independent sources of the virus called *vaccine*, namely, the heel of the horse when affected with grease, and the udder of the cow, from either of which the disease called vaccinia or cow-pox may be communicated to the human subject. It is also found that the grease of the horse's heel will produce cow-pox in the cow, although the latter also originates in the cow, without any infection from the horse.

The genuine cow-pox appears on the teats of the cow, in the form of vesicles, of a blue colour approaching to livid. These vesicles are elevated at the margin, and depressed at the centre. They are surrounded with inflammation. The fluid they contain is limpid. The animals are indisposed; and the secretion of milk is lessened. Solutions of the sulphates of zinc and copper are a speedy remedy for these pustules; otherwise they degenerate into ulcers, which are extremely troublesome. It must, however, be recollected, that much of the obstinacy attending these cases is owing to the friction of the pustules, in consequence of milking.

Similar effects are produced in the hands of the milkers, attended with febrile symptoms, and sometimes with tumours in the axilla. Other parts, where the cuticle is abraded, or where it is naturally very thin, are also liable to the same affection, provided active matter is applied. It even appears that, in some instances, pustules have been produced by the application of vaccine virus to the sound and perfect cuticle. One case of this kind may be found in a letter from Dr. Fowler, of Salisbury, to Dr. Pearson, published in the first work of Dr. Pearson on this subject.

Genuine cow-pox, as it appears in the cow, is an epizootic disease, and seldom, if ever, appears except when cattle are collected together in herds. It is not frequent under any circumstances; and, in the year 1828, the inquiries of the National Vaccine Board failed to discover a single instance of it in England. The disease appears to be sometimes slight, and chiefly confined to the udder; but it is occasionally very severe and fatal, accompanied with much fever, and a general eruption over the body. It is, therefore, in no instance a merely local disease, but an eruptive fever like the small-pox and measles in man. Cows are subject to other pustular diseases of the udder which, however, have nothing specific in their nature. The pustules have not the blue tint of the vaccine vesicle; they are not surrounded by erysipelatous redness; they are unattended by constitutional disturbance; they scab quickly, and do not occasion ulceration.

Dr. Jenner elucidated one point of the first importance, relative to the genuine cow-pox. It had frequently been observed, that when this disorder prevailed in a farm, some of the persons who contracted it by milking were rendered insusceptible of the small-pox, while others continued liable to that infection. This was owing to the different periods at which the disease was excited in the human subject. One person, who caught the disease while the virus was in an active state, was rendered secure from variolous contagion; while another, who received the infection of the cow-pox when it had undergone a decomposition, remained susceptible of the small-pox. This apparent uncertainty of the prevention was probably the reason why it was not before introduced into practice.

From the violent opposition which vaccine inoculation has met with, in consequence of casual failures, it may be doubted whether the public would ever have adopted the practice, had not this fallacy been detected by Dr. Jenner. To him, also, we are indebted for another discovery of the first importance, namely, that the vesicle excited in the human subject by vaccine matter, yields a fluid of a similar nature with that which was inserted. This experiment, so essential to the general extension of the practice, and so happy in its result, was never before attempted: it was reserved to crown the labours of Dr. Jenner.

A considerable number of instances are on record, to prove that farriers and others, who receive infection from the heel of a horse, are either partly or totally deprived of the susceptibility of the small-pox. When Dr. Jenner first published an account of his discoveries, this point was enveloped in some degree of obscurity. He then conceived, that the matter of grease was an imperfect preservative against the small-pox. This opinion was founded on the following circumstance: — It had been remarked, that farriers either wholly escaped the small-pox, or had that distemper in a milder manner than other people. This, however, is easily reconcilable to reason, if we only suppose, that in some cases the infection is communicated when the virus possesses all its prophylactic virtue; and in others, when its specific quality is in some measure lost.

This variation in the effects produced by the virus of the horse, inclined Dr. Jenner to believe that it was modified, and underwent some peculiar alteration in the teats of the cow. He concluded, that it is perfect when it excites the genuine disease in the cow; yet that a considerable advantage is derived from its being transferred to the latter animal, the nipples of which furnish a more obvious and a more abundant source of this inestimable fluid.

It is now ascertained, however, that the horse and the cow each furnish, independently of the other, a virus capable of communicating genuine cow-pox to the human subject. According to Dr. De Carro, the whole of British India was *equinated*, or originally derived the vaccine disease from the grease of a horse's heel at Milan.

A point respecting vaccine inoculation, which has been much controverted, is the permanency of its effects. Instances have been known where persons have escaped the small-pox for a number of years, and yet have ultimately proved not insusceptible of its infection. Hence many have been of opinion that the influence of vaccination on the system is impaired by time, and it has been contended that, at the ex-

piration of seven, ten, or fourteen years, the system becomes again susceptible of the variolous poison. The question cannot be considered as absolutely decided; on the whole, however, it seems probable that vaccination generally confers a permanent immunity from small-pox; but that a few exceptions to this rule occur, and that the great changes in the constitution sometimes induced by puberty, change of climate, and other less obvious causes, render some individuals liable to small-pox after vaccination.

A number of cases are recorded by Dr. Jenner, and other authors who have written on this subject, in which persons who have received the cow-pox by casual infection, twenty, thirty, forty, and fifty years before, still continued insusceptible of variolous contagion, in whatever form it was applied.

It was till lately denied by the more enthusiastic advocates of vaccination, that small-pox could ever occur after the genuine cow-pox; accumulated evidence to the contrary has, however, convinced dispassionate reasoners of the untenability of this position. The truth is, that vaccination, in a great majority of instances, confers a complete and permanent security against small-pox, but that this law is subject to exceptions. It is also perfectly established that, where the small-pox does occur after vaccination, it is generally divested of its formidable characters, and constitutes a comparatively mild disease: this is now recognised under the name of *modified small-pox*.

As the cow-pox destroys the susceptibility of the small-pox, so the small-pox destroys that of the cow-pox. To this general rule, however, a few exceptions are said to have occurred. Certain it is, that a pustule has now and then been excited by the insertion of vaccine virus, in those who have had the small-pox, and that this pustule has been known to yield the genuine virus; but it is not equally certain that the pustule has been perfect in all respects. Possibly it may have been defective in point of size or duration, in respect to its areola, or the limpidity of its contents. That such a pustule has, in some instances, yielded effectual virus, is admitted; but this is no more than what has often happened, in cases where persons who have had the small-pox are a second time inoculated with the variolous poison.

From the mutual prophylactic influence of cow-pox and small-pox, it has been surmised that they are in reality the same disease, and that the cow-pox is merely the small-pox modified by the constitution of the cow. This opinion was held by Jenner, who considered swine-pox, chicken-pox, cow-pox, and small-pox as essentially the same disease. He believed cow-pox to be the primitive disease from which all the rest spring, and small-pox its severest form. These views of Jenner, taken up on theoretical grounds, were supported by some and opposed by others, without any direct appeal to experiment, till lately. Within the last few years, however, Dr. Sonderland, of Bremen, has made experiments on cows, the alleged result of which is that these animals may be infected with the *cow-pox* by inhaling the effluvia of blankets saturated with the virus of the human *small-pox*. Other experiments are stated to have been made in Egypt, in which the cow inoculated with small-pox became affected with genuine cow-pox, affording a fine active lymph. These experiments, repeated by Dr. Gregory at the London Small-pox Hospital, by M. Numann at Utrecht, and by Mr. Macpherson in India, have *failed altogether*; and this, in conjunction with the loose manner in which the former experiments are detailed, divests them so much of credibility, that they may fairly be considered as worthy of little attention; and the general belief of pathologists in the present day, is that small-pox and cow-pox derive their origin from sources perfectly distinct.

The artificial cow-pox in the human subject is much milder than the casual disease; incomparably milder than the small-pox, even under the form of inoculation; and, unlike the latter disease, it is not communicable by contagious effluvia.

Cow-pox produces no pustulous eruptions. When such attend vaccine inoculation, they are owing to some adventitious cause; such as the small-pox, which it is well known may co-exist with the cow-pox. The vaccine vesicle is confined to the parts where matter is inserted; nevertheless, it is certain, that eruptions of other kinds, in some instances, attend vaccine inoculation; such as a nettle-rash, or an eruption resembling a tooth-rash, but rather larger than what is commonly called by that name.

That the cow-pox is not infectious by effluvia, is naturally concluded from its never being communicated from one person to another in the dairies, where the disease is casual, and appears under its worst form. The same inference may be drawn from its never spreading in a family, when only one person is inoculated at a time. To confirm this proposition more fully, the vaccine pustules have been ruptured, and persons who have never had the disorder have been suffered to inhale the effluvia several times a day, but to no purpose.

As to the constitutional indisposition, it is seldom considerable, unless there is a complication of this with some other distemper; and whenever any unfavourable symptoms appear, they may in general be traced to some other cause. We have, indeed, great reason to believe, that no ill-consequence ever arises from the cow-pox itself, unless from ignorance or neglect.

But notwithstanding the symptoms are so mild, they frequently occur at a very early period. A drowsiness, which is one of the most common attendants of the disease, is often remarked by the parents themselves, within forty-eight hours after the matter is inserted. In a majority of cases, a slight increase of heat is perceptible, together with an acceleration of the pulse, and other signs of pyrexia; but not in such a degree as to alarm the most timorous mother. Sometimes the patient is restless at nights; and now and then a case is met with in which vomiting occurs; but, in many cases no constitutional indisposition can be perceived. It is not found that the mildness of the disease

and the absence of constitutional disturbance, detracts in any degree from the antivariolous efficacy of the cow-pox, provided the vesicle has been perfect in all its characters.

This being the grand criterion of the security of the patient, too minute an attention cannot be paid to its rise, progress, and decline. The best mode of inoculating is by making a small oblique puncture in the arm, near the insertion of the deltoid muscle, with the point of a lancet charged with fluid matter. In order to render infection more certain, the instrument may be charged again, and wiped upon the puncture. It is a frequent error to make the puncture too small, with a view of preventing the escape of blood, which it is thought washes away the virus; but unless the skin be fairly penetrated, the operation frequently fails, and the flow of blood is not in reality found to prevent the effect, if the virus have been once fairly applied to the absorbing surface of the cutis vera.

It has been a matter of dispute whether one or more punctures should be made in each arm. It is not of much consequence. One will generally answer the purpose, but several render the effect more certain, and it is best, therefore, to make several.

The vaccine fluid may be taken for inoculation as soon as a vesicle appears; but if the vesicle is punctured at a very early period, it is more apt to be injured. When virus is wanting for inoculating a considerable number, it is better to let the pustule remain untouched, till about the eighth day, by which time it has in general acquired a reasonable magnitude. After that day, if the pustule has made the usual progress, the matter begins to lose its virtue; but it may, in general, be used with safety, though with less certainty of producing infection, till the areola begins to be extensive.

The first sign of infection commonly appears on the third day. A small red spot, rather elevated, may be perceived at the place where the puncture was made. Sometimes, however, the mark of infection having succeeded, is not visible till a much later period. It may be retarded, or even entirely prevented, by any other disorder; such as dentition, or any complaint attended with fever, or by extreme cold. Another frequent cause of a slow progress in the pustule, or a total failure of success, is debility. Sometimes it is impossible to discover any sign of infection for above a fortnight. In this respect the cow-pox is subject to the same laws, and liable to the same variation, as the small-pox.

When a considerable inflammation appears within two or three days after inoculation, there is reason to suspect that infection has not taken place; and if suppuration ensues, that suspicion ought, in general, to stand confirmed. Now and then, however, it happens, that after the spurious pustule, or more properly speaking, the phlegmon, has run its course, which is within a few days, a vesicle begins to appear, bearing every characteristic of the genuine vaccine disease, and yielding a limpid and efficient virus for future inoculations. In this case the patient is as perfectly secured from all danger of the small-pox, as if no festering of the puncture had preceded. The occurrence of such a case, though rare, is worthy to be recorded; because some practitioners have concluded a spurious pustule to be a certain proof of failure.

The areola commonly begins to be extensive on the ninth day, and to decline about the eleventh or twelfth. At this period also the pustule begins to dry; the first sign of which is a brown spot in the centre. In proportion as this increases, the surrounding efflorescence decreases, till at length nothing remains but a circular scab, of a dark brown mahogany colour, approaching to black. Sometimes it resembles the section of a tamarind stone; and it often retains the depression in the centre, which characterises this disease before exsiccation takes place.

Instances have been known where the vaccine pustule, though regular, and perfect in all other respects, has been totally destitute of areola; at least, where neither the medical practitioner, on visiting the patient, nor the attendants, have remarked any appearance of that symptom. In these cases, the patient has proved as insusceptible of variolous infection, as if the surrounding efflorescence had covered the whole arm. It must, however, be confessed, that we have no proof of the non-existence of an areola in these cases. It might have been trivial, it might have been transient; yet it might have been effectual. There is, however, greater reason to believe, that the surrounding efflorescence, though usually a concomitant circumstance, is not an essential requisite to the vaccine disease.

If, when the vaccine virus has been inserted, and a genuine vesicle has risen, the virus be again inserted on the fourth, fifth, or sixth day, the vesicle arising from this second insertion will be hurried in its progress, so that, on the ninth day, it will be surrounded by an areola, and will appear as mature as the first. This affords evidence of the constitution being fully under the influence of the disease; and in 1802 Mr. Bryce, of Edinburgh, recommended the reinsertion of the virus at the end of the fifth or beginning of the sixth day, as a test of the efficacy of the first operation, and this has since been extensively practised, and goes by the name of *Bryce's test*.

If by any accident the vesicle is ruptured, suppuration often ensues. In this case more attention than ordinary ought to be paid to the progress, and to all the phenomena of the local affection; both on account of the uncertainty of success in the operation, as a prophylactic, and the greater probability of tedious ulceration.

If there is room for the least doubt of the sufficiency of the first inoculation, a second ought to be performed without delay. This, if unnecessary, is seldom attended with inconvenience, and never with danger. Either no effect is produced, or a slight festering, which terminates in a few days. An exception occurs but rarely where a spurious, or perhaps even a genuine, pustule takes place in those persons who are known to have had the cow-pox, or the small-pox already; but this cannot be the least cause of alarm to any one who knows the benign character of the distemper.

Various topical applications, both stimulant and sedative, have been recommended, in order to allay the violence of inflammation. If the operation for the insertion of matter is not unnecessarily severe, nor the pustule irritated by friction, or pressure, or other violence, no such applications are necessary. Nevertheless, if either the anxiety of the professional man, or the importunity of a tender parent, should demand a deviation from this general rule, any of the following remedies may be had recourse to. The pustule may be touched with very diluted sulphuric acid; which should be permitted to remain on the part half a minute, and then be washed off with a sponge dipped in cold water. This has been called an escharotic; but any one who tries the application will soon discover that its operation is mild and harmless.

To avoid cavil, it is better to apply a saturnine lotion; compresses, dipped in such a lotion, may be applied at any time when inflammation runs high, and renewed as occasion requires.

If the pustule should chance to be broken, a drop of the liquor plumbi acetatis undiluted, may be applied as an exsiccant; but if ulceration threatens to become obstinate or extensive, a mild cataplasm is the best resource. In case the ulceration is only superficial, and not attended with immoderate inflammation, a bit of any adhesive plaster, spread on linen, will prove the most convenient dressing, and seldom fail of success. It will, in general, be unnecessary to renew it oftener than every other day.

These minute observations no one will despise, unless there be any person so ignorant as not to know that the care of the arm is almost the whole duty of the medical practitioner in vaccine inoculation; and that nothing disgusts the public so much against the practice as a sore arm, and the ill consequences which, from a neglect of that symptom, too often ensue.

When fluid virus cannot be procured, it is necessary to be cautious how it is preserved in a dry state. The most improper mode is that of keeping it on a lancet; for the metal quickly rusts, and the vaccine matter becomes decomposed. This method, however, is as likely to succeed as any when the matter is not to be kept above two or three days. If the virus be taken on glass, care must be taken not to dilute it much, otherwise it will probably fail.

Pointed pieces of ivory are much in use as vehicles of the vaccine virus. The point is made to penetrate the skin like a lancet; but these points are hardly ever sharp enough; they give unnecessary pain; and the virus is often not effectually introduced.

Cotton thread is a very commodious vehicle. If it is intended to be sent to any considerable distance, it ought to be repeatedly dipped in the virus. No particular caution is necessary with regard to the exclusion of air; nevertheless, as it can be done with so little trouble, and is more satisfactory to those who receive the matter, it is better to comply with the practice. On this account it may be enclosed in a glass tube, sealed at each end, or between two square bits of glass, which may, if necessary, be also charged with the matter, and wrapped in tin foil.

Nothing is more destructive to the efficacy of cow-pox matter than heat: on this account it must not be dried near the fire, nor kept in a warm place. The advantage of inserting it in a fluid state is so great, that it is to be wished every practitioner would endeavour to keep a constant supply for his own use, by inoculating his patients in succession, at such periods as are most likely to answer that purpose.

CO'XA. (*a*, *æ*. f.) The hip, haunch, or hip-joint; also the ischium and the os coccygis.

Coxæ ossa. The ossa innominata.

COXA'LGIA. (*a*, *æ*. f.; from *coxa*, the hip, and αλγος, pain.) A hybrid term applied to pain in the hip, whether from rheumatism or any other cause.

COXE'NDIX. (*ix*, *icis*. f.; from *coxa*, the hip.) The same as *coxa*.

Coxo-femoral articulation. The hip-joint.

Crab. See *Cancer*.

Crablouse. See *Pediculus*.

Crab-yaws. A name in Jamaica for a kind of ulcer on the soles of the feet, with callous lips, so hard that it is difficult to cut them. See *Frambœsia*.

CRA'MBE. (*e*, *es*. f. Κραμβη, cabbage or colewort.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia*; Order, *Siliculosa*.

Crambe maritima. The sea-cole, or sea-kale. This plant is indigenous on our shores. It is cultivated for the table, and has a delicate flavour. Like all oleraceous plants, it is flatulent and watery.

CRAME'RIA. (*a*, *æ*. f.; so named in commemoration of two German botanists, named Kramer, who flourished about the middle of the last century.) A genus of plants in the Linnæan system. Class, *Tetrandria*; Order, *Monogynia*.

Crameria triandra. *Crameria ixina*. The systematic name of the tree, the root of which is called *rhatany*, a substance that has been long known to the manufacturers of port wine. It is the production of Peru, and was formerly thought to be the root of the cinchona cordifolia. It is described as externally resembling the root of the rubia tinctorum. It is aromatic, bitter, and very astringent to the taste; its infusion or decoction turns black with sulphate of iron, and precipitates tannin. The principal virtues appear to reside in the cortical part of the root, which is thick and resinous. An opinion prevails that the substance sold in the shops under the name of foreign extract of bark is made from this root.

It is well known that the medicinal virtues of this root are those of a powerful tonic. In debility of the digestive organs, in chronic rheumatism, fluor albus, and in intermittent fevers, it has been employed with good effect. While given in doses similar to cinchona, it has the advantage of being only one third the price of that substance.

Cramp. (*Crampus*; from the German *krempen*, to contract.) See *Spasm*.

Cranesbill. See *Geranium.*

Cranesbill, bloody. See *Geranium sanguineum.*

Crangon. See *Cancer crangon.*

Crania. Κρανια. The Greek name of the cornel tree. See *Cornus.*

CRANIO'LOGY. (From κρανιον, the skull, and λογος, a discourse.) The study of skulls. The diversity of size, shape, and proportion in the skulls of different races of mankind, and different tribes of animals, is an object of considerable interest to the physiologist. The term craniology has been applied to the art of determining the intellectual and moral peculiarities of individuals by the shape of their skulls. See *Phrenology.*

Cranio'scopy. (From κρανιον, the skull, and σκοπεω, to explore.) The inspection of skulls. See *Phrenology.*

CRA'NIUM. (*um, ii.* n. Κρανιον, *quasi,* καρανιον; from καρα, the head.) The skull, or superior part of the head, which forms a great cavity containing the brain and its appendages. The cranium is composed of eight bones, six of which are called proper to the cranium, and two common to the cranium and face. The six proper to the cranium are the *os frontis,* the two *ossa parietalia,* the two *ossa temporum,* and the *os occipitis:* the two common to the cranium and face are the *os ethmoides* and the *os sphenoides.* This is an arbitrary and incorrect arrangement, since the frontal bone enters into the formation of the face quite as much as the ethmoid or sphenoid, and the temporal bone also partially.

Cranium humanum. The human skull. This was formerly an important article of the Materia Medica. It was esteemed alexipharmic and antiepileptic; and divers oils, tinctures, and other preparations were made from it. It is only of late years that its reputation in epilepsy has entirely faded.

Crante'res. (Κραντηρες. From κραινω, to make perfect.) A name given to the *dentes sapientiæ,* because they come last and complete the number of the teeth.

CRA'PULA. (*a, æ.* f. Κραιπαλη; derived according to Galen from καρηνον, the head, and παλλεσθαι, to be agitated.) A surfeit. The oppressed state of the stomach and head arising from excess in eating or drinking.

CRA'SIS. (*is, is.* f.; from κεραννυμι, to mix.) Mixture. Applied to the humours of the body, when there is such an admixture of their principles as to constitute a healthy state: hence in dropsies, scurvy, &c., the crasis, or healthy mixture of the principles of the blood, is said to be destroyed.

Cra'spedon. (Κρασπεδον, the hem of a garment; from κρεμαω, to hang down, and πεδον, the ground.) A relaxation of the uvula, when it hangs down like the hem of a garment.

Crassum intestinum. The large intestine.

Crassame'ntum. (*um, i.* n.; from *crassus,* thick.) See *Sanguis.*

CRA'SSULA. (*a, æ.* f.; from *crassus,* thick: so named from the thickness of its leaves.) 1. A name of the *Sedum telephium* and several other plants. 2. The name of a genus of plants in the Linnæan system. Class *Pentandria;* Order, *Pentagynia.*

Crassus pulsus. A strong and full pulse.

Crate'gonon. (From κρατεω, to gain strength, and γονον, the semen, because it was supposed to render the semen prolific.) An herb mentioned by Pliny, supposed to be the *Melampyrum cristatum* of Linnæus.

CRATÆ'GUS. (*us, i.* f.) A genus of plants in the Linnæan system. Class, *Icosandria;* Order, *Digynia.* The hawthorn, *C. oxyacantha,* and wild service tree, *C. torminalis,* belong to this genus.

CRATÆ'VA. The name of a genus of plants. Class, *Polyandria;* Order, *Monogynia.* The fruit of nearly all the species has a peculiar alliaceous odour, whence they have been called *garlic pears.* The *C. Religiosa* is the *Pura-au* of Tahiti, which is there planted in burial grounds. Its leaves are aromatic and stimulant. The bark of the *C. Tapia* is a bitter tonic, and is esteemed by the Indian practitioners as a febrifuge.

Crater. A brass vessel with a broad base and a narrow mouth.

Crati'cula. (From *crates,* a grate.) The grate which covers the ash-hole in a chemical furnace.

Craw-fish. See *Cancer fluviatilis.*

Crea. *Ocrea.* The anterior part of the leg. — *Blancard.*

Cream of Tartar. See *Potassæ bitartras.*

CRE'ASOTE. (*Creasoton,* from κρεας, flesh; σωζω, to preserve, on account of its antiseptic property.) A substance lately discovered by Reichenbach. The following account of it is taken from an excellent article in the Appendix to Dr. Gully's Translation of Magendie's Formulary: —

Creasote is an oily, colourless, transparent liquid, of a penetrating odour, resembling that of smoke, or smoked meat, and of a burning and exceedingly caustic taste. It has a specific gravity of 1·037.

It boils at 203° Centigrade, and is not congealed by a cold of —27° C.; it burns with a strongly fuliginous flame. With water at 20°, it forms two combinations, one a solution of one part in 80, and the other of 10 parts in 100. This aqueous solution does not change turnsol, nor is it neutralised by acids or alkalis. Nitric acid causes red vapours. A small portion of concentrated sulphuric acid turns it red, but a larger quantity blackens it, the acid itself being also decomposed. Acetic acid seems to be its specific solvent, for it holds any quantity of it. All the acids, even the carbonic, separate creasote from its combinations with potass and soda, without otherwise affecting it. It dissolves a great number of salts, some with, and some without heat. Alkohol, ether, carburetted sulphur, and acetic ether combine with it in any proportion. It decomposes or dissolves resins, resinous colouring matters, and other similar substances.

Shaken with white of egg, coagulation immediately takes place. Fresh meat, soaked for an hour in a solution of creasote, and then dried, may be exposed to the sun, without fear of

putrefaction; in a week it becomes hard, has the smell of smoked meat, and becomes reddish brown. Fish may be preserved in the same manner. Birds poisoned with creasote remain nearly two months without emitting any putrid odour.

These effects on animal matter closely resemble those of pyroligneous acid and tar water, and demonstrate almost to a certainty that creasote is the preservative principle of those fluids. This has been further shown by the extraction of creasote from both of them. Creasote is most abundantly and easily prepared from tar.

In the dry distillation of tar from wood the fluid collected in the receivers contains an empyreumatic acid water, which is rejected, and oil of tar, which is placed in glass retorts and rectified. In these two distillations the oil of tar is at first light, but as the heat is increased, its gravity augments. At one period of the process the oil sinks to the bottom, and a fluid which is poor in creasote, and consists mostly of *eupione*, and other substances that interfere with the purity of the creasote, floats above it: this is poured off, and the pale yellow tar-oil is heated. Carbonate of potass is added, until the carbonic acid is no longer disengaged on shaking: the mixture is decanted, in order to separate the acetate of potass, and the oil is again distilled in a glass retort, and all the first products that float on the water are rejected. The oil is then dissolved in a solution of caustic potass of the specific gravity 1·12; heat is thereby developed, and a portion of the materials composed of eupione, &c. not being dissolved, floats on the surface, and is removed. The alkaline solution is poured into an open capsule, and regularly heated to boiling. It rapidly absorbs the oxygen of the atmosphere, whereby a peculiar oxidisable principle in it is decomposed, and the mixture then turns brown. After cooling in the open air, diluted sulphuric acid is added until the oil is set at liberty. It is then distilled with water, holding a little caustic potass, and the whole is kept boiling until the quantity of oil which passes from the retort becomes diminished: at this point the distillation should cease. The oil and water in the receiver are again distilled with potass, and the same treatment with sulphuric acid repeated, as in the former instance. A third distillation is then made, and a little phosphoric instead of sulphuric acid is added, in order to take up some ammonia retained in the oil.

The oil is then for the third time dissolved in caustic potass, and if the preceding processes have been carefully managed, they combine, without leaving any residue of eupione, and the mixture, on exposure to the air, does not turn brown, but takes on a slightly reddish tint. As long, however, as any eupione remains, and the mixture turns brown, the solution in potass should be repeated. In this state the creasote is not entirely pure, but it may be used for medicinal purposes.

It may be obtained perfectly pure by distilling it with water alone, then rectifying the product of the distillation repeatedly until no water passes over when the heat is raised to 203° C. The last product is creasote unalloyed by eupione, picamare, water, or other matters.

M. Reichenbach endeavoured to simplify this tedious process; but he found that the product was always unfit for internal use, while its action on the surface was much impaired. So procured, its emetic effects were most violent; a single drop applied to the tongue caused in the space of a minute, excessive nausea with tremors, succeeded by vomiting, and great prostration of the powers. These effects he attributes to the presence of eupione, and he therefore recommends the process above described to be followed on all occasions.

Applied to the tongue in a concentrated form, creasote causes violent pain, though no redness or tumefaction is present: a strong taste of smoke extends to the throat. Poured on the skin, it produces a burning sensation with rubefaction and erosion.

Flies, spiders, and small fishes die in the course of two minutes, when immersed in a solution of twelve drops of creasote in two ounces of water.

Two drachms given in half an ounce of water to a puppy-dog induced the following symptoms: complete prostration of muscular power, drooping of the head, fixation of the eyes, vertigo, apparent stupefaction of all the senses; the respiration, from being laboured, was at the end of three minutes almost entirely stopped by an abundant secretion of viscid, filamentous mucus; to which was added vomiting of whitish milky fluid, with spasmodic contraction of the abdominal muscles. These symptoms got gradually worse for two hours, the respiration becoming more laborious, and at longer intervals, the limbs being seized with tremors, then with convulsive contractions, and the whole ending in death.

On opening the body of the animal all the tissues of the body, except the liver, exhaled a strong odour of creasote. The mucous digestive membrane gave signs of inflammation throughout its whole extent; the matters contained in the stomach coagulated white of egg, and heated, gave out the powerful tar smell of creasote. In the heart and the immediate great vessels the blood appeared to be much more firmly coagulated than usual. The lungs were gorged over the greater part of their extent with reddish brown blood; the more ruddy parts of them floated in water readily: the darker portions scarcely swam at all. No sign of congestion about the brain appeared.

On injecting equal parts of creasote and water into the carotid artery of a dog, the same symptoms were produced, but death ensued more speedily.

If concentrated or diluted creasote be added to blood, the latter thickens and becomes reddish brown, with small spots of white, probably coagulated albumen: on further exposure to the air the blood acquires a yellowish red colour.

The signs of poisoning with creasote, therefore, are the redness of the gastro-intestinal mucous membrane, the peculiar thickness and colour of the blood, the property possessed by the matters in the stomach of coagulating albu-

men, and more especially the peculiar odour exhaled by all the tissues of the body.

Plants watered with a solution of creasote, fade and die in the course of a few days.

M. Reichenbach's first trials of the medicinal virtues of creasote were made on slight burns, infantile excoriations and wounds. Subsequently he was induced to try it in extensive burns by hot iron and boiling fluids: in itch and various kinds of tetters; in gangrene consequent on extensive compound fracture of the leg; in caries of the phalanges of the fingers and toes; in toothach, though it fails to put a stop to the caries of the tooth; in open, fungous whitlow; in scrofulous ulcers of the throat, leg, and joints of the fingers; in ulcerated white-swelling of the knee of two years standing; in chancres and other syphilitic ulcers; in wounds from cutting and piercing instruments, caustic alkalis, &c., in which cases the wounds did not heal by suppuration, but by actual desiccation caused by the creasote. In all these instances he has found the remedy most effectual and astonishingly rapid in its operation. Thus in a case of old standing and scrofulous ulceration of the throat, with purulent discharge from the ears, the ointment of creasote to the former, and the injection of creasote water into the latter, put an end to both in the course of three weeks.

Internally, M. Reichenbach has given it in several cases of hemoptysis; in two of these, the sanguineous expectoration had continued for upwards of a week, when the administration of four drops of creasote, on sugar, daily for four days, arrested the flow of blood.

Turning to the practice of the French physicians, we find that creosote has been successfully employed in burns, by Berthelot and Goupil, who observe, that in treating these with creasote, the tendency to cicatrise from the circumference to the centre, and the consequent contractions and irregularities, are avoided; in various dry and moist tetters by Goupil, Coster, Berthelot, Martin-Solon, Duchesne-Duparc and Dauvergne; in chancres and old venereal ulcers, by Künckel, Lesseré, and others; in sanious ulceration of the cervix uteri, by Colombat; in a cancerous ulcer of the nose, by Breschet; in chronic inflammation with suppuration of the edges of the eyelids, by Coster; in cancer of the womb by Hippolyte Cloquet and Tealier; in varicose, ill-conditioned ulcers of the leg, by Goupil, &c. &c. Chilblains are also considerably benefited by frictions, with creasote ointment or water. M. Regnart relieved the celebrated M. Broussais from an excruciating toothach by the free application of a concentrated solution of creasote to the carious tooth.

Creasote has been employed by the French physicians in pulmonary phthisis; but the alleged successful cases are strained, and tell but little in favour of the remedy. It has not been more successfully used, in several cases of chronic bronchitis, by inhalation.

Creeping. See *Repens.*

CREMA'STER. (*er, eris.* m.; from κρεμαω, to suspend.) *Musculus testis. Musculus scroti.* A muscle of the testicle, by which it is suspended, and drawn up and compressed, in the act of coition. It arises from the lower edge of the internal oblique muscle of the abdomen, passes over the spermatic chord, and is lost in the cellular membrane of the scrotum covering the testicle.

CRE'MNUS. (Κρημνος, a precipice, or shelving place.) 1. The lip of an ulcer.

2. The labium pudendi.

CREMOCA'RPIUM. (From κρεμαω, to suspend, and καρπος, fruit.) The name given by Mirbel to a simple fruit united with the calyx, and divided into two indehiscent monospermatous *cocca*. This species of fructification occurs throughout the *Umbelliferæ*.

CRE'MOR. (*or, oris.* m.) 1. Cream. The oily part of milk which rises to the surface of that liquid, mixed with a little curd and serum.

2. Any substance floating on the top of a liquid, and skimmed off.

3. A thick decoction of barley. — *Blancard.*

CREMOR CALCIS. The pellicle of carbonate of lime, which forms on the surface of lime-water when exposed to the air.

CREMOR TA'RTARI. Cream of tartar. See *Potassæ bitartras.*

CRENA'TUS. Crenate: notched, or scolloped. Applied to a leaf or petal, when the indentations are blunted or rounded, and not directed towards either end of the leaf; as in *Glecoma hederacea.* The two British species of *Salvia* are examples of doubly crenate leaves. The petals of the *Linum usitatissimum* are crenate.

Creosote. See *Creasote.*

CREPA'TIO. *Crepatura.* In *Pharmacy*, the boiling of seeds till they burst.

CREPITATION. (From *crepito*, to make a crashing or crackling noise.) 1. The peculiar sound, or sensation, occasioned by pressure between the fingers, in cellular tissues filled with air; as the lungs in their natural state, or a part affected with emphysema.

2. The grating of the ends of broken bones. See *Crepitus.*

3. Synonymous in *Chemistry* with *decrepitation.*

CRE'PITUS. (*us, ûs.* m.; from *crepo*, to make a noise.) A crashing or cracking noise. A discharge of wind from the bowels upwards or downwards. In medicine, the term is usually applied to the grating sound which is heard when the ends of a fractured bone are rubbed on each other.

Crepitus lupi. See *Lycoperdon bovista.*

Crescent-shaped. See *Leaf.*

CRESS. A number of plants which have a more or less pungent flavour are called cresses.

CRESSIS. A barbarous Latin name of the *Nasturtium sativum.*

Cress, garden. See *Lepidium sativum.*

Cress, sciatica. See *Lepidium iberis.*

Cress, water. See *Sisymbrium nasturtium aquaticum.*

Cress, wild. See *Sysimbrium nasturtium aquaticum.*

Crest. See *Crista.*

Crested. See *Cristatus.*

CRE'TA. (*a, æ.* f.) Chalk. An impure carbonate of lime. See *Creta præparata.*

Creta præparata. Prepared chalk. Take of chalk a pound; add a little water, and rub it to a fine powder. Throw this into a large vessel full of water; then shake them, and after a little while pour the still turbid liquor into another vessel, and set it by that the powder may subside; lastly, pouring off the water, dry this powder. This is a pure carbonate of lime, and is antacid and absorbent. It is exhibited chiefly in the form of the cretaceous mixture. See *Mistura cretæ*. It is also an ingredient of many compound medicines.

CRETA'CEOUS. (*Cretaceus*; from *creta*, chalk.) Chalky: appertaining to chalk.

Cretaceous acid. See *Carbonic acid.*

Cretaceous mixture. See *Mistura cretæ.*

Cretaceous powder. See *Pulvis cretæ compositus.*

Crete, dittany of. See *Origanum dictamnus.*

CRETINISMUS. (*us, i.* m.) Cretinism: a peculiar endemic disease common in Switzerland, and found also in some other mountainous regions.

Cretinism makes a very close approach to rickets in its general symptoms. It differs principally in the tendency to the peculiar enlargement of the thyroid gland, which, in France, is denominated goitre, and with us, Derbyshire-neck, and in the mental imbecility which accompanies it from the first.

In cretinism the organ of the brain seems to follow the fate of the rest of the body, and, in many cases, even to take the lead, so that the chief imbecility is to be found in this region. For the peculiar symptom of goitre it is not so easy to account. We know so little of the purpose, and even of the fabric of this gland, as to be incapable of assigning its use in the animal economy, and hence, it is not much to be wondered at that its peculiar tendency to associate, in the present disease, with the morbid condition of the bones and of the intellect, should not hitherto have been ascertained. Goitre, however, does not always accompany the other symptoms, though it is, for the most part, an associate.

Cretinism was first distinctly noticed and described by Plater about the middle of the seventeenth century, as occurring among the poor in Carinthia and the Valais; and that it was afterwards found in a still severer degree in other valleys of Switzerland and the Alps generally; as it has since been detected in very distant regions where the country exhibits a similarity of features, as among a miserable race called Caggets, inhabiting the hollows of the Pyrenees, whose district and history have been given us by M. Raymond, and as far off as Chinese Tartary, where it is represented as existing by Sir George Staunton.

On the first discovery of cretinism, it was ascribed by some to the use of snow-water, and by others to the use of water impregnated with calcareous earth: both which opinions are entirely without foundation. The first is sufficiently disproved by observing that persons born in places contiguous to the glaciers, and who drink no other water than what flows from the melting of ice and snow, are not subject to the disorder, and that Sir John Pringle and Captain Cook have found melted snow or ice-water afford to seamen a peculiarly wholesome beverage: while on the contrary the disorder is observed in places where snow is unknown, as at Sumatra. The second is contradicted by the fact that the common waters of Switzerland, instead of being impregnated with calcareous matter, excel those of most other countries in Europe in purity and flavour. "There is not," observes Dr. Reeve, "a village, nor a valley, but what is enlivened by rivulets, or streams gushing from the rocks. The water usually drunk at La Batia and Martigny is from the river Dranse, which flows from the glacier of St. Bernard, and falls into the Rhone; it is remarkably free from earthy matter, and well tasted. At Berne the water is extremely pure, yet, as Haller remarks, swellings of the throat are not uncommon in both sexes, though cretinism is rare."

As comfortable and genial warmth form one of the best auxiliaries in attempting the cure of both cretinism and rickets, there can be no doubt that the chill of snow-water, if taken as such, must considerably add to the general debility of the system when labouring under either of these diseases, though there seems no reason for supposing that it would originate either. It is not difficult to explain why water impregnated with calcareous earth should have been regarded as a cause: for in cretinism, as in rhachia, the calcareous earth designed by nature for building up the bones, is often separated, and floats loose in various fluids of the body for want of a sufficiency of phosphoric acid to convert it into a phosphate of lime, and give it solidity. And as it is, in consequence hereof, pretty freely discharged by the urine, it seems to have given rise to the opinion that such calcareous earth was introduced into the system with the common beverage of the lakes or rivers, and produced the morbid symptoms.

M. de Saussure has assigned a far more probable, and unquestionably the real cause of the disease, in referring us to a few other physical features of the Alpine districts in which it makes its appearance chiefly. The valleys, he tells us, are surrounded by very high mountains, sheltered from currents of fresh air, and exposed to the direct, and, what is worse, the reflected rays of the sun. They are marshy, and the atmosphere is hence humid, close, and oppressive. And when to these chorographical causes we add the domestic ones, which are also well known to prevail very generally among the poor of these regions, such as meagre, innutritious food, indolence, and defect of cleanliness, with a predisposition to the disease from an hereditary taint of many generations, we can sufficiently account for the prevalence of cretinism in such places, and for the most humiliating characters it is ever found to assume.

The general symptoms of cretinism are those of rhachia; but the disease shows itself earlier, often at birth, and not unfrequently before this period, apparently commencing with the procreation of the fœtus, and affording the most evident proofs of ancestral contamination. The

child, if not deformed and cachectic at birth, soon becomes so; the body is stinted in its growth, and the organs in their development; the abdomen swells, the skin is wrinkled, the muscles are loose and flabby, the throat is covered with a monstrous prominence, the complexion wan, and the countenance vacant and stupid. The cranium bulges out to an enormous size, and particularly towards the occiput, for it is sometimes depressed on the crown, and at the temples; insomuch, that to a front view the head, in some cases, appears even diminutive. The blunted sensibility of these wretched beings renders them indifferent to the action of cold and heat, and even to blows or wounds. "They are, generally," observes, M. Pinel, "both deaf and dumb. The strongest and most pungent odours scarcely affect them. I know a Cretin who devours raw onions and even charcoal with great avidity: a striking proof of the coarseness and imperfect development of the organ of taste. Their organs of sight and feeling are equally limited in their operation. Of moral affections they seem wholly destitute; discovering no signs of gratitude for kindness shown to them, nor any attachment to their nearest relations."— *Mason Good.*

It is evident that medical treatment, generally speaking, can be of no avail except in as far as relates to the general health of the individual.

Cribra'tio. (*o*, *onis.* f.) The operation of sifting or passing through a sieve.

CRI'BRIFORM. (*Cribriformis*; from *cribrum*, a sieve, and *forma*, likeness; because it is perforated like a sieve.) Applied to one of the bones of the cranium. See *Ethmoid bone.* The tunica decidua of the ovum has been called *membrana cribriformis* by Osiander.

Cri'co-arytænoide'us latera'lis. A muscle which rises from the side of the cricoid cartilage and is inserted into the side of the base of the arytenoid cartilage. Its use is to open the glottis by separating the arytenoid cartilages.

Cri'co-arytenoide'us posti'cus. A muscle which arises from the back part of the cricoid cartilage, and is inserted into the back part of the base of the arytenoid cartilage. Its use is to draw back the arytenoid cartilage, to render the ligament of the glottis tense, and thereby to lengthen the glottis.

Crico-pharyngeus. See *Constrictor pharyngis inferior.*

Cri'co-thyroide'us. A muscle which rises from the side and anterior part of the cricoid cartilage and has two insertions, one into the under part of the ala of the thyroid cartilage, and the other into its inferior cornu. Its action is to draw the thyroid cartilage downwards and forwards, or the cricoid cartilage, upwards and backwards.

Cri'co-thy'ro-pharyngæ'us. The inferior constrictor muscle of the pharynx is so called by Dumas.

CRI'COID. (*Cricoides*; *Cricoideus*, from κρικος, a ring, and ειδος, resemblance.) Ring-like: applied to a round ring-like cartilage of the larynx. See *Cartilago cricoides.*

Cridones. The same as *crinones.* See *Crino.*

Crimno'des. (From κριμνον, bran, and ειδος, resemblance.) Bran-like; applied to urine, which deposits a sediment like bran.— *Hippocrates.*

Crina'le. An instrument formerly used to exert pressure in cases of fistula lachrymalis. It is named from having at one end a small cushion stuffed with hair.

Cri'nis. The hair. See *Capillus.*

Crino'myron. (From κρινον, a lily, and μυρον, ointment.) An ointment composed of lilies and aromatics; the same with the *Unguentum ægyptium album.*

CRI'NO. (*o*, *onis.*; from *crinis*, the hair.) 1. A genus of entozoa observed chiefly in horses and dogs, the description of which is so imperfect as to render it doubtful whether it ought to be considered as a separate genus.

2. A disease which, according to Ettmuller and others has prevailed epidemically among infants. It consisted in the eruption of rigid black hairs from the skin of the back, arms, and legs, accompanied with febrile irritation and emaciation. The hairs become blacker, and at last fall off. Three or four successive crops of them arise within the first month of the child's life. Children are liable to them as late as the end of the second year.

Crio'genes. An epithet of certain troches, mentioned by P. Ægineta, which he commends for cleansing ulcers.

CRI'SIS. (*is*, *is.* f. κρισις, a judgment or determination; from κρινω, to judge.) A sudden change for the better or worse taking place in the course of acute diseases, and especially fevers. A favourable crisis is sometimes attended with a diarrhœa, perspiration, or other sensible evacuation, and such evacuations are styled *critical.* At other times the crisis is unattended with any sensible evacuation. A crisis is *perfect* or *imperfect*; the former bringing the patient suddenly to a state of convalescence, the latter merely causing a marked alleviation of the symptoms. The crisis is also called *salutary* or *fatal*, according to the result. It has been a question from the time of Hippocrates down to the present, whether fevers have a tendency to a crisis on particular days of their course rather than on others. See *Critical days.*

Crispation. See *Crispatura.*

Crispatu'ra. (From *crispo*, to curl.) Crispation. A slight contraction of any part whether natural or induced by a morbid cause; thus, the skin when contracted so as to form what is called *cutis anserina* is in a state of crispation; the small arteries divided by a wound when they retract so as to arrest the hæmorrhage are in a state of crispation.

CRI'SPUS. Crisp: curled. Applied to a leaf, when the border is so much more dilated than the disk, that it necessarily becomes curled and twisted; as in *Malva crispa*, &c.

CRIS'TA. (*a*, *æ.* f. The comb of a cock; a crest.) This name is given, 1. In *Anatomy*, to several processes and parts of bones; as the *crista ilii*, and *crista galli* of the ethmoid bone.

2. In *Surgery*, to excrescences, like the comb of a cock, about the anus.

Crista galli. An eminence of the ethmoid

bone, so called from its resemblance to a cock's comb. See *Ethmoid bone.*

CRISTA'TUS. Crested: applied to parts of plants having an appendage resembling a crest.

Crithamum. See *Crithmum.*

CRI'THE. (*e, es.* f. Κριθη, barley.) A sty or small tumour on the eyelid, somewhat resembling a barleycorn. See *Hordeolum.*

CRITHE'RION. (From κρινω, to judge.) The same as crisis.

CRI'THUM. (*um, i.* n; from κρινω, to secrete: said to be so named from its supposed virtues in promoting a discharge of the urine and menses.) The name of a genus of plants. Class, *Pentandria;* Order, *Digynia.*

CRITHMUM MARITIMUM. The samphire, or sea-fennel. *Herba Sancti Petri. Crithmum* of the Pharmacopœias. It is a low perennial plant, and grows about the sea-coast in several parts of our island. It has a spicy aromatic flavour, and the country people use it as a potherb. Pickled with vinegar and spice, it makes a wholesome and elegant condiment.

CRI'TICAL. Appertaining to the *crisis;* determining the event of a disease. Applied to symptoms, evacuations, periods, &c. which have reference to a crisis.

CRITICAL DAYS. *Dies judicatorii. Dies decretorii. Dies principes. Dies radicales.* Hippocrates and Galen taught that there were certain days on which the crisis of fever was generally perfect and favourable; others on which it was imperfect or unfavourable; and others again, which were seldom marked by any particular change one way or the other. According to Galen, the 7th day is particularly favourable; next to this the 14th, then the 9th, 11th, and 20th; then the 17th and 5th; lastly, the 4th, 3rd, and 18th. The 6th day is very doubtful and unfavourable, and like it are the 8th, 10th, 12th, 16th, and 19th. The 13th day is intermediate and not marked by any considerable change. Diocles and Archigenes made the 21st one of the favourable days; but Galen agrees with Hippocrates in rejecting this and substituting the 20th. The doctrine of critical days has been much contested, and is so more or less to the present time. It is now generally disbelieved, however, by physicians that the critical days of fever can be determined with any degree of accuracy sufficient to render the doctrine practically useful.

CRO'CEUS. Deep yellow. In general use to designate the colour of plants, animals, minerals, &c.

Croci stigmata. See *Crocus.*

CROCIDI'XIS. (*is, idis.* f.; from κροκιδιζω, to gather wool.) Floccilation. See *Carphologia.*

CRO'CINUM. (From κροκος, saffron.) A mixture of oil and saffron, sometimes with the addition of aromatics.

CROCO'DES. (From κροκος, saffron; so called from the quantity of saffron it contains.) A troch mentioned by Paulus Ægineta.

Crocodilea. See *Cordylea.*

CROCOMA'GMA. (From κροκος, saffron, and μαγμα, thick oil or dregs.) A troch made of oil of saffron and spices.

CRO'CONATE. A salt formed by the union of the croconic acid with a base.

CROCO'NIC ACID. *Acidum croconicum.* So called from *crocus*, saffron, on account of the yellow colour of its salts. During the distillation of potassium from a mixture of carbonate of potash and charcoal a gray compound comes over, which forms a yellow solution with water. From this solution yellow crystals of croconate of potash may be obtained by evaporation. To separate the acid, purified crystals of coronate of potash are dissolved in strong alkohol, to which sulphuric acid is carefully added, so as barely to saturate the alkohol. Sulphate of potash is precipitated, and the croconic acid remains dissolved in the alkohol, from which it may be obtained by evaporation. It is in yellow prismatic crystals soluble in water. It is decomposed by a strong heat, and deposits pure charcoal. Gmelin considers it as a compound of carbon, oxygen, and hydrogen.

CRO'CUS. (*us, i.* and *um, i.* n. Κροκος. Κροκον. The story of the young Crocus, turned into this flower, may be seen in the fourth book of Ovid's Metamorphoses. Some derive this name from κροκη or κροκις, a thread; whence the stamens of the flowers are called κροκιδες, and from them the whole plant κροκος. Others, again, derive it from the Chaldee language.) Saffron.

1. The name of a genus of plants in the Linnæan system. Class, *Triandria;* Order, *Monogynia.* Saffron.

2. The pharmacopœial name of the prepared stigmata of the saffron plant. See *Crocus sativus.*

3. A name given by the older chemists to several preparations of metallic substances, from their colour; thus, *Crocus martis, Crocus veneris.*

CROCUS ANTIMONII. A sulphuretted oxide of antimony.

Crocus Germanicus. See *Carthamus.*

Crocus Indicus. See *Curcuma.*

CROCUS MARTIS. Burnt green vitriol.

CROCUS METALLORUM. A sulphuretted oxide of antimony. See *Antimony.*

Crocus officinalis. See *Crocus sativus.*

Crocus saracenicus. See *Carthamus.*

CROCUS SATIVUS. The systematic name of the saffron plant.

Crocus — spatha univalvi radicali, corollæ tubo longissimo, of Linnæus. This plant is a native of Greece and Asia Minor. It is sometimes found wild in England, but is probably not indigenous. It is cultivated abundantly for medicinal use in Cambridgeshire and Essex.

For the preparation of the saffron, the flowers are gathered early in the morning, just as they are about to blow. They are then spread upon a table, and the stigmas, with a proportion of the style, carefully picked out of the flower, which is thrown away as useless. The stigmas are then dried upon a portable kiln of a peculiar construction, over which a haircloth is stretched, and over it several sheets of white paper are laid, upon which the wet saffron is spread between two and three inches thick. It is now covered with other sheets of paper, and over them is a laid a coarse blanket, five or six

times doubled, which is pressed down with a board and a large weight after the fire is lighted. The first heat is strong, to make the saffron sweat; and, after an hour, when it is intended to form the saffron into a cake, it is turned, and the same degree of heat continued for another hour. The fire is then reduced to a moderate heat, which is kept up for twenty-four hours, during which time the cake is turned every half hour, so as to dry it thoroughly. It is then fit for the market. The finest saffron is not formed into a cake, but consists of the stigmas dried; and thence it is termed *hay* saffron.

In the shops, is found saffron from Sicily, France, and Spain, besides the English. The Spanish is generally spoiled with oil, in which it is dipped with the intention of preserving it; the Sicilian and French saffron is better than the Spanish; but the English as being fresher, more genuine, and better cured, is always preferred. It is sometimes adulterated with fibres of smoked beef, the petals of the safflower (*Carthamus tinctorius*), and of officinal marigold (*Calendula officinalis*): or saffron, from which tincture or infusion has been drawn, is mixed with a little good saffron, and again pressed into a cake. These frauds are detected by infusing the suspected saffron in hot water, when the expanded stigmas will be easily distinguished from the florets of the other flowers; and the deficiency of the presence of colour and odour, or an unpleasant odour arising when the saffron is thrown upon red-hot coals, will indicate the presence of the other fraudulent ingredients. It should be chosen fresh in hay, or in close, tough, compact cakes, moderately moist, and possessing, in an obvious degree, all the under-mentioned sensible qualities: the not staining the fingers, but making them oily, its exhaling a musty flavour; a whitish yellow or a blackish colour indicate that it is bad, or too old.

Qualities. — Good saffron has a sweetish, penetrating, diffusive odour; a warm, pungent, bitterish taste; and a rich deep orange-yellow hue in the hay, or an orange-red colour in cake. It yields its colour and active ingredients to water, alkohol, proof spirit, wine, vinegar, and, in a smaller degree, to ether. By distillation with water it affords a small quantity of a heavy golden-yellow coloured volatile oil; and it is to this oil that saffron owes its active properties: 32 parts of saffron yield one of oil. The watery infusion, which has a deep orange-colour, is rendered, when much concentrated, of a very deep purple by strong sulphuric acid, the mixture emitting the smell of vinegar, and yielding a copious black precipitate when diluted with water: chlorine produces a copious yellow precipitate, the liquid retaining only a very pale lemon-colour. Saffron seems to contain chiefly extractive, which, according to Hermbstadt, is nearly pure and in the proportion of ten parts in sixteen of the vegetable; but M. Henry has demonstrated that it contains volatile oil; and he contends that its stimulant influence is dependent on this oil: the remainder being chiefly ligneous fibre. This extractive, when pure, is named *polychroite* by Bouillon la Grange and Vogel, on account of the different colours it is capable of assuming when it is acted on by sulphuric acid, which changes it to indigo, which gradually becomes lilac: nitric acid gives it a green hue.

It also contains resin; for sulphuric ether digested on saffron is coloured, and when evaporated on the surface of water, a pellicle of resin is left, whilst the colour extractive, which is taken up with the resin, is dissolved in and colours the water.

Medical properties and uses. — Saffron is regarded as a stimulant and antispasmodic; but, from the experiments of Dr. Alexander, its powers appear to be inconsiderable. It was known to the ancients, who considered it as a remedy of great activity; of moderate doses exhilarating the spirits, easing pain, and producing sleep; but occasioning headachs, coma, delirium, convulsive laughter, and even fatal effects, when given in large doses. In modern practice, however, it is scarcely ever given except as a cordial adjunct to more active remedies. The dose in substance is from grs. x. to ʒ ss.; but it has been given in much larger doses without any sensible effect being produced. — *A. T. Thomson.*

It is extensively used in pharmacy as a colouring matter. The London College, a syrup, and the Edinburgh, a tincture of saffron.

Crocus veneris. Oxide of copper formed by calcining the metal.

Cromm'yon. (Παρα το τας κορας μυειν, because by its pungency it makes the eyes wink.) An onion.

Crommyoxyrre'gma. (From κρομμυον, an onion, οξυς, acid, and ρηγνυμι, to break out.) An acid eructation, accompanied with a taste resembling onions.

Crop. A dilation of the gullet in birds. See *Ingluvies.*

Cross birth. The popular name for what obstetricians call *Preternatural labour.* See *Parturitio.*

CRO'TALUS, *us, i.* m.; from κροταλον, a rattle.) The rattlesnake. A genus of venomous serpents abounding in various parts of the American continent. There are three species, the characters of which are well ascertained, *C. durissus, C. horridus,* and *C. miliarius:* a fourth *C. cascabella,* has been recently found in Brazil. The most remarkable characteristic of these reptiles is the rattle appended to their tails. This consists of a number of horny joints, which are moveable on one another, and make a rattling noise when the animal moves. The number of these joints increases with the age of the serpent, one being added every time it changes its cuticle.

The bite of the rattlesnake is almost uniformly fatal, being followed by gangrenous inflammation of the injured part and rapid sinking of the vital powers.

Crotaphi'tes. (From κροταφος, the temple.) Appertaining to the temple. Applied to the temporal artery, vein, or muscle.

Crota'phium. (From κροταφος, the temple.) A pain in the temples.

Cro'taphos. (Κροταφος; probably from κροτεω, to pulsate.) The temples.

CROTCHET. A curved instrument, with a hook, used to extract the fœtus in the operation of embryotomy.

CRO'TON. (*on, onis.* κροτων.) 1. The Greek name of the dog tick.

2. The name of a genus of plants in the Linnæan system. Class, *Monœcia;* Order, *Monadelphia.*

Croton benzoe. See *Styrax benzoe.*

Croton cascarilla. The systematic name of the plant which affords the Cascarilla bark: called also, *Cascarilla*, *Chocarille*, *Elutheria*, and *Eluteria*. It is a native of the Bahama islands, and found also in the West Indies. The London College orders an infusion of it, and the Dublin a tincture and an extract. The bark comes to us in quills, covered upon the outside with a rough, whitish matter, and brownish on the inner side, exhibiting, when broken, a smooth, close, blackish-brown surface. It has a light agreeable smell, and a moderately bitter taste, accompanied with a considerable aromatic warmth. It is very inflammable, and when burnt and extinguished gives out a fragrant musky smell. It yields its virtues partially to water and to alkohol, and entirely to proof spirit. According to Trommsdorff 4·696 parts of the bark consist of woody fibre, 3·024 mucilage, and a bitter principle 8·64, resin 6·88, volatile oil 72, and water 48. It is a very excellent tonic, astringent, and stomachic, and is deserving of a more general use than it has hitherto met with. The dose of the powdered bark is from grs. xij. to ʒj. three or four times a day.

Croton sebi'ferum. The tallow-tree of China, now referred to another genus. See *Stillingia.*

Croton ti'glium. The systematic name of the tree which affords the pavana wood, and tiglia seeds. *Croton — foliis ovatis glabris acuminatis serratis, caule arboreo,* of Linnæus. It is a native of the island of Ceylon, and is found in Malabar, China, Cochin China, and the Molucca Islands. Every part of the plant would seem to be endowed with medicinal activity: the *root* acts as a drastic purgative, and when pulverised, and exhibited in the dose of a few grains, is considered at Amboyna and Batavia, as a specific for dropsy; the *wood* (*lignum Pavanæ*) produces, when administered in small doses, a diaphoretic effect, and in larger ones it proves drastic; the *leaves* are also purgative, and when dried and powdered are supposed to afford an antidote against the bite of the *cobra del Capella.* The *seeds*, however, are the parts which have been more generally employed in medicine, the effects of which appear to have been well known for nearly a thousand years. They were early introduced into Europe, and long known under the names of *Grana Molucca — Tilii Grana, —* and *Grana Tiglia.* It appears that they were at first very frequently administered; but their extreme acrimony and violence, and probably the accidents which arose from their injudicious use, soon banished the article from medical practice; in India, however, these seeds are still employed as an effectual purgative, after first undergoing the process of roasting, or baking, for the purpose of removing the shell, rendering the nut pulverulent, and at the same time of moderating the acrimonious qualities. The expressed oil of these seeds does not appear to have been obtained in a separate form until a later period; Lemery speaks of it, and Geoffroy in directing its dose cautions us against giving more than ʒj.! — he probably meant a drop. Its use has very lately been revived, and there can be little doubt but that under proper restrictions, it may become a valuable acquisition to the practitioner. The profession is indebted for its late introduction, or rather revival, to Mr. E. Conwell, of the East India Company's Service.

This expressed oil has a yellow colour, a faint odour, and an acrid taste; these qualities, however, will be found to vary in different samples; but the fact, as Dr. Nimmo has justly observed, may be fairly explained, without suspecting the existence of any fraud, by supposing that the seeds have undergone a different degree of torrefaction, in order to separate the oil from the farinaceous part. The experiments of Dr. Nimmo have very satisfactorily shown that this oil consists of forty-five parts of an *acrid purgative principle*, and fifty-five of a fixed oil resembling that of olives, and not possessed of any cathartic property. The acrid matter consists of a peculiar acid and a resin. The acid has been named *crotonic* by M. Brandes. It was discovered by Pelletier and Caventou, who called it the *iatrophic.* This oil does not appear to produce any effects which cannot be commanded by other drastic purgatives; its value depends upon the facility with which it may be administered; in some cases it is amply sufficient to touch the tongue, in others a drop or two will be required. In mania, and in cases where the administration of bulky medicines is extremely difficult, it would seem to offer a decided advantage. It has been usually given in this country in the proportion of from one to two drops, in the form of pills. Dr. Nimmo's discovery with respect to the chemical composition of the oil, very naturally suggested to him the mode of administering it in the form of an alkoholic tincture, (*Tinctura Tiglii*) and he has found by experience that such a preparation furnishes the means of readily apportioning the dose to the various circumstances of the case; thus he found that in administering a tincture in doses equivalent to the number of drops decomposed, the same effects were produced as have been attributed to the entire oil. Much has been said upon the fraudulent admixture of this comparatively expensive article with the cheaper fixed oils, and we believe with much truth; a circumstance which will of necessity prevent the general use of the article, and occasion very different reports with respect to its value and activity. Dr. Nimmo, however, proposes a method of detecting such adulteration, by a process suggested by the results of his experiments upon its composition, and whose rationalé will be easily understood after the chemical history that has been just presented.

"Let a very light phial be counterpoised in an accurate balance; pour into it fifty grains of the suspected oil, add alkohol (which has been previously digested upon olive oil,) agitate them well, pour off the solution and add more alkohol as before, until the dissolved portion is diffused in such a proportion of alkohol that each half drachm measure shall contain equal to one dose of the oil of *Tiglium* for an adult. By afterwards placing the phial near a fire, to evaporate what remains of the alkohol in the bottle, *if the residuum be to that which has been abstracted by the alkohol as fifty-five to forty-five, the oil is genuine.* If olive, or any other oil little soluble in alkohol, has been employed as the adulterating agent, it is evident that the residuum will be in a larger proportion; but should *Castor Oil* have been employed for that purpose, the proportion of residuum will be smaller even than the genuine medicine." — *Paris.*

Croton tinctorium. The systematic name of the litmus plant. *Croton — foliis rhombeis repandis, capsulis pendulis, caule herbaceo,* of Linnæus. *Bezetta cærulea.* This plant, which is a native of the Levant, Italy, and the south of France produces the litmus or *turnsol,* called also *succus heliotropii* and *lacca carnea.*

Cro'tonate. A salt formed by the crotonic acid with a base.

Croto'ne. (From κροτον, the tick.) A fungus on trees produced by an insect like a tick; and, by metaphor, applied to small fungous excrescences on the periosteum.

Crotonic acid. See *Croton tiglium.*

CROUP. The disease which is called croup is known by a permanently laborious and suffocative breathing, accompanied by a stridulous noise, a short and dry cough, and frequently, towards the close, an expectoration of a concrete membraneous sputum. Three very distinct forms of disease have been described by authors under the name of croup: the acute, the chronic, and the spasmodic.

1. The *acute croup.* In this the sense of suffocation is great and constrictive, chiefly seated in the throat; the respiration is sonorous, the voice harsh, the cough ringing: there is great restlessness, and active inflammatory fever. The disease essentially consists of a peculiar inflammation, that spreads through different parts, or even the whole range of the windpipe, from the larynx to the minutest ramifications of the bronchiæ; and, as the whole tube was called *bronchus* by the ancients, the most appropriate name for it would be bronchitis. It has also received many other appellations, from its prominent symptoms, in the nosological arrangements of physicians; as *tracheitis, cynanche trachealis, cynanche laryngea, suffocatio stridula, angina perniciosa, cynanche stridula, morbus strangulatorius, catarrhus suffocativus, angina polyposa sive membranacea,* &c. &c. Dr. Home first called the attention of medical practitioners to it as a distinct disease. It usually commences in the larynx, or trachea, during which a peculiar secretion is effused, that readily assumes a membranous form, and lines the tube, not only above its bifurcation, but also in its minutest branches. When chemically examined, the secretion appears to consist chiefly, if not entirely, of the albuminous part of the blood, diluted with its serosity, and copiously combined with that peculiar substance of the blood called fibrin. How it happens that the mucous secernents of the air passages afford so unusual a secretion in this particular instance, we know not. It is not a little singular that children should be chiefly subject to this disease, at whose age fibrin is not peculiarly abundant, and whose blood contains, comparatively, but a small proportion of azote, which in fibrin is so large a constituent. Dr. Cullen asserts that acute croup seldom attacks infants till after they have been weaned; and that there is no instance of its occurring in children above twelve years of age. Those who have once had it are more susceptible of it than before; though the susceptibility gradually wears off as they grow older. It is found equally in midland regions and on the coast, but perhaps more frequently in low, marshy grounds, than in drier uplands. There is no unequivocal instance of its being contagious, though it seems to have been occasionally epidemic.

It commences usually with a slight cough, hoarseness, and sneezing, as though cold had been taken, and the patient was about to suffer from catarrh. To these symptoms, in a day or two, and sometimes in a few hours, succeed a peculiar shrillness and ringing of the voice, as if the sound were sent through a brazen tube.

"At the same time," says Dr. Cullen, who has well described the progress of the disease, "there is a sense of pain about the larynx, some difficulty of respiration, with a wheezing sound in inspiration, as if the passage of the air were straitened. The cough which attends it is sometimes dry; and if any thing be spit up, it is a matter of a purulent appearance, and sometimes films, resembling portions of a membrane. Together with these symptoms, there is a frequency of pulse, a restlessness, and an uneasy sense of heat. When the internal fauces are viewed they are sometimes without any appearance of inflammation; but frequently a redness and even swelling appear: and sometimes in the fauces there is an appearance of matter like to that rejected by coughing. With the symptoms now described, and particularly with great difficulty of breathing, and a sense of strangling in the fauces, the patient is sometimes suddenly cut off. The countenance generally exhibits great distress; the head and face are covered with perspiration, from the violence of the struggle, and the lips and cheeks are alternately pale and livid. The essence of this species of croup consists in the secretion of the concrete lining, which is perpetually endangering suffocation." Notwithstanding the latter affirmation, Dr. Cullen seems to consider spasm of the glottis as the more frequent cause of suffocation; adding, however, that he never found antispasmodic medicines of any use. Spasm was with him a favourite doctrine, and often warped his judgment. Dr. Marcus regards croup as a local inflammation alone, utterly independent of spasm, and attributes the danger to this symptom solely. That there is some degree of spasmodic action, however, is unquestionable;

and the locality of the disease, as well as the peculiar character of the inflammation, sufficiently distinguish it from catarrh, in which there is also some inflammation of the mucous membrane of the trachea, though of a common kind, and rarely limited to this organ.

The cure demands a prompt and active attention; and must depend, not so much upon searching into and correcting the remote cause, or even counteracting the spasm, as in counteracting and removing the membranous secretion, which is every moment in danger of producing suffocation; the more so, that in children the natural aperture of the glottis is much smaller in proportion than in adolescents, and occasionally not more than a line and a half in breadth. The patient makes frequent and painful efforts to remove this solid secretion by coughing; but the cough is, for the most part, dry and ineffectual, and nothing more than a little flaky mucus is excreted. Very copious bleeding, at the commencement of the attack, by breaking abruptly upon the inflammatory action, has sometimes carried off the disease at once. This may be effected from the jugular vein, and leeches may be applied afterwards, according to circumstances. Emetics have been given immediately after. These are of doubtful effect; in many instances, however, they have soon removed the disease. A full dose of tartrate of antimony is the best emetic in this case. The inhalation of warm vapour, recommended by Dr. Home, is, for obvious reasons, so rarely practicable, that it need scarcely be taken into consideration. The remedy principally relied on in the present day, and which in many instances has acted like a charm, is large and repeated doses of the submuriate of mercury. Of this, not less than five or six grains are commonly given to very young children, and continued every two or three hours, till there is a discharge of green bilious matter, which seems to be the criterion of its having taken effect. When depletion has been carried far enough, and the disease still continues, the application of a blister on the back of the neck or between the shoulders may be serviceable.

2. The *chronic* form of a croup is very rare. A concrete parenchymatous material, obstructing the bronchia, and formed occasionally in the trachea, is coughed up in smaller or larger masses. It is sometimes loose, and without any attachment to the sides of the bronchial tubes; and sometimes so extensively connected by the inosculation of vessels, as to cause a fatal hæmorrhage when expelled with violence. In some instances, the material is membranous, like white paper, the size of a shilling, or larger, or it is tubular, having the form of the bronchia. Dr. Warren gives a good account of this disease in the first volume of the Transactions of the College of Physicians. It is attended with a difficulty of breathing, a short, dry, and almost incessant cough, which vanish when the membrane is expelled. This disease returns by paroxysms, which recur as more membrane is forming. At other times there is little deviation from health, and febrile symptoms are seldom noticed. Mercury, in small doses, with expectorants, have, in the several cases which I have seen, removed the morbid and peculiar action of the mucous membrane, which is the essence of the disease.

3. The *spasmodic croup*. This is a very different disease from the two former, the very essence of which is inflammation, and a membrane-like secretion, neither of which exist in this, which is of a purely nervous or spasmodic nature. Dr. Good very properly gives it another name — *laryngismus stridulus*, and places it amongst nervous diseases. See *Laryngismus stridulus*.

Crowfoot. See *Ranunculus*.

Crowfoot-cranesbill. See *Geranium pratense*.

Crow-silk. See *Conferva rivalis*.

Crown. See *Corona*.

Crown imperial. See *Corona imperialis*.

CRU'CIAL. (*Crucialis*; from *crux*, a cross.) Cross-like. Applied in *Anatomy* to some parts disposed in the manner of a cross, as the crucial ligaments of the knee-joint. 2. In surgery, to an incision made in the shape of a cross.

Cruciа'lis. See *Crucial*.

Cruciа'tus. See *Cruciformis*.

CRU'CIBLE. (*Crucibulum*, *i*. n.; from *crucio*, to torment: so named, because, in the language of the old chemists, metals are tormented in it, and forced to yield up their powers and virtues.) A chemical vessel in which substances are exposed to the heat of a fire or furnace. They are of various materials, as earthenware, iron, black lead, platina, &c. Earthen crucibles of a triangular shape are those most used in common chemical operations.

CRUCI'FERÆ. (From *crux*, a cross, and *fero*, to bear.) Cruciform plants. A natural family of plants, the corollæ of which are in the shape of a cross. They all belong to Linnæan class *Tetradynamia*, and they are all more or less pungent and aromatic.

CRUCIFO'RMIS. *Cruciatus*. Cross-like. Applied to leaves, flowers, &c. which have the shape of a cross.

CRU'DITAS. (From *crudus*, raw.) A crudity. A term applied to undigested substances in the stomach, and formerly to humours in the body unprepared for concoction.

Cru'nion. (From κρουνος, a fountain.) A medicine mentioned by Aëtius, and named from the violence of its operation as a diuretic.

CRU'OR. (*or*, *oris*. m.; from κρυος, cold, it being that which appears like a coagulum as the blood cools.) The red part of the blood. See *Blood*.

Cru'ra. The plural of *crus*.

CRURÆ'US. (From *crus*, a leg.) *Cruralis*. A muscle situated on the fore-part of the thigh. It arises, fleshy, from between the two trochanters of the os femoris, but nearer the lesser, firmly adhering to the fore-part of the os femoris throughout the greater part of its length; and is inserted, tendinous, into the upper part of the patella, behind the rectus. Its use is to assist the vasti and rectus muscles in the extension of the leg.

CRU'RAL. (*Cruralis*; from *crus*, the leg.) Belonging to the *crus*, leg, or lower extremity.

Crural hernia. See *Hernia cruralis*.

Cruralis. See *Cruræus.*

CRUS. (*Crus, ris.* n.) 1. The leg.

2. The root or origin of some parts of the body, from their resemblance to a leg; as *Crura cerebri, Crura cerebelli; Crura* of the diaphragm, &c.

Crus clitoridis. See *Clitoris.*

Crus penis. See *Penis.*

CRU'STA. (*a, æ.* f.) 1. A shell.

2. A scab.

3. The scum of a fluid.

Crusta lactea. Milk scab. A name that has been given to the scald head. See *Porrigo.*

Crusta villo'sa. The mucous coat of the stomach and intestines.

CRUSTA'CEA. A class of articulated animals, which have the body protected by a hard shell. See *Animal kingdom.*

CRUSTA'CEOUS. Covered with a shell, or resembling a shell. Applied to various objects in zoology and botany.

Cru'stula. (Dim. of *crusta*, a shell.) An effusion of blood under the tunica conjunctiva of the eye, from a bruise or any other cause.

Crustumina'tum. A kind of rob prepared by the ancients with Crustuminian pears, and apples, boiled with honey.

Crymo'des. (Κρυμωδες, from κρυος, cold.) An epithet of a fever, wherein the external parts are cold, and the internal hot.

CRYO'PHORUS. (From κρυος, cold, and φερω, to bear.) The frost-bearer, or carrier of cold; an instrument, invented by Dr. Wollaston, to demonstrate the relation between evaporation at low temperatures, and the production of cold.

CRYPSO'RCHIS. (*is, idis.* m.; from κρυπτω, to conceal, and ορχις, a testicle.) A man whose testicles are hid in the belly, not having descended into the scrotum.

CRY'PTA. (*a, æ.* f.; from κρυπτω, to hide.) 1. The little rounded appearances at the end of the small arteries of the cortical substance of the kidneys, that appear as if formed by the artery being convoluted upon itself, are called *cryptæ.*

2. A *follicle*, or *follicular gland.*

Cryptoce'phalus. (From κρυπτος, hidden, and κεφαλη, a head. The name given by G. St. Hillaire to a monstrosity, in which the head is very small, and does not project from the trunk.

CRYPTOGA'MIA. (*a, æ.* f.; from κρυπτος, hidden, and γαμος, a marriage.) The twenty-fourth and last class of the Linnæan system of plants, comprehending those in which the parts essential to fructification have not been sufficiently ascertained to admit of their being referred to the other class. It contains four orders, *Filices, Musci, Algæ*, and *Fungi.*

CRYSTAL. (*Crystallus, i.* m.; Κρυσταλλος.) When liquid or gaseous bodies assume the solid form, their particles in some instances aggregate indiscriminately, forming irregular masses, and in other instances become connected in a certain order, so as to constitute defined mathematical figures. The researches of Romé de Lisle, Gahn, Bergman, and Haüy, have established that every body susceptible of crystallisation, crystallises in some *primitive form*, as the cube tetraëdron, octoëdron, &c.; and that all the *secondary forms* arise from the decrement of particles from the edges and angles of these primitive forms.

Crystal mine'ral. A French name of the *sal prunellæ* when in the form of cakes. See *Sal prunellæ.*

Crysalli. This name seems to have been given both to *Pemphigus* and to *Varicella.*

CRYSTALLINE. *Crystallinus.* Resembling crystal.

Crystalline lens. See *Oculus.*

CRYSTALLISATION. (*Crystallizatio, onis,* f.; from *crystallus*, a crystal.) A process in which crystallisable bodies tend to assume a reguiar form, when placed in circumstances favourable to that particular disposition of their particles. Almost all minerals possess this tendency; but it is most eminent in saline substances. The circumstances which are favourable to the crystallisation of salts, and without which it cannot take place, are two: 1. Their particles must be divided and separated by a fluid, in order that the corresponding faces of those particles may meet and unite. 2. In order that this union may take place, the fluid which separates the integrant parts of the salt must be gradually carried off, so that it may no longer divide them.

Cte'dones. (From κτηδων, a comb.) Fibres disposed in a pectinated manner, were so called by the Greek anatomists.

Cteis. (Κτεις, a comb.) 1. The os pubis.

2. The incisor teeth were called κτενες.

CUBE'BA. (*a, æ.* f.; from *cubabah*, Arab.) See *Piper cubeba.*

Cubebs. See *Piper cubeba.*

Cubiforme os. See *Os cuboides.*

Cubitæus externus. See *Extensor digitorum communis.*

Cubitæus internus. See *Flexor sublimis*, and *profundus.*

CU'BITAL. (*Cubitalis;* from *cubitus*, the fore-arm.) Belonging to the fore-arm.

Cubital artery. *Arteria cubitalis.* The ulnar artery. See *Ulnar artery.*

Cubital nerve. *Nervous cubitalis.* The ulnar nerve. See *Ulnar nerve.*

Cubitalis musculus. See *Anconeus.*

CU'BITUS. (*us, i.* m.; from *cubo*, to lie down: because the ancients used to lie down on that part at their meals.) 1. The fore-arm, or that part between the elbow and wrist.

2. The larger bone of the fore-arm is called *os cubiti.* See *Ulna.*

CUBOI'DES. (From κυβος, a cube or die, and ειδος, likeness.) Cuboid, resembling a cube.

Cuboides os. *Os cubiforme. Os grandinosum.* A tarsal bone of the foot. See *Tarsus.*

Cuckow-flower. See *Cardamine.*

Cuckow pint. See *Arum maculatum.*

CUCU'BALUS. (*us, i.* m.) The name of a genus or family of plants in the Linnæan system. Class, *Decandria;* Order, *Tryginia.*

Cucubalus bacciferus. The systematic name of the berry-bearing chick-weed, which is sometimes used as an emollient poultice.

Cucubalus behen. The systematic name

of the *Behen officinarum*, or spatling poppy, formerly used as a cordial and alexipharmic.

CUCULLA'RIS. (From *cucullus*, a hood: so named, because it is shaped like a hood.) See *Trapezius*.

Cuculatum majus. A barbarous name of brandy. — *Ruland*.

CUCULLA'TUS. Hooded; cone-shaped. Applied to a leaf, when the edges meet in the lower part, and expand in the upper, forming a sheath or hood, like the paper rolled by grocers to put small quantities of any thing in, or like a hollow cone, as in the genus *Sarcacenia*.

CUCU'LLUS. (*us, i.* m.) 1. A hood.

2. An odoriferous cap for the head.

Cucumber. See *Cucumis*.

Cucumber, bitter. See *Cucumis colocynthis*.

Cucumber, squirting. See *Momordica elaterium*.

Cucumber, wild. See *Momordica elaterium*.

CU'CUMIS. (*is, is.* m.; also *cucumer, ris.*; *quasi curvimer*, from its curvature.) The cucumber. 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Syngenesia*. The cucumber.

2. The pharmacopœial name of the garden cucumber. See *Cucumis sativus*.

Cucumis agrestis. See *Momordica elaterium*.

Cucumis asininus. See *Momordica elaterium*.

Cucumis colocynthis. The systematic name of the bitter apple, bitter gourd, or bitter cucumber. *Colocynthis*. *Alhandula* of the Arabians. *Coloquintida*. *Cucumis — foliis multifidis, pomis globobis glabris*, of Linnæus. This plant is an annual, a native of Turkey and Nubia, flowering from May till August, and much resembling the cucumber in its herbage. The root is branching, and strikes deep into the ground. The stems are trailing, beset with rough hairs; the leaves are on long petioles, of a triangular form, variously sinuated, obtuse, of a fine green colour on the upper surface, and whitish and rough beneath. The flowers are solitary, axillary, and of a yellow colour. The calyx of the male flowers is bell-shaped; the corolla the same shape with the limb, divided into five-pointed segments; and the anthers, which stand on three short filaments, are long, erect, and adhere together on the outer side. The female flower is like the male, but the filaments have no anthers. The fruit is a round berry or pepo, the size of a small orange, yellow, and smooth on the outside when ripe; trilocular, each cell containing many ovate, compressed, whitish seeds, enveloped by a white spongy pulp.

When the fruit is ripe and yellow, it is peeled and dried in a stove; and in this state it is brought to this country. When it is larger than a St. Michael's orange, and has black acute-pointed seeds, it is not good.

Qualities. — Dried coloquintida is inodorous; but has an extremely bitter nauseous taste, and the pulp feels mucilaginous when chewed. Independent of the seeds, it is altogether composed of a very light, easily torn, white, cellular matter. Ether, alkohol, and water extract its virtues. The infusion in boiling water has a golden-yellow colour, gelatinises as it cools, and resembles, except in colour and taste, mucilage of quince-seed. This mucilage is soluble in cold water. Alkohol and all the acids coagulate the solution, which is precipitated by solutions of acetate and subacetate of lead, and nitrate of silver. Sulphate of iron strikes with it a deep olive colour.

Its colour is rendered also greenish by solution of potassa, which precipitates it; but the mucilage is dissolved by solution of ammonia. Ether, digested on the pulp, deposits, when evaporated on the surface of water, a white, opaque, bitter resin, and some extractive; from which the water acquires the bitter taste of the fruit, and precipitates solutions of potassa, nitrate of silver, and acetate of lead. From these experiments colocynth pulp should consist chiefly of mucus, resin, a bitter principle, and some gallic acid. M. Vauquelin found that an alkoholic tincture formed from the residue of a strong decoction of colocynth, when evaporated and washed with a little water to free it from some acetate of potassa, yields a brittle orange-yellow substance, partially soluble only in water, the residue being a white filamentous mass, changing to yellow. This substance he has named *Colocythine*; and he regards it as the active principle of the drug. Colocynthine is more soluble in alkohol than in water. It is precipitated by infusion of nutgalls.

Medical properties and uses. — The pulp of this fruit is a very powerful drastic cathartic. It was employed by the ancients in dropsical, lethargic, and melancholic affections; but always with caution, on account of its violent effects. Orfila, from his own observations, asserts that one or two drachms of it only, applied to the cellular tissue of the interior of the thigh of a man, produced death in the space of twenty-four hours. When given alone, even in moderate doses, it purges vehemently, producing violent gripings, bloody dejections, and not unfrequently, convulsions and inflammation of the bowels. The watery decoction, or the infusion, is much less violent in its operation, and has been recommended in worm cases. It is scarcely ever given alone in any form, but is generally united with other purgatives to quicken their operation. The dose is from gr. j. to grs. v triturated with almonds, or gum, or some farinaceous matter.

Officinal preparations. — *Extractum Colocynthidis*, L. D. *Extractum Colocynthis comp.* L. D. *Pilulæ Colocynthidis comp.* E. D. *Pilulæ Aloe cum Colocynthide*, D. — *A. T. Thomson*.

Cucumis melo. The systematic name of the melon plant. *Melo*. Musk melon. The fruit, when ripe, has an agreeable cool flavour, but must be eaten moderately, with pepper, or some aromatic, as all this class of fruits are liable to produce flatulence and colic. The seeds possess mucilaginous qualities.

Cucumis sativus. The systematic name of the cucumber plant. *Cucumis*. *Cucumis — fructibus angulis rectis; pomis oblongis scabris* Linnæus. It is cooling and aperient, but very apt to disagree with bilious stomachs. It should always be eaten with pepper and oil. The seeds were formerly used medicinally.

Cucumis sylvestris. See *Momordica elaterium*

CU'CUPHA. A hood. An odoriferous cap for the head, containing aromatic drugs.

CUCU'RBITA. (*a. æ.* f.; *à curvitate*, according to Scaliger, the first syllable being doubled; as in *Cacula*, *Populus*, &c.) 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Syngenesia*. The pumpion.

2. The pharmacopœial name of the common gourd. See *Cucurbita pepo*.

3. A chemical distilling vessel, shaped like a gourd.

4. A cupping-glass.

CUCURBITA CITRULLUS. The systematic name of the water-melon plant, or Sicilian citrul, or water-melon. *Citrullus*. *Anguria*. *Tetranguria*. The seeds of this plant, *Cucurbita — foliis multipartitis*, of Linnæus, were formerly used medicinally, but now only to reproduce the plant. Water-melon is cooling and somewhat nutritious; but so difficult of digestion, as to prove highly noxious to some stomachs, and bring on spasms, diarrhœa, cholera, colic, &c.

Cucurbita lagenaria. See *Cucurbita pepo*.

CUCURBITA PEPO. The common pumpion, gourd, or bottle gourd. *Cucurbita*. The seeds of this plant, *Cucurbita — foliis lobatis, pomis lævibus*, are used indifferently with those of the *Cucurbita lagenaria — foliis subangulatis, tomentosis, basi subtus biglandulosis, pomis lignosis*. They contain a large proportion of oil, which may be made into emulsions, but is superseded by that of sweet almonds.

CUCURBITA'CEÆ. The name of an order of Linnæus's Fragments of a Natural Method, consisting of plants which resemble the gourd.

CUCURBITI'NUS. The *tænia solium*, a species of tape-worm, has been so named from its resemblance to the seed of the gourd. See *Tænia*.

CUCURBI'TULA. (*a, æ.* f.; a diminutive of *cucurbita*, a gourd: so called from its shape.) A cupping-glass. See *Cupping*.

CUCURBITULA CRUENTA. A cupping-glass, applied after scarification, to procure blood.

CUCURBITULA CUM FERRO. The same.

CUCURBITULA SICCA. A cupping-glass applied without scarification.

Cudweed. See *Filago*.

CULBI'CIO. A sort of strangury, or rather heat of urine.

CU'LEUS. A Roman measure containing twenty amphoræ.

CU'LEX. (*ex, icis.* m.) A genus of dipterous insects. The gnat family.

CULEX PIPIENS. The common gnat, and the musquito, the bite of which is so pungent. The best application to the bitten part is diluted spirit of hartshorn.

Culilawan. See *Laurus Culilawan*.

CULMIFERÆ. Plants which have smooth soft stems.

CU'LMUS. (*us, i.* m.; from the Greek καλαμος, a reed.) Culm. Straw. The stem of grasses, rushes, and plants nearly allied to them. It bears both leaves and flowers, and its nature is more easily understood than defined. The varieties of the culmus are,

1. *Teres*, round; as in *Carex uliginosa*.
2. *Tetragonus*; as in *Festuca ovina*.
3. *Triangularis*; as in *Eriocaulon triangulare*.
4. *Capillaris*; as in *Scirpus capillaris*.
5. *Prostratus*; as in *Agrostis canina*.
6. *Repens*; as in *Agrostis stolonifera*.
7. *Nudus*; as in *Carex montana*.
8. *Enodis*, without joints; as in *Juncus conglomeratus*.
9. *Articulatus*, jointed; as in *Agrostis alba*.
10. *Geniculatus*, bent like the knee; as in *Alopecurus geniculatus*.

It is also either solid or hollow, rough or smooth; sometimes hairy or downy, scarcely woolly.

CU'LTER. *ter, tri.* m. A knife or shear. The third lobe of the liver has been so called, from a supposed resemblance in shape.

Cumamus. See *Piper cubeba*.

CUMANA BRASSICA. Red colewort.

Cumin. See *Cuminum*.

CU'MINUM. (*um, i.* n.; from κυω, to bring forth: because it was said to cure sterility.) 1. The name of a genus of plants in the Linnæan system. Class, *Heptandria*; Order, *Digynia*. The cumin plant.

2. The pharmacopœial name of the cumin plant. See *Cuminum cyminum*.

Cuminum æthiopicum. See *Sison*.

CUMINUM CY'MINUM. The systematic name of the cumin plant; called also, *Fœniculum orientale*. A native of Egypt and Ethiopia, but cultivated in Sicily and Malta, from whence it is brought to us. The seeds of cumin, which are the only part of the plant in use, have a bitterish taste accompanied with an aromatic flavour, but not agreeable. They are generally preferred to other seeds for external use in discussing indolent tumours, as the encysted, scrofulous, &c. and give name both to a plaster and cataplasm in the Pharmacopœias.

CUNEA'LIS SUTURA. The suture by which the os sphenoides is joined to the os frontis.

CUNEIFORM. (*Cuneiformis*; from *cuneus*, a wedge, and *forma*, likeness.) Wedgelike. Applied in anatomy and natural history to various objects from their shape.

Cuneiformia ossa. See *Tarsus*.

CUNE'OLUS. (From *cuneus*, a wedge.) A crooked tent to put into a fistula.

CUNI'LA. A genus of plants. Class, *Diandria*; Order, *Monogynia*. The *C. mariana* is thought to be febrifuge.

CUNILA BUBULA. A name given by Pliny to marjoram.

CUNILA MASCULA. A name of the *inula dysenterica*. — *C. Bauhin*.

Cunilago. See *Cunila mascula*.

Cup. See *Calyx*.

CU'PEL. (*Kuppel*, a cup. German.) *Copella, Catullus cinereus, Cineritium, Patella docimastica, Testa probatrix, exploratrix*, or *docimastica*. A shallow earthen vessel like a cup, made of phosphate of lime, which suffers the baser metals to pass through it, when exposed to heat, and retains the pure metal. This process is termed cupellation.

CUPELLATION. *Cupellatio*. The purifying of perfect metals by means of an addition

of lead, which, at a due heat, becomes vitrified, and promotes the vitrification and calcination of such imperfect metals as may be in the mixture, so that these last are carried off in the fusible glass that is formed, and the perfect metals are left nearly pure. The name of this operation is taken from the vessels made use of, which are called cupels.

CUPPING. (So called, most probably, from the cup-like shape of the glasses.) The application of the *cucurbitula*, or cupping-glass. This practice is of great antiquity, being mentioned by Hippocrates, and then the instrument was made of horn or metal. A figure of a cupping apparatus may be seen in the surgical works of Albucasis.

Cupping is performed by glasses, called from their shape *cucurbitulæ*, of different sizes and shapes, mostly open like a cup, but more ample and round at the bottom part, a spirit lamp and a scarificator. When the operation is about to be done, a basin of warm water, a piece of fine sponge, and the lighted lamp must be at hand. As many of the cupping-glasses as may be judged necessary, are to be put into the basin. Each glass is then to be held for an *instant only* over the flame of the spirit lamp, and immediately placed upon the skin: by this the air in the glass is rarified; and the moment the glass is applied, the skin and integuments are drawn up, and become swollen, from the blood being drawn into the small vessels, where it becomes stagnant, and perhaps effused into the cellular tissue. When nothing more is done, the operation is called *dry cupping*. The glasses are removed after two or three minutes, and again applied in the same way five or six times: but cupping being mostly intended to remove a quantity of blood, the operator proceeds, after the glass has been on a minute, to remove it, which he does by pressing the nail of a finger between the edge of the glass and the skin to let the air in, and in its place he quickly applies the scarificator — See *Scarificator* — and as quickly lays it aside, and immediately puts on the cupping-glass, having rarified the air within it by the flame of the spirit lamp as before. This is called cupping with scarifications. The successful performance of this operation requires some dexterity, and depends in a great measure on the quickness with which the application of the scarificator succeeds the removal of the glass; and by this adroitness the patient is saved a degree of pain which he would otherwise suffer from the scarifications. When the glasses are so full as to be in danger of falling off, or the blood is coagulated in them, they should be removed, emptied, and applied again. For the sake of neatness, care should be taken to insert the nail under the upper part of the glass, and remove it so as to keep its bottom downwards, the scarifications being at the same time wiped with a sponge, wet with warm water. The glasses also, previously to each application, should be rinsed with warm water, but not dried.

A bit of soft rag is usually doubled and put over the scarified part, at the end of the operation.

CUPRE'SSUS. (So called, απο του κυειν παρισους τους ακρεμονας, because it produces equal branches.) Cypress.

1. The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Monadelphia*. The cypress-tree.

2. The pharmacopœial name of the cypress-tree. See *Cupressus sempervirens*.

Cupressus sempe'rvirens. The systematic name of the cupressus of the shops. *Cupressus —foliis imbricatis squamis quadrangulis*, of Linnæus; called also *cyparissus*. Every part of the plant abounds with a bitter, aromatic, terebinthinate fluid; and is said to be a remedy against intermittents. Its wood is extremely durable, and constitutes the cases of Egyptian mummies.

Cupri ammoniati liquor. See *Liquor cupri ammonio-sulphatis*.

Cupri rubigo. Verdigris.

Cupri sulphas. Sulphate of copper. Blue vitriol, called formerly, *Vitriolum cupri*, *Vitriolum cæruleum*, *Vitriolum Romanum*, and *Cuprum vitriolatum*. It possesses corrosive and styptic qualities; is esteemed as a tonic, emetic, astringent, and escharotic; and is exhibited internally in the cure of dropsies, hæmorrhages, and as a speedy emetic. The dose, as a tonic and astringent, is gr. $\frac{1}{6}$, gradually increased to gr. ij.; as an emetic, from gr. v. to gr. xv. Externally, it is applied to stop hæmorrhages, to hæmorrhoids, leucorrhœa, phagedænic ulcers, proud flesh, and condylomata.

CU'PRUM. (*Quasi æs Cyprium*; so called from the island of Cyprus, whence it was formerly brought.) See *Copper*.

Cuprum ammoniacale. See *Cupri ammonio sulphas*.

Cuprum ammoniatum. See *Cupri ammonio-sulphas*.

Cupri ammonio-sulphas. Ammoniated copper. Ammoniacal sulphate of copper. *Cuprum ammoniatum*. *Cuprum ammoniacale*. Take of sulphate of copper, half an ounce; subcarbonate of ammonia, six drachms: rub them together in a glass mortar, till the effervescence ceases; then dry the ammoniated copper, wrapped up in bibulous paper, in the air. In this process the suphate of copper is decomposed by the sesquicarbonate of ammonia, and a portion of the carbonic acid of the latter escapes. Carbonate of copper and sulphate of ammonia are formed, which, with the excess of sesquicarbonate of ammonia appears to constitute the substance under consideration. This preparation is much milder than the sulphate of copper. It is found to produce tonic and astringent effects on the human body. Its principal internal use has been in epilepsy, and other obstinate spasmodic diseases, given in doses of half a grain, gradually increased to five grains or more, two or three times a day. For its external application, see *Liquor cupri ammonio-sulphatis*.

Cuprum vitriolatum. See *Cupri sulphas*.

CU'PULA. An accidental part of a seed, being a rough calyculus, surrounding the lower part of a gland, as that of the oak, of which it is the cup.

CURA'TIO. *Cura*. The treatment of a dis-

ease or injury. It is not synonymous with our word *cure*; since it applies to treatment merely, whether successful or otherwise; thus *curare vulnus* does not mean to *cure* a wound, but to *dress* a wound.

CURA AVENACEA. A decoction of oats and succory roots, in which a little nitre and sugar were dissolved, was formerly used in fevers, and was thus named.

CURATIVUS. Relative to a cure.

Curcas. See *Jatropha curcas.*

CURCU'LIO. (From *karkarah*, Hebrew.) The throat, and the aspera arteria.

Curcum. See *Chelidonium majus.*

CURCU'MA. (*a*, *æ*. f.; from the Arabic *curkum*.) Turmeric.

1. The name of a genus of plants in the Linnæan system. Class, *Monandria*; Order, *Monogynia.*

2. The pharmacopœial name of the turmeric-tree. See *Curcuma longa.*

CURCUMA LONGA. The systematic name of the turmeric plant; also called, *Crocus Indicus*, *Terra marita*, *Cannacorus radice croceo*, *Curcuma rotunda*, and *Mayella*; *Kua kaha* of the Indians.

Curcuma — foliiis lanceolatis; nervis lateralibus numerossimis, of Linnæus. The Arabians call every root of a saffron colour by the name *curcum*. The root of this plant is imported here in its dried state from the East Indies, in various forms. Externally, it is of a pale yellow colour, wrinkled, solid, ponderous, and the inner substance of a deep saffron or gold colour: its odour is somewhat fragrant; to the taste it is bitterish, slightly acrid, exciting a moderate degree of warmth in the mouth, and, on being chewed, it tinges the saliva yellow. It is an ingredient in the composition of *Curry powder*, is valuable as a dyeing drug, and furnishes a chemical test of the presence of uncombined alkalis. It is now very seldom used medicinally, but retains a place in our pharmacopœias.

Curcuma rotunda. See *Curcuma longa.*

CURD. The coagulum, which separates from milk, upon the addition of acid and other substances.

CURE'TTE. (French.) An instrument, shaped like a little scoop, for taking away any opake matter that may be left behind the pupil, after extracting the cataract from the eye.

Curled. See *Crispus.*

CU'RMI. (Κουρμι.) Ale. A drink made from barley; a kind of ale. — *Dioscorides.*

Currant. See *Ribes.*

CURSUMA. *Curtuma.* See *Ranunculus ficaria.*

Curtain. See *Volva.*

CURVA'TOR COCCY'GIS. The name of a muscle described by Albinus.

CURVA'TUS. (From *curvo*, to bend.) Curvate: bent.

CUSCU'TA. (*a*, *æ*. f.; according to Linnæus, a corruption from the Greek κασυτας, or καδυτας, which is from the Arabic *chessuth*, or *chasuth*.) Dodder. 1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria*; Order, *Digynia.*

2. The pharmacopœial name of dodder of thyme. See *Cuscuta epithymum.*

CUSCUTA EPITHYMUM. The systematic name of the dodder of thyme; called also, *Intestina diaboli*, *epithymum*. *Cuscuta — foliis sessilibus, quinquifidis, bracteis obvallatis.* A parasitical plant, possessing a strong disagreeable smell, and a pungent taste, very durable in the mouth: recommended in melancholia, as cathartics. A large variety, common on heaths, on furze, and nettles, is sometimes called *hell-weed*, from the destruction it produces, and also *devil's guts.*

CUSCUTA EUROPÆA. The systematic name of a species of dodder. *Linangina. Cuscuta — floribus sessilibus*, of Linnæus.

CUSPA'RIA. (*a*, *æ*. f.) 1. The name given by Messrs. Humboldt and Bonpland to a genus of plants in which is the tree which yields the angustura bark. See *Bonplandia trifoliata*, in the *Supplement.*

2. The tree which yields the angustura bark. See *Bonplandia trifoliata*, in the *Supplement.*

CUSPIDA'TUS. (From *cuspis*, a point.) Cuspidate. 1. Four of the teeth are called *cuspidati*, because they have the two sides of their edge sloped off to a point. See *Teeth.*

2. Sharp-pointed: applied to leaves which are tipped with a spine, as in thistles. See *Leaf.*

CU'SPIS. (*is*, *idis*. f.) A point. 1. The glans penis has been so called, from its likeness to the point of a spear.

2. The name of a bandage.

CU'STOS OCULI. An instrument to fix the eye during an operation.

CUTA'MBULUS. (From *cutis*, the skin, and *ambulo*, to walk.) 1. A cutaneous worm; most probably the *Gordius medinensis.*

2. Scorbutic itching.

CUTA'NEOUS. (*Cutaneus*; from *cutis*, the skin.) Belonging to the skin.

Cuta'neus musculus. See *Platysma myoides.*

CU'TICLE. (*Cuticula*, *æ*. f.; a diminutive of *cutis*, the skin.) See *Cutis.*

CU'TIS. (*is*, *is*. fœm.) *Dermis. Pellis.* The skin. Skin has been said to consist of three parts: true skin (*cutis vera*), mucous net (*rete mucosum*), and scarf-skin, or cuticle. Haller, Camper, and Blumenbach are inclined to deny the existence of the mucous net in the skin of the white, and to admit it in that of the negro only; and in point of fact, indeed, its existence has been demonstrated in the negro race only, and inferred by analogy to exist in the white. "When a blister has been applied to the skin of a negro," says Cruickshank, "if it has not been very stimulating, in twelve hours after a thin transparent greyish membrane is raised, under which we find a fluid. This membrane is the cuticle or scarf-skin. When this with the fluid is removed, the surface under these appears black; but if the blister had been very stimulating, another membrane, in which this black colour resides, would also have been raised with the cuticle. This is *rete mucosum*, which is itself double, consisting of another grey transparent membrane, and of a black web very much resembling the *pigmentum nigrum* of the eye. When this membrane is removed, the surface of the true skin, as has been hitherto believed, comes in view, and is white like that of a European. The *rete mucosum* gives the

colour to the skin; is black in the negro; white brown or yellowish in the European."

Bichat denies the existence of a mucous coating or varnish (*corpus mucosum*), such as Malpighi describes it, and regards the vascular surface of the corion as the only mucous net.

According to Chaussier, the skin consists of two parts only, the *derma* (δερμα) *cutis vera* or corion, and the epidermis, cuticle, or scarf-skin; the first embracing the organic elements of this tissue; the second being an inorganic substance prepared by the organic, and deposited on its surface. This opinion is adopted by Gordon, according to whom the skin consists of two substances placed above each other like layers or plates (*laminæ*), the inner of which is the true skin, the outer the cuticle, or scarf-skin. Beclard, on the contrary, thinks that a peculiar matter, which occasions the colour by which the several races are distinguished, is found between the outer surface of the corion and the cuticle; and that no fair race is destitute of it except the *albino*, the peculiar appearance of whom he ascribes to the absence of the mucous net of the skin.

The *corion* of the human skin (*pellis, corium, derma, cutis vera*) seems to consist chiefly of very small dense fibres, not unlike those of the proper arterial coat, closely interwoven with each other, and more firmly compacted the nearer they are to its outer or cuticular surface. The inner surface of the corion is of a grey colour; and in almost all parts of the body presents a number of depressions, varying in size from $\frac{1}{10}$th to $\frac{1}{12}$th of an inch, and consequently forming spaces or intervals between them. These depressions, which correspond to eminences in the subjacent adipose tissue, have been termed *areolæ*. They are wanting in the corion of the back of the hand and foot only.

The outer or cuticular surface of the corion is quite smooth, of a pale or flesh-red tinge, and is much more vascular than its inner surface. It presents, further, a number of minute conical eminences (*papillæ*), which, according to the recent observations of Gaultier and Dutrochet, are liberally supplied with blood-vessels (*bourgeons sanguins*), and are the most vascular part of this membrane. In the ordinary state of circulation and temperature during life these eminences are on a level with the surrounding *corion;* but when the surface is chilled this membrane shrinks, while the papillæ either continue unchanged, or shrink less proportionally, and give rise to the appearance described under the name of *goose skin* (*cutis anserina*). This surface was said by the older anatomists to present numerous openings, orifices, or pores; but according to Gordon, if we trust to mere observation, no openings of this kind can be recognised, either by the eye or the microscope, except those of the sebaceous follicles. The hairs, indeed, are found to issue from holes in the corion, but they fill them up completely.

In certain situations, for instance, at the entrance of the external auditory hole, at the tip of the nose, on the margins of the eyelids, in the arm-pits, at the nipple, at the skin of the pubes, round the anus, and the female pudendum, are placed minute orifices, from which exudes an oleaginous fluid, which is quickly indurated. These openings lead into small sacs or cavities, called follicles (*folliculi*), or sebaceous glands (*glandulæ sebaceæ*). Of these sacs the structure is simple. They appear to consist simply of hollow surfaces secreting an oleaginous fluid, which is progressively propelled to the orifice, where it soon undergoes that partial inspissation which gives it the sebaceous or suet-like aspect and consistence.

The corion is liberally supplied with blood-vessels, nerves, and absorbents. After a successful injection, its outer surface appears to consist of an uniform network of minute vessels, subdivided to an infinite degree of delicacy, and containing during life blood coloured and colourless. It can scarcely be doubted that this vascular network (*rete vasculosum*) is the only texture corresponding to the *reticular body* of the older anatomists.

It is well known that this membrane when boiled sufficiently long is converted into a viscid glutinous liquor, which consists chiefly of gelatin (Chaptal, Seguin, Hatchett, Vauquelin, &c.), and that glue is obtained in great quantity from it for the purposes of art. As, however, in these operations a portion of matter is left undissolved, and as glue is completely soluble in water, while skin resists it for an indefinite time, it may be concluded, that though the chief constituent of the corion is gelatin, it is under some peculiar modification not perfectly understood. The union of this organised gelatin with the vegetable principle denominated *tannin* forms leather, which is quite insoluble in water.

Cuticle or scarf-skin (*epidermis, cuticula*) is a semitransparent, or rather translucent layer, of thin light-coloured matter, extended continuously over the outer surface of the corion. Its thickness varies, being thinnest on those parts least exposed to pressure and friction, but thickest in the palms and soles. It is destitute of blood-vessels, nerves, and absorbents; and there is reason to believe, from observing the phenomena and process of its reproduction, that it is originally secreted in the form of a semifluid viscid matter by the outer surface of the corion; and that, as it is successively worn or removed by attrition, it is in like manner repaired by a constant process of secretion or deposition. This semifluid viscid matter, which, in point of fact, is found between the outer surface of the corion and the firm cuticle, appears to be the substance mentioned by Malpighi, and so often spoken of as the mucous body or net (*corpus mucosum*). It is certainly quite inorganic; and it is impossible to explain its production otherwise than by ascribing it to the outer or vascular surface of the corion.

Cuticle is rendered yellow, and finally dissolved by immersion in nitric acid. It is also dissolved by sulphuric acid, in the form of a deep brown pulp. These, and some other experiments performed by Hatchett, appear to show that it consists chiefly of albuminous matter somehow modified.

This description shows, that, if strict observation be trusted, the mucous net has no exist-

ence, at least in the European. In the Negro, Caffre, and Malay, however, a black membrane is said to be interposed between the corion and cuticle, and to be the cause of the dark complexion of these races. On this subject I refer to the description given by Cruickshank, which is the best; the Essay of M. Gaultier already quoted; and the observations of Béclard. What is found in the skin of the mixed or half cast races, *i. e.* the offspring of an African and an European, or of a mulatto and European? and how is the transition between this colouring layer and its insensible diminution effected?

Nail is a substance very familiarly known. On its nature and structure we find many conjectures, but few or no facts in the writings of anatomists; and almost all that has been written is the result of analogical inference, rather than of direct observation. It is known that they drop off with the scarf-skin in the dead body; that they are destroyed or diseased by causes which act on the outer surface of the corion, and produce disease of the cuticle; and that, if forcibly torn out, the surface of the corion to which they were attached bleeds profusely and inflames. In other respects they are quite inorganic; but these facts appear to warrant the conclusion, that the root of the nail is connected with the organic substance of the corion, and that the whole substance is the result of a process of secretion quite similar to that by which the cuticle is formed.

According to the experiments of Hatchett, they consist of a substance which possesses the properties of coagulated albumen, with a very small trace of phosphate of lime. — *Craigie.*

The hair also is an appendage of the cutaneous texture. It has already been treated of in the article *Capillus.*

Cutis anseri'na. Goose-skin. The contracted state of the skin, arising from cold and other causes, in which its papillæ are rigid and prominent, giving it the appearance of the skin of a plucked goose.

Cutis vera. See *Cutis.*

Cutubuth. The Arabic name of a kind of melancholy, accompanied with extreme restlessness.

Cyani'a. (Κυανεια; from κυανος, blue.) An epithet of the blue disease. See *Cyanosis.*

CYANIC ACID. *Acidum cyanicum.* The existence of an acid, composed of cyanogen and oxygen, was first suspected by Vauquelin; but for the mode of obtaining it, its composition, and properties, we are indebted to Wöhler, and to Liebig, though it can scarcely be said to have been hitherto procured in a detached state. When cyanogen is passed into alkaline solutions, it is absorbed, and a cyanuret and cyanate are formed, which, however, cannot be effectually separated, so that, in this respect, the action of cyanogen on the alkaline solution corresponds with that of chlorine and of iodine. But, according to Wöhler, a true cyanate may easily be obtained by exposing a mixture of black oxide of manganese and ferrocyanate of potassa to a dull red heat, carefully avoiding too high a temperature, and boiling the resulting compound in spirit of wine of the specific gravity of 0·86. As the solution cools, tabular crystals of *cyanate of potassa* are deposited. When these are dissolved in cold water, the solution slowly decomposes; and, if boiled, carbonic acid and ammonia are produced, in consequence of the reaction of the elements present. Cyanic acid forms a soluble salt with baryta, but it occasions insoluble precipitates in solutions of lead, mercury, and silver; and these cyanates may be decomposed by diffusing them through water, and exposing them to the action of a current of sulphuretted hydrogen, not in excess. A sour liquid, smelling like vinegar, is thus obtained, but it is very prone to decomposition. (See *Cyanuric acid.*)

According to the analysis of Wöhler, corroborated by the experiments of Liebig, cyanic acid consists of

Carbon	2	12	35·2	Cyanogen	1	26	76·3
Nitrogen	1	14	41·1				
Oxygen	1	8	23·7	Oxygen	1	8	23·7
	1	34	100·0		1	34	100·0

Brande.

CYA'NOGEN. (*Cyanogenium, ii.* n. *Bicarburet of nitrogen.*) *Prussine.* This gaseous compound was discovered in 1815, by Gay Lussac, and termed *cyanogen,* (from κυανος, *blue,* and γενναω, *to generate,*) in consequence of its being essential to the formation of *Prussian blue.* It may be obtained from dry and pure crystals of *cyanuret of mercury.* This substance, when heated in a small glass tube to dull redness, becomes black, and a quantity of mercury passes over and condenses in the cold part of the tube: the gas which is at the same time evolved must be collected over mercury. Under a pressure of between three and four atmospheres at the temperature of 45°, Mr. Faraday condensed cyanogen into a limpid colourless liquid, of a specific gravity of about 0·9, and a refractive power rather less than that of water. When a tube containing it was opened, the expansion within appeared inconsiderable, and the liquid slowly evaporated, producing intense cold. It does not conduct electricity.

Cyanogen gas is colourless, and has a penetrating and very peculiar smell, somewhat resembling that of bitter almonds. When a lighted taper is dipped into it, it is immediately extinguished; but the gas takes fire and burns upon the surface, in contact with air, with a beautiful and very characteristic purple flame. Its specific gravity to hydrogen is as 26 to 1; and to common air as 1·82 to 1; 100 cubic inches weigh 55·5 grains. It sustains a high temperature without decomposition. Water dissolves 4·5 volumes, and alkohol 23 volumes of this gas. Sulphuric ether and oil of turpentine also absorb it. The aqueous solution reddens vegetable blues; and, according to Vauquelin (*Ann. de Chim.* Oct. 1818), is subject to spontaneous decomposition, being gradually converted into carbonic and hydrocyanic acids, ammonia, a peculiar acid, which he calls the *cyanic,* and a brown substance containing carbon: the ammonia saturates the acids, and the carbonaceous compound is deposited. These changes are referrible to the mutual reaction of the elements of cyanogen upon those of water. According to Wöhler, the mutual action of cy-

anogen and water is attended by the production of cyanic acid and ammonia, which, by combination, generate *urea*.

Cyanogen may be analysed by detonation with oxygen, or by passing it over red-hot oxide of copper. One volume, detonated over mercury, with two of oxygen, produces two volumes of carbonic acid and one of nitrogen. Whence it appears that cyanogen consists of its own volume of nitrogen, combined with carbon sufficient to form two volumes of carbonic acid; or of equal volumes of nitrogen and gaseous carbon; and if so constituted, as

	Grains.
100 cubic inches of carbon vapour weigh	25·4
100 nitrogen gas	30·1
100 cyanogen vapour should weigh	55·5

Cyanogen, therefore, is constituted of

				Vols.	S. G.
Carbon	2	12	46·1	1	0·843
Nitrogen	1	14	53·9	1	0·976
	1	26	100·0	1	1·819

Iodine, sulphur, and phosphorus may be sublimed in cyanogen without change; but when they are heated in contact with cyanuret of mercury, compounds of those bodies with cyanogen are the result. It also combines with several of the metals, and constitutes compounds which might be called *nitrocarburets*: they have sometimes been termed *cyanides*; but, perhaps, *cyanuret* is the least objectionable appellation. The cyanurets also combine with each other, and produce an extensive and curious class of salts, which have been termed *double cyanurets*. — *Brande*.

Cyanopathi'a. (*a*, *æ*. f.; from κυανος, blue, and παθος, a disease.) Blue disease. See *Cyanosis*.

CYANO'SIS. (*is*, *is*. m.; from κυανος, blue.) *Cyanopathia*. The blue disease. An unnatural blue colour of the whole skin. This generally arises from a congenital malformation of the heart, in which the right and left cavities directly communicate, so that the whole of the blood is not duly aerated in the lungs.

CYANURET. A compound of cyanogen with a base.

Cyanuret of mercury. *Cyanuretum hydrargyri*. This is a highly poisonous substance, analogous in its operation to the corrosive sublimate. It is used in France, however, in obstinate venereal and cutaneous diseases. The dose is from the sixteenth of a grain to half a grain, in pills or solution.

Cyanuret of potassium. This has been employed as a substitute for hydrocyanic acid, and is thought to possess similar properties. It has the advantage of keeping unchanged. The dose is from the fourth of a grain to a grain, in pill or solution.

Cyanuret of zinc. This is said to have nearly the same medicinal properties as the cyanuret of potassium, and may be given in the same doses.

Cyanuric acid. When uric acid is distilled *per se*, it yields carbonate and hydrocyanate of ammonia, and a sublimate of *pyrouric*, or *cyanuric* acid.

Cyanuric acid may also be obtained from *urea*, which, when gradually heated in a retort to about 600°, is resolved into ammonia and anhydrous cyanuric acid; the latter remains in the retort; to purify it, it is dissolved in hot sulphuric acid, and nitric acid dropped in till it occasions no further effervescence, and the solution becomes colourless: when cold, water is added, which throws down cyanuric acid in the form of a white crystalline powder. It may be obtained in large crystals, by evaporating its hot saturated solution to about half its bulk, at a temperature of 150°, and allowing it gradually to cool upon the sand-bath. Cyanuric acid is remarkably unchangeable by the action of acids, and when heated it sublimes unchanged in the form of acicular crystals. It may be obtained *anhydrous*, by dissolving the crystals in hot sulphuric acid, from which it is deposited on cooling. According to Wöhler and Liebig, cyanuric acid consists of 3 atoms of cyanogen, 3 hydrogen, and 6 oxygen; so that its ultimate components are

Carbon	6	36	27·8
Nitrogen	3	42	32·6
Hydrogen	3	3	2·4
Oxygen	6	48	37·2
Cyanuric acid	1	129	100·0

The conversion of hydrous cyanic acid, and of urea, into cyanuric acid, and other cases of its formation, will be intelligible by reference to its ultimate components; the hypothetical arrangements of which these will admit are too numerous to be here inserted. — *Brande*.

CY'AR. (Κυαρ, the eye of a needle.) The internal auditory foramen.

CYATHIFO'RMIS. (From *cyathus*, a cup or glass, and *forma*, resemblance.) Glass-shaped. Applied, in *Botany*, to a corol which is tubular, but dilated towards the top like a drinking-glass; as in the cup of Jacob's ladder, &c.

Cyathi'scus. (*us*, *i*. m.; from κυαθος, a cup.) A probe with a hollow at the end, to remove wax, &c. from the ear.

CY'ATHUS. (*us*, *i*. m. Κυαθος.) 1. A drinking cup.

2. A liquid measure used by the ancients, equal to the twelfth part of a *sextarius*.

3. A solid measure used by the ancients, equal to ten drachms.

4. In modern prescription the term cyathus signifies a wine glass.

Cyboi'des. See *Cuboides*.

CY'CAS. (Κυκας, of Theophrastus.) The name of a plam said to grow in Ethiopia. The name of a genus of plants, one of the *Palmæ pinnatifoliæ*, of Linnæus; but afterwards removed by him to the *filices*.

Cycas circina'lis. The systematic name of a palm-tree, or meal-bark tree, which affords *Sago*, a dry fecula, obtained from the pith of this palm, in the islands of Java, Molucca, and the Philippines. The same substance is also brought from the West Indies, but it is inferior to that brought from the East. Sago becomes

soft and transparent by boiling in water, and forms a light and agreeable liquid, much recommended in febrile, phthisical, and calculous disorders, &c. To make it palatable, it is customary to add to it, when boiled or softened with water, some lemon-juice, sugar, and wine.

Cy'ceum. (Κυκεων; from κυκαω, to mix.) An article of diet used by the ancient Greeks. It was of a pappy consistence. There were two kinds, one made simply of flour and water, and another of various kinds of flour, wine, honey, and sometimes cheese.

Cycima. Litharge. — *Ruland.*

CY'CLAMEN. (*en, inis.* n.; from κυκλος, circular; either on account of the round form of the leaves, or of the roots.) *Cyclaminus. Cyclaminum.* Cyclamen. 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Monogynia.*

2. The pharmacopœial name of the sow-bread. See *Cyclamen europæum.*

Cyclamen europæum. The systematic name of the sow-bread. *Arthanita* of the Pharmacopœias. The root is a drastic purge and errhine; and by the common people it has been used to procure abortion.

Cycli'scus. (Κυκλισκος; from κυκλος, a circle.) 1. A lozenge.

2. A kind of raspatory of a semilunar shape, used by the Greek surgeons.

Cycli'smus. The same as *cycliscus.*

CYCLONEU'RA. (From κυκλος, a circle, and νευρον, a nerve.) The name given by Dr. R. Grant to the radiated animals, from the distribution of their nervous system. See *Animal kingdom.*

Cyclopho'ria. (From κυκλος, a circle, and φερω, to bear.) The circulation of the blood, or other fluids.

Cyclo'rion. (From κυκλοω, to surround, and ωψ, the eye.) The white of the eye.

CYCLO'STOMI. (From κυκλος, a circle, and στομα, the mouth; because they have round mouths.) A genus of cartilaginous fishes.

CYCLOBRA'NCHIA. (From κυκλος, a circle, and βραγχια, gills.) An order of gasteropodous mollusca, so called from the circular arrangement of their gills.

Cy'clus metasyncri'ticus. (Κυκλος μετασυγκριτικος.) A long course of remedies, persisted in with a view of restoring the particles of the body to such a state as is necessary to health.

Cydar. An alchemical name of tin.

Cydo'natum. (Κυδωνατον.) A confection composed of quinces and aromatics. — *Paulus Ægineta.*

Cydo'nia. (*a, æ.* f.; from *Cydon*, a town in Crete, where the tree grows wild.) The quince-tree. See *Pyrus cydonia.*

Cydonium. See *Pyrus cydonia.*

Cydonium malum. (Κυδωνιον μηλον.) A quince. See *Pyrus cydonia.*

CYE'MA. (Κυημα; from κυω, to bring forth.) The product of conception. The ovum.

Cygnus. See *Anas.*

Cygnus mutus. The tame swan.

Cyli'chne. Κυλιχνη. Κυλιχνις. Κυλιχνιον. A pill box, a gallipot, or other vessel for holding medicines.

Cylindrical leaf. See *Leaf.*

Cyllo'sis. (Κυλλυσις; from κυλλοω, to maim or distort.) 1. In a general sense, distortion, mutilation, lameness of any kind.

2. Curvature of the leg outwards; that state of the leg commonly called a bandy leg.

CY'MA. (*a, æ.* f.) A cyme, or tuft. A species of inflorescence of plants, consisting of several flower-stalks, all springing from one centre or point, but each stalk is variously subdivided; and in this last respect, a cyme differs essentially from an umbel, the subdivisions of the latter being formed, like its primary divisions, of several stalks springing from one point. This difference is of great importance in nature. The mode of inflorescence agrees also with a corymbus in general aspect; but in the latter the primary stalks have no common centre, though the partial ones may sometimes be umbellate, which last case is precisely the reverse of a cyme.

From its division into primary stalks or branches, it is distinguished into,

1. *Trifid;* as in *Sedum acre.*

2. *Quadrifid;* as in *Crassula rubens.*

3. *Tripartite*, having three lesser cymes; as in *Sambucus ebulus.*

4. *Quinquipartite;* as in *Sambucus nigra.*

5. *Sessile*, or without stalk; as in *Gnaphalium frutescens.*

6. *Nude*, or naked; as in *Cornus sanguinea* and *sericea.*

Cy'ma. (*a, atis.* n.; κυμα, from κυω, to produce.) A sprout from a stalk.

Cymato'des. (Κυματωδης; from κυμα, a wave.) Applied by Galen and others to an unequal fluctuating pulse.

CY'MBA. (*a, æ.* f.; from κυμβος, hollow.) A boat, pinnace, or skiff. A bone of the wrist is so called from its supposed likeness to a skiff. See *Naviculare os.*

Cymbala'ria. This is now the specific name of a species of *antirrhinum* not used medicinally. Gerarde calls the pennywort by this name, and says that the aquatic kind is highly poisonous. See *Aquetta.*

Cymbala'ris cartila'go. The cricoid cartilage.

CYMBIFO'RMIS. (From *cymba*, a boat or skiff, and *forma*, likeness.) Skiff or boat like: applied to seeds, as those of the *Calendula officinalis*, and to a bone of the foot, usually called *Os naviculare.*

Cy'minum. See *Cuminum.*

CYMO'SUS. Having the character of a cyme: applied to aggregate flowers.

CYNA'NCHE. (*e, es.* f.; from κυων, a dog, and αγχω, to suffocate, or strangle: so called from dogs being said to be subject to it. "*Cynanche, synanche*, and *parasynanche* are terms met with in the Greek writers after Hippocrates, the common signification of all of which is strangulation or angina; while the prefixes cy, sy, and parasy, are of doubtful meaning. Ætius attempted to justify cynanche; but Cœlius Aurelianus and Paulus used synanche after Celsus. The Latins employed angina in the same extent as Hippocrates did paristhmia: quinsy is used in a parallel latitude among our-

selves." — *Good.*) Sore-throat. See *Tonsillitis*, *Pharyngitis*, and *Croup*.

Cynanche laryngea. See *Croup.*
Cynanche maligna. See *Tonsillitis.*
Cynanche parotidea. See *Parotitis.*
Cynanche pharyngea. See *Pharyngitis.*
Cynanche strepitora. See *Croup.*
Cynanche stridula. See *Croup.*
Cynanche suffocatica. See *Croup.*
Cynanche tonsillaris. See *Tonsillitis.*
Cynanche trachealis. See *Croup.*

CYNA'NCHICUS. (From κυναγχη, the quinsy.) Applied to medicines which relieve the quinsy.

CYNA'NCHUM. The name of a genus of plants. Class, *Pentandria*; Order, *Digynia*.

CYNANCHUM ARGHEL. An Egyptian plant, the leaves of which are employed to adulterate senna. See *Cassia senna.*

CYNANCHUM MONSPELIACUM. This yields the Montpellier scammony, which is purgative, but little used.

CYNANCHUM VOMITORIUM. This plant yields the ipecacuan of the Isle of France. It resembles the common ipecacuan in its properties. The dose also is the same.

CYNANTHRO'PIA. (From κυων, a dog, and ανθρωπος, a man.) This term is used by Bellini, *De Morbis Capitis*, to express a particular kind of melancholy, in which men fancy themselves changed into dogs, and imitate their actions.

Cy'nara. See *Cinara.*
Cynarocephalus. See *Cinarocephalus.*

CYNCHNIS. (Κυγχνις.) A vessel of any kind to contain medicines.

CYNIPS. A genus of hymenopterous insects.

CYNIPS QUERCUSFOLLII. The insect by the puncture of which oak galls are formed. See *Gallæ.*

CYNIPS ROSÆ. The insect whose bite produces the excrescences on rose trees called *Bedeguar.* See *Bedeguar.*

CYNOCRA'MBE. (*e, es.* f.; from κυων, a dog, and κραμβη, cabbage.) A herb of the cabbage tribe, with which dogs are said to physic themselves. See *Mercurialis perennis.*

CYNO'CTONUM. (*um, i.* n.; from κυων, a dog, and κτεινω, to kill.) A species of aconitum, said to destroy dogs. See *Aconitum napellus.*

CYNOCYTISIS. (From κυων, a dog, and κυτισος, the cytisus: so named, because it was said to cure the distemper of dogs.) The dog-rose. See *Rosa canina.*

CYNODE'CTOS. (*us, i.* m.; from κυων, a dog, and δακνω, to bite.) So Dioscorides calls a person bitten by a mad dog.

CYNO'DES OREXIS. (Κυνωδης ορεξις.) Canine appetite. See *Bulimia.*

CYNODE'SMION. (Κυνοδεσμιον. Κυνοδεσμος. Κυνοδεσμη; from κυων, a dog, and δεω, to bind: so named, because in dogs it is very discernible and strong.) The frænum of the prepuce. See *Frænum.*

CYNODO'NTES. (*Cynodentes, tum.* pl.; from κυων, a dog, and οδους, a tooth.) Canine teeth. See *Teeth.*

CYNOGLO'SSUM. (*um, i.* n.: from κυων, a dog, and γλωσσα, a tongue: so named, from its supposed resemblance.) Hound's tongue. 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.*

2. The pharmacopœial name of the hound's tongue. See *Cynoglossum officinale.*

CYNOGLOSSUM OFFICINALE. The systematic name for hound's tongue; called also, *Cynoglossum*, and *Lingua canina.*

Cynoglossum — staminibus corolla brevioribus; foliis lato lanceolatis, tomentosis, sessilibus, of Linnæus. It possesses narcotic powers, but is seldom employed medicinally. Acids are said to counteract the ill effects from an over-dose more speedily than any thing else, after clearing the stomach.

CYNO'LOPHI. (From κυων, a dog, and λοφος, a protuberance: so called, because they are prominent in dogs.) The spinous processes of the vertebræ.

CYNOLY'SSA. (*a, æ.* f.; from κυων, a dog, and λυσση, madness.) Canine madness.

CYNOMO'RIUM. (*um, ii.* n.) The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Monandria.*

CYNOMORIUM COCCINEUM. The systematic name of the *Fungus melitensis*, a small plant which grows in Sicily and Malta. A drachm of the powder is given for a dose in dysenteries and hæmorrhages, and with remarkable success.

CYNORE'XIA. (*a, æ.* f.; from κυων, a dog, and ορεξις, appetite.) A canine appetite. See *Bulimia.*

Cyno'sbatos. See *Cynosbatus.*

CYNO'SBATUS. (*os* and *us, i.* f.; from κυων, a dog, and βατος, a thorn: so called, because dogs are said to be attracted by its smell.) The dog-rose. See *Rosa canina.*

CYNOSPA'STUM. (From κυων, a dog, and σπαω, to attract.) The dog-rose. See *Rosa canina.*

CYOPHO'RIA. (*a, æ.* f.; from κυος, a fœtus, and φερω, to bear.) Pregnancy.

Cyparissus. See *Cupressus.*

CY'PERUS. (*us, i.* m.; from κυπαρος, a little round vessel, which its roots are said to resemble.) Cyperus. The name of a genus of plants in the Linnæan system. Class, *Triandria*; Order, *Monogynia.*

CYPERUS ESCULENTUS. The rush-nut. This plant is a native of Italy, where the fruit is collected and eaten, and said to be a greater delicacy than the chesnut.

CYPERUS LONGUS. The systematic and pharmacopœial name of the English galangale. *Cyperus — culmo triquetro folioso, umbella foliosa supra-decomposita; pedunculis nudis, spicis alternis*, of Linnæus. The smell of the root of this plant is aromatic, and its taste warm, and sometimes bitter. It is now totally fallen into disuse.

CYPERUS ROTUNDUS. This species, the round cyperus, *Cyperus — culmo triquetro subnudo, umbella decomposita; spicis alternis linearibus*, of Linnæus, is generally preferred to the former, being a more gratefully aromatic bitter. It is chiefly used as a stomachic.

CYPHE'LLA. (*a, æ.* f.) A peculiar sort

of pit or pore, on the under side of the frond, in that section of lichens called *stricta*.

CYPHI. (Κυφι.) An aromatic confection which according to Dioscorides, was used by the priests of Egypt. Several alexipharmic medicines took their name from it.

Cyphoma. See *Cyphosis.*

CYPHO'SIS. (Κυφωσις, κυφωμα, κυφος; from κυπτω, to bend.) Gibbosity. A hump back.

Cypress. See *Cyprus.*

Cypress spurge. See *Esula minor.*

CY'PRINUM OLEUM. (Κυπρινον ελαιον.) It was composed of oil of unripe olives, aspalathus, calamus, myrrh, cardamum, elecampane, and Jew's pitch. — *Dioscorides.*

CY'PRINUS. The name of a genus of fishes. Of the many species belonging to this, the carp genus, the five following only are used as food.

CYPRINUS ALBURNUS. The bleak. A small fish, about four or five inches long, thought good by some; but not generally much esteemed.

CYPRINUS BARBUS. The barbel: so called, because it has four appendages, like a beard, hanging from the under jaw. It is likewise denominated *barbus*, and *barbo*. A coarse and very common freshwater fish, eaten for want of better. The roe is a violent emetic. The young or fry, of this fish has been supposed to be the little fish known by the name of white bait, which is caught in the months of June and July, in great quantity, in the river Thames, between Deptford and Woolwich, but the white bait is now ascertained to be a distinct species. See *Clupea latulus.*

CYPRINUS CARPIO. The carp. A fish that delights in stagnant waters, and is bred in our ponds and canals. The flesh is coarse, and has an earthy taste. It is esteemed by some when stewed in a rich and vinous sauce.

CYPRINUS GOBIO. The gudgeon. A small fresh-water fish, of the size of a smelt. The flesh is white and soft, and of easy digestion.

CYPRINUS LEUCISCUS. The dace. This fish lives in still rivers, and seldom exceeds six or eight inches in length. Its flesh is white, and in some estimation.

CYPRIUM ÆS. Copper: so called because this metal was brought from the island of Cyprus.

CY'PRUS. (*us. i.* f.; so called, from the island of Cyprus, where it grew abundantly.) The cypress tree or eastern privet. See *Cupressus.*

CY'PSELE. Κυψελη. Κυψελις. *Cypselis.* A bee hive. The wax of the ear.

Cypselis. See *Cypsele.*

CYPTA'RION. The name of an antidote described by N. Myrepsus.

CYRTO'MA. (*a, atis.* n.; κυρτωμα, κυρτωσις: from κυρτος, curved.) *Cyrtosis.* 1. The same as gibbosity, or curvature.

2. Hippocrates applied the term κυρτωματα to swellings or tumours of the hypochondria.

CYRTO'NOSUS. (*us, i.* m.; from κυρτος, curved, and νοσος, a disease.) 1. The rickets.

2. Curved spine. — *Turton.*

Cyrtosis. See *Cyrtoma.*

CY'SSARUS. (From κυσος, the anus.) The intestinum rectum was so called, because it reaches to the anus.

CYSSA'NTHEMON. (From κυσσος, ivy, and ανθεμον, a flower.) The *cyclamen.*

CYSSOPHY'LLON. (From κυσσος, ivy, and φυλλον, a leaf.) A name of the *cyclamen.*

CYSSOTIS. (From κυσος, the anus.) An inflammation of the anus.

CYSTA'LGIA. (*a, æ.* f.) Painful spasmodic affection of the bladder. Such affections are not very common, but they are occasionally met with. The spasm comes on in paroxysms, which sometimes equal in severity those of the stone.

CYSTEO'LITHUS. (*us, i.* m.; from κυστις, the bladder, and λιθος, a stone.) A stone in the urinary-bladder or gall-bladder.

CY'STHUS. (Κυσθος.) The anus.

CY'STIC. (*Cysticus;* from κυστις, a bladder.) Belonging to the urinary or gall-bladder; as cystic duct, cystic bile, &c.

Cystic duct. See *Ductus cysticus.*

CYSTIC OXIDE. A peculiar animal product, discovered by Dr. Wollaston. See *Calculus, urinary.*

CYSTICA MEDICAMENTA. Medicines used in diseases of the bladder.

CYSTICE'RCUS. (*us, i.* m.; from κυστις, a bladder, and κερκος, a tail.) The tailed bladder worm. A genus of worms of the hydatid tribe, consisting of a cylindrical body, terminated by a caudal vesicle, and having a head furnished at its base with four nipples or suckers. Those which have been found in the human subject, are,

1. *Cysticercus tenuicollis* of Rudolphi. Dr. Brera found these in great quantity in the choroid plexus of a man, fifty-five years of age, who died of apoplexy. It is about an inch long when full grown, and its head is very small.

2. *Cysticercus finnia* of Zeder. This has been found by Werner. This species is always enclosed in a delicate cyst. The worm itself is ordinarily hidden within its caudal bladder, and is opaque and yellowish. It is of the size of a linseed.

3. *Cysticercus Fischerianus;* so called, by Laennec, after M. Fischer, of Leipsic, who found twenty-three in the choroid plexus of a man, where they caused no inconvenience.

4. *Cysticercus dicystus.* Doctor Laennec found this, once only, in the ventricle of the brain of a subject that died of apoplexy. It presented two vesicles; the one the ordinary caudal bladder, the other embracing the body anteriorly.

5. *Cysticercus punctatus.* Dr. Treutler has described this species, which he found in the choroid plexus of a woman twenty-two years of age. Its caudal bladder is globular, and presents several white spots.

CYSTIPHLO'GIA. (*a, æ.* f.; from κυστις, the bladder, and φλεγω, to burn.) An inflammation of the bladder. See *Cystitis.*

CYSTIRRHA'GIA. (*a, æ.* f.; from κυστις, the bladder, and ρηγνυμι, to burst forth.) A discharge from the bladder, whether of blood or mucus.

CYSTIRRHŒ'A. (From κυστις, the blad-

der, and ῥεω, to flow.) Discharge of mucus from the bladder; vesical catarrh.

CY'STIS. (*Cystis.* Κυστις, a bag.) 1. A cyst or bladder.

2. The urinary bladder in particular.

3. The membranous bag surrounding or containing any morbid substance.

Cystis choledocha. See *Gall-bladder.*

Cystis fellea. See *Gall-bladder.*

Cystis urinaria. See *Urinary-bladder.*

CYSTI'TIS. (*is, idis.* f.; from κυστις, the bladder.) Inflammation of the bladder. Inflammation affects chiefly the mucous coat of the bladder, but all the coats may be implicated. The disease may be either acute or chronic. The acute form is known by great pain in the region of the bladder, attended with fever and hard pulse, a frequent and painful discharge of urine or a suppression, and generally tenesmus. If the lower part of the bladder be chiefly affected, the pain extends to, and takes the course of, the perinæum. If the disease be seated in the neck of the organ, there is a retention of urine, with a constant urgency to evacuate; if in the fundus, the urine flows stillatitiously and without ceasing, the bladder feels as if constantly full, and the patient is perpetually and fruitlessly striving to empty it. If the disease be not soon subdued, the restlessness and anxiety increase, the extremities become cold, vomiting supervenes, and delirium and other marks of great general irritation: the disease runs its course with rapidity; and subsides or destroys the patient, in a few days.

With respect to the causes, they are those which excite inflammation of the other viscera: but the bladder often contains calculous concretions, which may produce cystitis; besides it is often irritated and inflamed by viscid substances that pass into the circulation, and particularly by cantharides, ardent spirits, and terebinthinate essences or balsams. The treatment is very similar to that of *Nephritis.*

Chronic inflammation of the bladder is attended with a highly irritable state of the organ, and a very copious excretion of mucus along with the urine, whence the name of *catarrhus vesicæ* which has been applied to it.

CY'STITOME. (*Cystitomus, i.* m.; from κυστις, a cyst, and τεμνω, to cut.) The name given by Lafaye to an instrument for opening the capsule of the crystalline lens.

CY'STO-BUBONOCE'LE. (From κυστις, the bladder, βουβων, the groin, and κηλη, a tumour.) A rare species of hernia, in which the urinary bladder is protruded through the inguinal aperture.

CYSTOCE'LE. (From κυστις, the bladder, and κηλη, a tumour.) Hernia of the bladder. This is rare. It occurs most frequently at the inguinal ring, less at the crural ring; the bladder has also been known to protrude through the perinæum, vagina, or thyroid foramen.

CY'STOMEROCE'LE. (From κυστις, the bladder, μερος, the thigh, and κηλη, a tumour.) A hernial protrusion of the bladder through the femoral ring. See *Cystocele.*

Cystophlogia. See *Cystiphlogia.*

CYSTOPLE'GIA. (From κυστις, the bladder, and πλησσω, to strike.) Paralysis of the bladder.

CYSTOPLE'XIA. The same as cystoplegia.

CYSTOPTO'SIS. (From κυστις, the bladder, and πιπτω, to fall.) A name given by Vogel to a relaxation of the internal coat of the bladder, whereby it protrudes into the urethra.

CYSTOSPA'STICUS. (From κυστις, the bladder, and σπαω, to draw.) Relating to spasm of the bladder.

CYSTOTO'MIA. (*a, æ.* f.; from κυστις, the bladder, and τεμνω, to cut.) The operation of cutting into the bladder.

CY'THION. The name of a collyrium mentioned by Celsus.

CY'TINUS. (*us, i.* m.; perhaps, as Martyn suggests, from κυτινος, a name given by Theophrastus to the blossoms of the pomegranate, the calyx of which the flower in question resembles in shape.) The name of a genus of plants. Class, *Gynandria;* Order, *Octandria,* of Linnæus.

CYTINUS HYPOCISTIS. Rape of cystus. A fleshy pale-yellowish plant, parasitical on the roots of several species of cystus in the south of Europe, from which the *succus hypocistidis* is obtained.

CY'TISINE. A bitter principle detected by Chevallier and Lassaigne, in the seeds of the *Cytisus laburnum.* It is of a nauseous taste, emetic, and poisonous.

CY'TISO-GENI'STA. The common broom.

CYZEMER. A swelling of the wrists.

CYZICE'NUS. The name of a plaster used by Galen for obstinate ulcers and wounds of tendinous parts.

D.

DAB. See *Pleuronectes limanda.*

Daberlocks. See *Fucus esculentus.*

Dace. See *Cyprinus leuciscus.*

DACNE'RON. (From δακνω, to bite.) The Greek epithet of a sharp eye-wash, composed of burnt copper, pepper, cadmia, myrrh, saffron, gum arabic, and opium.

DACRY'DIUM. (*ium, ii.* n.; from δακρυ, a tear.) Scammony, which flows from the tree liquid, and hardens into tears.

DACRYNO'MA. (From δακρυω, to weep.) Epiphora, from obstruction of the puncta lachrymalia. — *Vogel.*

DACTYLE'THRA. *Dactylithra.* (Δακτυληθρα.

δακτυλιθρα; from δακτυλος, a finger.) A name given to certain topical medicines which were thrust into the throat to excite vomiting. They were so called, either because they were shaped like a finger, or because they were applied with the fingers.

DACTYLE'TUS. (From δακτυλος, the date.) See *Hermodactylus.*

DACTY'LION. (From δακτυλος, a finger.) Vogel gives this name to preternatural adhesion of the fingers to each other. This is sometimes a congenital deformity, but more frequently a consequence of burns.

DA'CTYLIUS. (Δακτυλιος, a ring.) A lozenge; so called from its shape.

DA'CTYLUS. (*us, i.* m. δακτυλος.) 1. A finger. See *Digitus.*

2. The date. See *Phœnix dactylifera.*

DÆDA'LIA. The name of a genus of fungi.

Dædalia suaveolens. See *Boletus suaveolens.*

DÆ'DALUS. An old name of quicksilver.

DÆ'DIUM. (*um, ii.* n. δαιδιον; from δαις, a torch.) A small torch or candle. A bougie.

DÆMO'NIA. The same as *Dæmonomania.*

DÆMONOMA'NIA. (*a, æ.* f.; from δαιμων, a dæmon, and μανια, madness.) That species of melancholy where the patient supposes himself to be possessed by devils, or is in fear of the machinations of devils.

DAFFY'S ELIXIR. Compound tincture of senna, made with treacle instead of sugar candy, and with the addition of aniseed and elecampane root.

DAIE. *Deheb. Dehebeb. Doab.* Alchemical names of gold. — *Ruland.*

Daisy. See *Bellis perennis.*

Daisy, ox-eye. See *Chrysanthemum.*

DALBY'S CARMINATIVE. A nostrum much used as a carminative for children. It consists of carbonate of magnesia ℈ ij., oil of peppermint, ♏j., oil of nutmeg ♏ij., oil of aniseed ♏iij., tincture of castor, ʒ ss., tincture of assafœtida ♏ xv., tincture of opium ♏ v., spirit of pennyroyal ♏ xv., compound tincture of cardamoms ʒ ss., peppermint water ℥ ij.

DAMA. A deer. See *Cervus.*

Damask rose. See *Rosa centifolia.*

DAMNA'TUS. (From *damno*, to condemn.) The dry useless fæces, left in a vessel after the moisture has been distilled from it, was called by the old chemists *terra damnata*, or *caput mortuum.*

DAMSON. The fruit of a variety of the *Prunus domestica.*

DA'NAIS. A plant mentioned by Dioscorides, supposed to be the *conyza.*

Dandelion. See *Leontodon.*

Dandrif. See *Pityriasis.*

DANEVERT. The name of a mineral spring a few miles from Upsal, in Sweden. It contains carbonic acid, carbonate and sulphate of iron, sulphates of soda and lime, muriate of soda, and silica.

Danewort. See *Sambucus ebulus.*

DANICH. An Arabian weight of eight grains.

DANSE DE SAINT-GUY. The common French name of the disease which we call St. Vitus's dance. See *Chorea.*

DA'PHNE. (*e, es.* f. Δαφνη; from δαω, to burn, and φωνη, a noise: because its leaves crepitate when burnt; or from the nymph *Daphne*, who was fabled to have been changed into a laurel.) 1. The Greek name of the laurel.

2. The name of a genus of plants in the Linnæan system. Class, *Octandria;* Order, *Monogynia.* The laurel, or bay-tree.

DAPHNE ALPINA. This species of dwarf olive-tree, called also *Chamælea*, and *Chamelæa*, is said to be purgative in the dose of ʒ ij., and is sometimes given by country people. The French chemists have lately examined it chemically. See *Daphnine.*

Daphne, flax-leaved. See *Daphne.*

DAPHNE GNI'DIUM. The systematic name of the tree which affords the Garou bark. Spurge-flax; Flax-leaved Daphne. *Thymelæa; Oneoron. Daphne gnidium — panicula terminali foliis lineari lanceolatis acuminatis*, of Linnæus. This tree affords the Garou bark, which very much resembles that of our mezereum. It is to be immersed in vinegar for about an hour before it is wanted: a small piece, the size of a sixpence, thus steeped, is applied to the arm or any other part, and renewed once a day in winter and twice in summer. It produces a serous exudation from the skin, without excoriating or blistering. It is recommended, and is in frequent use in France and Russia, against some diseases of the eyes.

DAPHNE LAURE'OLA. The systematic name of the spurge-laurel. *Laureola daphnoides.* The bark of this plant is recommended to excite a discharge from the skin, in the same way as that of the *Daphne gnidium.*

DAPHNE MEZE'REUM. The systematic name of the mezereon. Spurge-olive; Widow-wail: called also *Ætolium*, and *Ætocion. Mezereum. Daphne mezerium — floribus sessilibus ternis caulinis, foliis lanceolatis deciduis*, of Linnæus. This plant is extremely acrid, especially when fresh, and, if retained in the mouth, excites great and long-continued heat and inflammation, particularly of the mouth and fauces; the berries, *grana cnidii* of old writers, also have the same effects; and, when swallowed, prove a powerful corrosive poison, not only to man, but to dogs, wolves, and foxes. Vauquelin thought he had discovered an alkali in the mezereum, but this has not been confirmed. (See *Daphnine.*) The bark of the root is the part employed medicinally in the *decoctum sarsaparillæ compositum*, intended to assist mercury in resolving nodes and other obstinate symptoms of syphilis. The antisyphilitic virtues of mezereum, however, have been by many writers very justly doubted. "The result of my own experience (says Mr. Pearson, of the Lock Hospital) by no means accords with the representation given of this root by former writers. From all that I have been able to collect, in the course of many years' observation, I feel myself authorised to assert, unequivocally, that the mezereum has not the power of curing the venereal disease in any one stage, or under any one form. If a decoction of this root should ever reduce a venereal node, where no mercury has been previously

given, yet the patient will by no means be exempted from the necessity of employing mercury for as long a space of time, and in as large a quantity, as if no mezereum had been taken. With respect to the power it is said to possess, of alleviating the pain, and diminishing the bulk of membraneous nodes, nothing peculiar and appropriate can be ascribed to the mezereum on these accounts, since we obtain the same good effects from sarsaparilla, guaiacum, volatile alkali, blistering plasters, &c. Nevertheless, venereal nodes, which have subsided under the use of any o 'these articles of the materia medica, will appear again, and often with additional symptoms, if a full and efficacious course of mercury be not submitted to. It has, indeed, been alleged, that mezereum always alleviates the pain occasioned by a venereal node, and generally reduces it, where the periosteum only is affected; and that it seldom fails in removing those enlargements of the periosteum which have not yielded during the administration of mercury.

"That some instances of success, in cases like these, may have fallen to the share of those who made the assertion, it would not become me to deny; but I have met with few such agreeable evidences of the efficacy of this medicine. I have given the mezereum in the form of a simple decoction, and also as an ingredient in compound decoctions of the woods, in many cases, where no mercury had been previously employed, but never with advantage to a single patient. I have also tried it, in numerous instances, after the completion of a course of mercury; yet, with the exception of two cases, where the thickened state of the periosteum was removed during the exhibition of it, I never saw the least benefit derived from taking this medicine. In a few cases of anomalous pains, which I supposed were derived from irregularities during a mercurial course, the mezereum was of service, after I had tried the common decoction of the woods without success; but, even in this description of cases, I have always found it a very uncertain remedy. I have made trial of this vegetable in a great number of scrofulous cases, where the membranes covering the bones were in a diseased state, and I am not sure that one single patient obtained any evident and material benefit from it.

"The late Dr. Cullen, whose reports may justly claim attention from all medical men, when treating of the mezereum, in his Materia Medica, says, 'I have frequently employed it in several cutaneous affections, and sometimes with success.' It were to have been wished that the professor of medicine had specified what those diseases of the skin were, in which the mezereum was sometimes applied with success; for, if I except an instance or two of lepra, in which the decoction of this plant conferred a temporary benefit, I have very seldom found it possessed of medicinal virtue, either in syphilis, or in the sequelæ of that disease, in scrofula, or in cutaneous affections. Indeed the mezereum is of so acrimonious a nature, often producing heat and other disagreeable sensations in the fauces, and, on many occasions, disordering the primæ viæ, that I do not often subject my patients to the certain inconveniences which are connected with the primary effects of this medicine, as they are rarely compensated by any other important and useful qualities."

DAPHNELÆ'ON. (*on, i.* n.; from δαφνη, the laurel, and ελαιον, oil.) Oil of bay-berries.

DA'PHNIA. A gem mentioned by Pliny, believed to have the power of curing epilepsy.

DAPHNINE. The bitter principle of the *Daphne alpina*. From the alkoholic infusion of this bark, the resin is separated by its concentration. On diluting the tincture with water, filtering and adding acetate of lead, a yellow *daphnate of lead* falls, from which sulphuretted hydrogen separates the lead, and leaves the daphnine in small transparent crystals. They are hard, of a greyish colour, a bitter taste when heated, evaporate in acrid acid vapours, are sparingly soluble in cold, but moderately in boiling water. It is stated, that its solution is not precipitated by acetate of lead; yet acetate of lead is employed in the first process to throw it down.

DAPHNI'TIS. (From δαφνη, the laurel.) The spurge-laurel.

DAPHNOI'DES. (From δαφνη, the laurel, and ειδος, a likeness.) The spurge-laurel. See *Daphne laureola*.

DARSENI. *Darsini.* An Arabic name of the *Canella alba*.

DA'RSIS. (*is, is.* m.; from δερω, to excoriate.) Excoriation. The anatomical process of removing the skin from the subjacent texture, or the morbid abrasion of the cuticle in the living body.

DA'RTA. A severe impetigo. — *J. N. Binninger.*

DA'RTOS. (Δαρτος; from δερω, to excoriate: so called from its raw and excoriated appearance.) The part so named, under the skin of the scrotum, is by some anatomists considered as a muscle, although it appears to be no more than a condensation of the cellular membrane lining the scrotum. It is by means of the dartos that the skin of the scrotum is corrugated and relaxed.

The word δαρτος is an adjective, with χιτων understood — δαρτος χιτων, *the excoriated coat or membrane*. Like many other such terms, it is used as a substantive.

DARTRE. A term variously and vaguely applied by French writers to cutaneous diseases: generally speaking, it corresponds with *herpes*.

DA'SYMA. (Δασυμα; from δασυς, rough.) A scabby roughness of the eyelids, the same with *trachoma*. — *Aëtius.*

Date. See *Phœnix dactylifera.*

Date plum, Indian. See *Dyospyrus lotus.*

DATU'RA. (*a, æ.* f. Blancard says it is derived from the Indian word *datiro*, of which he knows not the meaning.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia.*

DATURA STRAMONIUM. The systematic name of the thorn apple; called also, *Stramonium, Dutray, Barryococcalon, Solanum maniacum, Stramonium spinosum Solanum fœtidum*, and *Stramonium majus album.*

Datura stramonium—pericarpiis spinosis erectis vatis, foliis ovatis glabris, of Linnæus.

The odour of this plant is fœtid and narcotic, ccasioning headach and stupor. Its taste is itter and somewhat nauseous. Its componants re gum, resin, and carbonate of ammonia; the ecent experiments of M. Brandes have also eveloped an alkaline element of activity, to hich the name of *Daturia* has been assigned; appears to exist in native combination with alic acid; when in an uncombined state it is early insoluble in water, and in cold alkohol, t boiling alkohol dissolves it. It has been tained with difficulty in the form of quadranular prisms. The medicinal powers of the erb are alike extracted by aqueous and spiritous menstrua. The infusion is precipitated y the salts of lead, silver, mercury, and iron; e mineral acids would also appear to proce some essential changes which may diinish its efficacy. Acetic acid increases its owers, although it relieves the effects of an ver-dose, if administered after the stomach has een emptied. This apparent anomaly is easily xplained when we consider, that in the first ase its operation is purely *chemical*, increasing e solubility of the active principle of the plant, hile in the latter case it operates as a *vital* gent, restoring to the nervous system that nergy which has been suspended by the narotic influence of the vegetable. Stramoium is narcotic, and has been regarded by any authors as eminently antispasmodic; Dr. arton, an American physician, made very xtensive trials of its efficacy in mania, the esult of which is highly favourable to its use. r. Marcet first noticed its salutary effects in ronic diseases attended with violent pain; he ound it to lessen powerfully, and quickly, sensbility and pain, and to produce a sort of nervous hock, attended with a momentary affection of e head and eyes, with a degree of nausea, and ith phenomena resembling those which are roduced by intoxication. It seems to be more rticularly beneficial in chronic rheumatism, iatica, &c. Its root, smoked in the manner tobacco, has been much extolled as a remedy the paroxysms of spasmodic asthma; this ractice, however, is not unattended with danger; e same transient feelings of relief may be rocured by smoking a mixture of opium and y aromatic herb. Some discrepancy of opinn has existed as to the form in which this edicine should be exhibited. The native pracioners in the Carnatic give the powdered root. ufeland recommends a tincture of the whole ant. In this country an extract of the leaves, , more lately, of the seeds, has been preferred, d Dr. Paris has been informed by Sir Henry alford, that he has found a tincture made ith the seeds, a very efficient and unobjecnable preparation. Dr. Davy, at the request Dr. Paris, made a series of experiments upon e extracts prepared by Mr. Barry *in vacuo*, d his report upon the effects of that of stranium will be found under the article *Extract. ramonii*, which see. The dose of the powderd leaves at the commencement is gr. j.; that of e seeds gr. ss. It is said that the Turks sometimes use the stramonium instead of opium, and the Chinese infuse the seeds in beer. Cataplasms of the fresh-bruised leaves have been very successfully used in sores of a highly irritable and painful nature. — *Paris.*

Officinal preparation. — *Extract. Stramonii.*

Daturia. See *Datura stramonium.*

Dauci'tes vinum. Must, in which bruised carrots have been steeped. It was used by the ancients as an antispasmodic.

DAU'CUS. (*us, i.* m. Απο του δαυειν, from its relieving the colic, and discussing flatulencies.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia.*

2. The pharmacopœial name of the garden carrot. See *Daucus carota.*

Daucus alsaticus. See *Oreoselinum.*

Daucus annuus minor. See *Caucalis anthriscus.*

Daucus carota. The systematic name of the carrot plant; called also, *Daucus, Daucus sativus*, and *Pastinaca sylvestris tenuifolia officinarum.*

Daucus carota — seminibus hispidis, petiolis subtus nervosis, of Linnæus. The cultivated root, scraped and applied in the form of a poultice, is an useful application to phagedænic ulcers, and to cancers and putrid sores. The seeds, which obtain a place in the materia medica, have a light aromatic smell, and a warm acrid taste, and are esteemed for their diuretic qualities, and for their utility in calculous and nephritic complaints, in which an infusion of three spoonfuls of the seeds in a pint of boiling water has been recommended; or the seeds may be fermented in malt liquor, which receives from them an agreeable flavour, resembling that of lemon-peel. The boiled root is said by many to be difficult of digestion; but this is the case only when the stomach is weak. It contains a considerable quantity of the saccharine principle, and is very nutritious.

Daucus creticus. See *Athamanta.*

Daucus Macedonius. See *Apium graveolens.*

Daucus montanus. See *Oreoselinum.*

Daucus sativus. See *Daucus carota.*

Daucus selenoides. See *Oreoselinum.*

Daucus seprinius, Most probably chervil. See *Scandix cerefolium.*

Daucus sylvestris. Wild carrot, or bird's nest. The seeds of this wild plant have been thought more efficacious than those of the garden carrot; they are said to possess demulcent and aromatic qualities, and have been given, in infusion or decoction in calculous complaints.

Daucus vulgaris. See *Daucus sylvestris.*

Daura. Hellebore. Leaf-gold. — *Ruland.*

Day-mare, See *Ephialtes.*

Day-sight. See *Hemeralopia*, and *Nyctalopia.*

Dead-nettle. See *Lamium album.*

Deadly nightshade. See *Atropa.*

Deafness. See *Dysecoea.*

Deaf-dumbness. See *Aphonia.*

Dealbatio. See *Albatio.*

Dearticula'tio. (From *de*, and *articulus*, a joint.) The same as *abarticulatio.* See *Diarthrosis.*

DEASCIA'TIO. (From *de*, and *ascio*, to chip, as with a hatchet.) Synonymous with *aposceparnismus*, which see.

DEAURATIO. The wrapping up of pills in gold leaf.

DEBILITAS. (*as, atis.* f.) Weakness. Sauvage has constituted a peculiar class of diseases under the name of *Debilitates*, or those characterised by debility.

DECAGY'NIA. (*a, æ.* f.; from δεκα, ten, and γυνη, a woman.) The name of an order of the class *Decandria*, of the sexual system of plants.

DECAMY'RON. (From δεκα, ten, and μυρον, an ointment.) An aromatic ointment, mentioned by Oribasius, containing ten ingredients.

DECA'NDRIA. (*a. æ*, f.; from δεκα, ten, and ανηρ, a man.) The name of a class, and also of an order, of plants in the sexual system.

DECANTATION. *Decantatio.* The pouring off of a liquor clear from sediments.

DECAPHY'LLOUS. (*Decaphyllus;* from δεκα, ten, and φυλλον, a leaf.) Ten leaved: applied to the perianth of flowers.

DECE'MFIDUS. Ten-cleft: applied in *Botany*, to perianths.

DECEMLOCULA'RIS. Ten-celled; applied, in *Botany*, to capsules.

DECIDE'NTIA. (From *decido*, to fall down.) Synonymous with *cataptosis*, which see.

DECI'DUOUS. (*Deciduus;* from *decido*, to fall off, or down; to die.) Falling off. 1. In *Botany*, applied to trees, shrubs, &c. which, in most European countries, lose their leaves as winter approaches. This term is expressive of the second stage of duration, and, like *caducous*, has a different application according to the particular part to which it refers; thus leaves are deciduous which drop off in the autumn, petals which fall off with the stamina and pistils; and calyces are *deciduous* which fall off after the expansion, and before the dropping of the flower.

2. In *Anatomy*, applied to a very thin and delicate membrane, *Membrana decidua*, which adheres to the internal surface of the gravid uterus. It is generally supposed by anatomists of the present day, that the decidua is a sac without any aperture, lining the uterus previously to the descent of the ovum; and that when the ovum descends it pushes the decidua before it and is enveloped by it, except at the part where the placenta is afterwards formed. That part of the membrane which lines the uterus is called *Tunica decidua uteri*, and that which covers the ovum is called *Tunica decidua reflexa.*

DECIMA'NUS. (From *decem*, ten.) Returning every tenth day; formerly applied to some erratic fevers.

DECLINING. *Declinatus, Declivis.* Applied by botanical writers, to stems, pericarps, &c. when bent like a bow, with the arch downwards. Applied also formerly, to a muscle of the abdomen, because of its posture. See *Obliquus descendens.*

Declinatus. See *Declining.*

DECLI'VIS. (From *de*, and *clivis*, a hill.) Declining: descending. See *Obliquus descendens.*

DECO'CTUM. (*um, i.* n.; from *decoquo*, to boil.) A decoction. A preparation made by boiling in a watery fluid. In a chemical point of view, it is a continued ebullition with water, to separate such parts of bodies as are only soluble at that degree of heat. The following are among the principal decoctions used in medicine.

Decoctum album. See *Mistura cornu usti.*

DECOCTUM ALOES COMPOSITUM. Compound decoction of aloes. Take of extract of liquorice, seven drachms; carbonate of potash, one drachm; aloes powdered, myrrh powdered, saffron, of each a drachm and a half; water, a pint and a half. Boil down to a pint, and strain; then add compound tincture of cardamoms, seven fluid ounces. This decoction is altered from one in the former London Pharmacopœia, which was analogous to an article in very frequent use, invented by the late Dr. Devalingin, and sold under the name of *Beaume de vie.* By the proportion of tincture which is added, it will keep unchanged for any length of time.

DECOCTUM ALTHÆÆ. Decoction of marsh mallows. Take of dried marsh mallow roots, ℥ iv.; raisins of the sun stoned, ℥ ij.; water, O vij. Boil to five pounds; place apart the strained liquor, till the fæces have subsided, then pour off the clear part. This preparation, directed in the Edinburgh Pharmacopœia, may be exhibited as a common drink in nephralgia, and many diseases of the urinary passages, with advantage.

DECOCTUM ANTHEMIDIS. Chamomile decoction. Take of chamomile flowers, ℥ j.; caraway seeds, ℥ ss.; water, ℔ v. Boil fifteen minutes, and strain. A very common and excellent vehicle for tonic powders, pills, &c. It is also in very frequent use for fomentation and clysters. See *Decoctum chamæmeli.*

DECOCTUM ASTRAGALI. Take of the root of the astragalus escapus, ℥ j.; distilled water, O iij. These are to be boiled, till only a quart of fluid remain. The whole is to be taken, a little warmed, in the course of 24 hours. This remedy was tried very extensively in Germany and said to exert every powerful effects, as an antisphylitic.

DECOCTUM BARDANÆ. Take of bardana root, f. ℥ vj.; of distilled water, O vj. These are to be boiled till only two quarts remain. From a pint to a quart in a day is given, in those cases where sarsaparilla, and other remedies that are called alterative, are supposed to be requisite.

Decoctum chamæmeli. See *Decoctum anthemidis.*

DECOCTUM CINCHONÆ. Decoction of cinchona, commonly called decoction of Peruvian bark. Take of lance-leaved cinchona bark bruised, ten drachms; water, a pint. Boil for ten minutes, in a vessel slightly covered, and strain the decoction while hot. According to the option of the practitioner, the bark of either of the other species of cinchona, the cordifolia, or *yellow*, or the oblongifolia, or *red*, may be substituted for the lancifolia, or *quilled*; which is here directed. This way of administering the bark is very general, as all the other preparations may be mixed with it, as necessity requires. It is a

very good astringent lotion for prolapsus of the uterus or rectum.

Decoctum cornu. See *Mistura cornu usti.*

Decoctum cydoniæ. *Mucilago seminis cydonii mali. Mucilago seminum cydoniorum.* Decoction of quince seeds. Take of quince seeds, two drachms; water, a pint. Boil over a gentle fire for ten minutes, then strain. This decoction, in the later London Pharmacopœias, has been removed from among the mucilages, as being less dense than either of the others, and as being employed in larger doses, like other mucilaginous decoctions. In addition to gum, it contains other constituent parts of the seeds, and is, therefore, more apt to spoil than common mucilage, over which it possesses no other advantages than that it is more grateful, and sufficiently thin, without further dilution, to form the bulk of any liquid medicine. Its virtues are demulcent. Joined with syrup of mulberry and a little borax, it is useful against aphthæ of the mouth and fauces.

Decoctum daphnes mezerei. Decoction of mezereon. Take of the bark of mezereon root, ℥ ij.; liquorice root bruised, ʒ ss.; water, O iij. Boil with a gentle heat down to two pounds, and strain. From four to eight ounces of this decoction may be given four times a day, in some obstinate venereal and rheumatic affections. It operates chiefly by perspiration.

Decoctum dulcamaræ. Decoction of woody nightshade. Take of the incised stalks of woody nightshade, ʒ x.; distilled water, O jss. These are to be boiled away to a pint, and strained. The dose is half an ounce to two ounces, mixed with an equal quantity of milk. This remedy has been employed in inveterate cases of scrofula; in cancer and phagedæna; in lepra and other cutaneous affections; and in anomalous local diseases, originating in venereal lues. Its chief use is as a diuretic in dropsy. Dose ʒ ss. to ℥ i. three times a day.

Decoctum geoffrææ inermis. Decoction of cabbage-tree bark. Take of bark of the cabbage-tree, powdered, ʒ j.; water, O ij. Boil gently, with a gentle fire, down to one pound, and strain. This is a powerful anthelmintic. It may be given in doses of one table-spoonful to children, and four to adults. If disagreeable symptoms should arise from an overdose, or from drinking cold water during its action, we must immediately purge with castor oil, and dilute with acidulated drinks.

Decoctum guaiaci officinalis compositum. *Decoctum lignorum.* Compound decoction of guaiacum, commonly called decoction of the woods. Take of guaiacum raspings, ʒ iij.; raisins stoned, ʒ ij.; sassafras root, liquorice, each ʒ j.; water, O x. Boil the guaiacum and raisins with the water, over a gentle fire, to the consumption of one half; adding, towards the end, the sassafras and liquorice. Strain the liquor, without expression. This decoction possesses stimulant and diaphoretic qualities, and is generally exhibited in rheumatic and cutaneous diseases, which are dependent on a vitiated state of the humours. It may be taken by itself, in the quantity of a quarter of a pint, twice or thrice a day, or used as an assistant in a course of mercurial or antimonial alteratives; the patient, in either case, keeping warm, in order to promote the operation of the medicine.

Decoctum hellebori albi. Decoction of white hellebore. Take of the root of white hellebore, bruised, ʒ x.; distilled water two pints; rectified spirits of wine, f. ʒ iij. by measure. Boil the water, with the root, to one pint; and the liquor being cold, add the spirit, and press, and strain. This decoction, in the last London Pharmacopœia, is called decoctum veratri. It is considered an efficacious application, externally, as a wash, in tinea capitis, lepra, psora, &c. When the skin is very tender and irritable, it should be diluted with an equal quantity of water.

Decoctum hordei. *Decoctum hordei distichi. Aqua hordeata.* Barley water. Take of pearl barley, ʒ ij.; water, four pints and a half. First wash away any adhering extraneous substances with cold water; next, having poured upon the barley half a pint of water, boil for a few minutes. Let this water be thrown away, and add the remainder of the water boiling; then boil down to two pints, and strain. Barley-water is a nutritive and softening drink, and the most proper of all liquors in inflammatory diseases. It is an excellent gargle in inflammatory sore throats, mixed with a little nitre.

Decoctum hordei compositum. *Decoctum pectorale.* Compound decoction of barley. Take of decoction of barley, two pints; figs sliced, ʒ ij.; liquorice root, sliced and bruised, ʒ ss.; raisins stoned, ʒ ij.; water, a pint. Boil down to two pints, and strain. From the pectoral and demulcent qualities of this decoction, it may be administered as a common drink in fevers and other acute disorders, in catarrh, and several affections of the chest.

Decoctum hordei cum gummi. Barley water, O ij.; gum arab. ʒ j. The gum is to be dissolved in the barley decoction whilst warm. It then forms a suitable diluent in strangury, dysury, &c.

Decoctum lichenis. Decoction of Iceland moss or liverwort. Take of liverwort, one ounce; water, a pint and a half. Boil down to a pint, and strain. The dose is from ʒ j. to ʒ iv. This is now called *Decoctum cetrariæ.*

Decoctum lobeliæ. Take a handful of the roots of the *Lobelia sphilitica;* distilled water, O xij. These are to be boiled in the usual way, till only four quarts remain. The very desirable property of curing the venereal disease has been attributed to this medicine; but it is not more to be depended on than guaiacum, or other vegetable substances, of which the same thing has been alleged. The effects of this decoction are purgative, and the manner of taking it, as described by Swediaur, is as follows: — The patient is to begin with half a pint twice a day. The same quantity is then to be taken four times a day, and continued so long as its purgative effect is not too considerable. When the case is otherwise, it is to be discontinued for three or four days, and then had recourse to again till the cure is completed. This remedy is not admitted into our modern pharmacopœias, as no confidence is now placed in it.

Decoctum lusitanicum. Take of sliced sarsaparilla, lignum sassafras, lignum santalum rubrum, officinal lignum guaiacum, of each one ounce and a half; of the root of mezereon, coriander seed, of each half an ounce; distilled water, ten pounds. These are to be boiled till only half the fluid remains. The dose is a quart or more in a day.

Take of sliced sarsaparilla, lignum santalum rubrum, lignum santalum citrinum, of each ℥ jss.; of the root of glycyrrhisa and mezereon, of each ℥ij.; of lignum rhodii, officinal lignum guaiacum, and lignum sassafras, of each ℥ss.; of antimony, ℥ j.; distilled water, O v. These ingredients are to be macerated for twenty-four hours, and afterwards boiled till the fluid is reduced to half its original quantity. From one to four pints are given daily.

The late Mr. Hunter notices this, and also the following formula, in his Treatise on the Venereal Disease: —

Take of sliced sarsaparilla, of the root of China, of each ℥ j.; walnut-peels, dried, xx.; antimony, ℥ij.; pumice-stone, powdered, ℥ j.; distilled water, O x. The powdered antimony and pumice-stone are to be tied in separate pieces of rag, and boiled along with the other ingredients. This last decoction is reckoned to be the genuine Lisbon diet-drink, the qualities of which have been the subject of so much encomium.

Decoctum malvæ compositum. *Decoctum pro enemate. Decoctum commune pro clystere.* Compound decoction of mallows. Take of mallows, dried, an ounce; chamomile flowers, dried, half an ounce; water, a pint. Boil for a quarter of an hour, and strain. A very excellent form for an emollient clyster. A variety of medicines may be added to answer particular indications.

Decoctum mezerei. See *Decoctum daphnes mezerei.*

Decoctum papaveris. *Decoctum pro fomento. Fotus communis.* Decoction of poppy. Take of white poppy capsules, bruised, ℥iv.; water, four pints. Boil for a quarter of an hour, and strain. This preparation possesses slight anodyne properties, and is used as a fomentation in acute ophthalmia, painful swellings, &c.

Decoctum pro enemate. See *Decoctum malvæ compositum.*

Decoctum pro fomento. See *Decoctum papaveris.*

Decoctum quercus. Decoction of oak bark. Take of oak bark, ℥ x.; water, two pints. Boil down to a pint, and strain. This astringent decoction is chiefly used for external purposes, and its strength may be varied according to circumstances. It is a good lotion in prolapsus ani, and may be used also, in some cases, as an injection.

Decoctum sarsaparillæ. Decoction of sarsaparilla. Take of sarsaparilla root, sliced, ℥v.; boiling water, four pints. Macerate for four hours, in a vessel lightly covered, near the fire; then take out the sarsaparilla, and bruise it. After it is bruised, put it again into the liquor, and macerate it in a similar manner for two hours more; then boil it down to two pints, and strain. This decoction is much extolled by some practitioners, in various cachectic diseases, and to restore the strength after a long course of mercury. It is called *Decoctum sarzæ* in the present London Pharmacopœia.

Decoctum sarsaparillæ compositum. Compound decoction of sarsaparilla. Take of decoction of sarsaparilla, boiling, four pints; sassafras root sliced, guaiacum-wood shavings, liquorice root bruised, of each an ounce; mezereon-root bark, ℥ iij. Boil for a quarter of an hour, and strain. The alterative property of the compound is very great: it is generally given after a course of mercury, where there have been nodes and indolent ulcerations, and with great benefit. The dose is from half a pint to a pint in twenty-four hours. This is the *Decoctum sarzæ compositum* of the present London Pharmacopœia.

Decoctum sarzæ. See *Decoctum sarsaparillæ.*

Decoctum senegæ. Decoction of senega. Take of senega root, ℥x.; water, two pints. Boil down to a pint, and strain. This has been introduced into the later London Pharmacopœias, as being a useful medicine, especially in affections of the lungs, attended with debility and inordinate secretion.

Decoctum ulmi. Decoction of elm bark. Take of fresh elm bark, bruised, four ounces; water, four pints. Boil down to two pints, and strain. This may be employed with great advantage as a collyrium in chronic ophthalmia. It is given internally in some cutaneous eruptions.

Decoctum veratri. See *Decoctum hellebori albi.*

Decolora'tion. A term adopted from the French, signifying blanching or loss of the natural colour of any object.

Decompo'sitæ. The name of a class in Sauvage's Methodus Foliorum, consisting of such as have twice-compounded leaves; that is, have a common footstalk supporting a number of lesser leaves, each of which is compounded; as in *Fumaria*, and many umbelliferous plants.

DECOMPOSITION. (*Decompositio, onis*, f.; from *de*, and *compono*, to discompose or alter the arrangement of.) The separation of the component parts or principles of bodies from each other. The decomposition of bodies forms a very large part of the practice of chemistry. It seems probable, from the operations we are acquainted with, that it seldom takes place but in consequence of some combinations or compositions having been effected. It would be difficult to point out an instance of the separation of any of the principles of bodies which has been effected unless in consequence of some new combination. The only exceptions seem to consist in those separations which are made by heat, and voltaic electricity.

DECOMPO'SITUS. A term applied to leaves, and meaning doubly compound.

The decomposite, or doubly compound leaves are of three different kinds: —

1. *Bigeminate*, or twinforked, when a forked leafstalk bears several leafits at the end of each division or fork.

2. *Biternate*, or doubly threefold, when a leafstalk with three divisions bears three leafits upon the end of each division.

3. *Duplicato-pinnate*, or *bipinnate*, doubly winged, when a leafstalk has lateral ribs, and each of these ribs forms a winged leaf; as in *Tanacetum vulgare*, *Achillea millefolium*, &c.

DECORTICA'TION. (*Decorticatio, onis.* f. from *de*, from, and *cortex*, bark.) The stripping of any thing of its bark, husk, or shell: thus almonds, and the like, are decorticated; that is, deprived of their pellicle, when ordered for medicinal purposes.

DECREPITA'TION. (*Decrepitatio, onis.* f.; from *decrepo*, to crackle.) A kind of crackling noise, which takes place when some bodies, especially salts, are exposed to a certain degree of heat.

DECU'BITUS. (From *decumbo*, to lie down.) The attitude or disposition of the body of a patient when in the horizontal posture. This forms an important feature in some diseases.

DECU'MBENS. (From *decumbo*, to lie down.) Lying down. Drooping: a term applied to flowers which incline to one side and downwards.

DECU'RRENT. (*Decurrens;* from *decurro*, to run down.) Applied to leaves which run down the stem in a leafy border or wing; as in *Onopordium acanthium*, and many thistles, great mullein, and comfrey: and to leafstalks; as in *Pisum ochrus*.

DECU'RSIVE. (*Decursivus;* from *decurro*, to run down.) Applied to leaves of which the middle nerve only runs down the stem; as in *Ruellia decurrens*. Also to a style the base of which descends on one side of the ovary, as in the genus *Rivinea*.

DECU'SSATE. (*Decussatus*; from *decusso*, to cross after the manner of an X.) Applied to leaves and spines which are in pairs, alternately crossing each other; as in *Veronica decussata*, and *Genista lusitanica*.

DECUSSA'TION. (*Decussatio, onis.* f.; from *decusso*, to cross each other.) When nerves or muscular fibres cross one another, this distribution is called decussation.

DECUSSO'RIUM. (*um, ii.* n.; from *decusso*, to divide.) An instrument to depress the dura mater, after trepanning.

DEFECA'TION. The separating or freeing any thing from its fæces.

DEFECTIO ANIMI. The same as *deliquium animi*.

DEFENSIVE. (*Defensivus;* from *defendo*, to preserve.) Defensive; applied to plasters and dressings of wounds; and formerly to cordial medicines, or such as resist infection.

DE'FERENS. (From *defero*, to convey; because it conveys the semen to the vesiculæ seminales.) See *Vas deferens*.

DEFI'XUS. (From *defigo*, to fasten; because it was supposed that every man thus defective was bewitched, or fastened by some charm.) Impotent; incapable of the generative act.

DEFLAGRA'TIO. (*o, onis.* f.; from *deflagro*, to burn.) Deflagration. 1. A rapid combustion, such as that which takes place when a mixture of sulphur and nitre is inflamed. 2. The intermission of a fever. — *Blancard.*

DEFLE'XUS. (*us, ûs.* m.; from *deflecto*, to turn or bend.) Deflex: bending outwards in a small degree.

DEFLO'RATE. (*Defloratus;* from *defloresco*, to shed the blossoms.) Applied, in *Botany*, to the anthers of flowers when they have shed their pollen; and also to plants when their flowers have fallen.

DEFLORA'TION. The extinction of the marks of virginity by connexion with the male. See *Virginity*.

DEFLUVIUM CAPILLORUM. Falling off of the hair. See *Baldness*.

DEFLU'XION. (*Defluxio, onis.* f.; from *defluo*, to run off.) A descent of humours from a superior to an inferior part. A term much used by the humoral pathologists.

DEFOLIA'TION. (*Defoliatio, onis.* f.; from *de*, and *folium*, a leaf.) The fall of the leaf. A term opposed to *frondescentia*, or the renovation of the leaf.

DEFORMA'TIO. A deformity of the body whether from original malformation or disease.

DEGENERATION. In natural history and physiology, this term is used to signify a gradual falling off or deterioration in any class of animals, or of any particular organ in the animal or vegetable body from the operation of natural causes. In *Pathology*, degeneration signifies a morbid change in the structure of parts.

DEGLUTI'TION. (*Deglutitio, onis.* f.; from *de*, and *glutio*, to swallow) The act of swallowing, or the passage of a substance, either solid, liquid, or gaseous, from the mouth to the stomach. Though deglutition is very simple in appearance, it is nevertheless the most complicated of all the muscular actions that serve for digestion. It is produced by the contraction of a great number of muscles, and requires the concurrence of many important organs.

All the muscles of the tongue, those of the *velum* of the palate, of the pharynx, of the larynx, and the muscular layer of the œsophagus, are employed in deglutition.

The *velum* is a sort of valve attached to the posterior edge of the roof of the palate; its form is nearly quadrilateral; its free or inferior edge is pointed, and forms the *uvula*. Like the valves of the intestinal canal, the *velum* is essentially formed by a duplicature of the digestive mucous membrane; there are many mucous follicles that enter into its composition, particularly in the uvula. Eight muscles move it: it is raised by the two internal *pterygoid*, the external *pterygoid* hold it transversely; the two *palato-pharyngei*, and the two *constrictores isthmi faucium* carry it downwards. These four are seen at the bottom of the throat, where they raise the mucous membrane, and form the pillars of the *velum* of the palate, between which are situated the *amygdalæ*, a mass of mucous follicles. The opening between the base of the tongue below, the *velum* of the palate above, and the pillars laterally, is called the isthmus of the throat. By means of its muscular apparatus, the *velum* of the palate may have many changes of position. In the most common state it is placed vertically; one of its faces is anterior, the other posterior: in certain cases it becomes horizontal: it has then a superior and inferior aspect, and its free edge cor-

responds to the concavity of the pharynx. This last position is determined by the contraction of the elevating muscles.

The *pharynx* is a vestibule into which open the nostrils, the Eustachian tubes, the mouth, the larynx, and the œsophagus, and which performs very important functions in the production of voice, in respiration, hearing, and digestion.

The pharynx extends from top to bottom, from the basilar process of the occipital bone, to which it is attached, to the level of the middle part of the neck.

Its transverse dimensions are determined by the os hyoides, the larynx, and the pterygomaxillary aponeurosis, to which it is fixed. The mucous membrane which covers it interiorly is remarkable for the development of its veins, which form a very apparent plexus. Round this membrane is the muscular layer, the circular fibres of which form the three constrictor muscles of the pharynx, the longitudinal fibres of which are represented by the stylo-pharyngeus and constrictores isthmi faucium. The contractions of these different muscles are not generally subject to the will.

The *œsophagus* is the immediate continuation of the pharynx, and is prolonged as far as the stomach, where it terminates. Its form is cylindrical; it is united to the surrounding parts by a slack and extending cellular tissue, which gives way to its dilatation and its motions. To penetrate into the abdomen, the œsophagus passes between the pillars of the diaphragm, with which it is closely united. The mucous membrane of the œsophagus is white, thin, and smooth; it forms longitudinal folds, very proper for favouring the dilatation of the canal: above it is confounded with that of the pharynx.

There are found in it a great number of mucous follicles, and at its surface there are perceived the orifices of many excretive canals of the mucous glands.

The muscular layer of the œsophagus is thick, its tissue is denser than that of the pharynx; the longitudinal fibres are the most external and the least numerous; the circular are placed in the interior, and are very numerous.

Round the pectoral and inferior portion of the œsophagus, the two nerves of the eighth pair form a plexus which embraces the canal, and sends many filaments into it.

The contraction of the œsophagus takes place without the participation of the will.

Mechanism of Deglutition. — Deglutition is divided into three periods. In the first, the food passes from the mouth to the pharynx; in the second, it passes the opening of the glottis, that of the nasal canals, and arrives at the œsophagus; in the third, it passes through this tube and enters the stomach.

Let us suppose the most common case, that in which we swallow at several times the food which is in the mouth, and according as mastication takes place.

As soon as a certain quantity of food is sufficiently chewed, it is placed, by the effects of the motions of mastication, in part upon the superior face of the tongue, without the necessity, as some think, of its being collected by the point of the tongue from the different parts of the mouth. Mastication then stops: the tongue is raised and applied to the roof of the palate, in succession, from the point towards the base. The portion of food, or the alimentary bolus, placed upon its superior surface, having no other way to escape from the force that presses, is directed towards the pharynx: it soon meets the velum of the palate applied to the base of the tongue, and raises it; the velum becomes horizontal, so as to make a continuation of the palate. The tongue, continuing to press the food, would carry it towards the nasal canals, if the velum did not prevent this by the tension that it receives from the external peristaphyline muscles, and particularly by the contraction of its pillars; it thus becomes capable of resisting the action of the tongue, and of contributing to the direction of the food towards the pharynx.

The muscles which determine more particularly the application of the tongue to the top of the palate, and to the velum of the palate, are the proper muscles of the organ, aided by the mylo-hyoideus. Here the first time of deglutition terminates. Its motions are voluntary, except those of the velum of the palate. The phenomena happen slowly and in succession: they are few and easily noticed.

The second period is not the same; in it the phenomena are simultaneous, multiplied, and are produced with such promptitude, that Boerhaave considered them as a sort of convulsion.

The space that the alimentary bolus passes through in this time is very short, for it passes only from the middle to the inferior part of the pharynx; but it was necessary to avoid the opening of the glottis and that of the nasal canals, where its presence would be injurious. Besides, its passage ought to be sufficiently rapid, in order that the communication between the larynx and the external air may not be interrupted, except for an instant.

Let us see how nature has arrived at this important result. The alimentary bole no sooner touches the pharynx than every thing is in motion. First, the pharynx contracts, embraces and retains the bole; the velum of the palate, drawn down by its pillars, acts in the same way. On the other hand, and in the same instant, the base of the tongue, the os hyoides, the larynx, are raised and carried forward to meet the bole, in order to render its passage more rapid over the opening of the glottis. Whilst the os hyoides and the larynx are raised, they approach each other, that is, the superior edge of the thyroid cartilage engages itself behind the body of the os hyoides; the epiglottic gland is pushed back; the epiglottis descends, inclines downwards and backwards, so as to cover the entrance of the larynx. The crycoid cartilage makes a motion of rotation upon the inferior horns of the thyroid, whence it results that the entrance of the larynx becomes oblique downwards and backwards. The bole slides along its surface; and being always pressed by the contraction of the pharynx and of the velum of the palate, it arrives at the œsophagus.

It is not long since the position that the epi

glottis takes in this case was considered as the only obstacle opposed to the entrance of the food into the larynx, at the instant of deglutition; but it has been shown, by a series of experiments, that this cause ought to be considered as only accessary. In fact, the epiglottis may be entirely taken away from an animal, without deglutition suffering any injury from it. What is the reason, then, that no part of the food is introduced into the larynx the instant that we swallow? The reason is this: in the instant that the larynx is raised and engaged behind the os hyoides, the glottis shuts with the greatest closeness. This motion is produced by the same muscles that press the glottis in the production of the voice; so that if an animal has the recurrents and nerves of the larynx divided, whilst the epiglottis is untouched, its deglutition is rendered very difficult, because the principal cause is removed which opposes the introduction of food into the glottis.

Immediately after the alimentary bole has passed the glottis, the larynx descends, the epiglottis is raised, and the glottis is opened to give passage to the air.

After what has been said, it is easy to conceive why the food reaches the œsophagus without entering any of the openings which end in the pharynx. The velum of the palate, which, in contracting, embraces the pharynx, protects the posterior nostrils and the orifices of the Eustachian tubes; the epiglottis, and particularly the motion by which the glottis shuts, preserves the larynx.

Thus, the second period of deglutition is accomplished; by the effects of which the alimentary bole passes the pharynx, and is engaged in the superior part of the œsophagus. All the phenomena which concur in it take place simultaneously, and with great promptitude: they are not subject to the will; they are then different in many respects from the phenomena that belong to the first period.

The third period of deglutition is that which has been studied with the least care, probably on account of the situation of the œsophagus, which is difficult to be observed except in its cervical portion. The phenomena which are connected with it are not complicated. The pharynx, by its contraction, presses the alimentary bole into the œsophagus with sufficient force to give a suitable dilatation to the superior part of this organ. Excited by the presence of the bole, its superior circular fibres very soon contract, and press the food towards the stomach, thereby producing the distension of those more inferior. These contract in their turn, and the same thing continues in succession until the bole arrives at the stomach. In the upper two thirds of the œsophagus, the relaxation of the circular fibres follows immediately the contraction by which they displaced the alimentary bole. It is not the same with the inferior third: this remains some moments contracted after the introduction of food into the stomach.

All the extent of the mucous surface that the alimentary bole passes, in the three periods of deglutition, is lubricated by an abundant mucosity. In the way that the bolus passes, it presses more or less the follicles that it meets in its passage, it empties them of the fluid that they contain, and slides more easily upon the mucous membrane. We remark that in those places where the bole passes more rapidly, and is pressed with greater force, the organs for secreting mucus are much more abundant. For example, in the narrow space where the second period of deglutition takes place, there are found the tonsils, the fungous papillæ of the base of the tongue, the follicles of the velum of the palate, and the uvula, those of the epiglottis, and the arytenoid glands. In this case the saliva and the mucosity fulfil uses analogous to those of the synovia.

The mechanism by which we swallow the succeeding mouthfuls of food does not differ from that which we have explained.

Nothing is more easy than the performance of deglutition, and, nevertheless, all the acts of which it is composed are beyond the influence of the will and of instinct. We cannot make an empty motion of deglutition. If the substance contained in the mouth is not sufficiently chewed, if it has not the form, the consistence, and the dimensions of the alimentary bole, if the motions of mastication which immediately precede deglutition have not been made, we will frequently find it impossible to swallow it, whatever efforts we make. How many people do we not find who cannot swallow a pill, and who are obliged to fall upon other methods to introduce it into the œsophagus? — *Magendie.*

DE'GMUS. (Δηγμος; from δακνω, to bite.) A bite. Applied in medical language to a gnawing pain, especially that which is sometimes felt in the stomach.

DEHENE. *Dehim. Dem.* Barbarous words for blood. — *Ruland.*

DEHENEZ. *Duenec. Duhenec.* Vitriol. — *Ruland.*

DEHISCENCE. *Dehiscentia.* The state of a dehiscent capsule.

DEHI'SCENS. (From *dehisco*, to gape.) Dehiscent. Gaping. Applied in botany to capsules which split and gape wide when ripe, to give exit to the seed.

DEJECTION. (*Dejectio, onis.* f.; from *dejicio*, to go to stool.) A discharge of fæcal matter from the bowels, or the matter discharged.

DEJECTO'RIUS. (From *dejicio*, to cast out.) Purgative.

De la Motte's golden drops. See *Gouttes du Général Lamotte.*

DELA'PSIO. Improperly written for *delapsus.*

DELA'PSUS. Synonymous with *prolapsus.*

DELETE'RIOUS. (*Deleterius*; from δηλεω, to hurt or injure.) Poisonous.

DELIGA'TIO. (From *deligo*, to bind up.) The application of a bandage.

DELIQUE'SCENCE. (*Deliquescentia, æ.* f.; from *deliquesco*, to melt down.) Deliquation, or the spontaneous assumption of the fluid state of certain saline bodies, when left exposed to the air, in consequence of their attracting water from it.

DELI'QUIUM. (*um, i.* n.; from *delinquo*, to leave.) 1. A fainting. See *Syncope.*

2. In *Chemistry* and *Pharmacy*, the same as deliquescence.

Deli'quium animi. Fainting.

DELI'RIUM. (*um*, *i.* n.; from *deliro*, to rave.) The confusion of ideas which occurs in the progress of diseases from disturbed function of the brain. Delirium is either violent and frantic, *delirium ferox*, as in acute inflammation of the membranes of the brain; or low and muttering, *typhomania*, as in low fever.

Delirium tremens. An affection of the brain nearly peculiar to drunkards.

It is important to distinguish this affection from inflammation of the brain. Delirium tremens almost always arises from the inordinate use of ardent spirits, wine, or strong malt liquors. Dr. Armstrong met with only one exception, and in that case it arose from the use of opium. Dr. Ayre has seen several cases arising from lead. Delirium tremens is very often connected with mental anxiety, night-watching, or copious evacuation. Dr. Armstrong once saw a patient who at the onset had laboured under inflammation of the tonsils and adjacent mucous membrane, for which he was bled, purged, and kept on a low diet; and in the state of exhaustion thus produced the attack of delirium came on. In drunkards the delirium generally comes on in the state of exhaustion from leaving off, either in part or entirely, the accustomed stimulus. In fact, to a confirmed drunkard, wine, spirits, and ale, are as food; he lives by a sort of suction. As we live on flesh and bread, so he lives by drink; and if you abstract his food, you will very likely induce this peculiar condition of the nervous system. Dr. Armstrong has known the fumes of spirits produce this affection. He once saw a case in an individual of remarkably temperate habits, but he had been, for some days previous to the attack, exposed to the fumes of ardent spirits, which affected him very much. He was at first exceedingly excited by them, and in the subsequent exhaustion the attack of delirium tremens came on.

A person having been much addicted to the use of considerable potations, omits his accustomed stimulus, and the approach of an attack of delirium tremens is almost invariably announced by the patient being remarkably irritable, with fretfulness of the mind, and mobility of the body. Watchfulness next occurs, and the patient gets little or no sleep. He has frightful dreams, sees remarkable sights, or hears extraordinary sounds. He then begins to fancy that some conspiracy is forming against him, entertains suspicions about certain persons or things, and imagines that some mischief is intended towards him. Then he is perpetually busied about his affairs, and so on.

Some patients in this affection are very much alarmed, and fancy that a person in the next room is waiting to assassinate them.

Sometimes the delirium turns on some matter of business, such as settling of accounts, or telling of money.

The patient generally is in a perpetual bustle; his hands are constantly full; in short, he becomes a perfect man of business. The skin is damp and relaxed, and there is a variable active expression of the eye, and almost always tremour of the hands. The pulse is soft, compressible, and seldom above one hundred, except under great bodily exertions.

It is to be remarked, with respect to this affection —

1. That it comes on in a state of weakness, and almost always after hard drinking.

Indeed, it always occurs after the excessive use of spirits, &c., as far as Dr. Armstrong's observations have gone, with the one exception already mentioned.

2. It is preceded and attended by irritability of mind and mobility of body.

There is a remarkable sensibility of the body, an incessant tendency to move from one place to another, and the patient is prone to be irritated by very slight circumstances.

3. It is preceded and attended by watchfulness during the day and night, compared with the natural habits as to sleep.

4. An incessantly active bustling delirium supervenes, when the disease is fully developed.

And the illusions which attend this delirium, however vague and unfounded, operate on the patient with all the force of realities till he becomes furiously mad. He has extraordinary activity of mind, and is busied in enumerating his misfortunes or in counting his wealth.

5. The countenance is quick, variable, and wild at times.

No single description will apply to the expression of the countenance in these cases; for it varies with the predominant impression on the mind of the individual.

6. The skin is damp and relaxed, especially on any exertion.

7. The hands are generally tremulous.

Dr. Armstrong has seen some cases in which the tremor was entirely absent. When it exists it is most obvious when the patient's hand is held out. It is like the tremour which you may see in the hands of a drunkard in the morning, before taking his accustomed dram.

8. The patient is inclined to constant motion.

And he generally is so unless he is tied down. There is activity, not only of the mind, but of the body also. The whole mind is put constantly in action, and the whole body in motion. The individual is perpetually changing his place and displays considerable power both of body and mind.

9. The face is pale, and the conjunctiva generally blanched.

10. The surface is rarely hotter than natural. It is almost always damp.

11. The tongue is but slightly furred and very moist.

12. The appetite is good.

The patient will take what is offered him except in those cases where he labours under an illusion, and suspects that some person is about to poison him; for then he will often refuse every thing.

13. The pulse is soft and compressible compared with the pulse which occurs in inflammation of the brain and its membranes. I

is seldom above one hundred, if the individual be quiet; but if he use much exertion, it is sometimes excessively rapid and small. In some cases there are convulsions; sometimes they are very dangerous, but often they are not fatal if the patient be properly managed.

Delirium tremens is distinguished from inflammation of the brain by attention to the following particulars: —

1. In inflammation of the brain and its membranes there is a peculiar mixed expression of the eye, made up of a combination of physical brightness with intellectual dulness.

In the delirium of drunkenness the expression of the eye is generally remarkably vivid and intelligent, except when the patient labours under an apprehension of the approach of some great mischief to himself.

In inflammation of the brain the look is wearied, anxious, and oppressed, except when there is high delirium, and then it is wild.

In delirium tremens the eye is rolling and restless, exceedingly variable according to the present impression.

2. In inflammation of the brain there is dropping of one or both eyelids: in the first stage the pupil is contracted; and in the last stage, if effusion have taken place, it is dilated.

But in the brain fever the pupil is not contracted; nor is it dilated, except under great exertion.

3. In inflammation of the brain the conjunctiva is injected.

In delirium tremens the conjunctiva is blanched.

4. In inflammation of the brain the heat is very high on the surface, especially over the head, neck, and face.

This is not the case in delirium tremens, in which the skin is sometimes warm, but often cool and even chilly, from the excessive perspiration and consequent evaporation from the surface of the body. Sometimes, however, the surface is hotter than natural from great exertion.

5. In delirium tremens, too, the pulse continues remarkably soft, in comparison with the pulse which occurs in inflammation of the brain; and is slow, except when the patient makes violent exertions.

6. The skin is remarkably relaxed in delirium tremens; but it is not so in inflammation of the brain.

7. In delirium tremens the hands are generally tremulous from the commencement.

In inflammation of the brain the hands are tremulous only in the last stage.

8. In inflammation of the brain the strength fails from the beginning, and the patient staggers when he attempts to walk.

But in delirium tremens at the beginning, and during the progress, the patient manifests very great muscular power. He looks, speaks, moves, and does every thing with very great rapidity and energy. With respect to this, however, exhaustion often comes on very rapidly after great exertion, and the patient falls down from fatigue.

9. In inflammation of the brain the appetite is prostrate.

In delirium tremens the appetite is often good, although the patient may refuse food from a suspicion of an intention to poison him.

10. Delirium tremens is mostly the consequence of hard drinking.

Inflammation of the brain can, on the contrary, generally be referred to other remote occasions.

11. In deliriums tremens the patient is first irritable, then watchful, then fanciful, and, lastly, furiously mad.

In inflammation of the brain the patient first complains of pain in the head, with general debility of mind and body.

12. In delirium tremens the patient is constantly changing his place. He is in the state called jactitation.

In inflammation of the brain he lies on his back, with but little muscular power, except in occasional fits of delirium, in which his strength is remarkable.

13. In delirium tremens the patient does not often complain of pain in the head; but in inflammation of the brain he almost always complains of acute pain in the first stage.

14. Delirium tremens comes on and goes off suddenly; but inflammation of the brain comes on and goes off for the most part gradually, though to this there are some exceptions, especially in hot climates. — *Armstrong.*

The pathology of delirium tremens is not understood, nor have any appearances been observed on dissection, which can be reasonably regarded as having any essential relation to the disease.

The prognosis is generally rather favourable, if the ordinary health of the patient be not very bad, and if he be not far advanced in life.

In the treatment of this disease, opium is our sheet anchor. It should be given in large doses, as sixty minims of the tincture every hour or two, its effect being cautiously watched. If sound sleep be thus induced, the patient usually wakes free from disease. In many cases, the judicious use of alkoholic stimulants is of signal service; and these means, with laxatives, gentle diaphoretics, and proper moral management, will generally bring the case to a successful issue. Bleeding, to a small extent, may be required at the commencement, when the patient is young and plethoric, and there are symptoms of determination of blood to the head; but, generally speaking, bleeding should be considered as out of the question in this disease; patients who are largely bled hardly ever recover.

If the patient express a desire for food, he may be allowed light articles of diet: in some cases even animal food has been given with advantage, and indeed it might not be easy to give any good reason why this should be refused, if the state of the stomach be such as to incline the patient to ask for it.

Delitescence. (From *delitesco*, to hide oneself, abscond.) A French term used to signify the sudden resolution or disappearance of an inflammation.

Delivery. See *Parturition.*

Delocatio. (From *de*, from, and *locus*, a place.) The same as *dislocatio.*

Delphia. See *Delphinia.*

DE'LPHINATE. A salt formed by the union of the delphinic acid with a base.

Delphine. See *Delphinia.*

DELPHI'NIA. (*a, æ.* f.; so called because obtained from the plant called *delphinium.*) Delphine: a vegetable alkali discovered by Lassaigne and Fenuelle, in the stavesacre. See *Delphinium staphysagria.*

DELPHI'NIC ACID. *Acidum delphinicum.* The name of an acid, extracted from the oil of the dolphin, *delphinus.* M. Chevreuil, who discovered it, has since proposed to call it *phocenic,* because the former name might lead to the supposition that it was derived from the plant *delphinium.* See *Phocenic acid.*

DELPHI'NIUM. (*um, ii.* n.; from δελφιν, the dolphin: so called from the likeness of the flower to the dolphin's head.) The name of a genus of plants in the Linnæan system. Class, *Polyandria;* Order, *Trigynia.*

Delphinium — nectariis monophyllis, caule subdiviso, of Linnæus. Many virtues have been attributed to this plant. The flowers are bitter, and a water distilled from them is recommended in ophthalmia. The herb has been administered in calculous cases, obstructed menses, and visceral diseases,

DELPHINIUM CONSOLIDA. The systematic name of the *Consolida regalis;* called also *Calcatrippa.*

DELPHINIUM STAPHISAGRIA. The systematic name of stavesacre; called also, *Staphisagria, Staphis,* and *Pedicularia.*

Delphinium staphisagria — nectariis tetraphyllis petalo brevioribus, foliis palmatis, lobis obtusis, of Linnæus. The seeds, which are the only parts directed for medicinal use, are usually imported here from Italy; they are large, rough, of an irregular triangular figure, and of a blackish colour on the outside, but yellowish within; their smell is disagreeable, and somewhat fœtid; to the taste they are very bitter, acrid, and nauseous. They were formerly employed as a masticatory, but are now confined to external use, in some kinds of cutaneous eruptions, but more especially for destroying lice and other insects: hence, by the vulgar, the plant is called louse-wort.

An alkali was discovered in this plant by Lassaigne and Fenuelle, which is called *Delphinia,* or *Delphine;* it is obtained in the following way: — The seeds, deprived of their husks, and ground, are to be boiled in a small quantity of distilled water, and then pressed in a cloth. The decoction is to be filtered, and boiled for a few minutes with pure magnesia. It must then be re-filtered, and the residuum left on the filter is to be well washed, and then boiled with highly rectified alkohol, which dissolves out the alkali. By evaporation, a white pulverulent substance, presenting a few crystalline points, is obtained.

It may also be procured by the action of dilute sulphuric acid on the bruised but unshelled seeds. The solution of sulphate, thus formed, is precipitated by subcarbonate of potash. Alkohol separates from this precipitate the alkali in an impure state.

Pure delphinia obtained by the first process is crystalline while wet, but becomes opake on exposure to air. Its taste is bitter and acrid. Its action on animals, in an over-dose, is that of producing great agitation, convulsions, and death.

DE'LPHYS. (*ys, yos.* f.; δελφυς.) The uterus, or pudendum muliebre.

DE'LTA. (The Greek letter Δ.) The pudendum muliebre has been so called, from its triangular shape.

DELTOI'DES. (*Deltoides* and *deltoideus;* from δελτα, the Greek letter Δ, and ειδος, a likeness: shaped like the Greek delta.)

1. The name of a muscle of the superior extremity, situated on the shoulder. It arises exactly opposite to the trapezius, from one-third part of the clavicle, from the acromion and spine of the scapula, and is inserted, tendinous, into the middle of the os humeri, which bone it lifts up directly; and it assists with the supra-spinatus and coraco-brachialis in all the actions of the humerus, except the depression; it being convenient that the arm should be raised and sustained, in order to its moving on any side.

2. A leaf is called *folium deltoides,* which is trowel-shaped, or like the letter delta, having three angles, of which the terminal one is much further from the base than the lateral ones; as in *Chenopodium bonus henricus.*

DELTOIDEUS. Improperly written for *deltoides.*

DEME'NTIA. (*a, æ.* f.; from *de,* from, and *mens,* mind.) A form of insanity in which unconnected and imperfectly defined ideas chase each other rapidly through the mind; the powers of continued attention and of reflection are lost, and even the perceptive power at length becomes indistinct. Dementia is sometimes an accompaniment of old age, and is a frequent termination of mania.

DEME'RSUS. A leaf which is naturally under water, and different from those above, is so called. *Folia immersa,* and *submersa,* are the same as *demersa.* See *Natans.*

Demiazygos. See *Semiazygos.*

Demimetal. See *Semimetal.*

DEMOTI'VUS LA'PSUS. A strange term that has been used to signify sudden death.

DEMU'LCENT. (*Demulcens;* from *demulceo,* to soften.) A medicine which obviates acrimony, not by correcting or changing its nature, but by involving it in a mild and viscid matter, which prevents it from acting upon the sensible parts of our bodies, or by covering the surface exposed to their action.

Where such medicines are directly applied to the parts affected, it is easy to perceive how benefit may be derived from their application; but where they are received by the medium of the stomach into the circulating system, it has been supposed that they can be of no utility, as they must lose that viscidity on which their lubricating quality depends. Hence it has been concluded that they can be of no service in gonorrhœa, and some similar affections. It is certain, however, says J. Murray, in his Elements of Materia Medica and Pharmacy, that many substances which undergo the process of digestion are afterwards separated, in their entire

state, from the blood, by particular secreting organs, especially by the kidneys; and it is possible, that mucilaginous substances, which are the principal demulcents, may be separated in this manner. There can be no doubt, however, but that a great share of the relief demulcents afford, in irritation or inflammation of the urinary passages, is owing to the large quantities of water in which they are diffused, by which the urine is rendered less stimulating from dilution. In general, demulcents may be considered merely as substances less stimulating than the fluids usually applied.

Catarrh, diarrhœa, dysentery, calculus, and gonorrhœa, are the diseases in which demulcents are employed. As they are medicines of no great power, they may be taken in as large quantities as the stomach can bear.

The particular demulcents may be reduced to the two divisions of mucilages and expressed oils. The principal demulcents are, the acacia vera, astragalus, tragacanth, linum usitatissimum, althæa officinalis, malva sylvestris, glycyrrhiza glabra, cycas circinalis, orchis mascula, maranta arundinacea, triticum hybernum, ichthyocolla, olea europæa; amygdalus communis, cetaceum, and cera.

DENARIUS. (*us, i.* m.) A Roman weight equal to the seventh part of an ounce.

DENDROI'DES. (From δενδρον, a tree or shrub, and ειδος, resemblance.) Applied generally in natural history to objects which have an arborescent or tree-like appearances.

DENDROLI'BANUS. (*us, i.* m.; from δενδρον, a tree, and λιβανος, frankincense.) See *Rosmarinus officinalis.*

DENS. (*s, tis.* m.; *quasi edens;* from *edo,* to eat, or from οδους, οδοντος.) 1. A Tooth. See *Teeth.*

2. Many herbs have this specific name, from their fancied resemblance to the tooth of some animal; as *Dens leonis,* the dandelion; *Dens canis,* dog's tooth, &c.

DENS CABALLINUS. Horse's tooth. A name of Henbane.

Dens canis. See *Erythronium.*

DE'NTAGRA. (*a, æ.* f. From *dens,* a tooth, and αγρα, a seizure.)

1. The toothache. See *Odontalgia.*

2. An instrument for drawing the teeth.

DE'NTAL. (*Dentalis;* from *dens,* a tooth.) Appertaining to the teeth.

DENTA'LIS LA'PIS. The crust, or tartar, as it is called, which forms round the teeth. See *Tartar.*

DENTA'LIUM. (*um, i.* n.; from *dens,* a tooth, which it resembles in shape.) A genus of univalve shells. They were anciently used in the composition of ointments and plasters.

DENTA'RIA. (*a, æ.* f.; from *dens,* a tooth: called because its root is denticulated.) See *Plumbago europæa.*

DENTARPA'GA. (*a, æ.* f.; from οδους, a tooth, and αρπαζω, to take away forcibly.) An instrument for drawing teeth.

DENTA'TA. The second vertebra of the neck. It differs from the other cervical vertebræ in having a tooth-like process at the upper part of the body, whence its name. See *Vertebræ.*

DE'NTATE. (*Dentatus;* from *dens,* a tooth.) Toothed: applied to roots, leaves, petals, &c. which are beset with projecting, horizontal, rather distant teeth, of their own substance; as in the leaf of *Atriplex lacinata,* and the perianth of the *Marrubium vulgare,* and *Erica denticulata,* and the petals of the *Silene lusitanica.* The *Ophris corallorhiza* has a toothed root.

Dentatus processus. See *Vertebræ.*

Dented. See *Retusus.*

DENTES ACUTI. The incisor teeth.

DENTES ADULTI. The teeth of the second dentition.

DENTES ADVERSI. The incisor teeth.

Dentes bicuspidati. See *Teeth.*

Dentes bicuspides. See *Teeth.*

Dentes canini. See *Teeth.*

DENTES COLUMELLARES. The molar teeth.

Dentes cuspidati. See *Teeth.*

Dentes incisores. See *Teeth.*

Dentes lactei. See *Teeth.*

Dens leonis. See *Leontodon taraxacum.*

Dentes molares. See *Teeth.*

DENTICULA'TUS. Denticulate, or set with little teeth. Applied, in natural history and anatomy, to various objects from their appearance.

DENTIDU'CUM. (*um, i.* n.; from *dens,* a tooth, and *duco,* to draw.) An instrument for the drawing of teeth.

DE'NTIFRICE. (*Dentrificum, i.* n.; from *dens,* a tooth, and *frico,* to rub.) A powder for cleaning the teeth.

DENTILLA'RIA. (So called because its root is denticulated.) Tooth-wort. See *Plumbago europæa.*

DENTISCA'LPIUM. (*um, i.* n.; from *dens,* a tooth, and *scalpo,* to scrape.) An instrument for scaling teeth.

DENTIST. One who addicts himself especially to the treatment of diseases of the teeth.

DENTI'TION. (*Dentitio, onis.* f.; from *dentio,* to breed teeth.) The breeding or cutting of the teeth. See *Teeth.*

DENTITION, DIFFICULT. *Dentitio difficilis.* Dentition is a natural process, which, under favourable circumstances, is unattended with any symptoms which can be considered as morbid; in many instances, however, it is otherwise, and disease of an alarming and even fatal character may take place.

The most violent symptoms of dentition are those produced during the growth and cutting of the milk teeth, for the system is then in its tenderest state of infancy. The immediate cause of the difficulty is the pressure of the teeth in the gum, and the degree of irritation depends on the particular temperament of the child. As the teeth push forward, the superincumbent gum wastes from absorption, and is at last cut through, and the tooth makes its appearance. This pressure is not, however, uniformly exerted through the whole course of teething, but is divided into distinct periods or stages: —

1. The first active stage of teething is usually about the third or fourth month of infancy, and constitutes what is called *breeding the teeth,* or the conversion of the pulpy rudiment, buried in

the gum, and formed during fœtal life, into a solid material, which at the same time shoots downwards, and gives to every tooth a neck or fang. The first and most usual symptom of this change, is the looseness with which the infant grasps the nipple, and the frequency with which it lets go its hold, accompanied with fretfulness and crying, and succeeded by a copious discharge of saliva, the salivary glands sympathising with the gums. Next, the uneasiness of the gums is found to be relieved by the pressure of any hard substance upon them, which benumbs their excited irritability. If the irritation becomes very considerable, the gums swell, the child grows still more fretful, and starts in its sleep; or, on awaking suddenly, there is heat, thirst, and other concomitants of fever, with perhaps dulness or drowsiness; the bowels are affected, and a rash appears on the skin, usually the *red gum*; and if the irritation extends to the muscles of the chest, there is a dry and troublesome cough. In about ten days or a fortnight these symptoms subside; and though the infant may occasionally be teased with uneasiness, it generally passes on without much inconvenience till the arrival of the second stage.

2. The period of cutting the teeth. This usually takes place between the seventh and the close of the ninth month. This is the usual progress; but here, as in many other organs of the system, there is in some cases a precocity, and in others a backwardness of action: hence a child is occasionally born with teeth; many cut their teeth soon after birth; while, with some, no tooth appears until a very late period. At this time the gum is often extremely sensible, and, instead of being eased by the pressure of a hard substance, cannot endure the slightest touch. At the base it is florid and distended, but paler and whiter at the edge or upper part; and when the tooth is on the point of protrusion, seems covered with a flat and whitish blister. The other symptoms are a repetition of those just described, with a scabby eruption about the lips or head, inflammation about the ears, and occasionally spasmodic movements of the mouth and jaws, and convulsions.

The grand point is here to moderate the local irritation. A diarrhœa, or full discharge of saliva, does this naturally, and hence these are favourable symptoms; and if the former be too violent, or accompanied with griping, it should be merely corrected by the subcarbonate of magnesia, or carbonate of lime. If the bowels be confined, cooling laxatives are to be employed; and the discharge of a small quantity of blood from the gums, in the first stage, by lancing them, will often afford effectual relief. If the symptoms of oppression or spasmodic action be severe, as drowsiness, difficulty of breathing, stertor, or irregular motions of the jaws, leeches should be resorted to; after which, a blister will be found useful behind the ears or on the back. When the bowels have been thoroughly emptied, anodynes will be very serviceable, though they should be employed with great judgment, and never trusted to nurses. In the second stage, or when the teeth are on the point of protrusion, the lancet will often afford immediate relief, — not by the discharge of blood, for the upper part of the gum is now become so thin or wasted that little or none will flow, — but by giving a direct opening to the tooth, which will frequently make its appearance in the course of a few hours.

In cutting the *second* or *permanent set of teeth*, and the wise teeth, there is very seldom any difficulty. When so, there is painful swelling of the gums, and fever, and all that is wanted is to subdue inflammation by the usual means.

DENUDA'TÆ. (From *denudo*, to make bare.) Denude: naked. An order of Linnæus's Fragments of a Natural Method, embracing those plants the flowers of which are naked, or without a flower-cup.

DENUDA'TIO. (From *denudo*, to make bare.) The laying bare any part: usually applied to a bone.

DEO'BSTRUENT. (*Deobstruens*; from *de*, and *obstruo*, to obstruct.) Having the power of removing any obstruction.

DEO'PPILANS. (From *de*, and *oppilo*, to stop.) *Deoppilativus*. Having the property of removing obstructions.

DEPARTI'TIO. (From *de*, and *partior*, to divide.) An old chemical name for the process of separating metals.

DEPA'SCENS. (From *depasco*, to eat down.) Eating away; corroding: applied formerly to phagedænic ulcers.

DEPE'NDENS. Dependent: hanging down. Applied chiefly in botany.

Deperdi'tio. (From *deperdo*, to lose.) Abortion. — *Castelli*.

Depeti'go. (From *de*, and *petigo*, a running scab.) A ring-worm, tetter, scurf, or itch, where the skin is rough. — *Turton*.

DEPHLEGMA'TION. (*Dephlegmatio, onis*. f.; from *de*, and *phlegma*, phlegm.) The operation of rectifying or freeing spirits from their watery parts, or any method by which bodies are deprived of their water.

DEPHLOGI'STICATED. (*Dephlogisticatus*; from *de*, and *phlogiston*, a particular principle so called.) A term formerly applied by chemists to bodies which were supposed to be deprived of *phlogiston* or the inflammable principle. See *Phlogiston*.

Dephlogisticated air. See *Oxygen gas*.

Dephlogisticated muriatic acid. See *Chlorine*.

DEPI'LATORY. (*Depilatorius*; from *de*, of, and, *pilus*, the hair.) Any application which removes the hairs from any part of the body is so named; thus, a pitch cap, which pulls the hair of the head out by the roots, is a depilatory application.

Depluma'tio. (From *de*, and *pluma*, feather.) A disease of the eyelids, which causes the hair to fall off.

Deposi'tio. Deposition. The depression of the lens, in the operation of couching, has been so called.

DEPREHE'NSIO. (*o, onis*. f.; from *deprehendo*, to catch unawares.) This term has been applied. 1. To catalepsy.

2. To the *diagnosis* of a disease.

DEPRESSION. (*Depressio, onis.* f.; from *deprimo*, to press down.) The state of a part that has fallen down: thus we say, the depression of the lower jaw, or of the palate. The term is also applied to one of the operations for the cataract.

DEPRE'SSOR. (*or, oris.* m.; from *deprimo*, to press down.) A muscle, which depresses the part on which it acts.

Depressor alæ nasi. See *Depressor labi superioris alæque nasi.*

Depressor anguli oris. A muscle of the mouth and lip, situated below the under lip. *Triangularis*, of Winslow. *Depressor labiorum communis*, of Douglas. *Depressor labiorum*, of Cowper. It arises broad and fleshy, from the lower edge of the lower jaw, near the chin; and is inserted into the angle of the mouth, which it pulls downwards.

Depressor labii inferioris. A muscle of the mouth and lip. *Quadratus*, of Winslow. *Depressor labii inferioris proprius*, of Douglas and Cowper. It pulls the under lip and skin of the side of the chin downwards, and a little outwards.

Depressor labii superioris alæque nasi. A muscle of the mouth and lip. *Depressor alæ nasi*, of Albinus. *Incisivus medius*, of Winslow. *Depressor labii superioris proprius*, of Douglas. *Constrictores alarum nasi, ac depressores labii superioris*, of Cowper. It is situated above the mouth, draws the upper lip and ala nasi downwards and backwards. It arises, thin and fleshy, from the superior maxillary bone, immediately above the joining of the gums, with the two incisor teeth and cuspidatus; from thence it runs upwards, and is inserted into the upper lip and root of the ala of the nose.

Depressor labii superioris proprius. See *Depressor labii superioris alæque nasi.*

Depressor labiorum communis. See *Depressor anguli oris.*

Depressor oculi. See *Rectus inferior oculi.*

DEPRE'SSUS. Depressed: applied to the surface of a leaf when in a small degree concave, pressed down, flattened.

Folia depressa, as applied to radical leaves, means leaves which are pressed close to the ground, as is seen in *Plantago media*; but when applied to stem leaves, it regards their shape only, as being vertically flattened, in opposition to *compressa.*

Deprimens. See *Rectus inferior oculi.*

Deprimens Maxillæ Biventer. See *Digastricus.*

DEPU'RANS. (From *depuro*, to make clean.) Applied to a medicine, or article of diet which purifies the fluids of the animal body.

DEPURA'TION. (*Depuratio, onis.* f.; from *depuro*, to make clean.) 1. The defecation or clarification of a liquid.

2. The removal of impurities from the humours of the animal body.

DEPURATO'RIUS. (From *depuro*, to cleanse.) Depuratory: applied, 1. To certain diseases which were supposed to relieve the system from impurities. This idea was entertained with respect to agues, many cutaneous affections, &c.

2. To medicines or diet which were supposed to effect a similar depuration of the system.

Derbia. Impetigo has been so called.

Derbyshire neck. See *Bronchocele.*

DERIVATION. (*Derivatio, onis.* f.; from *derivo*, to drain off.) The drawing away any disease from its original seat to another part. Thus vesicatories epispastics, &c. were said to act by derivation.

Derivatives. *Deflectentia.* Medicines adapted to produce a *derivation.* See *Derivation.*

De'rma. (Δερμα, the skin.) See *Cutis.*

DERMATO'GRAPHY. (From δερμα, the skin, and γραφω, to describe.) The anatomical description of the skin.

DERMATOI'DES. (From δερμα, skin, and ειδος, a likeness.) Resembling skin. This epithet has been injudiciously applied by some writers to the dura mater.

DERMATO'LOGY. (*Dermatologia, æ.* f.; from δερμα, the skin, and λογος, a discourse.) A discourse or treatise on the skin.

Dermography. See *Dermatography.*

Dermoid. Improperly used for *dermatoid.*

Dermology. See *Dermatology.*

Derosne's Salt. See *Narcotine.*

De'rtron. Δερτρον. A word used by Hippocrates, as to the signification of which commentators differ, some making it the *omentum* or *peritonæum*, and others, the *small intestine.*

Descending aorta. See *Aorta, descending.*

Descenso'rium. (*um, ii.* n.; from *descendo*, to move downwards.) A furnace in which the distillation by descent is performed.

DESCE'NSUS. (From *descendo*, to move downwards.) *Destillatio per descensum.* The old chemists called it a distillation by descent, when the fire is applied at the top and round the vessel, the orifice of which is at the bottom.

DESCRIPTIVE ANATOMY. The name given by Bichat to that department of anatomy which treats of the form, appearance, position, distribution, and connexion of parts without reference to the particular textures of which they are composed. The consideration of *texture* belongs to *general anatomy.* See *Anatomy* and *General Anatomy.*

DESICCA'TION. (*Desiccatio*, from *desicco*, to dry up.) The drying up of anything moist.

DESI'CCATIVE. (*Desiccativus*; from *desicco*, to dry up.) Possessed of a drying property. Applied especially to medicaments used to dry up ulcers.

DESIPIE'NTIA. (*a, æ.* f.) This word properly means *folly*, but it has been used in medical language to signify *delirium.*

De'smos. (Δεσμος, from δεω, to bind.) A bandage.

DESPUMA'TION. (*Despumatio, onis.* f.; from *despumo*, to clarify.) The clarifying a fluid, or separating the scum from it.

DESQUAMA'TION. (*Desquamatio, onis.* f.; from *desquamo*, to scale off.) The separating of laminæ, or scales, from the skin or bones. It is more properly applied to the skin; in the case of bones it is generally called *exfoliation.*

Desquamato'rium tre'panum. *Trepanum exfoliativum.* A kind of trepan formerly used for detaching laminæ from exfoliating bones.

Destillation. See *Distillation.*

Destillatio per descensum. See *Descensus.*

DESUDA'TIO. (*o, onis.* f.; from *desudo*, to sweat much.) 1. Excessive sweating. 2. A miliary eruption to which children are chiefly subject. See *Sudamina.*

DETE'NTIO. (From *detineo*, to stop, or hinder: so called, from the suddenness with which the patient is seized.) Catalepsy.

DETE'RGENT. (*Detergens;* from *detergo*, to wipe away.) Applied to a medicine which cleanses foul wounds or ulcers.

DETERMINATE. *Determinatus.* Applied by botanists to branches and stems: *determinatè ramosus* abruptly branched, is when each branch, after terminating in flowers, produces a number of fresh shoots in a circular order from just below the origin of those flowers. The term occurs frequently in the latter publication of Linnæus, particularly the second *Mantissa;* but he does not appear to have any where explained its meaning. — *Smith.*

DETONA'TION. (*Detonatio, onis.* f.; from *detono*, to make a noise.) An explosion. See *Combustion.*

DETRA'CTOR. (*or, oris.* m.; from *detraho*, to draw.) *Detrahens.* Applied to a muscle, the office of which is to draw the part to which it is attached away from some other part.

De'trahens. See *Detractor.*

Detrahens quadratus. See *Platysma myoides.*

DETRU'SOR URI'NÆ. (*Detrusor*, from *Detrudo* to thrust out.) The muscular coat of the bladder, the office of which is to expel the urine from the bladder.

Deurens febris. An ardent fever.

DEUTE'RIA. (From δευτερος, second.) 1. A weak wine of second-rate quality used by the Greeks.

2. The bad symptoms arising from retention of the placenta. — *Vogel.*

DEUTE'RION. (From δευτερος, second; because it is discharged after the fœtus.) The secundines, or afterbirth.

DEUTEROPATHI'A. (*Deuteropatheia*, from δευτερος, second, and παθος, a suffering.) A sympathetic affection where a second part suffers, from consent with the part originally affected; as where the stomach is disturbed from an injury of the head.

DEUTEROPA'THIC. Appertaining to *Deuteropathia.*

Deutoxide. See *Oxide.*

Deutoxide of azote. See *Nitrogen.*

DEVALGA'TUS. (From *de*, and *valgus*, bow-legged.) Bandy-legged.

Devil's dung. See *Ferula assafœtida.*

DIABA'CANU. (Δια βακανου; from βακανον, a principal ingredient in it.) An hepatic remedy mentioned by Trallian.

DIABE'TES. (*es, is.* m.; Διαβητης; from διαβαινω, to pass through.) An immoderate flow of urine.

There are two species of this complaint: —

1. *Diabetes insipidus*, in which there is a superabundant discharge of limpid urine, of its usual urinary taste.

2. *Diabetes mellitus*, in which the urine is very sweet, and contains a great quantity of sugar.

Great thirst, with a voracious appetite, gradual emaciation of the whole body, and a frequent discharge of urine, containing a large proportion of saccharine and other matter, which is voided in a quantity even exceeding that of the aliment or fluid introduced, are the characteristics of mellitic form of the disease. Those of a shattered constitution, and those who are in the decline of life, are most subject to its attacks. It not unfrequently attends on hysteria, hypochondriasis, dyspepsia, and asthma; but it is always much milder when symptomatic, than when it appears as a primary affection.

Diabetes may be occasioned by the use of strong diuretic medicines, intemperance of life, and hard drinking; excess in venery, severe evacuations, or by any thing that tends to produce an impoverished state of the blood, or general debility. It has, however, taken place, in many instances, without any obvious cause.

Diabetes sometimes comes on slowly and imperceptibly, without any previous disorder; and it now and then arises to a considerable degree, and subsists long without being accompanied with evident disorder in any particular part of the system; the great thirst which always, and the voracious appetite which frequently, occur in it, being often the only remarkable symptoms; but it more generally happens, that a considerable affection of the stomach precedes the coming on of the disease; and that, in its progress, besides the symptoms already mentioned, there is a great dryness in the skin, with a sense of weight in the kidneys, and a pain in the ureters, and the other urinary passages.

Under a long continuance of the disease, the body becomes much emaciated, the feet œdematous, great debility arises, the pulse is frequent and small, and an obscure fever, with all the appearance of hectic, prevails.

The urine in diabetes mellitus, from being at first insipid, clear, and colourless, soon acquires a sweetish or saccharine taste, its leading characteristic; and, when subjected to experiment, a considerable quantity of saccharine matter is to be extracted from it. Sometimes it is so loaded with sugar, as to be capable of being fermented into a vinous liquor. Upwards of one twelfth of its weight of sugar was extracted from some diabetic urine by Cruickshank, which was at the rate of twenty-nine ounces troy a day, from one patient.

In some instances, the quantity of urine in diabetes is much greater than can be accounted for from all the sources united. Cases are recorded, in which 25 to 30 pints were discharged in the space of a natural day, for many successive weeks, and even months; and in which the whole ingesta, as was said, did not amount to half the weight of the urine. To account for this overplus, it has been supposed that water is absorbed from the air by the surface of the body; as also that a quantity of water is compounded in the lungs themselves.

Dissections of the bodies of those who have died of diabetes have often shown the kidneys to be much affected. In some instances, they have been found in a loose flabby state, much enlarged in size, and of a pale ash colour; it

others, they have been discovered much more vascular than in a healthy state, approaching a good deal to what takes place in inflammation, and containing, in their infundibula, a quantity of whitish fluid, somewhat resembling pus, but without any sign of ulceration whatever. At the same time that these appearances have been observed in their interior, the veins on their surface have been found to be much fuller of blood than usual, forming a beautiful network of vessels. Lastly, the kidneys frequently present no morbid appearances of any kind. In many dissections the whole of the mesentery has been discovered to be much diseased, and its glands remarkably enlarged; some of them being very hard, and of an irregular texture; others softer, and of an uniform spherical shape. Many of the lacteals have likewise been seen considerably enlarged. The liver, pancreas, spleen, and stomach, are in general perceived to be in a natural state; when they are not so, the occurrence is to be considered as accidental. The bladder, in many cases, is found to contain a considerable quantity of muddy urine.

With respect to the proximate cause of diabetes mellitus, many hypotheses have been advanced concerning it. The following are the principal: — That the disease depends upon,

1. A morbid action of the stomach and chylopoietic viscera.

2. A morbid crasis of the blood, produced by diseased action of the assimilating powers.

3. A retrograde motion of the lacteals.

4. A morbid condition of the kidneys.

The first of these opinions, though not the most ancient, originated with Dr. Mead, and has been lately supported by Drs. Dobson and Rollo, who fixed the seat of the disease in the stomach, and confined it to this organ, conceiving it to consist "in an increased action and secretion, with a vitiation of the gastric fluid, and probably too active a state of the lacteal absorbents; while the kidneys, and other parts of the system, as the head and skin, are only affected secondarily." According to this hypothesis, the blood is formed imperfectly from the first, and the sugar is formed in the stomach or its auxiliary organs. The experiments, however, of Drs. Wollaston and Marcet, and since of Nicholas, Sory, Thénard, and Bostock, all prove that "there is no trace whatever of sugar in the blood."

The second hypothesis was started by Dr. Willis, who says, "Diabetes is rather an immediate affection of the blood than of the kidneys, and thence derives its origin; for the mass of blood becomes, so to speak, melted down, and is too copiously dissolved into a state of serosity; which is sufficiently manifest from the prodigious increase of the quantity of urine, which cannot arise from any other cause than from the solution and waste of blood." Of this opinion was also Sydenham, and Place of Göttingen, and, of later date, Dr. Latham, who contends that the sugar, in respect to its elements, may exist in the blood, though the substance itself be not discoverable in it, being "so weakly and loosely oxygenated as to be again readily evolved by the secretory action of the kidneys, not from any fault in the kidneys themselves, but from the regular and natural exercise of their function, in separating from the imperfect blood such matters as are not properly combined with it."

Dr. Charles Darwin, a very acute and ingenious physiologist, brought forward the third hypothesis, which never had any support but from his father, the author of Zoonomia.

The fourth opinion places the disease in the kidneys, which were supposed, by the Greek writers, to be in a state of great relaxation and debility, and hence also of great irritability. To this irritability was ascribed their morbid activity, and the accumulation of blood with which they were overloaded; while their weakened and relaxed condition allowed the serous or more liquid parts of the blood to pass off through the patulous mouths of the excretories without restraint or change, and, consequently, in a crude and inelaborated form. Such was the explanation of Galen; and, of all the hypotheses, there is no one that seems to have been so generally received. It has been adopted by Bonet, Ruysch, Cullen, Cruickshank, Richter, Nicholas, Gueudeville, Dupuytren, Thénard, Satterly, &c.; several of whom, however, conceive the stomach or some other chylifactive organ to be affected at the same time, secondarily or sympathetically. Some of these writers regard the irritation of the kidneys as connected with inflammation, though several of them ascribe it to a spasm.

The formation of the saccharine matter, concerning which there has been much unsatisfactory discussion, is very generally believed to depend on a process in the stomach and bowels, somewhat analogous to fermentation, on materials which contain the principles of sugar, which are separated from their hidden form in the blood by a peculiar action of the kidneys, very different from all those which constitute the other forms of diabetes.

In the treatment of diabetes, we are led to that of the insipid species first, and then that of the mellitic.

1. Of the *insipid species.* This is mostly cured by tonics, stimulants, and mineral acids, as Peruvian bark, cascarilla, cortex quercûs, and the like, with sulphuric acid, taking care to invigorate the system by proper air, exercise, and diet. When symptomatic of any other disease, its remedies must also be conjoined. As a sympathetic affection, it very commonly attends hysteric and nervous diseases, against which the practitioner's attention must also be directed.

2. Of the *mellitic diabetes.* This is one of those affections in which almost every medicine and every plan has been resorted to, from which it is natural to infer that it is very little under the control of any. The indication of cure is,

To destroy that condition of the stomach and chylopoietic bowels, which permits the arrangement of the elements of sugar into those combinations that are received into the blood, and separated from it by the mellitic action of the kidneys.

To effect this, the following variety of plans and medicines have been adopted : —

1. To invigorate the debilitated organs, and give firmness and coagulability to the blood. The Greek physicians, and after them our countrymen Willis and Sydenham, held this always in view, and gave agglutinants and astringents, with a diet easy of digestion, and consisting of animal and vegetable substances, with wine; and this plan was generally followed until very lately. The warm gums and resins, bitters, and astringents, especially alum and alum whey, were then selected, and the cantharis; but these, like the former, mostly disappointed both patients and physicians.

2. The next mode of endeavouring to fulfil the leading indication was directing remedies and a diet, which the least favoured saccharine fermentation; and these were most of the medicines recommended for the cure of dyspepsia, and confining the patient to an animal diet, and enforcing an entire abstinence from every species of vegetable matter. To assist this, hepatised ammonia was given internally by Dr. Rollo, and phosphoric acid by Dr. Latham. The first was exhibited with a view of adding to the animal salts, which were thought deficient; and the latter, because in many cases there was an evident deficiency in the supply of phosphate of lime to the body.

3. To destroy the irritable, and, as some have imagined, the chronic inflammatory state of the kidneys, recourse has been had to copious and repeated bleedings. This practice is only justifiable in young persons with constitutions unimpaired, where there are no evidences of even a tendency to dropsy, much less when that disease is established in any part. In a few instances, under such circumstances, this plan has been successful.

4. Powerful narcotics, repeated in quick succession. Dover's powder has generally been given in preference to others; but the nauseating or sudorific power, in the doses which are resorted to, have induced those who selected narcotics to prefer pure opium, a grain two or three times a day, gradually and cautiously increased to three and four grains, twice a day. This plan, like the rest, has often failed.

It appears, from what has been said, that as the disease exists in different constitutions, it also requires different treatment.

Diaboli intestina. See *Cuscuta.*

Dia'bolus metallo'rum. A name given by the old chemists to tin, on account of the supposed intractability of its oxides.

DIABO'TANUM. (*um*, *i.* n. ; from δια, and βοτανη, an herb.) A plaster composed of a great number of herbs, used by the Greek physicians as a resolvent, suppurative, &c.

Diabro'sis. (From δια, and βρωσκω, to eat.) Erosion.

Diabro'tica. (Same etymon.) *Diabrotic.* Medicines which erode the parts to which they are applied. Some make diabrotics intermediate between escharotics and caustics.

Diaca'dmias. (From δια, and καδμια, cadmia.) A plaster, the basis of which was cadmia. — *Scribonius Largus.*

Diacalami'nthes. (From δια, and καλαμινθη, calamint.) An antidote, the chief ingredient in which was calamint. — *N. Myrepsus.*

Diaca'rcinon. (Δια καρκινων ; from δια, and καρκινος, a crab.) An antidote prepared from the flesh of crabs. It was used against the bite of a mad dog.

Diaca'ryon. (From δια, and καρυον, a nut.) Rob of nuts.

Diaca'ssia. (From δια, and κασσια, cassia.) Electuary of cassia.

Diacasto'rium. (From δια, and καστωρ, castor.) A compound medicine, the basis of which is castor. Two medicines bearing this name are mentioned by N. Myrepsus.

DIACATHO'LICON. (From δια, and καθολικος, universal.) A laxative electuary, so called from its general usefulness. It was composed of senna leaves, pulp of cassia and of tamarinds, root of male fern and of rhubarb, violets, aniseed, liquorice root, sweet fennel, and sugar.

Diacau'stic. (From διακαυω, to burn.) Applied to a double convex lens, or burning glass. Such lenses have been used to cauterize parts.

Diaceltatesson. *Diatessadelton.* Terms used by Paracelsus and his followers. They appear to have meant some emetic preparation of mercury, or the vomiting excited by such preparation.

Diacentau'rium. (From δια, and κενταυριον, centaury.) The Duke of Portland's powder was so called, because centaury was one of its ingredients.

Diace'raton. (From δια, and κερας, a horn.) A collyrium mentioned by Celsus, of which hartshorn was the principal ingredient.

Diachalci'teos. (From δια, and χαλκιτις, chalcitis.) A plaster, the chief ingredient in which was chalcitis, or colcothar.

Diachari'sta. (From δια, and χριω, to anoint.) The epithet of certain medicines which were applied to the fauces, palate, tongue, &c. — *Paulus Ægineta.*

Diachelido'nium. (From δια, and χελιδων, a swallow.) A Greek medicine, of which burnt swallows were an ingredient.

Diachore'ma. (Διαχωρημα ; from διαχωρεω, to separate from.) *Diachoresis.* Any excretion, or excrement, but chiefly that by stool.

Diachore'sis. Διαχωρησις. See *Diachorema.*

Diachry'sum. (From δια, and χρυσος, gold.) A plaster for fractured limbs, so named from its yellow colour.

DIA'CHYLON. (Διαχυλων ; from δια, and χυλος, juice.) This name was given by the Greeks to an emollient plaster, composed of the juices of herbs. In modern pharmacy two diachylon plasters are known, one as *white*, or *simple diachylon*, the other as *yellow diachylon*, or *diachylon with gums.* See *Diachylon simplex*, and *Diachylon cum gummi.*

Diachylon cum gummi. Yellow diachylon. Gum diachylon. This is made with simple diachylon, ℔ij., galbanum strained, ℥viij., common turpentine, frankincense, each, ℥iij.

Diachylon simplex. The plaster known by this name in the older dispensatories was the

emplastrum plumbi of the present day, with the addition of vegetable matters, as linseed, marshmallow, cornflag, &c., which varied according to different formulæ. In this country the *emplastrum plumbi* is universally substituted for it. See *Emplastrum plumbi*.

DIACINE'MA. (From δια, and κινεω, to move.) A subluxation.

DIACINNAMO'MUM. An antidote mentioned by N. Myrepsus.

DIACI'SSUM. (From δια, and κισσος, ivy.) An application containing ivy leaves.

DIACLY'SMA. (From διακλυζω, to wash out.) A gargle or wash for the mouth.

DIACOCCYME'LON. (From δια, and κοκκυμηλον, a prune.) An electuary made of prunes.

DIACO'DIUM. (From δια, and κωδια, poppy head.) Syrup of poppies.

DIACOLOCY'NTHIS. (From δια, and κολοκυνθις, the colocynth.) A preparation, the chief ingredient of which was colocynth.

DIA'COPE. (From διακοπτω, to cut through.) A deep cut or wound.

DIACOPRÆ'GIA. (From δια, κοπρος, dung, and αιξ, a goat.) A medicine prepared with goat's dung, and used against diseases of the spleen and swellings of the parotid gland. — *Blancard.*

DIACORONOPODIUM. A Greek antidote, of which the coronopus was the base.

DIA'CORUM. A confection, prepared with the acorus, or sweet flag, recommended by Mesue.

DIA'CRISIS. (*is, is.* f.; from διακρινω, to distinguish.) The distinguishing of diseases one from another by their symptoms. See *Diagnosis.*

DIACRO'CIUM. An electuary mentioned by Plater.

DIACURCU'MA. (From δια, and κυρκουμα, turmeric.) An antidote which contained turmeric.

DIACYDO'NIUM. (From δια, and κυδωνια, a quince.) Marmalade of quinces.

DIADAPHNI'DION. (From δια, and δαφνη, the laurel tree.) A drawing plaster, in which were bay berries.

DIADE'LPHIA. (*a, æ.* f.; from δις, twice, and αδελφις, a brotherhood: two brotherhoods.) The name of a class in the sexual system of plants, embracing those the flowers of which are hermaphrodite, and have the male organs united below into two sets of cylindrical filaments.

DIADE'MA. (*a, atis.* n. διαδημα; from διαδεω, to surround.) A diadem. A bandage for the head was so called, which was used in cases of headach, supposed to arise from relaxation of the sutures. — *Forest.*

DIADE'XIS. (From διαδεχομαι, to transfer.) *Diadoche.* A translation of humours from one place to another.

Dia'doche. See *Diadexis.*

DIA'DOSIS. (From διαδοσις.) 1. The distribution of nutritious matter throughout the system.

2. The remission or cessation of a disease.

DIÆ'RESIS. (*is, is.* f.; from διαιρεω, to divide or separate.) A solution of continuity, as a wound or ulcer.

DIÆRE'TICUS. From διαιρεω, to divide.) Escharotic. Corrosive.

DIÆ'TA. (*a, æ.* f.; from διαιταω, to nourish.) Diet; food. See *Diet*, and *Aliment.*

Diætetic. See *Dietetic.*

DIAGLAU'CIUM. (From δια, and the herb γλαυκιον.) An eye-water in which the juice of the *glaucium* was an ingredient.

DIAGNO'SIS. (*is, is.* f.; from διαγινωσκω, to discern or distinguish.) *Diacrisis.* The art of recognising a disease by its symptoms, and of distinguishing one disease from another.

Diagry'dium. See *Dacrydium.*

DIAHERMODA'CTYLUM. (From δια, and ἑρμοδακτυλος, the hermodactyl.) A purging medicine, the basis of which was the hermodactyl.

DIAI'REOS. (From δια, and ιρις, the iris.) An antidote in which the iris was an ingredient.

DIAI'UM. (From δια, and ιον, a violet.) A troche, the chief ingredient of which was violets.

DIALAGO'UM. (From δια, and λαγως, a hare.) A medicine in which was the dung of a hare. It was thought deobstruent.

DIALEI'MMA. (Διαλειμμα; from διαλειπω, to intermit.) The intermission of a fever.

DIALI'BANUM. (From δια, and λιβανον, frankincense.) A medicine in which frankincense was a chief ingredient.

DIA'LOES. (From δια, and αλοη, the aloe.) A name given by the ancients to several medicines, in which aloes were a principal ingredient.

DIALTHÆ'A. (From δια, and αλθαια, the marsh-mallow.) An ointment composed chiefly of marsh-mallows.

DIA'LYSES. (The plural of *dialysis.*) The name of an order in the class *Locales* of Cullen's Nosology, embracing diseases in which there is solution of continuity manifest to the eye or touch.

DIA'LYSIS. (*is, is.* f.; from διαλυω, to dissolve.) Relaxation or weakness of the limbs.

DIAMARGARI'TON. (From δια, and μαργαριτης, a pearl.) An antidote in which pearls were the chief ingredient. — *N. Myrepsus.*

DIAMASSE'MA. (*a, æ.* f.; from διαμασσαομαι, to chew.) *Diamastema.* A masticatory, or substance put into the mouth, and chewed to excite a discharge of saliva.

DIA'MBAR. The name of a stomachic and cordial medicine, which consisted of amber, musk, various aromatics, and other ingredients. — *N. Myrepsus.*

DIAMI'SYOS. (From δια, and μισυ, misy.) A composition in which misy was an ingredient.

Diamnes. See *Diapne.*

Diamond. See *Adamas.*

DIAMOND-SHAPED. Applied to leaves which resemble the figure of a diamond as painted on cards. See *Leaf.*

DIAMO'RON. (From δια, and μωρον, a mulberry.) A syrup used by the Greeks, made of honey and the juice of mulberries.

DIAMOTO'SIS. (From δια, and μοτος, lint.) The introduction of lint into an ulcer or wound.

DIA'NA. (*a*, *æ*. f.) The moon. A name formerly given to silver from its white shining appearance.

DIANANCA'SMUS. (Διαναγκασμος; from δια, and αναγκαζω, to force.) The reduction of a dislocation.

DIA'NDRIA. (*a*, *æ*. f.; from δις, twice; and ανηρ, a man.) The name of a class in the sexual system, consisting of hermaphrodite plants which have flowers with two stamina.

DIA'NTHUS. (*us*, *i*. m.; from Δις, Διος, Jove, and ανθος, a flower: so called, from the elegance and fragrance of its flower.) The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Digynia*.

DIANTHUS CARYOPHYLLUS. The systematic name of the clove-pink. Clove gilliflower. Clove July flower. *Caryophyllum rubrum*, *Tunica*, *Vetonica*, *Betonica*, *Coronaria*, *Caryophyllus hortensis*. This fragrant plant, *Dianthus —floribus solitariis, squamis calycinis subovatis, brevissimis, corollis crenatis*, of Linnæus, grows wild in several parts of England; but the flowers, which are pharmaceutically employed, are usually produced in gardens: they have a pleasant aromatic smell, somewhat allied to that of clove-spice; their taste is bitterish and sub-astringent. These flowers were formerly in extensive use, but are now merely employed in form of syrup, as a useful and pleasant vehicle for other medicines.

DIAPA'SMA. (*a*, *atis*. n.; from διαπασσω, to sprinkle.) A medicine reduced to powder, and sprinkled over the body, or any part.

DIAPEDE'SIS. (*is*, *is*. f.; from διαπηδαω, to leap through.) The transudation or escape of blood through the coats of a vessel.

DIAPE'NSIA. 1. An ancient name of the sanicle.

2. The name of a genus of plants. Class, *Pentandria*; Order, *Monogynia*.

DIAPE'NTE. (From δια, and πεντε, five.) A medicine composed of five ingredients. It was the same as the *diatessaron*, with the addition of ivory shavings. See *Diatessaron*.

DIA'PHANOUS. (*Diaphanosus*; from δια, through, and φαινω, to shine.) Transparent: applied to any substance which is transparent; as the hyaloid membrane covering the vitreous humour of the eye, which is as transparent as glass.

DIAPHŒ'NICUM. (From δια, and φοινιξ, a date.) The name of a plaster, and also of an electuary containing dates.

DIA'PHORE'SIS. (*is*, *is*. f.; from διαφορεω, to carry through.) A perspiration.

DIAPHORE'TIC. (*Diaphoreticus*; from διαφορεω, to carry through.) That which, from being taken internally, increases the discharge by the skin. When this is carried so far as to be condensed on the surface, it forms sweat; and the medicine producing it is named sudorific. Between diaphoretic and sudorific there is no distinction; the operation is in both cases the same, and differs only in degree from augmentation of dose, or employment of assistant means. This class of medicines comprehends five orders: —

1. *Pungent diaphoretics*; as the *volatile salts*, and *essential oils*, which are well adapted for the aged; those in whose system there is little sensibility; those who are difficultly affected by other diaphoretics; and those whose stomachs will not bear large doses of medicines.

2. *Calefacient diaphoretics*; such as *serpentaria contrayerva*, and *guaiacum*: these are given in cases where the circulation is low and languid.

3. *Stimulant diaphoretics*; as antimonial and mercurial preparations, which are best fitted for the vigorous and plethoric.

4. *Antispasmodic diaphoretics*; as *opium*, *musk*, and *camphire*, which are given to produce a diaphoresis, when the momentum of the blood is increased.

5. *Diluent diaphoretics*; as water, whey, &c. which are best calculated for that habit in which a predisposition to sweating is wanted, and in which no diaphoresis takes place, although there be evident causes to produce it.

Diaphoretic antimony. See *Antimonium diaphoreticum*.

Diaphoreticum joviale. See *Antihecticum poterii*.

DIAPHORETIC, MINERAL. The diaphoretic antimony. See *Antimonium diaphoreticum*.

Diaphoreticum martiale. See *Antimonium diaphoreticum martiale*.

DI'APHRAGM. (*Diaphragma*, *matis*. n.; from διαφρασσω, to separate by a partition.) *Phrenes*. *Septum transversum*. The midriff or diaphragm. A muscle that divides the thorax from the abdomen. It is composed of two muscles: the first and superior of these arises from the sternum, and the ends of the last ribs on each side. Its fibres, from this semicircular origination, tend towards their centre, and terminate in a tendon, or aponeurosis, which is termed the *centrum tendinosum*; and was called by the old anatomists, *centrum nerveum*. The second and inferior muscle comes from the vertebræ of the loins by two productions, of which that on the right side comes from the first, second, and third vertebræ of the loins; that on the left side is somewhat shorter; and both these portions join and make the lower part of the diaphragm, which joins its tendons with the tendon of the other, so that they make but one muscular partition. It is covered by the pleura on its upper side, and by the peritonæum on the lower side. It is pierced in the middle for the passage of the vena cava; in its lower part for the œsophagus, and the nerves, which go to the upper orifice of the stomach, and betwixt the productions of the inferior muscle, passes the aorta, the thoracic duct, and the vena azygos. It receives arteries and veins called phrenic or diaphragmatic, from the cava and aorta; and sometimes on its lower part two branches from the vena adiposa, and two arteries from the lumbares. It has two nerves which come from the third vertebra of the neck, which pass through the cavity of the thorax, and are lost in its substance. In its natural situation, the diaphragm is convex on the upper side towards the breast, and concave on its lower side towards the belly; therefore when its fibres swell and contract, it must become plain on each side, and consequently

the cavity of the chest is enlarged to give liberty to the lungs to receive air in inspiration; and the stomach and intestines are pressed for the distribution of their contents: hence the use of this muscle is very considerable: it is the principal agent in respiration, particularly in inspiration; for, when it is in action, the cavity of the thorax is enlarged, especially at the sides, where the lungs are chiefly situated; and as the lungs must always be contiguous to the inside of the thorax, and upper side of the diaphragm, the air rushes into them, in order to fill up the increased space. In expiration, it is relaxed and pushed up by the pressure of the abdominal muscles upon the viscera of the abdomen; and at the same time that they press it upwards, they pull down the ribs, by which the cavity of the thorax is diminished, and the air suddenly pushed out of the lungs.

DIAPHRAGMA'TIC. *Diaphragmaticus.* Appertaining to the diaphragm.

DIAPHRAGMATIC ARTERIES. *Arteriæ diaphragmaticæ. Arteriæ phrenicæ.* The diaphragm is supplied by four arteries: two superior, rising from the internal mammary artery, and distributed on the thoracic surface of the diaphragm; and two inferior rising from the abdominal aorta, or from the cœliac, and distributed to the abdominal surface of the diaphragm.

Diaphragmatic nerves. See *Phrenic nerves.*

DIAPHRAGMATIC VEINS. Four veins corresponding with the diaphragmatic arteries. They pour their blood into the vena cava above and below the diaphragm.

DIAPHRAGMATI'TIS. (From διαφραγμα, the diaphragm.) Inflammation of the diaphragm, which being formed of a large, flat, and strong muscle, covered above by the pleura, and below by the peritonæum, must be subject to inflammation of its upper and under membranes, and also to inflammation of its muscular structure, analogous to that of muscles in other parts. Inflammation beginning in, or being communicated to, the pleural covering must come under pleuritis; and so inflammation commencing in, or being communicated to, the peritonæum belongs to peritonitis; and in both these cases the inflammation dips into the cellular connecting tissue, and perhaps into the muscular or tendinous structure, and causes the same train of symptoms with those which result from an idiopathic inflammation of the muscular structure, which may, in like manner, extend into the investing membranes. The author does not recollect ever to have dissected a case of diaphragmatitis, in which the inflammation was evidently confined to the muscular structure, or appeared primarily to commence in it: whereas the *post mortem* examinations of those who died under diaphragmatitis, discovered extensive inflammation of either the pleura or peritonæum.

When the disease begins in the pleura over the diaphragm, or is communicated to it from the pleura near to it, the symptoms are very like to those of pleurisy, except that the pain is felt deeply seated between the sides, back, and stomach. There is a degree of fever commensurate with the extent of the inflammation and the state of the system. It is mostly violent; more so than when caused by inflammation of the costal pleura; the exacerbations are stronger. Some patents have cough, and there is a delirium of the low muttering kind. The breathing is always interrupted; the inspiration short of its natural depth; and, as the fever increases, the delirium becomes more violent; more like to that which inflammation of the brain produces: and hence the disease has been often called *paraphrenitis.* There is also frequently that spasmodic retraction of the angles of the mouth which is called *risus sardonicus.* The cough, difficult respiration, and delirium, continue as long as the inflammation exists purely as such; and the symptoms change as it may be resolved, or end in the formation and collection of a fluid in the cavity of the pleura, or by the fever being so violent as to kill.

When the peritonæum of the diaphragm is the seat of the inflammation, whether it commences there, or is communicated to it from other parts, the symptoms are nearly the same; for the diaphragm being the principal organ of respiration, the same interruption to its functions takes place, whether the disease is on its upper or lower surface; the fever is more violent than that from peritonitis elsewhere; there is difficult respiration, perhaps cough, and delirium takes place, as in inflammation of the pleural covering of the diaphragm. This delirium, which has been stated to be at first of the low, muttering kind, and becoming more violent, so as to simulate phrenitis, is supposed to be caused by the irritation that takes place in the phrenic nerve. The symptoms of inflammation of the diaphragm from the peritonæum, like those of the pleural disease, may depart, under a resolution of the inflammation; or they may vary from adhesions forming, or from the effusion of a fluid, or from the violence of the fever destroying life.

The treatment is the same with that of pleuritis and peritonitis; but the disease existing in a part, the office of which is so directly connected with an important and vital function, calls for the more prompt exhibition of the most active remedies. The lancet must be called for immediately, and large quantities of blood abstracted. After having cleared the bowels by a mercurial and saline purgative, full doses of antimonials, with submuriate of mercury, warm bath, and blisters, are the best remedies. As a symptomatic affection, diaphragmatitis results from pneumonia, carditis, hepatitis, and splenitis, and requires the same remedies with the primary disease.

Inflammation in the muscular structure of the diaphragm, or the true diaphragmatitis, produces the same symptoms, with the exception of the nature and seat of the pain. It exists chiefly as a secondary disease: being often produced by the retrocession of gout or rheumatism from the limbs. It is a most violent and dangerous affection, and often kills in a short time.

DIA'PHTHORA. (Διαφθορα; from διαφθειρω, to corrupt.) 1. The corruption of any part.

2. Abortion.

DIAPHYLA'CTICUS. (From διαφυλαττω, to preserve.) This term has been used in the same sense as *prophylactic.*

DIA'PHYSIS. (Διαφυσις; from διαφυω, to divide.) An interspace. In medical language the term has been applied,

1. By Ambrose Paré to a ligament of the knee joint; apparently what we call the crucial ligaments.

2. To the shaft of a long bone, to which the epiphyses are attached at each end.

DIAPISSELÆ'UM. (From δια, and πισσελαιον, the oil of pitch.) A medicine prepared with oil of pitch. — *Marcellus Empiricus.*

DIA'PLASIS. (From διαπλασσω, to form or shape.) The replacing a luxated or fractured bone in its proper situation.

DIAPLA'SMA. (*a, atis.* n.; from διαπλασσω, to anoint.) An unction or fomentation applied to the whole body or any part.

DIA'PNE. *Diamnes.* Some writers of barbarous Latin have used these terms to signify an involuntary discharge of urine.

DIA'PNOE. (From διαπνεω, to breathe through.) A gentle perspiration or breathing moisture on the skin.

Dia'pnoic. (*Diapnoticus*, or *diapnoicus*; from διαπνεω, to transpire.) Applied to a medicine which promotes gentle perspiration.

DIAPRA'SIUM. (From δια, and πρασιον, horehound.) A composition in which horehound was an ingredient.

DIAPRU'NUM. (From δια, and προυνη, a prune.) An electuary of prunes.

DIAPTE'RNES. (From δις, and πτερνα, the heel.) An old composition made from cow heels and cheese.

DIAPYE'MA. (From δια, and πυον, pus.) Suppuration.

DIAPYE'TICUS. (From διαπυημα, a suppuration.) Applied to a medicine which promotes suppuration.

DIA'RIUS. (From *dies*, a day.) Diary. Of one day's duration. Ephemeral. Applied to fevers.

DIAROMA'TICUM. (From δια, and αρομα τικον, an aromatic.) A composition of spices.

DIARRHODO'MELI. (From δια, ῥοδον, a rose, and μελι, honey.) A composition of the juice of roses, scammony, agaric, pepper, and honey.

DIA'RRHODON. (From δια, and ῥοδον, a rose.) A name given by the Greeks to several collyra; and by the moderns to several powders and confections of which roses are an ingredient.

DIARRHŒ'A. (*a, æ.* f.; from διαῤῥεω, to flow through.) A purging.

A diarrhœa, purging, or looseness, consists in the too frequently passing the fæces, or contents of the great intestines; preceded generally by a murmuring noise, and a little pain; that little a griping, and without any fever. It is not, like dysentery, a contagious disease. The proximate cause is an increased peristaltic action throughout the whole, or a great part, of the intestinal canal; and, as this may be produced by various means, and under different circumstances, it must often stamp a peculiarity in the character of the disorder, and lay a foundation for numerous species.

The peristaltic motion of the intestines may be increased, and, consequently, looseness or diarrhœa occasioned,

1. By irritating materials thrown into them by the mouth.

2. By a morbid change in the fluids which are naturally secreted into the intestinal canal.

3. By an irritable state of the intestines themselves, or the membrane that lines their inner surface.

4. By the irritation of worms.

Independently of these causes, the peristaltic motion may be increased by the irritation of other diseases in the neighbourhod, as abscesses; by the readiness with which the intestines associate in the action of remote parts, as sudden passion or commotion of mind, the recession of rashes from the skin, &c.; in which, and many other like instances, the diarrhœa is not idiopathic, but sympathetic, or symptomatic.

The most common of all the species of diarrhœa is that in which the fæces pass of common quality, but immoderately loose and copious. Dr. Cullen calls it *diarrhœa crapulosa*, because it mostly takes place from overloading the stomach; Dr. Good, *diarrhœa fusa*. It generally effects its own cure, without any medicine; for its common causes are food eaten to excess, or intermixed with an undue proportion of irritating materials, saline, saccharine, or vinous, in consequence of which they pass rapidly, and not thoroughly digested, from the stomach, and urge the motion of the intestines to an undue activity: hence often, antecedently to the looseness, there is a sense of sickness, and perhaps a few slight pains; but, if the disorder do not prove its own remedy, it is easily removed by any common purgative. In weak stomachs, or where the intestines are sluggish, this kind of looseness is also occasionally produced by a retardation of the aliment till it irritates from acescency, putrescency, or superabundant accumulation; and where it is not checked in due time, it will occasionally, like several of its cognate species, run into a chronic form, and prove extremely troublesome and obstinate. This species is also produced occasionally by sudden exposure to cold, and especially by cold bathing; by great agitation of mind, and particularly that of fright or anger.

Almost as frequent as the former species, is the *bilious diarrhœa*, in which the fæces are loose, copious, and of a bright yellow colour. From the very bilious state of the dejections, there can be no doubt that the bile, in this species, is secreted in a greater quantity than usual, and perhaps with an unusual degree of pungency. The most common remote cause of this species of diarrhœa, is a great and sudden increase in the temperature of the atmosphere, or a less than mean degree of heat operating for some time. Dr. Lind has remarked, that a rapid change of climate, whether from a colder to a hotter, or from a hotter to a colder state, is equally apt to excite diarrhœa. But the complaints hereby produced are of very different characters: that occasioned by sudden cold, consists of an acrid mucous discharge; the diarrhœa excited by passing rapidly from a cold into a hot climate, depends upon an increased secretion of bile, in many cases worked up to a higher degree of acrimony. The calorific

rays of the sun exercise a peculiar influence upon the liver, and soon stimulate it to an augmented action. In the intertropical regions, the quantity of bile hereby secerned is even more than the bile ducts can conveniently carry off; whence some portion of it retrogrades, and is carried by absorption into the system, and is one of the causes, though not the only cause, of the darker hue of the skin in those quarters. In our own country, this species of purging is, therefore, found most commonly in the earlier part of the summer, when suddenly and vehemently bursting upon a cold spring; or in the autumn, when the liver has for many weeks been exposed to the effects of a very ardent sun, and the whole system has become relaxed and debilitated. If at this time the atmosphere be pure, the disease is simple, and may be subdued without much difficulty by a few doses of the submuriate of mercury, given with a view of emulging the bilious pores of the liver, correcting the irritation of the organ, and subduing its increased action, with the assistance of mild diluents and demulcents, as infusions of linseed, quince seeds, tragacanth, and acacia, with mild bitter infusions. If the diarrhœa do not give way under these, and light glutinous broths, with arrow-root and the like, for the diet, opiates may be employed with advantage.

Another species of diarrhœa consists in the dejections containing a quantity of mucus. It bears a striking resemblance to the defluxion from the nostrils in catarrh, and has been denominated *catarrhus intestinorum*, and *diarrhœa catarrhalis*. It has hitherto been described as a species of diarrhœa, though it more properly belongs to dysentery. Its common cause is cold, particularly in the feet, acting upon the mucous follicles of the bowels, which are predisposed to take on a peculiar morbid action. Purging here is highly injurious. The best plan is warmth to the surface of the body, by the occasional use of a warm bath, pediluvium, and fomentations to the bowels; the internal administration of saline medicines, with Dover's powders, and afterwards astringents, with light bitters. Opiates at bed-time are very serviceable. The diet should consist of glutinous broths, arrow-root, dilute brandy, and light animal food.

A looseness consists sometimes of white, milky, or what have been called chylous stools. The colour of the dejections in this species, affords evident proof that the bile, which gives the usual tinge to the fæces, is either not secreted, or impeded in its flow into the intestines; it has also been supposed that the chyle is not duly absorbed and carried into the system. This singular and not common disease has been described as the *affectio* or *passio cœliaca*, and *diarrhœa cœliaca*. On the presumption that the white discharge is owing to the presence of chyle, and that none is absorbed, it has been concluded that the disease is the consequence of some cause preventing the absorption of chyle, especially an inertness or torpitude of the absorbents, or some disease of the mesenteric glands; but it is very likely that we are not yet in possession of the real cause, and that the disease is symptomatic of some other.

There is another kind of looseness, in which the food passes rapidly through the primæ viæ, without having been digested, and in the same state nearly as it was received into the stomach. It is described in ancient writings by the name of *lienteria*, or lubricity of the intestines. The causes of this disease, besides the increased peristaltic movement, are to be sought after in the stomach also, the digestive power of which is not brought into action, owing either to a deficiency of gastric juice, or a want of power to retain the food which it receives. The bile also, as in the cœliac species, is either deficient, or secreted of such a quality as not to impart a proper colour to the contents of the bowels, nor to perfect the separation of the chyle from the chyme if chymification had taken place. This *diarrhœa lienteria* is far from common, and is mostly an affection symptomatic of gout, scirrhus, or some organic disease. As a genuine diarrhœa, its cure is to be attempted by tonics, bitters, and the remedies recommended against indigestion, to which disease it is nearly allied.

The *diarrhœa serosa*, which is also called *diarrhœa aquosa*, is that species in which the dejections are watery, almost entirely liquid and limpid. In some cases, the serous discharge resembles the washings of flesh, and it has been supposed to proceed from the liver; on which account it has been called a hepatirrhœa, or hepatic flux. The purging is here dependent upon a very irritable and relaxed state of the excretory vessels of the intestines. The disease occurs mostly to the leucophlegmatic and weak. Its cure is to be attempted by warm cordials, with astringents and tonics, as gentian, calumba, simarouba, orange peel, with the peppers, and warm tinctures.

When a loose state of the bowels is caused by worms, *diarrhœa verminosa*, which is sometimes the case with ascarides, their presence and irritation in the rectum establish the species; and the cure is to be effected by vermifuges.

From what has been advanced, it is evident that, in conducting the cure of a diarrhœa, the objects are to obviate the several causes, to lessen the inordinate peristaltic motion, and to give tone to the intestines. To fulfil these, it has been usual to exhibit emetics, purgatives, and astringents, according to the circumstances of the case. Emetics are very seldom serviceable, unless in strong subjects, with a loaded stomach; in which case an emetic may at first be useful in speedily removing its contents: it may also assist in emulging the ducts of the liver, and determining to the skin; but its secondary operation is that of weakening, and ought, therefore, to be resorted to with great caution. Cathartics are serviceable in expelling worms, or indurated or acrimonious fæces; but any acrimony in the intestine generally causes its own discharge; and where there is much irritability, they aggravate the disease: however, in protracted cases, the alvine contents speedily become vitiated, and renew the irritation; which may be best obviated by an occasional mild aperient, particularly rhubarb. If the liver do not perform its office, the intestine will hardly recover its healthy condition; and

that may most probably be effected by the cautious use of mercury. Likewise, articles which determine the fluids to other outlets, diuretics, and particularly diaphoretics, in many cases contribute materially to recovery; the latter, perhaps, assisted by bathing, warm clothing, gentle exercise, &c. Diluent, demulcent, and antacid medicines are employed to correct acrimony, according to its particular nature. In children teething, the gums should be lanced; and if the bowels have been attacked on the repulsion of some other disease, it may often be proper to endeavour to restore this. But a matter of the greatest importance is the due regulation of the diet, carefully avoiding those articles which are likely to disagree with or irritate the bowels, and preferring such as have a mild astringent effect. Food the least acescent, as rice, arrow-root, tapioca, sago, bread, &c., are best; and, for the drink, sherry or brandy, sufficiently diluted, rather than malt liquors.

Some of the means already noticed will help to moderate the excessive peristaltic movement, as a wholesome diet, exercise, diaphoretics, &c.: but there are others of more power, which must sometimes be resorted to. At the head of these is opium, a full dose of which frequently at once effects a cure; but where there is some more fixed cause, and the complaint of any standing, moderate quantities, repeated at proper intervals, will answer better, and other subsidiary means ought not to be neglected: aromatics may prevent its disordering the stomach, rhubarb obviate its causing permanent constipation, &c. Tonics are generally proper, the discharge itself inducing debility; and, where there is a deficiency of bile particularly, the lighter forms of the aromatic bitters will materially assist. In protracted cases, mild chalybeates are sometimes serviceable; astringents come in aid of the general plan, and, where opium disagrees, they may be more necessary; but the milder ones should be employed at first, the more powerful only where the patient appears sinking. Chalk and limewater answer best where there is acidity; otherwise the pomegranate, logwood, catechu, kino, tormentil, &c. may be given; where these fail, galls, alum, or sulphate of zinc.

Diarrhœa carnosa. A form of dysentery, in which flesh-like portions are eliminated.

Diarrhœa cholerica. A bilious diarrhœa.

Diarrhœa chylosa. The ileac passion has been so called.

Diarrhœa urinosa. See *Diabetes.*

Diarthro'dial. Relating to diarthrosis. (See *Diarthrosis.*) The cartilages covering the articular extremities of bones are called *Diarthrodial cartilages.*

DIARTHRO'SIS. (*is, is.* f.; from διαρθροω, to articulate.) A moveable connexion of bones. It is divided into five species, viz. *enarthrosis, arthrodia, ginglymus, trochoides,* and *amphiarthrosis.*

Diasapo'nium. (From δια, and σαπων, soap.) An ointment in which soap was the principal ingredient.

Diasaty'rium. (From δια, and σατυριον, the orchis.) An electuary made principally of the orchis root. — *N. Myrepsus.*

Diasci'llium. (From δια, and σκιλλα, the squill.) Oxymel and vinegar of squills.

Diasci'ncus. (From δια, and σκιγκος, a kind of lizard.) A name for the mithridate, in the composition of which there was a part of the lizard called *scincus.*

DIASCO'RDIUM. (From δια, and σκορδιον, the water germander.) *Confectio Fracastorii.* Electuary of scordium. This electuary was first introduced into practice by Hieronymus Fracastorius, whose name it generally bore. It was composed of cinnamon, cassia lignea, each half an ounce; scordium, an ounce; dittany of Crete, tormentil, bistort, galbanum, gum arabic, of each half an ounce; storax, four drachms and a half; opium, seeds of sorrel, each a drachm and a half; gentian, half an ounce; Armenian bole, an ounce and a half; Lemnian earth, half an ounce; long pepper, ginger, of each two drachms; clarified honey, two pounds and a half; sugar of roses, one pound; Canary wine, eight ounces. It is cordial and astringent, and was formerly much used in dysentery. The dose for an adult is from ℈j. to ʒij.

Diase'na. (From δια, and *sena.*) An electuary of senna.

Diase'ricos. (From δια, and σηρικος, silk.) The name of a Greek medicine in which silk was an ingredient.

Diasmy'rnum. (From δια, and σμυρνη, myrrh.) *Diasmyrnes.* A wash for the eyes which contained myrrh.

Diaso'stica. (From διασωζω, to preserve.) *Diasostics.* This word has been used by some synonymously with *hygiene,* or that branch of medicine which relates to the preservation of health.

Diaso'sticus. (Same etymon.) 1. Applied to that which preserves health.

2. It has been used synonymously with prophylactic.

Diaspe'rmaton. (Δια σπερματων; from δια, and σπερμα, seed.) Two kinds of cataplasms, composed chiefly of seeds, were anciently so called.

Diasphy'xis. (From δια, and σφυζω, to strike.) The pulsation of an artery. — *Aretæus.*

DIA'STASIS. (*is, eos.* f.; from διἵστημι, to separate.) *Diastema.* A separation by disease or violence of bones or cartilages which are naturally connected; as that which occasionally happens to the bones of the cranium in some cases of hydrocephalus.

Diaste'aton. (From δια, and στεαρ, fat.) An ointment made of the fat of the stag, hog, goose, and hen. — *Marcellus Empiricus.*

Diaste'ma. (*a, atis.* n.) See *Diastasis.*

DIA'STOLE. (*e, es.* f.; from διαστελλω, to separate.) The dilatation of the heart and arteries. See *Circulation.*

Diastomo'tris. (Διαστομωτρις; from διαστομοω, to dilate.) Any dilating instrument, as a *speculum ani.*

Diastre'mma. (From διαστρεφω, to turn aside.) *Diastrophe.* A distortion of any part.

Dia'strophe. See *Diastremma.*

DIASU'LPHURIS. The epithet of several medicines containing sulphur, used by the old chemical physicians. We read of a *Balsamum diasulphuris,* an *Emplastrum diasulphuris,* and a *Tinctura diasulphuris.*

DIATA'RTARI. The name of a purgative powder, of which cream of tartar was the basis.

DIA'TASIS. (From διατεινω, to distend.) The extension of a fractured limb, in order to reduce it.

DIATECO'LITHUM. (From δια, and τηκολιθος, the Jew's stone.) An antidote containing lapis Judiacus.

DIATERE'TICUS. (From διατηρεω, to preserve.) A medicine which preserves health and prevents disease.

Diatessadelton. See *Diacellatesson.*

DIATE'SSARON. (Διατεσσαρων; from δια, and τεσσαρες, four.) 1. A medicine composed of the roots of gentian and aristolochia rotunda, of laurel berries and honey, made into a confection with extract of juniper. It was esteemed by the ancients as an alexipharmic.

2. The name of a plaster mentioned by Galen.

DIATE'TTIGON. (Δια τεττιγων; from δια, and τεττιξ, a grasshopper.) The epithet of a nephritic medicine in the composition of which were grasshoppers. — *Paulus Ægineta.*

DIA'THESIS. (*is, is.* f.; from διατιθημι, to dispose.) A natural predisposition to certain diseases, which is generally hereditary. The most remarkable diatheses are the *scrofulous, gouty, rheumatic, cancerous,* and *calculous.*

DIATRAGACA'NTHUM. (From δια, and τραγακανθα, tragacanth.) A demulcent medicine, composed of tragacanth, gum arabic, starch, sugar, and some other ingredients. The pulvis tragacanthæ compositus of the present pharmacopœia is a simplification of it.

DIATRION PIPEREON. (Το δια τριων πιπερεων.) The epithet of a medicine made of long pepper, white pepper, and black pepper.

DIATRITA'RII. A name given to the methodic physicians from their practising the *diatritos.* See *Diatritos.*

DIA'TRITOS. (From δια, and τρεις, three.) An abstinence during three days was first recommended by the methodic physicians. This period, not the abstinence, was called *diatritos;* and, from this circumstance, the methodics had the name of *diatritarii.* On the third day they gave such medicines as they thought of importance. Cœlius Aurelianus gives this name, not only to the whole period, but to the third day in particular.

DIA'TRIUM. (From δια, and τρεις, three.) A medicine composed of three simple ingredients.

DIATRIUM SANTALORUM. Δια τριων σανταλων αντιδοτος. The epithet of an antidote composed of three kinds of sandal wood, and a number of other ingredients. — *N. Myrepsus.*

DIAVOLETTI. *Diavolini.* An Italian name for lozenges made of cocoa and the most pungent aromatics, to excite venery.

DIAXYLA'LOES. (From δια, and ξυλαλοη, the lignum aloes.) A medicine containing lignum aloes.

DIAZO'MA. (From διαζωννυμι, to surround; because it surrounds the cavity of the thorax.) The diaphragm.

DIAZO'STER. (From διαζωννυμι, to surround; because when the body is girded, the belt usually lies upon it.) The twelfth vertebra of the back.

DIACENTE'TUM. (Διακεντητον; from διακεντεω, to prick.) A pungent wash for the eyes.

DICHA'LCUM. An ancient weight equal to two æreoli.

DICHASTE'RES. (From διχαζω, to divide; because they divide the food.) The incisores, or foreteeth.

DICHOPHY'IA. (From διχα, double, and φυω, to grow.) That condition of the hairs in which they split and grow forked.

DICHO'TOMOUS. (*Dichotomus;* from δις, twice, and τεμνω, to cut: that is, cut in two.) Bifurcate; forked. Applied to stems, styles, &c. which are forked or divided into two parts.

DICOC'CUS. (*us, i.* m.; from δις, and κοκκος, a berry.) Dicoccous: having two capsules united, each with one cell.

DICOTYLE'DONES. (Having two cotyledons.) The plants forming the third great division in Jussieu's Natural Method are so called.

DICOTYLEDONOUS PLANTS. Plants which have two cotyledons.

DICRÆUS. (Δικραιος; from δις, twice, and κραας, a head.) Bifid: cloven.

DICRO'TIC. (*Dicrotus;* from δις, twice, and κρουω, to strike.) Applied to a pulse in which the artery rebounds after striking, so as to convey the sensation of a double pulsation.

DICTAMNI'TES. (From δικταμνος, dittany.) Must fermented with dittany. It was believed to be emmenagogue.

DICTA'MNUS. (*us, i.* m.; from *Dicte,* a mountain of Crete, where the plant grew.) The name of a genus of plants in the Linnæan system. Class, *Decandria;* Order, *Monogynia.* Dittany.

DICTAMNUS ALBUS. White fraxinella, or bastard dittany. *Fraxinella* of the shops. *Dictamnus albus — foliis pinnatis, caule simplici,* of Linnæus. The root of this plant is the part directed for medicinal use; when fresh, it has a moderately strong, not disagreeable smell. Formerly it was much used as a stomachic, tonic, and alexipharmic, and was supposed to be a medicine of much efficacy in removing uterine obstructions and destroying worms; but its medicinal powers became so little regarded by modern physicians, that it had fallen almost entirely into disuse, till Baron Stoerck brought it into notice, by publishing several cases of its success, viz. in tertian intermittents, worms (lumbrici), and menstrual suppressions. In all these cases, he employed the powdered root to the extent of a scruple twice a day. He also made use of a tincture, prepared of two ounces of the fresh root digested in 14 ounces of spirit of wine; of this 20 to 50 drops, two or three times a day, were successfully employed in

epilepsies; and, when joined with steel, this root, we are told, was of great service to chlorotic patients. The dictamnus, undoubtedly, says Dr. Woodville, is a medicine of considerable power; but notwithstanding the account of it given by Stoerck, who seems to have paid little attention to its modus operandi, we may still say with Haller, "*Nondum autem vires pro dignitate exploratus est*," and it is now fallen again into disuse.

Dictamnus Creticus. See *Origanum dictamnus.*

Didymæ'a. Διδυμαια. The name of a malagma or cataplasm mentioned by Galen.

Di'dymi. (Διδυμοι, twins.) The testicles have been so called; because they are two in number, and like each other. The name was also given by the Greek anatomists to the posterior corpora quadrigemina, which are still called *testes.*

Di'dymous. (*Didymus*; διδυμος, double.) Applied, in *Botany*, to the anthers and germens, &c. of flowers, when, upon one filament, there are two anthers united, like a double nut; as in *Ranunculus, Anemone, Galium*, &c.

DIDYNA'MIA. (*a, æ.* f.; from δις, two, and δυναμις, power or predominance.) The name of a class in the sexual system of plants, consisting of those with hermaphrodite flowers which have four stamina, two of which are long and two short.

Didyna'mic. *Didynamicus.* Applied to plants of the Class *Didynamia.*

Diecbo'lium. (From δια, and εκβαλλω, to cast out.) A medicine causing abortion. — *Hippocrates.*

Diele'ctron. (From δια, and ελεκτρον, amber.) The name of a troch, in which amber was an ingredient.

Dierenbach. A city of Bavaria, in the neighbourhood of which are sulphureous, chalybeate, and saline waters.

Diervi'lla. (*a, æ.* f.; named in honour of Mr. Dierville, who first brought it from Arcadia.) See *Lonicera diervilla.*

DIET. *Diæta.* The dietetic part of medicine is no inconsiderable branch, and deserves a much greater share of regard than it commonly meets with. A great variety of diseases might be removed by the observance of a proper diet and regimen, without the assistance of medicine, were it not for the impatience of the sufferers. However, it may on all occasions come in as a proper assistant to the cure, which sometimes cannot be performed without a due observance of the non-naturals. That food is, in general, thought the best and most conducive to long life, which is most simple, pure, and free from irritating qualities, and such as approaches nearest to the nature of our own bodies in a healthy state, or is capable of being easiest converted into their substance by the vis vitæ, after it has been duly prepared by the art of cookery; but the nature, composition, virtues, and uses of particular aliments can never be learned to satisfaction, without the assistance of practical chemistry. See *Aliment.*

DIET DRINK. An alterative decoction employed daily in considerable quantities, at least from a pint to a quart. The decoction of sarsaparilla and merzereon, the Lisbon diet drink, is the most common and most useful.

DIETE'TIC. (*Dieteticus*; from διαιταω, to nourish.) Relating to diet.

Dietetica. See *Dietetics.*

Dietetice. (*e, es.* f.) See *Dietetics.*

DIETETICS. *Dietetica. Dietetice.* That department of medicine which relates to the regulation of diet.

DIEU LE FILT. A large town in the department of Drome, in France. It has chalybeate mineral waters. The water of the spring called St. Louis, is employed successfully as a tonic in diseases of the eyes, and some cutaneous affections. It is said to contain sulphate of iron and alum.

Diffla'tio. (From *difflo*, to blow away.) Transpiration.

DIFFO'RMIS. Irregular in shape; of different shapes.

DIFFUSE. *Diffusus.* Applied, 1. In *Pathology*, to diseases which spread widely, and have no distinctively defined limits as opposed to those which are circumscribed.

2. In *Botany*, to panicles and stems. *Panicula diffusa*, that is lax, and spreading; as in *Saxifraga umbrosa*, the London pride, so common in our gardens; and many grasses, especially the common cultivated oat. The *Bunias kakile*, or sea-rocket, has the *caulis diffusus.*

Diffuse Abscess. See *Abscess.*

Diffuse inflammation of the cellular membrane. This name was given by the late Dr. Andrew Duncan, junior, to the affection before known under the appellation of *phlegmonoid erysipelas.* Dr. Duncan investigated the anatomical and pathological characters of this morbid state more minutely than had previously been done. Diffuse inflammation may occur in the cellular membrane of any part of the body, and may affect either the subcutaneous or the intermuscular and deep seated layers.

Diffused false aneurism. See *Aneurism.*

Diffusible. A term applied to that which is easily dissipated; thus the stimulus of ether is said to be a diffusible stimulus, because it very soon passes off.

DIGA'STRICUS. (From δις, twice, and γαστηρ, a belly: so called from its having two bellies.) *Biventer maxillæ*, of Albinus. A muscle situated externally between the lower jaw and *os hyoides.* It arises, by a fleshy belly, from the upper part of the processus mastoideus; and descending, it contracts into a round tendon, which passes through the stylohyoideus, and an annular ligament which is fastened to the os hyoides; then it grows fleshy again, and ascends towards the middle of the edge of the lower jaw, where it is inserted. Its use is to open the mouth by pulling the lower jaw downwards and backwards; and when the jaws are shut, to raise the larynx, and consequently the pharynx, upwards, as in deglutition.

Di'gerens. (From *digero*, to digest.) Digestive. Applied to medicines which promote the secretion of proper pus in wounds and ulcers: thus we speak of a digestive ointment.

DIGESTER. A strong and tight iron vessel or kettle, furnished with a valve of safety, in

which bodies may be subjected to the vapour of water, alkohol, or ether, at a pressure above that of the atmosphere.

DIGESTION. (*Digestio, onis.* f.; from *digero*, to dissolve.)

I. An operation in *Chemistry*, and *Pharmacy*, in which such matters as are intended to act slowly on each other are exposed to a heat, continued for some time.

II. In *Physiology*, the change that the food undergoes in the stomach, by which it is converted into chyme.

The immediate object of digestion is the formation of chyle, a matter destined for the reparation of the continual waste of the animal economy. The digestive organs contribute also in many other ways to nutrition.

If we judge of the importance of a function by the number and variety of its organs, digestion ought to be placed in the first rank; no other function of the animal economy presents such a complicated apparatus.

There always exists an evident relation between the sort of aliment proper for an animal, and the disposition of its digestive organs. If, by their nature, the aliments are very different from the elements which compose the animal, if, for example, it is graminivorous, the dimensions of the apparatus will be more complicated, and more considerable; if, on the contrary, the animal feeds on flesh, the digestive organs will be fewer and more simple, as is seen in the carnivorous animals. Man, called to use equally animal and vegetable aliments, keeps a mean between the graminivorous and carnivorous animals, as to the disposition and complication of his digestive apparatus, without deserving, on that account, to be called omnivorous.

We may represent the digestive apparatus as a long canal, variously twisted upon itself, wide in certain points, narrow in others, susceptible of contracting or enlarging its dimensions, and into which a great quantity of fluids are poured by means of different ducts. The canal is divided into many parts by anatomists: —

1. The mouth.
2. The pharynx.
3. The œsophagus.
4. The stomach.
5. The small intestines.
6. The great intestines.
7. The anus.

Two membranous layers form the sides of the digestive canal in its whole length. The inner layer, which is intended to be in contact with the aliments, consists of a mucous membrane, the appearance and structure of which vary in every one of the portions of the canal, so that it is not the same in the pharynx as in the mouth, nor is it in the stomach like what it is in the œsophagus, &c. In the lips and the anus this membrane becomes confounded with the skin. The second layer of the sides of the digestive canal is muscular; it is composed of two layers of fibres, one longitudinal, the other circular. The arrangement, the thickness, the nature of the fibres which enter into the composition of these strata, are different, according as they are observed in the mouth, in the œsophagus, or in the large intestine, &c. A great number of blood-vessels go to, or come from, the digestive canal; but the abdominal portion of this canal receives a quantity incomparably greater than the superior parts. This presents only what are necessary for its nutrition, and the inconsiderable secretion of which it is the seat; whilst the number and the volume of the vessels that belong to the abdominal portion show that it must be the agent of a considerable secretion. The chyliferous vessels arise exclusively from the small intestine.

As to the nerves, they are distributed to the digestive canal in an order inverse to that of the vessels; that is, the cephalic parts, *cervical* and *pectoral*, receive a great deal more than the abdominal portion, the stomach excepted, where the two nerves of the eighth pair terminate. The other parts of the canal scarcely receive any branch of the cerebral nerves. The only nerves that are observed, proceed from the *subdiaphragmatic* ganglions of the great sympathetic. We shall see, farther on, the relation that exists between the modes of distribution of the nerves, and the functions of the superior and inferior portions of the digestive canal.

The bodies that pour fluids into the digestive canal, are, —

1. The *digestive mucous membrane*.
2. *Isolated follicles* that are spread in great number in the whole length of this membrane.
3. The *agglomerated follicles* which are found at the isthmus of the throat, between the *pillars* of the *velum* of the palate, and sometimes at the junction of the œsophagus and the stomach.
4. The *mucous glands*, which exist in a greater or less number in the sides of the cheeks, in the roof of the palate, and around the œsophagus.
5. The *parotid*, the *submaxillary*, and *sublingual glands*, which secrete the saliva of the mouth, the liver, and the pancreas; the first of which pours the bile, the second the pancreatic juice, by distinct canals, into the superior part of the small intestine, called duodenum.

All the digestive organs contained in the abdominal cavity are immediately covered, more or less completely, by the serous membrane called the peritonæum. This membrane, by the manner in which it is disposed, and by its physical and vital properties, is very useful in the act of digestion, by preserving to the organs their respective relations, by favouring their changes of volume, by rendering easy the sliding motions which they perform upon each other, and upon the adjoining parts.

The surface of the mucous digestive membrane is always lubricated by a glutinous adhesive matter, more or less abundant, that is seen in greatest quantity where there exist no follicles, — a circumstance which seems to indicate that these are not the only secreting organs. A part of this matter, to which is given generally the name of *mucus*, continually evaporates, so that there exists habitually a certain quantity of vapours in all the points of the digestive canal. The chemical nature of this substance, as taken at the intestinal surface, is still very little known. It is transparent, with a light grey tint; it adheres to the membrane which forms it; its taste is salt, and its acidity is shown by the re-agents: its formation still continues some time after death. That which is formed in the mouth, in the

pharynx, and in the œsophagus, goes into the stomach mixed with the saliva, and the fluids of the mucous glands, by movements of deglutition, which succeed each other at near intervals. According to this detail, it would appear that the stomach ought to contain, after it has been some time empty of aliments, a considerable quantity of a mixture of mucus, of saliva, and follicular fluid. This observation is not proved, at least in the greatest number of individuals. However, in a number of persons, who are evidently in a particular state, there exist, in the morning, in the stomach, many ounces of this mixture. In certain cases it is foamy, slightly troubled, very little viscous, holding suspended some flakes of mucus: its taste is quite acid, not disagreeable, very sensible in the throat, acting upon the teeth, so as to diminish the polish of their surface, and rendering their motion upon each other more difficult. This liquid reddens paper stained with turnsole.

In the same individual, in other circumstances, and with the same appearances as to colour, transparency, and consistency, the liquid of the stomach had no savour, nor any acid property; it is a little salt: the solution of potash, as well as the nitric and sulphuric acids, produced in it no apparent change.

When we examine the dead bodies of persons killed by accident, the stomach not having received any aliments or drink for some time, this organ contains only a very few acid mucosities adhering to the coats of the stomach, part of which, in the pyloric portion of that viscus, appears reduced to chyme. It is, then, very probable, that the liquid which ought to be in the stomach is digested by this viscus, as an alimentary substance, and that this is the reason why it does not accumulate there.

In animals, the organisation of which approaches to that of man, such as dogs and cats, there is no liquid found in the stomach after one, or many, days of complete abstinence; there is seen only a small quantity of viscous mucosity adhering to the sides of the organ, towards its *splenic* extremity. This matter has the greatest analogy, both chemical and physical, with that which is found in the stomach of man. But, if we make these animals swallow a body which is not susceptible of being digested, as a pebble, for example, there forms, after some time, in the cavity of the stomach, a certain quantity of an acid liquid mucus, of a greyish colour, sensibly salt, which, in its composition, is nearly the same as that found sometimes in man.

This liquid, resulting from the mixture of the mucosities of the mouth, of the pharynx, of the œsophagus, and the stomach, with the liquid secreted by the follicles of the same parts and with the saliva, has been called the *gastric juice*, and to which particular properties have been attributed.

In the small intestines there is also formed a great quantity of mucous matter, which rests habitually attached to the sides of the intestine; it differs little from that of which we have spoken above; it is viscid, tough, and has a salt and acid savour; it is renewed with great rapidity. If the mucous membrane of this intestine is laid bare, in a dog, and the layer of mucus absorbed by a sponge, it will appear again in a minute. This observation may be repeated as often as we please, until the intestine becomes inflamed by the contact of the air, and foreign bodies.

The mucus of the stomach penetrates into the cavity of the small intestine only under the form of a pulpy matter, grayish and opake, which has all the appearance of a particular chyme.

It is at the surface of this same portion of the digestive canal that the bile is delivered as well as the liquid secreted by the pancreas. In animals, such as dogs, the flowing of these liquids takes place at intervals; that is, about twice in a minute, there is seen to spring from the orifice of the ductus choledochus, or biliary canal, a drop of bile, which immediately spreads itself uniformly in a sheet upon the surrounding parts, which are already impregnated with it; there is, also, constantly found a certain quantity of bile in the small intestine.

The flowing of the liquid formed by the pancreas takes place much in the same manner, but it is much slower: sometimes a quarter of an hour passes before a drop of this fluid springs from the orifice of the canal which pours it into the intestine.

The different fluids deposited in the small intestine, which are the chymous matter that comes from the stomach, the mucus, the follicular fluid, the bile, and the pancreatic liquid, all mix together; but, on account of its properties, and, perhaps, of its proportions, the bile predominates and gives to the mixture its proper taste and colour. A great part of this mixture descends towards the large intestine, and passes into it; in this passage, it becomes more consistent, and the clear yellow colour which it had before becomes dark, and afterwards greenish. There are, however, in this respect, strong individual differences.

In the large intestine, the mucous and follicular secretion appears less active than in the small intestine; the mixture of fluids which comes from the small intestine acquires in it more consistence; it contracts a fœtid odour, analogous to that of ordinary excrements; it has, besides, the appearance of it, by its colour, odour, &c.

The knowledge of these facts enables us to understand how a person who uses no aliments can continue to produce excrements, and how, in certain diseases, their quantity is very considerable, though the sick person has been long deprived of every alimentary substance, even of a liquid kind. Round the anus exist follicles, which secrete a fatty matter of a singularly powerful odour.

We find gas almost always in the intestinal canal; the stomach contains only very little. The chemical nature of these gases has not yet been examined with care; but as the saliva that we swallow is always more or less impregnated with atmospheric air, it is probably the atmospheric air, more or less changed, which is found in the stomach: at least, it contains carbonic acid. The small intestine contains only a small quantity of gas; it is a mixture of carbonic acid, of azote, and hydrogen. The large in-

testine contains carbonic acid, azote, and hydrogen, sometimes carburetted, sometimes sulphuretted. Twenty-three per cent. of this gas was found in the rectum of an individual, whose large intestine contained no excrement.

The muscular layer of the digestive canal deserves to be remarked, in respect to the different modes of contraction it presents. The lips, the jaws, in most cases the tongue, and the cheeks are moved by a contraction, entirely like that of the muscles of locomotion. The roof of the palate, the pharynx, the œsophagus, and the tongue in certain particular circumstances, offer many motions which have a manifest analogy with muscular contraction, but which are very different from it, because they take place without the participation of the will.

This does not imply that the motions of the parts just named are beyond the influence of the nerves; experience proves directly the contrary. If, for example, the nerves that come to the œsophagus are cut, this tube is deprived of its contractile faculty.

The muscles of the velum of the palate, those of the pharynx, the superior two-thirds of the œsophagus, scarcely contract like digestive organs, but when they act in permitting substances to pass from the mouth into the stomach. The inferior third of the œsophagus presents a phenomenon which is important to be known: this is an alternate motion of contraction and relaxation, which exists in a constant manner. The contraction commences at the union of the *superior two-thirds* of the canal with the *inferior third;* it is continued, with a certain rapidity, to the insertion of the œsophagus into the stomach: when it is once produced, it continues for a time, which is variable; its mean duration is, at least, thirty seconds. Being so contracted in its inferior third, the œsophagus is hard and elastic, like a cord strongly stretched. The relaxation which succeeds the contraction happens all at once, and simultaneously in all the contracted fibres; in certain cases, however, it seems to take place from the superior to the inferior fibres. In the state of relaxation, the œsophagus presents a remarkable flaccidity, which makes a singular contrast with its state of contraction.

This motion of the œsophagus depends on the nerves of the eighth pair. When these nerves of an animal are cut, the œsophagus no longer contracts, but neither is it in the relaxed state that we have described; its fibres being separated from nervous influence, shorten themselves with a certain force, and the canal is found in an intermediate state between contraction and relaxation. The vacuity or distention of the stomach has an influence upon the duration and intensity of the contraction of the œsophagus.

From the inferior extremity of the stomach to the end of the intestine rectum, the intestinal canal presents a mode of contraction which differs, in almost every respect, from the contraction of the sub-diaphragmatic portion of the canal. This contraction always takes place slowly, and in an irregular manner: sometimes an hour passes before any trace of it can be perceived; at other times many intestinal portions contract at once. It appears to be very little influenced by the nervous system: for example, it continues in the stomach after the section of the nerves of the eighth pair; it becomes more active by the weakness of animals, and even by their death; in some, by this cause it becomes considerably accelerated; it continues though the intestinal canal is entirely separated from the body. The pyloric portion of the stomach, the small intestine, are the points of the intestinal canal where it is presented oftenest, and most constantly. This motion, which arises from the successive or simultaneous contraction of the longitudinal or circular fibres of the intestinal canal, has been differently denominated by authors: some have named it *vermicular*, others *peristaltic;* others again, *sensible organic contractility*, &c. Whatever it is, the will appears to exert no sensible influence upon it.

The muscles of the anus contract voluntarily.

The supra-diaphragmatic portion of the digestive canal is not susceptible of undergoing any considerable dilatation: we may easily see, by its structure, and the mode of contraction of its muscular coat, that it is not intended to allow the aliments to remain in its cavity, but that it is rather formed to carry these substances from the mouth into the stomach; this last organ, and the large intestine, are evidently prepared to undergo a very great distension: substances, also, which are introduced into the alimentary canal, accumulate, and remain for a time, more or less, in their interior.

The diaphragm, and the abdominal muscles, produce a sort of perpetual agitation of the digestive organs contained in the abdominal cavity; they exert, upon them, a continual pressure, which becomes sometimes very considerable.

The digestive actions which by their union constitute digestion, are, —

1. The apprehension of aliments.
2. Mastication.
3. Insalivation.
4. Deglutition.
5. The action of the stomach.
6. The action of the small intestines.
7. The action of the large intestines.
8. The expulsion of the fæcal matter.

All the digestive actions do not equally contribute to the production of chyle; the action of the stomach, and that of the small intestines, are alone absolutely necessary.

The digestion of solid food requires generally the eight digestive actions: that of drinks is much more simple; it comprehends only apprehension, deglutition, the action of the stomach, and that of the small intestine.

The mastication and deglutition of the food being effected, we have now to notice the action of the stomach on the aliment; chemical alterations will now present themselves to our examination. In the stomach, the food is transformed into a matter proper to animals, which is named *chyme*.

Before showing the changes that the food undergoes in the stomach, it is necessary to know the phenomena of their accumulation in this viscus, as well as the local and general effects that result from it.

The first mouthfuls of food swallowed are easily lodged in the stomach. This organ is not much compressed by the surrounding viscera; its sides separate easily, and give way to the force which presses the alimentary bole: but its distension becomes more difficult in proportion as new food arrives, for this is accompanied by the pressing together of the abdominal viscera, and the extension of the sides of the abdomen. This accumulation takes place particularly towards the right extremity and the middle part; the pyloric half gives way with more difficulty.

Whilst the stomach is distended, its form, its relations, and even its positions, undergo alterations: in place of being flattened on its aspects, of occupying only the epigastrium and a part of the left *hypochondrium*, it assumes a round form; its great *cul de sac* is thrust into this *hypochondrium*, and fills it almost completely; the greater *curvature* descends towards the umbilicus, particularly on the left side; the pylorus alone, fixed by a fold of the *peritonæum*, preserves its motion and its relations with the surrounding parts. On account of the resistance that the vertebral column presents behind, the posterior surface of the stomach cannot distend itself on that side: for that reason this viscus is wholly carried forward; and as the pylorus and the œsophagus cannot be displaced in this direction, it makes a motion of rotation, by which its great curve is directed a little forward; its posterior aspect inclines downwards, and its superior upwards.

Though it undergoes these changes of position and relation, it nevertheless preserves the recurved conoid form which is proper to it. This effect depends on the manner in which the three tunics contribute to its dilatation. The two plates of the serous membrane separate and give place to the stomach. The muscular layer suffers a real distension; its fibres are prolonged, but so as to preserve the particular form of the stomach. Lastly, the mucous membrane gives way, particularly in the points where the folds are multiplied. It will be noticed that these are found particularly along the larger curve, as well as at the splenic extremity.

The dilatation of the stomach alone produces very important changes in the abdomen. The total volume of this cavity augments; the belly juts out; the abdominal viscera are compressed with greater force; often the necessity of passing urine, or fæces, is felt. The diaphragm is pressed towards the breast, it descends with some difficulty; thence the motions of respiration, and the phenomena which depend on it, are more incommoded, such as speech, singing, &c.

In certain cases, the dilatation of the stomach may be carried so far that the sides of the abdomen are painfully distended, and respiration becomes difficult.

To produce such effects, the contraction of the œsophagus, which presses the food in the stomach, must be very energetic. We have remarked above the considerable thickness of the muscular layer of this canal, and the great number of nerves which go to it: nothing less than this disposition is necessary to account for the force with which the food distends the stomach. For more certainty, the finger has only to be introduced into the œsophagus of an animal by the cardiac orifice, and the force of the contraction will be found striking.

But if the food exerts so marked an influence upon the sides of the stomach and the abdomen, they ought themselves to suffer a proportionate re-action, and tend to escape by the two openings of the stomach. Why does this effect not take place? It is generally said that the cardia and pylorus shut; but this phenomenon has not been submitted to any particular researches.

The alternate motion of the œsophagus prevents the return of the food into this cavity. The more the stomach is distended, contraction becomes the more intense and prolonged, and the relaxation of shorter duration. Its contraction generally coincides with the instant of inspiration, when the stomach is most forcibly compressed. Its relaxation ordinarily happens at the instant of expiration.

We may have an idea of this mechanism by laying bare the stomach of a dog, and endeavouring to make the food pass into the œsophagus by compressing the stomach with both hands. It will be nearly impossible to succeed, whatever force is used, if it is done at the instant when the œsophagus is contracted: but the passage will take place, in a certain degree, of itself, if the stomach is compressed at the instant of relaxation.

The resistance that the pylorus presents to the passage of the aliments is of another kind. In living animals, whether the stomach is empty or full, this opening is habitually shut, by the constriction of its fibrous ring, and the contraction of its circular fibres. There is frequently seen another constriction in the stomach, at the distance of one or two inches, which appears intended to prevent the food from reaching the pylorus; we perceive, also, irregular and peristaltic contractions, which commence at the duodenum, and are continued into the pyloric portion of the stomach, the effect of which is to press the food towards the splenic part. Besides, should the pylorus not be naturally shut, the food would have little tendency to enter it, for it only endeavours to escape into a place where the pressure is less; and this would be equally great in the small intestine as in the stomach, since it is nearly equally distributed over all the abdominal cavity.

Amongst the number of phænomena produced by the food in the stomach, there are several, the existence of which, though generally admitted, do not appear sufficiently demonstrated: such is the diminution of the volume of the spleen, and that of the blood-vessels of the liver, or the *omenta*, &c.; such is also a motion of the stomach, which should preside over the reception of the food, distribute it equally by exerting upon it a gentle pressure, so that its dilatation, far from being a passive phænomenon, must be essentially active. Dr. Magendie has frequently opened animals, the stomachs of which were filled with food; he has examined the bodies of executed persons, a short time after death; and has seen nothing favourable to these assertions.

The accumulation of food in the stomach is accompanied by many sensations, of which it is necessary to take account: — At first it is an agreeable feeling, or the pleasure of a want satisfied. Hunger is appeased by degrees; the general weakness that accompanied it is replaced by an active state, and a feeling of new force. If the introduction of food is continued, we experience a sensation of fulness and satiety, which indicates that the stomach is sufficiently replenished; and if, contrary to this instinctive information, we still persist to make use of food, disgust and nausea soon arrive, and they are very soon followed by vomiting. These different impressions must not be attributed to the volume of the aliments alone. Every thing being equal in other respects, food very nutritive occasions, more promptly, the feeling of satiety. A substance which is not very nourishing does not easily calm hunger, though it is taken in great quantity.

The mucous membrane of the stomach, then, is endowed with considerable sensibility, since it distinguishes the nature of substances which come in contact with it. This property is very strongly marked if an irritating poisonous substance is swallowed: intolerable pain is then felt. We also know that the stomach is sensible to the temperature of food.

We cannot doubt that the presence of the aliments of the stomach causes a great excitement, from the redness of the mucous membrane, from the quantity of fluid it secretes, and the volume of vessels directed there; but this is favourable to chymification. This excitement of the stomach influences the general state of the functions.

The time that the aliments remain in the stomach is considerable, generally several hours: it is during this stay that they are transformed into chyme.

Changes of the aliments in the stomach. — It is more than an hour before the food suffers any apparent change in the stomach, more than what results from the perspiratory and mucous fluids with which they are mixed, and which are continually renewed.

The stomach is uniformly distended during this time; but the whole extent of the pyloric portion afterwards contracts, particularly that nearest the splenic portion, into which the food is pressed. Afterwards, there is nothing found in the pyloric portion but chyme, mixed with a small quantity of unchanged food.

The best authors have agreed to consider the chyme as a homogeneous substance, pultaceous, greyish, of a sweetish taste, insipid, slightly acid, and preserving some of the properties of the food. This description leaves much to be explained.

The result of Dr. Magendie's experiments are as follows: —

A. There are as many sorts of chyme as there are different sorts of food, if we judge by the colour, consistence, appearance, &c.; as we may easily ascertain, by giving different simple alimentary substances to dogs to eat, and killing them during the operation of digestion. He frequently found the same result in man, in the dead bodies of criminals, or persons dead by accident.

B. Animal substances are generally more easily and completely changed than vegetable substances. It frequently happens that these last traverse the whole intestinal canal without changing their apparent properties. He has frequently seen in the rectum, and in the small intestines, the vegetables which are used in soup, spinach, sorrel, &c., which had preserved the most part of their properties; their colour alone appeared sensibly changed by the contact of the bile.

Chyme is formed particularly in the pyloric portion. The food appears to be introduced slowly into it; and during the time they remain, they undergo transformation. The Doctor believes, however, that he has observed frequently chymous matter at the surface of the mass of aliments which fill the splenic portion; but the aliments in general preserve their properties in this part of the stomach.

It would be difficult to tell why the pyloric portion is better adapted to the formation of chyme than the rest of the stomach; perhaps the great number of follicles that are seen in it modify the quantity or the nature of the fluid that is there secreted. The transformation of alimentary substances into chyme takes place generally from the superficies to the centre. On the surface of portions of food swallowed, there is formed a soft layer easy to be detached. The substances seem to be attacked and corroded by a re-agent capable of dissolving them. The white of a hard egg, for instance, becomes in a little time as if plunged in vinegar, or in a solution of potash.

C. Whatever is the alimentary substance employed, the chyme has always a sharp odour and taste, and reddens paper coloured with turnsole.

D. There is only a small quantity of gas found in the stomach during the formation of chyme; sometimes there exists none. Generally it forms a small bubble at the superior part of the splenic portion. Once only in the body of a criminal a short time after death, he gathered with proper precautions a quantity sufficient to be analysed. Chevreuil found it composed of, oxygen, 11·00; carbonic acid, 14·00; pure hydrogen, 3·15; azote, 71·45; — total, 100·00. There is rarely any gas found in the stomach of a dog. We cannot then believe, with Professor Chaussier, that we swallow a bubble of air at every motion of deglutition, which is pressed into the stomach by the alimentary bole. Were it so, there ought to be found a considerable quantity of air in this organ after a meal: now the contrary is to be seen.

E. There is never a great quantity of chyme accumulated in the pyloric portion: the most that M. Magendie ever saw in it was scarcely equal in volume to two or three ounces of water. The contraction of the stomach appears to have an influence upon the production of chyme. The following is what he observed in this respect: — After having been some time immovable, the extremity of the duodenum contracts,

the pylorus and the pyloric portion contract also; this motion presses the chyme towards the splenic portion; but it afterwards presses it in a contrary direction, that is, after being distended, and having permitted the chyme to enter again into its cavity, the pyloric portion contracts from left to right, and directs the chyme towards the duodenum, which immediately passes the pylorus and enters the intestine.

The same phenomenon is repeated a certain number of times, but it stops to begin again, after a certain time. When the stomach contains much food, this motion is limited to the parts of the organ nearest the pylorus; but in proportion as it becomes empty, the motion extends farther, and is seen even in the splenic portion when the stomach is almost entirely empty. It becomes generally more strong about the end of chymification. Some persons have a distinct feeling of it at this moment.

The pylorus has been made to play a very important part in the passage of the chyme from the stomach to the intestine. It judges, they say, of the chymification of the food; it opens to those that have the required qualities, and shuts against those that have not. However, as we daily observe substances not digestible traverse it easily, such as stones of cherries, it is added, that becoming accustomed to a substance not chymified, which presents itself repeatedly, it at last opens a passage. These considerations, consecrated in a certain degree by the word *pylorus, a porter*, may please the fancy, but they are purely hypothetical.

F. All the alimentary substances are not transformed into chyme with the same promptitude.

Generally the fat substances, the tendons, the cartilages, the concrete albumen, the mucilaginous and sweet vegetables, resist more the action of the stomach than the caseous, fibrinous, and glutinous substances. Even some substances appear refractory; such as the bones, the epidermis of fruits, their stones, and whole seeds, &c.

In determining the digestibility of food, the volume of the portions swallowed ought to be taken into account. The largest pieces, of whatever nature, remain longest in the stomach; on the contrary, a substance which is not digestible, if it is very small, such as grape-stones, does not rest in the stomach, but passes quickly with the chyme into the intestine.

In respect of the facility and quickness of the formation of chyme, it is different in every different individual. It is evident, after what has been said, that to fix the necessary time for the chymification of all the food contained in the stomach, we ought to take into account their quantity, their chemical nature, the manner in which the mastication acts upon them, and the individual disposition. However, in four or five hours after an ordinary meal, the transformation of the whole of the food into chyme is generally effected.

The nature of the chemical changes that the food undergoes in the stomach is unknown. It is not because there have been no attempts at different periods to give explanations of them more or less plausible. The ancient philosophers said that the food became putrified in the stomach; Hippocrates attributed the digestive process to coction; Galen assigned the stomach attractive, retentive, concoctive, expulsive faculties, and by their help he attempted to explain digestion. The doctrine of Galen reigned in the schools until the middle of the seventeenth century, when it was attacked and overturned by the *fermenting chemists*, who established in the stomach an *effervescence*, a particular fermentation, by means of which the food was *macerated*, *dissolved*, *precipitated*, &c. This system was not long in repute, and digestion was next supposed to be only a trituration, a bruising, performed by the stomach; an innumerable quantity of little worms was supposed to attack and divide the food. Boerhaave thought he had found the truth by combining the different opinions that had reigned before him. Haller did not follow the ideas of his master; he considered digestion a simple *maceration*. He knew that vegetable and animal matters plunged into water are soon covered with a soft homogeneous layer; he believed that the food underwent a like change, by macerating in the saliva and fluids secreted by the stomach.

Réaumur and Spallanzani made experiments on animals, and demonstrated the falsity of the ancient systems: they showed that food, contained in hollow metallic balls pierced with small holes, was digested the same as if it was free in the cavity of the stomach. They proved that the stomach contains a particular fluid which they call *gastric juice*, and that this fluid was the principal agent of digestion; but they much exaggerated its properties, and they were mistaken when they thought to have explained digestion by considering it as a *solution*; because, in not explaining this solution, they did not explain the changes of food in the stomach.

In the formation of chyme, it is necessary to consider, 1st, The circumstances in which the food is found in the stomach. 2dly, The chemical nature of it.

The circumstances affecting the food in the stomach, during its stay there, are not numerous: 1st, It suffers a pressure more or less strong either from the sides of the abdomen, or from those of the stomach; 2dly, The whole is entirely moved by the motions of respiration; 3dly, It is exposed to a temperature of 30° to 32° degrees of Réaumur; 4thly, It is exposed to the action of the saliva, of the mucosities proceeding from the mouth and the œsophagus, as well as the fluid secreted by the mucous membrane of the stomach.

It will be remembered that this fluid is slightly viscous, that it contains much water, mucus, salts, with a base of soda and ammonia, and lactic acid of Berzelius.

With regard to the nature of the food, we have already seen how variable it is; since all the immediate principles, animal or vegetable, may be carried into the stomach in different forms and proportions, and serve usefully in the formation of chyme. Now, making allowance for the nature of the food, and the circumstances in which it is placed in the stomach,

shall we be able to account for the known phenomena of the formation of chyme? The temperature of 30° to 32°, R. = 100° to 104° F.; the pressure and the tossing that the food sustains, cannot be considered as the principal cause of its transformation into chyme; it is probable that they only co-operate in this: the action of the saliva and that of the fluid secreted in the stomach remain; but after the known composition of the saliva, it is hardly possible that it can attack and change the nature of the food; at most, it can only serve to divide, to imbibe it in such a manner as to separate its particles: it must then be the action of the fluid formed by the internal membrane of the stomach. It appears certain that this fluid, in acting chemically upon the alimentary substances, dissolves them from the surface towards the centre. To produce a proof of it, with this fluid of which we speak, there have been attempts made to produce what is called in physiology *artificial digestions*, that is, after having macerated food, it is mixed with gastric juice, and then exposed in a tube or any other vase to a temperature equal to that of the stomach. Spallanzani advanced that these digestions succeeded, and that the food was reduced to chyme; but, according to the researches of De Montègre, it appears that they are not; and that, on the contrary, the substances employed undergo no alteration analogous to chymification: this is agreeable to experiments made by Réaumur. But because the gastric juice does not dissolve the food when put with it into a tube, we ought not to conclude that the same fluid cannot dissolve the food when it is introduced into the stomach. The circumstances are indeed far from being the same: in the stomach, the temperature is constant, the food is pressed and agitated, and the saliva and gastric juice are constantly renewed; as soon as the chyme is formed, it is carried away and pressed in the duodenum. Nothing of this takes place in the tube or vase which contains the food mixed with gastric juice; therefore, the want of success in artificial digestions, proves nothing which tends to explain the formation of chyme.

But how does it happen that the same fluid can act in a manner similar upon the great variety of alimentary substances, animal and vegetable? The acidity which characterises it, though fit to dissolve certain matters, as albumen, for example, would not be suitable for dissolving fat.

To this it may be answered, that nothing proves the gastric juice to continue always the same; the small number of analyses that have been made of it demonstrate, on the contrary, that it presents considerable varieties in its properties. The contact of different sorts of food upon the mucous membrane of the stomach, may possibly influence its composition; it is at least certain, that this varies in the different animals. For example, that of man is incapable of acting on bones: and it is well known that the dog digests these substances perfectly.

Generally speaking, the action by which the chyme is formed prevents the re-action of the constituent elements of the food upon each other: but this effort takes place only in good digestions; in bad digestion, fermentation, and even putrefaction, may take place: this may be suspected by the great quantity of inodorous gases that are developed in certain cases, and the sulphuretted hydrogen which is disengaged in others.

The nerves of the eighth pair have long been considered to direct the act of chymification: in fact, if these nerves are cut, or tied in the neck, the matters introduced into the stomach undergo no alteration. But the consequence, says Dr. Magendie (from whose physiology this article is taken), that is deduced from this fact does not appear to me to be rigorous. Is not the effect produced upon the stomach by the injury done to respiration, confounded here with the direct influence of the section of the nerves of the eighth pair upon this organ? I am inclined to believe it; for, as I have many times done, if the two eighth pairs be cut in the breast *below* the branches which go to the lungs, the food which is introduced afterwards into the stomach is transformed into chyme, and ultimately furnishes an abundant chyle.

Some persons imagine that electricity may have an influence in the production of chyme, and that the nerves we mention may be the conductors: there is no established fact to justify this conjecture. The most probable use of the nerves of the eighth pair is, to establish intimate relations between the stomach and the brain, to give notice whether any noxious substances have entered along with the food, and whether they are capable of being digested.

In a strong person, the operation of the formation of chyme takes place without his knowledge; it is merely perceived that the sensation of fulness, and the difficulty of respiration, produced by the distension of the stomach, disappear by degrees: but frequently, with people of a delicate temperament, digestion is accompanied with feebleness in the action of the senses, with a general coldness, and slight shiverings; the activity of the mind diminishes, and seems to become drowsy; and there is a disposition to sleep. The vital powers are then said to be concentrated in the organ that acts, and to abandon for an instant the others. To those general effects are joined the production of the gas that escapes by the mouth, a feeling of weight, of heat, of giddiness, and sometimes of burning, followed by an analogous sensation along the œsophagus, &c. These effects are felt particularly towards the end of the chymification. It does not appear, however, that these laborious digestions are much less beneficial than the others.

From the stomach the food is received into the *small intestine*, which is the longest portion of the digestive canal; it establishes a communication between the stomach and the large intestine. Not being susceptible of much distension, it is twisted a great many times upon itself, being much longer than the place in which it is contained. It is fixed to the vertebral column by a fold of the peritonæum, which limits, yet aids, its motions; its longitudinal and circular fibres are not separated as in

the stomach; its mucous membrane, which presents many villi, and a great number of mucous follicles, forms irregular circular folds, the number of which is greater in proportion as the intestine is examined nearer the pyloric orifice: these folds are called *valvulæ conniventes*.

The small intestine receives many blood-vessels: its nerves come from the *ganglions* of the *great sympathetic*. At its internal surface the numerous orifices of the chyliferous vessels open.

This intestine is divided into three parts: called the *duodenum*, *jejunum*, and *ileum*. The mucous membrane of the small intestine, like that of the stomach, secretes abundance of mucus; viscous, thready, of a salt taste, and reddens strongly turnsole papers; all which properties are also in the liquid secreted by the stomach. Haller gave this fluid the name of *intestinal juice*: the quantity that is formed in twenty-four hours he estimated at eight pounds.

Not far from the gastric extremity of this intestine is the common orifice of the biliary and pancreatic canals, by which the fluid secreted by the liver and the pancreas flow into the intestinal cavity. If the formation of the chyme is still a mystery, the nature of the phænomena that takes place in the small intestine is little better known.

In the experiments which have been made on dogs and rabbits, the chyme is seen to pass from the stomach into the duodenum. The phænomena are these. At intervals, more or less distant, a contractile motion commences towards the middle of the duodenum; it is propagated rapidly to the site of the pylorus: this ring contracts itself, as also the pyloric part of the stomach; by this motion, the matters contained in the duodenum are pressed back towards the pylorus, where they are stopped by the valve, and those that are found in the *pyloric* part, are partly pressed towards the *splenic* part; but this motion, directed from the intestine towards the stomach, is very soon replaced by another in a contrary direction, that is, which propagates itself from the stomach towards the duodenum, the result of which is to make a considerable quantity of chyme pass the pylorus.

This fact seems to indicate that the valve of the pylorus serves as much to prevent the matters contained in the small intestine from flowing back into the stomach, as to retain the chyme and the food in the cavity of this organ.

The motion that has been described, is generally repeated many times following, and modified as to the rapidity, the intensity of the contraction, &c.; it then ceases to begin again after some time. It is not very marked in the first moments of the formation of the chyme; the extremity only of the pyloric part participates in it. It augments in proportion as the stomach becomes empty; and, towards the end of chymification, it often takes place over the whole stomach. It is not suspended by the section of the nerves of the eighth pair.

Thus the entrance of chyme into the small intestine is not perpetual. According as it is repeated, the chyme accumulates in the first portion of the intestine, it distends its sides a little, and presses into the intervals of the valves; its presence very soon excites the organ to contract, and by this means one part advances into the intestine: the other remains attached to the surface of its membrane, and afterwards takes the same direction. The same phenomenon continues down to the large intestine; but, as the duodenum receives new portions of the chyme, it happens at last that the small intestine is filled in its whole length with this matter. It is observed only to be much less abundant near the *cæcum* than at the pyloric extremity.

The motion that determines the progress of the chyme through the small intestine, has a great analogy with that of the pylorus: it is irregular, returns at periods which are variable, is sometimes in one direction, sometimes in another, takes place sometimes in many parts at once; it is always slow, more or less; it causes relative changes amongst the intestinal circumvolutions. It is beyond the influence of the will.

We should form a false idea of it were we merely to examine the intestine of an animal recently dead: it has then a much greater activity than during life. Nevertheless, in weak digestions it appears to acquire more than ordinary energy and velocity.

In whatever manner this motion takes place, the chyme appears to move very slowly in the small intestine: the numerous valves that it contains, the multitude of asperities that cover the mucous membrane, the many bendings of the canal, are so many circumstances that ought to contribute to retard its progress, but which ought to favour its mixture with the fluids contained in the intestine, and the production of the chyle which results from it.

Changes that the chyme undergoes in the small intestines. — It is only about the height of the orifice of the choledochus and pancreatic canal that the chyme begins to change its properties. Before this, it preserves its colour, its semi-fluid consistence, its sharp odour, its slightly acid savour; but, in mixing with the bile and the pancreatic juice, it assumes new qualities: its colour becomes yellowish, its taste bitter, and its sharp odour diminishes much. If it proceeds from animal or vegetable matters, which contained grease or oil, irregular filaments are seen to form here and there upon its surface; they are sometimes flat, at other times rounded, attach themselves quickly to the surface of the valve, and appear to consist of crude chyle. This matter is not seen when the chyme proceeds from matter that contained no fat; it is a greyish layer, more or less thick, which adheres to the mucous membrane, and appears to contain the elements of chyle. The same phenomena are observed in the *two superior thirds* of the small intestine: but in the *inferior third*, the chymous matter is more consistent; its yellow colour becomes more deep; it ends sometimes by becoming of a greenish brown, which pierces through the intestinal parietes, and gives an appearance to the *ileum*, distinct from that of the *duodenum* and *jejunum*. When it is examined near the *cæcum*, there are few or no whitish

chylous striæ seen; it seems, in this place, to be only the remainder of the matter which has served in the formation of the chyle.

After what has been said above, upon the varieties that the chyme presents, we may understand that the changes it undergoes in the small intestine are variable according to its properties; in fact, the phenomena of digestion in the small intestine vary according to the nature of the food. The chyme, however, preserves its acid property; and if it contains small quantities of food or other bodies, that have resisted the action of the stomach, they traverse the small intestine without undergoing any alteration. The same phenomena appear when the same substances have been used. Dr. Magendie has ascertained this fact upon the bodies of two criminals who, two hours before death, had taken an ordinary meal, in which they had eaten the same food nearly in equal quantity: the matters contained in the stomach, the chyme in the pyloric portion and in the small intestine, appeared to him exactly the same as to consistence, colour, taste, odour, &c.

There is generally gas found in the small intestine during the formation of chyle. Drs. Magendie and Chevreuil have made experiments upon the bodies of criminals opened shortly after death, and who, being young and vigorous, presented the most favourable conditions for such researches. In a subject of twenty-four years, who had eaten, two hours before his death, bread, and some Swiss cheese, and drank water reddened with wine, they found in the small intestine: — oxygen, 0·00; carbonic acid, 24·39; pure hydrogen, 55·53; azote, 20·08: total, 100·00.

In a second subject, aged twenty-three years, who had eaten of the same food at the same hour, and whose punishment took place at the same time: — oxygen, 0·00; carbonic acid, 40·00; pure hydrogen, 51·15; azote, 8·85: total, 100·00.

In a third experiment, made upon a young man of twenty-eight years, who, four hours before death, had eaten bread, beef, lentiles, and drank red wine, they found in the same intestine: — oxygen, 0·00; carbonic acid, 25·00; pure hydrogen, 8·40; azote, 66·60: total, 100·00.

They never observed any other gases in the small intestine. These gases might have different origins. They might possibly come from the stomach with the chyme; or they were, perhaps, secreted by the intestinal mucous membrane; they might arise from the reciprocal action of the matters contained in the intestine; or perhaps they might come from all these sources at once.

However, the stomach contains oxygen, and very little hydrogen, whilst they have almost always found much hydrogen in the small intestine, and never any oxygen. Besides, it is a daily observation, that the little gas that the stomach contains is generally passed by the mouth towards the end of chymification, probably because, at this instant, it can more easily advance into the œsophagus.

The probability of the formation of gases by the secretion of the mucous membrane could not be at all admissible, except for carbonic acid, which seems to be formed in this manner in respiration. With regard to the action of matters contained in the intestine, Dr. Magendie says he has many times seen the chymous matter let bubbles of gas escape very rapidly. This took place from the orifice of the ductus choledochus to the commencement of the *ileum*; there was no trace of it perceived in this last intestine, nor in the superior part of the duodenum, nor the stomach. He made this observation again upon the body of a criminal four hours after death: it presented no traces of putrefaction.

The alteration which chyme undergoes in the small intestine is unknown; it is easily seen to be the result of the action of the bile, of the pancreatic juice, and of the fluid secreted by the mucous membrane, upon the chyme. But what is the play of the affinities in this real chemical operation, and why is the chyle precipitated against the surface of the *valvulæ conniventes*, whilst the rest remains in the intestine to be afterwards expelled? This is completely unknown.

We have learned something more of the time that is necessary for this alteration of the chyme. The phenomenon does not take place quickly: in animals, it often happens that we do not find any chyle formed three or four hours after the meal.

After what has been said, we see that in the small intestine, the chyme is divided into two parts: the one which attaches itself to the sides, and which is the chyle still impure; the other, the true refuse, which is destined to be thrown into the large intestine, and afterwards entirely carried out of the body.

The manner in which drinks accumulate in the stomach differs little from that of the aliments: it is generally quicker, more equal, and more easy; probably because the liquids spread, and distend the stomach more uniformly. In the same manner as the food, they occupy more particularly its left and middle portion: the pyloric, or right extremity, contains always much less.

The distension of the stomach must not, however, be carried to a great degree, for the liquid would be expelled by vomiting. This frequently happens to persons who swallow a great quantity of drink quickly. When we wish to excite vomiting in persons who have taken an emetic, one of the best means is to make them drink a number of glasses of liquid quickly.

The presence of drinks in the stomach produces local phenomena like those which take place from the *accumulation of the aliments*; the same changes in the form and position of the organ, the same distension of the abdomen, the same contraction of the pylorus and the œsophagus, &c.

The general phenomena are different from those produced by the aliments: this depends on the action of the liquids upon the sides of the stomach, and the quickness with which they are carried into the blood.

Potations, in passing rapidly through the mouth and the œsophagus, preserve more than the food

their proper temperature until they arrive in the stomach. We therefore prefer them to those when we wish to experience in this organ a feeling of heat, or of cold: hence arises the preference that we give to hot drinks in winter, and cold drinks in summer.

Every one knows that the drinks remain much shorter time in the stomach than the aliments; but the manner of their passage out of this viscus is still very little known. It is generally supposed that they traverse the pylorus, and pass into the small intestine, where they are absorbed with the chyle; nevertheless, a ligature applied round the pylorus in such a manner as to hinder it from penetrating into the duodenum, does not much retard its disappearance from the cavity of the stomach.

Alteration of drinks in the stomach. — Fluids, in respect of the alterations that they prove in the stomach, may be divided into two classes: the one sort do not form any chyme, and the other are chymified wholly or in part.

To the first class belong pure water, alkohol, sufficiently weak to be considered as a drink, the vegetable acids, &c. During its stay in the stomach, water assumes an equilibrium of temperature with the sides of this viscus: it mixes at the same time with mucus, the gastric juice, and the saliva which are found in it; it becomes muddy, and afterwards disappears slowly without suffering any other transformation. One part passes into the small intestine; the other appears to be directly absorbed. There remains, after its disappearance, a certain quantity of mucus, which is very soon reduced to chyme, like the aliments. By observation we know that water deprived of atmospheric air, as distilled water, or water charged with a great quantity of salts, as well water, remain long in the stomach, and produce a feeling of weight.

Alkohol acts quite in a different manner. We know the impression of burning heat that it causes at first in its passage through the mouth, the pharynx, the œsophagus; and that which it excites when it enters the stomach: the effects of this action determine the contraction of this organ, irritate the mucous membrane, and augment the secretion of which it is the seat; it coagulates at the same time all the albuminous parts with which it is in contact; and as the different liquids in the stomach contain a considerable proportion of this matter, it happens that a short time after alkohol has been swallowed, there is in this viscus a certain quantity of concrete albumen. The mucus undergoes a modification analogous to that of the albumen; it becomes hard, forms irregular elastic filaments, which preserve a certain transparency.

In producing these phenomena, the alkohol mixes with the water that the saliva and the gastric juice contain; probably it dissolves a part of the elements that enter into their composition, so that it ought to be much weakened by its stay in the stomach. It disappears very quickly; its general effects are also very rapid, and drunkenness or death follow almost immediately the introduction of too great a quantity of alkohol into the stomach.

The matters coagulated by the action of the alkohol are, after its disappearance, digested like solid aliments.

Amongst the drinks that are reduced to chyme, some are reduced in part, and some wholly.

Oil is in this last case: it is transformed, in the pyloric part, into a matter analogous in appearance with that which is drawn from the purification of oils by sulphuric acid; this matter is evidently the chyme of oil. On account of this transformation, oil is, perhaps, the liquid that remains longest in the stomach.

Every one knows that milk curdles soon after it is swallowed: this curd then becomes a solid aliment, which is digested in the ordinary manner. Whey only can be considered as drink.

The greatest number of drinks that we use are formed of water, or of alkohol, in which are suspended or dissolved some immediate animal or vegetable principles, such as gelatine, albumen, ozmazome, sugar, gum, fecula, colouring or astringent matters, &c. These drinks contain salts of lime, of soda, of potash, &c.

The result of several experiments that have been made upon animals, and some observations that have been made on man, is, that there is a separation of the water and the alkohol in the stomach from the matters that these liquids hold in suspension or solution. These matters remain in the stomach, where they are transformed into chyme, like the aliments; whilst the liquids with which they were united are absorbed, or passed into the small intestine; lastly, they are conducted, as we have just now seen, in treating of water and alkohol.

Salts that are in solution in water do not abandon this liquid, and are absorbed with it. Red wine, for example, becomes muddy at first by its mixture with juices that are formed in, or carried into the stomach; it very soon coagulates the albumen of these fluids, and becomes flaky; afterwards, its colouring matter, carried, perhaps, by the mucus and the albumen, is deposited upon the mucous membrane: there is a certain quantity of it seen, at least, in the pyloric portion; the watery and alkoholic parts disappear with rapidity.

The broth of meat undergoes the same changes. The water that it contains is absorbed; the gelatine, the albumen, the fat, and, probably, the ozmazome, remain in the stomach, where they are reduced into chyme.

Action of the small intestine upon drinks. — After what has been said, it is clear that fluids penetrate, under two forms, into the small intestine: 1st, under that of liquid; 2dly, under that of chyme.

The liquids that pass from the stomach into the intestine remain but a short time, except under particular circumstances: they do not appear to undergo any other alteration than their mixture with the intestinal juice, the chyme, the pancreatic liquid, and the bile; they do not form any sort of chyle: they are generally absorbed in the duodenum, and the commencement of the jejunum; they are rarely seen in the ileum, and still more rarely in the large intestine. It appears that this last case does not happen, except in the

state of sickness; for example, during the action of a purgative.

The chyme that proceeds from drinks follows the same rule, and appears to undergo the same changes as that of the food; it therefore produces chyle.

Such are the principal phænomena of the digestion of drinks: we see how necessary it was to distinguish them from those that belong to the digestion of the aliments.

But we do not always digest the aliments and the drinks separately, as we have supposed; very frequently the two digestions take place at the same time.

Drink favours the digestion of the aliments: this effect is probably produced in various manners. Those that are watery, soften, divide, dissolve even certain foods; they aid in this manner their chymification and their passage through the pylorus.

Wine fulfils analogous uses, but only for the substances that it is capable of dissolving; besides, it excites by its contact the mucous membrane of the stomach, and causes a greater secretion of the gastric juice. Alkohol acts much in the same manner as wine, only it is more intense. It is thus that those liquors which are used after meals, are useful in exciting the action of the stomach. — *Magendie.*

DIGE'STIVE. (*Digestivus;* from *digero*, to digest.) A term applied by surgeons to those substances which, when applied to an ulcer or wound, promote suppuration: such are the *ceratum resinæ*, *unguentum elemi*, warm poultices, fomentations, &c.

Digestive salt of Sylvius. A muriate of potash.

Digesti'vum sal. See *Potassæ murias.*

DIGITA'LIS. (*is, is.* f.; from *digitale*, the finger of a glove, because the flower resembles the end of the finger of a glove.)

1. The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Angiospermia.* Foxglove.

2. The pharmacopœial name of the common foxglove. See *Digitalis purpurea.*

Digitalis purpurea. The systematic name of the foxglove. *Digitalis — calycinis foliolis ovatis acutis, corollis obtusis, labio superiore integro,* of Linnæus. The leaves of this plant have a bitter nauseous taste, but no remarkable smell; they have been long used externally to ulcers and scrofulous tumours with considerable advantage. When properly dried, their colour is a lively green. They ought to be collected when the plant begins to blossom, to be dried quickly before the fire, and preserved unpowdered.

The leaves of foxglove yield their virtues both to water and alkohol. They contain a considerable quantity of ammonia. It is not known on what principle the medicinal activity of foxglove depends. An alkaloid was lately said to have been discovered in it, and was accordingly named *digitaline;* but this matter is now ascertained to consist merely of chlorophylle, resin, and a fatty matter.

Of all the narcotics, digitalis is that which diminishes most powerfully the actions of the system; and it does so without occasioning any previous excitement. Even in the most moderate dose, it diminishes the force and frequency of the pulse, and, in a large dose, reduces it to a great extent, as from 70 beats to 40 or 35 in a minute, occasioning, at the same time, vertigo, indistinct vision, violent and durable sickness, with vomiting. In a still larger quantity, it induces convulsions, coldness of the body, and insensibility; symptoms which have sometimes terminated fatally. As a narcotic, foxglove has been recommended in epilepsy, insanity, and in some acute inflammatory diseases. Some years ago it was very extensively employed in phthisis. The beneficial effects which it produces in that disease are probably owing to its narcotic power, by which it reduces the force of the circulation through the lungs and general system. It is administered so as to produce this effect. One grain of the powdered leaves, or ten drops of the saturated tincture, may be given night and morning. This dose is increased one half every second day, till its action on the system becomes apparent. As soon as the pulse begins to be diminished, the increase of dose must be made with more caution; and, whenever nausea takes place, it ought rather to be reduced, or, if necessary, intermitted for a short time. If the sickness become urgent, it is best relieved by stimulants, particularly large doses of brandy, with aromatics. The tincture has been supposed to be the best form of administering digitalis, when the remedy is designed to act as a narcotic: it is also more manageable in its dose, and more uniform in its strength, than the dried leaves.

Besides its narcotic effects, digitalis acts as one of the most certain diuretics in dropsy, apparently from its power of promoting absorption. It has frequently succeeded where the other diuretics have failed. Dr. Withering has an undoubted claim to this discovery; and the numerous cases of dropsy related by him, and other practitioners of established reputation, afford incontestable evidence of its diuretic powers, and of its practical importance in the cure of those disorders. From Dr. Withering's extensive experience of the use of the digitalis in dropsies, he has been able to judge of its success by the following circumstances: — "It seldom succeeds in men of great natural strength, of tense fibre, of warm skin, of florid complexion, or in those with a tight and cordy pulse. If the belly, in ascites, be tense, hard, and circumscribed, or the limbs, in anarsarca, solid and resisting, we have but little hope. On the contrary, if the pulse be feeble or intermitting, the countenance pale, the lips livid, the skin cold, the swollen belly soft and fluctuating, the anasarcous limbs readily pitting under the pressure of the finger, we may expect the diuretic effects to follow in a kindly manner." Of the inferences which he deduces, the fourth is, "that if it (digitalis) fails, there is but little chance of any other medicine succeeding." Although the digitalis is now generally admitted to be a very powerful diuretic, yet it is but justice to acknowledge that this medicine has more frequently failed than could have been reasonably expected from a com-

parison of the facts stated by Dr. Withering. The dose of the dried leaves in powder is from one to three grains twice a day. But if a liquid medicine be preferred, a drachm of the dried leaves is to be infused for four hours, in half a pint of boiling water, adding to the strained liquor an ounce of any spirituous water. One ounce of this infusion, given twice a day, is a medium dose. It is to be continued in these doses till it either acts upon the kidneys, the stomach, the pulse, (which, as has been said, it has a remarkable power of lowering,) or the bowels.

The administration of this remedy requires to be conducted with much caution. Its effects do not immediately appear; and when the doses are too frequent, or too quickly augmented, its action is concentrated so as to produce frequently the most violent symptoms. The general rules are, to begin with a small dose, to increase it gradually, till the action is apparent on the kidneys, stomach, intestines, or vascular system; and immediately to suspend its exhibition, when its effects on any of these take place.

The symptoms arising from too large a dose of digitalis are extreme sickness, vertigo, indistinct vision, incessant vomiting, and a great reduction of the force of the circulation, terminating sometimes in syncope, or convulsions. They are relieved by frequent and small doses of opium, brandy, aromatics, and strong bitters, and by a blister applied to the region of the stomach.

DIGITA'TION. This term is applied by anatomists to parts which are more or less finger-shaped; thus the *serratus magnus* muscle is said to arise by a number of fleshy *digitations*.

DIGITA'TO-PINNA'TUS. Applied to a digitate leaf, the leaflets of which are pinnated.

DIGITA'TUS. Digitate: fingered. Applied generally to whatever resembles a finger; to a leaf, *folium digitatum*, when several leaflets proceed from the summit of a common footstalk, as in *Potentilla verna*, and *reptans*; to the receptacle of the *Arum maculatum*, and *Calla æthiopica*.

DIGITIFO'RMIS. Finger-like. Applied synonymously with *digitatus*.

Digi'tium. (From *digitus*, a finger.) Linnæus gives this name to a whitlow.

DI'GITUS. (*us*, *i.* m.) A finger. *Digitus manus*, is a finger, properly so called; and *digitus pedis*, a toe.

Digitus manus. A finger. The *fingers* and thumb in each hand consist of fourteen bones, there being three to each *finger*, and two to the thumb; they are a little convex and round towards the back of the hand, but hollow and plain towards the palm, except the last, where the nails are. The bones which compose them are called first, second, and third *phalanx*. The first is longer than the second, and the second longer than the third. What has been said of the fingers, applies to the toes also.

Digitus pedis. A toe. The toes are formed of the same number of bones as the fingers, and, like them, are arranged into phalanges.

DIGLO'SSUM. (*um*, *i.* n.; from δις, double, and γλωσσα, a tongue: so called, because above its leaf there grows a lesser leaf, giving an appearance as of two tongues.) The *Laurus alexandrina*. See *Ruscus hypoglossum*.

Digno'tio. (From *dignosco*, to distinguish.) Synonymous with *diagnosis*.

DIGY'NIA. (*a*, *æ*. f.; from δις, twice, and γυνη, a woman.) The name of an order in several classes of the sexual system of plants, embracing those plants which to the character of the class, whatever it may be, add the circumstance of having two styles.

Dihæ'maton. (From δια, and αιμα, blood.) A Greek medicine prepared with the blood of several animals.

Diha'lon. (From δια, and ἁλς, salt.) A plaster prepared with salt and nitre. It used to be applied to foul ulcers.

Dikalegi. *Decalegi*. *Dekalem*. Alchemical names of tin.

DILATA'TION. (*Dilatatio*, *onis*. f.; from *dilato*, to widen.) The widening of any part, whether by a natural or diseased action.

Dilatation of the heart. See *Heart, diseases of*.

DILA'TOR. (*or*, *oris*. m.; from *dilato*, to widen.) The name of some muscles, the office of which is to dilate the parts on which they act.

Dilator alæ nasi. See *Levator labii superioris*.

DILATO'RIUM. (*um*, *i.* n.; from *dilato*, to widen.) A surgical instrument for dilating any part. It is more frequently called a *speculum*.

Dill. See *Anethum graveolens*.

Dills. See *Fucus palmatus*.

DILUENT. (*Diluens*; from *diluo*, to wash away.) Those substances are so named which increase the proportion of fluid in the blood. It is evident that this must be done by watery liquors. Water is, indeed, properly speaking, the only diluent. Various additions are made to it, to render it pleasant, and frequently to give it a slightly demulcent quality. But these are not sufficiently important to require to be noticed, or to be classed as medicines.

Diluents are merely secondary remedies. They are given in acute inflammatory diseases, to lessen the stimulant quality of the blood. They are used to promote the action of diuretics in dropsy, and to favour the operation of sudorifics.

Dilu'tus. Dilute or diluted.

DIMIDIA'TUS. Half round; extending halfway round. Applied, in *Botany*, to the parts of plants.

Dimness of sight. See *Caligo*.

Dimpled. See *Umbilicatus*.

Dinant. A small town six leagues from St. Malo in France, which has mineral waters containing carbonates of iron, muriates of soda and potash, &c. These springs are much resorted to.

Di'nicus. (From δινος, giddiness.) Applied to a medicine which relieves giddiness.

Dinos. See *Dinus*.

DI'NUS. (*us*, *i.* m.; δινος; from δινεω, to turn round.) Dizziness, giddiness. See *Vertigo*.

Dio'bolon. Διωβολον. An ancient weight of two oboli, or a scruple.

Diodonce'phalus. (From δις, twice, οδους, a tooth, and κεφαλη, a head.) An ill constructed term used by G. St. Hilaire to designate a monstrosity in which there are double rows of teeth

DIŒ'CIA. (*a*, *æ*. f.; from δις, double, and οικος, a house.) The name of a class of plants in the sexual system of Linnæus, containing such as have barren, or male, flowers on one individual, and fertile, or female, ones on another of the same species.

DIŒNA'NTHES. (From δια, and οινανθη, the œnanthe.) An epithem anciently used in cholera, into the composition of which the herb-œnanthe or dropwort entered.

DIOI'CUS. (From δις, double, and οικος, a house.) Diœcious. Plants and flowers are so called, when the barren and fertile flowers grow on separate individuals.

DIONY'SIA. An epithet of ivy.

DIONYSI'SCUS. (From Διονυσος, Bacchus, who was of old represented as having horns.) Vogel gives this name to certain bony excrescences, near the temples.

DIOPO'RUM. (From δια, and οπωρα, autumnal fruits.) A medicine composed of ripe fruits, formerly used in quinsy.

DIO'PTRA. (From διοπτομαι, to see through.) *Dioptron.* An instrument for dilating any natural cavity, the better to see its condition. A speculum.

DIOPTRI'SMOS. The operation of dilating a part with the dioptra.

DIOPTRUM. Διοπτρον. The lapis specularis. See *Lapis specularis.*

DIO'ROBUM. (From δια, and οροβος, a vetch.) A Greek medicine, in the composition of which there were vetches.

Diorosis. See *Diorrosis.*

DIORRHE'SIS. Διορρησις. The same as *Diorrhosis.*

DIORRHO'SIS. (Διορρωσις, διορωσις; from δια, and ορρος, the serum.) The conversion of any part into serum.

DIORTHO'SIS. (From διορθοω, to correct.) The reduction of a fracture or dislocation.

DIOSCO'REA. (*a*, *æ*. f.; named in honour of Dioscorides.) The name of a genus of plants in the Linnæan system. Class, *Diœcia*; Order, *Hexandria.*

DIOSCOREA ALATA. The name of the plant which affords the esculent root, called the yam; which, however, is obtained from three species: the *alata*, *bulbifera*, and *sativa*. They grow spontaneously in both Indies, and their roots are promiscuously eaten as the potato is with us. There is great variety in the colour, size, and shape of yams; some are generally blue or brown, round or oblong, and weigh from one pound to two. They are esteemed when dressed as being nutritious and easy of digestion, and are preferred to wheaten bread. Their taste is somewhat like the potato, but more luscious. The negroes, whose common food is yams, boil and mash them. They are also ground, and made into bread and puddings.

When they are to be kept for some time, they are exposed upon the ground to the sun, as we do onions, and when sufficiently withered, they are put into dry sand in casks, and placed in a dry garret, where they remain often for many seasons without being any the worse for keeping.

Dioscorea bulbifera. See *Dioscorea alata.*

Dioscorea sativa. See *Dioscorea alata.*

DIOSCU'RI. (*i. e.* Διος Κουροι, the sons of Jupiter, or Castor and Pollux: so named from their twin-like equality in shape and position.) The parotid glands.

DIO'SMA. (*a*, *æ*. f.; from Δις, Διος, Jove, and οσμη, a smell: on account of its divine smell.) The smell of some of the species, however, is so far from divine, that a division called *Barosma* has been formed to include them. A genus of plants in the Class, *Pentandria*; Order, *Monogynia.*

DIOSMA CRENATA. *Barosma crenata.* This plant grows at the Cape of Good Hope, and is called by the natives *Buchu.* The leaves are diuretic and anodyne, and have been found useful in cases of chronic inflammation of the kidney and urinary bladder, and in irritable and spasmodic states of the latter organ. Both water and alkohol extract the medicinal virtues of the buchu leaves, which seem to reside in a volatile oil and extractive matter. The best way of administering it is in infusion of one ounce of the leaves to a pint of water, half of which should be taken at divided doses in the twenty-four hours. The London Pharmacopœia orders an infusion, and the Dublin an infusion and a tincture.

DIO'SMINE. A bitter matter detected by Mr. Brandes in the leaves of the *Diosma crenata*, and supposed to be their active principle.

DIO'SPYROS. (*os*, *i*. f.; from Δις, Διος, Jupiter, and either πυρ, a flame, or fire, or else πυρος, wheat: the application of either is unintelligible.) The name of a genus of plants in the Linnæan system. Class, *Polygamia*; Order, *Diœcia.*

DIOSPYROS EBE'NUM. The plant which yields the black ebony. See *Ebony.*

DIOSPYROS LOTUS. The Indian date plum. The fruit, when ripe, has an agreeable taste, and is very nutritious; when unripe, it is very astringent.

DIO'TA. (From δις, double, and ους, gen. ωτος, the ear.) 1. A drinking cup with two ears.

2. A circulatory vessel with two ears, used by the old chemists.

3. A wooden cup lined with resin and aromatics, to give a flavour to what is drunk out of it.

DIOXELÆ'UM. (From δια, οξυς, acid, and ελαιον, oil.) A cataplasm which contained oil and vinegar, used by the Greeks.

DIO'XUS. (From δια, and οξυς, acid.) A collyrium composed chiefly of vinegar.

DIPE'TALOUS. (*Dipetalus*; from δις, and πεταλον, a petal.) Two-petalled.

DI'PHRYGES. Διφρυγες. Oxide of copper.

DIPHTHERI'TIS. (From διφθερα, a skin or membrane.) *Angina pellicularis.* This name has been given by M. Bretonneau to a peculiar variety of pharyngitis, accompanied by the formation of a false membrane which was epidemic at Tours in 1818 and the three succeeding years. There are two objections to the term *diphtheritis*: the one is that it already exists as a Greek word, with a very different signification, namely, that of a *person clad in a hide*; the other is that, according to the analogy of other medical terms of similar construction, it would signify not inflammation

accompanied with the formation of a membrane, but inflammation of the membrane itself.

DIPHY'LLOUS. (*Diphyllus*, *i.* m.; from δις, double, and φυλλον, a leaf.) Two-leaved; applied to the perianth of flowers, when there are two calyces; as in *Papaver rhœas*.

DIPLASIA'SMUS. (From διπλοω, to double.) The re-exacerbation of a disease.

DI'PLOE. (*e*, *es.* f.; from διπλοω, to double.) The cancellated substance between the two tables of the skull.

DIPLO'MA. (*a*, *atis.* n.; διπλωμα; from διπλοω, to double: so called, because usually written on parchment and folded up.) 1. A writing which confers some privilege, and especially as relates to medical affairs, a licence to practise physic or surgery.

2. A double vessel: to boil *in diplomate*, is to boil in what is called a water bath. See *Balneum*.

DIPLO'PIA. (*a*, *æ.* f.; from διπλοος, double, and οπτομαι, to see.) *Visus duplicatus.* A disease in which the person sees an object double. The causes of this affection are very imperfectly known. When idiopathic, it is produced by some structural disease or by debility. It is mostly symptomatic of indigestion, intoxication, worms, hysteria, &c.

Dippel's animal oil. See *Oleum animale Dippelii.*

Dipsacon. See *Dipsacus.*

Dipsacum. See *Dipsacus.*

DI'PSACUS. (*us*, *i.* m.; from διψα, thirst: so called from the concave shape of its leaves, which hold water, by which the thirst of the traveller may be relieved.)

1. The name of a genus of plants in the Linnæan system. Class *Syngenesia*; Order, *Polygamia.* The teasel.

2. A diabetes has been so called, from the continual thirst attending it.

DI'PSAS. (From διψα, thirst.) The Greek name of a serpent, the bite of which was mortal, and caused a parching thirst.

DIPSE'TICUS. (From διψα, thirst.) Productive of thirst.

DIPSOMA'NIA. (From διψα, thirst, and μανια, madness.) A name that has been given to a disease which consists in an unconquerable desire for spirituous drinks. This is a strange sort of disease, and seems to be nothing more than the well-known vice of ebriety.

DIPSO'SIS. (From διψα, thirst.) Morbid thirst. See *Polydipsia.*

DI'PTERA. (From δις, twice, and πτερον, a wing.) An order of insects characterised by having two wings.

DIPTEROCA'RPEA. A natural family of plants, the type of which is the genus *Dipterocarpus.*

DIPYRI'TES. (From δις, twice, and πυρ, fire.) *Dipyros.* An epithet given by Hippocrates to bread twice baked, and which he recommended in dropsies.

DIRE'CTOR. (*or*, *oris.* m.; from *dirigo*, to direct.) 1. A grooved instrument for guiding the knife in some surgical operations.

2. The name of a muscle.

Director penis. See *Erector penis.*

Diringa. See *Acorus calamus.*

Disciform. (*Disciformis*; from *discus*, a quoit, and *forma*, likeness.) Resembling a disk, or quoit, in shape. Applied, in *Natural History*, *Anatomy*, and *Botany*, to various objects, from their shape.

DI'SCOID. (*Discoides*; from δισκος, a quoit, and ειδος, resemblance.) Synonymous with *disciform.*

DISCRETO'RIUM. The diaphragm has been so called, because it separates the thorax from the abdomen.

DISCRI'MEN. A kind of bandage formerly used in the operation of bleeding from the frontal vein. It seems to have been so called, because, in passing longitudinally in the direction of the sagittal suture, it *divided* the head into two equal parts.

DI'SCUS. (*us*, *i.* m.; from δισκος, a quoit or disk, and from its flat and round appearance like the circumference of the sun.) The disk, or central part of a leaf, and of a compound flower. In the common daisy, the white leaflets of the flower surround the disk.

The disk of a leaf is the whole flat surface within the margin, both above and below.

DISCU'TIENT. (*Discutiens*; from *discutio*, to shake to pieces.) *Discusorius*; *Diachyticus.* Applied to those substances which possess a power of repelling or resolving tumours.

DISEASE. *Morbus.* Any deviation from the natural and healthy actions of the whole system, or any particular organ.

Diseases may be,

Local. Affecting some particular part.

Constitutional. Affecting the whole system.

Specific. Marked by some disordered vital action, not common to diseases in general, but peculiar to the individual disease.

Idiopathic. Primary, and not dependent on any other disease.

Symptomatic, or *Sympathetic.* Dependent on and accompanying some other disease.

Periodical. Recurring at fixed periods.

Acute. Severe and of short continuance.

Chronic. Of long continuance.

Sporadic. Arising from adventitious causes affecting the individual.

Epidemic. Generally diffused among a population, and arising either from contagion, or some atmospheric or other cause, the influence of which is extensively felt.

Endemic. Peculiar to, or especially prevalent in, a certain region.

Intercurrent. Sporadic, but occurring during the prevalence of epidemic or endemic diseases.

Contagious, or *Infectious.* Communicable from one individual to another by personal contact, or by effluvia diffused through the air.

Congenital. Born with the individual.

Hereditary. Descending from parents to their offspring.

Acquired. Neither hereditary nor congenital, but dependent on some cause operating after birth.

Sthenic. Attended with strong activity of the vital powers.

Asthenic. Attended with sinking of the vital powers.

There are many other distinctions of diseases of more limited application: thus, diseases are *febrile*, attended with fever; *exanthematous*, consisting in an eruptive fever; *intermittent*, marked by a regular cessation and recurrence of the symptoms; *remittent*, marked by a regular diminution and exacerbation of the symptoms; *mild*, unaccompanied with any formidable symptoms; *malignant*, severely depressing the vital powers, dangerous, and intractable; the term malignant has no very definite signification, but is applied chiefly to febrile diseases of the asthenic kind, and to local affections of a cancerous nature; *infantile*, most frequent in childhood; *puerperal*, incident to women soon after parturition.

Diseases of artisans. Besides the common causes of disease to which all mankind are more or less subject, there are some connected with particular occupations and modes of life, the investigation of which is alike important in a practical and philosophical point of view. These causes of disease may, in a general way, be referred — 1. To confinement and bad ventilation. 2. To the effects of temperature and moisture. 3. To sedentary habits. 4. To over-fatigue. 5. To excessive exertion of some parts of the body, and inactivity of others. 6. To constrained and unnatural postures. 7. To the noxious influence of animal, vegetable, or mineral particles inhaled with the air, or otherwise applied to the body.

1. *Confinement and bad ventilation.* — The effects of these evils are most conspicuous in children, who suffer more severely from them than adults. In our manufacturing towns, where crowds of children are confined together in a close and impure atmosphere, it is found that the growth of the frame and the expansion of the mind are alike impeded, and the scrofulous diathesis induced; hence ensue deformity, defective development of the sexual system at puberty, and the various modifications of tubercular disease.

2. *Temperature and moisture.* — Constant exposure to either too high or too low a temperature is well known to debilitate the frame and impair the general health; and this effect is much increased, in either instance, by excessive moisture. It does not appear, however, that any ordinary exposure to these causes is productive of any particular diseases; and it is only when the body is subjected to sudden transitions from one to the other, that serious consequences ensue. These arise, chiefly, from the sudden obstruction of cutaneous perspiration, and rapid changes in the relative state of the circulation on the surface and in deep-seated organs. Brass and iron founders, glass-blowers, bakers, brewers, and various other artisans, are continually subjected to an injuriously warm atmosphere; and an imprudent transition to the open air, and still more an exposure to cold draughts, frequently gives rise to catarrhal and rheumatic affections, asthma, and visceral inflammations.

3. *Sedentary habits.* — The general effect of want of exercise is to diminish the tone of the muscles, to render the functions of the abdominal viscera torpid, and to induce languor and debility of the whole system, with a predominance of the lymphatic temperament: hence, dyspepsia, constipation, hæmorrhoids, obesity, and, in females, leucorrhœa, and derangements of the menstrual function. The sitting posture, also, when too long continued, is evidently inimical to the free performance of various important functions. Literary persons, clerks, weavers, sempstresses, and many others, are liable to suffer in their health from deficient exercise and the sitting posture. There are some occupations which combine an unnatural and constrained position of the body with sedentary habits: these cases will be presently noticed.

4. *Over-fatigue.* — An undue expenditure of muscular power doubtless tends to shorten the term of life, by gradually exhausting the vital energy; its effects, however, are seldom very appreciable, unless over-exertion be combined with intemperance, or habits otherwise unhealthy. Coal-heavers, porters, and various others are liable to suffer from over-exertion of the muscles.

5. *Excessive exertion of some parts of the body, and inactivity of others.* — The bad consequences of excessive exertion of particular organs is exemplified in diseases of the heart, lungs, and their great vessels, which are produced by over-exertion of the respiratory apparatus, in those who play on wind instruments, and in singers. Amaurosis, cataract, and other diseases of the eyes, are common among those whose occupation obliges them to exercise their vision for a length of time on very minute objects, or to expose their eyes to a glare of light; as watchmakers, engravers, those engaged about large furnaces, &c. To the combined influence of posture and local exertion, may be attributed the frequency of hernia at the groin in cavalry soldiers who ride with very long stirrups. The effect of inactivity on particular parts of the body seldom amounts to absolute disease; but muscular debility is the general result of insufficient exercise of any of the limbs: we have a familiar example in postilions, and others who are constantly riding, and who are frequently so weak in the legs, that, even when otherwise robust, they are unable to walk any distance without great fatigue.

6. *Constrained and unnatural postures.* — The evils arising from this cause are experienced by many classes of artisans. In tailors, shoemakers, button burnishers, and others, the bent position of the body weakens the spine, and interferes with the functions of the thoracic and abdominal viscera, while the strong pressure which is frequently made on the epigastrium is particularly injurious to the stomach: hence curvature of the spine, dyspepsia, gastrodynia, constipation, hæmorrhoids, asthma, and pulmonary diseases. Clerks in offices, who acquire the habit of leaning too much over the desk, and pressing the epigastrium against its edge, are subject to the same evils in a minor degree.

7. *The action of animal, vegetable, or mineral particles, inhaled with the air, or otherwise applied to the body.* — The principal morbific agents of this kind are mercury, lead, copper, arsenic, antimony, zinc, tin, the mineral acids, animal

putrefaction, vegetable putrefaction, soot, and fine powders of various kinds, which produce mechanical irritation.

Mercury. — Those who work in quicksilver mines, glass platers, and gilders of silver, brass, and copper, are the persons chiefly liable to suffer from the fumes of mercury. Many of the symptoms thus induced, are similar to those which result from the long continued use, or rather abuse, of mercury as a medicine; protracted salivation, extreme sensibility to cold, great nervous irritability, ulcerations of the mouth and fauces, pains resembling rheumatism, cachectic eruptions, and emaciation. There is one affection, however, common among workmen who are exposed to the fumes of mercury, and which is seldom if ever observed as a consequence of its medicinal use. This is a peculiar form of paralysis, which has been named the *mercurial palsy*. It sometimes comes on suddenly, but more frequently by slow degrees. The first symptom is usually a want of command over the muscles of the arms, which are affected also with slight convulsive twitchings; these symptoms increase to a continual tremor, which now extends to the lower limbs and to the whole body; the patient performs with difficulty any function in which the muscles are concerned, even that of mastication; the general health becomes greatly disordered; the patient is restless, depressed, and subject to headach, delirium, and disorders of the bowels. After a while the general health often improves somewhat, while the paralytic state of the muscles continues, and the patient lives many years in a helpless and miserable state. The disease under consideration generally arises from long continued exposure to mercurial vapours; but, in some instances, an exposure of only a few hours has been known to produce it. The treatment of this affection is little understood. An immediate removal from the source of the mischief is of course indispensable; and, in recent cases, is sometimes alone sufficient for the restoration of health. Persons who have once suffered from the mercurial palsy, are very liable to a relapse from the slightest exposure to the original cause.

Lead. — Those who suffer chiefly from the poison of lead, are the workmen in lead mines, those engaged in separating it from its ores, plumbers, painters, glaziers, colour-grinders, and type-founders. The poisonous effects of this metal constitute the disease called *Colica pictonum*, already treated of in the article *Colica*.

Copper. — It does not appear that artificers in copper are liable to suffer much from its poisonous effects. They are sometimes affected with a form of colic resembling the lead colic; but such cases are not frequent. Copper-filers are very liable to pulmonary diseases; but these are not referrible to the deleterious properties of the copper, considered as a metallic poison, but to the mechanical irritation of its finer particles inhaled into the lungs. Brass-founders also are very subject to asthma; but this may arise partly from the cause just referred to, and partly from the fumes of the zinc with which the copper is amalgamated.

Arsenic, antimony, zinc, and *tin.* — Arsenic, though of frequent use in the arts, is employed in small quantities, and for the most part in the metallic state: as it possesses no deleterious properties till oxidated, no particular bad consequences are known to result to the workmen. Antimony also is used, but in minute quantities, and seems to produce no bad effect. Those who are exposed to the fumes of zinc, do not usually suffer materially: it would seem, however, that they are not entirely harmless, as a case is given in Rust's Magazine of an apothecary's assistant, who, having inhaled them in large quantity, was seized with very alarming symptoms. (See *Poisons.*) Tin, in the metallic state, is largely used in the arts, but is then inert: the oxide and the muriates, which are poisonous, are employed by colour-makers and dyers, but not under circumstances in which any bad effects are likely to ensue.

Mineral acids. — The manufacturers of the mineral acids, and persons of other occupations who are exposed to their fumes, are liable, without due caution, to be asphyxiated, and to become subject to pulmonary diseases, from the irritating effects of the acrid vapours on the air-passages: these evils, however, are very easily avoided, by conducting such operations in a sufficiently free atmosphere, and other obvious precautions.

Animal putrefaction. — The influence of putrid animal effluvia in producing disease, was formerly much overrated, and they were regarded as a frequent cause of pestilential fevers. It is now well ascertained, that they have no particular tendency to engender fevers, and that serious effects of any kind arise from them only when they are in a concentrated state. The persons who suffer most from concentrated animal effluvia, are nightmen. From observations made at Paris, among the persons employed in emptying the extensive *fosses d'aisance* of that city, it appears that they are subject to several morbid affections caused by the evolution of different gases. Vapours consisting chiefly of ammoniacal gas are vulgarly called *La mitte*. They produce smarting in the eyes, accompanied with the sensation of a pungent and disagreeable smell; these are followed by pain, commencing in the orbit, and extending to the forehead, with discharge from the eyes, and sometimes blindness, which continues for several days. These symptoms are relieved by a flow of tears, and no treatment is required but shading the eyes from the light, and exposing them to the open air; in severer cases, cold water is applied, and the patient is kept in a dark room. The term *Le plomb* is applied to two kinds of effluvia; one consisting of sulphuretted hydrogen and hydrosulphuretted ammoniacal gases, which causes a convulsive affection; the other consisting of azotic gas, which produces asphyxia: the former is destroyed by the chlorides of lime and soda; the latter is rendered innocuous by a free circulation of fresh air.

The putrid effluvia evolved in dissecting-rooms, produces no other bad effects than indigestion, with depression of spirits, and frequently diarrhœa: these symptoms are only experienced

by those unaccustomed to the air of the dissecting-room, and they soon wear off.

The insertion of putrid matter into a wound, as often happens to anatomists, may be followed by very serious consequences: these are familiar even to the young student, and need not be enlarged upon here.

Vegetable putrefaction. — The noxious effects of the miasma arising from decomposing vegetable matter, are well known. The only persons who are particularly exposed to this cause by the nature of their occupation, are steepers of hemp, who are said to be very liable to intermittent fever.

Soot. — There is a disease of the scrotum, which, from its greater frequency among chimney-sweepers than any other class of persons, has been denominated *chimney-sweepers' cancer*. It was for some time supposed to arise exclusively from the application of soot to the part; but this is now generally disbelieved, because the disease has been observed to occur in persons who have not in any manner come in contact with soot. It commences as a wart-like excrescence on the lower part of the scrotum, which turns into a superficial, ragged, ill-looking, and painful sore, with hard and prominent edges. After a while it consumes the textures covering the testicle, and seizes on that organ, which becomes enlarged and indurated. It creeps along the spermatic cord into the abdomen, affecting the inguinal glands in its course; and finally attacks some of the viscera, and destroys the patient. The disease is not common. The only remedy is early extirpation of the part affected. The real cause of this disease is not understood.

Substances which act by the mechanical irritation of their particles. — A great variety of artisans suffer more or less from this cause; as needle-pointers, grinders of all kinds, filers of brass, iron, and other metals, stone-cutters, pearl and horn button makers, turners, sawyers, millers, starch-makers, flax-dressers, wool-carders, feather-dressers, weavers, and many others. Of these, needle-pointers and grinders suffer so frequently, that the chronic bronchitis which is the chief form of disease induced by all the occupations above enumerated, is vulgarly known by the names of *pointer's cough* and *grinder's rot*. The form of bronchial affection varies somewhat in different classes of artisans: in needle-pointers, grinders, and stone-cutters, it usually is of a purely inflammatory character; in horn and pearl button makers, it is frequently more or less of an asthmatic character.

The artisans mentioned above, as subject to pulmonary diseases from the effect of irritating powders, are also liable to ophthalmia from the same cause. Several contrivances have been proposed in this country and in France, for protecting the workmen from the effect of irritating powders. That of Mr. Abrahams, of Sheffield, is particularly valuable.

DISINFECTION. The process of dispelling and neutralising contagious miasmata. This is done by the copious admission of fresh air, and the use of certain chemical substances.

Disk. See *Discus.*

DISLOCA'TION. (*Dislocatio, onis.* f.) Luxation. The displacement of the articular extremity of a bone. When dislocation takes place as the result of violence, it is called *primitive*, or *accidental;* when it happens as a consequence of disease which has destroyed the textures forming the joint, it is called *consecutive*, or *spontaneous.*

DISPE'NSARY. (*Dispensarium, ii.* n.; from *dispendo*, to distribute.) 1. The shop or place in which medicines are prepared.

2. An institution, in which the poor are supplied with advice and medicines.

DISPE'NSATORY. (*Dispensatorium, ii.* n.; from *dispendo*, to distribute.) *Antidotarium.* A book which treats of the composition of medicines.

DISPE'RMUS. (From δις, twice, and σπερμα, a seed.) Dispermous, or two-seeded.

DISSE'CTION. (*Dissectio, onis.* f.; from *disseco*, to cut asunder.) The cutting to pieces of any part of an animal, or vegetable, for the purpose of examining its structure. See *Anatomy.*

DISSE'CTUS. Dissected. A term, applied by botanists synonymously with *incised* and *laciniated*, to leaves which are cut, as it were, into numerous irregular portions. See *Leaf.*

DISSEPIME'NTUM. (*um, i.* n.; from *dissepio*, to separate.) A partition. Applied by botanists to partitions which separate the cells of a capsule. See *Capsula.*

Disse'ptum. (From *dissepio*, to separate.) The diaphragm, or muscle which divides the cavity of the thorax from that of the abdomen.

DISSI'LIENS. (From *dissilio*, to burst.) Dissilient, or bursting suddenly asunder. Applied, in *Botany*, to capsules, &c.

Disso'lvent. (*Dissolvens*, from *dissolvo*, to loosen.) 1. Applied to a medicine which dissolves morbid concretions.

2. In *Chemistry*, a menstruum.

Dissolution. (*Dissolutio, onis.* f.; from *dissolvo*, to loosen.) 1. Death.

2. The humoral pathologists applied this term to a diminution of consistence in the blood.

Dissolu'tus. (From *dissolvo*, to loosen.) Loose. Dysentery has been called *dissolutus morbus* by some writers.

DI'STANS. Distant: applied to petals, stems, &c., which are directed away from each other.

Distempera'ntia. Synonymous with *Intemperies.*

Distended. See *Ventricosus.*

DISTE'NTIO. (From *distendo*, to stretch out.) Distension or dilatation.

Distentio nervorum. A spasm or convulsion. — *Celsus.*

Disti'chia. See *Distichiasis.*

DISTICHI'ASIS. (*is, is.* f.; from δις, double, and στιχος, a row.) *Distichiasis; Distichia.* A disease of the eyelid, in which there is a double row of eyelashes, one growing in the natural direction, and the other turned inwards, irritating the globe of the eye.

DI'STICHUS. (Same etymon.) Two-ranked. Applied to stems, leaves, &c., when they spread in two horizontal directions; as the

branches of the *Pinus picea*, or silver fir, and the leaves of the *Taxus baccata*, or yew.

Distillatio per descensum. See *Descensus.*

DISTILLA'TION. (*Distillatio, onis.* f.; from *distillo*, to drop little by little.) *Catastagmos.* 1. A chemical process, which consists in separating the volatile principles of bodies by subjecting them to heat in one vessel, and condensing the volatile part in another. Distillatory vessels are either alembics or retorts; the former consist of an inferior vessel called a cucurbit, designed to contain the matter to be examined, and having an upper part fixed to it, called the capital, or head. In this last, the vapours are condensed by the contact of the surrounding air, or, in other cases, by the assistance of cold water surrounding the head, and contained in a vessel called the refrigeratory. From the lower part of the capital proceeds a tube, called the nose, beak, or spout, through which the vapours, after condensation, are, by a proper figure of the capital, made to flow into a vessel called the receiver, which is usually spherical. These receivers have different names, according to their figure, being called mattresses, balloons, &c. Retorts are a kind of bottle of glass, pottery, or metal, the bottom being spherical, and the upper part gradually diminishing into a neck, which is turned on one side.

2. A defluxion of rheum; a catarrh.

DISTILLATION, DESTRUCTIVE. The decomposition of bodies by a strong heat in one vessel, and the collection of the products in another.

DISTILLATORIUS. Appertaining to distillation. — *Vasa distillatoria*, vessels used in distilling.

Distilled vinegar. See *Acetum.*

Distilled water. See *Water.*

DISTINCT. *Distinctus.* Applied, in *Botany*, to parts of plants which are free, not adherent to other parts.

DI'STOMA. (*a, atis.* n.; from δις, and στομα, a mouth.) Two-mouthed. The name of a genus of worms in Rudolphi's classification.

DISTOMA HEPATICUM. *Fasciola humana* of Gmelin and others. The liver fluke. A small flat flounder-like worm, about the size of the nail of the little finger; found very frequently in the bile ducts of sheep and oxen. They have been found by Pallas, Chabert, and Bucholz, in the human subject.

DISTO'RTION. (*Distortio*; from *distorqueo*, to wrest aside.) Properly, the wresting of any part from its natural position by violence; it is generally used, however, to signify an unnatural direction of parts, from whatever cause, as a curved spine, a wry mouth, squinting, &c.

Distortor oris. See *Zygomaticus minor.*

DISTRA'CTION. Chemists have used this term to signify the separation of the elements of bodies, when effected with difficulty.

DI'STRIX. (*ix, icis.* f; from δις, double, and θριξ, the hair.) A disease of the hair, in which it splits and divides at the end.

DISTYLUS. (From δις, twice, and στυλος, a style.) Distyle. Having two styles.

Dittander. See *Lepidium sativum.*

Dittany. See *Dictamnus.*

Dittany, bastard. See *Dictamnus albus.*

Dittany of Crete. See *Origanum.*

Dittany, white. See *Dictamnus albus.*

DIURE'SIS. (*is, is.* f. Διουρησις; from διουρεω, to void the urine.) The excretion of urine. It is frequently applied to a more than usually abundant excretion of urine, whether from disease or the operation of medicine.

DIURE'TIC. (Διουρητικος. *Diureticus*; from διουρησις, a discharge of urine.) Applied to any thing which, when taken internally, augments the flow of urine from the kidneys. It is obvious that such an effect will be produced by any substance capable of stimulating the secreting vessels of the kidneys. All the saline diuretics seem to act in this manner. They are received into the circulation; and passing off with the urine stimulate the vessels, and increase the quantity secreted.

There are other diuretics, the effect of which appears not to arise from direct application, but from an action excited in the stomach, and propagated by nervous communication to the secreting urinary vessels.

The diuretic operation of squill, and other vegetables, appears to be of this kind.

There is still, perhaps, another mode in which certain substances produce a diuretic effect; that is, by promoting absorption. When a large quantity of watery fluid is introduced into the circulating mass, it stimulates the secreting vessels of the kidneys, and is carried off by urine. If, therefore, absorption be promoted, and if a portion of serous fluid, perhaps previously effused, be taken up, the quantity of fluid secreted by the kidneys will be increased. In this way digitalis seems to act: its diuretic effect, it has been said, is greater when exhibited in dropsy than it is in health.

On the same principle (the effect arising from stimulating the absorbent system), may probably be explained the utility of mercury in assisting several diuretics.

The action of these remedies is promoted by drinking freely of mild diluents. It is also influenced by the state of the surface of the body. If external heat be applied, diuresis is frequently prevented, and diaphoresis produced. Hence the doses of them should be given in the course of the day, and the patient, if possible, be kept out of bed.

The direct effects of diuretics are sufficiently evident. They discharge the watery part of the blood; and, by that discharge, they indirectly promote absorption over the whole system.

Dropsy is the disease in which they are principally employed; and when they can be brought to act, the disease is removed with less injury to the patient than it can be by exciting any other evacuation. Their success is very precarious, the most powerful often failing; and, as the disease is so frequently connected with organic affection, even the removal of the effused fluid, when it takes place, only palliates, without effecting a cure.

Diuretics have been likewise occasionally used in calculous affections, in gonorrhœa, and with a view of diminishing plethora, or checking profuse perspiration.

Murray, in his Elements of Materia Medica, classes the super-tartrate of potash, or cream of tartar, and nitrate of potash, or nitre, the muriate of ammonia, or crude sal-ammoniac, potash, and the acetate of potash, or kali acetatum, among the *saline* diuretics; and selects the following from the *vegetable* kingdom: — scilla maritima, digitalis purpurea, nicotiana tabacum, solanum dulcamara, lactuca virosa, colchicum autumnale, graviola officinalis, spartium scoparium, juniperis communis, copaifera officinalis, pinus balsamea, and pinus larix; and the blistering fly from the *animal* kingdom.

In speaking of particular diuretics, Dr. Cullen says, the diuretic vegetables mentioned by writers are of very little power, and are employed with very little success. Of the umbellatæ, the medicinal powder resides especially in their seeds; but he never found any of them very efficacious. The semen dauci sylvestris has been commended as a diuretic; but its powers as such are not very remarkable. In like manner, some of the *plantæ stellatæ* have been commended as diuretics; but none of them deserve our notice, except the *rubia tinctorum*, the root of which passes so much by the kidneys as to give its colour to the urine. Hence it may fairly be supposed to stimulate the secretories; but Dr. Cullen found its diuretic powers did not always appear, and never to any considerable degree; and as, in brute animals, it has always appeared hurtful to the system, he does not think it fit to be employed to any extent in human diseases. The bardana, lithospermum, ononis, asparagus, inula campana, are all substances which seem to pass, in some measure, by the kidneys; but their diuretic powers are hardly worth notice.

The principal articles included by Dr. Cullen, in his catalogue of diuretics, are dulcamara, digitalis, scilla; some of the alliaceæ and siliquosæ; the balsams and resins; cantharides, and the diuretic salts.

Divapora'tio. Evaporation.

DIVARICATION. The separation of two things previously united. Applied in Anatomy, Botany, &c.

DIVARICA'TUS. Straddling; standing wide from each other.

Divellent affinity. See *Affinity, quiescent.*

DIVE'RGENS. Diverging. Applied, in *Botany*, to branches which spread wide from the stem, almost horizontally.

Diversiflo'rus. (From *diversus*, different, and *flos*, a flower.) A term applied to umbels which have regular florets in the centre and irregular towards the circumference.

Diverso'rium. (An inn or lodging; from *diversor*, to resort to.) A whimsical name given to the receptaculum chyli.

DIVERTI'CULUM. (*um*, *i.* n.; a by-way.) A term generally applied by anatomists to any hollow appendage attached to and communicating with the intestinal tube.

Diverticulum Nuckii. The opening on each side through which the round ligament of the uterus passes. Nuck asserted that it remained open a long time after birth.

Dividing bandage. *Fascia dividens.* A bandage used to keep parts separate from each other, and prevent adhesion, as in cases of burns.

Divulsio urinæ. This term has been used to signify that state of the urine in which a nebulous deposit is diffused through it.

Dixon's antibilious pills. These are composed of aloes, scammony, rhubarb, and emetic tartar.

DOCIMA'SIA. (From δοκιμαζω, to examine.) The art of examining fossils, in order to discover what metals, &c. they contain.

DOCIMA'STIC. Appertaining to the *Docimasia.*

Dock. See *Rumex.*

Dock-cresses. See *Lapsana.*

Dock, sour. See *Rumex acetosa.*

Dock, water. See *Rumex hydrolapathum.*

Docna Sara. A place among the Carpathian mountains, where there is a mineral spring containing sulphate, carbonate, and muriate of soda, silica, and iron.

Dodder. See *Cuscuta.*

DODECADA'CTYLUS. (Δωδεκα δακτυλος; from δωδεκα, twelve, and δακτυλος, a finger: so named because its length is about the breadth of twelve fingers.) A Greek epithet of the duodenum. It must be observed, that, at the time this name was given, anatomy consisted in the dissection of brutes; and the length was therefore probably adjudged from the gut of some animal, and not of man.

DODECA'NDRIA. (*a*, *æ.* f.; from δωδεκα, twelve, and ανηρ, a man.) The name of a class of plants in the sexual system, embracing those with hermaphrodite flowers, and twelve stamina.

Dodecapha'rmacum. (From δωδεκα, twelve, and φαρμακον, a medicine.) A name formerly given to any ointment consisting of twelve ingredients, as the *unguentum apostolorum.*

Dodeca'theon. (From δωδεκα, twelve, and θεος, a god.) An antidote consisting of twelve simples: so named after the twelve principal deities of the Greeks.

Do'dra. A drink used by the ancients, which was made of nine ingredients.

DO'DRANS. (*s*, *tis.* m.) A measure called a palm, or the space between the end of the thumb and the end of the little finger, when fully extended: about nine inches. This is nearly the palm of foreign nations, and is something more than the quarter of an English yard.

Dog's-bane, Syrian. See *Asclepias Syriaca.*

Dog-days. See *Dies caniculares.*

Dog's-grass. See *Triticum repens.*

Dog's-mercury. See *Mercurialis.*

Dog-rose. See *Rosa canina.*

Dog-stones. See *Orchis mascula.*

DOGMATISTS. (*Dogmatici*; δογματικοι; from δογμα, a doctrine.) A set of ancient physicians, of whom Hippocrates is presumed to be the first, who supposed principles from which they drew conclusions, and applied those principles and conclusions to particular diseases: hence they were also called *logici*, logicians, and were distinguished from the *empyrici* and *methodici.*

DOLABRIFO'RMIS. (From *dolabra*, a hatchet, and *forma*, resemblance.) Hatchet-shaped. Applied to a leaf, which is compressed,

with a very prominent dilated keel, and a cylindrical base; as in *Misembryanthemum dolabriforme*.

Dolet. An alchemical name of peroxide of iron.

DO'LICHOS. (*os*, *i.* m.; from δολιχος, long: so called from the length of its pods.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria*.

2. The pharmacopœial name of the cowhage. See *Dolichos pruriens*.

Dolichos pruriens. The systematic name of the *Dolichos*, or cowhage.

Dolichos — volubilis, leguminibus racemosis, valvulis subcarinatis hirtis, pedunculis ternis, of Linnæus. The pods of this plant are covered with sharp hairs, which are employed medicinally in form of electuary, as an anthelmintic. The manner in which these hairy spicula act, seems to be purely mechanical: for neither the tincture, nor the decoction, possess the least anthelmintic power.

Dolichos soja. The systematic name of the plant which affords the soy. It is much cultivated in Japan, where various culinary articles are prepared from it; but the two principal are a sort of butter, termed *miso*, and a pickle called *sooju*.

Several species of dolichos are used as food in different countries; as *D. ensiformis* in Jamaica, *D. tuberosus* in Martinique, *D. bulbosus* and *D. lignosus* in the East Indies.

DO'LOR. (*or*, *oris.* f.) Pain.

Dolo'res. Pains. The name given by some nosologists to a class of diseases of which pain is a prominent symptom.

Dolorosi morbi. Linnæus thus designates the class of diseases called *dolores* by other nosologists.

Dolphin. See *Delphinus*.

Dolphin, acid of. See *Delphinic acid*.

Domestic medicine. Medicine as practised by unprofessional persons in their own families. Many treatises have been written on domestic medicine. In as far as these consist of general precepts for the preservation of health, and guarding against the causes of disease, they are highly useful; but when they attempt to teach those who are unacquainted with the structure and functions of the animal body, to recognise and treat its diseases, they are highly pernicious, and are, in effect, often written with sinister intentions by persons who are little better than quacks.

Dominarum aqua. An emmenagogue medicine prescribed by Mynsicht.

Donax. A Latin word for a reed, and also for a species of shellfish.

Doradilla. See *Asplenium ceterach*.

DORE'MA. (Δωρημα, a gift.) A genus of plants. Class, *Pentandria*; Order, *Digynia*.

Dorema ammoni'acum. This is now ascertained to be the plant which yields ammoniacum, which, till lately, was supposed to be the produce of the *Heracleum gummiferum*. The true plant, which is a native of Persia, has been brought home by Colonel Wright, and described by Mr. Don. It is a robust perennial plant, upwards of seven feet high, and about four inches in circumference at the lower part of the stem. It grows wild between Yerdekaust and Kumesha, in the province of Irauk. When the plant has attained perfection, it is perforated by swarms of beetles, and through these punctures the ammoniacum exudes. It is also procured from incisions, and allowed to drop on the ground, where it hardens by exposure to the air and sun. The best ammoniacum is brought from the East Indies; that from Barbary is contaminated with red earth.

Ammoniacum is of a yellowish colour externally, and white within; it has a peculiar faint and not unpleasant smell, and a sweetish bitter nauseous taste. It is brittle when cold, but becomes ductile by the heat of the hand. It is partially soluble in water, alkohol, ether, vinegar, and alkaline solutions. When triturated with water, it forms a milky fluid. According to Braconnot, ammoniacum consists of resin 70·0, gum 18·4, glutinous matter 4·4, water 6·0; loss 1·2.

Ammoniacum agrees generally in its medicinal properties with the rest of the fœtid gums. Its chief use is as a stimulating expectorant, in cases of chronic bronchitis, asthma, &c. Its antispasmodic action is very similar to that of assafœtida, but less powerful. It is used externally as a discutient. The dose of ammoniacum, in substance, is from ten to thirty grains. Its officinal preparations are, *Mistura ammoniaci*, L. D.; *Emplastrum ammoniaci*, L.; *Emplastrum ammoniaci cum hydrargyro*, L.; *Emplastrum gummosum*, E.; *Pilulæ scillæ compositæ*, L. E.

Do'ridis humor. Sea-water: so named from *Doris*, daughter of Oceanus and Thetis.

DORO'NICUM. (*um*, *i.* n.; from *dorongi*, Arab.) A genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua*. Leopard's bane.

Doronicum germanicum. See *Arnica*.

Doronicum romanum. The pharmacopœial name of the Roman leopard's bane. See *Doronicum pardalianches*.

Doronicum pardalianches. The systematic name of the Roman leopard's bane; called also *Doronicum romanum*.

Doronicum — foliis cordatis, obtusis, denticulatis; radicalibus petiolatis; caulinis amplexicaulibus, of Linnæus. The root of this plant, in an overdose, is said to be an acrid poison: but instances are related of its efficacy in vertigo, epilepsy, and other nervous diseases.

DO'RSAL. (*Dorsalis*; from *dorsum*, the back.) Belonging to the back.

Dorsal vertebræ. See *Vertebræ*.

Do'rso-costa'lis. The name given by Chaussier to the *serratus posticus superior* muscle.

Do'rso-su'pra acromia'nus. The *trapezius* muscle. — *Chaussier*.

Do'rso-trachelia'nus. The *splenius colli* muscle. — *Chaussier*.

DORSTE'NIA. (*a*, *æ.* f.; named in honour of Dr. Dorsten.) The name of a genus of plants in the Linnæan system. Class, *Tetrandria*; Order, *Monogynia*.

Dorstenia braziliensis. The systematic name of a plant, the root of which is used by the natives of Brazil, internally and externally. They call it *Caa apia*. When chewed, it has the same effects as ipecacuanha. The wounds from poisoned darts are said to be cured with the juice of the root, which they pour into the wound.

Dorstenia contrayerva. The systematic name of the plant which affords the contrayerva root; called also, *Contrayerva; Drakena; Cyperus longus, odorus, peruanus; Bezoardica radix.* The contrayerva root was first brought into Europe about the year 1581, by Sir Francis Drake, whence its name Drakena. It is the root of a small plant found in Peru, and other parts of the Spanish West Indies. Dr. Houstoun observes, that the roots of different species of dorstenia are promiscuously gathered and exported for those of the contrayerva; and, as all the species bear a great resemblance to each other, they are generally used for medical purposes in this country. The tuberous parts of these roots are the strongest, and should be chosen for use. They have an agreeable aromatic smell; a rough bitter, penetrating taste; and, when chewed, they give out a sweetish kind of acrimony.

It is diaphoretic and stimulant, and was formerly much used in low fevers and other asthenic diseases.

By the assistance of heat, both spirit and water extract all its virtues; but they carry little or nothing in distillation; extracts made by inspissating the decoction, retain all the virtues of the root.

The compound powder of contrayerva is formed by combining five ounces of contrayerva root with a pound and a half of prepared shells. This powder was formerly made up in balls, and called *lapis contrayervæ*. See *Pulvis contrayervæ compositus*. The dose of the powdered root is from gr. x. to ʒ ss. It is seldom administered alone.

Dorstenia drakena. The systematic name for one sort of the contrayerva.

Dorstenia houstonii. A species of contrayerva. See *Dorstenia contrayerva*.

Dosis. (*is, is.* f.; from διδωμι, to give.) A dose. The determinate quantity in which any medicine is given.

Do'thien. Δοθιην. A Greek name of the furunculus.

DOTHINENTERI'TIS. (From δοθιην, a boil; and εντερον, an intestine.) An inflammatory enlargement of Peyer's and Brunner's glands, particularly described by M. Bretonneau, and regarded by him as the cause of those symptoms which constitute *typhus* and several other kinds of fever. This opinion has been very hastily adopted by many in France, and by some in this country. The term *dothinenteritis* is in all respects objectionable; δοθιην means a boil, not an enlarged mucous follicle, and the compound word would signify furuncular inflammation of the intestines, which is not the meaning intended.

Dotted. See *Punctatus.*

Double. See *Didymus.*

Dove. See *Columba.*

Dove's-foot. See *Geranium.*

Dover's powder. See *Pulvis ipecacuanhæ compositus.*

Down of seed. See *Pappus.*

DRA'BA. (*a, æ.* f. Δραβη.) The name of a genus of plants in the Linnæan system. Class, *Tetradynamia*; Order, *Siliculosa.*

Draba verna. The systematic name of a small plant, very common on most walls. The seed is hot and stimulating, and might be used for pepper.

DRACÆ'NA. The name of a genus of plants. Class, *Hexandria*; Order, *Monogynia.*

Dracæna draco. The dragon-tree. A huge tree of the Canary islands, which attains the height of fifty or sixty feet, and the stem of which is from forty to fifty feet in circumference. It is remarkable for its great age. A dragon-tree at Oratava, in Teneriffe, had attained the above proportions when the Spaniards first landed in the island in the fifteenth century, and it is alive now, though part of it fell in the year 1819. The inspissated sap of the *Dracæna draco* constitutes the purest kind of dragon's blood. See *Dragon's blood.*

Dracæna reflexa. This species inhabits the Isle of France and Madagascar. The young shoots are supposed to possess emmenagogue and abortive properties.

Dracæna terminalis. This tree is planted in India and China, to mark the boundaries of estates, whence its specific name. Its root is used against dysentery.

DRA'CO. (*o, onis.* m. Δρακων, the dragon.) This name was given by the ancients to a fabulous serpent, and also to a fish, otherwise called *araneus.* The term was afterwards applied to various objects by naturalists and chemists.

Draco herba. *Dracunculus esculentus.* The *Artemisia dracunculus* of Linnæus. It is slightly aromatic.

Draco mitigatus. The submuriate of mercury.

Draco sylvestris. See *Achillea.*

DRACOCE'PHALUM. (*um, i.* n.; from δρακων, a dragon, and κεφαλη, a head.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia.*

Dracocephalum moldavicum. This plant affords by distillation a fragrant essential oil, known in Germany by the name of *oleum syriæ.* The whole herb is aromatic: it is recommended to give tone to the stomach, and to strengthen the nervous system.

Dra'conine. *Dracine.* A red substance found in dragon's blood by Melandri, and alleged to be alkaline.

Draco'nis sanguis. Dragon's blood.

DRACO'NTIUM. (*um, i.* n.; from δρακων, a dragon: so called because its roots resemble a dragon's tail.) The name of a genus of plants. Class, *Gynandria*; Order, *Polyandria.*

Dracontium fœtidum. *Pothos fœtida. Ictodes fœtidus. Symplocarpus fœtidus.* Skunk cabbage. This exhales a very fœtid odour, which

is impaired by keeping. The powder of the root is given as an antispasmodic, in doses of ten or twenty grains.

DRACONTIUM PERTUSUM. *Arum dracontium.* This is an extremely acrimonious plant. The Indians cover dropsical parts with the fresh leaves, which produce vesications, and an oozing of serum.

DRACU'NCULUS. (*us, i.* m.; from δρακων, a serpent.) 1. Synonymous with *Dracontium.*

2. The Guinea worm. See *Filaria medinensis.*

Dracunculus esculentus. See *Draco herba.*

Dracunculus pratensis. See *Achillea.*

Dragacantha. See *Astragalus.*

Dragant gum. See *Astragalus.*

Dragon. See *Draco.*

DRAGON'S BLOOD. *Sanguis draconis.* A resinous concrete substance of a blood red colour, and heterogeneous texture. Various kinds of it are found in the shops, which appear to be the produce of different trees. That in tears, *Sanguis draconis in lachrymis,* is obtained by incision from the *Dracæna draco;* that in sticks, *Sanguis draconis in cannis,* is from the *Pterocarpus draco, P. indicus,* and *P. santalinus;* that in balls or cakes, *Sanguis draconis in placentis,* is obtained by maceration from the fruit of the *Calamus draco.* The Surinam dragon's blood is obtained from the trunk and root of the *Ecastaphyllum monetarus.* Dragon's blood was formerly prized as an astringent; but it appears to be inert as a medicine, and is now only used as an ingredient in varnishes and dentifrices.

Dragon tree. See *Dracæna.*

Dragon's wort. See *Arum dracunculus.*

DRAKE'NA. The contrayerva plant was once so named, after Sir Francis Drake, who first brought it over from America. See *Dorstenia contrayerva.*

DRASTIC. (*Drasticus.* Δραστικος, active, brisk; from δραω, to effect.) A term generally applied to those medicines which are very violent in their action; thus, drastic purges, emetics, &c.

DRIVELLING. An involuntary flow of saliva, from a sluggishness of deglutition, without their being any increased flow of the saliva. It happens in infancy, in old age, and idiocy.

DRO'MA. The name of a plaster described by Myrepsus.

Drooping. See *Nutans.*

DROPACI'SMUS. (From δρεπω, to pluck.) *Dropax.* A stimulant plaster of pitch, wax, &c., to take off hair.

DROPAX. Δρωπαξ. See *Dropacismus.*

Drop-serene. See *Amaurosis.*

Dropsy. See *Hydrops.*

Dropsy of the belly. See *Ascites.*

Dropsy of the brain. See *Hydrocephalus.*

Dropsy of the chest. See *Hydrothorax.*

Dropsy of the ovary. See *Ovarium.*

Dropsy of the skin. See *Anasarca.*

Dropsy of the testicle. See *Hydrocele.*

Dropwort. See *Œnanthe crocata,* and *Spiræa filipendula.*

Dropwort, hemlock. See *Œnanthe.*

Dropwort, water. See *Œnanthe.*

DRO'SERA. (*a, æ.* f.; from δροσος, dew; because the leaves are beset with glands resembling dew-drops.) The name of a genus of plants. Class, *Pentandria;* Order, *Hexagynia.* Sun-dew.

DROSERA ROTUNDIFOLIA. The systematic name of the sun-dew: called also, *Ros solis,* and *Rorella.*

Drosera rotundifolia — scapis radicatis; foliis orbiculatis, of Linnæus. This elegant little plant is said to be so acrid as to ulcerate the skin, and remove warts and corns; and to excite a fatal coughing and delirium in sheep who eat it. It is seldom given medicinally in this country, but by the lower orders, who esteem a decoction of it as serviceable in asthmas and coughs.

DROSOBO'TANUM. (From δροσος, dew, and βοτανη, an herb: so called because it has been said to be covered with an aromatic dew.) The herb betony. See *Betonica officinalis.*

DROSO'MELI. (From δροσος, dew, and μελι, honey.) Honey-dew. See *Æromeli.*

Drowning. See *Asphyxia.*

DRU'PA. (*a, æ.* f.; from *drupæ,* over-ripe olives.) A stone fruit, formed of a fleshy or coriaceous seed-vessel, inclosing a nut.

It is distinguished into, *Drupa:* —

1. *Succosa,* when of a succulent fleshy consistence; as the cherry, plum, peach, and nectarine.

2. *Fibrosa,* the nut being fibrose; as in *Cocos nucifera.*

3. *Exsicca,* dry and subcoriaceous; as the almond and horse-chestnut.

4. *Dehiscens,* opening; as in *Juglans regia* and *Myristica moschata.*

From the number of nuts it contains, the *drupa* is said to be, —

1. *Monosperm,* when there is but one; as the olive and *pistachia.*

2. *Disperm,* when there are two; as *Styrax.*

DRUPA'CEOUS. (*Drupaceus;* from *drupa.*) Resembling a drupe, or stone fruit; as the pod of *Erucago* and *Bunias.*

Duck. See *Anas.*

Duct. See *Ductus.*

DUCTI'LITY. *Ductilitas.* A property by which bodies are elongated by repeated or continued pressure. It is peculiar to metals. Most authors confound the words malleability, laminability, and ductility together, and use them in a loose indiscriminate way; but they are very different. Malleability is the property of a body which enlarges one or two of its three dimensions by a blow or pressure very suddenly applied; laminability belongs to bodies extensible in dimensions by a gradually applied pressure; and ductility is properly to be attributed to such bodies as can be rendered long and thinner by drawing them through a hole of less area than the transverse section of the body so drawn.

DUCTOR. The same as *director.*

Ducts, biliary. See *Hepar.*

DU'CTUS. (*us, us.* m.) A canal or duct.

Ductus ad nasum. See *Ductus nasalis.*

Ductus aquosi. The lymphatics have been called.

Ductus arteriosus. *Canalis arteriosus.* An arterial tube forming a direct communication between the pulmonary artery and aorta of the fœtus. After birth it becomes impervious. See *Fœtus.*

Ductus auris palatinus. The Eustachian tube. See *Auris.*

Ductus bartholinia'nus. Duct of Bartholin. The duct of the sublingual gland.

Ductus biliaris. The biliary duct. See *Hepar.*

Ductus communis choledocus. See *Hepar.*

Ductus cy'sticus. The cystic duct. The duct by which the bile regurgitates into the gall bladder. See *Hepar.*

Ductus excretorius. Excretory duct. The duct which proceeds from a gland, and carries the secreted fluid to its destination, is called the excretory duct of that gland.

Ductus hepaticus. The hepatic duct. See *Hepar.*

Ductus hygroble'phari. (*Hygroblepharus;* from *ὑγρος*, moist, and *βλεφαρον*, the eyelid.) The Meibomian glands.

Ductus hygrophtha'lmici. (*Hygrophthalmicus;* from *ὑγρος*, moist, and *οφθαλμος*, the eye.) The Meibomian glands.

Ductus incisorius. The little canal leading from the foramen incisivum into the cavity of the nares.

Ductus lachrymalis. The lachrymal duct. See *Lachrymal apparatus.*

Ductus lactiferi. *Ductus galactophori.* The excretory ducts of the glandular substance composing the female breast. The milk passes along these ducts to the nipple.

Ductus nasalis. Nasal or lachrymal duct. The duct which conveys the tears from the lachrymal sac to the nose. See *Lachrymal apparatus.*

Ductus pancrea'ticus. The pancreatic duct. It is white and small, and arises from the left extremity of the pancreas, runs through the gland a little below its middle towards the duodenum, into which it pours its contents by an opening common to it and the *ductus communis choledochus.*

Ductus rori'ferus. The thoracic duct; absurdly so called by Ludovic de Bils.

Ductus salivalis inferior. The duct of the submaxillary gland. See *Ductus Warthonianus.*

Ductus salivalis superior. The parotid duct. See *Ductus Stenonis.*

Ductus stenonis. The Stenonian or parotid duct, which is so called after its discoverer, *Steno.* It arises from all the small excretory ducts of the parotid gland, and passing transversely over the masseter muscle, penetrates the buccinator, and opens into the mouth opposite to the space between the second and third molar tooth of the upper jaw.

Ductus thoracicus. See *Thoracic duct.*

Ductus veno'sus. *Canalis venosus.* A venous tube forming a communication in the fœtus between the umbilical vein and the left hepatic vein, just where the latter vein enters the vena cava. The ductus venosus becomes impervious after birth, and dwindles into a whitish cord. See *Fœtus.*

Ductus umbilicalis. The umbilical cord.

Ductus warthonia'nus. The excretory duct of the maxillary gland; so named after its discoverer. It passes forward between the mylohyoideus and genioglossus muscles, and under the sublingual gland, opening finally on each side the frænum linguæ.

Ductus wirtsungi. The pancreatic duct; so named after Wirtsung, the anatomist who first described it in the human body.

Duelech. *Dulech.* A term used by Paracelsus and Van Velmont, to signify a species of tartar which forms in the human body and causes divers evils.

Due'lla. An ancient weight of eight scruples.

Dulcama'ra. (*a, æ.* f.; from *dulcis*, sweet, and *amarus*, bitter.) The bitter sweet. See *Solanum dulcamara.*

Dulce. See *Fucus palmatus.*

Dulce, red. See *Fucus edulis.*

Dulce'do amo'ris. The clitoris.

DULCIFICA'TIO. (*o, onis.* f.; from *dulcis*, sweet, and *facio*, to make.) Dulcification. The mixing of the mineral acids with alkohol to render them milder, was thus named by the old chemists.

Dulesh. See *Fucus palmatus.*

Dumbness. See *Aphonia.*

Dumo'sæ. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting of shrubby plants, which are thick set with irregular branches, and bushy.

DUMO'SUS. (From *dumus*, a bush.) Dumose; bushy.

DUODE'NUM. (*um, i.* n.; from *duodeni*, twelve: so called because it was supposed not to exceed the breadth of twelve fingers; but as the ancients dissected only animals, this does not hold good in the human subject.) The first portion of the small intestines. See *Intestines.*

DU'PLEX. (From *duo*, two, and *plico*, to fold.) Double or two-fold. In *Botany*, applied to leaves, petals, perianths, &c. The *perianthum duplex* is seen in *Malva althæa* and *Hibiscus.*

DUPLICA'TUS. (From *duplex*, double.) Duplicate; doubled: applied, in *Botany*, to flowers which have two series or rows of petals.

DU'RA MA'TER. (*Durus*, hard; from its hardness as compared with the *pia mater.*) *Dura meninx; Membrana dermatoides.* The tough sero-fibrous membrane which invests the brain externally to the arachnoid membrane, and forms the internal periosteum of the cranium. See *Encephalos.*

Dura meninx. See *Dura mater.*

Dutch drops. The balsam of turpentine is sold under this name, which is also given to a preparation consisting of oil of turpentine, tincture of guaiac, spirit of nitric ether, and oils of amber, and cloves.

Dutch gold. An alloy of copper and zinc.

Dwale. See *Atropa belladonna.*

DWARF. *Nanus. Pumilio. Pumilo.* An animal or plant, the growth of which has been

stunted so that its stature is greatly inferior to the average height of the species to which it belongs. Absolute dwarfishness is not common in the human species, and it seems to be much rarer among the inferior animals, while in plants it is very common, when the individual grows in a soil ill adapted to it. The height of human dwarfs varies; but, in general, they have not been less than three feet. The famous Polish dwarf, Borulawski, was, however, but twenty-eight inches; and Bebe, kept by Stanislaus, King of Poland, measured only thirty-three inches. Their intellectual faculties are, in general, imperfect: they are lively, but simple; and sharp, but timorous. Borulawski, who was known to the author, possessed superior mental powers. For some ingenious views as to the causes of dwarfishness, see *I. G. St. Hilaire, sur les Anomalies de l'Organisation*, tom. i. p. 162. Paris, 1832.

Dwarf elder. See *Sambucus ebulus.*

Dyna'mic school. This name has been given to the physiologists who followed Stahl in believing that the vital phenomena proceeded from the operation of an internal force or *power* (δυναμις) acting in a great measure independently of external causes. This power was supposed to be the rational soul. See *Life.*

Dy'namis. (Δυναμις.) A power or faculty. Galen frequently uses this word to signify a medicine.

DYSÆSTHE'SIA. (*a*, *æ*. f.; from δυς, with difficulty, and αισθανομαι, to feel or perceive.) Hebetude of any of the senses, especially that of touch.

Dysæsthe'siæ. (The plural of *dysæsthesia.*) The name of an order in the class *Locales* of Dr. Cullen's Nosology, containing those diseases in which the senses are depraved or destroyed, from a defect of the external organs.

Dyscatabro'sis. (From δυς, with difficulty; and βρωσκω, to eat.) Difficult deglutition.

Dyscata'posis. (From δυς, and καταπινω, to drink.) A difficulty of swallowing liquids. Dr. Mead gives this name to hydrophobia.

DYSCINE'SIA. (*a*, *æ*. f.; from δυς, with difficulty, and κινεω, to move.) Diminution or abolition of the power of motion.

Dyscine'siæ. (The plural of *dyscinesia.*) The name of an order in the class *Locales* of Cullen's Nosology; embracing diseases in which the motion is impeded or depraved, from an imperfection of the organ.

DYSCRA'SIA. (*a*, *æ*. f.; from δυς, with difficulty, and κεραννυμι, to mix.) A bad *crasis* or habit of body.

DYSECŒ'A. (*a*, *æ*. f.; from δυς, with difficulty, and ακοη, hearing.) Deafness. Hearing diminished or destroyed. Dr. Cullen has two species of this genus: —

1. The *organic*, which arises from wax in the meatus, injuries of the membrane, or inflammation and obstruction of the tube.

2. The *atonic*, when without any discernible injury of the organ.

DYSENTERY. (*Dysenteria*, *æ*. f.; from δυς, with difficulty, and εντερα, the bowels.) The bloody flux. This disease is known by contagious fever; frequent griping stools; tenesmus; stools, chiefly mucous, sometimes mixed with blood, the natural fæces being retained or voided in small, compact, hard substances, known by the name of scybala; loss of appetite, and nausea. It occurs chiefly in summer and autumn, and is often occasioned by much moisture succeeding quickly intense heat, or great drought, whereby the perspiration is suddenly checked, and a determination made to the intestines. It is likewise occasioned by the use of unwholesome and putrid food, and by noxious exhalations and vapours: hence it appears often in armies encamped in the neighbourhood of low marshy grounds, and proves highly destructive. But the cause which most usually gives rise to it, is a specific contagion; and when it once makes its appearance, where numbers of people are collected together, it not unfrequently spreads with great rapidity. A peculiar disposition in the atmosphere seems often to predispose, or give rise to the dysentery, in which case it prevails epidemically.

It frequently occurs about the same time with autumnal intermittent and remittent fevers, and with these it is often complicated.

The disease, however, is much more prevalent in warm climates than in cold ones; and in the months of August, September, and October, which is the rainy season of the year in the West Indies, it is very apt to break out and to become very general among the negroes on the different plantations in the colonies. The body having been rendered irritable by the great heat of the summer, and being exposed suddenly to much moisture with open pores, the blood is thereby thrown from the exterior vessels upon the interior, so as to give rise to dysenteries.

An attack of dysentery is sometimes preceded by loss of appetite, costiveness, flatulency, sickness at the stomach, and a slight vomiting, and comes on with chills, succeeded by heat in the skin, and frequency of the pulse. These symptoms are, in general, the forerunners of the griping and increased evacuations which afterwards occur.

Inflammation soon takes place in the lower part of the intestinal tube: the stools then become more frequent, and less abundant; and, in passing through the inflamed parts, they occasion great pain, so that every evacuation is preceded by a severe griping, as also a rumbling noise.

The motions vary both in colour and consistence; being sometimes composed of frothy mucus, streaked with blood, and at other times of an acrid watery humour, like the washings of meat, and with a very fœtid smell. Sometimes pure blood is voided: now and then lumps of coagulated mucus, resembling bits of cheese, are to be observed in the evacuations; and in some instances a quantity of purulent matter is passed.

Sometimes what is voided consists merely of a mucous matter, without any appearance of blood; exhibiting that disease which is known by the name of dysenteria alba, or morbus mucosus.

Whilst the stools consist of these various matters, and are voided frequently, it is seldom

hat we can perceive any natural fæces among hem; and when we do, they appear in small ard balls, called scybala, which being passed, he patient is sure to experience some temporary elief from the griping and tenesmus.

It frequently happens, from the violent efforts which are made to discharge the irritating matters, that a portion of the gut is forced beyond the verge of the anus, which, in the progress of the disease, proves a troublesome and distressing symptom; as does likewise the tenesmus, there being a constant inclination to go to stool, without the ability of voiding any thing, except, perhaps, a little mucus.

More or less fever usually attends with the symptoms which have been described, throughout the whole of the disease, where it is inclined to terminate fatally, and is either of an inflammatory or putrid tendency. In other cases, the febrile state wholly disappears after a time, while the proper dysenteric symptoms probably will be of long continuance. Hence the distinction into acute and chronic dysentery.

When the symptoms run high, produce great loss of strength, and are accompanied with a putrid tendency, and a fœtid and involuntary discharge, the disease often terminates fatally in the course of a few days: but when they are more moderate, it is often protracted to a considerable length of time, and goes off at last by a gentle perspiration, diffused equally over the whole body; the fever, thirst, and griping then ceasing, and the stools becoming of a natural colour and consistence. When the disease is of long standing, and has become habitual, it seldom admits of an easy cure; and when it attacks a person labouring under an advanced stage of scurvy, or pulmonary consumption, or whose constitution has been much impaired by any other disorder, it is sure to prove fatal. It sometimes appears at the same time with autumnal intermittent and remittent fevers, as has been observed, and is then more complicated and difficult to remove.

Upon opening the bodies of those who die of dysentery, the internal coat of the intestines (but more particularly of the colon and rectum) appears to be affected with inflammation and its consequences, such as ulceration, gangrene, and contractions. The peritonæum, and other coverings of the abdomen, seem likewise, in many instances, to be affected with inflammation.

Dysentery often exists as a mild disease, being attended with very little fever or constitutional derangement, and the excretions affording occasionally relaxed or scybalous fæcal matter, but more frequently slimy, gelatinous, or sanguineous stools. In this form it is soon controlled by medicines and diet; and it may be doubted whether it is contagious. It was formerly the practice to commence with blood-letting; but in the present day this is never thought of, unless a very plethoric state of the vascular system exists, or an inflammatory diathesis, or actual inflammation; in which latter state the disease of course requires the lancet. Mild aperients, of sulphate of magnesia, tartarised soda, senna, rhubarb, tamarinds, manna, and the like, are exhibited every or every other morning, and an opiate at night. Sydenham gave rhubarb, with tamarinds and senna, in preference to other aperients, and in full doses. "I prefer," says he, "the use of rhubarb in this form to giving it alone, or in a smaller quantity, because, unless it acts thoroughly, it does not much conduce to a cure; and because, also, though more powerful cathartics might be employed, they would but aggravate the gripings, and increase the general disorder, and especially the depression of spirits: and hence, even after the rhubarb purge, I commonly give the anodyne at an earlier hour than usual, — indeed, at any time in the afternoon, as soon as the laxative has ceased to operate, — and thus get rid of the excitement it has occasioned. This purgative I repeat twice every other day, always following up the dose with an anodyne, as above; and I resort to the anodyne every morning and evening, even when no aperient is given, that I may repress the violence of the symptoms, and gain a truce while I am evacuating the peccant humour. The anodyne I make use of, is sixteen or eighteen drops of laudanum in a dose of cordial water of any kind." Sydenham depended principally on his celebrated liquid laudanum: and so attached was he to it, and so persuaded of its permanent efficacy, that where the symptoms were more violent he increased the dose, and gave it three times a day instead of twice; prescribing also daily an opiate injection. In mild cases, indeed, he omitted evacuants, and trusted to opium alone. The principles on which this mode of practice is founded, are clear and rational, and indicate an attempt to diminish inflammatory action, to relax the spasmodic constriction, which both blocks up the fæces and produces the griping pains, and to assist the discharge of fæces, as the natural passage is sufficiently opened.

Rhubarb has been objected to on account of its astringency, but many advocate its employment as clearing the primæ viæ better than any other purgative. Its astringent effect may be well guarded against by giving a little carbonate of magnesia, tamarinds, or manna.

Castor oil is perhaps the best of all purgatives in dysentery: if this be given every other day, in a dose to clear the bowels, and some saline sudorific with the compound powder of ipecacuanha night and morning, the disease will soon vanish.

The other form of dysentery, which is highly contagious, and is attended with acute fever, is always an important and more complicated disease. The fæces, when discharged, are of various colours and consistence, highly fœtid, and mixed with putrid sanies, membranous films, and sanguineous coagula; and the fever which attends is either inflammatory or typhous. In one of these forms, the disease spreads with tremendous rapidity through camps, or crowds of any kind, consociating too closely together without sufficient ventilation, and particularly in swamps, or other moist lowlands. In the present day, Dr. Good observes, the accompanying fever is most commonly typhous. "I am induced to believe," he says, "that it is chiefly

in sporadic cases that the dysenteric fever is a cauma, — that is, inflammatory; while in those of epidemic or contagious origin, the fever is of a typhous, or at least of a synochous character; of a mixed breed, with a strongly marked tendency to run from a caumatic to a typhous type."

In laying down a curative plan for these more acute forms of dysentery, our first attention must be paid to the nature and degree of fever with which the disease opens. When, therefore, the pulse is hard and full, and particularly when there is a general pain and tension over the belly, indicating an inflammatory diathesis, blood should be drawn copiously, and with all possible speed, and the evacuation repeated according as circumstances may require. There is no disease that more requires the exercise of a sound judgment on this point, than dysentery: for if not typhous from the first, it has a general tendency to pass into this type; and the intestinal inflammation is perhaps of the erysipelatous kind; and hence, unless the indications for it are strong and prominent, this mode of cure had better not be ventured upon, and if blood is to be abstracted, it should be by leeches.

The next most probable means of diminishing the febrile action, is by the use of general relaxants, and particularly those which may operate equally on the skin and the whole range of the intestinal canal: these are emetics and sudorifics, and especially those medicines which produce both these effects at the same time. An emetic will, in many instances, be found extremely serviceable; and in public practice, in the navy and army, a solution of tartar emetic and sulphate of magnesia has been resorted to, in the beginning of acute and inflammatory dysentery, with decided benefit. Of two grains of tartar emetic, and six drachms of sulphate of magnesia, dissolved in eight ounces of any aromatic water, a fourth part should be given every two hours, until the desired effect takes place. After having by these or similar means cleared the primæ viæ, diaphoretics and opium are to be administered, resorting to local bleeding, fomentation, and blisters, if there be reason to think any tendency to inflammation exists, and occasionally administering saline or oleaginous purgatives. The best diaphoretics are, antimonial powder, submuriate of mercury, opium, or Dover's powder, in combination, every four or six hours: when the irritation is much in the lower bowels, and especially when there is tenesmus, and very frequent and loose motions, opium introduced into the rectum acts like a charm. Four ounces of the decoctum lini, or decoctum amyli, with a drachm of the tinctura opii, form the best injection, which may be used night and morning, or oftener, according to circumstances.

In the other acute forms of dysentery, in which the accompanying fever is typhous, as well as with those which, though in the commencement accompanied by a fever of an inflammatory or mixed type, have become typhous, the bowels are to be cleared from their putrescent fæcal contents from time to time, by solutions of sulphate of magnesia, with dilute mineral acids, and light infusions of roses, calumba, cascarilla, cinchona, simarouba, cortex conessi, liquor calcis: the nitric acid is much esteemed by some, the nitro-muriatic acid also, and the chlorides of lime and soda. With all these opium must be given, at the same time, either in combination, or a full dose night and morning. Five drops of dilute nitric acid, with ten of liquid laudanum, and twelve drachms of cinnamon water, every four or six hours, is a valuable compound. Ten drops of dilute sulphuric acid, with as much tincture of opium, and an ounce and a half of the infusion or decoction of any of the above-mentioned barks or roots, sweetened, is the proper dose and way of administering them. Some symptoms require particular attention in all cases of dysentery: — thus, a diarrhœal state will call for the addition of kino or catechu, or hæmatoxylum; — great pain is only relieved by large doses of opium, fomentations, and the warm bath; — flatulence, by the addition of carminatives, &c. &c.

The diet should consist of farinaceous decoctions, especially those of arrow-root, sago, salep, gruel, barley, and rice. In simple cases, a little light mutton, veal, or beef broth or tea will be useful; but in acute ones, no preparation of animal substances is permitted: for if there be a tendency to inflammation, or if synochous or typhous fever be present, it will prove too stimulating to the one, and increase the putrescent state of the contents of the intestinal canal in the other. Severe cases, especially where the spasmodic pains are severe, will be benefited by the free use of vegetable gluten, and isinglass. Wine, brandy, and the like, are serviceable in all cases where there is debility, or a typhous fever.

Great attention should also be given to the clothing: the feet must be kept warm, and the skin kept moist, if possible, but never so as to weaken by strong perspirations.

Dysepulo'ticus. (From δυς, with difficulty, and επυλοω, to cicatrise.) *Dysepulotus.* Difficult to be healed: applied to ulcers.

Dyshæmorrhœ'a. (From δυς, with difficulty, αἱμα, blood, and ῥεω, to flow.) The same as *dyshæmorrhois.*

Dyshæmorrhoi'is. (From δυς, with difficulty, and αἱμοῤῥοις, the piles.) Suppression of the bleeding from piles.

Dyslalia. (From δυς, with difficulty, and λαλια, speech.) Indistinct articulation.

DYSLOCHI'A. (*a*, *æ*. f.; from δυς, with difficulty, and λοχια, the lochia.) An imperfect excretion or suppression of the lochia.

DYSMENORRHŒ'A. (*a*, *æ*. f.; from δυς, with difficulty, and μηνοῤῥοια, the menses.) Difficult or painful menstruation, accompanied with severe pains in the back, loins, and bottom of the belly.

In most cases of difficult and painful menstruation, the secretion is scanty throughout the period, or particularly during the two first days, when the pain is often extremely severe, and, in some few cases, so much so as to produce convulsions, especially in hysterical women, for which state dysmenorrhœa often lays the foundation. The secretion, in some cases, becomes

more abundant after the two first days, and the pain subsides. In many cases the discharge is unhealthy, being mixed with flakes like an organised decidua, small portions of membrane, the size of a sixpence or larger, and sometimes mixed with coagula.

Cold, mental anxiety, and a natural debility of the uterus, are its common causes.

The treatment is directed to the disease when present, and to the prevention of its return, by remedies administered during the interval.

In the first instance, opium, ether, assafœtida, tepid baths, and fomentations, with stimulants, have been found useful. A full dose of the former, taken just as the period is about to arrive, sometimes relaxes the spasms, or destroys the susceptibility for pain, and the secretion goes on well. When the hip bath and fomentations are beneficial, they are resorted to during the day of the first appearance, or persevered in for a day or two before. Opium applied to the loins is often serviceable; and so likewise is laudanum and assafœtida, thrown into the rectum in a glyster, or solid opium, with assafœtida introduced as a suppository. Hyoscyamus, extract of poppy, and other sedatives, are, in milder cases, sometimes sufficient to remove the disease.

The means to be resorted to in the interval between the periods are very various. Occasionally cupping the loins, applying leeches to the perinæum, and the observance of an abstemious diet, is most advisable; and this plan is especially indicated in those whose fibres are rigid, and who have a vascular plethora. In other and opposite states, where the patient is pallid, and there is reason to believe that laxity and debility prevail, a generous and stimulating diet, with chalybeates, or tonics of bark and cascarilla, and the fœtid gums, and cold bathing, must be preferred.

DYSO'DES. (Δυσωδες; from δυς, bad, and ὀζω, to smell.) Fœtid. The epithet of a malagma for a pleurisy, and an acopon, prescribed by Galen and Paulus.

DYSO'DIA. (Δυσωδια, a bad smell.) A genus in Sauvage's nosology, including diseases characterised by fœtor.

DYSODONTI'ASIS. (From δυς, with difficulty, and ὀδοντιασις, dentition.) Difficult dentition.

DYSO'PIA. (α, æ. f.; from δυς, badly, and ὀψ, an eye.) Bad sight. Sight depraved. Under this term are comprehended,

1. *Night-sight*; called by the Greeks Nyctalopia. See *Nyctalopia*.

2. *Day-sight*; or hemeralopia of the Greeks. See *Hemeralopia*.

3. *Longsightedness*. In this, near objects are seen indistinctly, while those which are more distant are seen plainly. It occurs at every period of life, but mostly in old age: and hence it is usually denominated presbyopia. See *Presbyopia*.

4. *Shortsightedness*. This is, in most respects, an opposite disease to the last. See *Myopia*.

5. *Lateral vision*, or skewsightedness. The vision is here accurate only when the object is viewed obliquely, so that the person can only see in an oblique direction, in consequence of some partial opacity of the cornea, which usually proceeds from slight scars, or of the humours through which the light is transmitted, or from a partial paralysis of the retina. It is a very different thing from squinting: for the axis of the eye affected usually coincides with that of the sound eye; whereas, in squinting, the two axes do not coincide, and the judgment is formed from the strongest eye.

DYSOPIA LUMINIS. Day blindness. See *Nyctalopia*.

DYSOPIA TENEBRARUM. Night blindness. See *Hemeralopia*.

DYSORE'XIA. (α, æ. f.; from δυς, badly, and ὀρεξις, appetite.) A depraved appetite.

DYSOREXIÆ. The name of an order in the Class *Locales* of Cullen's Nosology, which he divides into two sections, *appetitus erronei*, and *deficientes*.

DYSO'SMIA. Diminution of the sense of smell. The proper term is *dysosphresia*, for οσμη signifies an *odour*, not the *sense* of smell.

DYSOSPHRE'SIA. (From δυς, with difficulty, and οσφρησις, the sense of smell.) An impaired state of the sense of smell.

DYSPATHI'A. Δυσπαθεια. Indisposition to a disease. — *Galen*.

DYSPE'PSIA. (α, æ. f.; from δυς, with difficulty, and πεπτω, to concoct.) Indigestion. This very common disease consists generally in a want of appetite, a sudden and transient distension of the stomach, eructations of various kinds, heartburn, pain in the region of the stomach, perhaps vomiting, rumbling noise in the bowels, and frequently costiveness or diarrhœa. A long train of nervous symptoms are also frequent attendants.

In some cases a few only of the above symptoms are present, while in others many additional ones are experienced, such as severe pains in the head and chest, and various affections of the sight, as slight degrees of amaurosis, double vision, &c.

It occurs at all ages, but chiefly in persons between thirty and forty years of age, and is principally to be met with in those who devote much time to study, or who lead either a very sedentary or an irregular life. A great singularity attendant on it is, that it may and often does continue a great length of time, without any aggravation or remission of the symptoms.

Grief and uneasiness of mind, intense study, profuse evacuations, excess in venery, hard drinking, particularly of spirituous liquors, and the abuse of tea, tobacco, opium, and other narcotics, immoderate repletion, and over-distension of the stomach, and much exposure to moist and cold air, when without exercise, are the causes which usually occasion dyspepsia.

Dyspepsia never proves fatal, unless when, by a very long continuance, it gives rise to some other disease, as organic lesions of the viscera, dropsy, or phthisis; but it is at all times very difficult to remove, and particularly so in warm climates.

It is often a secondary and symptomatic disease, caused by structural alterations of some part of the stomach; and there are few organic diseases in the neighbouring viscera from which

the stomach does not become weakened, and indigestion result.

The term dyspepsia has been very vaguely used, and a great variety of symptoms, arising from a proportionate number of different morbid states, have been associated under the same name. The writings of Marcus and Broussais have led many to refer these symptoms universally to inflammatory states of different parts of the gastro-enteric membrane, a doctrine which, like most others of a similar exclusive character, is at once confuted by an appeal to actual observation; and which is especially pernicious in a practical point of view, in as much as it too often inflicts leeches and starvation, where they can very ill be borne. It is indeed true, that dyspeptic symptoms are often produced by the inflammatory states alluded to; and it is true, as illustrated by Dr. Wilson Philip, that when functional derangement has existed for a length of time, the vascular actions of the part become affected, and inflammation is set up; but if we are content to be guided simply by what is to be seen on the dissection of those, who when living have been subject to dyspepsia, we shall be convinced that chronic inflammation is far from being the general cause of this affection. The morbid states which give rise to dyspeptic symptoms appear to be atony and torpor of the organs; morbid irritability, distinct from an inflammatory state; depraved secretion; and chronic inflammation. To these, severally, or combined in various degrees, restricted to particular parts, or more extensively involving the alimentary canal, the diversity of symptoms, included under the term indigestion, may for the most part be traced.

The treatment of dyspepsia consists, 1. In obviating, as far as possible, the several causes. 2. In relieving urgent symptoms. 3. In restoring the tone of the chylopoietic viscera, and invigorating the general system. If the view we have taken of the subject be correct, it is obvious that no general rules can be given for the treatment of dyspepsia, considered as a single disease, because it involves widely different conditions. Atony is to be obviated by tonics, especially the vegetable bitters, and a careful adaptation of the diet, both in quantity and quality, to the digestive powers of the individual; disordered secretion is to be corrected by mild mercurials and laxatives, with the use of antacids where a morbid acrimony prevails; irritability and spasm are to be allayed by a bland but sufficiently nutritious diet, and the use of antispasmodics, and the liquor potassæ, which medicine has a well known, though unexplained power of allaying irritability of the mucous surfaces; inflammatory action is to be subdued by the occasional use of leeches, and abstinence from animal food, and all stimulating articles of diet. Since, however, these states are liable to be indefinitely combined in the same case, and since, in protracted cases, we are likely to encounter every one of them at some period or other, the practitioner is called upon to exercise his individual judgment as to the course most proper to be pursued in this or that particular case; and it is from the neglect of such discrimination, that we too often see, on the one hand, chronic inflammation aggravated to the most serious degree by bitters and brandy and water; and, on the other hand, atony increased by the repeated application of leeches, and the strength of the system impaired by an antiphlogistic regimen, when a generous though light diet would be much more appropriate. It is not to be forgotten, also, that maladies which may have their origin in the intestinal canal exert a sympathetic influence on distant surfaces, and are in their turn reacted upon by the state of those surfaces. This is particularly true with respect to the skin, the state of which always claims the attention of the practitioner in dyspeptic cases. There are many affections which frequently accompany indigestion, which are treated of in other parts of this work, as *Cardialgia*, *Constipation*, *Diarrhœa*, &c.

DYSPHA'GIA. (*a*, *æ*. f.; from δυς, with difficulty, and φαγω, to eat.) A difficulty of deglutition. This may arise from a great variety of causes. The organs principally concerned in the act of swallowing are the tongue, the parts constituting the fauces, the œsophagus; all of which, when diseased, may produce a difficulty of swallowing. It very seldom occurs as an idiopathic disease, but is common as a symptomatic and sympathetic affection. As the former, it occurs in paralytic states of the tongue, parts about the fauces, and œsophagus; in enlargements, natural or diseased, of the tongue; in diminished diameter of the œsophagus, from stricture, scirrhus, ossification, carcinoma of the tongue, œsophagus, and the cardiac opening of the stomach, and from the like diseases, and others, as aneurism, bronchocele, &c. around the fauces or œsophagus; from extraneous bodies lodging in the fauces and œsophagus; in inflammation of these and neighbouring parts. Sympathetic dysphagia frequently occurs in hysteria, tetanus, trismus, hypochondriasis, &c.

In the idiopathic disease, the uvula is relaxed and elongated, or the muscular coat of the pharynx and œsophagus is in an extremely relaxed and weak state; and the remedies are such as stimulate the œsophagus, as spices and dilute spirituous gargles, and the internal use of tonics and stimulants. In the symptomatic and sympathetic forms, the remedies must be derived from attention to the diseases of which this affection is a symptom.

DYSPHO'NIA. (*a*, *æ*. f.; from δυς, badly, and φωνη, the voice.) Dissonant voice. Nosologists comprehend, under this generic term, those alterations or states of the voice in which the sound is imperfect or depraved; as the weak, whispering, scarcely audible voice; the change of the voice which happens about the age of puberty; the rough and harsh voice; the nasal voice; the squeaking, whizzing, guttural, palatine voice.

DYSPHO'RIA. (*a*, *æ*. f.; from δυς, and φορεω, to bear.) The restlessness and anxiety that accompany many diseases.

DYSPNŒ'A. (*a*, *æ*. f.; from δυς, with difficulty, and πνεω, to breathe.) *Dyspnoon*. Difficul respiration. A permanent difficulty of breathing

or anhelation. There has been no small perplexity, Dr. Good observes, felt by nosologists in arranging the various diseases which are chiefly characterised by difficult breathing. The lungs, like the stomach, maintain a close connection with most of the functions of the body, and the organs which are instrumental to them: while the complaints affecting respiration, that originate in the chest, run so frequently into each other, as to require the utmost nicety in drawing the line between what ought to be regarded as genera, and what as species. There are three thoracic disorders that are particularly obnoxious to this remark: those which are described under the names of dyspnœa, orthopnœa, and asthma. Celsus, following the Greek physicians, regards them as only modifications of the same malady, merely differing from each other in degree. "Each," says he, "consists in difficulty of breathing. When this difficulty is moderate, and not suffocative, it is called dyspnœa; when it is more vehement, so that the breathing is sonorous and wheezing, it constitutes asthma; and when it can only take place in an erect position it is denominated orthopnœa. The first is usually a chronic affection, the two latter acute." Almost all the continental physicians make each affection a separate genus. Cullen makes a genus of dyspnœa, as well as of asthma, and merges orthopnœa in the former. In his first lines, he expresses doubts, whether, under almost every modification, it is to be regarded otherwise than as a vicarious or symptomatic affection.

Chronic dyspnœa, or an uniformly short and difficult breathing, is mostly accompanied by a little cough. The causes of it may exist in the chest, or at the origin of the respiratory nerves; they are inbred, or the result of accident, arising from original deformity, acquired disease, or accidental injury. In the majority of cases there is some obvious vice of conformation, or organic disease in the chest; and, even where there has originally been no organic disease of the thoracic viscera, the long continued disturbance of function generally produces it at last. In all these cases little is to be expected from our art. The most perfect tranquillity of mind and body, gentle exercise, a mild diet, with total abstinence from every kind of food that proves flatulent, and an undeviating habit of regular hours, comprises, perhaps, all that can be recommended by the physician, with any prospect of advantage.

Various artizans are subject to dyspnœa from the effects of irritating particles, inhaled with the air they breathe. See *Diseases of artizans.*

The breathing is sometimes permanently difficult in persons of a phlegmatic temperament whose vascular action is very sluggish. In such persons, whatever depresses the living power will affect the breathing; and taking cold in the feet, and checking the perspiration, are almost sure to do so. Tonic and gently stimulating medicines are here decidedly useful; as the warm gums, camphire, terebinthinate preparations, bitters, and iron, and the like, combined with squills. The warm bath is also serviceable in these cases; and good exercise, with a moderately stimulating diet.

Another cause of permanent difficult respiration is corpulency. Abstinence from spirits, wines, and fermented drinks, and a scanty allowance of animal food, with strong exercise, and occasional purges, are the most likely to afford relief.

Chronic difficulty of breathing appears also as a symptom or sequel in various other diseases, as chronic bronchitis, hydrothorax, and morbid conditions of the lungs, heart, and aorta.

In cases of permanent dyspnœa, produced in the above-mentioned ways, it must be remarked, that the difficulty of breathing is occasionally very much increased; there being, as it were, paroxysms or exacerbations of it, which state is widely different from asthma. This is mostly produced by some accidental augmentation of the ordinary cause, or by some sudden excitement of body or mind, or some diseased action that is capable of uniting with the primary one, directly or remotely. In asthma, the returns are for the most part strictly periodical, and, in the intervals, the breathing is not difficult. Much good, in an increased state of dyspnœa, is often effected by position, volatile alkali, camphire, and a small blister to the chest, and unloading the bowels.

Dr. Cullen arranges dyspnœa into the eight following species: —

1. *Dyspnœa catarrhalis,* when with a cough there are copious discharges of viscid mucus: called also *asthma catarrhale, pneumodes, pneumonicum,* and *pituitosum.*

2. *Dyspnœa sicca,* when there is a cough without any considerable discharge.

3. *Dyspnœa aërea,* when much increased by slight changes of the weather.

4. *Dyspnœa terrea,* when earthy or calculous matters are spit up. See *Calculus, pulmonary.*

5. *Dyspnœa aquosa,* when there is a scarcity of urine and œdematous feet, without the other symptoms of a dropsy in the chest.

6. *Dyspnœa pinguedinosa,* from corpulency.

7. *Dyspnœa thoracica,* when parts surrounding the chest are injured, or deformed.

8. *Dyspnœa extrinseca,* from manifest external causes.

Dyspnoon. See *Dyspnœa.*

Dysrachi'tis. The name of a plaster, described by Galen. It was used in cases of fistula.

Dysspermasia. Used synonymously with *Dysspermatismus.*

DYSSPERMATI'SMUS. (*us, i.* m.; from δυς, with difficulty, and σπερματισμος, emission.) Slow or impeded emission of semen during coition, insufficient for the purpose of generation. According to Cullen, the species of *dyspermatismus* are,

1. *Urethralis,* when the obstruction is in the urethra.

2. *Nodosus,* when a tumour is formed in either corpus cavernosum penis.

3. *Præputialis,* when the impediment is from a straitness of the orifice of the præpuce.

4. *Mucosus,* when the urethra is obstructed by a viscid mucus. (A very doubtful cause.)

5. *Hypertonicus,* when there is an excess of erection of the penis.

6. *Epilepticus,* from epileptic fits coming on during coition.

7. *Apractodes*, from a want of vigour in the genitals.

8. *Reflluus*, in which the semen is thrown back into the urinary bladder.

Dystherapeu'tos. (From δυς, difficulty, and θεραπευω, to heal.) Difficult to heal.

DYSTHY'MIA. (*a*, *æ*. f.; from δυς, bad, and θυμος, mind.) Despondency. Melancholy.

Dystochia. Improperly written for *Dystocia*.

DYSTO'CIA. (*a*, *æ*. f.; from δυς, with difficulty, and τικτω, to bring forth.) Difficult parturition.

DYSTŒCHI'ASIS. (*is*, *is*. f.; from δυς, badly, and στοιχος, order.) An irregular disposition of the hairs in the eyelids. Castelli cites this term from Forest. It is improperly formed, and does not express the meaning.

DYSU'RIA. (*a*, *æ*. f.; from δυς, with difficulty, and ουρον, urine.) Difficulty in discharging the urine. When there are frequent, painful, or uneasy urgings to discharge the urine, and it passes off only by drops, or in very small quantities, the disease is called strangury. When a sense of pain or heat attends the discharge, it passes with difficulty, and is styled ardor urinæ, heat of the urine. Dysuria is acute, or chronic. Dr. Cullen enumerates six species: —

1. *Dysuria ardens*, with a sense of heat, without any manifest disorder of the bladder.

2. *Dysuria spasmodica*, from spasm.

3. *Dysuria compressionis*, from a compression of the neighbouring parts.

4. *Dysuria phlogistica*, from violent inflammation.

5. *Dysuria calculosa*, from stone in the bladder.

6. *Dysuria mucosa*, from an abundant secretion of mucus.

The causes which give rise to these diseases are an inflammation of the urethra, occasioned either by gonorrhœa, or by the use of acrid injections, tumour or ulcer of the prostate gland, inflammation of the kidneys or bladder, considerable enlargements of the hæmorrhoidal veins, a lodgment of indurated fæces in the rectum, spasm at the neck of the bladder, the absorption of cantharides applied externally or taken internally, and excess in drinking either spirituous or vinous liquors; but particles of gravel sticking at the neck of the bladder, or lodging in the urethra, and thereby producing irritation, prove the most frequent cause. A gouty affection of the neck of the bladder will sometimes occasion these complaints.

In dysury, there is a frequent inclination to make water, with a smarting pain, heat, and difficulty in voiding it, together with a sense of fulness in the region of the bladder. The symptoms often vary, however, according to the cause which has given rise to it. If it proceeds from a calculus in the kidney or ureter, besides the affections mentioned, it will be accompanied with nausea, vomiting, and acute pains in the loins and region of the ureter and kidney of the side affected. When a stone in the bladder, or gravel in the urethra, is the cause, an acute pain will be felt at the end of the penis, particularly on voiding the last drops of urine, and the stream of water will either be divided into two, or twisted like a corkscrew. If a scirrhus of the prostate gland has occasioned the suppression or difficulty of urine, a hard indolent tumour, unattended with any acute pain, may readily be felt in the perinæum, or by introducing the finger into the rectum. The cure of this disease, which is always symptomatic, requires the removal of the several causes, and the administration of those medicines and means which are recommended for the removal of the primary affection.

E.

EAGLE. See *Falco*.

Eagle stone. See *Aëtitis*.

Ear, inflammation of. See *Otitis*.

Ear-shaped. See *Auriculatus*.

Ear-wax. See *Cerumen*.

Earache. See *Otalgia*.

EARTH. (*Terra*, *æ*. f.) Although there seems to be an almost infinite variety of earthy substances scattered on the surface of this globe, analysis has shown that the various stony or pulverulent masses which form our mountains, valleys, and plains result from the combination or intermixture, in various numbers and proportions, of nine primitive earths, namely, Baryta, Strontia, Lime, Magnesia, Alumina, or clay, Silica, Glucina, Zirconia, Yttria, Thorina. The earths were long considered as simple bodies, but the discovery by Sir H. Davy, in 1808, of the metallic bases of potash, soda, baryta, strontia, and lime, subverted this idea, and taught us to regard the earths as all belonging, by most probable analogies, to the metallic class.

Chemically considered, the earths are those solid bodies composing the mineral strata, which are incombustible, colourless, not convertible into metals by the ordinary methods of reduction, and, when reduced by more refined processes, possessing but an evanescent metallic existence, and which, either alone, or when combined with carbonic acid, are insipid and insoluble in water.

Earth, absorbent. See *Absorbent*.

Earth, aluminous. See *Alumina*.

Earth, argillaceous. See *Alumina*.

Earth-bath. See *Balneum.*

Earth of bones. Phosphate of lime. See *Os.*

Earth, bolar. See *Bole.*

Earth, fuller's. See *Fuller's earth.*

Earth, heavy. See *Barytes.*

Earth, Japan. See *Acacia catechu.*

Earth, sealed, Terra sigillata. See *Bole.*

Earth-nut. See *Bunium.*

Earth-worm. See *Lumbricus terrestris.*

Eaton's styptic. A solution of green vitriol in alkohol, with the addition of some other ingredients.

Eau d'arquebusade. *Aqua vulneraria spirituosa.* A vulnerary water formerly in great repute, especially for gun-shot wounds, whence its name. It is composed of the dried tops of sage, wormwood, fennel, hyssop, marjoram, savory, thyme, rosemary, calamint, balm, peppermint, scordium, fresh angelica leaves, leaves of basil, lavender flowers, of each four ounces, steeped for a fortnight in two gallons of proof spirit and distilled, only one gallon and a half being brought over.

Eau de belloste. A mixture of equal parts of muriatic acid, brandy, and saffron, with or without the addition of water. It was formerly employed as a resolvent.

Eau des carmes. *Aqua melissæ composita.* A preparation much esteemed in France as a stomachic, stimulant, &c. It consists of spirit of balm, eight parts; spirits of rosemary, thyme, and canella, of each one part; spirit of nutmeg, two parts; spirit of anise, marjoram, hyssop, sage, angelica, and cloves, of each one part; spirit of orange peel, four parts; spirit of coriander, two parts.

Eau de Javelle. See *Aqua Alkalina Oxymuriatica.*

Eau-de-luce. See *Spiritus ammoniæ succinatus.*

Eau de rabel. *Aqua Rabelii.* A mixture of one part of concentrated sulphuric acid with three of alkohol. It is used as an astringent.

Eau de Vie. See *Brandy.*

Eau medicinale. *Aqua medicinalis Hussonii.* A nostrum long celebrated for the cure of gout. It is generally believed to be a vinous infusion of the root of colchicum, and does not differ in its operation from the *vinum colchici* of our pharmacopœias. Some say it is a vinous infusion of the flowers of colchicum.

Eau vegeto-minerale. See *Aqua vegeto-mineralis.*

Ebeaupin. A place about a league from Nantes, where there is a mineral spring which contains carbonic acid, carbonates of lime, magnesia, and iron muriates of lime, magnesia and soda, &c.

Ebel. The seeds of sage, or of juniper.

Ebenaceæ. The name given by Jussieu to a family of plants allied to the tree which produces ebony, *Diospyros ebenum.*

E'benum. (*um, i.* n.) *Ebenus. Hebenus.* Ebony.

Ebes'mech. Quicksilver.

Ebiscus. See *Hibiscus abelmoschus.*

E'BONY. A name given to various hard woods, the principal of which are the *black* ebony, and the *green* or American ebony. The black is the produce of the *Diospyros ebenum,* of most botanists, or *Ebenoxylon verum* of Loureiro, and is brought from Madagascar, Ceylon, and the Mauritius. The green ebony is the produce of a tree which has been referred to the genus *Pterocarpus,* and several others, to none of which, however, it properly belongs. The late professor Burnet has proposed to name the genus *Wheeleria,* in honour of Mr. Wheeler of St. Bartholomew's Hospital. Ebony is used chiefly for mechanical purposes, but has also been esteemed in medicine as a diaphoretic and alterative.

EBRACTEA'TUS. Ebracteate; without a bractea, or floral leaf.

Ebriecasum. A name given by Paracelsus to an affection of the mind resembling that produced by drunkenness.

Ebriety. See *Intoxication.*

Ebsemech. Quicksilver.

EBULLI'TION. (*Ebullitio. onis.* f.; from *ebullio,* to bubble up.) Boiling. This takes place during the change which a fluid undergoes from a state of liquidity to that of an elastic fluid, in consequence of the application of heat, which dilates and converts it into vapour.

E'bulus. See *Sambucus ebulus.*

Ebur. See *Ivory.*

Ebur fossile. Fossil unicorn. See *Unicornu.*

Ebur Ustum Nigrum. See *Ivory black.*

Ecalcula'tus. Without a spur, or horn.

Ecbo'licus. (From εκβαλλω, to cast out.) Applied to medicines which cause abortion or facilitate labour.

Ecbra'smata. (Εκβρασμα; from εκβραζω, to expel with ebullition.) Hippocrates gives this name to an eruption of fiery pimples.

Ecbyrso'ma. (*a, atis.* n.; from εκ, and βυρσα, the skin.) A protuberance of a bone at the joints, appearing through the skin.

Eccatha'rticus. (From εκκαθαιρω, to purge outwards.) According to Gorræus, eccathartics are medicines which open the pores of the skin. Sometimes expectorants are thus called, and also purgatives.

Ecchylo'ma. (From εκ, and χυλος, juice.) An extract.

Ec'chyma. (From εκχυω, to pour out.) Synonymous with *eczema.*

Ecchymoma. The same as *ecchymosis.*

Ecchymoma arteriosum. The false aneurism.

ECCHYMO'SIS. (Εκχυμωσις; from εκχυω, to pour out.) *Ecchymosis.* Extravasation. A black and blue swelling, either from a bruise or spontaneous extravasation of blood. It is removed by the application of leeches and cold stimulating lotions.

E'CCLISIS. (*is, is.* f.; from εκκλινω, to turn aside.) A luxation, or dislocation.

E'CCOPE. (*e, es.* f.; from εκκοπτω, to cut off.) The cutting off any part.

Ecco'peus. (From εκκοπτω, to cut off.) An ancient instrument, the raspatory, used in trepanning.

ECCOPRO'TIC. (*Eccoproticus;* from εκ, and κοπρος, dung.) A term applied to laxatives which evacuate merely the natural contents of the bowels, without occasioning any liquid discharge; this is generally the case with rhubarb and aloes.

ECCRINO'LOGY. (*Eccrinologia*, *æ*. f.: from εκκρινω, to excrete, and λογος, a discourse.) The doctrine of excretions. The term is ill formed. It should have been *eccriseology*.

E'CCRISIS. (*is*. *eos*, f.; from εκκρινω, to secrete.) An excretion of any kind.

ECCRI'TICA. (Same etymon.) Diseases of the excernent function. The sixth class in Dr. Good's Nosology.

ECCYE'SIS. (From εκ, and κυησις, *gravidity*.) Extra uterine fœtation.

Eccymosis. See *Ecchymosis*.

E'CDORA. (*a*, *æ*. f.; from εκδερω, to excoriate.) An excoriation: and particularly an excoriation of the urethra. — *James*.

ECDO'RIUS. (From εκδερω, to excoriate.) Applied to that which excoriates and eats through the skin.

ECHECO'LLON. (From εχω, to have, and κολλα, glue.) *Echecollum*. Any topical glutinous remedy.

ECHETRO'SIS. The white bryony.

ECHINA'TUS. (*Echinatus*, from εχινος, a hedge-hog.) Bristly; set with prickles: applied, in *Botany*, to any thing beset with bristles; as the pod of *Glycyrrhiza echinata*, and the seed-vessel of the gourd.

ECHINOCO'CCUS. (*us*, *i*. m.) Rudolphi calls the small granular bodies, found in the acephalocysts, by the name of echinococci.

ECHINODE'RMA. (From εχινος, a sea-urchin, and δερμα, a skin.) A class of radiated animals with hard skins like that of the echinus, or sea-urchin. The term *echinodermata* has been very generally, but improperly, substituted for this: echinodermata signifies simply the skins of echini, not animals having skins like the echinus.

Echinodermata. See *Echinoderma*.

ECHINOMELOCA'CTOS. (From εχινος, a hedge-hog, μηλον, an apple, and κακτος, a thistle.) The melon-thistle.

ECHINOPHTHA'LMIA. (*a*, *æ*. f.; from εχινος, a hedge-hog, and οφθαλμια, an inflammation of the eye.) An inflammation of that part of the eyelids where the hairs bristle out like the quills of a hedge-hog.

ECHINOPO'DIUM. (*um*, *ii*. n.; from εχινος, a hedge-hog, and πους, a foot: so named because its flowers resemble the foot of a hedge-hog.) A species of broom, probably the *Spartium scoparium*.

ECHI'NOPS. (*ops*, *opis*. m.; from εχινος, a hedge-hog, and ωψ, appearance.) The name of a genus of plants. Class, *Syngenesia*; Order, *Polygamia segregata*.

ECHINOPS SPHÆROCE'PHALUS. The systematic name of the globe-thistle; called also, *Crocodilion*, *Acanthalruca*, *Scabiosa carduifolia*, *Sphærocephala elatis*, and *Echinopus*. It is raised in our gardens. The root and seeds are moderately diuretic, but seldom used.

Echinopus. See *Echinops*.

ECHINORHY'NCUS. (From εχινος, a hedge-hog, and ρυγχος, a beak.) A very numerous genus of intestinal worms, belonging to the order *Acanthocephaliæ* of Rudolphi: only one species has been found in man, namely, the *echinorhyncus bicornis*.

ECHI'NUS. (*us*, *i*. m.) Εχινος. 1. The hedgehog. See *Erinaceus*.

2. The sea-urchin.

3. Formerly applied to several plants, which are beset with spines or thorns.

4. A genus in the Linnæan system, included in the molusca order of vermes.

5. The prominent points on the surface of the *pileus*, or upper part of mushrooms, are called *echini*. See *Fungus*.

ECHINUS MARINUS. The sea hedge-hog, or urchin, the petrified spine of which is called *amygdaloides*, from its shape.

ECHIOI'DES. (From εχις, a viper, and ειδος, resemblance.) The trivial name of some plants, from their supposed resemblance to the *Echium*.

E'CHIUM. (*um*, *ii*. n.; from εχις, a viper: so called because it was said to heal the sting of the viper.) The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Monogynia*. Viper's bugloss.

ECHIUM ÆGYPTIACUM. Wall bugloss, the root of which is sudorific, and was used with oil as a dressing for wounds.

ECLACTI'SMA. (Εκλακτισμα.) Convulsive agitation of the limbs in children. — *Hippocrates*.

ECLA'MPSIA. (From εκλαμπω, to shine.) See *Eclampsis*.

ECLA'MPSIS. (*is*, *is*. f.; from εκλαμπω, to shine.) *Eclampsia*. Splendour, brightness. Applied 1. To the appearance of flashes of light before the eyes, common in many diseases.

2. To the epilepsy of infants: the reason of the latter application is not obvious.

ECLE'CTIC. (*Eclecticus*; from εκλεγω, to select.) Archigenes and some others selected from all other sects what appeared to them to be the best and most rational: hence they were called *Eclectics*, and their medicine *Eclectic medicine*.

ECLE'CTOS. Synonymous with *eclegma*.

ECLE'GMA. (From εκλειχω, to lick.) *Eclectos*. *Ecleictos*. A linctus, or form of medicine of a semifluid consistence, which is licked off the spoon.

E'CLYSIS. (*is*, *eos*. f.; from εκλυω, to dissolve.) An universal faintness.

ECONOMIC. Appertaining to economy, or the useful distribution and application of things. Thus economic botany means the application of botany to medicine, cookery, or other useful arts.

ECONOMY. In scientific language the orderly arrangement of things with a view to an useful end; thus the total of the parts which constitute a living being is called the *animal* or *vegetable* economy.

ECPHLYSIS. (*is*, *is*. f. Εκφλυσις; from εκφλυζω, to boil, or bubble up or over.) A vesicular eruption.

ECPHRA'CTIC. (*Ecphracticus*; from εκφρασσω, to remove obstructions.) Synonymous with *deobstruent*.

ECPHRA'XIS. (*is*, *is*. f.; from εκφρασσω, to remove obstruction.) The opening of obstructed pores.

ECPHRO'NIA. (*a*, *æ*. f. Εκφρωνη, o

εκφροσυνη; from εκφρων, *extra mentem*, out of one's mind.) Insanity. Craziness.

E'CPHYAS. (From εκ, and φυω, to produce.) 1. An appendix, or excrescence.

2. The appendicula cæci vermiformis.

ECPHYMA. (*a, atis.* n.; from εκφυω, *educo, egero.*) A cutaneous excrescence.

ECPHYSE'SIS. (From εκφυσαω, to breathe through.) A quick expulsion of the air from the lungs.

E'CPHYSIS. (From εκφυω, to produce.) 1. An apophysis, appendix, or process of any kind.

2. The duodenum.

ECPIE'SMA. (From εκπιεζω, to press out.) 1. A fracture of the skull, with depression of the bone. — *Galen.*

2. An expressed juice. — *Dioscorides.*

ECPIE'SMOS. (From εκπιεζω, to press, or press out.) A disorder of the eye, in which the globe is almost pressed out of the socket by an afflux of humours.

ECPLERO'MA. (From εκπληροω, to fill.) In Hippocrates they are hard balls of leather, or other substances, adapted to fill the arm-pits, while by the help of the heels, placed against the balls, and repressing the same, a luxated os humeri is reduced into its place.

ECPLE'XIS. (*is, is.* f.; from εκπλησσω, to terrify or astonish.) A stupor or astonishment, from sudden external accidents.

E'CPNOE. (From εκπνεω, to breathe.) Expiration.

ECPTO'MA. (From εκπιπτω, to fall out.) *Ecptosis.* A falling down of any part: applied to a luxation; the expulsion of the placenta; the falling off of gangrenous parts; to hernia of the uterus, &c.

ECPY'ETICUS. (From εκπυκαζω, to condense.) Rendering the fluids more solid.

ECPYE'MA. (*a, atis.* n.; from εκ, and πυον, pus.) A collection of pus.

ECPYE'SIS. (*is, is.* f.; from εκπυω, to suppurate.) Humid scalp.

ECPYE'TIC. (Same etymon.) Suppurative.

ECRE'GMA. (From εκρηγνυμι, to break.) A rupture.

ECRE'XIS. (From εκρηγνυμι, to break.) A rupture: applied by Hippocrates to a rupture or laceration of the womb.

ECRHY'THMOS. (From εκ, and ρυθμος, rhythm.) Irregular: anciently applied to the pulse.

E'CROE. (From εκρεω, to flow out.) An efflux, or the course by which any humour which requires purging is evacuated.

E'CRYSIS. (Εκρυσις; from εκρυω, to flow out.) In Hippocrates it is an efflux of the semen before it receives the conformation of a fœtus, and therefore is called an efflux, to distinguish it from abortion.

ECSARCO'MA. (*a, atis.* n.; from εκ, and σαρξ, flesh.) A fleshy excrescence.

E'CSTACY. (*Ecstasis, cos.* f. Εκστασις; from εξισταμαι, to be out of one's senses.) 1. An ecstacy. This disease consists in a total suspension of sensibility and voluntary motion, and mostly of mental power; the muscles are rigid, the body erect and inflexible; the pulsation of the heart is felt, and the breathing not affected. The exciting cause of this disease is generally some mental affection. It differs from catalepsy and trance in the inflexible and rigid state of the muscles, and the obvious continuance of the breathing and the heart's action. It occasionally exists with a plethoric state of the blood-vessels; in which case bleeding and depletions are found useful. In other more obviously nervous states, the nervous stimulants and aperients are to be preferred.

2. In Hippocrates it signifies a delirium.

ECSTRO'PHIUS. (From εκστρεφω, to invert.) An obsolete epithet for any medicine that makes the blind piles appear outwardly.

ECTHELY'NSIS. (From εκθηλυνω, to render effeminate.) Softness. Applied formerly to the skin and flesh, when lax and soft, and to bandages, when not sufficiently tight.

ECTHLI'MMA. (From εκθλιβω, to press out.) An ulceration of the skin caused by pressure.

ECTHLI'PSIS. (From εκθλιβω, to press out.) Elision, or expression. Kraus would make it signify abrasion, or the wounding of a part by pressure. The truth is, it is not a medical term at all, but simply a Greek word signifying squeezing out or expression.

E'CTHYMA. (*a, atis.* n. Εκθυμα; from εκθυω, to break out.) An eruption of phlyzacious pustules, which are usually distinct, arising at a distance from each other, seldom very numerous, unaccompanied by fever, and not contagious.

This eruption, unconnected with any other disease, does not very frequently demand the assistance of medicine. It shows itself under three or four varieties, and is usually attributed to long continued exertion and fatigue, to much watching, to imperfect nutrition, to the influence of cold, to a state of pregnancy, or to the debilitating effects of previous malignant fevers, especially of small-pox, measles, and scarlatina. It occurs chiefly on the extremities. The diagnosis of this eruption, from the contagious pustular diseases, as well as from some of the secondary appearances of syphilis, is of considerable importance in practice. There are three species in this genus. 1. The *Ecthyma vulgare* is the slightest form of the disorder, and consists of a partial eruption of small hard pustules, on some part of the extremities, or on the neck and shoulders, which is completed in three or four days. In the course of a similar period, the pustules successively enlarge, and inflame highly at the base, while pus is formed in the apex; and in a day or two more they break, pour out their pus, and afterwards a thinner fluid, which speedily concretes into brown scabs. In a week more, the soreness and inflammation subside, and the scabs soon afterwards fall off, leaving no mark behind.

This eruption commonly supervenes a state of languor, of some continuance, with loss of appetite, irregularity of the alvine evacuations, and pains in the stomach or limbs. Young persons are principally subject to it, and children are sometimes affected with it, especially in the spring or summer after being overheated, or fatigued, or disturbing the digestive organs by improper food. The constitutional

derangement is not immediately relieved on the appearance of the eruption, but ceases before its decline. The use of gentle purgatives, in the early stage, and of the decoction of cinchona, after the maturation of the pustules, appears to comprehend all that is requisite in regard to medicine.

2. The *Ecthyma infantile* occurs in weakly infants, during the period of lactation, when sufficient nutriment is not afforded them. The pustules are, in appearance, the same as those of the preceding species, and go through similar stages of progress in the same time. But the disorder does not terminate here: fresh eruptions of phlyzacia continue to rise in succession, and to a much greater extent than in the ecthyma vulgare, appearing not only over the extremities and trunk, but on the scalp, and even on the face; in which situation the pustules do not occur in the other varieties of ecthyma. Hence, also, the duration of the eruption is much greater than in the preceding species, being sometimes protracted for several months. Yet the patients usually remain free from fever, and the pain and irritation seem to be inconsiderable, except when a few of the pustules become very large and hard, with a livid base, and ulcerate to some depth: in this case, also, a slight whitish depression is permanently left on the seat of the pustule.

The principal means of cure will be found in changing the nurse; and the advantages of better aliment will be aided by proper clothing and exercise, as well as by moderate alteratives, and by the cinchona, or chalybeates.

3. *Ecthyma luridum.* The most obvious peculiarity of this variety of the phlyzacious pustules is the dark red colour of their base, which is likewise hard and elevated. But they differ also from the two preceding varieties in being of a larger size; and, from the first, in the slow but long succession in which they arise, and in the extent of surface over which they spread, the face alone being exempt from their occurrence. This form of the disease is most frequently seen in persons of an advanced age, who have injured their constitutions by hard labour, intemperance in the use of spirits, and night-watching; and it is most severe in the winter season. Under these circumstances, the pustules, as might be expected, are slow in healing. They break in the course of eight or ten days, and discharge a curdly, sanious, or bloody matter: the ulcerated cavities, extending beyond the original boundary, soon become filled with hard, dark scabs, and remain surrounded by a deep-seated hardness in the flesh, and dark inflamed borders, until the scabs are about to separate; a period generally of several weeks, and sometimes of many months. The scabs generally adhere firmly; but, if removed by violence, they are not speedily reproduced: on the contrary, tedious ulcers, with callous edges, and a sanious discharge, are often thus produced.

The treatment must be chiefly directed to the amendment of the constitution, by means of good diet, by the occasional use of the warm bath, and by the bark and decoction of the woods internally.

ECTHYMO'SIS. (From εκθυζω, to effervesce.) Effervescence or agitation of the blood.

ECTILLO'TICUS. (From εκτιλλω, to pull out.) Applied to that which eradicates tubercles or corns, or destroys superfluous hair.

ECTOMON. Εκτομον. Black hellebore.

ECTO'PIA. (*a*, *æ*. f.; from εκτοπος, out of place.) A displacement of any part.

ECTOPIÆ. An order in the class *Locales* of Cullen's Nosology.

ECTOPROTIC. Improperly written for *eccoprotic*.

ECTRI'MMA. (From εκτριβω, to rub off.) An excoriation.

ECTRO'MA. (Εκτρωμα; from εκτιτρωσκω, to miscarry.) An abortion.

E'CTROPE. (From εκτρεπω, to divert, pervert, or invert.) 1. A duct by which morbid humours are diverted and drawn off.

2. In Paulus Ægineta it is the same as *Ectropium*.

ECTRO'PIUM. (*um*, *ii*. n.; from εκτρεπω, to evert.) An eversion of the eye-lids, so that their internal surface is outermost.

There are two species of this disease: one produced by an unnatural swelling of the lining of the eyelids, which not only pushes their edges from the eyeball, but also presses them so forcibly, that they become everted; the other arising from a contraction of the skin covering the eyelid, or of that in the vicinity, by which means the edge of the eyelid is first removed for some distance from the eye, and afterwards turned completely outward, together with the whole of the affected eyelid.

The morbid swelling of the lining of the eyelids, which causes the first species of ectropium, arises mostly from a congenital laxity of this membrane, afterwards increased by chronic ophthalmies, particularly of a scrophulous nature, in relaxed, unhealthy subjects; or else the disease originates from the small-pox affecting the eyes.

The second species is not unfrequently a consequence of puckered scars, produced by a confluent small-pox, deep burns, or the excision of tumours, without saving a sufficient quantity of skin. This disease is only to be cured by a surgical operation. Caustics have been tried by Mr. Ware, Scarpa, and many able surgeons; but, they all acknowledge, with uncertain effect. The operation proposed and practised by Sir William Adams is now generally resorted to. It consists, first, in removing the whole of the fungous growth by a small curved bistoury; next, in stripping away a piece of the edge of the tarsus, in the form of the letter V; afterwards, in separating the eyelid from the cheek, whenever it adheres to it; and, finally, in supporting the lid, now raised into the proper place, and confining the edges of the cut eyelid, brought into a state of juxtaposition by a proper bandage. The divided edges heal by the first intention; and the cure is often completed in a fortnight, with a restoration of the eyelid to its healthy form.

ECTRO'SIS. (*is*, *is*. f. Εκτρωσις; from εκτιτρωσκω, to miscarry.) A miscarriage.

ECTRO'TICUS. (From εκτιτρωσκω, to mis-

carry.) *Ectyroticus, Ectyloticus.* Causing an abortion.

Ectyloticus. See *Ectilloticus.*

Ectyroticus. See *Ectroticus.*

ECZEMA. (Εκζεμα; from εκζεω, to boil out.) *Eczesma.* A cutaneous disease, characterised by an eruption of small vesicles on various parts of the skin, usually set close or crowded together, with little or no inflammation round their bases, and unattended by fever. It is not contagious.

This eruption is generally the effect of irritation, whether internally or externally applied, and is occasionally produced by a great variety of irritants, in persons whose skin is constitutionally very irritable. It differs from miliaria, inasmuch as it is not the result of fever; and, unless it be very extensively diffused, is not accompanied with any derangement of the constitution: even in the most violent cases, the functions of the sensorium and of the stomach are seldom disturbed. When limited to the fingers, hands, and part of the fore-arm, it is not unfrequently mistaken for itch: but it may be distinguished by the appearance of its acuminated and pellucid vesicles; by the closeness and uniformity of their distribution; by the absence of surrounding inflammation, and of subsequent ulceration; and, in many cases, by the sensations of smarting and tingling, rather than of itching, which accompany them. According to the nature of the irritating cause, the extent and form of the disease are somewhat various. The species of this affection are,

1. *Eczema solare*, which occurs in the summer season, and is the effect of irritation from the direct rays of the sun, or from the heated air. Hence it affects almost exclusively those parts of the surface which are exposed to their influence; as the face, the neck, and fore-arms in women, but more particularly the back of the hands and fingers. They are popularly termed *heat-spots.*

This eruption is successive, and has no regular period of duration or decline: it commonly continues for two or three weeks, without any particular internal disorder. The included lymph becomes more milky, and is gradually absorbed, or dried into brownish scales, which exfoliate, or into brownish yellow scabs, of the size of a small pin's head, especially when the vesicles are broken. But successive eruptions of the vesicles are liable to appear, which terminate in a similar manner by exfoliation or scabbing; and in those persons who, by the peculiar irritability of their skin, are much predisposed to the disorder, it is thus continued many weeks, to the end of autumn, or even prolonged to the winter. When this happens, the vesicles generally pour out an acrid serum, bywhich the surface is inflamed, rendered tender, and even slightly ulcerated, and the disease assumes the form of impetigo.

The course of this disorder does not appear to be materially shortened by the operation of medicine. The mineral acids, with a decoction of cinchona, or other vegetable tonic, and a light but nutritious diet, seem to be most effectual in diminishing the eruption. Simple ablution with tepid water contributes to relieve the smarting and tingling of the parts affected, which do not bear unguents, or any stimulant application.

2. *Eczema impetiginodes.* A local eczema is produced by the irritation of various substances; and, when these are habitually applied, it is constantly kept up in a chronic form, differing from the impetigo only in the absence of pustules. Small separate vesicles, containing a transparent fluid, and, like the psydracious pustules, but slightly elevated, arise, and slowly increase: they are attended with pain, heat, smarting, and often with intense itching. When they break, the acrid lymph that is discharged irritates and inflames the surrounding cuticle, which becomes thickened, rough, reddish, and cracked, as in the impetiginous state. The alliance, indeed, of this affection with impetigo is further proved by the circumstance, that, in some cases, vesicles and pustules are intermixed with each other; and, in different individuals, the same irritant will excite a pustular or a vesicular eruption respectively; the vesicular disease being always the most painful and obstinate.

The first step towards the cure of this species of eczema is to remove the irritating cause, where that is obvious. The eruption, however, is not easily removed: but the painful sensations connected with it are greatly alleviated by simple poultices; lotions containing hydrocyanic acid or acetate of lead are also useful. Where there is any other evidence of a cachectic condition of the patient, similar treatment must be prescribed for the improvement of the general health as is recommended in ecthyma.

3. *Eczema rubrum.* The most remarkable variety of the eczema rubrum is that which arises from the irritation of mercury; whence it has been called *eczema mercuriale*, and *erythema mercuriale*, and *hydrargyria.* But the disease is not exclusively occasioned by this mineral, either in its general or more partial attacks: it has been observed to follow exposure to cold, and to recur in the same individual at irregular intervals, sometimes without any obvious or adequate cause.

It is preceded by a sense of stiffness, burning heat, and itching, in the part where it commences, which is most frequently the upper and inner surface of the thighs, and about the scrotum in men; but sometimes it appears first in the groins, axillæ, or in the bend of the arms, or about the wrists and hands, or in the neck. These sensations are soon followed by an appearance of redness, and the surface is somewhat rough to the touch. This, however, is not a simple erythema: for on examining it minutely between the light and the eye, or with a convex glass, the roughness is found to be occasioned by innumerable minute and pellucid vesicles, which have been mistaken for papulæ. In two or three days, these vesicles, if they are not ruptured, attain the size of a pin's head; and, the included serum then becoming somewhat opake and milky, the character of the eruption is obvious. It soon extends itself over the body and limbs in successive large patches,

and is accompanied by a considerable swelling of the integuments, such as is seen in small-pox, and other eruptive fevers, and by great tenderness of the skin, and much itching. When the vesicles begin to lose their transparency, they generally burst, and discharge, from numerous points, a thin acrid fluid, which seems to irritate the surface over which it passes, and leaves it in a painful, inflamed, and excoriated condition. The quantity of this ichorous discharge is very considerable, and it gradually becomes thicker and more adhesive, stiffening the linen which absorbs it, and which thus becomes a new source of irritation: it emits also a very fœtid odour. This process takes place in the successive patches of the eruption, until the whole surface of the body, from head to foot, is sometimes in a state of painful excoriation, with deep fissures in the bends of the joints, and in the folds of the skin of the trunk; and with partial scaly incrustations, of a yellowish hue, produced by the drying of the humour, by which also the irritation is augmented. The extreme pain, arising from the pressure of the weight of the body upon an extensive portion of such a raw surface, is sufficient to give rise to an acceleration of the pulse, and white tongue; but the functions of the stomach and of the sensorium commune are not evidently disturbed by this disease.

The duration of this excoriation and discharge is uncertain and irregular: when only a small part of the body is affected, it may terminate in ten days; but, when the disorder has been universal, the patient seldom completely recovers in less than six weeks, and is often afflicted to the end of eight or ten weeks. By so severe an inflammation, the whole epidermis is destroyed in its organisation; and, when the discharge ceases, it lies loose, assuming a pale brown colour, which changes almost to black before it falls off in large flakes. As in other superficial inflammations, however, the new red cuticle that is left is liable to desquamate again, even to the third or fourth time, but in smaller branny scales, of a white colour; and a roughness sometimes remains for a considerable period, like a slight degree of psoriasis. In some instances, not only the cuticle, but the hair and nails are also observed to fall off; and the latter, when renewed, are incurvated, thickened, and furrowed, as in lepra.

The eczema rubrum, however, even from the irritation of mercury, is often limited to a small space; and then the discharge is slight, and its whole duration short. Similar local attacks of it occur in irritable constitutions, especially in hot weather, affecting the hands and wrists, the neck and external ear, and other parts, but without any constitutional disorder. Successive crops of the vesicles arise, in irregular patches, with a red blush around them, which produce partial incrustations, as the ichor, that issues, is dried: and by these vesications and desiccations of the matter the affection is kept up for some weeks.

The treatment of this species of eczema may be comprised in few words; for it is principally palliative. But although medicine may not possess the power of shortening the period of its duration, yet the omission of the palliative measures will allow an extreme aggravation of the sufferings of the patient to take place, and probably prolong it beyond its natural course, as well as contribute to wear out the powers of the constitution.

The misery and exhaustion, resulting from the excessively tender and irritated state of the skin, may be greatly alleviated by frequent ablution or fomentation with warm gruel, or strained bran and water; or by the frequent use of the warm bath, which has the advantage of cleansing the surface, without occasioning any abrasion by friction. A constant application of poultices has produced considerable ease to the patient, when the affection was confined to the extremities. Where the cuticle has exfoliated, Mr. Pearson recommends the application of a mild cerate, consisting of litharge plaster, wax, and oil, spread thickly on linen rollers, and renewed twice a day. With the same view of diminishing the irritation of the surface, the bed and body linen of the patient, which becomes hard and stiff as the discharge dries upon it, should be frequently changed.

Every additional irritation from stimulating food and drink should be avoided; the bowels should be kept open by the administration of occasional laxatives; and some saline diaphoretic, or an antimonial, should be given regularly, to which an opiate may be added, for the purpose of soothing the sensations of the patient. The sulphuric acid is grateful and refreshing; and, in the decline of the swelling and discharge, it may be combined advantageously with the liberal exhibition of cinchona and sarsaparilla.

Eczema mercuriale. See *Eczema.*

EDENTA'TA. The fifth order of the Class *Mammalia* in Cuvier's System of Zoology. It comprises animals all of which are without incisor teeth, and some without any teeth.

Edes. Amber.

Ede'ssenum. An old collyrium, made with tragacanth, gum-arabic, opium, &c.

Edetz. Amber.

Edic. *Edich; Edir.* Iron.

EDU'LCORANT. (*Edulcorans*; from *edulco*, to make sweet.) Applied to a medicine which purifies the fluids by depriving them of their acrimony.

EDULCORA'TION. (*Edulcoratio, onis.* f.) 1. The affusion of water on any substance to remove from it saline or other particles which are soluble in water.

2. The sweetening of a medicine with sugar.

Eel. See *Muræna anguilla.*

Eel, conger. See *Muræna conger.*

Eel fat. *Adeps anguillæ.* This is obtained from eels while roasting, and is used as an ointment for stiff joints.

EFFERVESCENCE. (*Effervescentia, æ.* f.; from *effervesco*, to grow hot.) 1. That agitation which is produced by mixing substances together which cause the evolution of a gas.

2. A small degree of ebullition.

Effides. Cerusse. — *Ruland.*

E'ffila. Freckles.

EFFLORESCENCE. (*Efflorescentia*, æ. f.; from *effloresco*, to blow as a flower.) 1. In *Pathology*, a morbid redness of the skin.

2. In *Chemistry*, that effect which takes place when bodies spontaneously become converted into a dry powder. It is almost always occasioned by the loss of the water of crystallisation in saline bodies.

3. In *Botany*, the evolution of the flower.

EFFLU'VIUM. (*um*, *ii*. n.; from *effluo*, to flow out.) An exhalation. The term is generally applied to such exhalations as are noxious, or disagreeable to the senses; thus we speak of contagious effluvia, and the effluvia of putrefying animal and vegetable substances. See *Ague*, *Contagion*, and *Febris*.

EFFRACTU'RA. (From *effringo*, to break down.) A fracture of the cranium, in which the bone is much depressed. — *Ambrose Paré*.

EFFUSION. (*Effusio*, *onis*. f.; from *effundo*, to pour out.) In *Pathology*, the escape of any fluid out of the vessel, or viscus, naturally containing it, and its lodgment in another cavity, in the cellular substance, or in the substance of parts. Effusion also sometimes signifies the morbid secretion of fluids from the vessels; thus pathologists frequently speak of coagulable lymph being effused on different surfaces.

EGE'RIES. (From *egero*, to carry out.) *Egestio*. An excretion, or evacuation.

Egg. See *Ovum*.

Egg-shaped. See *Ovatus*.

Eighth pair of nerves. See *Nervous system*.

EILAMIDES. (From ειλεω, to involve.) The membranes involving the brain.

EILE'MA. (Ειλημα; from ειλεω, to convolute.) In Hippocrates it signifies painful convolutions of the intestines from flatulence. Vogel applies the term to a fixed pain in some part of the bowels, as if a nail were driven in.

Ei'leon. See *Ilium*.

Ei'leos. See *Ileus*.

EI'SPNOE. (From εισπνεω, to inspire.) Inspiration of air.

EJA'CULANS. (From *ejaculor*, to cast out.) *Ejaculatorius*. The vessels which convey the seminal matter secreted in the testicles to the penis are called *ejaculantia*. These are the epididymis, the vasa deferentia, and the vesiculæ seminales, which are the receptacles of the semen.

Ejaculator seminis. See *Accelerator urinæ*.

ELACA'LLI. The Indian name of the *Euphorbia nervifolia* of Linnæus, which is cathartic.

ELÆA'GNON. (From ελαιον, oil, and αγνος, chaste.) See *Vitex agnus castus*.

ELÆO'MELI. (From ελαιον, oil, and μελι, honey.) A sweet purging oil, the produce of a Syrian tree. — *Dioscorides*.

ELÆOSA'CCHARUM. (*um*, *i*. n.; from ελαιον, oil, and σακχαρον, sugar.) A mixture of an essential oil with sugar. The chief use of such preparations is to render the oil soluble in water; for this purpose the sugar must exceed thirteen times the weight of the oil.

ELÆOSELI'NUM. See *Eleoselinum*.

ELAÏDATE. A salt formed by the *elaidic acid* with a base.

ELAÏDIC ACID. The name given by Boudet to an acid resulting from the saponification of elaidine.

ELAÏDINE. The name given by Boudet to a substance resembling stearine, which results from the action of hyponitric acid upon olive, almond, and some other oils.

ELAIN. (From ελαιον, oil.) The oily principle of solid fats. See *Adeps*.

ELAIODATE. A salt formed by the elaiodic acid with a base.

Elaiodic acid. See *Oleoricinic acid*.

ELAIODON. (From ελαιον, oil.) A name given by Herberger to the fluid part of volatile oils.

ELAIS GUINEE'NSIS. A species of palm, which grows spontaneously on the coast of Guinea, but is much cultivated in the West Indies. It is from this tree that the oil, called in the West Indies *Mackaw fat*, is obtained. It affords, also, an oil which is considered as an emollient and strengthener in all kinds of weakness of the limbs. It also is recommended against bruises, strains, cramps, pains, swellings, &c.

ELAMBICA'TIO. A method of analysing mineral waters. See *Castelli Lexicon*, *in voce*. Ed. Lipsiæ, 1713.

ELANULA. Alum.

ELAPHOBO'SCUM. (*um*, *i*. n.; from ελαφος, a stag, and βοσκω, to eat: so called because deer eat it greedily.) A name given by the ancient botanists to several umbelliferous plants.

ELAPHOSCO'RODON. (From ελαφος, the stag, and σκοροδον, garlic.) Stag's or viper's garlic. A species of allium.

ELAQUIR. Red vitriol.

ELA'SMA. (From ελαυνω, *impello*; *ductile opus facio*.) A lamina of any kind. A clyster-pipe.

ELASTIC. (*Elasticus*; from ελαστης, *impulsor*, which is from ελαυνειν, to impel, to push.) Springy; having the power of returning to the form from which it has been forced to deviate, or from which it is withheld: thus, a blade of steel is said to be elastic, because if it is bent to a certain degree, and then let go, it will of itself return to its former situation; the same will happen to the branch of a tree, a piece of Indian rubber, &c. See *Elasticity*.

Elastic fluid. See *Gas*.

Elastic gum. See *Caoutchouc*.

ELASTICITY. *Elasticitas*. A force in bodies by which they endeavour to restore themselves to the posture from which they were displaced by any external force. To account for this property, many have recourse to the universal law of nature, attraction, by which the parts of solid and firm bodies are caused to cohere together: whereby, when hard bodies are struck or bent, so that the component parts are a little moved from one another, but not quite disjoined or broken off, nor separated so far as to be out of the power of the attracting force, by which they cohere together, they certainly must, on the cessation of the external violence, spring back with a very great velocity to their former state. But in this circumstance, the atmospherical pressure will account for it as well; because such a violence, if it be not great

enough to separate the constituent particles of a body far enough to let in any foreign matter, must occasion many vacuola between the separated surfaces, so that upon the removal of the external force, they will close again by the pressure of the aërial fluid upon the external parts, *i. e.* the body will come again into its natural position. The included air, likewise, in most bodies, gives the power of resilition upon their percussion.

If two bodies perfectly *elastic* strike one against another, there will be or remain in each the same relative velocity as before, *i. e.* they will recede with the same velocity as they met together. For the compressive force, or the magnitude of the stroke in any given bodies, arises from the relative velocity of those bodies, and is proportional to it, and bodies perfectly *elastic* will restore themselves completely to the figure they had before the shock; or, in other words, the restitutive force is equal to the compressive, and therefore must be equal to the force with which they came together, and consequently they must by elasticity recede again from each other with the same velocity. Hence, taking equal times before and after the shock, the distances between the bodies will be equal; and therefore the distances of them from the common centre of gravity will, in the same times, be equal. And hence the laws of percussion of bodies perfectly elastic are easily deduced.

ELATERINE. A crystallisable matter distinct from elatin, found by Mr. Hennel in the juice of elaterium. See *Momordica elaterium*.

ELATE'RIUM. (*um, i.* n. Ελατηριον; from ελαυνω, to stimulate or agitate.) This name was given by the Greeks to any drastic purgative, and to the juice of the wild cucumber in particular. At present, it signifies a peculiar substance deposited from the juice of the wild cucumber. See *Momordica elaterium*.

ELATHE'RIA. (*a, æ.* f.) A name of the cascarilla bark.

E'LATIN. The active principle of elaterium. See *Momordica elaterium*.

ELATI'NE. (*e, es.* f.; from ελαττων, smaller, being the smaller species.) See *Antirrhinum elatine*.

ELATI'TES. Bloodstone.

ELCO'SIS. (*is, cos.* f.; from ελκος, an ulcer.) Ulceration. Sauvages applies this term especially to a cachectic disease attended with fœtid, carious, and chronic ulcers.

Elder. See *Sambucus.*

Elder, dwarf. See *Sambucus ebulus.*

Elecampane. See *Inula.*

Elective affinity, double. See *Affinity.*

Elective attraction. See *Affinity.*

Elective attraction, double. See *Affinity.*

ELECTRICITY. (*Electricitas, atis.* f.) When certain substances, such as amber, glass, sealing-wax, and sulphur, are rubbed, and then brought near small fragments of paper, cork, or other light bodies, the latter move rapidly towards the former, and adhere during a longer or shorter interval to their surface. If the body which is thus excited by friction is light and freely suspended, it will move towards the substances in its vicinity. After a while the excited body loses its influence; but it may be renewed for any number of times by friction. The movement observed in these instances is attributed to a peculiar kind of attraction, and the unknown cause of this attraction is called *Electricity*, from the Greek word ηλεκτρον, amber, because the electric property was first noticed in this substance.

The ancients were aware that amber and the *lyncurium* (supposed to be our tourmalin), may be rendered electric by friction, but it was not known that other bodies may be similarly excited until the commencement of the seventeenth century, when Dr. Gilbert, of Colchester, detected the same property in a variety of other substances. Of those which he has enumerated in his treatise *de Magnete*, the principal are the diamond, rock crystal, and several of the precious stones, glass, sulphur, mastic, sealing-wax, and resin; and in making this discovery he laid the foundation of the science of Electricity. A few additional facts were noticed during the course of the same century by Boyle, Otto de Guericke, and Dr. Wall, and in 1709 Mr. Hawkesbee published an account of many curious electrical experiments; but no material progress was made in this department of knowledge till between the years 1729 and 1733, when the discovery of new and important facts by Mr. Stephen Grey in this country, and M. Dufay in France, attracted general attention to the subject, and speedily acquired for it the regular form of a science.

The most important fact established by Mr. Grey was the fundamental one, that electricity passes freely along certain substances, and that its progress is more or less entirely arrested by others. Dufay, in repeating the experiments of Grey, observed that an electrified substance not only attracts light bodies, but causes them after contact to fly off from its surface as if by a principle of repulsion. This singular phenomenon, which is termed *electrical repulsion*, had been previously noticed by Otto de Guericke, but the merit of original observation seems also justly due to the French philosopher. Dufay likewise noticed that the electricity excited on glass is different from that of resin, and he hence inferred the existence of two kinds of electricity, the *vitreous* and *resinous*, the former belonging to glass, and the latter to resin. He established an excellent mode of distinguishing them, by finding that substances possessed of the same kind of electricity always repel each other; and that attraction is as uniformly exerted between substances which are in opposite states of electrical excitement.

Another fact of consequence, relative to the excitement of electricity by friction, was discovered in 1759 by Mr. Symmer (*Philos. Trans.* li. 340.), who found that when two bodies are rubbed together, both are excited, and that one always possesses vitreous and the other resinous electricity. This induced Symmer to modify the doctrine of the two electricities. Dufay conceived vitreous electricity to be peculiar to some substances, and resinous electricity to others. Symmer, on the contrary, maintained, that bodies in their ordinary un-

excited condition contain both kinds of electricity in a state of combination; and, as they then neutralise or counteract each other's effects, no electrical phenomena are apparent; that friction produces excitement by separating the two principles; and that excitation continues until that kind of electricity, which has been withdrawn, is restored.

Dufay's doctrine of the two electricities, as modified by Symmer, is at present extensively adopted. Agreeably to this theory, as now understood, there exists two electric fluids, both equally subtile and elastic, universally diffused, and therefore present in all bodies, each highly repulsive to particles of its own kind, and attractive to those of an opposite nature. An unexcited substance possesses both fluids in an equal degree and in a state of combination; whereas any circumstance, such as friction, contact, or chemical action, which disunites the combined electricities, and thereby occasions the whole or part of a body to have more of one electricity than of the other, causes electric excitement. The repulsion exerted among the particles of each electricity to those of its own kind diminishes as the squares of the distance; and the mutual attraction of dissimilar electricities is regulated by the same law. This accounts for the inaction of unexcited contiguous bodies: for, though each electricity in each body repels that electricity of the same kind in the other with a force varying as the squares of the distance, attraction to exactly the same amount is exerted between the opposite electricities; and, therefore, as the two substances are reciprocally attracted and repelled in an equal degree, no effect whatever is apparent. When either of the electric fluids is in excess, its particles by their repulsion recede from each other as much as possible, and would escape from the excited body altogether, unless their passage were impeded by a non-conductor, that is, by a substance through which electricity is transmitted with difficulty. If, for instance, an excited substance be enveloped in dry air, the electricity, after reaching the surface of the body, will be retained by the air, and be accumulated at that surface: its effort to escape gives rise to pressure against the air, and is often productive of motion. This is familiarly shown by suspending near each other light substances, such as pieces of paper or pith balls, and communicating electricity to them. If similarly electrified, the effort of the electric fluid to pass off in contrary directions causes the substances themselves to fly asunder; and, when oppositely excited, they are drawn together by the effort which the fluids make to coalesce. Should the oppositely electrified bodies be fixed instead of easily movable, and their mutual attraction overcome the resistance of the air, the two fluids rush together with violence, causing heat, light, and noise in their passage, and the electric equilibrium is thereby instantly restored.

The celebrated Dr. Franklin proposed a different theory of electricity, which, as subsequently extended by Æpinus and Cavendish, affords an elegant explanation of electrical phenomena, and, though scarcely so philosophical as that of Dufay, is strongly recommended by its simplicity. It is founded on the supposition of a single electric fluid, the particles of which repel each other with a force diminishing as the squares of the distance, and are attracted by matter in general according to the same law. Material substance in its unelectric state is a compound of electricity and matter, saturated and neutralised with each other. It is also an assumption, shown to be necessary by Æpinus and Cavendish, but properly considered as the weak part of the doctrine, that ponderable bodies repel each other with the same force and according to the same law as the particles of electricity. From the nature of these postulates it will be easy to anticipate their application. Unelectric bodies are such as have their natural quantity of electricity, which precisely suffices to saturate and neutralise the matter of which they consist. They are then electrically indifferent; because the repulsion exerted between the electricity and matter of contiguous bodies is exactly counteracted by the attraction of the electric fluid in each for the matter of the other. Electrical excitement is occasioned either by increase or diminution of the natural quantity of electricity. On rubbing a tube of glass with a woollen cloth, the electrical condition of both is disturbed: the glass acquires more electricity than it naturally possesses, or is overcharged with electric fluid; and the cloth, losing what the glass gained, contains less than its natural supply, or is undercharged. These opposite states are denoted by the algebraic terms *positive* and *negative*, the former corresponding to the vitreous, the latter to the resinous, electricity of Dufay. Bodies positively excited repel each other by reason of the repulsion among the particles of the electricity with which they are surcharged; and the equal tendency of negatively excited bodies to separate is ascribed to the mutual repulsion among the particles of matter. The electric equilibrium in excited substances is restored by the electricity escaping from those where it is in excess, and passing to those where it is defective.

The theory of Dufay has a manifest advantage over that of Franklin in the simplicity of its postulates, being founded solely on the assumption of two different fluids, universally diffused, each highly repulsive to its own particles, and attractive of one another. The foundation of the Franklinian doctrine is more complex, and involves the assumption of matter being repulsive to itself, or containing a principle which causes repulsion, a supposition which has been thought at variance with the laws of gravitation, and therefore irreconcileable with the known properties of matter. The only plausible mode of meeting this objection is by supposing matter, considered apart from electricity, to be repulsive to its own particles; but when combined with the electric fluid, as it always is more or less in its ordinary state, that it is subject to gravity. But, though less satisfactory than the other in its basis, the theory of a single fluid gives an equally complete explanation of electrical phenomena, and in point

of facility of application is even entitled to a preference. On this account we shall continue to employ the language of Franklin.

It will be remembered that, in both the theories above explained, electricity is regarded as essentially material, though so light and subtile as not to exhibit to our senses the ordinary attributes of matter. It is, however, possible, as with light and heat, to account for electrical phenomena, not by the agency of a specific substance, but by some property or state of common matter, just as sound is produced by a vibrating medium. But the effects of electricity are so similar to those of a mechanical agent, it appears so distinctly to emanate from substances which contain it in excess, and rends asunder all obstacles to its progress so exactly like a body in rapid motion, that the impression of its materiality forces itself irresistibly on the mind. All nations, accordingly, have spontaneously concurred in considering electricity as a material principle; and scientific men give a preference to the same view, because it offers an easy explanation of every phenomenon, and suggests a natural language easily intelligible to all.

Electricity may be excited in all solid substances by friction. This assertion seems at first view contrary to fact. It is well known that a metallic substance, if held in the hand, may be rubbed for any length of time without exhibiting the least sign of electricity, — an observation which led to the division of bodies into such as may be excited by friction, and into those that, under the same circumstances, give no sign of electrical excitement. The former were called *Electrics*, the latter *Non-electrics*. But the distinction is not founded in nature. A metallic substance does not indeed exhibit any trace of electricity when rubbed in the same way as a piece of glass; but if, while it is rubbed with the dry fur of a cat, it is supported by a glass handle, it may then be readily excited.

The difficulty and apparent impossibility of exciting metallic bodies receives an explanation from the fact observed by Grey, that the electric fluid passes with great facility along the surface of some substances, and with difficulty over that of others; and this discovery has led to the division of bodies into *conductors* and *non-conductors* of electricity. If an excited conductor, such as a metallic wire, be made to communicate at one of its extremities with the earth, the electricity will pass to it from the opposite end in an instant, even though it were several miles in length; so that, when the equilibrium is disturbed, it will be at once restored along the whole wire, just as effectually as if every point of it communicated with the ground. But an excited stick of glass or resin is not affected in the same manner; for, as electricity does not obtain a free passage along them, the equilibrium is restored in those parts only which are actually touched. For this reason a non-conductor of electricity, though held in the hand, may be readily excited; but a good conducting body cannot be brought into that state, unless it be *insulated*, that is, cut off from communication with the earth by means of some non-conductor. This is generally effected either by supporting a body with a handle of glass, or by placing it on a stool made with glass feet.

To the class of conductors belong the metals, charcoal, plumbago, water, and most substances which contain water in its liquid state, such as animals and plants. The conductive power of these substances is different. Of the metals, according to the experiments of Mr. Harris, silver and copper are the best conductors of electricity; and then follow gold, zinc, platinum, iron, tin, and lead. (*Philos. Trans. for* 1827, Part I. 21.) To the list of non-conductors belong glass, resins, sulphur, the diamond, dried wood, precious stones, silk, hair, and wool. Atmospheric air is also a non-conductor If it were not so, no substance could retain its electricity when surrounded by it. Aqueous vapour suspended in the air injures the non-conducting property of the latter, and hence electrical experiments do not succeed so well when the air is charged with moisture as when it is dry. The presence of a little moisture communicates conducting properties to the most imperfect conductor; and hence it is impossible to excite glass by rubbing it with a moist substance.

A knowledge of the different conducting power of bodies is required for explaining some circumstances which appear contradictory to a preceding statement. It is above mentioned, that when two bodies are excited by friction they are rendered oppositely electric; but, if a tube of glass be rubbed by a person communicating with the ground, the glass will become positively electrical, while the hand of the operator manifests no sign whatever of excitement. The cause of this is obvious. The operator is not electrified, because the earth restores the electric fluid as soon as it is withdrawn by the glass; but, if he is insulated, the indications of negative electricity will immediately appear. Hence it is a rule to insulate a conductor, whenever it is wished to examine its electrical condition.

The experiments which have been made concerning the effects of friction have demonstrated that the same substance is not always similarly electrified. Its electricity is influenced partly by the state of its surface, and partly by the nature of the body with which it is rubbed. Thus smooth glass is rendered positive by friction with woollen cloth; whereas, if its surface be rough, it becomes negative from the same treatment. Smooth glass, which is positive with woollen cloth, is rendered negatively electrical by being rubbed with a cat's fur. The following table, from Cavallo's Complete Treatise on Electricity, shows the kind of excitement produced by the friction of various substances.

	Is rendered	By Friction with
The back of a cat	Positive	Every substance with which it has been hitherto tried
Smooth glass	- Positive	Every substance hitherto tried except the back of a cat.

	Is rendered	By Friction with
Rough glass	Positive	Dry oiled silk, sulphur, and metals.
	Negative	Woollen cloth, quills, wood, paper, sealing-wax, white wax, the human hand.
Tourmalin	Positive	Amber, a current of air.
	Negative	Diamond, the human hand.
Hare's Skin	Positive	Metals, silk, loadstone, leather, the hand, paper, baked wood.
	Negative	Other finer furs.
White silk	Positive	Black silk, metals, black cloth.
	Negative	Paper, hand, hair, weasel's skin.
Black silk	Positive	Sealing-wax.
	Negative	The skin of the hare, weasel, and ferret, loadstone, brass, silver, iron, and the hand.
Sealing-wax	Positive	Metals.
	Negative	The skin of the hare, weasel, and ferret, the hand, leather, woollen cloth, paper.
Baked wood	Positive	Silk.
	Negative	Flannel.

Mr. Singer states that sealing-wax is not rendered positive by friction with all metals; — iron, steel, lead, and bismuth, as also plumbago, leave it negative. Mr. Cavallo's statement with respect to white silk and paper does not agree with my observation. The effect of white paper is variable; but in a number of trials I found that by coarse brown paper white silk was invariably rendered positive.

The foregoing remarks on the effects of friction will render intelligible the principle of the electrical machine. In the time of Grey a supply of electricity was obtained for experimental purposes by rubbing a glass tube with the dry hand. Glass globes made to revolve by machinery were afterwards substituted for the tube, the friction being at first produced with the hand, and subsequently by means of a fixed rubber. As now constructed, the electrical machine is formed either with a cylinder or plate of glass, which is pressed during its rotation by cushions stuffed with hair. The cushion is usually covered with an amalgam of tin and zinc, which, partly by increasing the friction, and partly by the oxidation of the metals, materially assists the action of the machine. The electricity developed on the glass is conducted away by an insulated bar of brass placed close to it, called the *prime conductor*, on which it is collected in considerable quantity. By this means the electricity spread over the whole surface of the prime conductor may be carried off at the same instant, and thus act with far greater power than if accumulated on glass or any other imperfectly conducting substance.

The electricity, which is so freely and unceasingly evolved during the action of a good electrical machine, is derived from the great reservoir of electricity, the earth. This is obvious from the fact that, if the whole apparatus be insulated, the evolution of electricity immediately ceases; but that the supply is as instantly restored, when the requisite communication with the ground is re-established. In the state of complete insulation the glass and prime conductor are positive as usual, and the rubber is negatively excited; but, as the electricity then developed is derived solely from the machine itself, its quantity is exceedingly small. When the machine is used, therefore, the rubber is made to communicate with the earth. As soon as friction is begun, the glass becomes positive, and the rubber negative; but, as the latter communicates with the ground, it instantly recovers the electricity which it had lost, and thus continues to supply the glass with an uninterrupted current. If the rubber be insulated, and the prime conductor communicate with the ground, the electricity of the former and all conductors connected with it is carried away into the earth, and they are negatively electrified.

Friction is not the only cause of electrical excitement. Bodies are sometimes excited by elevation of temperature, a property first noticed in certain crystallised minerals, such as tourmalin and boracite, which do not possess that symmetric arrangement of parts commonly existing in crystals. The electric equilibrium is disturbed in metallic rods or wires by one extremity having a different temperature from that of the other, as was first observed by Professor Seebeck, and since shown to be true of all metals by Professor Cumming. (*Annals of Phil.* v. 427. N.S.) The experiment is usually made by heating the point of junction of two metallic wires, which are soldered together; but M. Becquerel has proved that the contact of one metal with another is not essential. (*An. de Ch.* xli. 353.)

Another and apparently very fruitful source of electricity is chemical action. This was strongly denied by the late Sir H. Davy in his Bakerian lecture for 1826; but the experiments of Becquerel, De la Rive, and Pouillet, afford decisive proof that chemical union and decomposition are both attended with electrical excitement. (*An. de Ch. et Ph. T.* 35, 36, 37, 38, and 39.) Pouillet, in particular, has demonstrated that the gas arising from the surface of burning charcoal is positive, while the charcoal itself is negative; and he has proved that similar phenomena are produced by the combustion of hydrogen, alkohol, oil, and other inflammables of the same kind. In all these instances the combustible, in the act of burning, renders contiguous particles negative; while the oxygen imparts electricity to the products of combustion, which thereby become positive. The fact, with respect to charcoal, was originally noticed by Volta, La Place, and Lavoisier, but was subsequently denied by Saussure and Sir H. Davy. Pouillet has reconciled these conflicting statements by showing that the result depends on the mode in which the experiment is conducted. For if the carbonic acid be completely removed from the burning mass at the instant of its formation, both are found to be electrical; but if, on the contrary, the carbonic acid subsequently flows over the surface of the charcoal, the equilibrium will instantly be restored; and of course no sign whatever of excitement be perceptible.

Another reputed source of electricity is contact of different substances, especially of metals; a source originally suggested by Volta, who founded on it a theory of galvanism. The facts on which Volta rested his opinion were of this nature. Well-cleaned plates of zinc and cop-

per were furnished with glass handles, by which they could be both supported and insulated: the zinc plate, held by its glass handle, was laid repeatedly on the copper, which at the time need not be insulated, and after each contact the zinc was made to touch the instrument, shortly to be described, called the *condenser*. A positive charge was gradually accumulated; and, on operating in the same manner with the insulated plate of copper, it was found to communicate a negative charge. From such experiments it was inferred, that the contact of zinc and copper disturbs the electric equilibrium in both metals, the latter yielding electricity to the former and becoming negative, while the zinc is thereby rendered positive. But the inference is not free from objection. In fact, so long as contact continues, there is no electric appearance whatever; and the metals are assumed to be differently electrified *at that time*, in consequence of the phenomena which they exhibit *after* their separation. There is, therefore, an obvious assumption. But, on the other hand, the absence of the indications of excitement is not conclusive against the doctrine; because, consistently with the laws of electricity, the oppositely electrical state of the two metals, while they continue together, must counteract the effect to which either separately would give rise.

The excitement of electricity by contact has been denied by some philosophers, and of late this doctrine has been attacked by De la Rive of Geneva. (*An. de Ch. et Ph.* xxxix. 297.) He there contends that the phenomena ascribed to metallic contact are really due to slight oxidation produced by moisture and the oxygen of the air acting on the plate of zinc. He has adduced experiments to prove, that if the oxidation of the zinc be increased by acid fumes, the electric charge is proportionally augmented; and that the same effects arise when a very oxidable metal, such as potassium, is substituted for the zinc. He further states that when the experiment is made in a vessel of hydrogen or nitrogen, no electricity whatever is developed. This last observation, however, the only decisive argument adduced, has since been corrected by Professor Pfaff of Kiel, in whose experiments the contact of zinc and copper affected the electrometer as much when made in a jar of hydrogen or nitrogen as in atmospheric air; but Parrot of Petersburg contends that in the experiments of Pfaff, Volta, and others, the electricity ascribed to contact was in reality due to friction. On bringing the metallic plates into contact, and then after an interval separating them cautiously so as to avoid friction, he could discover with the most delicate instruments no trace whatever of electric disturbance. (*An. de Ch. et Ph.* xlvi. 361.) The evidence adduced by Volta in proof of excitement by contact is, therefore, unsatisfactory; and any arguments in favour of the doctrine should be drawn, not from the state of the metals after separation, but from their chemical agencies evinced during contact. Some curious facts will be mentioned on this subject in the section on Galvanism.

Change of form, such as liquefaction and the passage of liquids into the solid state, and the formation and condensation of vapour, is another reputed source of electricity. To processes of this nature, continually taking place in the atmosphere, the electricity of the clouds is generally ascribed. But the essays of Pouillet on the source of atmospheric electricity, tend to subvert the opinions hitherto received. He has proved the evaporation of water from a vessel of platinum to be unattended with electrical appearances; whereas if the process be accompanied with chemical decomposition, as in the evaporation of saline solutions, or if the vessel consist of iron or other oxidable material, which is more or less chemically attacked by the evaporating water, then the development of electricity is very decisive. From experiments of this kind Pouillet concludes that the electricity, hitherto referred to changes of form, is entirely owing to the chemical action by which they are generally attended; and these phenomena, of which the evaporation of water from the ocean, from rivers, and the surface of the earth, affords an instance, as also the chemical changes that attend the growth and nutrition of plants, he regards as a fertile source of the electricity of the atmosphere. (*An. de Ch. et Ph.* xxxv. 401. and xxxvi. 5.)

Another cause of excitement is proximity to an electrified body; and as the explanation of many electrical phenomena depends on a knowledge of this fact, it is of importance to understand it clearly. When a substance excited positively is brought near another in its natural state and insulated, the electric equilibrium of the latter is instantly disturbed; the parts nearest to the former become negative, and the distant parts positive. If the body be not insulated, it imparts electricity to the earth, and becomes negatively electrical. If, on the contrary, the exciting substance be negative, the adjacent parts of a body in its vicinity become positive. Hence it may be established as a law, that an electrified body tends to produce in contiguous substances an electric state opposite to its own. The electricity developed in this way is said to be *induced*, or to be excited by *induction*. The movement of light bodies towards an excited stick of sealing-wax, or glass tube, is accounted for on this principle. Thus, the vicinity of the negative sealing-wax renders the surrounding objects positive, and therefore a mutual attraction is exerted. When the inside of a glass bottle is rendered positive by contact with the prime conductor of the electrical machine, the outside, if in communication with the earth, parts with electricity, and becomes negative. Both surfaces, therefore, are electrified, and are in opposite states; and, if a communication be established between them by means of a good conductor, the excess of electricity instantly passes along it, and both sides of the glass return to their natural condition. That the experiment may succeed in the most perfect manner, it is necessary to cover the bottle externally and internally, except to within three or four inches of its summit, with tinfoil or some

other good conductor, in order that every point of both sides of the glass may be brought into communication at the same moment. For without this precaution, the electric equilibrium of the two surfaces of the bottle, owing to the imperfect conducting power of glass, will be restored on those points only which are touched. The apparatus thus described is much employed by electricians, and has received the name of the Leyden phial, in consequence of its remarkable effects having been first exhibited at the University of Leyden. To render it more convenient for use, the aperture of the glass jar or phial is closed by some imperfect conductor, such as dry wood, through the centre of which passes a metallic rod that communicates with the tinfoil in the inside of the jar. The phial is electrified or *charged* by holding the outside in the hand, or placing it on the ground, while the metallic rod is made to receive sparks from the prime conductor of an electrical machine. If the jar is insulated, no charge will be received, or at least very slight indications of excitement will be manifested. By arranging a number of Leyden phials in a box lined with tinfoil, so that they may all communicate freely by their outer surfaces, and then bringing their inner surfaces into communication by wires, the whole series may be charged and discharged in the same manner as a single phial. This arrangement is known by the name of the *electrical battery*.

Some of the phenomena of lightning are explained on the principle of induced electricity. When, for instance, a negatively electrified cloud approaches the earth, all objects in its vicinity are positively excited; and when it comes within what is called the *striking distance*, that is, so near that the effort of the electricity to pass from the positive to the negative body overcomes the resistance of the intermediate stratum of air, the equilibrium is restored with a report and flash of light, exactly as in the discharge of a Leyden phial. A similar effect is produced by an electrified cloud on other clouds within the sphere of its influence.

The principle of induced electricity was ingeniously applied by Volta in the construction of the condenser. This apparatus consists of two brass plates, which we shall call A and B, supported on a common stand. One of the plates is attached to the stand by means of a joint, so that it admits of being moved from a perpendicular to a horizontal position, and thus withdrawn from the vicinity of the plate, the support of which is made of glass. On communicating electricity to the insulated plate by contact with a positively excited body, the plate B, which for that purpose is placed close to A, is rendered negative by induction, electricity passing along the stem into the earth; and, as happens in the Leyden jar, the excitement of B will be proportional to that of A. The negative charge of B tends to preserve the positive charge of A, which will consequently receive electricity from any positive surface without losing what it had previously acquired. Thus is electricity accumulated or *condensed* on A; so that a substance too feebly excited to produce any appreciable effects of itself, may, by repeated contact with the insulated plate of a condenser, communicate a charge of considerable intensity. The effect of the accumulation is made apparent by withdrawing B, and bringing A in contact with a delicate electrometer. The condenser is much employed in experiments of delicacy, and the plate A. is often permanently fixed on the gold leaf electrometer invented by Bennett.

The passage of electricity is frequently attended with the production of heat and light, effects which invariably ensue when it meets with an impediment to its progress, as in passing through an imperfect conductor. The most familiar illustration of this is afforded by its passage through the air, when it gives rise to a spark accompanied with a peculiar snapping noise, if in small quantity; or to the phenomena of thunder and lightning, when it takes place on a large scale. On the contrary, it passes along perfect conductors, such as the metals, without any perceptible warmth or light, provided the extent of their surface is in proportion to the quantity of electricity to be transmitted by them; but if the charge is too great in relation to the extent of the conducting surface, intense heat will be produced.

Electricity acts with surprising energy on the animal system. When a large quantity of the electric fluid passes through the body, the vital functions cease on the instant, as is exemplified by the numerous accidents on record of persons being killed by lightning. Even the small quantity of electricity contained in a Leyden phial gives a very powerful shock, exciting a sudden spasm of the muscles along which it passes, so violent as to produce a disagreeable or even painful sensation. The shock from a large electrical battery is much more severe, and smaller animals, such as rabbits and fowls, are destroyed by its action.

It is very important, in conducting electrical experiments, to possess an easy method of discovering when any substance is electrified, of ascertaining its *intensity* or the degree to which it is excited, and distinguishing the kind of excitement. The mode of effecting these objects is founded on electrical attraction and repulsion, and the instruments employed for the purpose are called *Electroscopes* and *Electrometers*, the latter denoting the intensity of electricity, the former merely indicating excitement, and the electrical state by which it is produced. The term electrometer, however, is often indiscriminately applied to all such instruments, since the methods of ascertaining the kind of excitement give at the same time some idea of its intensity. A body is known to be excited by its power of attracting light substances; and a small ball made of the pith of elder, suspended on a silk thread, affords a convenient material for the experiment. Another mode of acquiring the same information is by means of two pith balls suspended from the same point by silk threads of equal length. When all the surrounding objects are unexcited, the pith balls remain in contact; but on the approach of any electrified body, the two balls are excited by induction, and, having the same electricity, diverge or retreat from each other. A more delicate con-

trivance, but of a similar kind, was invented by Mr. Bennett, and is known by the name of the *Gold Leaf Electrometer*. It consists essentially of a cylindrical glass bottle, with its aperture closed by a brass plate, from the centre of which two slips of gold leaf are suspended. The brass plate, with its slips of gold leaf, are thus insulated, and the latter prevented from being moved by currents of air by the glass with which they are surrounded. The approach of any electrified body, even though feebly excited, to the brass plate, is immediately detected by the divergence of the leaves.

A very simple method of distinguishing the kind of excitement is the following. If a piece of white silk be drawn a few times rapidly between the fingers, it will become negative; and if in this state it is suspended in the air, it will be attracted by a body positively excited, and repelled by one which is negative. When rubbed on black cloth the silk is rendered positive, and will then of course retreat from a substance similarly electrified, and be attracted by one in an opposite state. The indications of the gold leaf electrometer are still more delicate. If the leaves are diverging with positive electricity, the approach of a positively excited body to the brass plate increases the divergence; because the electric equilibrium is immediately disturbed, and while the plate becomes negative, the gold leaves acquire a still greater excess of electricity. The approach of a negatively excited body would of course be productive of a change precisely opposite, and the divergence, if produced by positive electricity, would be diminished, or even entirely destroyed. To prepare the electrometer for an observation, it is however necessary to communicate to it a known state of excitement. This may be done by touching the electrometer with an electrified body, such as an excited glass tube or stick of sealing-wax, when the whole metallic surface of the electrometer is electrified in the same manner as the substance by which it was touched. A more convenient method is to communicate electricity permanently by induction. Thus, on placing a negatively excited body, as for example a stick of sealing-wax after friction on woollen cloth, near the brass plate of the electrometer, the electric equilibrium of its whole metallic surface is disturbed: the brass plate becomes positive, and the slips of gold leaf diverge from being negative. On withdrawing the sealing-wax, the excess of electricity accumulated on the plate returns to the leaves, and the equilibrium is restored; but if, while the sealing-wax is near the top of the instrument, the plate be touched with the finger, a portion of electricity is supplied to the gold leaves from the earth, and the divergence ceases more or less completely, while the excess of electricity is preserved on the plate by the vicinity of the negative sealing-wax. On removing *first* the finger, and *then* the sealing-wax, the brass is left with an excess of electricity, which extends over the whole metallic surface of the electrometer, and thus produces a divergence which continues for a considerable time if the glass be dry, and the atmosphere moderately free from moisture.

The electrometer most frequently used for estimating the intensity of electricity in ordinary experiments, is that invented by Mr. Henley, and called the *quadrant electrometer*. It consists of a smooth round stem of wood, about seven inches long, to the upper part of which, and projecting from its side, is attached a semicircular piece of iron. In the centre of the semicircle is fixed a pin, from which is suspended, to serve as an index, a slender piece of wood or cane, four inches in length, and terminated by a small ball. When the apparatus is screwed on the prime conductor of the electrical machine, or placed on any electrified body, it indicates differences of electric intensity by the extent to which the index recedes from the stem; and in order to express the divergence in numbers, the lower half of the semicircle, which is traversed by the index, is divided into 90 equal parts called *degrees*. But this instrument, though convenient for experiments of illustration, is not suited to researches of delicacy, wherein the object is to examine the effects of substances feebly electrified, and ascertain their relative forces with accuracy. For such purposes the electrometer invented by Coulomb, commonly called the *electrical balance*, should be employed. It consists of a small needle of gum-lac or other non-conducting substance, suspended horizontally by a silk thread as spun by the silk-worm, or by a fine silver wire; on the point of the needle is fixed a small gilt ball made of the pith of elder; and the whole is covered with a glass case to protect it from moisture and currents of air. The pith ball, when the apparatus is at rest, is in contact with the knob of a metallic conductor, which passes through a hole in the glass case, and is secured in its place by cement; but when an excited body is made to touch the conductor, the pith ball in contact with it is similarly excited, and recedes from it to an extent proportional to the degree of excitement. The needle consequently describes the arc of a circle, and in its revolution twists the supporting thread more or less according to the length of the arc described. The torsion thus occasioned calls into play the elasticity of the thread, — a feeble but constant force, which opposes the movement of the needle, measures by the extent to which it is overcome the intensity of the excited body, and brings back the needle to its original position as soon as the electric equilibrium is restored.

In some of the preceding remarks a term has been employed which requires explanation. By electric *tension* or *intensity* is meant that state of a body which is estimated by an electrometer. When a body acts feebly on the electrometer its intensity is low, and it differs but little from its natural state; and, on the contrary, if it affects the electrometer powerfully, its electric tension is great. The higher the intensity of a body the more is it removed from its natural state, and the greater its tendency to return to an equilibrium. *Intensity* is distinct from *quantity* of electricity. That intensity is not dependent on quantity alone, is proved by the fact that the tension of a charged Leyden phial may be equal to that of a large battery containing twenty

times more electricity. The tension appears to depend on the quantity of electricity accumulated or deficient on a given space; so that the intensity of those substances is greatest, which have the greatest excess or deficiency of electricity in proportion to their surface.

This accounts for the freedom with which electricity is conducted away by pointed surfaces. For the electricity accumulated on a sharp point, though its quantity may be very small, is nevertheless large compared with the surface: the electric tension of the point is therefore very great; and hence, if positive, it gives off electricity to surrounding objects, and if negative receives it from them with extreme velocity.

Electricity appears to diffuse itself over the surface of bodies; and the quantity contained on the same substance, all other circumstances being the same, depends on the extent of surface, and is not connected with quantity of matter. Thus a solid sphere of brass cannot contain more electricity than a hollow sphere of the same diameter. — *Turner.*

ELE'CTRO-MA'GNETISM. The name given to a class of very interesting phenomena, first observed by M. Oersted, of Copenhagen, in the winter of 1819-20, and which have since received great illustration from the labours of M. Ampère, M. Arago, Sir H. Davy, Dr. Wollaston, Mr. Faraday, M. de la Rive, and several other philosophers. The following is an outline merely of the fundamental principles of the new science which has sprung from these observations.

Let the opposite poles of a voltaic battery be connected by a metallic wire, which may be left of such length as to suffer its being bent or turned in various directions. This is the conjunctive wire of M. Oersted. Let us suppose that the rectilinear portion of this wire is extended horizontally in the line of the magnetic meridian. If a freely suspended compass needle be now introduced, with its centre *under* the conjunctive wire, the needle will instantly deviate from the magnetic meridian; and it will decline towards the *west*, under that part of the conjunctive wire which is nearest the negative electric pole, or the copper end of the voltaic apparatus. The amount of this declination depends on the strength of the electricity, and the sensibility of the needle. Its *maximum* is 90°.

We may change the direction of the conjunctive wire, out of the magnetic meridian, towards the east or the west, provided it remains above the needle, and parallel to its plane, without any change in the above result, except that of its amount. Wires of platinum, gold, silver, brass, and iron, may be equally employed; nor does the effect cease though the electric circuit be partially formed by water. The effect of the conjunctive wire takes place across plates of glass, metal, wood, water, resin, pottery, and stone.

If the conjunctive wire be disposed horizontally *beneath* the needle, the effects are of the same nature as those which occur when it is *above* it; but they operate in an inverse direction; that is to say, the pole of the needle under which is placed the portion of the conjunctive wire which receives the negative electricity of the apparatus, declines in that case towards the *east*.

To remember these results more readily, we may employ the following proposition: — *The pole* ABOVE *which the negative electricity enters, declines towards the* WEST; *but if it enters* BENEATH *it, the needle declines towards the* EAST.

If the conjunctive wire (always supposed horizontal) is slowly turned about, so as to form a gradually increasing angle with the magnetic meridian, the declination of the needle increases, if the movement of the wire be towards the line of position of the disturbed needle: it diminishes, on the contrary, if it recede from its position.

When the conjunctive wire is stretched alongside of the needle in the same horizontal plane, it occasions no declination either to the east or west; but it causes it merely to incline in a vertical line; so that the pole adjoining the negative influence of the pile on the wire dips when the wire is on its west side, and rises when it is on the east.

If we stretch the conjunctive wire, either above or beneath the needle, in a plane perpendicular to the magnetic meridian, it remains at rest, unless the wire be very near the pole of the needle; for, in this case, it rises when the entrance takes place by the west part of the wire, and sinks when it takes place by the east part.

When we dispose the conjunctive wire in a vertical line opposite the pole of the needle, and make the upper extremity of the wire receive the electricity of the negative end of the battery, the pole of the needle moves towards the *east*; but if we place the wire opposite a point betwixt the pole and the middle of the needle, it moves to the *west*. The phenomena are presented in an inverse order, when the upper extremity of the conjunctive wire receives the electricity of the positive side of the apparatus.

It appears from the preceding facts, says M. Oersted, that the electric conflict (action) is not enclosed within the conducting wire, but that it has a pretty extensive sphere of activity round it. We may also conclude from the observations, that this conflict acts by revolution; for without this supposition we could not comprehend how the same portion of the conjunctive wire, which, placed *beneath* the magnetic pole, carries the needle towards the east, when it is placed *above* this pole, should carry it towards the west. But such is the nature of the circular action, that the movements which it produces take place in directions precisely contrary to the two extremities of the same diameter. It appears also, that the circular movement, combined with a progressive movement in the direction of the length of the conjunctive wire, ought to form a kind of action which operates *spirally* around this wire as an axis.

The most remarkable discovery on this subject, after Oersted's, is unquestionably that of Mr. Faraday's on the electro-magnetic movement. He has demonstrated, by experiments, that the electro-magnetic polarity depends on its producing, in one of the poles of the magnet, a

tendency to move continuously to the right hand round the electric current, while the other pole tends to move to the left in the opposite direction. Consequently, since both of them tend with equal force towards opposite points, the axis of polarization of the needle must arrange itself so as to make a right angle with the electric current. If the metallic wire by which the discharge of the battery is effected, instead of being placed in a horizontal direction between the opposite poles of the pile, be directed from above downwards, terminating below in a vessel filled with mercury, into which a second wire conducts the electricities to the other pole; and if a light magnet, a magnetized sewing needle for instance, be so loaded with a bit of platina wire at one of its ends as to dip a little into the mercury standing vertically, this needle begins to move in a circle round the pole, when the voltaic current is terminated through the vertical wire. The motion continues while the electro-motion is active. If the positive electricity comes from above, and if the upper end of the magnetized sewing needle be its north pole, the needle will revolve from right to left. If the pole of the needle, or the direction of the electricity in the wire of communication, be changed, the needle will come to revolve from left to right. If the magnetized needle be fixed in the mercury, so that it cannot revolve while the wire is mobile, the latter will revolve round the magnet, agreeably to the same laws. This phenomenon may be exhibited by placing at the end of a large flat magnetic bar, laid horizontally, a small glass or porcelain dish filled with mercury, from which issues a metallic wire that communicates with one pole of a voltaic battery, while the wire conducting to its other pole ends in an eye or minute ring, a few inches above the quicksilver dish. To this eye a platina wire is suspended, which dips into the mercury, and is tipped at its lower end with a bit cork, to prevent its sinking too deeply into the liquid metal. As soon as the voltaic circuit is completed, this wire moves round the point of the pole of the magnet, which does not lie at the very end of the bar, but a little within it. This motion continues as long as the electrical current is sustained.

The electro-magnetic motion may, however, be represented in a still simpler and easier manner. Take a glass tube, four inches long and about half an inch diameter, and close its two ends with cork. Through one of these pass an iron wire, which may project an inch on each side; then turn down this end of the tube, and pour mercury into it till merely the point of the wire remain visible. Introduce through the upper cork a metallic wire, which terminates in the interior of the tube by an eye, to which is hung a platina wire reaching to the mercury. If now the lower wire be connected to one end of a voltaic battery, and the upper wire to the other, the electricities will be discharged by communication through the mercury and the moveable wire in the tube. Place, at this time, the pole of a very powerful magnet near the outer end of the iron wire: this wire will acquire polarity, and the platina wire suspended within the tube will begin to move in a circle round the inner tip of the iron wire. On changing the pole of the magnet, the wire turns round on its axis, and begins to revolve in an opposite direction. Mr. Faraday has succeeded by means of suitable apparatus, to make the conjunctive wire describe circular movements, under the influence of the magnetic polarity of the earth. In this case it always describes circles, whose plan intersects at a right angle the line including the inclination of the magnetic needle.

The *calorimeter* of Hare is the best form of voltaic battery for these experiments; or Mr. Pepys's large voltaic coil of zinc and copper sheets. For further information, Mr. Faraday's able paper, in the Journal of Science, xii. 74. may be consulted; as also M. Ampère's several ingenious memoirs in the Annales de Chimie et de Physique, vol. xv. *et seq.* — *Ure.*

No less curious and important than Oersted's discovery of the production of magnetism by electricity, is that of Mr. Faraday, with respect to the production of electricity by magnetism, constituting another branch of the science of electricity, which is called *Magneto-electricity.* See *Magneto-electricity.*

ELECTRO'METER. (*Electrometrum*, *i.* n.; from ελεκτρον, and μετρον, a measure.) See *Electricity.*

Electro-puncture. See *Acupuncture.*

ELE'CTROSCOPE. (From ελεκτρον, and σκοπεω, to observe.) Synonymous with *Electrometer.*

ELE'CTRUM. (*um*, *i.* n. Ελεκτρον.) *Succinum.* Amber.

ELECTRUM MINERALE. The tincture of metals. It is made of tin and copper, to which some add gold, and double its quantity of martial regulus of antimony melted together; from these there results a metallic mass, to which some chemists have given the name of *electrum minerale.* This mass is powdered and detonated with nitre and charcoal to a kind of scoria; it is powdered again whilst hot, and then digested in spirit of wine, whence a tincture is obtained of a fine red colour.

ELECTUA'RIUM. (*um*, *i.* n.) An electuary. The London Pharmacopœia refers those articles which were formerly called electuaries to confections. See *Confectio.*

ELECTUARIUM ANTIMONII. R. Electuar sennæ, ℥j.; guaiaci gummi, hydrargyri cu sulphure, antimonii ppti. sing. ʒss.; syru simplicis q. s.; misce. This electuary w formerly used in chronic cutaneous disease generally in conjunction with decoction of el bark, or of sarsaparilla. The dose is one two drachms twice a day.

Electuarium cassiæ. See *Confectio cassiæ.*

ELECTUARIUM CATECHU COMPOSITUM. *Confectio japonica.* Electuary of catechu, formerly called Japonic confection. Take mimosa catechu, four ounces; kino, th ounces; cinnamon, nutmeg, each one ounc opium, diffused in a sufficient quantity of Spanish white wine, one drachm and a half: syrup red roses, boiled to the consistence of hon two pounds and a quarter. Reduce the sol to powder, and, having mixed them with

opium and syrup, make them into an electuary. A very useful astringent, and perhaps the most efficacious way of administering catechu. Ten scruples of this electuary contain one grain of opium.

ELECTUARIUM CINCHONÆ CUM SODA. R. Sodæ carbonatis, ʒij.; pulveris cinchonæ, unciam; mucilaginis gummi arabici, q. s.: misce. In this composition, mucilage is preferred to syrup on account of its covering the taste of the bark much more advantageously. It should for this purpose, however, be made thin, otherwise it will increase the bulk of the electuary too much. The dose is two drachms, twice or thrice a day.

Electuarium opiatum. See *Confectio opii.*

ELELI'SPHACOS. Ελελισφακος. The Greek name of a species of sage.

E'LEMENT. (*Elementum, i.* n.) A substance which can no further be divided or decomposed by chemical analysis. The ancients believed earth, air, water, and fire, to be of this simple nature; and hence they are still called, in common language, the four elements. The three first are now well known to be compound bodies.

E'LEMI. (Indeclinable; an Ethiopian name.) Gum-elemi. See *Amyris elemifera.*

ELEOCHRY'SUM. (*um, i.* n.; from ηλιος, the sun, and χρυσος, gold: so called from its shining gold-like appearance.) Goldilocks. See *Gnaphalium stœchas.*

ELEOSELI'NUM. (*um, i.* n.; from ελος, a lake, and σελινον, parsley.) Smallage. See *Apium graveolens.*

Elephantia. See *Elephantiasis.*

ELEPHANTI'ASIS. (*is, is.* f. Ελεφαντιασις, from ελεφας, an elephant.) It has already been stated in the article *Barbadoes leg*, that two very different diseases have passed under the name of *Elephantiasis.* That at present to be treated of is the *Elephantiasis Græcorum.* It is chiefly a disease of warm climates, as Africa, the East and West Indies, Madeira, and the Isle of France; but occasional instances of it seem to occur in all climates. A learned history of this affection has been given by Dr. Bateman, in his work on cutaneous diseases; and from this, the greater part of the present article is taken.

The *Elephantiasis,* as described by the Greeks, is principally characterised by the appearance of shining tubercles, of different sizes, of a dusky red, or livid colour, on the face, ears, and extremities; together with a thickened and rugous state of the skin, a diminution or total loss of its sensibility, and a falling off of all the hair, except that of the scalp.

The disease is described as very slow in its progress, sometimes continuing for several years, without materially deranging the functions of the patient. During this continuance, however, great deformity is gradually produced. The alæ of the nose become swelled and scabrous, and the nostrils dilate; the lips are tumid; the external ears, particularly the lobes, are enlarged and thickened, and beset with tubercles; the skin of the forehead and cheeks grows thick and tumid, and forms large and prominent rugæ, especially over the eyes: the hair of the eyebrows, the beard, the pubes, axillæ, &c., falls off; the voice becomes hoarse and obscure; and the sensibility of the parts affected is obtuse, or totally abolished, so that pinching or puncturing them gives no uneasiness. This disfiguration of the countenance suggested the idea of the features of a satyr or a wild beast; whence the disease was by some called *Satyriasis,* and by others *Leontiasis.*

As the malady proceeds, the tubercles begin to crack, and at length to ulcerate: ulcerations also appear in the throat, and in the nose, which sometimes destroy the palate and the cartilaginous septum; the nose falls; and the breath is intolerably offensive: the thickened and tuberculated skin of the extremities becomes divided by fissures, and ulcerates, or is corroded under dry sordid scabs, so that the fingers and toes become gangrenous, and separate, joint after joint.

Aretæus and the ancients in general consider Elephantiasis as an universal *cancer* of the body, and speak of it with terror: they depict its hideous and loathsome character, its contagious qualities, and its unyielding and fatal tendency, in strong metaphorical language, which, indeed, tends to throw some doubt on the fidelity of their description. The very appropriation of the name is poetical; and Aretæus has absurdly enough prefixed to his description of the disease an account of the elephant, in order to point out the analogy between the formidable power of the beast, and of the disease. It is probable, that his terrors led him to adopt the popular opinion respecting the malady, without the correction of personal observation; for, although his account has been copied by subsequent writers, and the same popular opinions have been constantly entertained, there is much reason to believe that some of the prominent features of his portrait are incorrectly drawn.

Notwithstanding the care with which the separation and seclusion of lepers have been enforced, in compliance with the ancient opinion, there is great reason to believe that Elephantiasis is *not contagious.* M. Vidal long ago controverted that opinion, having never observed an instance of its communication from a leprous man to his wife, or *vice versâ,* although cohabiting for a long series of years. Dr. T. Heberden daily observed many examples of the same fact in Madeira, and affirms that "he never heard of any one who contracted the distemper by contact of a leper." And Dr. Adams has more recently given his testimony to the same truth, remarking that none of the nurses in the lazar-house at Funchall have shown any symptoms of the disease; and that individual lazars have remained for years at home, without infecting any part of their family.

With respect to the *libido inexplebilis,* which is said to be one of the characteristics of Elephantiasis, the evidence is not so satisfactory. Its existence is affirmed by most of the modern writers. MM. Vidal and Joannis mention it among the symptoms of the disease at Martigues. Dr. Bancroft senior states its occurrence in the Elephantiasis of South America: and

Prof. Niebuhr asserts, that it appears in the Dsjuddam of Bagdat. Dr. Adams, however, affirms that the genitals become wasted if the disease occur after puberty, and interrupted in their development if it occur before. The latter appears to have happened in a case detailed by Mr. Lawrence, in the Medico-chirurgical Transactions. In the four cases which came under the observation of Dr. Bateman, the sexual power was abolished, and the appetite extinguished.

The morbid anatomy of Elephantiasis has been little investigated. The cuticle is much thickened. The subcutaneous tubercles are described by some as solid fatty tumours, by others as cysts containing a reddish glutinous fluid. The cutis vera has been found inflamed only at those points where the tubercles have been softened, and in a state of suppuration. The immediate cause of death, in most cases, appears to be inflammation of the mucous lining of the air-passages and lungs.

It is generally affirmed, that the Elephantiasis was extensively prevalent in Europe, in the middle ages, especially subsequent to the crusades; and it is certain, that every country abounded with hospitals, established for the exclusive relief of that disease, from the tenth to the sixteenth century; and that an order of knighthood, dedicated to an imaginary St. Lazarus, was instituted, the members of which had the care of lepers, and the control of the lazarettoes assigned to them, and ultimately accumulated immense wealth. From these facts, however, nothing satisfactory is to be collected respecting the actual prevalence of Elephantiasis at those periods. For although it is obvious, from the nature of the examination instituted by the physicians of those lazarettoes, that the tubercular disease was the object of their inquiry; yet it is also evident, that, in consequence of the general application of the term *leprosy* to the Elephantiasis, to the leprosy of the Jews, to the proper scaly Lepra, and even to other cutaneous affections, which have no affinity with either of the diseases just mentioned, almost every person, afflicted with any severe eruption or ulceration of the skin, was deemed *leprous*, and was received into the lazarettoes. This fact, indeed, is acknowledged by many of the physicians to these hospitals, in the sixteenth century and subsequently. Greg. Horst, who was one of the appointed examiners at Ulm, towards the close of that century, and who has given a minute detail of his investigations, admits that "where the tubercles of the face, the thick lips, acuminated ears, flattened nose, round eyes (the essential symptoms of Elephantiasis), are absent; yet if the patients are affected only with a dry and foul scabies, with pustular eruptions, fissures, and branny exfoliations, which constitute the *Psora* of the Greeks, — or even with great itching, emaciation, ulceration, and exfoliations of thicker scales, which are the *Lepra* of the Greeks, — nevertheless they are sent to the lazarettoes, if they are poor, for the means of subsistence. Hence it happens," he adds, "that here and elsewhere, *very few instances of real Elephantiasis* are found in the lazarettoes, while *many* are there affected only with an obstinate Psora or Lepra græcorum." Forestus, who held a similar office at Alcmaer and Delft, in the same century, affirms that a very small proportion of the persons who wandered about the Low Countries, as lepers and beggars, were true lepers; but were merely affected with scabies, or some external defœdation of the skin. "Nay," he says, "not one in ten of them is truly a leper, or afflicted with the legitimate Elephantiasis." Riedlin makes a similar observation respecting the patients admitted into the leper-hospital at Vienna. Indeed there is little doubt, that every species of cachectic disease, accompanied with ulceration, gangrene, or any superficial derangement, was deemed *leprous;* and hence that, in the dark ages, when the desolation of repeated wars, and the imperfect state of agriculture, subjected Europe to almost constant scarcity of food, the numerous modifications of Scurvy and Ignis sacer, which were epidemic during periods of famine, and endemic wherever there was a local dearth, were in all probability classed among the varieties of leprosy; more especially as the last stage of the Ignis sacer was marked by the occurrence of ulceration and gangrene of the extremities, by which the parts were mutilated, or entirely separated.

Under the head of Elephantiasis, Dr. Winterbottom appears to have described the *Leuce*, and not the Elephantiasis of the Greeks; the *Baras*, and not the *Juzam* of the Arabians. The principal symptoms which he witnessed, were the *pale* colour of the skin (in black subjects) and its loss of sensibility, which are distinctly stated as the leading symptoms of Leuce, by Celsus, and by the other Roman and Greek physicians, as well as of Baras by the Arabians. Some of the Greeks and Arabians, indeed, seem to consider the Leuce, or Baras, as possessing an affinity with Elephantiasis, and sometimes terminating in it; and, if they be not modifications of the same disease, it is probable that some of the symptoms of the one (Leuce), such as the insensibility, and change of the colour and strength of the hair, may have been transferred in description to the other. The numerous large tubercles of the nose, forehead, and ears, which are deemed characteristic of Elephantiasis, did not appear in the disease seen by Dr. Winterbottom. The swellings or tuberosities of the joints of the hand and feet, which terminate in ulcerations that occasion the fingers and toes to drop off, appear also to belong to the two diseases in common, and afford another proof of their affinity. Nevertheless, as we have no where any account of the regular succession of the tubercular state (Elephantiasis or Juzam) to that of mere discoloration and insensibility (Leuce or Baras), we are not warranted in drawing the conclusion, that they are but degrees or stages of the same disease. Accurate histories of the Elephantiasis, Leuce, and other modifications of the formidable cutaneous diseases that occur in hot climates, and especially where agriculture and the arts of civilisation are imperfectly advanced, must be deemed still among the *desiderata* of the pathologist.

Dr. Bateman, in corroboration of this view,

xtracts the following account of the *Baras*, as ccurring in Hindustan, from a paper by Mr. Robinson, since published in the Medico-chirurgical Transactions: —

"One or two circumscribed patches appear pon the skin (generally the feet or hands, but ometimes the trunk or face), rather lighter oloured than the neighbouring skin, neither aised nor depressed, shining and wrinkled, the urrows not coinciding with the lines of the ontiguous sound cuticle. The skin thus circumscribed is so entirely insensible, that you ay with hot irons burn to the muscle, before he patient feels any pain. These patches pread slowly until the skin of the whole of he legs, arms, and gradually often the whole ody, becomes alike devoid of sense: wherever is so affected, there is no perspiration; no ching, no pain, and very seldom any swelling. Until this singular apathy has occupied the reater part of the skin, it may rather be considered a blemish than a disease: nevertheless it most important to mark well these appearnces, for they are the invariable commencement f one of the most gigantic and incurable iseases, that have succeeded the fall of man; nd it is in this state chiefly (though not exlusively) that we are most able to be the means f cure. The next symptoms (which occur in ome patients at two months, but in others not ll after five or six years) are the first which enote internal disease or derangement of any unctions. The pulse becomes very slow (from 0 to 60), not small but heavy, 'as if moving hrough mud;' the bowels are very costive, the oes and fingers numbed, as with frost, glazed nd rather swelled, and nearly inflexible. The nind is at this time sluggish and slow in appreension, and the patient appears always half sleep. The soles of the feet and the palms of he hands then crack into fissures, dry, and hard s the parched soil of the country; and the exremities of the toes and fingers under the nails re incrusted with a furfuraceous substance, and he nails are gradually lifted up, until absorption nd ulceration occur. Still there is little or no ain; the legs and fore-arms swell, and the skin s every where cracked and rough. Cotemporary vith the last symptoms, or very soon afterwards, lcers appear at the inside of the joints of the oes and fingers, directly under the last joint of he metatarsal or metacarpal bones, or they corode the thick sole under the joint of the os alcis, or os cuboides. There is no previous umour, suppuration, or pain, but apparently a imple absorption of the integuments, which lough off in successive layers of half an inch n diameter. A sanious discharge comes on; he muscle, pale and flabby, is in turn destroyed; nd the joint being penetrated as by an auger, he extremity droops, and at length falls a victim o this cruel, tardy, but certain poison. The vounds then heal, and other joints are attacked n succession, whilst every revolving year bears vith it a trophy of this slow march of death. Thus are the limbs deprived one by one of their xtremities, till at last they become altogether seless. Even now death comes not to the elief of, nor is it desired by, the patient, who, 'dying by inches,' and a spectacle of horror to all besides, still cherishes fondly the spark of life remaining, and eats voraciously all he can procure: he will often crawl about with little but his trunk remaining, until old age comes on, and at last he is carried off by diarrhœa or dysentery, which the enfeebled constitution has no stamina to resist. Throughout the progress of this creeping but inveterate complaint, the health is not much disturbed, the food is eaten with appetite, and properly though slowly digested. A sleepy inertness overpowers every faculty; and seems to benumb, almost annihilate, every passion as well of the soul as of the body, leaving only sufficient sense and activity to crawl through the routine of existence."

Mr. Robinson adds, that he has never seen this disease attack the larger joints, destroy the nose, nor affect any of the bones, except those of the hands and feet; and that the tuberculated Elephantiasis, though it sometimes supervenes, is by no means connected with, caused by, or necessarily subsequent to it.

Mr. Robinson affirms that the cure of this disease may be generally accomplished in the early stage, by the use of a plant which grows abundantly in India, and which appears to possess remedial qualities which entitle it to an introduction into the Pharmacopœias of Europe, namely, the *Asclepias gigantea*, especially in combination with alterative doses of mercury and antimony, and with topical stimulants.

Elephantiasis Italica. See *Pelagra.*

Elephantinum emplastrum. See *Emplastrum elephantinum.*

E'LEPHAS. (*as, antis.* m. Ελεφας, the elephant.) 1. The name of an animal.

2. The name of a disease. See *Elephantiasis.*

3. An alchemical name of *aqua fortis.*

Elersna. An alchemical name of molybdenum.

Elesmatis. An alchemical name of burnt lead.

Elettari. (A Malabar word.) The lesser cardamom. See *Elettaria.*

ELETTA'RIA. (*a, æ.* f.; from *elettari.*) The name of a new genus of plants formed by Dr. Maton, and to which he referred the lesser cardamom plant, under the name of *Elettaria cardamomum.* It is now referred to the genus *Alpinia.* See *Alpinia cardamomum*, in the Supplement.

Eleutheria. See *Croton.*

Eleva'tio. (From *elevo*, to lift up.) Elevation; sublimation.

ELEVA'TOR. (*or, oris.* m.; from *elevo*, to lift up.) 1. A muscle is so called, the office of which is to lift up the part to which it is attached.

2. A chirurgical instrument, with which surgeons raise any depressed portion of bone, especially of the cranial bones.

Elevator labii inferioris proprius. See *Levator labii inferioris.*

Elevator labii superioris proprius. See *Levator labii superioris alæque nasi.*

Elevator labiorum. See *Levator anguli oris.*

Elevator nasi alarum. See *Levator labii superioris alæque nasi.*

Elevator oculi. See *Rectus superior.*

Elevator palpebræ superioris. See *Levator palpebræ superioris.*

Elevator scapulæ. See *Levator scapulæ.*

ELEVATO'RIUM. (*um*, *i.* n.; from *elevo*, to lift up.) The surgical instrument generally called an elevator.

ELI'BANUM. The same as olibanum.

ELICHRY'SUM. (*um*, *i.* n.; from ηλιος, the sun, and χρυσος, gold: so called from its gold-like, or shining yellow appearance.) See *Gnaphalium stœchas.*

ELI'DRION. *Elidrium.* This name has been given, 1. To gum mastich.

2. To the rhaponticum.

3. To mercury.

4. To an alloy of silver, gold, and brass.

ELI'GMA. A linctus. See *Eclegma.*

Elioselinum. See *Eleoselinum.*

ELIQUA'TION. An operation by means of which a more fusible substance is separated from another which is less fusible. It consists in the application of a degree of heat, sufficient to fuse the former, but not the latter.

Elithroid. See *Elytroid.*

ELIXA'TIO. (From *elixo*, to boil.) The process of seething, or boiling.

ELI'XIR. (*Elixir*, n. ind.; from *elekser*, an Arabic word, signifying quintessence.) A term formerly applied to many preparations, and chiefly to compound tinctures.

ELIXIR ANTIASTHMATICUM BOERHAVII. *Boerhaave's antiasthmatic elixir.* This is composed of alkohol, aniseed, and the roots of orris, assarabacca, sweet flag liquorice, and elecampane. The dose is twenty or thirty drops.

ELIXIR PAREGORICUM. See *Tinctura camphoræ composita*, and *Tinctura opii ammoniata.*

ELIXIR PROPRIETATIS. An old preparation nearly corresponding with the compound tincture of aloes now in use.

ELIXIR PROPRIETATIS CUM ACIDO. The elixir proprietatis, acidulated with sulphuric acid.

ELIXIR PROPRIETATIS TARTARIZATUM. The elixir proprietatis, with the addition of salt of tartar.

ELIXIR SACRUM. A tincture made principally of rhubarb and aloes.

Elixir salutis. See *Tinctura sennæ.*

ELIXIR STOMACHICUM. The compound tincture of gentian.

ELIXIR VITÆ MATHIOLI. This was composed of a great number of aromatic and stimulant substances, digested in alkohol.

ELIXIR VITRIOLI. The same with the *Acidum sulphuricum aromaticum*, of the present Edinburgh and Dublin Pharmacopœias. See *Acidum sulphuricum aromaticum*, in the supplement.

ELIXIVIA'TIO. (From *lixivium*, a lye.) The extraction of a fixed salt from vegetables, by the affusion of water. See *Lixiviation.*

ELLA'GIC ACID. *Acidum ellagicum.* The deposit which forms in infusion of nut-galls, left to itself, is not composed solely of gallic acid and a matter which colours it. It contains besides a little gallate and sulphate of lime, and a peculiar acid on which Braconnot has made observations, and calls it *ellagic*, from the word *galle* reversed. Probably this acid does not exist ready formed in nut-galls.

Elleborum. See *Helleborus.*

ELLI'PTIC. (*Ellipticus.* Ελλειπτικος; from ελλειψις, an ellipse.) Applied, in *Botany*, to leaves which are of an elliptical shape.

Elm. See *Ulmus.*

Elm-leaved sumach. See *Rhus coriaria.*

ELO'DES. (From ελος, a swamp.) An epithet of the sweating fever or sweating sickness. See *Sudor anglicus.*

ELONGA'TIO. (From *elongo*, to lengthen out.) 1. An imperfect luxation, where the ligaments are only lengthened, and the bone not put out of its socket.

2. The extension of a limb for the purpose of reducing a dislocation or fracture.

ELUTRIA'TION. (*Elutriatio*; from *elutrio*, to cleanse.) The pouring a liquor out of one vessel into another, in order to separate the clear fluid from the sediment. Synonymous with *decantation.*

ELU'VIES. (*es*, *ei.* f.; from *eluo*, to wash out.) A swamp or quagmire. Some writers give this name to the discharge of a fluid, and especially to fluor albus.

ELUXA'TIO. The same as *luxatio.*

ELYMAGRO'STIS. (From ελυμος, the herb panic, and αγρωστις, wild.) Wild panic. See *Panicum.*

E'LYMUS. (*us*, *i.* m. Ελυμος; according to some from ελυω, to fold up, in allusion to the sheath which incloses the spike; according to others, from ελος, a marsh, because it grows in marshy places.) 1. The herb panic.

2. The name of a genus of grasses, in the Linnæan system. Class, *Triandria*; Order, *Monogynia.*

ELYTRI'TIS. This term has been introduced to signify inflammation of the vagina, but improperly, as the word ελυτρον, a sheath, is never used by any Greek writer as meaning the vagina of the female.

ELYTROCE'LE. (*e*, *es.* f.; from ελυτρον, the vagina, and κηλη, a tumour.) A hernia in the vagina. The term is ill derived. See *Elytritis.*

ELY'TROID. (*Elytroides*; from ελυτρον, a sheath, and ειδος, form.) Like a sheath. The tunica vaginalis is so called by some writers, because it includes the testis like a sheath. This epithet is also given to a pessary invented by M. Jules Cloquet.

ELY'TRON. (*Elytrum*, *i.* n.; a sheath, from ελυω, to involve.) 1. The membranes involving the spinal cord are called ελυτρα, by Hippocrates.

2. The wing sheath of an insect.

3. The word has been incorrectly used to signify the female vagina.

ELYTROPTO'SIS. (From ελυτρον, the vagina, and πτωσις, a falling down.) A name given by Callisen to inversion of the vagina. The term is not correct. See *Elytritis.*

Emaciation. See *Atrophy* and *Marasmus.*

EMANSIO MENSIUM. Retention of the menses. See *Amenorrhœa* and *Chlorosis.*

EMA'RGINATE. *Emarginatus.* Nicked: that is, having a small acute notch at the sum-

mit; as the leaf of the bladder senna, *Colutea arborescens*, and the petals of the *Allium roseum*.

EMA'SCULATE. *Emasculatus.* Applied to a male deprived of the generative power.

EMASCULA'TION. The act of destroying the generative power in the male by lesion or removal of the organs on which it depends.

Embalming. See the Supplement.

EMBA'MMA. (Εμβαμμα; from εμβαπτω, to dip in.) The Greek name of any liquid condiment in which the food was dipped.

E'MBOLE. (From εμβαλλω, to put in.) The setting of a dislocated bone.

EMBRE'GMA. An embrocation.

EMBROCA'TIO. (*o, onis.* f.; from εμβρεχω, to moisten or soak in.) An embrocation: a fluid application to rub any part of the body with. The following embrocations are in general use: —

EMBROCATIO ALUMINIS. R. Aluminis, ʒ ij. Aceti, spiritus vinosi tenuioris, sing. ℔ss. For chilblains and diseased joints.

EMBROCATIO AMMONIÆ. R. Embrocationis ammoniæ acetatis, ℥ ij. Aquæ ammoniæ puræ, ʒ ij. For sprains and bruises.

EMBROCATIO AMMONIÆ ACETATIS. R. Liquoris ammoniæ acetatæ, solutionis saponis, sing. ʒ j. M. For bruises with inflammation.

EMBROCATIO AMMONIÆ ACETATIS CAMPHORATA. R. Solutionis saponis cum camphora, liq. ammoniæ acetatæ, sing. ℥ j. Aquæ ammoniæ puræ, ℥ ss. For sprains and bruises. It is also frequently applied to disperse chilblains which have not suppurated. It is said to be the same as Steer's opodeldoc.

EMBROCATIO CANTHARIDIS CUM CAMPHORA. R. Tinct. cantharidis, spiritus camphoræ, sing. ʒ j. M. This may be used in any case in which the object is to stimulate the skin. The absorption of cantharides, however, may bring on a strangury.

E'MBROCHE. An embrocation.

E'MBRYO. (*o, onis.* m.; from εμβρυω, to bud forth.) 1. The germ of a plant; called by Linnæus the *corculum*. See *Corculum* and *Cotyledon*.

2. The *fœtus in utero* is so called before the fifth month of pregnancy, because its growth resembles that of the budding of a plant.

EMBRYO'CTONY. (From εμβρυον, a fœtus, and κτεινω, to kill.) Synonymous with embryotomy.

EMBRYO'GRAPHY. (From εμβρυον, the fœtus, and γραφω, to describe.) The anatomical description of the fœtus.

Embryon. See *Embryo*.

EMBRYOTHLA'STES. (From εμβρυον, the fœtus, and θλαω, to break.) *Embryorectes.* An instrument for breaking the bones of a dead fœtus to promote its delivery.

EMBRYO'TOMY. (*Embryotomia, æ.* f.; from εμβρυον, a fœtus, and τεμνω, to cut.) The dismemberment of the fœtus whilst *in utero*, to extract it.

EMBRYU'LCIA. (*a, æ.* f.; from εμβρυον, the fœtus, and ἑλκω, to draw.) 1. The obstetric art.

2. The extraction of the dead fœtus, in particular, has been so called; and many use the term synonymously with *embryotomy*.

EMBRYU'LCUS. (From εμβρυον, a fœtus, and ἑλκω, to draw.) The blunt hook or forceps, for drawing the child from the womb.

EME'RSUS. (From *emergo*, to rise up or appear out of the water.) Raised above the water; as the upper leaves accompanying the flowers of the *Meriophyllum verticillatum*, while its lower ones are *demersa*.

EMERUS. A name of the bastard senna. See *Colutea arborescens*.

EME'SIA. (*a, æ.* f.; εμεσια; from εμεω, to vomit.) *Emesma; Emesis.* The act of vomiting.

EMESIS. Εμεσις. See *Emesia*.

EME'TIC. (*Emeticus,* εμετικος; from εμεω, to vomit.) 1. As an adjective; possessed of the power of exciting vomiting.

2. Used substantively; a medicine which has the power of exciting vomiting. Any substance taken into the stomach in too great quantity, or any thing which has an intolerably nauseous taste or smell, may occasion vomiting; but the term emetic is applied only to substances which excite vomiting by a specific action on the stomach, independently of their quantity, taste, or odour.

The susceptibility of vomiting is very different in different individuals, and is often considerably varied by disease.

Emetics are employed in many diseases.

When any morbid affection depends upon, or is connected with, over-distension of the stomach, or the presence of acrid, indigestible matters, vomiting gives speedy relief. It is also highly useful in some cases of impaired appetite, acidity in the stomach, in intoxication, and where poisons have been swallowed.

From the pressure of the abdominal viscera in vomiting, and the relaxation which they occasion, emetics are serviceable in jaundice, arising from biliary calculi obstructing the ducts.

The expectorant power of emetics, and the relief which they give in spasmodic affections of the air passages, is well known but not easily explained.

Emetics were formerly much used at the commencement of fever, with a view of cutting it short; but their utility is little confided in by practitioners of the present day, and those of the antimonial kind are sometimes injurious, by exciting inflammation of the gastro-enteric mucous membrane.

Emetics given in such doses as only to excite nausea, are frequently very useful in restraining hæmorrhage, and diminishing the force of the pulse.

Different species of dropsy have been cured by vomiting, from its having excited absorption. To the same effect, perhaps, is owing the dispersion of swelled testicle, bubo, and other swellings, which has occasionally resulted from this operation.

The operation of vomiting is dangerous, or hurtful, in the following cases: where there is determination of the blood to the head, especially in plethoric habits; in visceral inflammation, or where there is a probability of its occurrence; in the advanced stage of pregnancy; in hernia, and prolapsus uteri. The frequent use of emetics weakens the tone of the stomach. An

emetic should always be administered in the fluid form. Its operation may be promoted by drinking any tepid diluent, or light bitter infusion.

The individual emetics may be arranged under two heads, — those derived from the vegetable, and those from the mineral kingdom. From the vegetable kingdom are numbered, ipecacuanha, scilla maritima, anthemis nobilis, sinapis alba, asarum europæum, nicotiana tabacum. From the mineral kingdom, antimony, the sulphates of zinc and copper, and the subacetate of copper. To these may be added ammonia and its hydrosulphuret.

EMETIN. *Emetina.* Digest ipecacuan root, first in ether and then in alkohol. Evaporate the alkoholic infusion to dryness, redissolve in water, and drop in acetate of lead. Wash the precipitate, and then diffusing it in water, decompose by a current of sulphuretted hydrogen gas. Sulphuret of lead falls to the bottom, and the emetin remains in solution. By evaporating the water, this substance is obtained pure.

Emetin forms transparent brownish-red scales. It has no smell, but a bitter acrid taste. At a heat somewhat above that of boiling water, it is resolved into carbonic acid, oil, and vinegar. It affords no ammonia. It is soluble both in water and alkohol, but not in ether; and uncrystallisable. It is precipitated by protonitrate of mercury and corrosive sublimate, but not by tartar emetic. Half a grain of emetin acts as a powerful emetic, followed by sleep; six grains cause violent vomiting, and produce stupor and death. The lungs and intestines are inflamed. — *Pelletier* and *Magendie.*

EMETOCATHA'RTIC. (*Emetico-catharticus;* from εμεω, to vomit, and καθαιρω, to purge.) Operating both by vomit and stool.

Eminentiæ quadrigeminæ. See *Tubercula quadrigemina.*

EMISSARIA DURÆ MATRIS. The processes of the dura mater, which accompany the cerebral nerves through the foramina of the cranium.

EMISSA'RIUM. (*um, i.* n.) A canal through which any fluid passes out.

EMISSORIA SANTORINI. *Venæ emissoriæ santorini.* The different small veins which pass through the foramina of the cranium, forming communications between the external veins of the head, and the sinuses of the dura mater; as those which pass through the *foramina parietalia,* and *foramina mastoidea.*

EMISSORIÆ VENÆ SANTORINI. Emissory veins of *Santorin.* See *Emissora santorini.*

EMISSO'RIUS. Emissory. Applied to that which conducts any fluid out of the body; especially to certain veins. See *Emissoriæ venæ santorini.*

EMME'NAGOGUE. (*Emmenagogus;* from εμμηνια, the menses, and αγω, to move.) Whatever possesses the power of promoting that monthly discharge by the uterus, which, from a law of the animal economy, should take place in certain conditions of the female system. The articles belonging to this class may be referred to four orders: —

1. *Stimulating emmenagogues,* as *mercurial* and *antimonial preparations,* which are principally adapted for the young, and those with peculiar insensibility of the uterus.

2. *Irritating emmenagogues,* as *aloes, savine,* and *Spanish flies:* these are to be preferred in torpid and chlorotic habits.

3. *Tonic emmenagogues,* as *ferruginous preparations, cold bath,* and *exercise,* which are advantageously selected for the lax and phlegmatic.

4. *Antispasmodic emmenagogues,* as *assafœtida, castor,* and *pediluvia:* the constitutions to which these are more especially suited are the delicate, the weak, and the irritable.

EMME'NIA. (From εν, in, and μην, a month.) The menses.

E'MMOTOS. (Εμμοτος; from εν, in, and μοτος, lint.) 1. Any medicament which is spread on lint and applied to a wound.

2. Hippocrates seems also to designate by the same word, an ulcer requiring the application of lint.

EMO'LLIENT. (*Emolliens;* from *emollio,* to soften.) Possessing the power of relaxing the living animal fibre, without producing that effect from any mechanical action. The different articles belonging to this class of medicines may be comprehended under the following orders: —

1. *Humectant emollients,* as *warm water* and *tepid vapours,* which are fitted for the robust and those in the prime of life.

2. *Relaxing emollients,* as *althæa, malva,* &c. These may be employed in all constitutions, while at the same time they do not claim a preference to others from any particular habit of body.

3. *Lubricating emollients,* as *bland oils, fat,* and *lard.* The same observation will hold of this order as was made of the last mentioned.

4. *Atonic emollients,* as *opium* and *pediluvia.* These are applicable to any constitution, but are to be preferred in habits where the effects of this class are required over the system in general.

Empalement. See *Calyx.*

EMPAS'MA. (Εμπασμα; from εμπασσω, to sprinkle upon.) A powder sprinkled upon the body, to restrain sweat. Compare *Catapasma.*

EMPATHE'MA. (*a, atis.* n. Εμπαθης; from παθμηα, *passio, affectio.*) Ungovernable passion. A genus of disease in Good's Nosology.

EMPEI'RIA. (From εν, and πειρω, to endeavour.) Empirical medicine, or that founded on experience alone.

EMPHLYSIS. (*is, is.* f.; from εν, in, and φλυσις, a vesicular tumour or eruption.) A vesicular tumour or eruption.

EMPHRA'CTIC. (*Emphracticus;* from εμφραττω, to obstruct.) A medicine which, applied to the skin, shuts up the pores.

EMPHYMA. A tumour originating below the integuments, and unaccompanied with inflammation, at least in its commencement, such as fleshy, bony, and other morbid growths. — *Good.*

EMPHYSE'MA. (*a, atis.* n.; from εμφυσαω, to inflate.) See *Pneumatosis.*

E'MPHYTON THE'RMON. (Εμφυτον θερμον. *Ca-*

idum innatum. Innate heat.) Animal or vital heat.

EMPI'RIC. (*Empiricus.* Εμπειρικος; from εν, in, and πειρα, experience.) One who practises the healing art upon experience, and not theory. This name was borne by an ancient sect of Greek physicians, founded according to some by Acron, and according to others by Serapion. The term is now applied, in a very different sense, to those who deviate from the line of conduct pursued by scientific and regular practitioners, and vend nostrums, or sound their own praise in the public papers.

EMPLA'STICUS. (From εμπλασσω, to obstruct.) Emplastic. Applied to medicines which, when spread upon the skin, stop the pores.

EMPLA'STRUM. (*um, i.* n.; from εμπλασσω, to spread upon.) A plaster. Plasters are composed of unctuous substances, united either to powders or metallic oxides, &c. They ought to be of such a consistence as not to stick to the fingers when cold, but to become soft, so as to be spread out in a moderate degree of heat, and in that of the human body, to continue tenacious enough to adhere to the skin. They owe their consistence either to metallic oxides, especially those of lead, or to wax, resin, &c. They are usually kept in rolls wrapped in paper, and spread, when wanted for use, upon thin leather; if the plaster be not of itself sufficiently adhesive, it is to be surrounded at its margin by a boundary of resin plaster.

Emplastrum adhesivum. See *Emplastrum resinæ.*

EMPLASTRUM ALEXANDRIUM. An old plaster, called also *Emplastrum viride*, described by Celsus, and made of wax, alum, &c.

EMPLASTRUM AMMONIACI. Take of purified ammoniacum, five ounces; acetic acid, half a pint. Dissolve the ammoniacum in the acid, then evaporate the liquor with a slow fire, constantly stirring it, until it acquires a proper consistence. This plaster is stimulant and discutient.

EMPLASTRUM AMMONIACI CUM HYDRARGYRO. Take of ammoniacum, a pound; mercury, three ounces; olive oil, a fluid drachm; sulphur, eight grains. Add the sulphur gradually to the heated oil, stirring constantly with a spatula till they unite; then rub the mercury with them till the globules disappear; lastly, add by degrees the ammoniacum, previously melted, and mix the whole together. This plaster is discutient, and is applied to nodes, indurated glands, and indolent tumours.

Emplastrum antihystericum. See *Emplastrum assafœtidæ.*

EMPLASTRUM ASSAFŒTIDÆ. *Emplastrum antihystericum.* Plaster of assafœtida. Take of plaster of semi-vitrified oxide of lead, assafœtida, each two parts; galbanum, yellow wax, each one part. This plaster is said to possess anodyne and antispasmodic virtues. It is, therefore, occasionally directed to be applied to the umbilical region in hysterical cases.

Emplastrum attrahens. See *Emplastrum ceræ.*

EMPLASTRUM CANTHARIDIS. Blistering-fly plaster. *Emplastrum vesicatorium.* Take of blistering flies, in very fine powder, a pound; wax plaster, a pound and a half; lard half a pound. Having melted the plaster and lard together, and removed them from the fire, a little before they become solid, sprinkle in the blistering flies, and mix the whole together. See *Blister* and *Cantharis.*

EMPLASTRUM CERÆ. Wax plaster. *Emplastrum attrahens.* Take of yellow wax, prepared suet, of each three pounds; yellow resin, a pound. Melt them together and strain. This is a gently-drawing preparation, calculated to promote a moderate discharge from the blistered surface, with which intention it is mostly used. Where the stronger preparations irritate, this will be found in general to agree.

Emplastrum commune. See *Emplastrum plumbi.*

EMPLASTRUM CUMINI. Cumin plaster. Take of cumin-seeds, caraway-seeds, bay-berries, of each three ounces; dried pitch, three pounds; yellow wax, three ounces. Having melted the dried pitch and wax together, add the remaining articles previously powdered, and mix. A warm stomachic plaster, which, when applied to the stomach, expels flatulency. To indolent scrofulous tumours, where the object is to promote suppuration, this is an efficacious plaster.

EMPLASTRUM ELEPHANTINUM. A plaster composed of cerusse, wax, oil, and water. — *Celsus.*

EMPLASTRUM GALBANI COMPOSITUM. Compound galbanum plaster, formerly called *Emplastrum lithargyri compositum*, and *Diachylon magnum cum gummi.* Take of galbanum eight ounces; lead plaster, three pounds; common turpentine, ten drachms; powdered resin of the spruce fir, three ounces. Having melted the galbanum with the turpentine, mix in first the resin of the spruce fir, and then the lead plaster, previously melted by a slow fire, and mix the whole. This plaster is used as a warm digestive and suppurative, calculated to promote maturation of indolent or scirrhous tumours, and to allay the pains of sciatica, arthrodynia, &c.

In the present London Pharmacopœia this is called simply *emplastrum galbani.*

EMPLASTRUM HYDRARGYRI. Mercurial plaster. *Emplastrum lithargyri cum hydrargyro.* Take of mercury, three ounces; olive oil, a fluid drachm; sulphur, eight grains; lead plaster, a pound. Add the sulphur by degrees to the heated oil, stirring them constantly with a spatula till they unite them; rub the mercury with them until the globules disappear; lastly, add, by degrees, the lead plaster melted by a slow fire, and mix the whole.

EMPLASTRUM LADANI COMPOSITUM. Take of soft labdanum, three ounces; of frankincense, one ounce; cinnamon and expressed oil of mace, each half an ounce; essential oil of mint, one drachm: add to the frankincense, melted first, the labdanum a little heated, till it becomes soft, and then the oil of mace; afterwards mix in the cinnamon with the oil of mint, and beat them together into a mass, in a warm mortar, and keep it in a vessel well closed. This may be used with the same intentions as the cumin-plaster, to which it is in no way superior, though composed of more expensive materials. For-

merly, it was considered as a very elegant stomach plaster, but it is now disused.

Emplastrum lithargyri. See *Emplastrum plumbi.*

Emplastrum lithargyri compositum. See *Emplastrum galbani compositum.*

Emplastrum lithargyri cum hydrargyro. See *Emplastrum hydrargyri.*

Emplastrum lithargyri cum resina. See *Emplastrum resinæ.*

Emplastrum lyttæ. See *Emplastrum cantharidis.*

Emplastrum opii. Plaster of opium. Take of hard opium, powdered, half an ounce; resin of the spruce fir, powdered, three ounces; lead plaster, a pound; water, eight fluid ounces. Having melted the plaster, add the resin of the spruce fir, opium, and water, and boil down the whole with a slow fire to a proper consistence. Opium is said to produce somewhat, though in a smaller degree, its specific effect when applied externally.

Emplastrum picis. *Emplastrum picis compositum.* Compound pitch plaster. *Emplastrum picis Burgundicæ.* Take of Burgundy pitch, two pounds; resin of spruce fir, a pound; yellow resin, yellow wax, of each four ounces; expressed oil of nutmegs, an ounce; olive oil, water, of each two fluid ounces. Having melted together the pitch, resin, and wax, add first the resin of the spruce fir, then the oil of nutmegs, the olive oil and the water; lastly, mix the whole together, and boil down to a proper consistence. From the slight degree of redness this stimulating application produces, it is adapted to gently irritate the skin, and thus relieve rheumatic pains. Applied to the temples, it is useful in pains of the head.

Emplastrum picis burgundicæ. See *Emplastrum picis.*

Emplastrum plumbi. Lead plaster. *Emplastrum lithargyri; Emplastrum commune; Diachylon simplex.* Take of oxide of lead, in very fine powder, six pounds; olive oil, a gallon; water, two pints. Boil them with a slow fire, constantly stirring until the oil and litharge unite, so as to form a plaster. A little boiling water is to be added, towards the end of the process, if required. Excoriations of the skin, slight burns, and the like, may be covered with this plaster: but it is in more general use, as a defensive, where the skin becomes red from lying a long time on the part. This plaster is also of great importance, as forming the basis by addition to which many other plasters are prepared.

Emplastrum resinæ. Resin plaster. *Emplastrum adhæsivum; Emplastrum lithargyri cum resinâ.* Take of yellow resin, half a pound; lead plaster, three pounds. Having melted the lead plaster over a slow fire, add the resin in powder, and mix. This adhesive plaster is chiefly used for keeping on other dressings, and for retaining the edges of recent wounds together.

Emplastrum roborans. See *Empiastrum thuris compositum.*

Emplastrum saponis. Soap plaster. Take of hard soap sliced, half a pound; lead plaster, three pounds. Having melted the plaster, mix in the soap; then boil it down to a proper consistence. Discutient properties are attributed to this elegant plaster, with which view it is applied to indolent tumours. It forms an admirable defensive and soft application, spread on linen, to surround a fractured limb.

Emplastrum thuris compositum. Compound frankincense plaster. Take of frankincense, half a pound; dragon's blood, three ounces; litharge plaster, two pounds. To the melted lead plaster, add the rest powdered. This plaster is said to possess strengthening, as well as adhesive powers. By keeping the skin firm, it may give tone to the relaxed muscles it surrounds, but cannot, in any way, impart more strength than the common adhesive plaster.

Emplastrum vesicatorium. See *Emplastrum cantharidis.*

Emplatto'mena. The same as *emplastica.*

Empneumato'sis. (From ἐν, in, and πνεω, to blow.) An inflation of the stomach and abdomen. — *Galen.* The term has also been used synonymously with *emphysema.*

Empo'rium. (*um, i.* n.; from ἐμπορεω, to negotiate.) A mart. The name formerly given to an imaginary reservoir in the brain in which the animal spirits were collected.

EMPRE'SMA. (From ἐν, in, and πρηθω, to influence.) Mason Good uses this as the generic name for visceral inflammation.

E'mprion. (From ἐν, and πριων, a saw.) Serrated. Applied by Galen to a particular kind of irregular pulse.

EMPROSTHO'TONOS. (*os, i.* m.; from ἐμπροσθεν, before, or forwards, and τεινω, to draw.) That form of tetanus in which the body is bent forwards. See *Tetanus.*

E'MPTYSIS. (*is, is.* f.; from ἐμπτυω, to spit out.) A discharge of blood from the mouth.

EMPYE'MA. (*a, atis.* n.; from ἐν, within, and πυον, pus.) A collection of pus in the cavity of the thorax. It is one of the terminations of pleuritis. There is reason for believing that matter is contained in the cavity of the chest, when, after a pleurisy, the patient has a difficulty of breathing, particularly when lying on the side opposite the affected one; and when an œdematous swelling is externally perceptible. Empyema is generally fatal, but is occasionally cured by the operation of making an opening into the chest at the most painful or tender part, or between the sixth and seventh ribs.

EMPYE'SIS. (*is, is.* f.; from ἐμπυοω, or ἐμπυεω, *suppuro.*) Dr. Good has applied this term (found in the fifth book of Hippocrates's Aphorisms) to a genus of disease, characterised by phlegmonous pimples, which gradually fill with a purulent fluid; as small-pox.

Empyoce'le. (From ἐν, in, πυον, pus, and κηλη, a tumour.) A collection of pus within the scrotum has been so called.

Empyo'mphalus. (From ἐν, in, πυον, pus, and ομφαλος, the navel.) An abscess under the navel.

Empyreal air. Scheele gave this name to oxygen gas.

EMPYREU'MA. (*a, atis.* n.; from εμπυρευω, to kindle.) A peculiar and offensive smell that distilled waters and other substances receive from being exposed to heat in closed vessels, or when burned under circumstances which prevent the accession of air to a considerable part of the mass.

EMPYREUMA'TIC. (*Empyreumaticus*; from εμπυρευω, to kindle.) Smelling as it were burnt: thus empyreumatic oils are those distilled with a great heat, and impregnated with *empyreuma*.

EMU'LGENT. (*Emulgens*; from *emulgeo*, to milk out: applied to the artery and vein which go from the aorta, and vena cava to the kidneys, because the ancients supposed they drained, and, as it were, milked the serum through the kidneys.) The vessels of the kidneys are so termed. The emulgent artery is a branch of the aorta. The emulgent vein evacuates its blood into the ascending cava.

Emulsio acaciæ. See *Mistura acaciæ.*

Emulsio amygdalæ. See *Mistura acaciæ.*

EMU'LSIO CAMPHORA'TA. Take of camphire, one scruple; sweet almonds, blanched, refined sugar, of each half an ounce; water, a pint and a half. This is to be made in the same manner as the common emulsion. It is an elegant way of administering a larger dose of camphire than is contained in the mistura camphoræ.

EMU'LSION. (*Emulsio, onis.* f.; from *emulgeo*, to milk.) An emulsion. A soft and somewhat oily medicine resembling milk. An imperfect combination of oil and water, by the intervention of some other substance capable of combining with both these substances.

Emulsion, almond. See *Mistura amygdalæ.*

Emulsion, Arabic. See *Mistura acaciæ.*

Emulsion of assafœtida. See *Mistura assafœtida.*

Emulsion, camphorated. See *Emulsio camphorata.*

Emulsion of gum-ammoniac. See *Mistura ammoniaci.*

EMU'NCTORY. (*Emunctorium, ii.* n.; from *emungo*, to drain off.) The excretory ducts of the body, and the cavities containing fluids to be excreted, are so called.

EMU'NDANS. Applied to a liquid medicament which deterges a wound or ulcer, and at the same time washes away the sordes. — *Blancard.*

ENÆ'MOS. (From εν, and αἱμα, blood.) So Hippocrates and Galen call any topical medicine which is applied to a wound to stop bleeding.

ENÆOREU'MA. (From εν, and αιωρεω, to lift up.) A deposit which floats in the middle of the urine.

Enamel. See *Teeth.*

ENANTHE'SIS. (*is, is.* f.; from εν, *in*, ανθρα, and ανθεω, *floreo*: efflorescence from within, or from internal affection.) A rash: in opposition to *exanthesis*, an eruption on the skin, not connected with internal affection. — *Good.*

ENANTE'SIS. (From εν, and ανταω, to meet.) The near approach of ascending and descending vessels.

ENARTHRO'SIS. (*is, is.* f.; from εν, in, and αρθρον, a joint.) The ball and socket-joint. A species of diarthrosis, or moveable connexion of bones, in which the round head of one is received into a cavity of another, in such a manner as to admit of motion in every direction; as the head of the os femoris with the acetabulum of the os innominatum. See *Articulation.*

ENCA'NTHIS. (*is, is.* f.; from εν, and κανθος, the angle of the eye.) A disease of the caruncula lachrymalis, of which there are two species: *Encanthis benigna*, and *Encanthis maligna seu inveterata.* The encanthis, at its commencement, is nothing more than a small, soft, red, and sometimes rather livid excrescence, which grows from the caruncula lachrymalis, and at the same time from the neighbouring semilunar fold of the conjunctiva. This excrescence, on its first appearance, is commonly granulated, like a mulberry, or is of a ragged and fringed structure. Afterwards, when it has acquired a certain size, one part of it represents a granulated tumour, while the rest appears like a smooth, whitish, or ash-coloured substance, streaked with varicose vessels, sometimes advancing as far over the conjunctiva, covering the side of the eye next the nose, as where the cornea and sclerotica unite.

The encanthis keeps up a chronic ophthalmy, impedes the action of the eyelids, and prevents, in particular, the complete closure of the eye. Besides, partly by compressing and partly by displacing the orifices of the puncta lachrymalia, it obstructs the free passage of the tears into the nose. The inveterate encanthis is ordinarily of a very considerable magnitude; its roots extend beyond the caruncula lachrymalis and semilunar fold of the membranous lining of one or both eyelids. The patient experiences very serious inconvenience from its origin and interposition between the commissure of the eyelids, which it necessarily keeps asunder on the side towards the nose. Sometimes the disease assumes a cancerous malignancy. This character is evinced by the dull red, and, as it were, leaden colour of the excrescence: by its exceeding hardness, and the lancinating pains which occur in it, and extend to the forehead, the whole eyeball, and the temple, especially when the tumour has been, though but slightly, touched. It is also shown, by the propensity of the excrescence to bleed, by the partial ulcerations on its surface, which emit a fungous substance, and a thin and exceedingly acrid discharge.

ENCATALE'PSIS. (From εν, and καταλαμβανω, to seize.) Used by Hippocrates synonymously with *apolepsis* and *catalepsis.*

ENCATHI'SMA. (*a, atis.* n.; from εν, and καθιζομαι, to sit down.) A semicupium, or bath for half the body.

ENCAU'MA. (*a, atis.* n.; from εν, in, and καιω, to burn.) The mark left by a burn, or a vesicle raised by a burn.

ENCAU'SIS. (*is, is.* f.; from εν, and καιω, to burn.) A burn. See *Burn.*

ENCEPALOCE'LE. (*e, es.*; from εγκεφαλος, the brain, and κηλη, a tumour.) A hernia of the brain. See *Hernia cerebri.*

ENCEPHALI'TIS. (From εγκεφαλος, the

brain.) Inflammation of the brain. The word εγκεφαλος was used by the Greeks in the same manner as we use the word brain; sometimes in a lax signification to denote the whole contents of the cranium, but more generally in a restricted sense to denote the *cerebrum*, or brain proper. Till of late years, few attempts were made to distinguish accurately between the phenomena of inflammation in the substance, and in the membranes, of the brain, and they were all brought together under the term *phrenitis* — a singularly ill chosen one, since the Greek word φρην signifies the *mind*, not the brain. It is still doubted by some writers of high authority, whether valid distinctions can really be established between the symptoms of inflammation in the membranes, and in the substance of the brain; it seems probable, however, and consonant with analogy, that inflammation in these different textures is not without its diagnostic symptoms, and the difficulty of discerning them, in many cases, appears to arise from the fact, that it is much more common for the brain and its membranes to be simultaneously affected, than either of them separately, and hence that the greater number of cases which occur in practice are of a mixed character. We may then recognise three cases of inflammation within the head, viz. *meningitis*, or inflammation of the membranes; *cerebritis*, or inflammation of the substance of the brain; and *encephalitis* — the last term being used to signify that mixed case in which the membranes and substance of the brain, are both implicated in the inflammatory state.

1. *Meningitis.* — When this occurs in a separate form, it seems to present the general characteristics of membranous, as opposed to those of parenchymatous inflammation; that is to say, the pain is more acute, and the inflammatory excitement of the whole system greater. The ordinary symptoms of *acute* meningitis are sharp pains in the head, with great intolerance of light and sound; restlessness and violent delirium; a quick and hard pulse; thirst; a hot skin, flushed countenance, and injected conjunctiva; spasmodic twitchings of the muscles, or convulsions, terminating in somnolency, coma, and entire loss of muscular power. Vomiting is a very frequent attendant on meningitis; and a peculiar sharp quick cry, indicative of sudden and violent pain, is, when it occurs, a very characteristic symptom. Inflammation of the arachnoid membrane does not seem to be distinguishable, by its symptoms, from that of the pia mater. Acute meningitis is frequent in children, and is one of the various affections confounded together by authors under the name of acute hydrocephalus. Inflammation of the dura mater is not common, except as the result of mechanical injury of the head; and the best illustrations of it are to be found in surgical writings. It terminates, if not checked, in separation of the membrane from the bone, effusion of pus between them, and sloughing of the membrane itself. Chronic meningitis differs from the acute in the minor intensity of its symptoms, and the delirium is either absent or not violent.

The organic changes arising from inflammation of the membranes of the brain, consist chiefly in an injected state of the pia mater, sometimes with extravasation of blood in its tissue; loss of transparency, and thickening of the arachnoid membrane; adhesion of the membranes to each other, and effusions of serum and lymph between the membranes, in the ventricles of the brain, and at its base. Purulent effusions under the arachnoid, or between it and the pia mater, are sometimes observed, though not frequently, and ulceration and sloughing of these membranes are very rare.

2. *Cerebritis.* — Inflammation of the substance of the brain. This may be *general* or *partial*, *acute* or *chronic*. Acute inflammation affecting the whole or the greater part of the cerebral substance, is indicated by symptoms very similar to those of acute meningitis; the pain in the head is intense, and the febrile excitement high: it may be observed, however, that the attack is generally less sudden in cerebritis, and is more frequently preceded by premonitory symptoms, such as pain and sense of fulness in the head; vertigo; drowsiness; confusion of thought; deviation from ordinary habits; various derangements of sensation; muscular pain and debility; tendency to spasm; and other symptoms indicative of lesion of the cerebral functions. The symptoms of general cerebritis also usually terminate in coma, and a collapsed state of the system, much sooner than those of meningitis. It is however to be observed, that general cerebritis hardly ever takes place, without more or less affection of the pia mater; and hence that the case we are speaking of ought rather to be considered as a mixed one, with a predominance of cerebritis over the meningeal affection, than as one of pure inflammation of the substance of the brain. General cerebritis is almost always an acute affection, and terminates fatally in a very short time. The patient sometimes dies within twenty-four or even twelve hours, and seldom survives longer than a week.

Partial cerebritis may be acute, subacute, or chronic. The acute form is marked by those symptoms generally indicative of inflammation of the substance of the brain, the lesion of particular functions being more or less remarkable, according to the part of the organ principally implicated.

The subacute form, which is the most frequent, presents the general symptoms of the acute in a minor degree of intensity. Here the approach of the disease is usually very insidious, the symptoms often consisting, at first, of headach, which may not be very severe, slight dizziness; dimness of sight; some disposition to stammer or drawl in the speech; an unsteady gait; but all this without fever or delirium, so that the extent of the danger is little apprehended by the patient or his friends, till he is suddenly seized with coma and paralysis of a limb, or hemiplegia, under which he sometimes sinks rapidly; but at other times partially recovers, and eventually falls a victim to a second or third attack of palsy.

The chronic form of cerebritis generally begins with slight paralysis of one of the extremities, or of the muscles of one side of the

face, or dimness of sight in one of the eyes, or loss of command over the tongue — the pulse remaining natural, and the general health being little disturbed. The paralysis goes on increasing, the memory and intellect are impaired, and all the functions of the system debilitated. This state of things is protracted often for many months, and then terminates suddenly with fatal coma and convulsions, or the patient at last dies gradually emaciated and exhausted.

The structural changes occasioned by inflammation of the cerebral substance, vary according to its degree and duration. In *acute cerebritis* the only appearances usually observed are a florid injection of the diseased substance, which, when cut into, presents a number of red dots, proceeding from the capillary vessels, and bloody striæ and patches, proceeding from the rupture of the capillaries. Suppuration is seldom found in this case, nor does the rapidly fatal course of the disease afford time for those changes of structure, which are the common result of the less acute varieties. Mortification of the brain is not common, but more so where the inflammation results from injury than where it is idiopathic. The cerebral substance, in the state of mortification, is dissolved in its consistence, of various shades of brown or of a greyish black colour, and a fœtid smell.

The subacute forms of cerebritis give rise to *abscess*, which is most frequent in the hemispheres of the brain — *simple softness* or *flaccidity* of the texture of the brain — pulpy disorganisation, the *ramolissement* of the French pathologists — *induration* of the substance of the brain, which has been most frequently found in maniacs, and those who have died of typhoid fevers, *hypertrophy* and *atrophy* of the whole organ, or of particular parts.

The *chronic* cerebritis generally occasions simple softening or induration, but the lesions arising from the subacute form are also sometimes consequent on this.

3. *Encephalitis.* — Inflammation of the brain and its membranes: the disease commonly met with in practice under the name of *phrenitis*. In this, we find the symptoms of meningitis and cerebritis variously blended, according as the one or the other affection predominates; and hence the general inapplicability of the nosological definitions which have been given of inflammation of the brain. This disease, like others of an inflammatory nature, usually commences with rigors, to which succeed a morbid heat, particularly about the head. Pain, more or less acute, sometimes is felt extending over the whole head, but more frequently confined to some particular region. High inflammatory fever is soon developed, commonly attended with parching thirst, but sometimes with a morbid absence of that sensation. The countenance is flushed, the eyes bloodshot, the pupils contracted, and the brows knit. There is furious delirium, with the most distressing intolerance of light and sound: in some cases this state of cerebral excitement alternates with one of stupor. The external senses are variously disordered, giving rise to double vision, spectra, illusory sounds, imaginary odours, &c., and the faculties of speech and deglutition are impaired. These symptoms having continued for three or four days, the fever assumes a typhoid type; the tongue is covered with a dark fur; there is stupor, with low muttering delirium, and subsultus tendinum. The patient drawls when he attempts to speak, and often cannot articulate at all; and the mouth is drawn to one side, or some other paralytic symptoms are present. Trembling of the muscles, and convulsions, often occur at all periods of the disease; convulsions frequently make their appearance for the first time, when coma begins to supersede the stage of excitement. Encephalitis, in the acute form just described, is generally fatal within a week, unless checked by vigorous practice at its first onset. A natural crisis sometimes takes place, when the inflammatory symptoms are at their height, by means of a copious epistaxis, or the hæmorrhoidal or menstrual flux. Hæmorrhage, from the bowels and other parts, sometimes occurs at a more advanced stage of the disease, after the appearance of typhoid symptoms; but it is then never salutary, and resembles similar discharges which take place in cases of low fever. Encephalitis, like cerebritis and meningitis, may assume a subacute or a chronic form; but, when idiopathic, it is generally an acute disease. As a symptomatic or secondary affection, subacute cephalitis often forms a prominent feature of continued fever. In the acute, subacute, and chronic forms, it frequently occurs also in the course of maniacal affections. Cephalitis is liable to be confounded with *delirium tremens*: for the diagnosis between them, see *Delirium tremens*. When cephalitis occurs as an accompaniment of continued fever, it is of importance to distinguish it from an idiopathic affection, because the measures of active depletion, which are called for in the one case, might be highly injurious in the other. The diagnosis, however, will not generally be difficult, if due attention be paid to the history and circumstances of the case.

Encephalitis is a highly dangerous disease. The acute form may often be arrested at the commencement by judicious practice; but if the disorder be allowed to gain head, it generally goes on to a fatal termination. In the subacute and chronic forms, the prognosis is upon the whole unfavourable, because the approach of the disease is insidious, and it has frequently made dangerous progress before its presence is suspected.

In the acute form the treatment is simple. The patient must be bled as largely as his strength will admit of. Some recommend the temporal artery or jugular vein to be opened, with a view to a more immediate effect on the cerebral circulation; but in this, as in other cases, venesection in the arm will be found the most convenient and effectual way of abstracting blood from the system. This general evacuation is to be repeated, or topical blood-letting by cupping or leeches substituted for it, according to circumstances. The next measure is to cause a deriviation from the head, by an active and irritating purgative; which intention may be answered by a full dose of calomel and jalap,

followed up by saline purgatives. A remedy, the importance of which is second to none, is the application of cold to the head. In the early stage, while the vascular actions are still powerful, the *douche* or continued stream of cold water falling from a height upon the head, is by far the best way of applying cold. The effect of this is often very remarkable; the most inflammatory pulse is in a short time reduced to a thread, and the patient, who was before in a state of violent excitement, becomes pale, quiet, and almost fainting. This depressing effect, which renders the douche so valuable an agent in the early stage, forbids its use at a more advanced period; and cloths, dipped in cold water, should then be substituted for it. The application of blisters should be deferred till the vascular actions have been diminished by other means, and it will then be better to apply them to the extremities than to the head. Antimonials should be given to keep the skin moist, and the antiphlogistic regimen exactly enforced. In the comatose and sinking state, very little can be done; the object of the judicious practitioner is to prevent, if possible, the accession of this state, by subduing the inflammation at first: it is possible, however, that, by bringing the system under the influence of mercury, we may sometimes check an incipient disorganising process, or promote the absorption of fluids that may have been effused. Throughout the disease, the position of the patient should be such as least favours the determination of blood to the head.

The subacute and chronic forms of inflammation of the brain, afford less chance of success to the practitioner than the acute. In these, active depletion is not called for, and would be injurious. The repeated abstraction of small quantities of blood by the lancet, cupping, or leeches, according to circumstances — continued counter-irritation by blisters or setons — laxatives — attention to diet — and, in some instances, the cautious use of mercury, constitute the means which are most likely to prevail; but, as before said, we are not to be very sanguine of success in these cases.

ENCE'PHALOID. (From εγκεφαλος, the brain, and ειδος, resemblance.) *Cerebriform.* Resembling the matter of the brain. The epithet given by Laennec to that species of morbid matter which constitutes the mass of the disease called *fungus hæmatodes.* Encephaloid matter is found also irregularly blended with other morbid formations, in the substance of malignant tumours, as with schirrus, melanosis, &c.

Encephalon. See *Encephalos.*

ENCE'PHALOS. (Εγκεφαλος; from εν, in, and κεφαλη, the head.) A Greek word applied in a general sense to the contents of the cranium, comprehending the cerebrum and cerebellum, their processes and membranes, but more particularly to the *brain proper*, or *cerebrum*, the cerebellum being called παρεγκεφαλις; εγκρανιον; επικρανις; οπισθιος εγκεφαλος. In modern medical language the word *encephalon*, which is the accusative of *encephalos*, has been erroneously substituted for it. This error has been properly pointed out by Dr. Kühn, the very learned editor of Blancard's Lexicon. Since the brain proper is now always called *cerebrum*, and the lesser brain *cerebellum*, it is convenient to employ the term *encephalos* in a general sense, for the contents of the cranium, which is, in fact, its etymological meaning. The contents of the cranium are the *cerebrum*, *cerebellum*, *tuber annulare*, and *medulla oblongata*, with their investing membranes, their blood-vessels, and nerves. The whole nervous mass within the skull generally weighs in the human subject about forty-eight or fifty ounces, and is larger, in proportion to the nerves proceeding from it, than in any other animal. The cerebrum, cerebellum, and their appendages, are invested by three membranes — the dura mater, the tunica arachnoides, and the pia mater; these also pass down from the brain upon the spinal cord, and invest it to its termination.

The *dura mater* (μηνιγξ σχληρη), which is the most external of the three, is thick, firm, and resisting, and belongs to the class of fibrous, or rather fibro-serous membranes, as it is in reality a compound structure; the outer lamella being fibrous, the inner serous and derived from the arachnoid membrane. It is in close apposition with the cranium, which it lines, at the same time that it invests the brain, and sends inwards processes, which are interposed between its different parts, serving to sustain them. It is, moreover, prolonged in a tubular form through the spinal canal, but is separated from the bones by a lamella of adipose tissue and the great spinal veins. It adheres closely to the arch of the skull, particularly along the sutures, but at its base the points of connexion are multiplied by its passing over the inequalities of the surface, and still more so by sending tubular prolongations through the different foramina, serving to enclose and protect the nerves which they transmit. Along the spinal column similar prolongations pass out with the nerves through the inter-vertebral foramina: these constitute its chief connexion with the bones. But towards the lower part of the sacral canal it is fixed by some irregular fibrous bands.

The processes formed by the dura mater are the following: —

The *falx cerebri* is lodged in the longitudinal fissure between the hemispheres of the brain, forming a partition between them. It is narrow before, broad behind, and presents a curved border inferiorly, so that in shape it resembles a sickle: hence its name. It extends from the crista galli of the ethmoid bone, which is inserted between its lamellæ, to the internal occipital protuberance, on a level with which it branches out at each side, becoming blended with the tentorium cerebelli. It seems as if formed in the following manner: — The fibres of the dura mater, on approaching the sagittal suture from each side, divide into two lamellæ, one of which is continued uninterruptedly across, thereby maintaining the continuity of the membrane, but the other dips down, converging to that of the opposite side, by which means they enclose between them an angular interval, viz. the longitudinal sinus. After their

union they continue to descend to the margin of the falx, where they separate, and unite again, so as to form the inferior longitudinal sinus. A section of the upper sinus is found to be triangular, of the lower circular. On the surface of the dura mater, in the sinus, or upon the cerebral hemispheres, small albuminous masses occasionally exist, called glandulæ Pacchioni, apparently resulting from morbid action.

The *tentorium cerebelli* spreads out from the base of the falx, and serves to support the posterior lobes of the brain: one border of it is attached all around to the lateral grooves on the occipital bone, and to the margin of the pars petrosa; the other, concave and free, encloses an oval interval, which transmits the crura cerebri, processus ad testes, and basilar artery.

The *falx cerebelli* is a narrow fold placed between the lobes of the cerebellum, extending vertically from the under surface of the tentorium to the foramen magnum; its base lodges the occipital sinuses.

The arachnoid membrane has already been described. See *Arachnoid membrane.*

The *pia mater* in its anatomical characters differs considerably from the other membranes. It is made up of a thin lamella of cellular tissue, permeated by a multitude of minute capillary arteries, which ramify in it previously to their entrance into the cerebral substance. It invests the medulla spinalis, as well as the brain, and dips into the sulci between the convolutions of the latter: we also find it enclosed within the ventricles, where it is named "plexus choroides." Its inner surface is in close contact with the cerebral substance; the external is in apposition with the arachnoid membrane on the surface of the convolutions, but loses all connexion with it after passing into the sulci.

Plexus choroides. — In the fissure observable at the base of the brain, between the inner margin of its middle lobe and the crus cerebri, the pia mater, which invests the external surface, is continuous with that process of it (plexus choroides) which is found in the ventricles; so that when we trace it, we find it, as it were, entering at the inferior cornu of the ventricle, where it corresponds at first with the interstice between the corpus fimbriatum and the crus cerebri, and afterwards lies along the floor of the ventricle, in which it ascends upon the thalamus nervi optici, and unites at the foramen or fissure of Monro with the plexus of the other side. At its entrance into the ventricle the plexus is drawn together so as to resemble a small vascular bundle, and becomes invested by the arachnoid membrane, which, by its reflection from the sides of the ventricles to the plexus, maintains the integrity of the cavity.

Where the pia mater is prolonged on the medulla oblongata, it forms a small plexus, which enters into the fourth ventricle, and becomes also invested by a duplicature of the arachnoid. As the membrane descends into the spinal canal it becomes firm, resistant, and much paler in colour. Its inner surface is in close contact with the cord, the exterior is but slightly connected with the arachnoid; but the nerves, at the different points at which they pass outwards, derive from it their immediate investment, or neurilema. The difference of character here pointed out between the spinal and cerebral parts of the pia mater, appears to MM. Jules and Hippolite Cloquet sufficient to induce them to consider it as a distinct structure. But it would be difficult to show where the continuity of the membrane is interrupted; and as to any difference of character and consistence that may appear, they are merely such as may be supposed to arise from the different circumstances in which the membrane is placed. In the spine it is exposed, at least in some degree, to the influence of motion and pressure, which necessarily produce the same effect on it as on cellular tissues elsewhere; that is to say, they render it thick and lamellar. Again, in the skull it is in contact with gray substance, in the spine with white; so that we can readily account for the difference of the vascularity in the membrane, by recurring to the relative vascularity of the structures with which it is in contact.

The cerebrum. — The part of the central mass of the nervous system which is lodged within the skull, presents, even on a superficial inspection, a division into parts, which differ in position, size, and form, as well as in the arrangement of their components; these have been named cerebrum, cerebellum (or great and little brain), cerebral protuberance, and lastly, the connecting link between these and the spinal part, viz. the medulla oblongata.

The brain (*cerebrum*) forms the largest portion of the central mass of the nervous system, and occupies the principal part of the cranial cavity. It extends from the frontal bone to the occipital fossæ, resting on the orbital processes of the former, on the tentorium cerebelli posteriorly, and in the centre descends into the middle fossæ, at the base of the skull. Its superior surface is convex and arched, corresponding with the vault of the cranium, beneath which it is placed, and presents along the middle line a deep fissure, running from before backwards, by which it is divided into two equal parts (*hemispheres*). The surface of the brain is rendered unequal by several depressions and elevations marked upon it. The elevations are called *convolutions* (*gyri*), and are situated between the depressions (*sulci*). The course of the convolutions is winding and tortuous, as the name implies, and their size presents many varieties in different places. It should be observed, that the anterior extremity of the brain, which corresponds with the frontal bone, is narrower than the posterior, which is in apposition with the occipital bone.

Hemispheres. — The external surface of each hemisphere is convex in its general outline; the internal is flat and compressed, as it rests against its fellow of the opposite side, the falx major being interposed between them. The inferior surface presents several depressions and inequalities, corresponding with those of the base of the skull.

Lobes. — On the inferior surface of each hemisphere is observed its division into three *lobes*. The anterior lobe rests on the orbital process of the frontal bone and the smaller wing of the sphenoid bone; the posterior is supported

by the tentorium cerebelli; and the middle is received into the central fossa, at the base of the skull. The anterior is separated from the middle lobe by a deep fissure (*fissura Sylvii*); but there is no precise line of demarcation between the latter and the posterior.

The *Brain — its external surface.* — The relation of size, form, and situation of the different objects seen on the external surface of the brain, should be carefully noted, as allusions are constantly being made to them during the description of the parts deeply seated, and also when tracing the progress of its development in the human subject, or in the animal series, and particularly when, after the manner of Gall and Spurzheim, we follow the course of the nervous fibres through the successive steps of their expansion, as the phrase is, from the medulla upwards into the cerebral hemispheres. Nothing of consequence remains to be noticed on the superior and external surface, in addition to what has been already stated.

The *Brain — its base or inferior surface.* — When we turn to the inferior surface, we observe that it presents in the middle line, and in front, a fissure, being the continuation of the longitudinal one, which establishes the separation between the hemispheres. It lodges the anterior extremity of the falx cerebri, its depth being limited by the corpus callosum, which passes across from one hemisphere to the other. The inferior surface of each anterior lobe, as it corresponds with the orbital plate on which it rests, is slightly concave.

Sulcus olfactorius. — A few lines external to the longitudinal fissure, and parallel with it, is a groove, resembling one of the sulci, which lodges the olfactory nerve, and at its posterior extremity is a rounded papilla, from which one root of that nerve is derived.

Fissure of Sylvius. — Posterior to the groove just noticed is the fissure (fissura Sylvii) which marks the separation between the anterior and middle lobes, and lodges the middle artery of the brain. It inclines from within outwards and upwards, and gradually terminates amongst the convolutions on the exterior of the hemisphere, its direction corresponding with that of the small wing of the sphenoid bone. At its internal termination it forms a right angle with another fissure, which extends from before backwards, and which is bounded externally by the middle lobe, internally by the crus cerebri and tractus opticus, and deserves notice because it transmits the pia mater from the external surface into the lateral ventricle.

The angular part of the anterior lobe, which is included between the internal termination of the fissure of Sylvius, the longitudinal fissure, and the commissure of the optic nerves, has been named by Vicq-d'Azyr *substantia perforata antica*, and by Reil *lamina cribrosa*, because it presents several foramina for the transmission of vessels. It deserves attention, inasmuch as the white lines seen at its inner border are continuous with those of the corpus callosum.

Optic commissure. — Between the fissuræ Sylvii, and corresponding with the interval between their internal terminations, is situated the *commissure of the optic nerves*. It is flat and quadrilateral in its form: one surface looks upwards to the brain, and is connected with the anterior termination of the corpus callosum, which passes upon it in the form of a thin semi-transparent lamella; the other surface rests upon the depressed part of the sphenoid bone, which lies before the pituitary fossa; the lateral and anterior margins are free, but the posterior one is intimately connected with a delicate stratum of gray matter, which is inserted between the nerves as they converge to their commissure.

Tuber cinereum. — The piece of gray matter just referred to is called by Sœmmering *tuber cinereum*: it extends from the posterior margin of the optic commissure to the corpora albicantia, gradually becoming a little thicker and firmer; for in front it is so thin as to be torn by the slightest touch. Its superior surface forms part of the floor of the third ventricle; the inferior one is slightly convex, and gives attachment by its centre to a funnel-shaped process, called *infundibulum* (tige pituitaire). This is a thin elongated process of reddish gray matter, inclined obliquely downwards and forwards from the tuber cinereum to the pituitary gland: its extremities are slightly expanded, and its centre constricted, which gives it an hour-glass shape.

Pituitary gland or *body.* — The pituitary gland appears to have received its name from its being supposed, in the infancy of anatomy, to communicate with the nose, and to secrete the viscid mucus (pituita) of that cavity; it is lodged in the excavation in the upper surface of the body of the sphenoid bone, and is unequally divided into two portions or lobes: the anterior, which is larger and more firm than the other, is convex in front, and concave behind, so as to receive the other, whose border is round and convex. The situation of the pituitary gland is peculiar: it is interposed between the two lamellæ of the fibro-serous membrane. The dura mater will be found to line the surface of the bone on which the gland rests; but the arachnoid membrane, after having formed a funnel-shaped process round the infundibulum, is reflected off from it at its lower extremity, and stretched across the upper surface of the gland until it reaches the clinoid processes, where it becomes continuous with the inner lamella of the fibro-serous membrane. When cut into thin slices, it appears to consist of two substances, one being reddish gray, the other white.

Mammillary bodies. — Immediately behind the tuber cinereum are placed two small bodies, called corpora mammillaria (albicantia, pisiformia). Their size is about that of a pea, but they are not quite round, being slightly compressed on three sides. Placed in apposition with one another, they are connected by a delicate process of gray matter, of which substance the greater part of their mass consists; they are, however, invested by a lamella of white matter, derived from the anterior pillars of the fornix, of which they may be regarded as the termination.

Behind the mammillary bodies is situated a thin lamella of white substance, which is pierced

by a number of foramina for the transmission of vessels, and called *locus perforatus*, and sometimes *pons Tarini*. Its shape is triangular, the sides being formed by the crura cerebri, the base by the mammillary bodies, the apex being at the border of the pons Varolii; it forms part of the floor of the third ventricle.

The *crura cerebri* are two thick rounded bodies, about three-fourths of an inch long, and situated towards the centre of the base of the brain, from which they project rather prominently. They are extended from the pons Varolii forwards and upwards to the under surface of the hemispheres, into which they seem as if inserted. They are nearly in contact behind, but diverge as they pass forwards, so as to leave an interval, which is occupied by the locus perforatus. The external surface of the crura consists of white matter, which is about two lines thick, and presents a distinctly fibrous character; within this is enclosed a quantity of gray substance, so dark as to have received the name of *locus niger*. The arrangement of these structures can be readily seen by making a transverse section of the crus: the dark part is found to be convex inferiorly, and concave above, so that the section of it presents a lunated form. The optic nerves rest upon the external surface of the crura as they pass forwards to their commissure.

The *great commissure — corpus callosum*. — All the parts of the brain hitherto noticed can be examined without any division of its texture, as they are placed superficially; but several are enclosed within its interior, which cannot be seen without dissection. Between the hemispheres, and extending transversely from one to the other, is placed the *corpus callosum* (mesolobe, commissura magna cerebri); its form is that of a broad layer of white fibres placed horizontally, but nearer to the anterior than to the posterior margin of the brain. Its extent from before backwards is about three inches, but its breadth from side to side cannot be assigned, as it becomes blended with the substance of the hemispheres. Its superior surface is convex in its general outline, and concealed by the hemispheres, which overlap it. When these are removed, a superficial linear impression will be perceived exactly in the middle line, and at each side of it a slight longitudinal elevation. To this the term raphé, or suture, is applied, as it indicates the point at which the union of the hemispheres takes place when their development is being completed. The fibres obviously are transverse from without inwards, for they commence at the circumference of the hemispheres, and terminate by their junction along the raphé. The inferior surface of the corpus callosum forms the roof of the lateral ventricles on each side, and towards the middle line it rests on the fornix, with which it is blended posteriorly: in front it gives attachment to the septum lucidum. Its anterior extremity, which, when viewed externally, presents a rounded border, is prolonged downwards and backwards to the base of the brain, where it forms a thin semi-transparent lamella. This reflected part is nearly horizontal in its direction, so that it lies beneath the corpora striata, and above the commissure of the optic nerves, to which it adheres but still passes backwards, and becomes continuous with the tuber cinereum in the middle line, whilst at each side its margins are blended with the substantia perforata. The posterior border of the corpus callosum is thick and rounded at the middle line, its thickness being greater (as may be seen when it is cut through perpendicularly) than that of the anterior border, owing to its receiving a greater number of converging fibres from the posterior lobes. A little more externally, the border of the corpus callosum gives off at each side two fasciculi of fibres, which can be traced, one into the posterior, the other into the descending cornu of the ventricle; one of these forms the medullary investment of the hippocampus minor, the other that of the hippocampus major.

Lateral ventricles (ventriculi tricornes). — Beneath the corpus callosum are situated the lateral ventricles, occupying the interior of the hemispheres. Their shape is very irregular, and can scarcely be said to bear a resemblance to any known figure. Each of them may be considered as divisible into a body or central portion, and three cornua or diverticula, which pass away in different directions. The central part lies horizontally: one cornu extends forwards from it into the anterior lobe, another backwards into the posterior, and the third downwards into the middle one; each of these presents certain peculiarities referable to the parts seen within them, which deserve notice. In the central part will be observed the corpus striatum, and thalamus nervi optici, and between them the tænia semicircularis; also the margin of the fornix, and part of the plexus choroides. These objects are for the present merely enumerated; each of them shall be noticed separately.

Septum inter ventriculos. — Previously to describing the objects just named, it may be observed that the lateral ventricles are separated by a partition (*septum lucidum*), which extends from the corpus callosum perpendicularly down to its reflected lamella in front, and to the fornix behind; it is round and broad before, but becomes narrowed to a point posteriorly. It consists of two thin lamellæ of white substance, between which is a fissure, or interval, called the *fifth ventricle*.

Fornix. — Beneath the corpus callosum and septum lucidum is a triangular lamella of white matter, which is extended from behind forwards over the third ventricle, and is thence termed *fornix*. Its upper surface gives attachment to part of the septum lucidum, and posteriorly becomes united with the corpus callosum; the inferior one overlays the third ventricle and the thalami nervorum opticorum, but is separated from them by the velum interpositum. Some oblique lines are traced on this surface, on which account it has been termed *lyra*, or *corpus psalloides*. The anterior extremity of the fornix is narrow, and divides into two fasciculi (*pillars of the fornix*), which curve downwards at the fore part of the third ventricle, immediately behind the anterior commissure, and terminate at the

base of the brain by investing the corpora mammillaria. The base or posterior extremity of the fornix gives off at each angle a thin flat process, which passes into the descending cornu of the ventricle, and assumes the name of *corpus fimbriatum*.

The *anterior cornu* of each ventricle inclines forwards and outwards, diverging from its fellow of the opposite side; the corpus striatum (its fore part) projects a little into its floor: the remainder of it resembles a groove in the cerebral substance. The *posterior cornu*, called the *digital cavity*, converges towards that of the opposite side, and presents in its floor the *hippocampus minor* (calcar unguis). This is a slight elevation, composed of a lamella of white matter (continuous with, or derived from, the corpus callosum), enclosing some cineritious substance; it gradually tapers to a point, and reaches to within an inch of the posterior extremity of the hemisphere.

The *inferior* or *descending cornu* passes at first backwards and outwards from the body of the ventricle; but after descending a little, it changes its direction altogether, and proceeds forwards and inwards, to terminate at the base of the brain, within a few lines of the fissure of Sylvius. This is the largest of the cornua: its convexity looks outwards and backwards, its concavity in the opposite direction: the under surface of the thalamus forms its roof, and the plexus choroides rests loosely on its floor, concealing the hippocampus major and corpus fimbriatum.

The *hippocampus major* (cornu ammonis) resembles in shape a cerebral convolution; it is curved so that its convex border looks outwards, and the concave inwards, conforming with the direction of the cavity in which it lies. Its anterior extremity expands somewhat, and presents two or three, and sometimes as many as five small prominences, separated by slight depressions, which make it to resemble somewhat the back of the hand when shut close. Some of the older anatomists called it *pes hippocampi*, from its resemblance to the clubbed foot of some of the lower animals. External to the part where the cornu makes its curve forwards, a slight elevation is observed, which is called *pes accessorius*.

Corpus fimbriatum. — Along the inner border of the cornu is a narrow falciform process of white substance (corpus fimbriatum), which is adherent by one edge to the floor of the cornu. It gradually becomes narrow, and ends in a point a little behind the pes hippocampi. Near the inner border of the corpus fimbriatum a narrow line of cineritious substance (*fascia dentata*) is placed; it is not perceptible until the middle lobe, together with the inferior cornu of the ventricle, is drawn outwards, as it is excluded from the cavity of the cornu by the reflection of the arachnoid membrane; its free border is marked by several transverse notches, giving it a dentated appearance, from which its name is derived.

The cornu ammonis consists externally of a lamella of white substance, which, if traced upwards into the body of the ventricle, will be found continuous with the corpus callosum. The corpus fimbriatum, in like manner, will be found continuous with the fornix.

The *corpora striata* (ganglions cérébraux supérieurs, Gall) are two in number, situated one in the body of each lateral ventricle. Each of these bodies is pyriform in its shape, the larger extremity being turned forwards and inwards, the smaller backwards and outwards. The superior surface is smooth and slightly prominent in the cavity, all the rest being embedded in the substance of the hemisphere. Their position is so oblique, that though in front they are separated by not more than three or four lines, their posterior extremities are from an inch and a half to two inches apart, the interval being occupied by the optic thalami and the third ventricle. Their external surface is composed of gray substance, but internally the gray and white are intermingled, so as to produce a striated appearance, whence the name is derived. The white fibres here found are continuous with those of the anterior pyramids and of the crura cerebri. They spread out considerably as they pass through the mass of gray matter of which the corpora striata consist, and appear to be at the same time enlarged and increased. Hence these bodies are considered by Dr. Gall to be ganglia of increase placed in the course of the fibres which are diverging to form the cerebral hemispheres.

The *optic thalami* (thalami nervorum opticorum, ganglions cérébraux postérieurs, Gall) are placed behind and between the corpora striata. The upper surface of each projects into the body of the corresponding ventricle; the inferior one forms the roof of its descending cornu, and the external is blended with the corpus striatum and the substance of the hemisphere. The internal surface of each thalamus, which is contiguous to that of the opposite side, is united to it by a soft lamella of gray substance called the *soft commissure* (commissura mollis). The union, however, may be called partial, for before and behind the commissure a small interval exists, where the thalami are unconnected, being merely in apposition.

Corpora geniculata. — On the posterior border of each thalamus are observed two slightly raised papillæ (*corpus geniculatum internum et externum*), which are connected by medullary striæ to the tubercula quadrigemina, the external one being also united to the origin of the optic nerve.

Tænia semi-circularis. — The contiguous borders of the optic thalamus and corpus striatum are separated by a thin fasciculus of nervous matter, of a pale straw colour (tænia semi-circularis), commencing near the anterior pillar of the fornix; it extends from before backwards between the bodies just named, and can be traced as far as the posterior border of the thalamus, and for a little way into the roof of the descending cornu, where it seems to cease.

Pineal gland and its peduncles. — Along the inner margins of the thalami two delicate white fasciculi arise, and pass backwards, converging to the pineal gland, whose *peduncles* they form,

and at the same time constitute its only bond of connexion with the substance of the brain. The pineal gland is a small mass of gray substance of a conical shape, and is sometimes called *conarium*, occasionally also *acervulus*. Its base rests on the tubercula quadrigemina; it usually contains in its interior some sabulous matter; at its first formation it consists of two masses, which unite into one.

The *third ventricle*. — The optic thalami enclose between them a narrow cavity (*third ventricle*), which corresponds exactly with the middle line, and resembles a longitudinal fissure. Its sides are formed by the thalami, its floor by the locus perforatus and tuber cinereum; the velum interpositum and fornix cover it in. The anterior commissure, and the pillars of the fornix, bound it in front. Into this cavity leads an aperture (*foramen commune anterius, foramen Monroi*), which is a rima between the anterior pillars of the fornix and the thalami, and which establishes a communication between the third and the lateral ventricles; a foramen leads out of it downwards and forwards (*iter ad infundibulum*). It may be observed that the infundibulum becomes imperforate at its middle, which appears to be owing to a small cul-de-sac of arachnoid membrane which is prolonged into it. From the posterior extremity of the ventricle another foramen opens into a canal (*iter à tertio ad quartum ventriculum; aquæductus Sylvii*), which leads obliquely downwards and backwards into the fourth ventricle.

Commissures, anterior and posterior. — Two cord-like fasciculi are stretched across the extremities of the third ventricle, and prolonged into the hemispheres which they connect, serving as commissures. The *anterior commissure* lies just before the pillars of the fornix, and as it extends laterally it will be found embedded in the substance of the corpora striata at each side, but does not become blended with them; its extremities arch backwards a considerable way, so as to form a curve whose convexity looks forwards. The *posterior commissure* is much shorter than the preceding, and extends but a few lines on each side into the thalami: it lies behind the ventricle, before the tubercula quadrigemina, and above the aqueduct of Sylvius.

The cerebellum. — The second division of the central mass of the nervous system is the cerebellum, which differs in situation and size, as well as in the arrangement of its component parts, from the cerebrum. It is lodged in the recess formed between the tentorium cerebelli and the inferior occipital fossæ, its weight as compared with that of the brain being as 1 to 16 in the infant and as 1 to 8 in the adult. Its surface, instead of convolutions, is divided into a number of concentric lamellæ (*folia cerebelli*), placed perpendicularly on their edges, and enclosed one within the other. If, however, the sulci between them be opened, several other lamellæ will be found enclosed within them, but smaller, more irregular, and with various degrees of inclination.

Lobes. — The cerebellum is divided into two lateral lobes, the division being established behind by a fissure, which receives the falx cerebelli, and in front by a deep excavation, which lodges the medulla oblongata.

Superior vermiform process. — The superior surface of the cerebellum is slightly depressed on each side where the tentorium rests upon it, but along the middle line a rounded ridge (processus vermiformis superior) runs from before backwards, and seems as if produced by the rippling up or admixture of the lamellæ of the lobes as they extend from without inwards. There appear to be from sixty to seventy lamellæ on the upper surface of the cerebellum, which are aggregated into five fasciculi.

Inferior vermiform process. — The inferior surface is convex, and dips down into the occipital fossæ; along the middle line runs the *inferior vermiform process*, interposed between the lateral lobes; it resembles a lobule formed of short transverse plates; its anterior extremity has been compared to a mamillary process.

The mass of medullary matter enclosed within the cerebellum is connected with three pairs of medullary fasciculi; viz. processus è cerebello ad testes, corpora restiformia, and crura cerebelli, which require a detailed notice.

Processus è cerebello ad testes. — From the interior of the lobes, two fasciculi of white fibres pass forwards and upwards to the lower pair of the tubercula quadrigemina; the name given to them indicates the points between which they lie; they converge in their ascent, and are connected by a semi-transparent medullary lamella, named the valve of Vieussens. The valve (*valvula Vieussini*) presents on its upper surface a slight groove, running from above downwards, and sometimes a linear ridge, like a raphè; it overhangs the fourth ventricle.

Posterior pyramids (corpora restiformia, pyramides postérieures). — Two white rounded processes pass obliquely upwards and outwards from the medulla oblongata into the cerebellum, named by Ridley "restiform" bodies, by Gall "posterior pyramids;" we have already noticed them as part of the medulla oblongata.

Peduncles of the cerebellum (crura cerebelli.) — These are the largest of the fasciculi here referred to; they are at first concealed within the lobes, and even when about to emerge from their substance, they are overlapped by some minor lobules. They incline forwards and inwards, descending somewhat, and become continuous with the fibres of the pons Varolii, which are thus derived from the crura cerebelli. The pons, from its mode of formation, bears the same relation to the cerebellum that the corpus callosum does to the cerebrum, as it is composed of converging fibres, and may therefore be called a commissure.

Fourth ventricle. — The cerebellum encloses a cavity called the "fourth ventricle," the roof of which is formed by the valve of Vieussens and processus ad testes, the sides by the lobes of the cerebellum; the dorsal surface of the medulla oblongata forms its floor, and it is completed inferiorly by a reflection of the arachnoid membrane: a process of pia mater projects into it at this situation, called *plexus choroides minor*.

Corpus dentatum. — If a vertical section be made of one of the lobes of the cerebellum, in

such a way as that two-thirds of its breadth shall lie external to the incision, an oval nucleus of gray substance (corpus dentatum, vel rhomboideum) will be exposed: its texture is usually firm, and its border notched, so as to give it a dentated appearance. Gall considers it as a ganglion of increase to the formative fibres of the cerebellum. The surface of the section here indicated presents rather a peculiar appearance: the white substance will be found so disposed as to represent the stalk and branches of a tree, hence called *arbor vitæ*. The branches project into the lamellæ of the cerebellum, which are not unfrequently in figurative phrase termed *folia*, for the gray substance invests them so as to make them resemble pinnatifid leaves. If a horizontal section be made, so as to divide the lobe into two equal parts, the quantity of white substance will appear considerably greater than that of the gray.

Tuber annulare. — *The cerebral protuberance* (nodus cerebri, pons Varolii, protuberantia annularis) is much the smallest portion of the central mass; its relative size being to that of the rest as 1 to 72. It is placed beneath the cerebrum, above the medulla oblongata, and before the cerebellum, having intimate relations with each by continuity of substance; hence it has been termed *nodus encephali*. It is a square mass, its depth being about equal to its length. Its anterior surface is convex, and rests against the basilar process of the occipital bone, and is composed of the converging fibres of the cerebellum, disposed so as to form a portion of a ring, which encloses the contiguous extremities of the crura cerebri and medulla oblongata; — it is termed *protuberantia annularis* or *pons Varolii*. Its upper border is bounded by a transverse line, marking its separation from the crura cerebri, and the lower by another line which divides it from the medulla oblongata; along its middle is a shallow groove, running from above downwards, which corresponds with the basilar artery.

Tubercula quadrigemina. — Upon the posterior surface of the cerebral protuberance, which is almost entirely concealed by the cerebellum, are placed four white rounded bodies (tubercula, vel corpora quadrigemina), disposed in pairs, one above the other, and separated by two decussating lines. The upper pair are the larger, and called *nates* — the lower *testes*: they are connected in front with the thalami, inferiorly with the processus ad testes and the valve of Vieussens, and between their upper surface and the corpus callosum is a rima or fissure (*fissure of Bichât*,) through which the arachnoid membrane enters to line the ventricles.

Communication between the ventricles of the brain. — The irregular vacuities disposed in the interior of the cerebellum and brain communicate freely with one another by certain constricted portions, or foramina. If, whilst the brain and cerebellum remain *in situ*, the latter be divided by a vertical incision made from the valve of Vieussens downwards through its substance, the fourth ventricle will be exposed. This cavity contracts towards its upper part into a tube (aqueduct of Sylvius,) which is directed upwards and forwards, under the tubercula quadrigemina and the posterior commissure, into the middle or third ventricle. The latter again communicates at each side with the lateral ventricles by a rima (*foramen Monroi*), situated between the pillars of the fornix and the thalami, on which they rest. When the ventricles have been distended with fluid, this rima assumes a rounded form, and then only represents a foramen. These vacuities, then, should be considered not as so many separate cavities, but as a series of compartments of one cavity contained within the cerebral mass; and this is the appearance they present during the earlier periods of fœtal life. The cavity, however, is not a shut sac, for the membrane which lines it is continuous with that which invests the external surface of the brain and cerebellum. It has been already stated, that the arachnoid membrane passes in through the fissure of Bichât. Two other fissures are situated, one on each side between the corpus fimbriatum and the crus cerebri, through which the pia mater enters, to form the plexus choroides. These may be considered as chinks between the portions of cerebral substance just referred to; but they are closed up by the manner in which the arachnoid membrane is reflected from the sides of the cornua of the ventricles upon the plexus choroides.

Medulla oblongata. — The upper part of the spinal cord, before it emerges from the cranium, is called medulla oblongata. It is broad and thick superiorly near the pons Varolii, but tapers gradually towards the occipital foramen. Its anterior aspect is rounded, the posterior is somewhat flattened, and each presents a continuation of the median sulcus (anterior and posterior) by which it is divided into two symmetrical parts. The lateral depressions, which correspond with the points of origin of the spinal nerves, are also continued upwards into the medulla oblongata. But though inferiorly the divisions established by these lines are so slightly marked as to have escaped notice, until Chaussier directed his attention to the subject, yet in the superior part (*medulla oblongata*) they are so well defined as to have been deemed deserving of particular names. The anterior and posterior pair have been called the anterior and posterior pyramids; the middle, from their shape, the corpora olivaria. These, according to Gall, are made up of the primitive or formative fibres of the cerebrum and cerebellum; for if they be traced upwards, the anterior pyramids and the corpora olivaria will be found continuous with the fibres which are expanded into the cerebral hemispheres, whilst the posterior pyramids (usually called, since Ridley's time, *corpora restiformia*) are evolved into the lobes of the cerebellum. Besides these parts, which have been noticed by all anatomists, Sir C. Bell has described another, which is situated between the corpus olivare and restiforme. This consists of a narrow line of white matter, which may be traced along the medulla oblongata, and from thence downwards between the anterior and posterior roots of the spinal nerves. It is but slightly marked in the lower part of its extent, but becomes more perceptible opposite the corpus olivare; after which it narrows, and ceases

altogether at the margin of the pons, "not being continued upwards into the cerebral mass." This may be termed *tractus respiratorius*, as it gives origin to the class of respiratory nerves is established by Sir C. Bell.

Structure. — A transverse section of the medulla shows it to consist of a thin lamella of white matter, enclosing the gray or cineritious substance. The latter is disposed in a very peculiar way; it presents two lateral portions, each of a crescentic form, their concavities looking outwards; the convex sides of each are turned towards the middle line, and are connected by a short transverse fasciculus of gray matter. The anterior cornua of the lateral masses are rather thick and rounded; the posterior extend as far as the corresponding collateral sulci.

The *anterior pyramids* (corpora pyramidalia) are close together, being separated only by the anterior sulcus, and extend, enclosed between the corpora olivaria, from the margin of the pons Varolii to the foramen magnum. Some of the fibres of each pyramid which are close to the sulcus pass across it obliquely, and so a decussation is produced between them. The rest continue their course uninterruptedly, so that only a part of the pyramids change place, or decussate.

The *olivary bodies* (corpora olivaria), when stripped of their medullary lamella, are found to consist each of an oblong mass of gray matter, surrounded by a fringed or scalloped border, and attached towards the middle line by a slight petiole. Owing to this arrangement, it presents, when divided by a transverse section, an arborescent appearance.

The *posterior pyramids* (corpora restiformia, pyramides postérieures, Gall) correspond with the posterior and lateral parts of the medulla; they diverge as they ascend towards the lobes of the cerebellum. The posterior aspect of the medulla oblongata is slightly concave, and divided into two lateral parts by the median sulcus, to which two oblique lines converge, giving it an indented appearance. This has been termed *calamus scriptorius*. One or two elongated cords are also observable on this surface, which have not as yet received names, "but whose offices may one day be discovered."

Intimate structure of the Brain. The cerebral hemispheres are considered by Gall as resulting from an expansion or evolution of the fibres of the medulla oblongata, which he therefore terms primitive, or formative fasciculi.

Diverging fibres. — The fibres of the anterior pyramids may be traced upwards to the margin of the pons, where they become somewhat constricted. From the inner border of each, some fibres pass across the middle sulcus, and mutually change place, or decussate; those of the right side passing to the left, and *vice versâ*. If an incision, a line or two in depth, be made through the pons, so that one lateral half of it may be turned outwards, the fibres of the pyramid will be observed to pass into a quantity of gray substance lodged in the interior of the nodus encephali. In this situation the fibres diverge and separate, and are also considerably increased: at the upper margin of the pons they become continuous with the crus cerebri. Here an additional increase is derived from their passage through the gray substance lodged in the interior of the crus, after which they proceed through the inferior cerebral ganglion (*thalamus nervi optici*), and in the next place through the superior one (*corpus striatum*), being successively increased and rendered still more divergent, until finally they reach the anterior and middle lobes, where they are evolved into their inferior, external, and anterior convolutions. The corpus olivare contains within itself a small ganglion; its fibres pass, without any decussation, into the gray substance lodged in the cerebral protuberance, where, like the pyramids, they receive additions, after which they pass into the crus cerebri, of which they form the posterior and inner part. Continuing their ascent, after being increased in the locus niger, they pass through the optic thalamus, and thence into the corpus striatum, receiving additions as they radiate through each, and finally are continued upwards into the convolutions at the summit of the hemisphere, and backwards into those of the posterior lobe. Previously to entering the optic thalamus, some fibres of the corpus olivare have been observed to turn inwards, so as to give to the tubercula quadrigemina their medullary investment, and also to unite with those of the opposite side, to form the valve of Vieussens. Finally, the diverging fibres traced up, as has been pointed out, through their successive steps of increase, terminate in the gray substance of the cerebral convolutions.

Converging fibres. — Another order of fibres may be observed quite distinct from those above noticed, and taking a different direction. These are called the "converging fibres," as they commence at the peripheral terminations of the preceding set, and pass from without inwards to the middle line, so as to connect the lateral parts, and bring them into relation with one another; on which account they are called commissures. The anterior and posterior commissures are formed in this way, as is also the corpus callosum; though the greater number of the fibres which compose the latter are transverse, those towards its extremities are oblique. This is owing to the manner in which the converging fibres of the anterior lobe are constrained to pass from before backwards, and those of the posterior lobe from behind forwards, in order to gain the corresponding borders of the corpus callosum. By this arrangement a greater number of fibres is collected to its extremities, which renders them thicker (particularly the posterior one) than any other part of its extent. Some of the inferior fibres thus traced from without inwards, instead of uniting with the corresponding set along the middle line, become reflected downwards from the under surface of the corpus callosum to the fornix, and so form the septum lucidum. The convolutions of the posterior lobe are brought into relation with those of the middle one by means of the fornix, the fibres of which are stretched from behind forwards, in such a way, that whilst its body is in a manner unattached, the extremities are identified with the parts just referred to.

Diverging fibres of the cerebellum. — The formative fibres of the cerebellum are derived from the posterior pyramids, or corpora restiformia; they pass upwards and outwards, and soon meet the corpus rhomboideum, which is considered as the ganglion of the cerebellum: the fibres are supposed to proceed through the gray substance of which it is composed, though it is difficult to demonstrate the fact; after which they pass outwards, diverging into the lobes of the cerebellum.

Converging fibres. — From the peripheral terminations of the diverging fibres in the folia, a new set arise, which incline inwards towards the middle line. These are the converging fibres, which, by their union, form the crura cerebelli; and the fibres of each crus, expanding as they pass downwards and inwards, constitute by their junction the pons Varolii, which brings the lateral lobes of the cerebellum into relation, and becomes thereby their commissure. The processus à cerebello ad testes bring the lobes of the cerebellum into intimate connexion with the cerebral hemispheres.

The weight of the brain in the adult is about three pounds; that of the cerebellum about four ounces and a half, and of the medulla oblongata half an ounce.

Vessels. — The brain is supplied with blood by the two internal carotid arteries, and the two vertebral; its residual blood is returned by the two internal jugular veins.

The preceding anatomical description of the encephalos is taken from Professor Quain's Manual of Anatomy. Nine, or, according to the arrangements of Sœmmering, twelve pair of nerves rise from the brain, and make their exit at the different foramina of the skull.

For the enumeration of these, see *Nervous System.*

ENCHARA'XIS. (*is, is.* f.; from ἐν, and χαρασσω, to scarify.) A scarification.

Enchiloma. See *Enchyloma.*

ENCHO'NDRUS. (From ἐν, and χονδρος, a grain, or a cartilage.) 1. Granular.

2. Cartilaginous.

ENCHO'RIOS. (Ἐγχωριος; from ἐν, and χωρος, a region.) Enchorial. Belonging to a particular country or district. Synonymous in medical language with *endemic.*

ENCHRI'STUM. (From ἐγχριω, to anoint.) An ointment or liniment.

Enchusa. See *Anchusa.*

ENCHYLO'MA. (From ἐν, and χυλος, juice.) An inspissated juice. An elixir, according to Lemery.

ENCHYMO'MA. (Ἐγχυμωμα; from ἐν, and χυμος, juice.) An infusion or pouring in of fluids. In the writings of the ancient physicians, this word expresses a sudden injection of blood into the cutaneous vessels, which arises from joy, anger, or shame: and, in the last instance, is what we usually call blushing.

ENCHYMO'SIS. Ἐγχυμωσις. The same as *enchymoma.*

E'NCHYTA. (Ἐγχυτα; from ἐγχυω, to pour in.) Applied to medicines which are dropped into the eyes. — *Galen.*

ENCLY'SMA. (From ἐν, and κλυζω, to cleanse out.) A clyster.

ENCŒ'LIA. (From ἐν, within, and κοιλια, the belly.) The abdominal viscera.

ENCOLPI'SMUS. (From ἐγκολπεω, to insinuate.) The introduction of any medicament into the female vagina.

Encranis. See *Encranium.*

ENCRA'NIUM. (Ἐγκρανιον; from ἐν, within, and κρανιον, the skull.) The cerebellum.

ENCRASI'CHOLUS. (From ἐν, in, κερας, the head, and χολη, bile; because it was said to have the gall in its head.) The anchovy. See *Clupea.*

ENCY'STED. *Saccatus.* A term applied to those tumours which consist of a fluid or other matter, enclosed in a sac or cyst.

ENCY'STIS. (From ἐν, in, and κυστις, a bag.) An encysted tumour.

ENDE'MIC. (*Endemius; endemicus;* from ἐν, in, and δημος, people.) A disease is so termed which is peculiar to, or particularly prevalent in, a particular region. Enchorial is a preferable term.

ENDERMATIC. (*Endermaticus;* from ἐν, and δερματικος, cutaneous.) Applied to that method of using medicines in which they are rubbed into the skin.

ENDERMIC. Improperly written for *Endermatic.*

Endive. See *Cichorium.*

ENDI'VIA. (*a, æ.* f.) Blancard says this word is a Tuscan corruption of the Latin *Intubum.* See *Cichorium.*

ENDOBRANCHIA'TA. (From ἐνδον, within, and βραγχια, gills.) The name given by Dumeril to a family of the class annelides, which have no external gills.

ENDOCARDI'TIS. (From ἐνδον, within, and καρδια, the heart.) Inflammation of the lining membrane of the heart. See *Heart, diseases of the.*

ENDODONTI'TIS. (From ἐνδον, within, and ὀδους, a tooth.) Inflammation of the membrane lining the internal cavity of a tooth.

ENDOGASTRI'TIS. (From ἐνδον, within, and γαστηρ, the stomach.) Inflammation of the lining membrane of the stomach.

ENDO'GENOUS. (From ἐνδον, within, and γενναω, to engender.) Applied to plants, the vessels of which are dispersed through the whole stem, and are so disposed that the oldest are exterior, and hence the growth of the plant takes place from within.

E'NDONENTERI'TIS. (From ἐνδον, within, and ἐντερον, an intestine.) Inflammation of the lining membrane of the intestines.

E'NDOŒSOPHAGI'TIS. (From ἐνδον, within, and οισοφαγος, the gullet.) Inflammation of the lining membrane of the œsophagus.

E'NDOPHLEBI'TIS. (From ἐνδον, within, and φλεψ, a vein.) Inflammation of the lining membrane of a vein.

E'NDOSIS. Ἐνδοσις. The remission of a fever.

ENDOSMO'SIS. (From ἐνδον, within, and ωσμος, impulsion.) The passage of liquids through the membranes of the living bodies from the exterior to the interior.

ENE'CIA. (From ηνεκης, continuous.) The

generic name given by Mason Good to continued fever.

E'NEMA. (*a, atis.* n.; from ενιημι, to inject.) A glyster, or clyster. A liquid or gaseous form of medicine thrown into the rectum. The objects for which glysters are administered are several: —

1. For emptying the bowels of fæces, or as an aperient.

2. For relaxing the powers of the body, and producing fainting; as when tobacco fumes are sent into the rectum, in order to effect the reduction of a strangulated hernia.

3. For the purpose of killing worms that are nidulating in the rectum; as the thread-worm.

4. For defending the bowels from the irritation of the bile or acrimonious secretions.

5. For restraining a diarrhœa.

6. For nourishing the body, when aliment cannot be received or retained in the stomach.

7. For allaying spasms in various parts; as the intestines, the stomach, the lungs, kidneys, &c.

8. For allaying vomiting, caused by inverted peristaltic movements of the small intestines.

To answer these several purposes, the ingredients, of course, will be varied: — aloes, colocynth, senna, purging salts, and turpentine, and the like, with gruel, decoction of marshmallows, and linseed, are selected to procure motions, to bring the peristaltic movement of the bowels into its proper direction: these medicines will also kill worms. Tobacco infusion, or the smoke, will relax spasm, and produce syncope. Mild mucilage, and glutinous substances, will defend the irritated coats of the rectum; as decoctions of starch, gum acacia, isinglass, glue, &c., with opium; which are also likely to restrain diarrhœa, especially if logwood, catechu, or oak bark be combined with them. The shanks of mutton, veal, and beef, and glue, boiled in broth, will nourish the body. Opium, so administered as to be duly retained in the bowels, is best calculated to allay spasm of the bowels, stomach, uterus, bladder, &c. The following forms are in general use: —

Enema ano'dynum. Take of starch jelly, half a pint; tincture of opium, forty to sixty drops. Mix. The whole to be injected by means of a clyster-syringe, in cases of dysentery or violent purging, and pain in the bowels.

Enema antispasmodicum. Take of tincture of assafœtida, half an ounce; tincture of opium, forty drops; gruel, half a pint. Mix. For spasmodic affections of the bowels.

Enema laxativum. Take of sulpaate of magnesia, two ounces; dissolve in three quarters of a pint of warm gruel, or broth, with an ounce of fresh butter, or sweet oil.

Enema nicotianæ. Take of the infusion of tobacco from a half to a whole pint. Employed in cases of strangulated hernia.

Enema nutriens. Take of strong beef tea, twelve ounces; thicken with hartshorn shavings, or arrow-root.

Enema terebinthinæ. Take of common turpentine, half an ounce; the yolk of one egg, and half a pint of gruel. The turpentine being first incorporated with the egg, add to them the gruel. This clyster is generally used, and with great good effect, in violent fits of the stone.

E'NERGY. (*Energia, æ.* f.; from ενεργεω, to act.) A term conveniently applied in physiology to certain powers of which we see the operation but are ignorant of the nature: thus we speak of the *vital energy*, the *nervous energy*, &c.

ENE'RVIS. *Enervius.* Ribless: applied to leaves which are without lines or ribs.

Engala'ctum. (From εν, and γαλα, milk; so called, because it was eaten by nurses to increase their milk.) Most probably the *Salsola kali* of Linnæus.

Engastrimy'thus. (*us, i.* m.; from εν, in, γαστηρ, the belly, and μυθεομαι, to discourse.) A ventriloquist; one who appears to speak from his belly. See *Ventriloquism.*

Engeiso'ma. (Εγγειισωμα; from γεισον, the eaves or edges of a roof.) A fracture of the skull in which the broken portion of bone slides under the adjacent sound portion. — *Kühn.*

Enghien. A small town near Paris, which has mineral waters, containing sulphuretted hydrogen gas, muriates of magnesia and soda, carbonates of lime and magnesia, free carbonic acid, &c.

English mercury. See *Mercurialis.*

Englo'tto-ga'stor. (From εν, γλωττη, the tongue, and γαστηρ, the belly.) A ventriloquist.

ENGOMPHO'SIS. (*is, is.* m.; from εν, and γομφος, a nail.) That species of articulation which resembles a nail driven into wood, as a tooth in its socket.

Engo'nios. (From εν, and γωνια, an angle.) The flexure, or angle made by the bending of a joint.

Engorgement. A French term synonymous with congestion.

Engoument. A French term signifying obstruction. Thus, *engoument des bronches*, obstruction of the bronchi by effused mucus.

Enhæmon. Εναίμον. The epithet of a plaster mentioned by N. Myrepsus.

Eni'xum paracelsi. The caput mortuum of the distillation of nitric acid, which is a super-sulphate of potash.

ENNEA'NDRIA. (*a, æ.* f.; from εννεα, nine, and ἀνηρ, a man.) The name of a class of plants in the sexual system, containing such as have hermaphrodite flowers with nine stamina.

Enneapha'rmacum. (From εννεα, nine, and φαρμακον, a medicine.) A medicine composed of nine simple ingredients.

Enneaphy'llum. (*um, i.* n.; from εννεα, nine, and φυλλον, a leaf: because its flower consists of nine leaves.) A name for helleboraster, or bear's-foot.

ENO'DIS. Without knots; without joints: jointless. Applied to stems of plants. — *Culmus enodis*; that is, a smooth culm, as in our common rushes.

Enormon. (Ενορμοῦν; from ενορμαω, to impel.) *Impetum faciens.* A term used by Hippocrates to designate the vital principle. See *Impetum faciens.*

Enosto'sis. (From εν, in, and οστεον, a bone.) A tumour formed in the medullary canal of a bone.

ENRYTHMUS. (Ενρυθμος; from εν, and ρυθμος, number.) A Greek epithet of a pulse which follows some sort of order, although it may not be exactly ευρυθμος, that is, perfectly regular both as to frequency and force.

ENS. An entity, or thing actually existing. By this term Paracelsus signified a natural power capable of influencing the human body. Of such powers he enumerates five — an *ens astrale*, *ens venenale*, *ens naturale*, *ens spirituale*, and *ens Deale*. In imitation of this jargon, the old chemists applied the term *ens* to denote certain substances which they conceived to be particularly active and powerful.

ENS MARTIS. An oxide of iron.

ENS PRIMUM SOLARE. Antimony.

ENS VENERIS. The muriate of copper.

ENSA'TÆ. (From *ensis*, a sword.) The name of a natural order of plants, consisting of such as have sword-shaped leaves.

ENSA'TUS. (From *ensis*, a sword.) Shaped like a sword.

E'NSIFORM. (*Ensiformis*; from *ensis*, a sword, and *forma*, resemblance.) Sword-shaped: sword-like. 1. In *Anatomy*, applied to some parts from their resemblance; as the ensiform cartilage. See *Cartilago ensiformis*.

2. In *Botany*, a leaf is called *folium ensiforme*, which has two edges, and tapers to a point, like a sword. See *Leaf*.

ENSTA'CTUM. (From εν, and σταζω, to instil.) A liquid medicine, which is applied *stillatim*, or drop by drop.

ENTALI. An alchemical name of the alumen plumosum.

ENTA'SIA. (*a*, *æ*. f.; from ενταση, *intentio vehementia*.) The generic name applied by Dr. Good to constrictive spasm, embracing trismus, tetanus, priapism, &c. &c.

ENTA'TICUS. (Ενταικος; from ενταινω, to strain: provocative.) Applied to that which excites venereal inclination.

ENTERADE'NES. (From εντερον, an intestine, and αδην, a gland.) The intestinal glands.

ENTERALGIA. (From εντερον, the intestine, and αλγος, pain.) The generic name given by Swediaur to painful affections of the bowels.

ENTERE'NCHYTA. (From εντερα, the bowels, and εγχυω, to infuse into.) An instrument for administering clysters. A clyster-pipe.

ENTE'RIC. (*Entericus*; from εντερον, the intestine.) Appertaining to the intestines.

ENTERI'TIS. (*is*, *idis*. f.; from εντερον, an intestine.) Inflammation of the intestines. Inflammation may attack any portion of the intestinal canal, and any of the three textures, mucous, muscular, or serous, which enter into its formation. The term enteritis has been most frequently applied to the commonest form of acute inflammation of the intestines, namely, that in which all the three coats are more or less implicated. See *Inflammation of the Stomach and Intestines*.

ENTEROCE'LE. (*e*, *es*. f.; from εντερον, an intestine, and κηλη, a tumour.) An intestinal rupture, or hernia. Every hernia may be so called that is produced by the protrusion of a portion of intestine, whether it is at the groin, navel, or elsewhere.

E'NTERO-EPI'PLOCE'LE. (From εντερον, an intestine, επιπλοον, the omentum, and κηλη, a tumour.) A rupture formed by the protrusion of part of an intestine, with a portion of the omentum.

E'NTERO-EPIPLO'MPHALUS. (From εντερον, an intestine, επιπλοον, the omentum, and ομφαλος, the navel.) A very long word, used to designate an umbilical hernia, in which both intestine and omentum are protruded. Most umbilical herniæ are of this kind.

E'NTERO-GASTROCE'LE. (From εντερον, an intestine, γαστηρ, the belly, and κηλη, a tumour.) An abdominal hernia.

ENTERO'GRAPHY. (*Enterographia*; from εντερον, an intestine, and γραφω, to describe.) The anatomical description of the intestines.

E'NTERO-HYDROCE'LE. (From εντερον, an intestine, ὑδωρ, water, and κηλη, a tumour.) This may be applied either to a common scrotal hernia, with a good deal of water in the hernial sac; or to a congenital hernia (in which the bowels descend into the tunica vaginalis testis), attended with a collection of fluid in the cavity of this membrane.

E'NTERO-HYDRO'MPHALUS. (From εντερον, an intestine, ὑδωρ, water, and ομφαλος, the navel.) An umbilical hernia, containing a portion of intestine and much serosity. This is sometimes the case when umbilical hernia co-exists with ascites, and the hernial sac communicates with the cavity of the abdomen.

E'NTERO-I'SCHIOCE'LE. (From εντερον, an intestine, ισχιον, the ischium, and κηλη, a tumour.) An intestinal hernia at the ischiadic foramen.

ENTERO'LITHUS. (*us*, *i*. m.; from εντερον, an intestine, and λιθος, a stone.) Intestestinal concretion, or calculus. This term embraces all those concretions which resemble stones, generated in the stomach and bowels. Intestinal calculi are common in many of the inferior animals, and they occur also in man, but much less frequently. For an account of the intestinal calculi in animals, see the article *Bezoar*.

The most common kind of intestinal calculi in the human subject are of large size, brown colour, and fibrous texture; they are somewhat soft and spongy to the feel, but yield very little to pressure. It is found that these concretions are formed chiefly of the fibrous matter of oats — a fact first suggested by Mr. Clift, and confirmed by Dr. Wollaston. They seem to be more frequent in Scotland than in England, from the more extensive use of oatmeal in the former country. In Lancashire, where oatmeal is also much used, intestinal calculus appears not to be uncommon. Besides the vegetable matter, these calculi contain albumen, muriate of soda, and phosphates of lime and soda.

Intestinal calculi are sometimes formed in the human intestines of other substances than those above described. The excessive and long-continued use of carbonate of magnesia has caused the formation of large calculi consisting of that substance. Some calculi, brought from Lancashire, were found by Mr. Children to consist of alternate layers of the fibrous matter of the

oat, and the triple phosphate, which is a common ingredient in the intestinal calculi of animals. In some instances the calculus is formed upon a nucleus, as a gall-stone, or the kernel of a fruit. Some intestinal calculi examined by Dr. Marcet consisted of a curdy, or caseous matter.

ENTEROLO'GY. (*Enterologia*, *æ*. f.; from εντερον, an intestine, and λογος, a discourse.) The part of anatomy which treats of the intestines.

E'NTERO-MEROCE'LE. (From εντερον, an intestine, μηρος, the thigh, and κηλη, a tumour.) A femoral hernia.

ENTERO'MPHALUS. (*us*, *i*. m.; from εντερον, an intestine, and ομφαλος, the navel.) An umbilical hernia, produced by the protrusion of a portion of intestine.

E'NTERON. (Εντερον, an intestine, and plural εντερα, the intestines; from εντος, within.) 1. An intestine, or the intestines in general.

2. Hippocrates calls the bag in which medicines for fomentations were formerly enclosed, by this name.

ENTERO'PHYTUM. (*um*, *i*. n.; from εντερον, an intestine, and φυτον, a plant.) A plant which grows in the form of a gut; the sea-chitterling. — *Turton*.

ENTERO'RAPHY. (*Enteroraphia*, *æ*. f.; from εντερον, an intestine, and ραφη, a suture.) A suture of the intestines, or the sewing together the divided edges of an intestine.

E'NTERO'SCHEOCE'LE. (*e*, *es*. f.; from εντερον, an intestine, οσχεον, the scrotum, and κηλη, a rupture.) A scrotal hernia, or descent of the intestines into the scrotum.

E'NTHLASIS. A depressed fracture of the skull. — *Galen*.

ENTHUSIASM. (*Enthusiasmus*; Ενθουσιασμος; from ενθυσιαζω, to rave.) Galen signifies by this term the delirious raving of those who fancy themselves inspired.

Entire. See *Integer*.

ENTOZO'A. (From εντος, within, and ζωον, an animal.) A general name for those parasitical animals which infest the bodies of other animals. The presence of such parasites in the intestinal canal has been known to physicians of all ages as the source of many diseased actions. Among modern nosologists these animals have passed under the name of worms, *vermes*; and the train of symptoms induced by their presence has obtained no proper designation. We therefore hear the expression "a case of worms," used as if the worms were the disease, instead of merely being the irritating cause which produces the disease. The term *vermes*, as applied to the animals in question, is very incorrect in a zoological point of view, as many of them bear no resemblance whatever to what have usually been called worms; and it is still more incorrectly applied as the designation of a disease: we shall therefore include intestinal worms, along with other parasites inhabiting the bodies of animals, under the term *entozoa*, which is unobjectionable, because it has reference merely to their common parasitical nature; and we shall consider the diseased actions to which they give rise under the head *Invermination*, — a term which has lately come into use, and is much preferable to the old one of "worms."

Parasites are found in all classes of animals, even the invertebrate; and many species are peculiar to particular animals: thus man, the horse, the dog, the cat, and other animals, have each their own particular species of tape-worm, which is not found in the rest.

The entozoa of the human body, of which alone it is here necessary to treat, may be divided into those which inhabit only the alimentary canal, and those which are found in other parts.

Of *alvine entozoa* there are two classes: —

First class. This contains those which are generated and nourished in the human intestinal canal, and which there propagate their species.

Second class comprehends those insects or worms that accidentally enter the human primæ viæ *ab externo*, and which never propagate their species in that canal, but are soon eliminated from the body.

The *first class*, from the variety it affords, may be divided into different orders, genera, and species.

Order I. Round worms.

Genus I. Intestinal ascarides.

Character. Body round, head obtuse, and furnished with three vesicles.

Species 1. *Ascaris lumbricoides*. The long round worm, or lumbricoid ascaris. The *Ascaris* of Rudolphi.

Character. When full grown, a foot in length. Mouth triangular.

2. *Ascaris vermicularis*. The thread or maw-worm. The *Oxyuris* of Rudolphi.

Character. When full grown, half an inch in length; tail terminates in a fine point.

Genus II. Intestinal trichurides.

Character. Body round, tail three times the length of the body, head without vesicles.

Species 1. *Trichuris vulgaris*. The trichuris, or long thread-worm. This worm is the *Trichocephalus dispar* of Rudolphi, whose account of the head and tail are probably the most correct.

Character. The head furnished with a proboscis.

Order II. The flat worms.

Genus I. Intestinal tape-worm.

Character. Body flat and jointed.

Species 1. *Tænia osculis marginalibus*. The long tape-worm. The *Tænia solium* of Rudolphi.

Character. The oscula are situated upon the margin of the joints.

2. *Tænia osculis superficialibus*. The broad tape-worm. The *Bothriocephalus latus* of Rudolphi.

Character. The oscula are placed upon the flattened surface.

These worms were all known to the ancients, the trichuris only excepted, and are mentioned in the works of Hippocrates, Galen, Celsus, Paulus Ægineta, and Pliny.

The second class embraces such as do not belong to the human body, but which are by accident carried there. Of these many have been found.

1. The *Fasciola hepatica*, or fluke, a flat worm like a flounder in miniature, of the size of the nail of the little finger. This worm is very common in the bile-ducts of rotten sheep, and in the alvine canal of many animals. It is very rarely found in man.

2. The *Scarabæus*. Several species of this genus have been found in the external openings of the body of man; as the *meatus auditorius externus*, the alvine canal, the rectum, the vagina, &c.

3. The *Œstrus*, a fly, the ovula of which are deposited under the skin in wounds in fetid ulcers, and where the larvæ or maggots produce great mischief.

4. The *Gordius*, or horse-hair worm, which inhabits soft stagnant waters, and is taken into the stomach with the water in many parts of Lapland.

5. The *Hirudo*, or leech, which is taken in the same way.

6. The *Musca*. Several of this genus deposit their eggs in the nose, antra of Highmore, and in the rectum: especially the *Musca carnaria*, or flesh-fly; the *M. vomitoria*, or blow-fly; the *M. cibaria*, or pantry-fly; the *M. putris*, or hopper-fly maggot.

The third class comprehends those animalcules which are found in other parts, as the viscera of the head, thorax, &c., and under the skin. These are,

1. The *Acephalocystis*, or animal hydatid. This very singular animal is formed like a bladder, and distended with an aqueous fluid. These animals are sometimes formed in the natural cavities of the body, as the abdomen and ventricles of the brain, but more frequently in the liver, kidney, and lungs, where they produce diseased actions of those viscera. If the vires naturæ medicatrices are not sufficient to effect a cure, the patient mostly falls a sacrifice to their ravages. Dr. Baillie gives the following interesting account of the hydatids, as they are sometimes found in the liver: — "There is no gland in the human body in which hydatids are so frequently found as the liver, except the kidneys, where they are still more common. Hydatids of the liver are usually found in a cyst, which is frequently of considerable size, and is formed of very firm materials, so as to give to the touch almost the feeling of cartilage. This cyst, when cut into, is obviously laminated, and is much thicker in one liver than another. In some livers it is not thicker than a shilling, and in others it is near a quarter of an inch in thickness. The laminæ which compose it are formed of a white matter, and on the inside there is a lining of a pulpy substance, like the coagulable lymph. The cavity of the cyst I have seen, in one instance, subdivided by a partition of this pulpy substance. In a cyst may be found one hydatid, or a greater number of them. They lie loose in the cavity, swimming in a fluid; or some of them are attached to the side of the cyst. They consist of a round bag, which is composed of a white, semi-opake, pulpy matter, and contain a fluid capable of coagulation. Although the common colour of hydatids be white, yet I have occasionally seen some of a light amber colour. The bag of the hydatid consists of two laminæ, and possesses a good deal of contractile power. In one hydatid this coat, or bag, is much thicker and more opake than in another; and even in the same hydatid, different parts of it will often differ in thickness. On the inside of an hydatid smaller ones are sometimes found, which are commonly not larger than the heads of pins, but sometimes they are even larger in their size than a gooseberry. These are attached to the larger hydatid, either at scattered irregular distances, or so as to form small clusters; and they are also found floating loose in the liquor of the larger hydatids. Hydatids of the liver are often found unconnected with each other; but sometimes they have been said to enclose each other in a series, like pill-boxes. The most common situation of hydatids of the liver is in its substance, and enclosed in a cyst; but they are occasionally attached to the outer surface of the liver, hanging from it, and occupying more or less of the general cavity of the abdomen. The origin and real nature of these hydatids are not fully ascertained; it is extremely probable, however, that they are a sort of imperfect animalcules. There is no doubt at all, that the hydatids in the livers of sheep are animalcules: they have been often seen to move when taken out of the liver and put into warm water; and they retain this power of motion for a good many hours after a sheep has been killed. The analogy is great between hydatids in the liver of a sheep and those of the human subject. In both they are contained in strong cysts, and in both they consist of the same white pulpy matter. There is undoubtedly some difference between them in simplicity of organisation; the hydatid in the human liver being a simple uniform bag, and the hydatid in that of a sheep having a neck and mouth appendant to the bag. This difference need be no considerable objection to the opinion above stated. Life may be conceived to be attached to the most simple form of organisation. In proof of this, hydatids have been found in the brains of sheep resembling almost exactly those in the human liver, and which have been seen to move, and therefore are certainly known to be animalcules. The hydatids of the human liver, indeed, have not, as far as I know, been found to move when taken out of the body and put into warm water: were this to have happened, no uncertainty would remain. It is not difficult to see a good reason why there will hardly occur any proper opportunity of making this experiment. Hydatids are not very often found in the liver, because it is not a very frequent disease there; and the body is allowed to remain for so long a time after death before it is examined, that the hydatids must have lost their living principle, even if there were animalcules, and it appears even more difficult to account for their production, according to the common theory of generation, than for that of intestinal worms. We do not get rid of the difficulty by asserting that the hydatids in the human liver are not living animals, because in sheep they are certainly such,

where the difficulty of accounting for their production is precisely the same."

2. The *Cysticercus*, or bladder-tail hydatid. See *Cysticercus*.

3. The *Polycephalus*, or many-headed worm. See *Polycephalus*.

4. The *Echino-coccus*. See *Echino-coccus*.

5. The *Filaria medinensis*, or Guinea worm. See *Filaria*.

6. The *Acarus* of the itch. See *Scabies*.

With respect to those entozoa, the origin of which cannot be traced from without, it has been supposed by some that they are produced by a spontaneous or equivocal generation within the body of the animal they inhabit; by others, that they have really been accidentally introduced from without, but so metamorphosed by the peculiarities of their parasitical life that they can no longer be identified with the species to which they originally belonged; by others, that the ova of these entozoary animals are transmitted from one individual to another of the same or different species, and from the parents to the offspring in the same species, the ova becoming evolved whenever they meet with a favourable nidus. The two latter hypotheses are extremely improbable, and ill supported by facts; and we must, for the present, rest contented with the supposition that these singular beings originate in the animal in which they are found — how or wherefore it is impossible to form the smallest notion. As to the hereditary tendency to the formation of worms, it throws no more light on their origin than an hereditary tendency to gout or scrofula throws light on the origin of those diseases.

The symptoms arising from the presence of entozoary animals in the intestines, and the treatment required for their removal, will be found under the head *Invermination*.

ENTRO'PIUM. (*um*, *i*. n.; from εν, and τρεπω, to turn.) A disease of the eyelids, in which the eyelashes and eyelid are inverted towards the bulb of the eye.

ENTYPO'SIS. (Εντυπωσις; from εντυποω, to make an impression.) The glenoid cavity of the scapula. — *Gorrhæus*.

E'NULA. (*a*, *æ*. f.; a corruption of *Helenium*.) See *Inula helenium*.

Enula campana. See *Inula helenium*.

ENU'LON. Ενουλον. The Greek name for the substance of the gums inside the teeth; that on the outside being called ουλον, and that between the teeth ἁρμος.

ENURE'SIS. (*is*, *is*. f.; from ενουρεω, to make water.) An incontinency or involuntary flow of urine. This disease usually proceeds either from relaxation or a paralytic affection of the sphincter of the bladder, induced by various debilitating causes, as too free a use of spirituous liquors, manustupration, and excess in venery; or it arises from compression on the bladder, from a diseased state of the organ, or from some irritating substance contained in its cavity. Dr. Cullen makes two species: — 1. *Enuresis atonica*, the sphincter of the bladder having lost its tone from some previous disease.

2. *Enuresis ab irritatione, vel compressione vesicæ*, from an irritation or compression of the bladder. It is often cured by the internal exhibition of the tinctura cantharidis, by tonics, and by stimulating the rectum with aloetic suppositories: blisters to the perinæum are also serviceable. When symptomatic of stone, or any other disease, it requires the remedies for such complaint.

E'ON. Ηων. A shore or bank. The circumference of the orbits of the eyes was so named. — *Julius Pollux*.

EPACMA'STICOS. (Επακμαστικος; from επακμαζω, to grow vigorous.) Applied by the Greeks to a fever which gradually increases in severity till it arrives at the crisis. — Compare *Acmasticos*.

EPA'CME. (Επακμη; from επακμαζω, to increase.) The increase, or exacerbation of a disease.

EPAGO'GIUM. (Επαγωγιον; from επαγω, to cover.) The præpuce.

EPANADIPLO'SIS. (Επαναδιπλωσις; from επαναδιπλοω, to reduplicate.) Reduplication: applied to the return of the cold fit of an ague before the hot fit is ended.

EPANA'STASIS. (Επαναστασις; from επανιστημι, to excite, to erect.) A tubercle, or small pustule. — *Hippocrates*.

EPANCYLO'TUS. (Επαγκυλωτος; from επι, and αγκυλος, crooked.) A sort of serpentine bandage.

EPANE'TUS. (From επανιημι, to remit.) A generic term applied by Dr. Mason Good to remittent fevers.

EPAPHÆ'RESIS. Επαφαιρεσις. A Greek term signifying repeated evacuation, and especially that of blood.

EPA'RMA. (From επαιρω, to elevate.) *Eparsis*. A tumour of any part. It has usually been more especially applied to a tumour of the parotid gland — according to Blancard, "*eo quod aures hoc vitio eriguntur*." With the Greek writers it seems merely to mean a tumour.

Eparsis. See *Eparma*.

EPE'NCRANIS. (Επεγκρανις; from επι, εν, in, and κρανιον, the skull.) The name given by Erisistratus to the cerebellum. — *Galen*.

EPHEBÆ'UM. (Εφηβαιον; from επι, and ηβη, the groin.) The parts above the pubes.

E'PHEDRA. (From εφεζομαι, to sit upon.) *Ephedrana*. 1. The buttocks.

2. A species of horse-tail.

Ephe'drana. See *Ephedra*.

EPHE'LCIS. (From επι, upon, and ελκος, an ulcer.) 1. The crust of an ulcer.

2. Hardened purulent expectoration.

EPHE'LIS. (*is*, *idos*. f.; from επι, and ἡλιος, the sun.) This term denotes not only the freckles, or little yellow lentigines or spots, which appear on persons of fair skin, and the larger brown patches, which likewise arise from exposure to the direct rays of the sun, as the name imports; but also those large dusky patches, which are very similar in appearance, but occur on other parts of the surface which are constantly covered. The best applications to such blemishes are very dilute alkohol, mineral acids, and potash, — so dilute as just to be sensible to the tongue.

EPHE'MERA. (*a, æ.* f.; from επι, upon, and ημερα, a day.) A fever of a day's duration.

EPHE'MERIS. (*is, idis.* f.; from εφημερις, an almanack: so called because, like the moon's age, it may be foretold by the almanack.) Van Helmont thus names any disease, the return of which is determined by the movements of the moon or stars.

EPHE'SIUM EMPLA'STRUM. A stimulating plaster described by Celsus, and recommended to be applied to bites.

EPHIA'LTES. (*es, is.* m.; from εφαλλομαι, to leap upon: so called because it was thought a dæmon leaped upon the chest.) Night-mare. Distressing sensations during sleep, mostly preceded by a fearful dream, in which some known or unknown enemy is in close pursuit, and from whom the person who is affected cannot escape, and is unable to speak, though he is constantly endeavouring so to do: in this struggle a great oppression or weight is felt on the chest, as if some dæmon were sitting upon the patient, who attempts to cry out, but makes only a horrible noise: he fancies that he is falling down precipices, and is threatened with destruction by wild beasts, monsters, and divers indescribable apparitions. The causes of this affection are mental irritation from fatigue, and a dyspeptic state of the stomach.

It sometimes arises from flatulence, caused by indigestible matter in the stomach, after too heavy a supper; which, pressing the stomach against the diaphragm, impedes respiration, or renders it short and convulsed. Inflated intestines may likewise produce similar effects, or mental perturbations.

There is another species of night-mare mentioned by authors, which has a more dangerous tendency; and this arises from an impeded circulation of blood in the lungs, when lying down, or too great relaxation of the heart and its impelling powers. Epilepsy, apoplexy, or sudden death, are sometimes among the consequences of this species of disturbed sleep.

EPHIA'LTIA. (From *ephialtes*, the night-mare: so called because it was said to cure the night-mare.) The herb peony.

EPHIDRO'SIS. (*is, is.* f.; from εφιδροω, to perspire.) A violent and morbid perspiration.

EPHI'PPIUM. (*um, ii.* n. A saddle, which it is thought to resemble.) See *Sella turcica.*

E'PHODOS. (Εφοδος; from επι, and οδος, a way.) In Hippocrates it hath three significations: — 1. The ducts or passages, by which the excrements of the body are evacuated.

2. The periodical attack of a fever, from the common use of it to express a hostile incursion.

3. The access of similar or dissimilar things, which may be useful or hurtful to the body.

Epia'ltes. See *Ephialtes.*

EPI'ALOS. (From ηπιον, gently, and αλεαζω, to heat.) The name given by the Greeks to a fever in which the morbid sensation of heat is accompanied with irregular shiverings. The Latin writers call it *Quercera.*

EPICA'NTHIS. (From επι, and κανθος, the angle of the eye.) The angle of the eye.

EPICA'RPIUM. (Επικαρπιον; from επι, upon, and καρπος, the wrist.) A medicament in the form of a plaster or cataplasm, applied to the wrist. Such applications, of various composition, were anciently used with a view of affecting the pulse. They were employed in intermittent fever, in cases of great debility, convulsions, &c.

EPICA'RPIUM. (From επι, upon, and καρπος, fruit.) The outer covering or skin of a fruit is thus called by M. Richard.

EPICA'UMA. (From επι, and καιω, to burn.) The same as *encauma.*

EPI'CERAS. (*as, atis.* n.; επικερας; from επι, and κερας, a horn: so called because its pods are shaped like a horn.) See *Trigonella fœnum græcum.*

EPICERA'STICUS. (From επι, and κεραννυμι, to mix.) Applied to medicines which obtund acrimony of the humours.

EPI'CHOLUS. (Επιχολος; from επι, and χολη, the bile.) Bilious.

EPICHO'RDIS. (Επιχορδις; from επι, upon, and χορδη, a gut.) The mesentery.

EPICHO'RION. (From επι, upon, and χωριον, the chorion.) The *tunica decidua uteri* is thus named by M. Chaussier.

EPICHO'RIOS. (From επι, and χωρα, a region.) The same as *enchorios.*

EPICHRO'SIS. (*is, is.* f. επιχροσις; from επιχρωζω, to tinge superficially.) Mason Good applies this term to maculæ on the skin.

E'PICLINE. (*Epiclinus*; from επι, upon, and κλινη, a bed.) An adjective term, applied by Mirbel to the nectary when it is placed on the receptacle of the flower.

EPICŒ'LIS. (From επι, upon, and κοιλις, the eyelid.) The margin of the eyelid, or the eyelashes; synonymous with *cilium.*

EPICO'LIC. (*Epicolicus*; from επι, upon, and κωλον, the colon.) That part of the surface of the abdomen which lies over the colon on each side was named by Glisson the epicolic region.

EPICO'NDYLE. (*Epicondylus*; from επι, upon, and κονδυλος, a condyle.) Chaussier gives this name to the protuberance at the outer side of the distal extremity of the humerus, from which the extensor and supinator muscles of the forearm and hand rise by a common tendon.

EPICO'NDYLO-CUBITA'LIS. Chaussier's name for the anconeus muscle.

EPICO'NDYLO-RADIA'LIS. The *supinator radii brevis.*

EPICO'NDYLO-SU'PRA-METACARPIA'NUS. The *extensor carpi radialis brevior.*

EPICO'NDYLO-SU'PRA-PHALENGE'TTIANUS COMMUNIS. The *extensor digitorum communis.*

EPICO'NDYLO-SU'PRA-PHALANGETTIA'NUS MINIMI DIGITI. The *extensor proprius minimi digiti.*

EPICOPHO'SIS. (From επι, and κωφος, deaf.) The same as *cophosis*; deafness. Castelli says that it applies more particularly to deafness supervening in the course of another disease.

EPICRA'NIUM. (*um, i.* n.; from επι,

and κρανιον, the cranium.) This term is most usually applied to the tendinous expansion of the occipito-frontalis muscle; but some writers apply it to the skin of the head, and others to the whole of the soft parts which form the scalp.

Epicra'nius. See *Occipito frontalis.*

EPI'CRASIS. (From επι, and κεραννυμι, to temper.) A critical evacuation of bad humours. When a cure is performed in the alterative way, it is called *per Epicrasin.*

EPICTE'NIUM. (From επι, about, and κτεις, the pubes.) The parts above and about the pubes.

EPICYE'MA. (From επι, upon, and κυω, to conceive.) *Epicyesis.* Superfœtation.

Epicye'sis. See *Epicyema.*

EPIDE'MIC. (*Epidemicus;* from επι, upon, and δημος, the people.) Applied to a disease which attacks a multitude of persons at the same time and in the same place. Epidemic diseases may arise from contagion or from some atmospheric cause, or from both combined, which last is probably the case in most instances.

EPI'DEMY. (Same etymon.) An epidemic disease. The word epidemic is sometimes improperly used for this; *epidemic* is an adjective term.

EPIDE'NDRUM. (*um, i.* n.; from επι, upon, and δενδρον, a tree: because all this genus of plants grow parasitically on the trunks or branches of trees.) The name of a genus of plants in the Linnæan system. Class, *Gynandria;* Order, *Monandria.*

EPIDENDRUM VANILLA. The systematic name of the vanelloe plant; called also, *Vanilla, Banilia, Banilas,* and *Aracus aromaticus.*

Epidendrum — scandens, foliis ovato oblongis nervosis sessilibus caulinis, cirrhis spiralibus, of Linnæus. The vanelloe is a long flattish pod, containing, under a wrinkled brittle shell, a reddish brown pulp, with small shining black seeds, which have an unctuous aromatic taste, and a fragrant smell, like that of some of the finer balsams heightened with musk. Although chiefly used as perfumes, they are said to possess aphrodisiac virtues.

EPI'DERIS. (Επιδερις; from επι, and δερας, the skin.) The clitoris.

EPIDE'RMIC. (*Epidermicus;* from επιδερμις, the scarf skin.) Relating to the epidermis.

EPIDE'RMIS. (*is, idis.* f. Επιδερμις; from επι, upon, and δερμα, the skin.) The scarf skin, or cuticle of an animal or plant. See *Cutis,* and *Bark.*

EPIDE'RMOID. (From επιδερμις, and ειδος, resemblance.) Resembling the epidermis. This word, though introduced by Bichat, and in general use, is ill constructed. It should be *epidermatoid.* Compare *Dermatoid.*

EPI'DESIS. (From επι, upon, and δεω, to bind.) The arresting of a discharge of blood by means of a bandage.

EPIDE'SMUS. (From επι, upon, and δεω, to bind.) A bandage by which splints, bolsters, &c. are secured.

EPIDI'DYMIS. (*is, is.* m.; from επι, upon, and διδυμος, a testicle.) A hard, vascular, oblong substance, that lies upon the testicle, formed of a convolution of the *vas deferens.* It has a thick end, which is convex, and situated posteriorly; and a thin end, which is rather flat, and situated inferiorly. The epididymis adheres to the testicle by its two extremities only, for its middle part is free, and the tunica vaginalis dips between it and the testicle, forming a little pouch.

EPI'DOSIS. (Επιδοσις; from επιδιδωμι, to grow upon.) The Greek writers use this word to signify either the natural growth of the body, or the increase of a disease. Sagar, in his Nosological System, applies this term to the preternatural magnitude of any part without disease, as of the ears, penis, &c.

EPI'DROME. (From επιδρεμω, to run upon.) An afflux of humours.

EPIGA'STRIC. (*Epigastricus;* from επι, upon, or above, and γαστηρ, the stomach.) Appertaining to the *epigastrium.*

EPIGASTRIC ARTERY. A branch given off by the external iliac artery just where it passes under Poupart's ligament. The epigastric artery, having made a curve downwards towards the ligament, ascends first between the rectus muscle and the peritoneum, and then within the sheath of the rectus. It inosculates with the internal mammary. The epigastric artery is an important object in the surgical anatomy of inguinal and crural hernia.

Epigastric region. See *Abdomen.*

EPIGA'STRIUM. (*um, i.* n.; from επι, upon, or above, and γαστηρ, the belly.) The part immediately over the stomach.

EPIGASTROCE'LE. This term has been applied to abdominal herniæ, situated at or near the epigastrium. The word should have been *epigastriocele.*

EPIGENE'MA. (From επιγινομαι, to generate upon.) The same as *epiginomenon.* See *Epiginomena.*

EPIGE'NESIS. (Επιγενεσις; from επιγινομαι, to generate upon.) A name given to that theory of generation which consists in regarding the fœtus as the joint production of matter afforded by both sexes. This use of the term is of modern origin: with the Greek writers it is only used synonymously with *epigenema.*

EPIGINO'MENA. (Επιγινομενα; from επιγινομαι, to succeed or supervene.) Adventitious symptoms occurring in the course of a disease, but not necessarily connected with it.

EPIGLO'SSUM. (*um, i.* n.; from επι, upon, and γλωσσα, the tongue: so called because a lesser leaf grows above the larger in the shape of a tongue.) The Alexandrian laurel. See *Ruscus hypoglossum.*

EPIGLOTTIC GLAND. *Periglottis. Caro glandulosa.* A collection of minute glands situated at the base of the anterior surface of the epiglottis.

EPIGLOTTICUS. Relating to the *epiglottis.*

EPIGLO'TTIS. (*is, idis.* or *is, is.* f.; from επι, upon, and γλωττις, the tongue.) The cartilage at the root of the tongue that falls upon the glottis, or superior opening of the larynx.

Its figure is nearly oval; it is concave posteriorly, and convex anteriorly. Its apex, or superior extremity, is loose; and is always elevated upwards by its own elasticity. While the back of the tongue is drawn backwards in swallowing, the epiglottis is put over the aperture of the larynx: hence it shuts up the passage from the mouth into the larynx. The base of the epiglottis is fixed to the thyroid cartilage, the os hyoides, and the base of the tongue, by a strong ligament.

Epiglo'ttum. (*um*, *i.* n.; from επιγλωττις, the epiglottis, which it resembles in shape.) An instrument mentioned by Paracelsus for elevating the eyelids.

Epiglou'tis. (From επι, upon, and γλουτος, the buttocks.) The superior parts of the buttocks.

Epigo'natis. (From επι, upon, and γονυ, the knee.) The patella, or knee-pan.

Epigo'nides. (From επι, and γονυ, the knee.) About the knees: formerly applied to the muscles inserted into the knees.

Epi'gonum. (Επιγωνον; from επιγινομαι, to succeed; to be produced in addition to something else.) A superfœtation.

Epila'mpsis. The same as *eclampsis*.

Epilempsis. See *Epilepsy*.

E'PILEPSY. (*Epilepsia*, *æ.* f. Επιληψια; from επιλαμβανω, to seize upon: so called from the suddenness of its attack.) *Morbus comitialis*. *Morbus sacer*. *Morbus caducus*. The disease vulgarly called falling sickness, from the patient, when attacked, suddenly falling to the ground. It consists of convulsions, with coma, and usually foaming at the mouth. Cullen divides the disease into three species: —

1. *Epilepsia cerebralis;* attacking suddenly, without manifest cause, and not preceded by any unpleasant sensation, unless, perhaps, some giddiness or dimness of sight.

2. *Epilepsia sympathica;* without manifest cause, but preceded by a sensation of an aura ascending from some part of the body to the head.

3. *Epilepsia occasionalis;* arising from manifest irritation, and ceasing on the removal of this. It comprehends several varieties: —

E. traumatica, arising from an injury of the head.

E. à dolore, from pain.

E. verminosa, from the irritation of worms.

E. à veneno, from poisons.

E. exanthematica, from the repulsion of cutaneous eruptions.

E. à cruditate ventriculi, from crudities of the stomach.

E. ab inanitione, from debility.

E. uterina, from hysterical affections.

E. ex onanismo, from onanism, &c.

This disease attacks by fits, and, after a certain duration, goes off, leaving the person most commonly in his usual state: but sometimes a considerable degree of stupor and weakness remain behind, particularly where the disease has frequent recurrences. It is oftener met with among children than grown persons, and boys seem more subject to its attacks than girls. Its returns are periodical, and its paroxysms commence more frequently in the night than in the day, being somewhat connected with sleep. It is sometimes counterfeited, in order to extort charity or excite compassion.

Epilepsy is properly distinguished into idiopathic and sympathetic. It is often manifestly sympathetic, and dependent upon some other affection, such as acidities in the stomach, worms, teething, &c.; but it also appears very frequently as an idiopathic, or primary disease, neither dependent on, nor proceeding from, any other.

The causes which give rise to epilepsy are blows, wounds, fractures, and other injuries done to the head by external violence, together with lodgments of water in the brain, tumours, concretions, and polypi. Violent affections of the nervous system, sudden frights, fits of passion, great emotions of the mind, acute pains in any part, worms in the stomach or intestines, teething, the suppression of long-accustomed evacuations, too great emptiness or repletion, and poisons received into the body, are causes which likewise produce epilepsy. Sometimes it is hereditary, and at others it depends on a predisposition, arising from mobility of the sensorium, occasioned either by plethora, or a state of debility.

An attack of epilepsy is now and then preceded by a heavy pain in the head, dimness of sight, noise in the ears, palpitations, flatulency in the stomach and intestines, weariness, and a small degree of stupor, and, in some cases, there prevails a sense of something like a cold vapour or *aura*, proceeding from some part of the body towards the head, and well known under the name of *aura epileptica;* but it more generally happens that the patient falls down suddenly without much previous notice; his eyes are distorted, or turned so that only the whites of them can be seen; his fingers are closely clinched, and the trunk of his body, particularly on one side, is much agitated; he foams at the mouth, and thrusts out his tongue, which often suffers great injury from the muscles of the lower jaw being affected; he loses all sense of feeling, and not unfrequently voids both urine and fæces involuntarily. The spasms abating, he recovers gradually; but, on coming to himself, feels languid and exhausted, and retains not the smallest recollection of what has passed during the fit.

When the disease arises from an hereditary disposition, or comes on after the age of puberty, or where the fits recur frequently, and are of long duration, it will be very difficult to effect a cure; but when its attacks are at an early age, and occasioned by worms, or any accidental cause, it frequently yields to judicious treatment. In some cases, it has been entirely carried off by the occurrence of a fever, or by the appearance of a cutaneous eruption. It has been known to terminate in apoplexy, and in some instances to produce a loss of the powers of the mind, and to bring on idiotism.

Morbid anatomy has hitherto thrown no light on the proximate cause of epilepsy. A vast variety of morbid appearances within the cranium and spinal canal have been recorded and

insisted on by different authors as the cause of the disease. There is some organic lesion of these parts in a large proportion of cases; but since there is no uniformity in the nature of such lesion, and since, in many cases, there are no morbid appearances at all, it is fair to infer that none of those hitherto observed have any essential relation to the disorder.

During the epileptic paroxysm in general, little or nothing is to be done, except using precautions that the patient may not injure himself; and it will be prudent to remove any thing which may compress the veins of the neck, to obviate congestion in the head. Should there be a considerable determination of blood to this part, or the patient be very plethoric, it may be proper, if you can keep him steady, to open a vein, or the temporal artery; and, in weakly constitutions, the most powerful antispasmodics might be tried in the form of clyster, as they could hardly be swallowed; but there is very seldom time for such measures. In the intervals the treatment consists: 1. In obviating the several exciting causes. 2. In correcting any observable predisposition. 3. In the use of those means which are most likely to break through the habit of recurrence.

I. The manner of fulfilling the first indication requires little explanation: after an injury of the head, or where there is disease of the bone, an operation may be necessary, to remove irritation from the brain; in children teething, the gums ought to be lanced; where the bowels are foul, or worms suspected, active purgatives should be exhibited, &c. In those instances, in which the aura epileptica is perceived, it has been recommended to destroy the part where it originates, or divide the nerve going to it, or correct the morbid action by a blister, &c.; such means would certainly be proper when there is any disease discoverable in it. Making a tight ligature on the limb above has sometimes prevented a fit; but, perhaps, only through the medium of the imagination.

II. Where a plethoric state appears to lay the foundation of the disease, which is often the case, the patient must be restricted to a low diet, frequent purges exhibited, and the other excretions kept up; and he should take regular moderate exercise, avoiding whatever may determine the blood to the head; and, to counteract such a tendency, occasional cupping, blisters, issues, &c. may be useful, as well as the shower-bath; but, in urgent circumstances, the lancet ought to be freely used. If, on the contrary, there are marks of inanition and debility, a generous diet, with tonic medicines, and other means of strengthening the system, will be proper. The vegetable tonics have not been so successful in this disease as the metallic preparations, particularly the sulphate of zinc, the nitrate of silver, and the ammoniated copper; but the last cannot, perhaps, be so safely persevered in: where the patient is remarkably exsanguious, chalybeates may answer better; and, in obstinate cases, the arsenical solution might have a cautious trial. In irritable constitutions, sedatives are indicated, as digitalis, opium, &c.; but the free use of opium is restricted by a tendency to congestion in the head. Where syphilis appears to be concerned, a course of mercury is proper; in scrofulous habits, bark, or steel, with iodine, soda, and sea-bathing; and so on.

III. The third division of remedies comes especially in use, where the fits are frequent, or where their recurrence can be anticipated: emetics will often prevent them, or a full dose of opium; also other powerful antispasmodics, as ether, musk, valerian, &c.; or strong odours, and, in short, any thing producing a considerable impression on the system. Bark taken largely might perhaps be more successful on this principle. The disease has sometimes been cured, especially when originating from sympathy, by inspiring fear or horror; and many frivolous charms may, no doubt, have taken effect through the medium of the imagination. Also, long voyages have removed it, which might especially be hoped for at the age of puberty, particularly if a considerable change in the mode of life were made in other respects; those who had lived indolently being obliged to exert themselves, the diet properly adapted to the state of the system, &c.

On these several plans, the following observations should be attended to: — Colocynth, croton oil, gamboge, sulphates of soda and magnesia, with senna and calomel, are the best purgatives; and, where worms are suspected, rectified oil of turpentine: which has also been found serviceable, in small doses, against epilepsy excited by other causes. When the purgative plan is determined on, whatever medicine may be selected, it will be necessary to give an active dose about twice a week. Many practitioners have found purgatives of great benefit; and the good appears to have resulted from removing, by their use, some visceral congestion. The bug agaric, *Amanita muscaria*, was once used as a purgative against epilepsy; but, in the present day, it is never thought of.

The *emetic* plan consists in giving the sulphate of zinc, or ipecacuanha, in effective doses early in the morning, when the stomach is empty, twice a week. De Haen gave a vomit every day, for a week or fortnight. In some, but few cases, this operation has emulged the liver, and seemed in this way to have contributed with other means to remove the disease; but, in the generality, it has not done any good.

Sedatives and *tonics* are now very universally given, with a view of overcoming the irritability of the nervous system. Of these medicines, opium, conium, musk, camphor, valerian, hyosciamus, stramonium, and oleum cajeputæ, are selected in their turn, and given first singly, in full doses, and where they fail, which they too often do, in combination. The stramonium, a few years since, cured several patients at Stockholm, under the direction of Dr. Odhelius, who gave the extract and powder in pills. In this country it has not answered. The *viscus quercinus*, or misletoe of the oak, was at one time highly extolled, as a specific against epilepsy. It was exhibited in full doses, from one to two drachms of the powder of the fruit

three times a day, in any carminative distilled water, as peppermint or caraway. This remedy is now discarded. Peruvian bark, orange-peel, and orange-flowers, are to be given in full doses. From five to ten grains of the sulphate of quinine, with infusions of orange-peel or flowers, three times a day. Of less efficacy are cascarilla and the bitters. The metallic tonics are in very general use, especially preparations of steel, zinc, copper, arsenic, mercury, and silver. Mercury has been tried in almost every form, as an alterative, purgative, and sialagogue; but no essential benefit has resulted, except from the removal of some local disease. The sulphate of zinc is to be given in doses of from one to ten grains, three times a day: it is thought well of by many practitioners. If no good results from it when given alone, Peruvian bark, cascarilla, and other tonics, may also be given at the same time; and if they fail, the sedatives in their turn. The oxide of zinc, in the dose of from five to ten grains three times a day, frequently mitigates the violence of the fits, and renders them less frequent: it may, also, be given with other tonics and sedatives. Arsenite of potash has occasionally been found serviceable in the dose of from eight to twelve minims of the liquor arsenicalis, three times a day. The cuprum ammoniatum has been found not only to diminish the frequency of epilepsy, but also, in several instances, to effect a radical cure. The *pilula ammoniureti cupri*, of the Edinburgh pharmacopœia, is a good formula for its exhibition: each of these pills contains half a grain of the ammoniated copper, and one pill may be given for a dose night and morning at first, and the dose gradually increased to four or five of the pills. The nitrate of silver has been given in the dose of from one grain to two or three, in pill or solution, every six hours, in some cases with decided benefit; but, like all the other medicines, in most cases without any advantage; and there is one singular effect of this medicine, which is so frequent as almost to prevent its exhibition, namely, that of giving a livid or blue colour to the skin, which in some cases disappears in a year or two, but in others is permanent. See *Argenti nitras*. The best preparations of steel are the compound mixture of the pharmacopœias of its sulphate with an alkali; the peroxide; the sulphate; and a solution of the muriate in ether.

EPILEPTIC. *Epilepticus*. Affected with epilepsy, or of the nature of epilepsy; thus we speak of an epileptic patient, and an epileptic fit. Some authors also speak of an *epileptic medicine*, but improperly: it should be *antepileptic*.

Epime'lis. (Επιμηλις; from επι, near to, and μηλον, an apple-tree: because the plant grows near apple-trees.) By this name Galen is supposed to designate the *Arbutus unedo*, and Dioscorides the *Mespilus Germanica*.

Epi'mylis. (Επιμυλις; from επι, and μυλη, the knee.) The patella, or knee-pan.

Epino'tium. (Επινωτιον; from επι, upon, and νωτος, the back.) The shoulder-blade.

EPINY'CTIDES. (Επινυκτιδες; from επι, and νυξ, night.) Vesicles rising during the night and disappearing in the morning. A fugacious kind of nettle-rash.

Epiparoxy'smus. (From επι, upon, and παροξυσμος, a paroxysm.) The febrile paroxysm occurring with unusual frequency.

Epipa'stum. (Επιπαστον; from επιπασσω, to sprinkle upon.) A pulverulent medicine to be sprinkled upon any part.

Epipe'talous. *Epipetalus*. A term applied by botanists to stamina, or to glands which are attached to the corolla of a flower. The stamina of the labiated plants are epipetalous.

Epiphlogi'sma. (From επι, and φλογιζω, to inflame.) A burning heat of any part.

EPI'PHORA. (*a*, *æ*. f.; επιφορα, from επιφερω, to carry forcibly.) The watery eye. An involuntary flow of tears. A superabundant flow of a serous humour from the eyes. The humour which flows very copiously from the eye in epiphora, appears to be furnished, not only by the lachrymal gland, but from the whole surface of the conjunctive membrane, Meibomius's glands, and the caruncula lachrymalis; which increased and morbid secretion may be induced from any stimulus seated between the globe of the eye and lids, as sand, acrid fumes, and the like; or it may arise from the stimulus of active inflammation; or from the acrimony of scrofula, measles, small-pox, &c.; or from general relaxation. The disease may also arise from a more copious secretion of tears than the puncta lachrymalia can absorb, or, as is most common, from an obstruction in the lachrymal canal, in consequence of which the tears are prevented from passing freely from the eye into the nose.

EPIPHRA'GMA. (*a*, *atis*. n.; from επι, upon, and φραγμα, a partition.) The slender membrane which sometimes shuts the peristoma of mosses, as is seen in *Polytrichum*.

Epiphy'lla. (From επι, upon, and φυλλον, a leaf.) The parasitical funguses which grow on the leaves of other plants are so called.

Epiphyllospe'rmæ. (From επι, upon, φυλλον, a leaf, and σπερμα, a seed.) A name given by Haller to those cryptogamic plants which have the reproductive organs on the back of the leaf, as ferns, asplenia, &c.

EPI'PHYSIS. (*is*, *is*. f.; from επι, upon, and φυω, to grow.) A portion of bone growing upon another, but separated from it by a cartilage. All the long bones, and many others, have epiphyses until the end of the juvenile period of life. See *Os*.

Epi'phyta. Parasitical funguses which grow on other plants, dead or living.

Epipi'gma. Επιπιγμα. A surgical apparatus in the shape of the letter Π, used for the reduction of a luxated humerus. — *Oribasius*.

Epipla'sma. (From επιπλασσω, to spread upon.) 1. A poultice.

2. A preparation made by boiling wheat meal in hydrelæum. It was applied to wounds. — *Galen*.

EPIPLOCE'LE. (*e*, *es*. f.; from επιπλοον, the omentum, and κηλη, a tumour.) An omental hernia. A rupture produced by the protrusion of a portion of the omentum. See *Hernia*.

EPI'PLOIC. (*Epiploicus*; from επιπλοον, the omentum.) Appertaining to the epiploon or omentum.

EPIPLOIC ARTERIES. *Arteriæ epiploicæ.* Branches of the gastro-epiploic artery distributed to the omentum.

EPIPLOI'TIS. (*is, idis.* f.; from επιπλοον, the omentum.) Inflammation of the epiploon or omentum. See *Peritonitis.*

EPI'PLOI'SCHIOCE'LE. (From επιπλοον, the omentum, ισχιον, the ischium, and κηλη, a tumour.) An omental hernia protruding through the ischiadic foramen.

EPI'PLOMEROCE'LE. (From επιπλοον, the omentum, μηρος, the thigh, and κηλη, a tumour.) A femoral hernia formed by the omentum.

EPIPLO'MPHALON. (From επιπλοον, the omentum, and ομφαλος, the navel.) An omental hernia situated at the navel.

Epiploomphalon. See *Epiplomphalon.*

EPI'PLOON. (*on, i.* n.; from επιπλοω, to sail over, because it floats, as it were, upon the intestines.) A duplicature of the peritonæum, otherwise called the *omentum.* See *Omentum.*

EPIPLOSCHEOCE'LE. (*e, es.* f.; from επιπλοον, the omentum, οσχεον, the scrotum, and κηλη, a tumour.) A rupture in which the omentum descends into the scrotum.

EPIPO'LASIS. (Επιπολασις; from επιπολαζω, to swim on the top.) 1. A fluctuation of humours.

2. A species of chemical sublimation. See *Ruland. Lexicon Alchemiæ.*

EPIPO'MA. The same with *epipigma.*

EPIPORO'MA. (Επιπιρωμα; from επιπωρεω, to harden.) A hard tumour about the joints.

EPISARCI'DIUM. (*um, i.* n.; Επισαρκιδιον; from επι, upon, and σαρξ, the flesh.) Synonymous with *anasarca.*

EPI'SCHESIS. (Επισχεσις; from επισχεω, to restrain.) A suppression of excretions.

EPISCHESES. An order in the class *Locales* of Cullen's Nosology, including diseases which arise from the suppression of excretions.

EPI'SCHIUM. (*um, i.* n.; επισχιον; from επι, upon, and ισχιον, the hip-bone.) The os pubis.

EPISCOPA'LES VA'LVULÆ. The mitral valves have been so called from their resemblance to the mitre of a bishop, επισκοπος.

EPISEI'ON. Επισειον. Επισιον. The pubes. — *Hippocrates.*

EPISPA'DIA. (From επι, upon, and σπαω, to draw.) This name, not particularly significant, has been given to that malformation of the urethra in which it opens on the dorsum of the penis. The word does not exist in the Greek, but is formed analogically in the same manner as *hypospadia.* See *Hypospadia.*

EPISPA'STIC. (*Epispasticus*; from επισπαω, to draw.) A term applied to those substances which have the power of inflaming the skin and causing an effusion of serum under the cuticle. Synonymous with *vesicatory.* See *Vesicatorium.*

EPISPE'RMA. (From επι, upon, and σπερμα, a seed.) M. Richard gives this name to the outer envelope of a seed.

EPISPHÆ'RIA. (From επι, and σφαιρα, a sphere: so called from the spherical shape of the brain.) The convolutions of the brain have been so called.

EPISTA'GMOS. (Επισταγμος; from επσταζω, to drop or trickle.) According to Schneider, Dioscorides uses this word for a catarrh.

EPISTAPHYLI'NUS. (From επι, and σταφυλη, the uvula.) An epithet of the *azygos uvulæ muscle.*

EPI'STASIS. (Επιστασις.) Hippocrates uses this word in the same sense as επισχεσις, a suppression of any kind; but in the writings of the Greek physicians generally it signifies any matter that is suspended near the surface of the urine, as opposed to υποστασις, *hypostasis,* the sediment.

EPISTA'XIS. (*is, is.* f.; from επισταζω, to distil from.) Bleeding at the nose.

This is very frequent in young persons of a plethoric habit. Females are less subject to it than males, especially after the age of puberty. It often appears, however, in girls as a vicarious discharge when the menses are suppressed. When it occurs in advanced life it is symptomatic of vascular turgescence in the head, and is a common precursor of apoplexy.

Epistaxis comes on at times without any previous warning; but at others, it is preceded by a pain and heaviness in the head, flushing in the face, heat and itching in the nostrils, a throbbing of the temporal arteries, and a quickness of the pulse. In some instances, a coldness of the feet, and shivering over the whole body, together with a costive belly, are observed to precede an attack of this hæmorrhage.

This complaint is to be considered as of little consequence, when it occurrs in young persons, being never attended with any danger; but when it arises in those who are advanced in life, when the blood flows profusely, and returns frequently, it indicates too great fulness of the vessels of the head, and not unfrequently precedes apoplexy, palsy, &c.; and therefore, in such cases, is to be regarded as a dangerous symptom. When this hæmorrhage arises in the course of typhous fever, it is to be considered as a symptom of great danger.

In general, we need not be very anxious to stop a discharge of blood from the nose, particularly where there are marks of fulness of the vessels of the head; but if it occurs under a debilitated state of the system, or becomes very profuse, means must be employed to suppress it. These are chiefly of a local nature; applying pressure to the bleeding vessels, introducing astringents into the nostrils, as solutions of alum, sulphate of zinc, sulphate of copper, &c.; applying cold to the head, or to some very sensible part of the skin, or in the course of the spine, &c. At the same time the patient should be kept in the erect position. If the hæmorrhage be of an active character, the antiphlogistic regimen should be carefully observed: the patient kept cool and quiet; the saline cathartics, refrigerants, as nitrate of potash, and the acids, digitalis, diaphoretics, &c. administered internally; and blood may be taken from the temples, by leeches, or even from the arm, if the patient be very plethoric. Sometimes, after the failure

of other means, closing the posterior as well as anterior outlets from the nose, and preventing the escape of the blood for some time mechanically, has been successful; and this might be particularly proper, where it was discharged copiously into the fauces, so as to endanger suffocation, on the patient falling asleep.

EPISTHO'TONOS. (*os, i.* m.; from επισθεν, forwards, and τεινω, to extend.) A tetanic affection of the muscles on the anterior part of the body, by which the trunk is bent forwards. It is synonymous with *emprosthotonos*, which latter term is more frequently used. See *Tetanus*.

Epistrophalus. See *Epistrophis.*

EPISTRO'PHEUS. (*ei*, m.; from επιστρεφω, to turn round, because the head is turned upon it.) The second cervical vertebra. See *Dentatus.*

EPI'STROPHIS. (*is, is.* m.; from επιστρεφω, to turn about: so called because it turns about on the second vertebra, as upon an axis.) *Epistrophalus. Epistrophia.* The first vertebra of the neck.

EPITHE'LIUM. (*um, ii.* n.) The cuticle covering a mucous membrane.

Kühn observes on this term, that Ruysch, from whom it appears to have been adopted, used *epthelia* adjectively with *membrana* understood; that it is derived from θηλη, the nipple; and that *epithelia membrana* would properly signify nothing more than the cuticle covering the nipple. Hence *epithelium* as generally used appears to be a misapplied term.

EPITHE'MA. (*a, atis.* n.; from επιτιθημι, to place upon or apply.) A lotion, fomentation, or any external application.

EPITHEMA'TIUM. The same.

EPI'THESIS. (From επιτιθημι, to place.) The straightening of crooked limbs by means of instruments.

EPI'THYMUM. (*um, i.* n.; from επι, upon and θυμος, the herb thyme.) See *Cuscuta epithymum.*

EPIZOO'TIC. (*Epizooticus*; from επι, upon, and ζωον, an animal.) When a disease prevails among the inferior animals in the same manner as an epidemic does among men, it is said to be *epizootic.*

EPIZOO'TY. An epizootic disease.

EPO'DE. (From επι, upon, and ωδη, a song.) *Epodos.* The ancient method of curing diseases by incantation.

EPO'MIS. (From επι, upon, and ωμος, the shoulder.) The acromion, or upper part of the shoulder.

EPOMPHA'LIUM. (From επι, upon, and ομφαλος, the navel.) An application to the navel.

EPSOM. The name of a village in Surrey, about eighteen miles from London, in the neighbourhood of which is a considerable mineral spring, called Epsom water. *Aqua Epsomensis.* This water, evaporated to dryness, leaves a residuum, the quantity of which has been estimated from an ounce and a half in the gallon, to five drachms and one scruple. Of the total residuum, by far the greater part, about four or five sixths, is sulphate of magnesia mixed with a very few muriates, such as that of lime, and probably magnesia, which render it very deliquescent, and increase the bitterness of its taste, till it is purified by repeated crystallisations. There is nothing sulphureous or metallic ever found in this spring. The diseases in which it is employed are similar to those in which we use Seidlitz water.

EPSOM SALT. A purging salt, formerly obtained by boiling down the mineral water found in the vicinity of Epsom, but now manufactured by chemists on a large scale. See *Magnesiæ sulphas.*

EPU'LIS. (*is, idis.* f.; from επι, and ουλα, the gums.) A swelling on the gums.

EPULO'TIC. (*Epuloticus*; from επουλοω, to cicatrize.) That which promotes cicatrization.

EQUISE'TUM. (*um. i.* n.; from *equus*, a horse, and *seta*, a bristle: so named from its resemblance to a horse's tail.) 1. The name of a genus of plants in the Linnæan system. Class, *Cryptogamia*; Order, *Filices.*

2. The pharmacopœial name of the mare's tail. See *Hippuris vulgaris.*

EQUISETUM ARVENSE. See *Hippuris.*

E'QUITANS. Equitant: applied to leaves which are disposed in two opposite rows, and clasp each other by their compressed base; being, as it were, laminated, or folded one upon another; as in *Narthecium ossifragum.*

Equivalent. See *Combination, chemical.*

E'QUUS. (*us, i.* m.) The name of a genus of animals of the order *Belluæ.* The horse.

EQUUS ASINUS. The systematic name of the animal called an ass: the female affords a light and nutritious milk. See *Milk, asses'.*

ERADICATI'VUS. A term formerly applied to violent purgation or violent purgatives, in opposition to *minorativus*, as applied to those of a milder description.

ERA'NTHEMUS. (From ηρ, the spring, and ανθεμος, a flower: so called because it flowers in the spring.) A spring flower: applied to a species of chamomile.

ERAVAY. The African name of a small species of ricinus which grows in Guinea, and is used as a purgative. — *Clusius.*

EREBI'NTHUS. Ερεβινθος. The vetch.

ERECTILE TISSUE. A peculiar tissue described by Dupuytren and Rullier, which is susceptible of erection, or active turgescence, by an increased flow of blood. It is formed of arteries, veins, and nervous filaments, and consists of a spongy substance, the areolæ of which communicate with each other. This tissue is found in the corpora cavernosa of the penis, and clitoris, in the corpus spongiosum urethræ, the nipples, lips, iris, &c. This tissue is sometimes developed as a morbid structure, as in the case of nævus maternus, and aneurism by anastomosis. Some deny the distinct existence of the erectile tissue, and consider it merely as a congeries of blood-vessels largely supplied with nerves.

ERE'CTOR. (*or, oris.* m.) That which raises anything up: applied to several muscles, the office of which is to raise up the part into which they are inserted.

ERECTOR CLITO'RIDIS. First muscle of the

clitoris, of Douglas. *Ischio-cavernosus*, of Winslow. A muscle of the clitoris that draws it downwards and backwards, and serves to make the body of the clitoris more tense, by squeezing the blood into it from its crus. It arises from the tuberosity of the ischium, and is inserted into the clitoris.

ERECTOR PENIS. *Ischio-cavernosus*, of Winslow. A muscle of the penis that drives the urine or semen forwards, and, by grasping the bulb of the urethra, pushes the blood towards the corpus cavernosum and the glans, and thus distends them. It arises from the tuberosity of the ischium, and is inserted into the sides of the cavernous substance of the penis.

ERE'CTUS. Upright. A term very generally applied in natural history: in *Botany*, it expresses the direction of the stem, branches, leaves, petals, stamens, pistils, &c.; thus *caulis erectus*, an upright stem, as in *Lysimachia vulgaris*; *folium erectum*, forming an acute angle with the stem, as in *Juncus articulatus*, &c., *petala erecta*, as in *Brassica erecta*.

Ere'mus. See *Cenobium*.

ERETHI'SMUS. (*us*, *i.* m.; from ερεθιζω, to excite or irritate.) Increased sensibility and irritability. A term variously applied by modern writers. Mr. Pearson has described a state of the constitution produced by mercury acting on it as a poison. He calls it the mercurial erethismus, and mentions that it is characterised by great depression of strength, anxiety about the præcordia, irregular action of the heart, frequent sighing, trembling, a small quick, sometimes intermitting pulse, occasional vomiting, a pale contracted countenance, a sense of coldness; but the tongue is seldom furred, nor are the vital and natural functions much disturbed. In this state any sudden exertion will sometimes prove fatal.

ERE'TRIUS. (From *Eretria*, in the Negropont, the place whence it came.) Dioscorides and Galen describe two kinds of *terra Eretria*, which were much esteemed as alkaline and absorbent earths.

ERU'GMOS. (From ερευγω, to belch.) *Ereuxis.* An eructation.

ERGASTE'RIUM. (From εργον, work.) 1. A laboratory. 2. That part of a furnace in which is contained the matter to be acted upon.

Ergot. See *Secale cornutum*.

ERGOTISM. The poisonous effects of the ergot of rye, which are of two kinds. See *Secale cornutum*.

ERI'CA. (*a*, *æ.* f.; from ερεικω, to break: so named from its fragility, or because it is broken into rods to make besoms of.) The name of a genus of plants in the Linnæan system. Class, *Octandria*; Order, *Monogynia*. Heath.

Ericaceæ. See *Ericeæ*.

ERI'CEÆ. *Ericaciæ.* Ericineæ. A family of plants including the heaths.

ERICE'RUM. (Ερεκειρον; from ερεικα, heath.) The name of several collyria mentioned by Aëtius, into the composition of which heath entered.

Erici'neæ. See *Ericiæ*.

ERI'GERON. (*um*, *i.* m. Ηριγερων, of the Greek writers; from ηρ, the spring, and γερων, an old man: because, in the spring, it has a white hoary blossom, like the hair of an old man.) 1. The name of a genus of plants. Class, *Syngenesia*; Order, *Polygamia superflua*.

2. The common groundsel was formerly so called. See *Senecio vulgaris*.

ERIGERON ACRE. This is most probably the *conyza cerula* of old pharmacopœias.

ERIMOIDES. A word used by Paracelsus, and supposed to mean sand deposited from the urine.

ERINA'CEUS. (*us*, *i.* m.) The name of a genus of small mammiferous animals. The hedge-hog tribe.

ERINACEUS EUROPEUS. The hedge-hog. The flesh, which is difficult of digestion, was once considered a delicacy.

ERMESIA. Ερμεσια. A composition used by the Magians to make people beget beautiful and well-dispositioned children (!) It consisted of the kernels of pine nuts, triturated with honey, myrrh, saffron, and palm oil, and was drunk mixed with milk. — *Corrhæus.*

ERODE'NTIA. Medicines which cause erosion.

ERO'SION. (*Erosio*, *onis.* f.; from *erodo*, to gnaw out, or eat into.) The gradual destruction of the substance of a part by increased action of the absorbents, whether spontaneous, or excited by the application of some irritating substance.

ERO'SUS. Jagged; gnawed. A leaf is called *folium erosum*, the margin of which is irregularly cut or notched, especially when otherwise divided besides; as in *Senecio squalidus*.

ERO'TIC. (*Eroticus.* Ερωτικος; from ερως, love.) Appertaining to the passion of love; as erotic melancholy.

ERO'TOMA'NIA. (*a*, *æ.* f.; from ερως, love, and μανια, madness.) That melancholy, or madness, which is the effect of love.

Erpes. See *Herpes*.

Erpetology. See *Herpetology*.

ERRA'TIC. (*Erraticus*; from *erro*, to wander.) Wandering; irregular. A term occasionally applied to pains, or any disease which is not fixed, but moves from one part to another; as gout, erysipelas, &c.

Erratic ague. See *Ague*.

E'RRHINE. (*Errhinus*; ερρινα, from εν, in, and ρις, the nose.) By errhines are understood those medicines which, when topically applied to the internal membrane of the nose, excite sneezing, and increase the secretion, independent of any mechanical irritation. Such are tobacco, asarabacca, turbith mineral, &c. Medicines of this kind are also called *sternutatories*.

E'RROR LOCI. Boerhaave introduced this term, from the opinion that the vessels were of different sizes, for the circulation of blood, lymph, and serum, and that when the larger sized globules were forced into the lesser vessels, they became obstructed, by an *error of place*.

Eru'ca. See *Brassica eruca*.

ERUCA SYLVESTRIS. The wild rocket. See *Brassica eruca*.

ERUCTATION. (*Eructatio, onis.* f.) Belching. See *Flatulency.*

ERUPTION. *Eruptio.* In medical language, the sudden appearance of a disease on the skin; thus we speak of the eruption of measles, small-pox, scarlet fever, &c. The term applies both to the disease itself, as developed on the skin, and the act of its breaking out.

Ervilla. See *Ervum.*

E'RVUM. (*um, i.* n.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia;* Order, *Decandria.*

2. The pharmacopœial name of tare. See *Ervum ervilia.*

ERVUM ERVILLA. The seeds of this plant, which is the *Orobus* of many writers, and the *Ervum ervilia — germinibus undato-plicatis, foliis imparipinnatis,* of Linnæus, have been made into bread in times of scarcity, which is not the most salubrious. The meal was formerly used as a resolvent in the form of poultice.

ERVUM LENS. The systematic name of the lentil. *Lens.* Φακος of the Greeks. *Ervum — pedunculis subbifloris; seminibus compressis, convexis,* of Linnæus. There are two varieties; the one with large, the other with small seeds. They are eaten in many places as we eat peas, than which they are more flatulent, and more difficult to digest. A decoction of these seeds is used as a lotion to the ulcerations after small-pox, and, it is said, with success.

ERY'NGIUM. (*um, i.* n.) Ηρυγγιον. Eryngo, or sea-holly. 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.*

2. The pharmacopœial name of the sea-holly. See *Eryngium maritimum.*

ERYNGIUM CAMPESTRE. The root of this plant, *Eryngium — foliis radicalibus, amplexicaulibus, pinnato-lanceolatis,* of Linnæus, is used in many places for that of the sea-eryngo. See *Eryngium maritimum.*

ERYNGIUM MARITIMUM. The systematic name of the sea-holly, or eryngo. *Eryngium — foliis radicalibus subrotundis, plicatis spinosis, capitulis pedunculatis, paleis tricuspidatis,* of Linnæus. The root of this plant is directed for medicinal use. It has no particular smell, but to the taste it manifests a grateful sweetness; and, on being chewed for some time, it discovers a light aromatic warmth or pungency. It was formerly celebrated for its supposed aphrodisiac powers, but it is now very rarely employed.

Eryngo. See *Eryngium.*

Eryngo, sea. See *Eryngium.*

Eryngo-leaved lichen. See *Lichen.*

ERY'SIMUM. (*um, i.* n.; Blancard derives this word from ερυω, *Salvum conservo,* on account of the great virtues attributed to it by the ancients; others from ερεικω, to cleave, because the leaves are much cleft; others from εριτιμον, precious.) 1. The name of a genus of plants in the Linnæan system. Class, *Tetradynamia;* Order, *Siliquosa.*

2. The pharmacopœial name of the hedge-mustard. See *Erysimum officinale.*

ERYSIMUM ALLIA'RIA. The systematic name of Jack in the hedge, Sauce alone, or stinking hedge-mustard; which is also called, *Alliaria Camelina,* and *Chamæplion,* by Oribasius. The plant to which these names are given, is the *Erysimum foliis cordatis,* of Linnæus; it has sometimes been exhibited in humid asthma and dyspnœa, with alleged success. It has been esteemed powerfully diaphoretic, diuretic, and antiscorbutic.

ERYSIMUM BARBAREA. The systematic name of the *barbarea* of the shops. The leaves of this plant, *Erysimum — foliis lyratis, extimo subrotundo,* of Linnæus, have been ranked among the antiscorbutics. They are seldom used in practice.

ERYSIMUM OFFICINALE. The systematic name of the hedge-mustard. *Erysimum — siliquis spicæ adpressis, foliis runcinatis,* of Linnæus. It was formerly much used for its expectorant and diuretic qualities, which are now forgotten. The seeds are warm and pungent, and very similar to those of mustard in their sensible effects.

ERYSI'PELAS. (*as, atis.* n. Ερυσιπελας; from ερυω, to draw, and πελας, adjoining: so named from its tendency to spread to the neighbouring parts.) *Ignis sacer.* St. Anthony's fire. Called also, in common language, the Rose. A peculiar form of inflammation which occurs chiefly in the skin; and is generally accompanied with vesications on the affected part, and with symptomatic fever.

1. *Erysipelas phlegmonodes.* Phlegmonoid erysipelas. This form of erysipelas frequently occurs in the face, affecting usually one side of it only: sometimes it attacks one of the extremities; and in both cases it is ushered in by a smart feverish attack. The colour is higher than in the other species, and the burning heat and tingling in the part are exceedingly distressing. The swelling generally appears on the second night, or third day of the fever; the vesications rise on the fourth and fifth, and break or subside on the fifth or sixth, when the redness changes to a yellowish hue, and the swelling and fever begin to diminish, and on the eighth day both disappear: on the tenth, the new cuticle is commonly left exposed, the old one having separated, and the brownish or dark scab, which had formed where the fluid of the vesications had been discharged, having fallen off. The progress of the disease, however, is more rapid, and its duration shorter, in young and sanguine habits, than in those more advanced in life: in the former, the tumefaction is sometimes fully formed on the second day, and the whole terminates on the sixth or seventh; while in the latter, it may be protracted to the tenth or twelfth, and the desquamation may not be completed before the fourteenth day. The vesications, in the latter instances, are often succeeded by a profuse discharge of acrimonious lymph, for several days, so that scabs do not form. Phlegmonoid erysipelas frequently terminates in suppuration, and in sloughing of the cellular membrane, and it is indeed the circumstance of the latter texture being involved that gives to this form of disease its peculiar characters. It has recently been very accurately described by the late Dr.

Andrew Duncan, junior, under the name of Diffuse inflammation of the cellular membrane.

2. The *Erysipelas œdematodes* is less severe in its attack: the tumour is more gradual in its rise and extension, is of a paler red, or of a yellowish brown colour, and is accompanied by less heat and local distress: its surface is smooth and shining; and, if it be strongly pressed with the finger, a slight pit remains for a short time. Vesications, which are smaller, less elevated, and more numerous than in the former species, appear on the third or fourth day from the commencement of the swelling; and are succeeded, in two or three days, by thin dark-coloured scabs, giving an appearance not unlike the confluent small-pox, from the edges of which a clear lymph exudes. The whole face is much enlarged, so that the form of the features is scarcely recognised, and the appearance is not unaptly compared by Dr. Willan to that of a bladder distended with water.

This species of erysipelas is attended with considerable danger, when it affects the face as above described; for the disorder of the functions increases with the advancement of the external disease. Vomiting, rigors, and delirium, followed by coma, take place about the height of the disorder, and often terminate fatally on the seventh or eighth day; while, in other cases, the symptoms continue undiminished, and death occurs at a later period; or a slow and tedious convalescence ensues.

This form of erysipelas most commonly affects persons of debilitated constitution, dropsical persons, and those who have long been subject to other chronic maladies, or live in habitual intemperance. It is not attended with danger, however, when it affects one of the extremities. In some unfavourable cases, matter is formed, which is liable to make its way through the cellular substance, producing irregular sinuses between the muscles, which it often materially injures, and prolonging the sufferings of the patient for many weeks.

3. The *Erysipelas gangrænosum* commences sometimes like the one and sometimes like the other of the foregoing species, and most commonly occurs in the face, neck, or shoulders. It is accompanied with symptoms of low fever, and with delirium, which is soon followed by coma, which remains through the subsequent course of the disease. The colour of the affected part is a dark red; and scattered phlyctanæ, with a livid base, appear upon the surface, which frequently terminate in gangrenous ulcerations. Even when it terminates favourably, suppuration and gangrene of the muscles, tendons, and cellular substance, often take place, producing little caverns and sinuses, which contain an ill-conditioned pus, together with sloughs of the mortified parts, which are ultimately evacuated from the ulcers. It is an exceedingly dangerous affection, the vital powers being frequently quite overwhelmed from the very first of the attack, and death taking place in a few hours.

A peculiar variety of gangrenous erysipelas occasionally occurs in infants, a few days after birth, especially in lying-in hospitals, and is often fatal. Sometimes, indeed, infants have been born with livid patches, vesications, and even gangrene already advanced. It most frequently commences about the umbilicus or the genitals, and extends upwards or downwards, affecting the parts which it reaches with moderate swelling, and slight hardness; the skin puts on a dark red colour, and vesications with livid bases break out, terminating in sphacelus, which, if the child is not speedily cut off, nearly destroys some of the fingers, or toes, the genitals, or other parts. In the milder cases, when the extremities alone are affected, suppurations take place rapidly about the joints of the hands and feet. The *Erysipelas infantum*, however, often terminates favourably in ten or twelve days.

4. In the *Erysipelas erraticum* the morbid patches appear, one after another, on different parts of the body: in some cases, those which appeared first remain till the whole eruption is completed; in others, the first patches decline, as fresh ones appear. Sometimes the disease thus travels progressively from the face downwards to the extremities. It commonly terminates favourably, however, in a week or ten days.

It has been the subject of some discussion, whether erysipelas is not occasionally propagated by contagion. It is sometimes epidemic, and in hospitals it frequently happens that certain wards are so infested by it, that patients labouring under other complaints are seized with it in great numbers; and almost every wound, however trifling, becomes surrounded by erysipelatous inflammation. Instances of its apparent communication by contagion in private houses are much rarer; but still they occur, and, on the whole, we conceive there can be very little reasonable doubt that erysipelas is, in its nature, a contagious disease, although, like fever, it sometimes shows very little disposition to spread in this manner.

Erysipelas is mostly an inflammatory affection of the skin, and then it is apparent and known: but it also affects internal parts, especially the mucous membrane of the throat, primæ viæ, and air passages. It is more liable to attack women and children, and those of an irritable habit, than those of a plethoric and robust constitution.

It is remarkable that erysipelas sometimes returns periodically, attacking the patient once or twice a year, or oftener, and then by its repeated attacks it often gradually exhausts the strength, especially in old and debilitated constitutions.

When the inflammation is a mere blush, and is not attended by much affection of the system, it is called *erythema*; but when the system is affected, it is named erysipelas.

Erysipelas attacks all parts of the surface of the body; but it more frequently appears on the face, legs, and feet, than in any other situation. It occurs oftener in warm climates than in temperature or coldness.

It has been attributed to a certain matter generated within the body, and thrown out on its surface. A particular state of the atmo-

sphere sometimes renders it epidemical. And it has frequently been known to accompany malignant fever.

In slight cases, where it attacks the extremities, it makes its appearance with a roughness, heat, pain, and redness of the skin, which becomes pale when the finger is pressed upon it, and again returns to its former colour, when it is removed. There prevails likewise a slight febrile disposition, and the patient is rather hot and thirsty. If the attack is mild, these symptoms will continue only for a few days, the surface of the part affected will become yellow, the cuticle or scarf-skin will fall off in scales, and no further inconvenience will perhaps be experienced. When however the attack has been severe, and the inflammatory symptoms have run high, then there will ensue pains in the head and back, great heat, thirst, and restlessness; the part affected will slightly swell; the pulse will become small and frequent; and, about the fourth day, a number of little vesicles, containing a limpid, and, in some cases, a yellowish fluid, will arise. In some instances, the fluid is viscid, and instead of running out, as generally happens when the blister is broken, it adheres to and dries upon the skin.

In unfavourable cases, these blisters sometimes degenerate into obstinate ulcers, which now and then become gangrenous. This, however, does not happen frequently; for although it is not uncommon for the surface of the skin, and the blistered places, to appear livid or even blackish, yet this usually disappears with the other symptoms.

The period at which the vesicles show themselves is very uncertain. The same may be said of the duration of the eruption. In mild cases, it often disappears gradually, or is carried off by spontaneous sweating. In some cases it continues without showing any disposition to decline for twelve or fourteen days, or longer.

The trunk of the body is sometimes attacked with erysipelatous inflammation, but less frequently so than the extremities. It is not uncommon, however, as before observed, for infants to be attacked in this manner a few days after birth; and in these it makes its appearance about the genitals. The inflamed skin is hard, and apparently very painful to the touch. The belly often becomes uniformly tense, and sphacelated spots sometimes are to be observed. From dissections made by Dr. Underwood, it appears, that the disease frequently spreads to the abdominal viscera.

When erysipelas attacks the face, it comes on with chilliness, succeeded by heat, restlessness, thirst, and other febrile symptoms, with a drowsiness, or tendency to coma or delirium, and the pulse is very frequent and full. At the end of two or three days, a fiery redness appears on some part of the face, and this extends at length to the scalp, and then gradually down the neck, leaving a tumefaction in every part the redness has occupied. The whole face at length becomes turgid, and the eyelids are so much swelled as to deprive the patient of sight. When the redness and swelling have continued some time, blisters of different sizes, containing a thin colourless acrid liquor, arise on different parts of the face, and the skin puts on a livid appearance in the blistered places; but in those not affected with blisters, the cuticle, towards the close of the disease, falls off in scales.

No remission of the fever takes place on the appearance of the inflammation on the face; but, on the contrary, it is increased as the latter extends, and both will continue probably for the space of eight or ten days. In the course of the inflammation, the disposition to coma and delirium are sometimes so increased as to destroy the patient between the seventh and eleventh days of the disease. When the complaint is mild, and not leading to a fatal event, the inflammation and fever generally cease gradually without any evident crisis.

If the disease arises in a bad habit of body, occupies a part possessed of great sensibility, is accompanied with much inflammation, fever, and delirium, and these take place at an early period, we may suppose the patient exposed to imminent danger. Where translations of the morbid action take place, and the inflammation falls on either the brain, lungs, or abdominal viscera, we may entertain the same unfavourable opinion. Erysipelas seldom terminates in suppuration, unless combined with some degree of phlegmonous inflammation, which is sometimes the case; but, in a bad habit, it is apt to terminate in gangrene, in which case there will be also great danger. When the febrile symptoms are mild, and unaccompanied by delirium or coma, and the inflammation does not run high, we need not be apprehensive of danger.

Where the disease has occupied the face, and proves fatal, inflammation of the brain and its consequences are, in some cases, met with on dissection.

The treatment of erysipelas must vary greatly according to the form of the disease. When it occurs in robust plethoric constitutions, partaking of the phlegmonous character, with severe inflammatory fever, it will be proper to begin by taking a moderate quantity of blood; then direct cooling saline purgatives, antimonial diaphoretics, a light vegetable diet, &c. But if the accompanying fever be more of the typhoid type, bloodletting is inadmissible, and the patient's strength must be supported: after clearing out the primæ viæ, and endeavouring to promote the other secretions by mild evacuants, when the pulse begins to fail, a more nutritious diet, with a moderate quantity of wine, and the decoction of bark with sulphuric acid, or the compound tincture, may be resorted to; and, if necessary, the sulphate of quinine, ammonia, and other powerful stimulants. In the decidedly gangrenous form of erysipelas, all depletion is out of the question, and a tonic and stimulating treatment must be resorted to from the first. Opium should be given in full doses, and calomel may be useful in correcting the disordered state of the abdominal secretions. Besides the constitutional treatment of erysipelas, there are certain local means which are found highly useful.

The ordinary local means of allaying inflammation have, till lately, been little employed in

erysipelas. It has been thought that leeches have a tendency to induce gangrene, and that cold lotions may be injurious by repelling the inflammation. These opinions, however, are now giving way, and many practitioners apply both leeches and cold lotions with excellent effect.

In cases of erysipelas, where the means used to arrest the inflammation have failed, and suppuration and sloughing of the cellular membrane have taken place, which they often do to a very great extent, it is usual to make incisions to give exit to the discharge, and to relieve the tension of the limb. This is an old practice, which was revived in this country by Mr. Copland Hutchison. He recommends the incisions to be made about an inch and a half in length, from two to four inches apart, and varying in number from four to eighteen, according to the extent of the disease. Mr. Lawrence prefers to these numerous small incisions one or two long ones, carried in the direction of the long dimension of the limb or other part. Mr. Lawrence considers this treatment as applicable not only to the suppurating and sloughing state of the disease, but at its commencement, with a view to preventing these occurrences. Mr. Lawrence applies the treatment by incision exclusively to phlegmonoid erysipelas. Incisions are chiefly practised in cases of phlegmonoid erysipelas of the limbs. A copious flow of blood generally follows the application of the knife; and this, unless too profuse, should be encouraged by warm fomentations; but great care must be taken to keep the hemorrhage within proper limits. The part should then be enveloped in a warm poultice.

The use of blisters and cauteries applied to the diseased surface is frequent among the French surgeons, and is said to be advantageous; but it has been little adopted in this country. Compression by bandages has also been recommended; but it is difficult to conceive what effect it can have, except that of producing gangrene. A very ingenious practice has been introduced by Mr. Higginbottom of Nottingham, which consists in the application of nitrate of silver in the following manner: — The part is first cleaned with soap and water, and wiped dry. The inflamed skin, and also the healthy skin, to the extent of an inch or more beyond it, is then to be moistened with water, and the nitrate of silver passed over it twice, thrice, or oftener. The part is left exposed to the air to dry, and is to be kept cool. The result of this practice, in many cases, appears to be a complete change of action in the part, and a resolution of the disease.

Erysipelas infantum. See *Erysipelas.*

Erysipelatoid. (*Erysipelatodes*; from ερυσιπελας, and ειδος, likeness.) Resembling erysipelas.

ERYTHE'MA. (*a, atis.* n.; from ερυθρος, red.) 1. Simple redness. — *Hippocrates.*

2. Rash, or inflammatory blush without fever. — *Cullen.*

3. A lesser degree of erysipelas. — *Callisen.*

4. A nearly continuous redness of some portion of the skin, attended with disorder of the constitution, but not contagious. — *Willan.*

Dr. Willan has described six varieties, which will include all the ordinary forms of the efflorescence. In some of them, as will appear from their titles, the surface is more or less elevated at some period of its course, approximating to the papular or tubercular tumours: but these are obscurely formed, and soon subside, leaving the redness undiminished.

1. *Erythema fugax*, consists of red patches, of an irregular form and short duration, resembling the redness produced from pressure. These patches appear successively on the arms, neck, breast, and face, in various febrile diseases, and in bilious diarrhœa, generally denoting, as Hippocrates and the ancients have observed, a tedious and dangerous disease. They sometimes occur in chronic affections, especially those in which the primæ viæ are deranged; as in dyspepsia, hysteria, hemicrania, &c.

2. The *Erythema læve* exhibits an uniformly smooth, shining surface, and chiefly appears on the lower extremities, in confluent patches, and is generally accompanied by anasarca. It affects young persons, who are sedentary, with slight fever, and terminates gradually, after an uncertain period, in extensive desquamation, as soon as the anasarca has disappeared. Exercise, with diuretics and corroborants, contributes to shorten its duration in this class of patients. It occurs also in elderly persons, labouring under anasarca (especially in those accustomed to excessive drinking), and is liable to terminate in gangrenous ulcers. Indeed, under whatever circumstances anasarca occurs, so as to stretch the skin greatly, this erythema is liable to be produced, and is often chequered with patches and streaks of a dark red or purple hue. Relief is afforded by the horizontal posture of the limbs, by the internal use of diuretics and bark, and also by a weak spirituous lotion applied to the surface.

It sometimes occurs without œdema, when the bowels have been much disordered; and occasionally, in women, at the menstrual periods.

3. The *Erythema marginatum* occurs in patches, which are bounded on one side by a hard, elevated, tortuous, red border, in some places obscurely papulated: but the redness has no regular boundary on the open side. The patches appear on the extremities and loins, in old people, and remain for an uncertain time, without producing any irritation in the skin. They are connected with some internal disorder, and their occurrence is to be deemed unfavourable.

4. The *Erythema papulatum* occurs chiefly on the arms, neck, and breast, in extensive irregular patches, of a bright red hue, presenting not an inelegant painted appearance. For a day or two, before the colour becomes vivid, the surface is rough, or imperfectly papulated. The redness afterwards continues for about a fortnight; and, as the eruption declines, it assumes a blueish hue, especially in the central parts of the patches. This eruption is sometimes attended with great disorder of the constitution, especially with a frequent, small pulse, total anorexia, and

extreme depression of strength and spirits, and with acute pains and great tenderness of the limbs: but the general disorder is often trifling. Light diet, with diaphoretics, and the mineral acids, and an attention to the state of the bowels, comprise all that is necessary in the treatment of this disorder.

5. *Erythema tuberculatum* resembles the last variety in the large irregular patches of red efflorescence which it exhibits; but there are small slightly elevated tumours interspersed through the patches, which subside in about a week, leaving the erythema, which becomes livid and disappears in about a week more. It commences with fever, and is accompanied with great langour, irritability, and restlessness, and succeeded by hectic. In the only three cases of this erythema, which had occurred to Dr. Willan, the medicines employed did not appear to alleviate the symptoms, or to prevent the subsequent hectic.

6. The *Erythema nodosum*, which is a more common and milder complaint, seems to affect females only, and occurs on the fore part of the legs. It is preceded by slight febrile symptoms for a week or more, which generally abate when the erythema appears. It shows itself in large oval patches, the long diameter of which is parallel with the tibia, and which slowly rise into hard and painful protuberances, and as regularly soften and subside, in the course of nine or ten days; the red colour turning blueish on the eighth or ninth day, as if the leg had been bruised. It has always gone through its course mildly, under the use of laxatives, followed by the mineral acids, and other tonics.

Erythema mercuriale. See *Eczema.*

ERYTHRIC ACID. (*Erythric*; from ερυθρος, red.) An acid obtained by the action of nitric acid on lithic acid. Its colour is yellow, but when exposed to the sun's rays, it turns red — whence its name.

ERYTHRI'NA. (From ερυθρος, red.) 1. A genus of plants. Class, *Diadelphia*; Order, *Decandria*. *Erythrina corallodendron*, the coral tree, a native of the Antilles, is celebrated for the beauty of its scarlet blossoms. The bark of *E. Indica* is considered febrifuge. *E. Monosperma* is much frequented by the insect that forms gum lac.

2. The name given by Heeren to the colouring matter of the *Lichen roccella*.

ERYTHRO'DANUM. (From ερυθρος, red: so called from the colour of its juice.) See *Rubia tinctorum*.

ERYTHROEI'DES. (Ερυθοειδες; from ερυθρος, red, and ειδος, appearance: so called from its colour.) A Greek epithet of the *tunica vaginalis testis*, which has the red fibres of the cremaster dispersed upon its inner surface.

ERYTHRO'NIUM. (From ερυθρος, red: so called from the red colour of its juice.) The name of a genus of plants. Class, *Hexandria*; Order, *Monogynia*.

ERYTHRONIUM AMERICANUM. *Erythronium Indicum.* The root is emetic, but is seldom used.

ERYTHRONIUM DENS CANINUS. *Dens canis.* Dog's tooth violet. The root of this plant has been given against colic and epilepsy, and applied externally in scald-head.

ERYTHRO'XYLUM. (*um*, *i.* n.; from ερυθρος, red, and ξυλον, wood: so named from its colour.) See *Hæmatoxylum.*

E'RYTHRUS. (From ερυθρος, red: so named from the red colour of its juice.) The sumach. See *Rhus coriaria.*

E'SAPHE. (Εσαφη; from εσαφαω, to feel with the hand.) The touch; or feeling the mouth of the womb, to ascertain its condition.

E'SCHAR. (*Eschara*, *æ.* f. Εσχαρα; from εσχαροω, to scab over.) *Eschara.* The portion of animal substance that is destroyed by the application of a caustic, and which sloughs away.

ESCHARO'TIC. (*Escharoticus*; from εσχαροω, to scab over.) A substance which possesses the power of destroying the texture of the various solid parts of the animal body to which it is directly applied. This class of substances may be arranged under two orders: —

1. *Eroding escharotics*; as blue vitriol, *alumen ustum*, &c.

2. *Caustic escharotics*; as *potassa pura*, *argenti nitras*, *acidum sulphuricum*, *nitricum*, &c.

E'SCULENT. *Esculentus.* An appellation given to such animals and plants, or any part of them, as may be used for food.

ESCULIC ACID. A peculiar acid found by M. Bussy in the bark of the horse-chesnut.

E'SOX. (*ox*, *ocis.* m.) The name of a genus of abdominal fishes.

ESOX LUCIUS. The systematic name of the pike fish, from the liver of which an oil is obtained, which is termed, in some pharmacopœias, *oleum lucii piscis.* It is used in some countries, by surgeons, to disperse opacities of the cornea.

ESENBECKINE. An alkaline substance found by Buchner in the Esenbeckia febrifuga.

E'SSENCE. (*Essentia*, *æ.* f.) Properly that part of anything on which its most remarkable qualities depend. The term has been variously applied by chemists; but it is now generally restricted to the volatile oils obtained from vegetables by distillation.

ESSENCE OF COLT'S-FOOT. This is made of equal parts of balsam of tolu, and compound tincture of benzoin, with double the quantity of rectified alkohol. It is sold as a pectoral.

ESSENCE OF MUSTARD. This is made of oil of turpentine, camphor, spirit of rosemary, and flower of mustard.

ESSENCE OF SPRUCE. This is prepared by decoction from the twigs of the spruce fir. When mixed with treacle or sugar, and water, and fermented, it forms spruce beer. See *Spruce beer.*

ESSENTIAL. *Essentialis.* Relating to the essence of anything.

ESSENTIA BINA. A preparation used to colour brandy, porter, and other strong drinks. It is made by boiling coarse sugar till it becomes black and bitter, and then mixing it with lime water to the consistence of a syrup.

ESSENTIAL SALT OF BARK. The quack medicine sold under this name, is merely a watery extract of Peruvian bark.

ESSENTIAL SALT OF LEMONS. The preparation

so called, is a mixture of cream of tartar and binoxalate of potash.

Essential oil. See *Oil.*

E'SSERA. (*a*, *æ*. f.; from *Eshera*, an Arabic word literally meaning *papulæ*.) *Sora. Sare.* A species of cutaneous eruption, distinguished by broad, shining, smooth, red spots, mostly without fever, and differing from the nettle rash in not being elevated. It generally attacks the face and hands.

Esthio'menos. (From εσθιω, to eat.) A term formerly applied to any disease which rapidly destroyed, or, as it were, ate away the flesh; as some forms of herpes, lupus, cancer.

E'SULA. (*a*, *æ*. f.; from *esus*, eaten, because it is eaten by some as a medicine.) Spurge.

Esula major. See *Euphorbia palustris.*

Esula minor. See *Euphorbia cyparissias.*

Ether. See *Æther.*

Ether, acetic. Acetic naphtha. An etherial fluid, drawn over from an equal admixture of alkohol and acetic acid, distilled with a gentle heat from a glass retort in a sand-bath. It has a grateful smell, is extremly light, volatile, and inflammable. Its medicinal properties nearly resemble the other ethers, and may be given in the same doses. It is seldom used.

Ether, hydrochloric. Muriatic ether. Marine ether. This is obtained by mixing and distilling alkohol with extremely concentrated muriate of tin. Its operation on the animal economy resembles that of other ethers. It is scarcely ever used.

Ether, hydrocyanic. This has been employed by M. Magendie in some cases as a substitute for hydrocyanic acid, but the smell was found so insufferable that its use could not be continued.

Ether, muriatic. See *Ether, hydrochloric.*

Ether, nitrous. Nitric naphtha. This may be obtained by distilling with a very gentle heat a mixture of equal weights of alkohol and strong nitric acid; or by the process recommended in the Dublin Pharmacopœia, which is perhaps the best. See *Æther nitrosus.* It is very little used in medicine.

Ether, sulphuric. See *Æther.*

Ether, vitriolic. See *Æther.*

ETHERIAL. (*Ethereus*; from *æther.*) A term applied to any highly rectified essential oil or spirit. See *Oleum æthereum.*

Ethiops. See *Æthiops.*

ETHMOI'D. (*Ethmoides*; from εθμος, a sieve, and ειδος, form: because it is perforated like a sieve.) Sieve-like.

Ethmoid bone. *Os ethmoides. Os ethmoideum.* Cribriform bone. A bone of the head. This is, perhaps, one of the most curious bones of the human body. It appears almost a cube, not of solid bone, but exceedingly light, spongy, and consisting of many convoluted plates, which form a network, like a honey comb. It is curiously enclosed in the os frontis, betwixt the orbitary processes of that bone. One horizontal plate receives the olfactory nerves, which perforate that plate with such a number of small holes, that it resembles a sieve; whence the bone is named cribriform, or ethmoid bone. Other plates, dropping perpendicularly from this one, receive the divided nerves, and give them an opportunity of expanding into the organ of smelling; and these bones, upon which the olfactory nerves are spread out, are so much convoluted as to extend the surface of this sense very greatly, and are named spongy bones. Another flat plate lies in the orbit of the eye; and being very smooth, by the rolling of the eye, it is named the os planum, or smooth bone. So that the ethmoid bone supports the fore-part of the brain, receives the olfactory nerves, forms the organ of smelling, and makes the chief part of the orbit of the eye: and the spongy bones, and the os planum, are neither of them distinct bones, but parts of this ethmoid bone.

The *cribriform plate* is exceedingly delicate and thin; lies horizontally over the root of the nose; and fills up neatly the space betwixt the two orbitary plates of the frontal bone. The olfactory nerves, like two small flat lobes, lie out upon this plate, and adhering to it, shoot down like many roots through this bone, so as to perforate it with numerous small holes, as if it had been dotted with the point of a pin, or like a nutmeg-grater. This plate is horizontal; but its processes are perpendicular, one above, and three below.

1. The first perpendicular process is what is called *crista galli*; a small perpendicular projection, somewhat like a cock's comb, but exceedingly small, standing directly upwards from the middle of the cribriform plate, and dividing that plate into two: so that one olfactory nerve lies upon each side of the crista galli; and the root of the falx, or septum, betwixt the two hemispheres of the brain, begins from this process. The foramen cæcum, or blind hole of the frontal bone, is formed partly by the root of the crista galli, which is very smooth, and is said sometimes to be cellular.

2. Exactly opposite this, and in the same direction with it, *i. e.* perpendicular to the ethmoid plate, stands out the *nasal plate* of the ethmoid bone. It is sometimes called azygous, or single process of the ethmoid, and forms the beginning of that septum, or partition, which divides the two nostrils. This process is thin, but firm, and composed of solid bone; it is commonly inclined a little to one side, so as to make the nostrils of unequal size. The azygous process is united with the vomer, which forms the chief part of the partition; so that the septum, or partition of the nose, consists of the azygous process of the ethmoid bone above, of the vomer below, and of the cartilage in the fore or projecting part of the nose; but the cartilage rots away, so that whatever is seen of the septum in the skull must be part either of the ethmoid bone or vomer.

3. Upon either side of the septum, there hangs down a *spongy bone*, one hanging in each nostril. They are each rolled up like a scroll of parchment; they are very spongy; are covered with a delicate and sensible membrane; and, when the olfactory nerves depart from the cribriform plate of the ethmoid bone, they attach themselves to the septum, and to these upper spongy bones, and expand upon them, so that

the convolutions of these bones are of material use in expanding the organ of smelling, and detaining the odorous effluvia, till the impression be perfect. Their convolutions are more numerous in the lower animals, in proportion as they need a more acute sense. They are named spongy or turbinated bones, from their convolutions resembling the many folds of a turban.

The spongy bones have a great many honeycomb-like cells connected with them, which belong also to the organ of smell, and which are useful, perhaps, by detaining the effluvia of odorous bodies, and also by reverberating the voice. Thus, in a common cold, while the voice is hurt by an affection of these cells, the sense of smelling is almost lost.

4. The *orbitary plate* of the ethmoid bone is a large surface, consisting of a very firm plate of bone, of a regular square form, exceedingly smooth and polished: it forms a great part of the socket for the eye, lying on its inner side. When we see it in the detached bone, we know it to be just the flat side of the ethmoid bone; but while it is incased in the socket of the eye, we should believe it to be a small square bone: and from this, and from its smoothness, it has got the distinct name of *os planum*.

The cells of the ethmoid bone, which form so important a share of the organ of smell, are arranged in great numbers along the spongy bone. They are small, neat cells, much like a honeycomb, and regularly arranged in two rows, parted from each other by a thin partition; so that the os planum seems to have one set of cells attached to it, while another regular set of cells belongs in like manner to the spongy bones. There are thus twelve in number opening into each other, and into the nose.

These cells are frequently the seat of venereal ulcers; and the spongy bones are the surface where polypi often sprout up. And from the general connections and forms of the bone, we can easily understand how the venereal ulcer, when deep in the nose, having got to these cells, cannot be cured, but undermines all the face; how the venereal disease, having affected the nose, soon spreads to the eye; and how even the brain itself is not safe. We see the danger of a blow upon the nose, which by a force upon the septum, or middle partition, may displace the delicate cribriform plate, so as to oppress the brain with all the effects of a fractured skull, and without any operation which can give relief. And we also see the danger of pulling away polypi, which are firmly attached to the upper spongy bone.

Ethmoidal cells. See *Ethmoid bone.*

Ethmoides. See *Ethmoid.*

E'TRON. Ητρον. The hypogastrium.

EUA'NTHEMUM. (From ευ, well, and ανθεμος, a flower: so named from the beauty of its flowers.) The chamomile.

EUA'PHIUM. (Ευαφιον; from ευ, well, and αφη, the touch: so called from the lenity of its operation.) A medicine for the piles mentioned by Galen.

EU'CHLORINE. (*Euchlorium, ii.* n.; from ευ, intensive, and χλωρος, green.) The protoxide of chlorine: so called from its vivid green colour. See *Chlorine.*

EUDIOMETER. (*Eudiometrum, i.* n.; from ευδια, purity of air, and μετρον, a measure: so called because it determines the quantity of pure or good air.) An instrument for ascertaining the quantity of oxygen in a given bulk of atmospheric air. See *Atmosphere.*

EUDIOMETRY. (*Eudiometria, æ.*; from ευδια, purity of air, and μετρεω, to measure.) The art of determining the quantity of oxygen contained in a given bulk of atmospheric air.

EUGE'NIA. (*a, æ.* f.; so named by Micheli, in compliment to Prince Eugene of Savoy, who sent him from Germany almost all the plants described by Clusius.) The name of a genus of plants in the Linnæan system. Class, *Icosandria;* Order, *Monogynia.*

EUGENIA CARYOPHYLLA'TA. The systematic name of the tree which affords the clove. *Caryophyllus aromaticus.* It grows in the East Indies, the Moluccas, &c. The clove is the unexpanded flower, or rather the calyx; it has a strong agreeable smell, and a bitterish, hot, not very pungent, taste. The oil of cloves, commonly met with in the shops, and received from the Dutch, is highly acrimonious and sophisticated. Clove is accounted the hottest and most acrid of the aromatics; and, by acting as a powerful stimulant to the muscular fibres, may, in some cases of atonic gout, paralysis, &c., supersede most others of the aromatic class; and the foreign oil, by its great acrimony, is also well adapted for several external purposes: it is directed by several pharmacopœias, and the clove itself enters many officinal preparations.

EUGENIA JAMBOS. The systematic name of the Malabar plum-tree. The fruit smells, when ripe, like roses. On the coast of Malabar, where the trees grow plentifully, these plums are in great esteem. They are not only eaten fresh off the trees, but are preserved in sugar, in order to have them eatable all the year. Of the flowers, a conserve is prepared, which is used medicinally as a mild astringent.

EUGE'US. (Ευγαιος; from ευ, well, and γαια, the earth: so called because of its fertility.) The uterus.

EU'LE. (From ευλαζω, to putrefy.) A worm bred in foul and putrid ulcers.

EUNU'CHIUM. (From ευνουχος, an eunuch: so called because it was formerly said to render those who eat it impotent like an eunuch.) The lettuce. See *Lactuca sativa.*

EUPATO'RIOPHA'LACRON. (From ευπατωριον, agrimony, and φαλακρος, bald.) A species of agrimony with naked heads.

EUPATO'RIUM. (*um, i.* n.; ευπατωριον; from *Eupator,* its discoverer: or, *quasi hepatorium,* from ηπαρ, the liver; because it was said to be useful in diseases of the liver.) 1. The Greek name of the herb agrimony. See *Agrimonia eupatoria.*

2. The name of a genus of plants in the Linnæan system. Class, *Syngenesia;* Order, *Polygamia æqualis.*

3. The pharmacopœial name of the *Eupatorium.* See *Eupatorium cannabinum.*

Eupatorium arabicum. See *Eupatorium cannabinum.*

EUPATORIUM CANNABI'NUM. The systematic name of the hemp agrimony. *Eupatorium; Eupatorium arabicum.* The juice of this very bitter and strong-smelling plant, *Eupatorium — foliis digitatis,* of Linnæus, proves violently emetic and purgative, if taken in sufficient quantity, and promotes the secretions generally. It is recommended in dropsies, jaundices, agues, &c., and is in common use in Holland, amongst the lower orders, as a purifier of the blood in old ulcers, scurvy, and anasarca.

Eupatorium Græcorum. See *Agrimonia eupatoria.*

Eupatorium Mesues. See *Achillea ageratum.*

Eupatorium veterum. See *Agrimonia eupatoria.*

EUPE'PSIA. (*a, æ.* f.; from εν, well, and πεπτω, to concoct.) Good digestion.

EUPE'PTIC. (*Eupepticus;* from εν, good, and πεπτω, to digest.) Easy of digestion.

EUPHO'RBIA. (*a, æ.* f.; from *Euphorbus,* the physician to King *Juba,* in honour of whom it was named.) The name of a genus of plants in the Linnæan system. Class, *Dodecandria;* Order, *Trigynia.*

EUPHORBIA ANTIQUORUM. The systematic name of a plant supposed to produce the *Euphorbium.*

EUPHORBIA CANARIENSIS. In the Canary islands this species of spurge affords the gum euphorbium.

EUPHORBIA CYPARISSIAS. The systematic name of the cypress spurge; called also *Esula minor,* and *Tithymalus cyparissias.* This, like most of the spurges, is very acrimonious, inflaming the eyes and œsophagus after touching them. It is now fallen into disuse, whatever virtues may have been formerly ascribed to it, one of which, no doubt, was that of opening the bowels; for, amongst rustics, it was called poor man's rhubarb.

EUPHORBIA LATHYRIS. The systematic name of the plant which affords the lesser cataputia seeds. *Cataputia minor. Euphorbia — umbella quadrifida, dichotoma, foliis oppositis integerrimis,* of Linnæus. The seeds possess purgative properties; but if exhibited in an over-dose, prove drastic and poisonous: a quality common to all the *Euphorbiæ.*

EUPHORBIA OFFICINARUM. The systematic name of the plant which affords the euphorbium in the greatest abundance. Euphorbium is an inodorous gum-resin, in yellow tears, which have the appearance of being worm-eaten; said to be obtained from several species of euphorbiæ, but principally from the *Euphorbia officinarum — aculeata nuda multangularis, aculeis geminatis,* of Linnæus: it is imported from Ethiopia, Libya, and Mauritania. It contains an active resin, and is very seldom employed internally; but, it enters as an ingredient into many resolvent and discutient plasters.

EUPHORBIA PALUSTRIS. The systematic name of the greater spurge. The officinal plant ordered by the name *Esula major,* in some pharmacopœias, is the *Euphorbia palustris — umbella multifida, bifida, involucellis ovatis, foliis lanceolatis, ramis sterilibus,* of Linnæus. The juice is exhibited in Russia as a common purge; and the plant is given, in some places, in the cure of intermittents.

EUPHORBIA PARALIAS. *Tithymalus paralias.* Sea-spurge. Every part of this plant is violently cathartic and irritating, inflaming the mouth and fauces. It is seldom employed in the practice of this country; but where it is used, vinegar is recommended to correct its irritating power.

Eupho'rbium. See *Euphorbia.*

EUPHRA'SIA. (*a, æ.* f.; corrupted from *Euphrosyne,* ευφροσυνη, from ευφρων, joyful: so called because it exhilarates the spirits.) 1. The name of a genus of plants in the Linnæan system. Class, *Didynamia;* Order, *Angiospermia.*

2. The pharmacopœial name of eye-bright. See *Euphrasia officinalis.*

EUPHRASIA OFFICINALIS. The systematic name of the eye-bright. This beautiful little plant, *Euphrasia — foliis ovatis, lineatis, argute dentatis,* of Linnæus, has been greatly esteemed by the common people, as a remedy for all diseases of the eyes; and has also received the encomiums of some medical writers, notwithstanding which, it is now wholly fallen into disuse. It is an ingredient in the British herb-tobacco.

EUSTACHIAN TUBE. *Tuba eustachiana. Iter à palato ad aurem.* The tube, which forms a communication between the posterior nares and the ear; so named after its discoverer, *Eustachius.* See *Auris.*

Eustachian valve. See *Valvula Eustachii.*

EVAPORA'TION. (*Evaporatio, onis.* f.) The conversion of any substance into vapour. As an artificial operation, it is usually performed by applying heat to any compound substance, in order to dispel the volatile parts. It differs from distillation in its object, which chiefly consists in preserving the more fixed matters, while the volatile substances are dissipated and lost: and the vessels are accordingly different; evaporation being commonly performed in open shallow vessels, and distillation in an apparatus nearly closed from the external air.

Evaporation is a process of infinite importance in the economy of nature; and in the animal body, evaporation from the skin, and lungs, is one of the most obvious causes of diminution of temperature. See *Animal temperature.*

Evergreen. See *Sempervirens.*

EVERRI'CULUM. (From *everro,* to sweep away.) A scoop, used to clear the bladder from the small calculous particles which may remain after the operation of lithotomy.

EVOLUTION. (*Evolutio, onis,* f.; from *evolvo,* to unroll.) 1. In the general language of physiology, this term is synonymous with *development.*

2. That hypothesis respecting generation which supposes that the germ is not organised in the body of the parent, but pre-existent, already organised, and only developed by the process of generation, is called the hypothesis of *Evolution:* it is opposed to that of the *Epigenesis.* Compare *Epigenesis.*

3. In obstetrics, the term *spontaneous evolution* has been applied by Dr. Denman to that case in which the arm and shoulder of the child, being protruded from the vagina, a spontaneous turning takes place, and the child is expelled by the breach, as if in a natural presentation of that part. The occasional occurrence of the fact, is generally admitted; but the opinions of obstetricians are divided as to the precise manner in which it takes place.

Evolution, spontaneous. See *Evolution.*

EXACERBATION. (*Exacerbatio*; from *exacerbo*, to become violent.) An increase of intensity in the symptoms of a disease recurring at intervals. The term is generally applied to an increase of febrile symptoms, and is synonymous with *paroxysm.*

EXÆ'RESIS. (From εξαιρεω, to remove.) That division of the art of surgery which comprises the removal of whatever is injurious or superfluous to the body; as the extraction of foreign bodies, amputation of limbs, excision of tumours, &c. The word is not now in use.

Examblo'ma. (Εξαμβλωμα; from εξαμβλοω, to miscarry.) An abortion.

Examblo'sis. Εξαμβλωσις. An abortion.

Exanastomo'sis. (From εξ and αναστομοω, to relax, or open.) The opening of the mouths of vessels, to discharge their contents.

EXANGI'A. (*a, æ.* f.; from εξ, and αγγειον, a vessel.) The generic name given by Mason Good, to diseases which consist in enlargement, breach, or other morbid perforation of a large blood-vessel, without external opening. The genus includes *aneurism, varix,* and *cyania.*

EXA'NIA. (*a, æ.* f.; from *ex*, out of, and *anus.*) Prolapsus of the rectum. See *Procidentia ani.*

EXANTHE'MA. (*a, atis.* n. Εξανθημα; from εξανθεω, *effloresco*, to effloresce, or break forth on the surface.) *Exanthisma.* 1. An eruption of the skin, called a rash. The Greek writers employed this term in a very general sense, as we do the word eruption.

2. In the present day, nosologists have limited it to an eruption or rash which is accompanied with fever, and which has its regular periods of efflorescence and decline. In Dr. Willan's arrangement, it is appropriated solely to those appearances which are usually called rashes; namely, to patches of superficial redness of the skin, of various extent and intensity, occasioned by an unusual determination of blood into the cutaneous vessels, sometimes with partial extravasation; it has no reference, therefore, to the existence of fever or contagion. It comprehends measles, scarlet fever, nettle-rash, rose-rash, purples, and erythema.

Exanthe'mata. (The plural of *exanthema.*) The name of an order of diseases, of the class *Pyrexiæ*, in Cullen's Nosology.

Exanthematic. *Exanthematicus.* Eruptive.

EXANTHE'SIS. (Εξανθησις; from εξανθεω, to effloresce.) Properly the breaking out of an efflorescence on the skin; but applied also to the efflorescence itself.

Exanthi'sma. See *Exanthema.*

Exanthro'pia. (From εξ, without, and ανθρωπος, a man.) The same as *Apanthropia.*

Exarthre'ma. (Εξαρθρημα; from εξαρθροω, to put out of joint.) *Exarthroma; Exarthrosis.* A dislocation, or luxation.

Exarthro'ma. Εξαρθρωμα. See *Exarthrema.*

Exarthro'sis. Εξαθρωσις. See *Exarthrema.*

Exarticula'tio. (From *ex*, out of, and *articulus*, a joint.) A luxation, or dislocation of a bone from its socket.

Excæcaria agallocha. See *Lignum aloes.*

Exci'pulum. (From *excipio*, to receive.) A chemical receiver.

EXCITABI'LITY. (*Excitabilitas*; from *excito*, to excite.) That condition of living bodies wherein they can be made to exhibit the functions and phenomena which distinguish them from inanimate matter, or the capacity of organised beings to be affected by various agents called stimuli.

Exci'tans. Exciting. Stimulating. Applied to medicines which excite the actions of the system — *excitantia.* These are either *general*, acting on the whole system, as alkohol, or *particular*, acting only on certain parts, as diuretics, expectorants, &c.

EXCITATION. (*Excitatio*; from *excito*, to excite.) Synonymous with *excitement*; but the term *excitement* is more frequently applied to the activities of living, and *excitation* to those of inorganic, bodies.

EXCI'TEMENT. 1. That state in which excitability is called into action.

2. The act of awakening excitability.

Exciting cause. See *Ætiology.*

EXCORIA'TION. (*Excoriatio, onis.* f.; from *excorio*, to take off the skin.) An abrasion of the skin.

E'XCREMENT. (*Excrementum, i.* n.; from *excerno*, to separate from.) Any useless matter ejected from the body, but generally applied to the fæces discharged from the bowels.

Excrementi'tious. Of the nature of excrement.

EXCRE'SCENCE. (*Excrescentia, æ.* f.; from *excresco*, to grow from.) Any preternatural growth.

EXCRE'TION. (*Excretio, onis.* f.; from *excerno*, to separate from.) 1. The expulsion, by the various outlets of the body, of such matters as would be superfluous or injurious if they remained.

2. Any matter so thrown off, as the fæces, urine, &c.

E'XCRETORY. (*Excretorius*; from *excerno*, to purge, sift, &c.) This term is applied to the ducts which convey the secreted fluids from the glands. Some glands have only one excretory duct, and others several.

Excretory ducts. See *Excretory.*

Excu'tia ventri'culi. A stomach brush. An instrument consisting of a ferule of iron or brass, with a bunch of hog's bristles at the end of it. It was formerly used to extract foreign bodies from the œsophagus; and some absurdly attempted to cleanse the stomach of viscous matters by means of it.

EXERCISE. (*Exercitatio, onis.* f.) 1. The use of the muscles in subordination to the will.

Exercise has been divided into *active* and *passive*; but many of the movements included in the latter cannot properly be called exercise. See *Gestation*. Active exercise comprehends walking, running, dancing, and all those exercises usually termed athletic. They are of great importance in the preservation of health, and in the removal of disease. The ancient physicians paid much more attention to this subject than the modern, in so much that *gymnastic medicine* formed, with them, a distinct department of the art. See *Gymnastic medicine*.

EXFOLIA'TION. (*Exfoliatio*; from *exfolio*, to cast the leaf.) The separation of a dead piece of bone from the living.

Exfoliativus. Conducive to exfoliation. Medicines which promote exfoliation have been called *exfoliativa*.

Exfoliati'vum tre'panum. A raspatory, or instrument for scraping exfoliating portions of bone.

Exi'schios. (From εξ, out of, and ισχιον, the ischium.) A luxation of the thigh-bone.

Exitu'ra. (From *exeo*, to come from.) Any abscess which emits a sanious fluid. — *Ruland.*

E'xochas. (Εξοχας; from εξεχω, to project.) In general, a tumour. Paul of Ægina applies the term to soft tubercles at the anus — probably piles.

E'xoche. See *Exochas.*

Exocy'ste. See *Exocystis.*

Exocy'stis. (From εξω, without, and κυστις, the bladder.) *Exocyste.* A prolapsus of the inner membrane of the bladder.

EXO'GENOUS. *Exogenus.* A term applied by De Candolle to plants, the vessels of which are so disposed that the older occupy the circumference of the stem, and the younger the centre; so that the growth of the plant takes place from within.

EXO'MPHALUS. (*us, i.* m.; from εξ, out of, and ομφαλος, the navel.) *Exomphalos.* An umbilical hernia. See *Hernia umbilicalis.*

EXOPHTHA'LMIA. (*a, æ.* f.; from εξ, out, and οφθαλμος, the eye.) A swelling or protrusion of the bulb of the eye, to such a degree that the eyelids cannot cover it. It may be caused by inflammation, when it is termed *exophthalmia inflammatoria*; or from a collection of pus in the globe of the eye, when it is termed the *exopthalmia purulenta*; or from a congestion of blood within the globe of the eye, *exophthalmia sanguinea.*

EXOSTO'SIS. (*is, is.* m.; from εξ, and οστεον, a bone.) *Hyperostosis.* A morbid enlargement, or hard tumour of a bone. The bones most frequently affected with exostosis, are those of the cranium, the lower jaw, sternum, humerus, radius, ulna, bones of the carpus, the femur, and tibia. There is, however, no bone of the body which may not become the seat of this disease. It is not uncommon to find the bones of the cranium affected with exostosis in their whole extent. The ossa parietalia sometimes become an inch thick.

Exostosis, however, mostly rises from the surface of the bone, in the form of a hard round tumour; and venereal exostoses, or nodes, are observed to arise chiefly on compact bones, and such of these as are only superficially covered with soft parts; as, for instance, the bones of the cranium, and the anterior surface of the tibia.

EXO'TIC. (*Exoticus*; from εξω, without.) Belonging to a foreign country. Plants which are not *indigenous* or native in a country, are called *exotic*. The phrase *exotic botany* is used, though not very correctly, to signify the botanical study of exotic plants.

Expanding. See *Patens.*

EXPANSION. The increase of bulk which a body undergoes by the recession of its particles from one another, so that it occupies a greater space while its weight remains the same. Expansion is one of the effects of the agency of caloric. See *Caloric.*

EXPE'CTORANT. (*Expectorans*; from *expectoro*, to discharge from the breast.) Applied to that which increases the discharge of mucus from the lungs.

"Expectorants," says Dr. Good, "are those medicines which rather promote the separation of the viscid phlegm with which the bronchiæ are loaded, than simply inviscate or dilute it; though these are also treated of as expectorants by many writers. The list of the proper expectorants employed formerly was very voluminous; in the present day they are comparatively few; and this proscription has, perhaps, been carried too far. The principle upon which they act is, in some degree, doubtful. The simplest way of accounting for it, is by means of a specific determination to the lungs; for as there are pretty clear proofs of medicines operating specifically on other organs, as that of mercury on the salivary glands, and cinchona on the irritable fibre, there is no reason why we should not expect a like operation on the viscera of the chest. Dr. Cullen is quite at a loss on this subject, from not admitting of specific medicines, or a specific action on any organ. As a general rule, he supposes expectorants to operate on the bronchiæ merely by a diaphoretic power, or that of increasing the flow of the superficial exhalents at large, and consequently the exhalents of the lungs, by which the mucus present in the follicles may be poured out in a less viscid form, and hence in a state to be more easily thrown up by the trachea. But this is a very unsatisfactory view of the question. For, first, admitting there are medicines that act directly upon the exhalents of the skin, a specific power is hereby immediately conceded to one set of organs: and, if such a power exist in respect to one set, there is no reason why it may not in respect to fifty. Next, we see evident proofs of an expectorant power in many medicines, as in gum-ammoniac, where we have no proof whatever of increased exhalation from the surface of the body; and, further, the general explanation gives us no clew to the different operations of particular expectorants. It is possible that in all these cases there is a particular stimulus; but whether this depends upon any sensible quality they possess, we cannot easily determine: for though many of them are more pungent to the taste than others, their degree of expectorant power does not, in every instance, keep pace with their degree of pungency."

EXPECTORATION. (*Expectoratio, onis.* f. ; from *expectoro*, to throw out of the chest.) The act of ejecting matters from the chest. The term is sometimes loosely applied to the matter expectorated, but this is more correctly termed *sputum*. See *Sputum*.

EXPIRA'TION. (*Expiratio ;* from *expiro*, to breathe.) That part of respiration in which the air is expelled from the lungs. See *Respiration*.

EXPLORA'TIO. (From *exploro*, to search out.) Exploration. The investigation of the *physical signs* of disease, as opposed to the diagnosis derived from *symptoms*. Exploration, as it is called, is used chiefly in diseases of the thorax and abdomen, and consists of, *Inspection*, or examination by the eye ; *Palpation*, manual examination, or examination by the sense of touch ; *Mensuration*, or geometrical measurement, with a view to ascertaining the comparative size of the two sides of the chest or belly ; *Percussion*, or striking with the hand, which affords indications cognisable both by the touch and the sense of hearing ; *Auscultation*, which affords indications recognised only by the ear, either unaided or assisted by the intervention of the stethoscope.

EXPRESSED OIL. An oil obtained by pressing it out of the substance containing it ; as olive oil from the olive, almond oil from the almond.

EXPRESSION. (*Expressio, onis.* f. ; from *exprimo*, to press out.) 1. A mechanical operation by which the juices of plants, and various fixed oils, are obtained ; as the *succus conii*, *oleum amygdalæ*, &c.

2. The indications of the state of the feelings, passions, and sensations, presented by the countenance, attitude, and gesture. See *Physiognomy*.

EXPUI'TION. (From *exspuo*, to spit out.) The ejection of redundant fluids from the mouth and fauces.

EXPULSIVE. *Expellens. Expulsorius.* 1. A bandage constructed for exerting pressure on parts, so as to expel pus or other fluids, is called the *expulsive bandage*.

2. The pains which occur in the second stage of parturition, and by which the child is expelled, are called *expulsive pains*.

3. Diaphoretics have been called expulsive medicines.

EXSANGUI'NITY. Bloodlessness. See *Anæmia ;* and *Anæmia, partial*, in the Supplement.

EXSER'TUS. Protruding : opposed, in *Botany*, to enclosed.

EXSICCA'TION. (*Exsiccatio ;* from *exsicco*, to dry up.) Drying. A pharmaceutical and chemical operation, by which plants, chemical preparations, &c., are deprived of their humidity. This is done by exposure to the sun, or to fire, on dry or absorbent substances.

EXSTRO'PHIA. (From εκστρεφω, to invert.) This term is used by Chaussier, synonymously with *extroversion*. It ought to be written *ecstrophia*.

EXSUCCA'TIO. (From *ex*, out of, and *succus*, humour.) Synonymous with *Echymoma*.

EXTE'NSOR. (*or, oris.* m. ; from *extendo*, to stretch out.) A term applied to those muscles the office of which it is to extend any part ; the term is in opposition to flexor.

EXTENSOR BREVIS DIGITORUM PEDIS. A muscle of the toes, situated on the foot. *Extensor brevis*, of Douglas. It arises fleshy and tendinous from the fore and upper part of the os calcis, and soon forms a fleshy belly, divisible into four portions, which send off an equal number of tendons that pass over the upper part of the foot, under the tendons of the extensor longus digitorum pedis, to be inserted into its tendinous expansion. Its office is to extend the toes.

EXTENSOR CARPI RADIALIS BREVIOR. An extensor muscle of the wrist, situated on the fore-arm. *Radialis externus brevior*, of Albinus. *Radialis secundus*, of Winslow. It arises tendinous from the external condyle of the humerus, and from the ligament that connects the radius to it, and runs along the outside of the radius. It is inserted by a long tendon into the upper and back part of the metacarpal bone of the middle finger. It assists in extending and bringing the hand backward.

EXTENSOR CARPI RADIALIS LONGIOR. An extensor muscle of the carpus, situated on the fore-arm, that acts in conjunction with the former. *Radialis externus longior*, of Albinus, *Radialis externus primus*, of Winslow. It arises thin, broad, and fleshy, from the lower part of the external ridge of the os humeri, above its external condyle, and is inserted by a round tendon into the posterior and upper part of the metacarpal bone that sustains the forefingers.

EXTENSOR CARPI ULNARIS. *Ulnaris externus*, of Albinus and Winslow. It arises from the outer condyle of the os humeri, and then receives an addition from the edge of the ulna : its tendon passes in a groove behind the styloid process of the ulna, to be inserted into the inside of the basis of the metacarpal bone of the little finger.

EXTENSOR DIGITORUM COMMUNIS. A muscle situated on the fore-arm, that extends all the joints of the fingers. *Extensor digitorum communis manus*, of Douglas and Winslow. *Extensor digitorum communis, seu digitorum tensor*, of Cowper. *Cum extensore proprio auricularis*, of Albinus. It arises from the external protuberance of the humerus ; and at the wrist it divides into three flat tendons, which pass under the annular ligament, to be inserted into all the bones of the fore, middle, and ring fingers.

Extensor digitorum longus. See *Extensor longus digitorum pedis.*

Extensor indicis. See *Indicator.*

EXTENSOR LONGUS DIGITORUM PEDIS. A muscle situated on the leg, that extends all the joints of the four small toes. *Extensor digitorum longus.* It arises from the upper part of the tibia and fibula, and the interosseous ligament ; its tendon passes under the annular ligament, and then divides into five, four of which are inserted into the second and third phalanges of the toes, and the fifth goes to the basis of the metatarsal bone. This last Winslow reckons a distinct muscle, and calls it *Peroneus brevis.*

Extensor longus pollicis pedis. See *Extensor proprius pollicis pedis.*

Extensor magnus. See *Gastrocnemius.*

Extensor major pollicis manus. See *Extensor secundi internodii.*

Extensor minor pollicis manus. See *Extensor primi internodii.*

EXTENSOR OSSIS METACARPI POLLICIS MANUS. An extensor muscle of the wrist, situated on the fore-arm. *Abductor longus pollicis manus*, of Albinus. *Extensor primi internodii*, of Douglas. *Extensor primus pollicis*, of Winslow. *Extensor primi internodii pollicis*, of Cowper. It arises fleshy from the middle and posterior part of the ulna, from the posterior part of the middle of the radius, and from the interosseous ligament, and is inserted into the os trapezium, and upper part of the metacarpal bone of the thumb.

Extensor pollicis primus. See *Extensor primi internodii.*

Extensor pollicis secundus. See *Extensor secundi internodii.*

EXTENSOR PRIMI INTERNODII. A muscle of the thumb, situated on the hand, that extends the first bone of the thumb obliquely outwards. *Extensor minor pollicis manus*, of Albinus. This muscle, and the *Extensor ossis metacarpi pollicis manus*, are called *Extensor pollicis primus*, by Winslow; *Extensor secundi internodii*, by Douglas; *Extensor secundi internodii ossis pollicis*, by Cowper. It arises fleshy from the posterior part of the ulna, and from the interosseous ligament, and is inserted tendinous into the posterior part of the first bone of the thumb.

EXTENSOR PROPRIUS POLLICIS PEDIS. An extensor muscle of the great toe, situated on the foot. *Extensor longus*, of Douglas. *Extensor pollicis longus*, of Winslow and Cowper. It arises by an acute, tendinous, and fleshy beginning, some way below the head and anterior part of the fibula, along which it runs to near its lower extremity, connected to it by a number of fleshy fibres, which descend obliquely, and form a tendon, which is inserted into the posterior part of the first and last joint of the great toe.

EXTENSOR SECUNDI INTERNODII. A muscle of the thumb, situated on the hand, that extends the last joint of the thumb obliquely backwards. *Extensor major pollicis manus*, of Albinus. *Extensor pollicis secundus*, of Winslow. *Extensor tertii internodii*, of Douglas. *Extensor internodii ossis pollicis*, of Cowper. It arises tendinous and fleshy from the middle part of the ulna, and interosseous ligament; it then forms a tendon, which runs through a small groove at the inner and back part of the radius, to be inserted into the last bone of the thumb. Its use is to extend the last phalanx of the thumb obliquely backwards.

Extensor secundi internodii indicis proprius. See *Indicator.*

Extensor tarsi minor. See *Plantaris.*

Extensor tarsi suralis. See *Gastrocnemius internus.*

Extensor tertii internodii indicis. See *Prior indicis.*

Extensor tertii internodii minimi digiti. See *Abductor minimi digiti manus.*

Extenuatio. See *Leanness.*

Externus mallei. See *Laxator tympani.*

EXTINCTION. The trituration of mercury with other substances till the globules disappear, is sometimes called the extinction of the mercury.

EXTIPULA'TUS. Without stipulæ: applied to stems of plants.

EXTIRPATION. (*Extirpatio*; from *extirpo*, to eradicate.) The complete removal or destruction of any part, either by cutting instruments, or the action of caustics.

E'XTRACT. (*Extractum*, *i.* n.; from *extraho*, to draw out.) 1. When chemists use this term, they generally mean the product of an aqueous decoction.

2. In *Pharmacy*, it includes all those preparations from vegetables which are separated by the agency of various liquids, and afterwards obtained from such solutions, in a solid state, by evaporation of the menstruum. It also includes those substances which are held in solution by the natural juices of fresh plants, as well as those to which some menstruum is added at the time of preparation. Now, such soluble matters are various, and mostly complicated; so that chemical accuracy is not to be looked for in the application of the term. Some chemists, however, have affixed this name to one peculiar modification of vegetable matter, which has been called *extractive*, or extractive principle; and, as this forms one constituent part of common extracts, and possesses certain characters, it will be proper to mention such of them as may influence its pharmaceutical relations. The extractive principle has a strong taste, differing in different plants: it is soluble in water, and its solution speedily runs into a state of putrefaction, by which it is destroyed. Repeated evaporations and solutions render it at last insoluble, in consequence of its combination with oxygen from the atmosphere. It is soluble in alkohol, but insoluble in ether. It unites with alumina, and if boiled with neutral salts thereof, precipitates them. It precipitates with strong acids, and with the oxides from solutions of most metallic salts, especially muriate of tin. It readily unites with alkalis, and forms compounds with them, which are soluble in water. No part, however, of this subject has been hitherto sufficiently examined.

In the preparation of all the extracts, the London Pharmacopœia requires that the fluid be evaporated as speedily as possible, in a broad, shallow dish, by means of a water-bath, until the extract acquires a consistence proper for making pills; and that towards the end of the operation they should be constantly stirred with a spatula. We are also directed to sprinkle a small quantity of rectified alkohol on the softer extracts in order to prevent them from becoming mouldy. These general rules require minute and accurate attention, more particularly in the immediate evaporation of the solution, whether prepared by expression or decoction, in the manner as well as the degree of heat by which it is performed, and the promotion of it by changing the surface by constant stirring, when the liquor begins to thicken, and even by directing a strong current of air over its surface,

if it can conveniently be done. It is impossible to regulate the temperature over a naked fire, or, if it be used, to prevent the extract from burning; the use of a water-bath is, therefore, absolutely necessary, and the uniformity of consistence and strength in extracts prepared in this manner, sufficiently demonstrates its advantages.

EXTRAC'TION. (*Extractio*; from *extraho*, to draw out.) The taking extraneous substances out of the body. Thus we speak of the *extraction* of bullets and splinters from wounds; and of stones from the urethra or bladder. Surgeons also sometimes apply the term *extraction* to the removal of tumours out of cavities; as, for instance, to the taking of cartilaginous tumours out of the joints. They seldom speak of extracting any diseased original part of the body; though they do so in one instance, viz. the cataract.

Extractive. See *Extract.*

EXTRA'CTUM. (From *extraho*, to draw out.) An extract. See *Extract.*

Extractum aconiti. Extract of aconite. Take of aconite leaves, fresh, a pound: bruise them in a stone mortar, sprinkling on a little water; then press out the juice, and, without any separation of the sediment, evaporate it to a proper consistence. The dose is from one grain to five grains. For its virtues, see *Aconitum.*

Extractum aloes purificatum. Purified extract of aloes. Take of aloes, powdered, fifteen ounces; boiling water, a gallon. Macerate for three days, in a gentle heat; then strain the solution, and set it by, that the dregs may subside. Pour off the clear solution, and evaporate it to a proper consistence. The dose is from five to fifteen grains. See *Aloes.*

Extractum anthemidis. Extract of chamomile, formerly called extractum chamæmeli. Take of chamomile flowers, dried, a pound; water, a gallon: boil down to four pints, and strain the solution while it is hot, then evaporate it to a proper consistence. The dose is ten grains to a scruple. For its virtues, see *Anthemis nobilis.*

Extractum belladonnæ. Extract of belladonna. Take of deadly night-shade leaves, fresh, a pound. Bruise them in a stone mortar, sprinkling on a little water; then press out the juice, and, without any previous separation of the sediment, evaporate it to a proper consistence. The dose is from one to five grains. For its virtues, see *Atropa belladonna.*

Extractum cinchonæ. Extract of bark. The London College in their present Pharmacopœia order an *extractum cinchonæ cordifoliæ*, *extractum cinchonæ lancifoliæ*, and *extractum cinchonæ oblongifoliæ*. The formula for each is the same. Take of the bruised bark, fifteen ounces; distilled water, four gallons: boil down in a gallon of water to six pints, and strain the liquor while hot. In like manner boil down the bark in an equal measure of water four times, and strain. Lastly, all the liquors being mixed, evaporate to a proper consistence. This extract should be kept soft for making pills, and hard to be reduced to powder.

Extractum cinchonæ resinosum. Resinous extract of bark. Take of lance-leaved cinchona bark, bruised, a pound; rectified spirit, four pints: macerate for four days, and strain. Distil the tincture in the heat of a water-bath, until the extract has acquired a proper consistence. This is considered by many as much more grateful to the stomach, and at the same time producing all the effects of bark in substance; and by the distillation of it, it is intended that the spirit which passes over shall be collected and preserved. The dose is from ten grains to half a drachm. See *Cinchona.*

Extractum colchici aceticum. Acetic extract of meadow saffron. Take of the fresh cormus of meadow saffron, a pound; acetic acid, three fluid ounces: bruise the cormus gradually sprinkled with the acetic acid, then press out the juice, and evaporate it to a proper consistence in an earthen vessel, which is not glazed with lead. This extract has been introduced by the London College into their last Pharmacopœia. The dose is from one to two grains twice or thrice a day. It is used in the same cases as the other preparations of colchicum.

Extractum colchici cormi. Extract of the cormus of meadow saffron. Take of the cormus of fresh meadow saffron a pound. Bruise the cormus, sprinkled with a little water, in a stone mortar; then press out the juice, and evaporate it unstrained to a proper consistence. This also is one of the new preparations in the last London Pharmacopœia. It is given in the dose of a grain every four hours, and is a very efficacious preparation of colchicum.

Extractum colocynthidis. Extract of colocynth. Take of colocynth, cut in pieces, a pound; water, two gallons. Mix, and boil with a slow fire for six hours, frequently adding distilled water, that it may always fill the same measure; strain the solution while it is hot, and evaporate it to a proper consistence. The dose is from five to thirty grains. For its virtues, see *Cucumis colocynthis.*

Extractum colocynthidis compositum. *Extractum catharticum.* Compound extract of colocynth. Cathartic extract. Take of colocynth pulp, cut in pieces, six ounces; purified extract of aloes, twelve ounces; scammony, powdered, four ounces; cardamom, powdered, an ounce; proof spirit, a gallon. Macerate the colocynth in the spirit, for four days, in a gentle heat: strain the solution, and add it to the aloes, scammony, and soap; then, by means of a water-bath, evaporate it to a proper consistence, the cardamom being mixed in towards the end of the process. The dose is from five to thirty grains.

Extractum conii. Extract of hemlock, formerly called succus cicutæ spissatus. Take of fresh hemlock leaves, a pound. Bruise them in a stone mortar, sprinkling on a little water; then press out the juice, and, without any separation to the sediment, evaporate it to a proper consistence. The dose is from five grains to a scruple.

Extractum digitalis. Extract of foxglove. Take of fresh leaves of digitalis, a pound.

Bruise them, sprinkled with a little water, in a stone mortar; then press out the juice, and evaporate it unstrained to a proper consistence. This has been introduced into the last London Pharmacopœia; but it is necessarily a preparation of very uncertain strength, and therefore not so safe as the powder or tincture. The dose is from half a grain to two grains.

Extractum elaterii. Extract of elaterium. Cut the ripe wild cucumbers into slices, and pass the juice, very gently expressed, through a very fine hair sieve; then set it by for some hours, until the thicker part has subsided; the thinner part, which swims at the top, being rejected. Dry the thicker part which remains in a gentle heat. The dose is from half a grain to three grains. For its virtues, see *Momordica elaterium*.

Extractum gentianæ. Extract of gentian. Take of gentian, sliced, two pounds and a half; boiling distilled water, two gallons. Macerate for twenty-four hours, then boil down to a gallon; strain the hot liquor, and evaporate to a proper consistence. Dose from ten to thirty grains. See *Gentiana*.

Extractum glycyrrhizæ. Extract of liquorice. Take of liquorice root, sliced, two pounds and a half; boiling distilled water, two gallons: macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate to a proper consistence. Dose, from one drachm to half an ounce. See *Glycyrrhiza*.

Extractum hæmato'xyli. Extract of logwood, formerly called extractum ligni campechiensis. Take of logwood, powdered, two pounds and a half; boiling distilled water, two gallons: macerate for twenty-four hours; then boil down to four pints: strain the hot liquor, and evaporate it to a proper consistence. Dose, from ten grains to half a drachm. For its virtues, see *Hæmatoxylon campechianum*.

Extractum humuli. See *Extractum lupuli.*

Extractum hyoscyami. Extract of henbane. Take of fresh henbane leaves, a pound: bruise them in a stone mortar, sprinkling on a little water; then press out the juice, and evaporate it, unstrained, to a proper consistence. Dose, from three to twenty grains. For its virtues, see *Hyoscyamus*.

Extractum jalapæ. Extract of jalap. Take of jalap-root, powdered, two pounds; rectified spirit, a gallon; distilled water, two gallons: macerate the jalap-root in the spirit for four days, and pour off the tincture; boil down the remaining powder in the water to half a gallon; then strain the tincture and decoction separately, and let the former be distilled and the latter evaporated, until each begins to grow thick. Lastly, mix the extract with the resin, and evaporate it to a proper consistence. Let this extract be kept in a soft state, fit for forming pills, and in a hard one, so that it may be reduced to powder. The dose is from ten to twenty grains. For its virtues, see *Convolvulus jalapa*.

Extractum lactucæ. Extract of lettuce. Take of fresh lettuce leaves, a pound. Bruise them, sprinkled with a little water, in a stone mortar; then press out the juice, and evaporate it, unstrained, to a proper consistence. For the virtues, see *lactuca sativa*. Dose, from five to ten grains twice or thrice a day.

Extractum lupuli. *Extractum humuli.* Extract of hops. Take of hops half a pound; boiling distilled water, two gallons: macerate for twenty-four hours, boil down to a gallon; strain while yet hot, and evaporate to a proper consistence. This extract contains the bitter and narcotic principle of the hop, without the aromatic. Dose, gr. v. to ℈j.

Extractum opii purificatum. Extract of opium, formerly called *extractum thebaicum* and *opium colatum*. Take of opium, sliced, twenty ounces; distilled water, a gallon; pour a small quantity of the water upon the opium, and macerate it for twelve hours, that it may become soft; then, adding the remaining water gradually, rub them together until the mixture be complete. Set it by, that the fæculencies may subside; then strain the liquor, and evaporate it to a proper consistence. Dose, from half a grain to five grains.

Extractum papaveris. Extract of white poppy. Take of white poppy capsules bruised, and freed from the seeds, fifteen ounces; boiling distilled water, a gallon. Macerate for twenty-four hours, then boil down to four pints; strain the hot liquor, and evaporate it to a proper consistence. Six grains are about equivalent to one of opium. For its virtues, see *Papaver album*.

Extractum pareiræ. Extract of pareira. Take of pareira, bruised, two pounds and a half; boiling distilled water, two gallons. Macerate for four and twenty hours, boil down to a gallon, strain while yet hot, and evaporate to a proper consistence. This extract may be supposed to contain the virtues of the plant, if indeed the latter possess any. See *Cissampelos pareira*. The extract is given in doses of from ten grains to half a drachm.

Extractum rhei. Extract of rhubarb. Take of rhubarb root, powdered, fifteen ounces; proof spirit, a pint; water, seven pints. Macerate for four days in a gentle heat; then strain and set it by, that the fæculencies may subside. Pour off the clear liquor, and evaporate to a proper consistence. This extract possesses the purgative properties of the root, and the fibrous and earthy parts are separated; it is, therefore, a useful basis for pills. It is also given separately. Dose, from ten to thirty grains.

Extractum rutæ. Extract of rue. This may be prepared like other simple extracts. It is bitter, but does not possess the more active properties of the plant, as these are dissipated along with the volatile oil.

Extractum sarsaparillæ. Extract of sarsaparilla. Take of sarsaparilla root, sliced, two pounds and a half; boiling water, two gallons. Macerate for twenty-four hours, then boil down to a gallon; strain the hot liquor, and evaporate it to a proper consistence. In practice, this is much used, to render the common decoction of the same root stronger and more efficacious. Dose, from ten grains to a drachm. For its virtues, see *Smilax sarsaparilla*.

Extractum saturni. See *Plumbi acetatis liquor.*

Extractum stramonii. Extract of thorn apple. Take of the seeds of stramonium, fifteen ounces; boiling distilled water, one gallon. Macerate for four hours in a lightly covered vessel, near the fire; then take out the seeds, and having bruised them in a stone mortar, put them again into the liquor. Then boil down to four pints; strain while yet hot, and evaporate to a proper consistence. This extract is given in doses of from half a grain to two grains, in the form of pill. It is not at all to be depended on as to uniformity of strength; but Dr. J. Davy informed Dr. Paris, that after many trials of the extract of stramonium as prepared by Mr. Barry *in vacuo*, he found it more uniformly powerful than the common preparation.

Extractum tara'xaci. Take of dandelion root, fresh and bruised, fifteen ounces; boiling distilled water, a gallon. Macerate for twenty-four hours; boil down to four pints, and strain the hot liquor; then evaporate it to a proper consistence. Dose, from ten grains to a drachm. For its virtues, see *Leontodon taraxacum.*

EXTRAFOLIA'CEOUS. *Extrafoliaceus.* Underneath the leaf: applied to stipulæ, which are below the footstalk, and external with respect to the leaf; as in *Astragalus onobrichis.*

EXTRAVASA'TION. (*Extravasatio;* from *extra*, without, and *vas*, a vessel.) A term applied, by pathologists, to the effusion of fluids from their proper vessels or receptacles. Thus, when blood is effused on the surface, or in the ventricles of the brain, it is said that there is an extravasation. When blood is poured from the vessels into the cavity of the peritonæum, in wounds of the abdomen, this accident is called an extravasation. An extravasation of urine is said to take place when, in consequence of a wound, sloughing, or ulceration, the urine makes its way into the cellular substance, or among the abdominal viscera. When the bile spreads among the convolutions of the bowels, from wounds of the gall-bladder, this is also a species of extravasation.

EXTREMITY. *Extremitas.* This term is applied to the limbs, as distinguishing them from the other divisions of the animal, the head and trunk. The extremities are four in number, divided, in man, into upper and lower; in other animals, into anterior and posterior. Each extremity is divided into four parts: the upper, into the shoulder, the arm, fore-arm, and the hand; the lower, into the hip, the thigh, the leg, and the foot.

EXULCERATION. (*Exulceratio, onis.* f.; from *exulcero*, to cause ulcers.) Mostly applied to the commencement of ulceration.

EXU'VIÆ. (*iæ, arum.* pl. f.; from *exuo*, to strip off.) The cast off skins of those animals which change their skins by a natural process. The exuviæ of serpents, *anguium senectæ*, were formerly boiled in wine, and used as a cure for deafness, &c.

Eye. See *Oculus.*

Eye-bright. See *Euphrasia.*

Eyebrow. See *Oculus.*

Eyelid. See *Oculus.*

Eye-tooth. The fangs of the two upper cuspidati are very much larger than those on each side, and extend up near to the orbit, on which account they have been called eye-teeth. See *Teeth.*

F.

F. or ft. In a prescription these letters are abbreviations of *fiat* or *fiant*, let it, or them be made; thus, *f. bolus*, let the substance or substances prescribed be made into a bolus.

FA'BA. (*a, æ.* f. By the Falisci, a people in *Hetruria*, the bean was called *haba;* and from thence, perhaps, *faba*. Martinus derives it from παω, to feed.) See *Bean.*

Faba crassa. See *Sedum telephium.*

Faba ægyptiaca. See *Nymphæa.*

Faba febrifuga. See *Ignatia amara.*

Faba indica. See *Ignatia amara.*

Faba major. See *Bean.*

Faba marina. See *Umbilicus marinus.*

Faba minor. It differs no otherwise from the garden bean than in being less.

Faba pechurim. See *Laurus pechurim.*

Faba porcina. See *Hyoscyamus.*

Faba purgatrix. See *Ricinus.*

Faba sancti Ignatii. See *Ignatia.*

Faba suilla. See *Hyoscyamus.*

Fabaginea. See *Zygophyllum.*

Fabago. See *Zygophyllum.*

Faba'ria. (From *faba*, a bean, which it resembles.) See *Sedum telephium.*

FABRA'RUM AQUA. Forge water. Water in which red-hot iron has been quenched. This is a good mild chalybeate.

FACE. *Facies.* The lower and anterior part of the head. The bones of the face are usually divided by anatomists into those of the upper and lower jaw. In the former, besides the teeth, we find fifteen bones, viz. two *ossa nasi;* two *ossa unguis;* two *ossa malarum;* two *ossa maxillaria superiora;* two *ossa palati;* two *ossa spongiosa inferiora;* two *ossa triangularia;* and the *vomer.* The lower jaw consists of only one bone besides the teeth; the *os maxillaria inferius.* The muscles of the face are numerous, and admit in the human subject of an infinite variety of action, so that all the stronger emotions of the mind have their corresponding characters in the countenance. The minute blood-vessels distributed to the integu-

ments of the face are extremely numerous, and endowed with a high degree of irritability; hence arise continual changes of complexion according to the state of the mind, of the bodily health, of temperature, &c. From these two circumstances, the variety of muscular action, and the changes in the minute circulation, we derive the science of *physiognomy*, which, however it may have been exposed to ridicule when placed upon a false foundation, is of no small utility in the ordinary intercourse of life, and which in the practice of medicine is invaluable as a means of diagnosis. See *Physiognomy*.

The face contains several of the more important organs of sense, and is copiously supplied with arteries, veins, and nerves. These will be found under their respective heads, and need not be described here.

FA'CIAL. *Facialis.* Belonging to the face; as facial nerve, &c.

Facial angle. See *Angle facial.*

Facial artery. 1. The artery, otherwise called the *labial*, the *external maxillary* or angular artery. It is a branch of the external carotid, which, passing under the stylo-hyoid muscle and the tendon of the digastric, penetrates the submaxillary gland, and mounts over the side of the jaw to the angle of the mouth, and thence ascends to the inner angle of the eye, where it is dispersed. In this course it gives off palatine and lingual branches, branches to the submaxillary gland, and to various muscles: a copious supply of blood is sent to the lips by the *inferior labial*, and two coronary branches of this artery.

2. M. Chaussier has given the name of *facial* to the external carotid artery.

Facial nerve. *Nervus facialis.* The eighth pair of nerves. See *Portiodura.*

Facial vein. The vein which returns the blood from the facial artery. It usually joins the external jugular, but sometimes passes to the internal jugular.

Facies. See *Face.*

FA'CIES HIPPOCRA'TICA. That state of the countenance which immediately precedes death; so called, because it has been particularly described by Hippocrates, who calls it προσωπου διαφθορη; (*Coac. Prænot.* 212.) The nose is sharp, the eyes hollow, the temples sunk, the ears cold and contracted, and their lobes inverted; the skin about the forehead hard, tense, and dry; the countenance pale, greenish, or dark.

Facies rubra. See *Gutta rosacea.*

FACTI'TIOUS. *Factitius.* A term applied to any thing which is made by art, in opposition to that which is native, or found already made in nature.

Fæ'ces. The plural of *fæx.* The alvine excretions.

FÆ'CULA. (*a, æ.* f.; diminutive of *fæx.*) A substance obtained by bruising or grinding certain vegetables in water. It is that part which, after a little, falls to the bottom. The fæcula of plants differs principally from gum or mucus in being insoluble in cold water, in which it falls with wonderful quickness. There are few plants which do not contain fæcula; but the seeds of gramineous and leguminous vegetables, and all tuberous roots, contain it most plentifully.

FÆX. (*Fæx, æcis.* f.; an excretion.)

1. The sediment of any fermented liquor; as beer, wine, &c.

2. The alvine excretions are called *fæces.*

FAGA'RA. (*a, æ.* f.; from *fagus*, the beech, which it resembles.) The name of a genus of plants in the Linnæan system. Class, *Tetrandria*; Order, *Monogynia.*

Fagara major. See *Fagara piperita.*

Fagara octandra. The systematic name of the plant which affords that kind of *tacamahaca* which is imported in shells. See *Tacamahaca.*

Fagara piperita. *Fagara major. Castana Luzonis.* This plant is found in Japan and the Philippine islands. Its berries are called Japan pepper, and resemble, in their virtues, the cubebs; they are aromatic, and, according to Avicenna, heating, drying, good for cold, weak stomachs, and astringent to the bowels.

Fago'pyrum. (*um, i.* n.; from *fagus*, the beech, and πυρος, wheat: because its seeds were supposed to resemble the mast, *i. e.* fruit of beech.) See *Polygonum fagopyrum.*

Fagotri'ticum. (*um, i.* n.; from *fagus*, the beech, and *triticum*, wheat.) The buckwheat. See *Fagopyrum.*

FA'GUS. (*us, i.* f; from φαγω, to eat: its nut being one of the first fruits used by man.) 1. The name of a genus of plants in the Linnæan system. Class, *Monœcia*; Order, *Polyandria.*

2. The pharmacopœial name of the beech. See *Fagus sylvatica.*

Fagus casta'nea. The systematic name of the chesnut tree; called also, *Castanea Lopima, Mota, Glans Jovis Theophrasti.* Jupiter's acorn, and Sardinian acorn. The fruit of this plant, *Fagus — foliis lanceolatis, acuminato-serratis, subtus nudis*, of Linnæus, are much esteemed as an article of luxury after dinner. Toasting renders them more easy of digestion; but, notwithstanding, they must be considered as improper for weak stomachs. They are moderately nourishing, as containing sugar, and much farinaceous substance.

Fagus sylvatica. The systematic name of the beech tree; called also, *Fagus, Oxya, Balanda*, and *Valanida.* The fruit and interior bark of this tree, *Fagus — foliis ovatis, obsolete serratis*, of Linnæus, are occasionally used medicinally, the former in obstinate head-ache, and the latter in the cure of hectic fever. The oil expressed from beech nuts is supposed to destroy worms; a child may take two drachms of it night and morning; an adult an ounce. The poor people of Silesia use this oil instead of butter.

Fainting. See *Syncope.*

FAIRBURN. The name of a village in the county of Ross, in North Britain, where there is a sulphureous spring.

Falcanos. Orpiment. — *Ruland.*

FA'LCIFORM. (*Falciformis*; from *falx*, a scythe, and *forma*, resemblance.) Resembling a scythe.

Falciform process. The falx. A process

of the dura mater, that arises from the crista galli, separates the hemispheres of the brain, and terminates in the tentorium.

FA'LCO. (*o*, *nis*. m. ; from *falco*, to hook : so called from the hooked form of its bill.) A genus of birds, of the order *Accipitres*, including the various species of eagle, falcon, hawk, &c. Different parts of these birds had formerly medicinal virtues attributed to them. The dung and fat of the hawk in particular were esteemed in diseases of the eyes. The stone said to be found in the nest of the eagle enjoyed great reputation for its medicinal efficacy. See *Aetites.*

FALDE'LLA. A compress of lint.

Falling of the uterus. See *Prolapsus uteri.*

Falling-sickness. See *Epilepsia.*

Fallopian ligament. See *Poupart's ligament.*

Fallopian tube. See *Tuba Fallopiana.*

FALLTRANCK. *Faltranck.* (German, from *fall*, a fall; and *tranck*, drink.) This name is given in Switzerland and Germany to an infusion of certain herbs gathered among the Alps, which is believed to be of great efficacy in fortifying the body against the effects of falls and blows. These herbs, when dried, are called in France *vulneraire Swisse*, *especes vulneraire*, and *thé Swisse*. The mixture consists of alchemilla, creeping bugloss, betony, periwinkle, pilosella, golden rod, vervain, and several species of artemisia, mint, and veronica.

False aneurism. See *Aneurism.*

False angustura. See *Brucea.*

False pains. See *Parturition.*

False sight. See *Pseudoblepsis.*

False winter's bark. See *Canella alba.*

FALX. (*Falx*, *cis*. f. A scythe.) See *Falciform process.*

FA'MES. Hunger. See *Hunger.*

Fames canina. See *Bulimia.*

FAMES LUPINA. The same as *Fames canina.*

FAMIGERATI'SSIMUM EMPLA'STRUM. (From *famigeratus*, renowned; from *fama*, fame, and *gero*, to bear : so named from its excellence.) A plaster used in intermittent fevers, made of aromatic, irritating substances, and applied to the wrists.

FAMILY. *Familia.* A term used by different naturalists in various acceptations. It is now usually applied to a collection of a number of genera, which are nearly allied to each other by characters derived from their organisation.

FANTÔME. A phantom. The French give this name to the figures or dolls which are used by surgeons to demonstrate the application of bandages, and by obstetricians to illustrate the mechanism of labour.

FARCIMINA'LIS. (From *farcimen*, stuffing, or sausage-meat.) See *Allantoid.*

FARCTU'RA. Stuffing. An operation of the old pharmacy, which consisted in cramming medicinal substances into the body of an eviscerated animal, or the empty rind of a fruit.

FA'RFARA. (*a*, *æ*. f. ; from *farfarus*, the white poplar : so called because its leaves resemble those of the white poplar.) See *Tussilago farfara.*

FARI'NA. (*a*, *æ*. f. ; from *far*, corn, of which it is made.) Meal, or flour. A term given to the pulverulent and glutinous part of wheat, and other seeds, which is obtained by grinding and sifting. It is highly nutritious, and consists of gluten, starch, and mucilage. See *Triticum.*

FARINA FOSSILIS. The agaric mineral. See *Agaricus mineralis.*

FARINÆ RESOLVENTES. Resolvent flowers. This name was formerly given to a mixture of the flower of the seeds of the white lupin, tare, bean, and barley. Emollient cataplasms were made of this meal.

FARINA'CEOUS. (*Farinaceus ;* from *farina*, flour.) A term given to all articles of food which contain *farina ;* those substances called *cerealia*, *legumina*, and *nuces oleosæ*. See *Farina.*

FA'RREUS. (From *far*, corn.) Scurfy. Applied to urine, when it deposits a branny sediment.

FA'SCIA. (*a*, *æ*. f. ; from *fascis*, a bundle: because, by means of a band, materials are collected into a bundle.) 1. A bandage, fillet, or roller.

2. The tendinous expansions of muscles, which bind parts together, are termed *fasciæ*. See *Aponeurosis.*

FASCIA CRIBRIFORMIS. A small web of cellular substance, stretched from the lower edge of Poupart's ligament over the inguinal glands.

FASCIA ILI'ACA. Iliac fascia, or aponeurosis. The strong fascia which covers the inner surface of the iliac and psoas muscles. Externally it is attached to the crista of the ilium. Internally it is continued behind the external iliac vessels to the ridge of the ilium, which bounds the superior aperture of the pelvis. Below this fascia is attached to Poupart's ligament in the two outer thirds of its length.

FASCIA INFUNDIBULIFORMIS. A portion of cellular membrane of a funnel shape, which passes down on the spermatic cord, where it penetrates the fascia transversalis.

FASCIA LATA. A thick and strong tendinous expansion, sent off from the back and from the tendons of the glutei and adjacent muscles, to surround the muscles of the thigh. It is the thickest on the outside of the thigh and leg, but towards the inside of both becomes gradually thinner. A little below the trochanter major, it is firmly fixed to the linea aspera ; and, further down, to that part of the head of the tibia that is next the fibula, where it sends off the tendinous expansion along the outside of the leg. It serves to strengthen the action of the muscles, by keeping them firm in their proper places when in action, particularly the tendons that pass over the joints where this membrane is thickest.

FASCIA PROPRIA. The name given by Sir A. Cooper to the proper cellular envelop of a hernial sac.

Fascia spiralis. See *Spiral bandage.*

FASCIA SUPERFICIALIS. A very thin layer of cellular membrane, which covers the abdominal muscles immediately under the skin. It adheres to the crural arch of the fascia lata, and is continued downwards upon the spermatic cord to the scrotum.

FASCIA TORTILIS. A tourniquet.

Fascia transversa'lis. The cellular membrane lining the inner surface of the *transversalis abdominis* muscle. The anatomy of this fascia is minutely described in the splendid work of Sir A. Cooper on hernia.

Fa'scial. (*Fascialis*; from *fascia*, a band.) Of or belonging to a fascia.

Fascia'tio. (From *fascia*, a band.) The binding up any diseased or wounded part with bandages.

FASCICULA'RIS. (From *fascis*, a bundle.) Fascicular: bundled. Applied to roots which are sessile at their base, and consist of bundles of finger-like processes; as the root of the *Ophris nidus avis*.

FASCICULA'TUS. Fasciculate: bundled or clustered. Applied to nerves, stems of plants, leaves, &c.

FASCI'CULUS. (From *fascis*, a bundle.) 1. In *Pharmacy*, a handful.

2. In *Botany*, a fasiculus means a number of flowers on little stalks, variously inserted and subdivided, collected into a close bundle, level at the top; as in sweet-william. It differs from,

1. A *corymb*, in the little stalks coming only from about the apex of the peduncle, and not from its whole length.

2. An *umbel*, from the stalks not coming from a common point.

3. A *cyme*, in not having its principal division umbellate.

Fascina'tio. (*o*, *onis*; f.) Fascination. It was believed in superstitious times that magicians had the power of inflicting various diseases and evils on individuals by a spell or a look, without coming in contact with them, or administering any thing to them: this was called *fascination*, and divers medicines, amulets, and ceremonies were put in operation against it. The notion of the *evil eye*, which is not yet entirely extinct among the ignorant, is a vestige of this superstition.

Fasciola. (*a*, *æ*. f; diminutive of *fascia*.) The name of a genus of entozoa in some arrangements. The *fluke worm*. See *Distoma*.

Fasciola hepatica. See *Distoma hepaticum*.

Fasciola humana. See *Distoma hepaticum*.

Fastidium cibi. Want of appetite. See *Anorexia*.

FASTIGIA'TUS. Flat-topped: applied to umbelliferous flowers and others when there are many together which rise to the same height, so as to form a flat surface at the top.

FASTING. A want of the supply of food to the stomach. When produced by want of appetite, without any other apparent affection of the stomach, this often arises from too great fatigue, or protracted fasting; from violent passions of the mind; and from habit, or other cause, enabling the system to sustain almost total abstinence for a long time. The newspapers, and even medical journals of different nations, and the transactions of learned societies, abound with examples of persons having fasted for a term of time so apparently extravagant as to exceed credibility. In most of these cases, and probably in all, if they had been critically investigated, water, tea, or some other fluid, would have been found to have been occasionally taken.

Fat. See *Adeps*.

Fatu'ity. (*Fatuitas*; from *fatuus*, silly.) Idiotism. See *Amentia*.

Fau'ces. (Plural of *faux*.) See *Faux*.

Faufel. An Arabic name of the Areca nut.

FAUX. (*Faux*, *cis*. f.; in the plural, *fauces*.) 1. In *Anatomy*, the gorge, or opening of the pharynx. See *Deglutition*.

2. In *Botany*, applied to the mouth, or opening of the tube of a monopetalous corol. See *Corolla*.

FAVO'SUS. (From *favus*, a honeycomb.) Favose: honeycomb-like. Applied, 1. To some cutaneous diseases; as *porrigo favosa*, which is covered with a honeycomb-like gummy secretion.

2. To parts of plants; as the receptacle of the onopordium, which has cells like a honeycomb.

FA'VUS. (*us*, *i*. m.; a honeycomb.) A pustule larger than the *acor*, flatter, and not acuminated. It contains a more viscid matter than the acor; its base, which is often irregular, is slightly inflamed; and it is succeeded by a yellow, semi-transparent, and sometimes cellular scab, like a honeycomb; whence its name.

Feathered. See *Plumosus*.

FE'BRES. (The plural of *febris*.) An order in the class *Pyrexiæ* of Cullen, characterised by the presence of pyrexia, without primary local affection.

FEBRI'CULA. (*a*, *æ*. f.; dim. of *febris*, a fever.) A slight fever.

Febri'fuga. (*a*, *æ*. f.; from *febrem fugare*, to drive away a fever.) The plant feverfew; lesser centaury, &c.

FE'BRIFUGE. (*Febrifugus*; from *febris*, a fever, and *fugo*, to drive away.) That which possesses the property of curing or alleviating fever. Applied chiefly to medicines used against the ague.

Febrifugum crenii. Regulus of antimony.

Febrifugum oleum. Febrifuge oil. The flowers of antimony, made with sal-ammoniac and antimony sublimed together, and exposed to the air, which causes them to deliquesce.

Febri'fugus. See *Febrifuge*.

Febrifugus pulvis. Febrifuge powder. The Germans give this name to the pulvis stypticus Helvetii. In England, a mixture of oculi cancrorum and emetic tartar, in the proportion of half a drachm and two grains, has obtained the same name; in fevers, it is given in doses of gr. iii. to iv.

Febrifugus sal. A muriate of potash.

FE'BRIS. (*is*. *is*, f.; from *ferveo*, to be hot.) *Pyrexia*. Fever. The name of a very extensive and important class of diseases which, although much diversified, are generally conceived to have something common in their nature. In a wide acceptation, the term *fever* has been applied to every case in which there is acceleration of the pulse, increased heat of the surface of the body, thirst, and more or less general disturbance of the functions of the whole system. Now these symptoms present themselves in connexion

both with idiopathic fever, and with those symptomatic affections which arise from local inflammation; hence fever is divided into *idiopathic* and *symptomatic*. With reference to symptomatic fever, there is no doubt of its immediate dependence on local disease or injury; with respect to what is called idiopathic fever, although many attempts have been made of late years to show that it also is merely symptomatic of inflammation in some particular organ, the general opinion of pathologists is adverse to this supposition, and, in truth, on a fair comparison of these morbid states, it seems not a little surprising that their identity should ever have been maintained. In the present article, therefore, we shall treat only of idiopathic fever, referring to the article *Inflammation* for an account of the constitutional disturbance attendant on that state; and to the article *Hectic Fever* for an account of that more protracted form of irritation which accompanies local diseases that wear out the powers of the constitution or tax them very severely for a great length of time.

Idiopathic fever is generally divided into *intermittent*, *remittent*, and *continued*. An intermittent fever is what is commonly called an *ague*, and has already been treated of under that head. A remittent fever is one in which the symptoms never entirely intermit, but undergo a marked diminution and exacerbation at periods more or less regular. The paroxysm of an ague has been considered by many practical writers as a sort of type of fever in general, and it doubtless concentrates many of the more prominent symptoms of this affection, and we therefore refer to it in order to avoid some very tedious and not very useful descriptions of the more protracted forms of fever; which will be much better understood by the diligent observation of a few cases, than by all the descriptions ever written. At the same time, we would by no means be understood to imply that all fevers are made up merely of agues variously interwoven; an extremely hypothetical notion, which, though entertained by some writers of high authority, and among others by Dr. Cullen, is in no degree countenanced by what is known of the etiology, phenomena, and treatment of febrile diseases. The subject of remittent fever is one of considerable extent, and which has been involved in much controversy; it is, moreover, rendered more intelligible by the previous consideration of intermittent and continued fever: we shall therefore treat of it separately (See *Remittent Fever*), and shall at present confine ourselves to the consideration of *continued fever*. Continued fever has been divided by nosologists into *synocha* or inflammatory fever; *typhus*, or low fever; and *synochus* or common continued fever, in which the symptoms at the commencement are allied to synocha, and towards the termination to typhus.

Synocha is a rare form of fever. It appears to be more frequent in warm than in temperate climates, and among us occurs so seldom that many have doubted its existence as an idiopathic form of fever. We see no reason to doubt the probability of its occasional occurrence independently of local inflammation, because in the hot stage of an ague in a young and plethoric patient we have every symptom of the highest inflammatory excitement of the system without any local affection to account for it.

Typhus is that form of fever which has been known under the names of *putrid fever*, *petechial fever*, *spotted fever*, *asthenic fever*, *jail fever*, *camp fever*, *low fever*, *malignant fever*, *pestilential fever*. In its more strongly marked forms, it is characterised by great debility and exhaustion of the vital powers, indicated, as the disease advances, by a very rapid and feeble pulse; low muttering delirium; subsultus tendinum; a dark fur upon the tongue and sordes on the teeth; effusions of blood under the skin causing petechiæ and vibices; sometimes passive hæmorrhage from the nose or intestines; aphthæ in the mouth and fauces; an extremely vitiated state of all the secretions, causing an offensive odour from the body of the patient; an anxious yet vacant physiognomy; an attitude expressive of entire exhaustion of the muscular power, and a cadaverous complexion of the countenance and of the whole surface of the body. Two forms of typhus have been distinguished, namely, *typhus gravior*, malignant typhus, or putrid fever of the older writers, and *typhus mitior*, mild typhus, or what is sometimes called *nervous fever*, in which the symptoms are less formidable, there is less tendency to the formation of petechiæ, and the case approximates to one of ordinary continued fever with an unusual degree of debility and nervous depression.

Synochus, or common continued fever, is the most familiar form of fever in this country. It varies greatly in its type according to the constitution of the atmosphere, the locality, and the circumstances of those among whom it is prevalent; it sometimes assumes a distinctly inflammatory form; at others it presents highly typhoid symptoms, and occasionally it is little disposed to either of these deviations, but preserves its course as common continued fever, with or without some slight inflammatory affection of the head, chest, or abdomen.

It has been matter of much dispute whether typhus is merely a modification of ordinary fever, or whether it is *sui generis*, and arises from a specific contagion. Few, however, who have seen much of the disease, will deny, that in the same epidemy we occasionally observe every shade of variety in the type of fever; that in different parts of the same district we find the character of fever greatly modified by the relative salubrity of different situations, and the degrees of cleanliness and domestic comfort among different masses of the same population; and that the type of fever is often entirely changed in the same individual by a transition from bad air, filth, and wretchedness, to a pure atmosphere, cleanliness, and comfort. It is indeed argued by some, that, although common continued fever may under certain circumstances assume very much the appearance of typhus, it is nevertheless only highly *typhoid* or resembling typhus without actually being typhus; but we submit that since we know nothing whatever of the essence of typhus, and can only infer its

existence from the presence of certain symptoms, we are warranted in concluding that a case so typhoid as not to be distinguishable by its symptoms from typhus is in effect *typhus*. On the whole then there seems much reason to believe that the different kinds of continued fever are essentially the same, and that the particular type of the fever is determined by various causes, some of which we are able to trace, while others, and those the most influential, entirely elude our observation. Another question on which there has been much diversity of opinion is the contagious nature of fever; but we need not discuss this point here, because almost all practical men are now agreed that *typhus* is essentially a contagious disease; again, it is generally admitted that it evinces no great tendency to spread in this manner unless where a number of persons are crowded together in a close atmosphere or under other insalubrious circumstances; lastly, it is well known that common continued fever under similar circumstances always assumes more or less of the typhoid character: we may hence infer with much probability that continued fever in general involves in its nature a contagious principle, which is seldom very active in sporadic cases where ventilation and cleanliness are properly attended to, but which becomes highly active under opposite circumstances.

There are several diseases which, although they present the phenomena of continued fever, are distinguished from the common forms of fever by some remarkable peculiarities, and which arise from a specific contagion that always generates the same disease: such are small-pox, scarlet fever, measles, and the plague. These will therefore be considered separately.

The proximate cause of fever has been a subject of enquiry from the earliest times. For the following survey of the principal hypotheses that have been maintained down to the commencement of the present century, we are indebted to Dr. Mason Good.

I. *That of the Greek schools founded on the doctrine of a concoction and critical evacuation of morbific matter.* It was the opinion of Hippocrates, that fever is an effort of nature to expel something hurtful from the body, either ingenerated, or introduced from without. Beholding a violent commotion in the system, followed by an evacuation from the skin and kidneys, with which the paroxysm terminated, he ascribed the commotion to a *fermentation*, *concoction*, or *ebullition*, by which the noxious matter was separated from the sound humours; and the evacuation to a despumation or scum which such separation produced, or rather to the discharge of this morbid scum from the emunctories that open externally. Galen supported this view with all the medical learning of his day; and it is the only explanation of fever to be met with in medical writings, through the long course of three thousand years; in fact, till the time of Sydenham, who still adhered to it, and whose pages are full of the language to which it naturally gave birth. It blended itself almost insensibly with the language of the chemists of the day.

And hence, the supposed despumation was contemplated as possessed, according to different circumstances, of different chemical qualities and characters; and particularly as being acid, alkaline, effervescent, or charged with some other acrimonious principle, too highly exalted, or in too great a proportion.

This doctrine, considered merely hypothetically, is not only innocent, but highly ingenious and plausible. It is in unison with several of the phænomena of febrile diseases; and derives a strong collateral support from the general history of eruptive fevers, in which we actually see a peccant matter, producing general commotion, multiplying itself as a ferment, and at length separated and thrown off at the surface by a direct depuration of the system.

So far, therefore, as relates to eruptive fevers, the opinion is sufficiently correct. But the moment it is brought forward as the proximate cause of fever, properly so called, in which there is no specific eruption, it completely fails.

For, first, no explanation is here given as to the means by which any such concoction or fermentation, or multiplication of morbific matter in any way takes place. Next, there are many fevers produced evidently by cold, fear, and other excitements, as well mental as corporeal, in which, most certainly, there is no morbific matter introduced, and wherein we have no reason to conceive there is any generated internally; while the disease, limited perhaps to a single paroxysm, closes nevertheless with an evacuation from the skin or the kidneys. And, thirdly, we sometimes behold fevers suddenly cured, as Dr. Cullen has observed, by a hæmorrhage so moderate, as, for example, a few drops of blood from the nose, as to be incapable of carrying out any considerable portion of a matter diffused over the whole mass of the blood; while we are equally incapable of conceiving how such diffused morbific matter could collect itself at a focal point, or pass off at a single outlet; or of tracing in the discharge, after the minutest examination, any properties different from those of blood in a state of full health.

II. *That of Boerhaave founded on the doctrine of a peculiar viscosity or lentor of the blood.* The acute and penetrating mind of Boerhaave, who was born in 1668, was sufficiently sensible of this danger; and the discoveries which were now taking place in chemistry and physiology, led him progressively to the construction of a new theory, which, in a few years, became so popular, as to obtain a complete triumph over that of the Greek schools.

Leeuwenhoeck, by a delicate and indefatigable application of the microscope to animals of a transparent skin, had endeavoured to establish it as a fact, that the constituent principles of the blood consist of globular corpuscles; but that these corpuscles differ in size in a regular descending series, according to the constituent principles themselves; and that each set of principles has its peculiar blood-vessels, possessing a diameter just large enough to admit the globules that belong to it, and con-

sequently incapable, without force, of allowing an entrance of those of a larger magnitude; and hence that the blood-vessels possess a descending series as well as the particles of the blood.

It was upon this supposed fact, that Boerhaave built his hypothesis. He conceived that almost all diseases may be resolved into an introduction of any given series of particles of blood into a series of vessels to which they do not properly belong; and he distinguished such introduction by the name of *error loci*. He conceived still farther, that this heterogeneous admixture is very frequently taking place; and that its chief cause consists in a disproportion of one or more sets of the sanguineous principles to the rest, by which their globular form is occasionally broken down and destroyed, and rendered either too thin and serous, or too gross and viscid. The viscidity of the blood he distinguished by the name of *lentor*; and to a prevalence of this lentor, or viscidity, he ascribed the existence of fever; maintaining that the general disturbance which constitutes fever proceeds from an *error loci* of the viscid blood, whose grosser corpuscles, from their undue momentum as well as superabundance, press forcibly into improper series of vessels, and stagnate in the extremities of the capillaries; whence the origin of the cold stage, and consequently of the stages that succeed it, to which the cold stage gives rise.

The system of Boerhaave, therefore, consisted of an elegant and artful combination of both the earlier and later doctrines of corpuscular physiology.

The most triumphant fact in favour of the Boerhaavian hypothesis is, that the crust on the blood in inflammatory fever, is often found peculiarly dense. But as fevers (and certainly the greater number) are found without any such crust; and as a similar crust, though perhaps not quite so dense, exists under other and very different states of body, as in pregnancy and scurvy, even this leading appeal has long lost its power of conviction: whilst the abruptness with which fevers make their assault from sudden occasional causes, and in constitutions of every diversity, forbid the supposition that, in such cases, a lentor or sizy crasis of the blood can have time to be produced, however it may exist occasionally, and be perhaps the source of other disorders.

III. *That of Stahl, Hoffman, and Cullen, founded on the doctrine of a spasm on the extremities of the solidum vivum or living fibre.* To this period of time, in the production of fever, and indeed of all other diseases, the human body was regarded as almost entirely passive, a mere organic machine operated upon by some *autocrateia*, as *Nature*, or a *vis medicatrix*, but in the same manner as other machines, and mostly by similar laws. Its muscles were contemplated as mechanical levers, and its vessels as hydraulic tubes, whose powers were calculated upon the common principles of mechanics and hydronamics; and were only supposed to be interfered with by the internal changes perpetually taking place in the fluids they had to convey. A new era, however, at length began to dawn upon the world; a more comprehensive spirit to pervade medical study: the animal frame was allowed to exhibit pretensions superior to the inanimate, and not only to be governed by powers of its own, but by powers which are continually and systematically, from a given point, operating to a preservation of health, where it exists, and to a restoration of health, whare it has been lost or injured. Stahl, who was contemporary with Boerhaave, and in the university of Hall, in 1694, first started this loftier and more luminous idea,—more luminous, though the light was still struggling with darkness—made the mind the controlling principle, and the *solidum vivum*, or nervous system, the means by which it acted. Fever, on his hypothesis, consisted in a constrictive or *tonic spasm*, in his own language, *spasmus tonicus*, produced by a torpor or inertness of the brain, at the extremity of the nerves, and counteracted by the remedial exertions of the mind, the *vires medicatrices* of his hypothesis, labouring to throw off the assailing power; whence the general struggle and commotion by which the febrile paroxysm is characterised. Hoffman, who was a colleague of Stahl, took advantage of this new view; followed up the crude and primary ideas of Stahl with much patient and laborious investigation; and soon presented to the world a more correct system, in a more attractive style, but apparently with a disingenuous concealment of the source from which he had borrowed his first hints. He omitted the metaphysical part of the Stahlian hypothesis, took from the mind the conservative and remedial power over the different organs with which Stahl had so absurdly endowed it; seated this power as a law of life in the general organisation; separated the nervous from the muscular fibres, the latter of which were regarded as only the extremities of the former by Stahl; allowed a wider range and longer term to the constrictive spasm of fever; and changed its name from spasmus *tonicus* to spasmus *peripheric us*: giving, also, to the moving power of the muscular or irritable fibres the name of *vis insita*, as that of the nervous fibre was called *vis nervea*.

It is highly to the credit of Boerhaave, that his mind, in the latter part of his life, was so fully open to the merits of this hypothesis, that he admitted the agency of the nervous power, though a doctrine that struck at the root of his own system.

Dr. Cullen, about the year 1760, boldly ventured upon a new attempt for the purpose of simplifying and facilitating the pathology of fever. As his basis he took the hypothesis of Stahl, as modified and improved by Hoffman: and on this basis erected his stately and elaborate structure, so well known to the medical world, full of ingenuity and daring genius, and which, if it be at this moment crumbling into decay, certainly is not falling prostrate before any fabric of more substantial materials, or more elegant architecture. Cullen has been accused of the same want of ingenuousness towards Hoffman, as Hoffman is chargeable with

towards Stahl; and of having introduced his system to the public with little or no acknowledgment of the sources from which he has drawn. But surely no one can bring forward such an accusation, who has read with any degree of attention the preface to his Practice of Physic, in which he gives a full account of Dr. Hoffman's system in his own words, and pays complete homage to his merits.

According to the more elaborated principles of the Cullenian system, the human body is a congeries of organs, regulated by the laws not of inanimate matter, but of life, and superintended by a mobile and conservative power or energy, seated in the brain, but distinct from the mind or soul; acting *wisely*, but *necessarily*, for the general health; correcting deviations, and supplying defects, not from a knowledge and choice of the means, but by a pre-established relation between the changes produced, and the motions required for the restoration of health; and operating, therefore, through the medium of the moving fibres, upon whose healthy or unhealthy state depends the health or unhealthiness of the general frame: which fibres he regarded with Stahl, as simple nerves, the muscular filaments being nothing more than their extremities, and by no means possessed of an independent *vis insita*.

The brain, therefore, upon this hypothesis, is the *primum mobile*, but it closely associates in its action with the heart, the stomach, and the extreme vessels. The force of the heart gives extension to the arteries, and the growth of the body depends upon such extension in conjunction with the nutritious fluid furnished by the brain, and deposited by the nerves in the interstices of their own fibres; the matter of which fibres is a solid of a peculiar kind, whose parts are united by chemical attraction. All nervous power commences in the encephalon; it "consists in a motion beginning in the brain, and propagated from thence into the moving fibres, in which a contraction is to be produced. The power by which this motion is propagated, we name," says Dr. Cullen, "the *energy* of the brain; and we therefore consider every modification of the motions produced as modifications of that energy." He further lays it down as a law of the economy, that the energy of the brain is alternately excited and collapsed, since every fibrous contraction is succeeded by a relaxation: whence spasms and convulsions are *motus abnormes*, and consist in an irregularity of such alternation. But we must distinguish, in this system, between the energy of the brain and the vital fluid it sends forth by the nerves; for while the former rises and sinks alternately, the latter remains permanently the same. It is not a secretion, but an inherent principle, never exhausted, and that never needs renewal.

This hypothesis, in its various ramifications, influenced every part of his theory of medicine, and consequently laid a foundation for his doctrine of fever. The proximate cause of fever was, in his opinion, a collapse or declination of the energy of the brain, produced by the application of certain sedative powers, as contagion, miasm, cold, and fear, which constitute the remote causes. This diminished energy extends its influence over the whole system, and occasions an universal debility; but chiefly over the extreme vessels, on which it induces a spasm; and in this spasm the cold fit is supposed to consist.

"Such, however," to adopt the words of Cullen himself, "is the nature of the animal economy, that this debility proves an indirect stimulus to the sanguiferous system; whence by the intervention of the cold stage, and spasms connected with it, the action of the heart and larger arteries is increased, and continues so till it has had the effect of restoring the energy of the brain, of extending this energy to the extreme vessels, of restoring, therefore, their action, and thereby especially overcoming the spasm affecting them; upon the removing of which, the excretion of sweat, and other marks of the relaxation of the excretories, take place."

This relaxed or perspiratory section of the paroxysm, however, is not regarded by Cullen as a part of the disease, but as the prelude to returning health. Yet the fit still consists of three stages: the first of debility or diminished energy; the second, of spasm; and the third, of heat. And though Cullen had some doubts whether the remote causes of fever might not produce the spasm as well as the atony of the nervous system, yet he inclined to ascribe the second stage to the operation of the first, as he did most decidedly the third to that of the second: and thus to regard the whole as a regular series of actions, employed by the *vis medicatrix naturæ* for the recovery of health.

That fever, in its commencement or earliest stage, is characterised by debility of the living fibre, or, more closely in the words of Cullen, by diminished energy of the brain, extending directly or indirectly to the voluntary muscles and capillaries, cannot for a moment be doubted by any one who accurately watches its phenomena. And thus far the Cullenian hypothesis is unquestionably correct; as it appears to be, also, in supposing the cold stage to be the foundation of the hot, and of the excretion of sweat by which the hot stage is succeeded. But it fails in the two following important points, without noticing a few others of smaller consequence. The spasm of the minute vessels produced by debility takes the lead in the general assault; and, though it forms only a link in the remedial process, is the most formidable enemy to be subdued: and hence all that follows in the paroxysm is an effort of the system to overcome this spasm. The effort at length proves successful: the debility yields to returning strength; the spasm is conquered, and the war should seem to be over. But this is not the fact: the war continues notwithstanding; there is nothing more than a hollow truce; debility and spasm take the field again, and other battles remain to be fought. There is nothing in this hypothesis to account for a return of debility and spasm, after they have been subdued; nor to show why spasm should ever, in the first instance, be a result of debility.

The next striking defect is, that debility is here made a cause of strength; the weakened action of the first stage giving rise to the increased action and re-excited energy that restore the system to a balance of health: and here, again, we stand in need of the interposition of some present divinity to accomplish such an effort by such means.

IV. *That of Brown and Darwin founded on the doctrine of accumulated and exhausted excitability or sensorial power.* It is not, therefore, to be wondered at that this system, with all its ingenuity and masterly combination, should not have proved satisfactory to every one. In reality, it did not for many years prove satisfactory to every one in the celebrated school in which it was first propounded. And hence, under the plastic hands of Brown, arose another hypothesis, of which we shall proceed to give a very brief outline, together with the modification it received under the finishing strokes of Darwin.

It had great simplicity of principle, and some plausibility of feature; it attracted the curious by its novelty, the indolent by its facility, and every one by the boldness of its speculations. It circulated widely, and soon acquired popularity abroad, as well as at home.

Man, according to Dr. Brown, is an organised machine, endowed with a principle of excitability, or predisposition to excitement, by means of a great variety of stimuli, both external and internal, some of which are perpetually acting upon the machine; and hence the excitement which constitutes the life of the machine is maintained. Excitability, therefore, is the nervous energy of Cullen, and, like that, is constantly varying in its accumulation and exhaustion; yet not, like the nervous energy of Cullen, under the direction and guidance of a *vis conservatrix et medicatrix naturæ*, distinct from the matter of the organisation itself, but passively exposed to the effect of such stimuli as it may chance to meet with, and necessarily yielding to their influence.

Upon this hypothesis, excitement is the vital flame, excitability the portion of fuel allotted to every man at his birth, and which, varying in every individual, is to serve him without any addition for the whole of his existence: while the stimuli by which we are surrounded, are the different kinds of blasts by which the flame is kept up. If the fuel or excitability be made the most of, by a due temperature or mean rate of blasts or stimuli, the flame or excitement may be maintained for sixty or seventy years. But its power of supporting a protracted flame may be weakened by having the blast either too high or too low. If too high, the fuel or excitability will, from the violence of the flame, be destroyed rapidly, and its power of prolonging the flame be weakened directly: and, to this state of the machine, Brown gave the name of indirect debility, or exhausted excitability. If the blasts or stimuli be below the mean rate, the fuel, indeed, will be but little expended, but it will become drier and more inflammable, and its power of prolonging the flame will be still more curtailed than in the former case; for half the blast that would be required to excite rapid destruction antecedently, will be sufficient to excite the same effect now. This state of the machine, therefore, the author of the hypothesis contradistinguished by the name of direct debility, or accumulated excitability.

Upon these principles he founded the character and mode of treatment of all diseases. They consist but of two families, to which he gave the name of sthenic and asthenic: the former produced by accumulated excitability, and marked by direct debility; the latter occasioned by exhausted excitability, and marked by indirect debility.

Fevers, therefore, under this hypothesis, like other diseases, are either sthenic or asthenic: they result from accumulated or exhausted excitability. Inflammatory fever belongs to the first division, and typhus to the second.

The Brunonian hypothesis offers one principle that is unquestionably founded on fact, and is peculiarly worthy of attention: that of accumulated excitability from an absence or defect of stimuli; in colloquial language, an increase of energy by rest. And it is this principle which forms the hinge on which turns the more finished system of Darwin.

Sensible of the objection that weighs equally against that part of the system of Cullen and Brown, which represents the energy or excitability of the living frame as capable of recruiting itself after collapse or exhaustion, without a recruiting material to feed on, he directly allows the existence of such a material; regards it as a peculiar secretion, and the brain as the organ that elaborates and pours it forth. The brain, therefore, in the system of Darwin, is the common fountain from which every other organ is supplied with sensorial fluid, and is itself supplied from the blood, as the blood is from the food of the stomach.

All this is intelligible; but when, beyond this, he endows his sensorial fluid with a mental as well as a corporeal faculty, makes it the vehicle of ideas as well as of sensation, and tells us that ideas are the actual "contractions, or motions, or configurations of the fibres which constitute the immediate organ of sense," he wanders very unnecessarily from his subject, and clogs it with all the errors of materialism.

He supposes the sensorial power thus secreted, to be capable of exhaustion in four different ways, or through four different faculties of which it is possessed: the faculty of *irritability*, exhausted by external stimuli, affecting simple irritable fibres: that of *sensibility*, exhausted by stimuli affecting the fibres of the organs of sense: that of *voluntarity*, exhausted by stimuli affecting the fibres of the voluntary organs acting in obedience to the command of the will: and that of *associability*, exhausted by stimuli affecting organs associated in their actions by sympathy or long habit. By all or any of these means, the sensorial power becomes evacuated, as by food and rest it becomes replenished, often, indeed, with an accumulation or surplus stock of power.

In applying this doctrine to fever, he con-

siders its occasional causes, whatever they may be, as inducing a quiescence or torpor of the extreme arteries, and the subsequent heat as an inordinate exertion of the sensorial power hereby accumulated to excess; and, consequently, the fever of Darwin commences a stage lower than that of Cullen, or in the cold fit, instead of in a collapse of the nervous energy lodged in the brain.

Now, allowing this explanation to account for the cold and hot stages of a single paroxysm of fever, like the spasm of Cullen, it will apply no farther. For when the sensorium has exhausted itself of its accumulated irritability, the disease should cease. It may, perhaps, be said, that a second torpor will be produced by this very exhaustion, and a second paroxysm must necessarily ensue. Admitting this, however, for a moment, it must be obvious that the first or torpid stage only can ensue; for the system being now quite exhausted, the quiescence that takes place during the torpor can only be supposed to recruit the common supply necessary for health: we have no reason to conceive, nor is any held out to us, that this quantity can again rise to a surplus. Yet it must be farther remarked, that in continued fevers we have often no return of torpor or quietude whatever, and, consequently, no means of reaccumulating irritability; but one continued train of preternatural action and exhaustion, till the system is completely worn out. And to this objection the Darwinian hypothesis seems to be altogether without a reply. — *Good's Study of Medicine*, vol. ii. p. 44. *et seq.*

All these doctrines once so laboriously sustained and so fiercely assailed, have now become obsolete, and have given place to others which appear not to be at all more consonant with just reasoning, and which are much more obviously opposed to the evidence of our senses. Of late years there has been a great tendency to localise fever, and to regard it as the result of inflammation of some particular organ. Dr. Clutterbuck has written to prove that all fever consists in inflammation of the brain. M. Broussais is equally certain that fever commences in inflammation of the mucous membrane of the stomach and intestines. Professor Marcus also believes that fever consists essentially in inflammation, but regards inflammation of the brain as the cause of typhus only, while he ascribes hectic fever to inflammation of the lungs, puerperal fever to that of the peritonæum, and catarrhal fever to that of the mucous membrane of the trachea. Lastly, M. Bretonneau has promulgated the opinion that continued fever arises from an inflammatory enlargement of the conglomerate mucous glands of the lower portion of the ileum, and solitary mucous glands of the cœcum — a lesion which he has minutely described under the name of *Dothen-enteritis*. MM. Petit and Serres had previously described a continued fever prevalent in Paris in 1811, and the two following years, the symptoms of which they ascribed to a certain morbid state of the mucous membrane of the lower portion of the small intestines, and of the cœcal valve, accompanied with enlargement and suppuration of the mesenteric glands; but M. Bretonneau first described the anatomical lesion of Peyer's and Brunner's glands. His opinion has been espoused and supported in a very elaborate work by the distinguished Louis, and is now very extensively adopted by the French pathologists.

It is fortunate, perhaps, for the cause of truth, that these conflicting hypotheses have all arisen within a few years, and consequently that they tend to neutralise one another. If it be asserted by one set of observers, that fever depends exclusively on inflammation of the brain, by another, that it depends exclusively on general inflammation of the gastro-enteric mucous membrane, and by a third, that it depends exclusively on an inflammatory enlargement of the mucous glands of the intestines, it is quite clear that they cannot all be right, and we are naturally led to inquire whether there has not been something defective in the principle on which these observations have been conducted? Now, if we cast a glance backwards over the past history of fever as recorded by the most diligent observers in different ages and in different countries, we shall find that an infinite variety of morbid states have presented themselves as accompaniments of continued fever, and formed peculiar features of certain epidemics; — every form of visceral inflammation, membranous, and parenchymatous, cynanche, catarrh, erysipelas, and a host of other affections. We shall further find, that particular complications occur in the ordinary fever of a city or country for a series of years and then give place to other complications. Thus the putrid fever, as it was called, which formerly prevailed in this country, appears to have combined the worst symptoms of scurvy with those of fever, and presented indications of a dissolved and putrescent state of the fluids from which it obtained its popular name, and in which it was thought by many to consist. Such a case is now scarcely, if ever, to be met with in England: yet nobody doubts that this putrid fever was essentially the same malady as the typhus of the present day. This kind of fever was prevalent in London in Sydenham's time; whereas, even the common form of petechial fever is now rare in this metropolis, and the prevailing type of fever is synochous rather than typhous. Again, if we compare the continued fever of London with that of Paris in the present day, we shall find that lesions of the brain are more common in the former city, and those of the intestinal canal in the latter; hence the premature conclusion of Dr. Clutterbuck that fever is inflammation of the brain, and of M. Broussais that it is gastro-enteritis: had these two pathologists changed places, they would probably have also changed doctrines. Finally, it would appear from the testimony of Louis, Andral, Cruveilhier, and other highly distinguished observers, that enlargement of the mucous follicles of the intestines is at present almost an universal appearance on dissection of those who have died of fever in France: not so in England; we sometimes observe this lesion, but in a great majority of cases it is absent, and hence the doctrine of the necessary dependence of fever

on *dothenenteritis*, however high the authority by which it is supported, gains few converts among us. The rationale of what has just been advanced is simply this: recent pathologists appear to have erred, not for want of accuracy of observation in the cases that have come before them, but from generalising too hastily, and mistaking the transient peculiarities of certain epidemies for the permanent and essential characteristics of continued fever. Dr. Tweedie, in his very judicious and practical illustrations of fever, gives the following valuable statement of the results of the dissection of 521 cases of fever, selected from the records of the London Fever Hospital:

Cases in which the fever was not apparently complicated with local inflammation in any organ	163
Cases complicated with cerebral affection	114
thoracic affection	103
abdominal affection	71
cerebral and thoracic affection	26
cerebral and abdominal affection	30
cerebral, thoracic, and abdominal affection	14

We must conclude then, that the proximate cause of fever remains to be discovered, and we may sum up our knowledge of the subject in the often quoted words of Fordyce, one of the most accurate and philosophical of medical reasoners. "A fever," says this author, "is a disease that affects the whole system; it affects the head, the trunk of the body, and the extremities; it affects the circulation, the absorption, and the nervous system; it affects the skin, the muscular fibres, and the membranes; it affects the body, and affects likewise the mind. It is, therefore, a disease of the whole system in every kind of sense. It does not, however, affect the various parts of the system uniformly and equally; but, on the contrary, sometimes one part is much affected in proportion to the affection of another part."

For the treatment of continued fever, as well as for some further description of its varieties, the reader is referred to the articles *Synochus* and *Typhus*.

Feet, distortion of the. Children are often born with the feet distorted inwards or outwards. A child with its feet turned inwards is called *varus*; when they are turned outwards it is styled *valgus*. The proper use of bandages early applied will generally correct these deformities; but if they be neglected in infancy they become incurable.

Feigned diseases. Under this head are generally included the diseases simulated by impostors to answer their own ends, and also diseases which, though real, have been voluntarily induced or aggravated. Such deceptions are practised chiefly by vagrants to excite compassion and extort money, or by soldiers or sailors

o escape duty. In the case of soldiers, this as got the name of *malingering*. It is highly necessary for the practitioner to be aware of the various devices by which diseases are simulated. Much useful information on this subject is to be found in the different works on legal medicine, especially those of Mahon and Foderé. Dr. Hennen's Military Surgery may also be consulted with great advantage.

Fel. See *Bile*.

Fel naturæ. Aloes have been so called on account of their bitterness.

Fel-wort. (So called from its bitter taste, like bile.) See *Gentiana lutea*.

Felli'culus. The gall-bladder.

Felliflua passio. See *Cholera*.

Felon. See *Paronychia*.

Femen. See *Femur*.

FEMI'NEUS. Female. A flower is termed female, which is furnished with pistils and not with the stamens.

FE'MORAL. (*Femoralis*; from *femur*, the thigh.) Of or belonging to the thigh.

Femoral artery. Arteria femoralis. Crural artery. A continuation of the external iliac along the thigh, from Poupart's ligament to the ham. For about two inches of its course below Poupart's ligament it is called the *inguinal* or *common femoral artery*. This gives off the external pudic arteries, and divides into the *proper femoral* and the *profunda*. The proper femoral artery passes down the thigh, covered by the fascia, between the vastus internus and second head of the triceps; about the middle of the inside of the thigh, it is situated behind the sartorius muscle; it afterwards perforates the triceps muscle and passes into the ham, where it is called popliteal: it finally divides into the anterior and posterior tibial. The branches of the proper femoral artery are the *external* and *internal circumflex*, which, however, arise in many subjects from the profunda; and the *ramus anastomoticus magnus*.

FE'MORIS OS. The thigh-bone. A long cylindrical bone, situated between the pelvis and tibia. Its upper extremity presents three considerable processes; these are, the head, the trochanter major, and trochanter minor. The head, which forms about two-thirds of a sphere, is turned inwards, and is received into the acetabulum of the os innominatum, with which it is articulated by enarthrosis. It is covered by a cartilage, which is thick in its middle part, and thin at its edges, but which is wanting in its lower internal part, where a round spongy fossa is observable, to which the strong ligament, usually, though improperly called the *round* one, is attached. This ligament is about an inch in length, flattish, and of a triangular shape, having its narrow extremity attached to the fossa just described, while its broader end is fixed obliquely to the rough surface near the inner and anterior edge of the acetabulum of the os innominatum, so that it appears shorter internally and anteriorly, than it does externally and posteriorly.

The head of the os femoris is supported obliquely, with respect to the rest of the bone, by a smaller part, called the *cervix*, or *neck*, which, in the generality of subjects, is about an inch in length. At its basis we observe two oblique ridges, which extend from the trochanter major to the trochanter minor. Of these ridges, the posterior one is the most prominent. Around this neck is attached the capsular ligament of the joint, which likewise adheres to the edge of the cotyloid cavity, and is strengthened anteriorly by many strong ligamentous fibres, which begin from the lower and anterior part of the ilium, and spreading broader as they descend, adhere to the capsular ligament, and are attached to the anterior oblique ridge at the bottom of the neck of the femur. Posteriorly and externally, from the basis of the neck of the bone, a large unequal protuberance stands out, which is the *trochanter major*. The upper edge of this process is sharp and pointed posteriorly, but is more obtuse anteriorly. A part of it is rough and unequal, for the insertion of the muscles; the rest is smooth, and covered with a thin cartilaginous crust, between which and the tendon of the glutæus maximus that slides over it, a large bursa mucosa is interposed. Anteriorly, at the root of this process, and immediately below the bottom of the neck, is a small process called *trochanter minor*. Its basis is nearly triangular, having its two upper angles turned towards the head of the femur, and the great trochanter, while its lower angle is placed towards the body of the bone. Its summit is rough and rounded. These two processes have the name of *trochanters*, from the muscles that are inserted into them, being the principal instruments of the rotatory motion of the thigh. Immediately below these two processes the body of the bone may be said to begin. It is smooth and convex before, but is made hollow behind by the action of the muscles. In the middle of this posterior concave surface is observed a rough ridge, called *linea aspera*, which seems to originate from the trochanters, and extending downwards, divides at length into two branches, which terminate in the tuberosities near the condyles. At the upper part of it, blood-vessels pass to the internal substance of the bone, by a hole that runs obliquely upwards.

The lower extremity of the os femoris is larger than the upper one, and somewhat flattened, so as to form two surfaces, of which the anterior one is broad and convex, and the posterior one narrower and slightly concave. This end of the bone terminates in two large protuberances, called *condyles*, which are united before so as to form a pulley, but are separated behind by a considerable cavity, in which the crural vessels and nerves are placed, secure from the compression to which they would otherwise be exposed in the action of bending the leg. Of these two condyles, the external one is the largest; and when the bone is separated from the rest of the skeleton, and placed perpendicularly, the internal condyle projects less forwards, and descends nearly three tenths of an inch lower than the external one; but in its natural situation, the bone is placed obliquely, so that both condyles are then nearly on a level with each other. At the side of each condyle, externally, there is a tuberosity, the situation of

which is similar to that of the condyles of the os humeri. The two branches of the linea aspera terminate in these tuberosities, which are rough, and serve for attachment of ligaments and muscles.

Femorocele. See *Hernia cruralis.*

FE'MUR. (*Femur, oris.* n.) The thigh. According to the Latin Grammarians *femur* means the anterior part of the thigh, while the inner part is called *femen.* The thigh consists of one bone, the os femoris; of several muscles, — the psoas magnus, iliacus internus, gluteus maximus, medius, and minimus, the pectineus, triceps, obturator externus and internus, pyriformis, gemini, quadratus, tensor vaginæ femoris, sartorius, gracilis, rectus, crureus, vasti, semimembranosus, semitendinosus, and biceps. These muscles are bound by a strong fascia and surrounded by the common integuments. The ligaments of the thigh are those of its articulation with the os innominatum; viz. — the ligamentum teres and capsulare. The artery is the femoral, a continuation of the external iliac. Its veins and absorbents are numerous, and run parallel with the artery. The nerves are formed by the lumbar and sacral, and are the ischiadic, the obturator, and the crural. The glands are the inguinal and synovial.

FENE'STRA. (*a, æ.* f.; a window.) A name given by anatomists to two foramina in the ear.

Fenestra ovalis. An oblong or elliptical foramen, between the cavity of the tympanum and the vestibulum of the ear. It is shut by the stapes. See *Auris.*

Fenestra rotunda. A round foramen leading from the tympanum to the cochlea of the ear. It is covered by a membrane in the fresh subject. See *Auris.*

Fennel. See *Anethum fœniculum.*

Fennel, hog's. See *Peucedanum.*

Fenugreek. See *Trigonella.*

FERMENTA'TION. (*Fermentatio, onis.* f.; from *fermento,* to ferment.) When aqueous combinations of vegetable or animal substances are exposed to ordinary atmospherical temperatures, they speedily undergo spontaneous changes, to which the generic term of fermentation has been given. There are several circumstances required in order that fermentation may proceed: such are, 1. A certain degree of fluidity; thus, dry substances do not ferment at all. 2. A certain degree of heat. 3. The contact of air. Chemists, after Boerhaave, have distinguished three kinds of fermentation: —

1. The *vinous* or *spirituous,* which affords ardent spirit.

2. The *acetous,* which affords vinegar, or acetic acid.

3. The *putrid* fermentation, or putrefaction, which produces volatile alkali.

I. The conditions necessary for vinous fermentation are: 1. A saccharine mucilage. 2. A degree of fluidity slightly viscid. 3. A degree of heat between 55 and 65 of Fahrenheit. 4. A large mass, in which a rapid commotion may be excited. When these four conditions are united, the vinous fermentation takes place, and is known by the following characteristic phænomena: 1. An intestine motion takes place. 2. The bulk of the mixture then becomes augmented. 3. The transparency of the fluid is diminished by opake filaments. 4. Heat is generated. 5. The solid parts mixed with the liquor rise and float, in consequence of the disengagement of elastic fluid. 6. A large quantity of carbonic acid gas is disengaged in bubbles. All these phenomena gradually cease in proportion as the liquor loses its sweet and mild taste, and it becomes brisk, penetrating, and capable of producing intoxication. In this manner, wine, beer, cider, &c. are made. All bodies which have undergone the spirituous fermentation are capable of passing on to the acid fermentation: but, although it is probable that the acid fermentation never takes place, before the body has gone through the spirituous fermentation, yet the duration of the first is frequently so short and imperceptible, that it cannot be ascertained. Besides the bodies which are proper for spirituous fermentation, this class includes all sorts of fæcula boiled in water.

II. The conditions required for the acid fermentation, are: 1. A heat from 70 to 85 degrees of Fahrenheit. 2. A certain degree of liquidity. 3. The presence of atmospheric air. 4. A moderate quantity of fermentable matter. The phenomena which accompany this fermentation, are an intestine motion, and a considerable absorption of air. The transparent liquor becomes turbid, but regains its limpidity when fermentation is over. The fermented liquor now consists, in a great measure, of a peculiar acid, called the acetic acid, or vinegar. Not a vestige of spirit remains, it being entirely decomposed; but the greater the quantity of spirit in the liquor, previous to the fermentation, the greater will be the quantity of true vinegar obtained. As the ultimate constituents of vegetable matter are oxygen, hydrogen, and carbon; and of animal matter, the same three principles with azote, we can readily understand that all the products of fermentation must be merely new compounds of these three or four ultimate constituents. Accordingly, 100 parts of real vinegar, or acetic acid, are resolvable, by Gay Lussac and Thénard's analysis, into 50·224 carbon + 46·911 hydrogen and oxygen, as they exist in water, + 2·863 oxygen in excess. In like manner, wines are all resolvable into the same ultimate components, in proportions somewhat different. The aëriform results of putrefactive fermentation are in like manner found to be hydrogen, carbon, oxygen, and azote variously combined, and associated with minute quantities of sulphur and phosphorus. The residuary matter consists of the same principles mixed with the saline and earthy parts of animal bodies.

Lavoisier was the first philosopher who instituted, on right principles, a series of experiments to investigate the phænomena of fermentation; and they were so judiciously contrived, and so accurately conducted, as to give results comparable to those derived from the more rigid methods of the present day. Since then, Thénard and Gay Lussac have each contributed most important researches. By the labours of

these three illustrious chemists, those material metamorphoses, formerly quite mysterious, seem susceptible of a satisfactory explanation.

As sugar is a substance of uniform and determinate composition, it has been made choice of for determining the changes which arise when its solution is fermented into wine or alkohol. Lavoisier justly regarded it as a true vegetable oxide, and stated its constituents to be, 8 hydrogen, 28 carbon, and 64 oxygen, in 100 parts. By two different analyses of Berzelius, we have, —

Hydrogen,	6·802	6·891
Carbon,	44·115	42·704
Oxygen,	49·083	50·405
	100·000	100·000

Gay Lussac and Thénard's analyses give,

Hydrogen,	6·90 } 57·53 water,	
Oxygen,	50·63 }	
Carbon,	42·47	42·47
	100·00	100·00

It has been said that sugar requires to be dissolved in at least 4 parts of water, and to be mixed with some yeast, to cause its fermentation to commence. But this is a mistake. Syrup stronger than the above will ferment, in warm weather, without addition. If the temperature be low, the syrup weak, and no yeast added, acetous fermentation alone will take place. To determine the vinous, therefore, we must mix certain proportions of saccharine matter, water, and yeast, and place them in a proper temperature.

To observe the chemical changes which occur, we must dissolve 4 or 5 parts of pure sugar in 20 parts of water, put the solution into a matrass, and add 1 part of yeast. Into the mouth of the matrass a glass tube must be luted, which is recurved, so as to dip into the mercury of a pneumatic trough. If the apparatus be now placed in a temperature of from 70° to 80°, we shall speedily observe the syrup to become muddy, and a multitude of air bubbles to form all around the ferment. These unite, and attaching themselves to particles of the yeast, rise along with it to the surface, forming a stratum of froth. The yeasty matter will then disengage itself from the air, fall to the bottom of the vessel, to re-acquire buoyancy a second time by attached air bubbles, and thus in succession. If we operate on 3 or 4 ounces of sugar, the fermentation will be very rapid during the first ten or twelve hours; it will then slacken, and terminate in the course of a few days. At this period, the matter being deposited which disturbed the transparency of the liquor, this will become clear.

The following changes have now taken place: — 1. The sugar is wholly, and the yeast partially, decomposed. 2. A quantity of alkohol and carbonic acid, together nearly in weight to the sugar, is produced. 3. A white matter is formed, composed of hydrogen, oxygen, and carbon, equivalent to about half the weight of the decomposed ferment. The carbonic acid passes over into the pneumatic apparatus; the alkahol may be separated from the vinous liquid by distillation, and the white matter falls down to the bottom of the matrass with the remainder of the yeast.

The quantity of yeast decomposed is very small. 100 parts of sugar require, for complete decomposition, only two and a half of that substance, supposed to be in a dry state. It is hence very probable, that the ferment, which has a strong affinity for oxygen, takes a little of it from the saccharine particles, by a part of its hydrogen and carbon, and thus the equilibrium being broken between the constituent principles of the sugar, these so react on each other as to be transformed into alkohol and carbonic acid. If we consider the composition of alkohol, we shall find no difficulty in tracing the steps of this transformation.

Neglecting the minute products which the yeast furnishes in the act of fermentation, let us regard only the alkohol and carbonic acid. We shall then see, on comparing the composition of sugar to that of alkohol, that to transform sugar into alkohol, we must withdraw from it one volume of vapour of carbon, and one volume of oxygen, which form by their union one volume of carbonic acid gas. Finally, let us reduce the volumes into weights, we shall find, that 100 parts of sugar ought to be converted, during fermentation, into 51·55 of alkohol, and 48·45 of carbonic acid.

When it is required to preserve fermented liquors in the state produced by the first stage of fermentation, it is usual to put them into casks before the vinous process is completely ended; and in these closed vessels a change very slowly continues to be made for many months, and perhaps for some years.

But if the fermentative process be suffered to proceed in open vessels, more especially if the temperature be raised to 90°, the acetous fermentation comes on. In this, the oxygen of the atmosphere is absorbed; and the more speedily in proportion as the surfaces of the liquor are often changed by lading it from one vessel to another. The usual method consists in exposing the fermented liquor to the air in open casks, the bunghole of which is covered with a tile to prevent the entrance of the rain. By the absorption of oxygen which takes place, the inflammable spirit becomes converted into an acid. If the liquid be then exposed to distillation, pure vinegar comes over instead of ardent spirit.

III. When the spontaneous decomposition is suffered to proceed beyond the acetous process, the vinegar becomes viscid and foul; air is emitted with an offensive smell; volatile alkali flies off; an earthy sediment is deposited; and the remaining liquid, if any, is mere water. This is the putrefactive process. See also *Putrefaction*.

FERME'NTUM. (*um*, *i.* n.; *quasi fervimentum*, from *ferveo*, to ferment.) Yeast.

Fermentum cerevisiæ. Yeast; barm: the scum which collects on beer while fermenting, and has the property of exciting that process in various other substances. Medicinally it is antiseptic and tonic; and has been found useful internally in the cure of typhus fever attended with an obvious tendency to putrefaction in the

system, with petechiæ, vibices, and the like: the best way to administer it, is to mix a fluid ounce with seven of strong beer, and give three table-spoonsful to an adult every three or four hours. Externally, it is used in the fermenting cataplasm.

Fern. See *Filix*, *Pteris*, *Aspidium*, and *Polypodium*.

Fern, male. See *Aspidium filix mas.*

Fern, female. See *Pteris aquilina.*

Fern, mules. See *Asplenium hemonitis.*

Ferri alkalini liquor. Solution of alkaline iron. Take of iron, two drachms and a half; nitric acid, two fluid ounces; distilled water, six fluid ounces; solution of subcarbonate of potash, six fluid ounces. Having mixed the acid and water, pour them upon the iron, and when the effervescence has ceased, pour off the clear acid solution; add this gradually, and at intervals, to the solution of subcarbonate of potash, occasionally shaking it, until it has assumed a deep brown-red colour, and no further effervescence takes place. Lastly, set it by for six hours, and pour off the clear solution. This preparation was first described by Stahl, and called tinctura martis alkalina. It is expunged from the last London Pharmacopœia. The dose is from half a drachm to a drachm.

Ferri ammo'nio-chlo'ridum. Ammonio-chloride of iron; formerly known by the names of *flores martiales; flores salis ammoniaci martiales; ens martis; ens veneris Boylei; sal martis muriaticum sublimatum; ferrum ammoniacle*, and *ferrum ammoniatum*. Take of sesquioxide of iron, three ounces; hydrochloric acid, half a pint; hydrochlorate of ammonia, two pounds and a half; distilled water, three pints. Pour the acid on the sesquioxide, and digest in a sand-bath for two hours: afterwards add the hydrochlorate of ammonia, dissolved in distilled water; strain and evaporate all the fluid; lastly, reduce the residuum to powder. This preparation is a mixture of sesquichloride of iron and hydrochlorate of ammonia. It is tonic and astringent, in doses from three to fifteen grains, or more, in the form of bolus or pills, prepared with some gum. It is exhibited in most cases of debility, in chlorosis, asthenia, menorrhagia, intermittent fevers, &c. This, or some other strong preparation of iron, as the Tinct. ferri muriatis, Mr. Cline recommended in scirrhous affections of the breast. See *Tinctura ferri, ammonio-chloridi.*

Ferri carbo'nas. See *Ferri sesquioxydum.*

Ferri iodidum. Iodide of iron. Take of iodine, six ounces; iron filings, two ounces; distilled water, four pints and a half. Mix the iodine with four pints of the water, and to these add the iron. Heat them in a sand-bath, and pour off the liquor when it has acquired a greenish colour. Wash what remains with the half pint of water, boiling. Let the mixed and strained liquors evaporate at a heat not exceeding 212° in an iron vessel, that the salt may be dried. Keep it in a well-stopped vessel, the access of light being prevented.

The solution obtained is one of iodide or protiodide of iron; it is of a green colour, and by evaporation with as little contact of air as possible, green tabular crystals may be formed. By evaporation to dryness, and heating moderately, this salt is fused, and on cooling becomes an opaque crystalline mass of an iron-grey colour and metallic lustre. When exposed to the air it attracts moisture, and is very soluble both in water and in alkohol: in order to prevent the deposition of sesquioxide of iron by the absorption of oxygen, the solution should be kept with an iron wire in it.

Composition. — Iodide or protiodide of iron is composed of

One equivalent of iodine.....	126	or	63·3
One equivalent of iron	28		14·
Five equivalents of water....	45		22·7
Equivalent.....	199		100·

— *Phillips.*

This medicine has been lately introduced into British practice by Dr. A. T. Thomson, who recommends it in every form of scrofula, in chlorosis, atonic amenorrhœa, hysteria, secondary syphilis, incipient cancer, and other cases. The dose is from three to eight grains, or more.

Ferri limatura purificata. Purified iron filings. These possess tonic, astringent, and deobstruent virtues, and are calculated to relieve chlorosis, and other diseases in which steel is indicated, where acidity in the primæ viæ abounds.

Ferri potassio tartras. Potassio-tartrate of iron. Formerly called *tartarus chalybeatus; mars solubilis; ferrum potabile;* and *ferrum tartarizatum*. Take of sesquioxide of iron, three ounces; hydrochloric acid, half a pint; solution of potash, four pints and a half, or as much as may be sufficient; bitartrate of potash, eleven ounces and a half; solution of sesquicarbonate of ammonia, a pint, or as much as may be sufficient; distilled water, three gallons. Mix the sesquioxide of iron with the acid, and digest for two hours in a sand-bath. Add to these, two gallons of the water, and set aside for an hour; then pour off the supernatant liquor. The solution of potash being added, wash the precipitate frequently with water, and while yet moist, boil it with the bitartrate of potash, previously mixed with a gallon of the water. If the liquor should be acid when tried by litmus, drop into it solution of sesquicarbonate of ammonia until it is saturated. Lastly, strain the liquor, and with a gentle heat let it evaporate, so that the salt may remain dry. — *Phillips.*

This salt is composed very nearly of one equivalent of tartrate of potash and one of tartrate of the sesquioxide of iron. It is a mild and efficacious chalybeate, and is less nauseous to the taste than the other preparations of iron. The dose is from grs. x. to 3ss. in solution or bolus, combined with an aromatic bitter.

Ferri rubigo. See *Ferri sesquioxydum.*

Ferri sesquioxydum. *Ferri subcarbonas; Ferri carbonas; Ferrum præcipitatum;* formerly called *chalybis rubigo præparata*, and *ferri rubigo*. Sesquioxide of iron, commonly called subcarbonate of iron. Take of sulphate of iron, four pounds; carbonate of soda, four pounds two ounces; boiling water, six gallons. Dissolve the sulphate of iron and subcarbonate

of soda separately, each in three gallons of water; then mix the solutions together, and set it by, that the precipitated powder may subside; then, having poured off the supernatant liquor, wash the precipitate of iron with hot water, and dry it. This preparation, which was originally for a subcarbonate of iron, is found to consist principally of the sesquioxide of that metal; the name has therefore been changed in the last London Pharmacopœia. It possesses mild corroborant and stimulating properties, and is exhibited with success in leucorrhœa, ataxia, asthenia, chlorosis, dyspepsia, rachitis, &c. Dose from two to ten grains.

Ferri subcarbonas. See *Ferri sesquioxydum.*

FERRI SULPHAS. Sulphate of iron; formerly called *sal martis, vitriolum martis, vitriolum ferri,* and *ferrum vitriolatum.* Green vitriol. Take of iron filings, eight ounces; sulphuric acid, fourteen ounces; water, four pints. Mix together the sulphuric acid and water, and add thereto the iron; then, after the effervescence has ceased, filter the solution, and set it aside that crystals may form. Evaporate the decanted liquor that it may again yield crystals. Dry them all. This is an excellent preparation of iron, and is exhibited, in many diseases, as a styptic, tonic, astringent, and anthelmintic. Dose from one grain to five grains.

FE'RRO-CHYA'ZIC ACID. *Acidum ferro-chyazicum:* so called from *ferrum* and *chyazium.* An acid obtained by adding to a solution of ferro-cyanite of barytes, sulphuric acid just enough to precipitate the barytes. It has a pale yellow colour, no smell, and is decomposed by gentle heat or strong light, in which case hydrocyanic acid is formed, and white hydrocyanite of iron is deposited, which becomes blue by exposure.

FE'RRO-CY'ANATE. *Ferro-cyanas.* A compound formed of ferro-cyanic acid with a salifiable base.

FE'RRO-CYA'NIC ACID. (*Ferrum* and *cyanicus.*) *Acidum ferro-prussicum. Acidum ferro-cyanicum.* Into a solution of the amber-coloured crystals, usually called prussiate of potash, pour hydro-sulphuret of barytes, as long as any precipitate falls. Throw the whole on a filter, and wash the precipitate with cold water. Dry it; and having dissolved 100 parts in cold water, add gradually thirty of concentrated sulphuric acid; agitate the mixture, and set it aside to repose. The supernatant liquid is ferro-prussic acid, called by Porrett, who had the merit of discovering it, *ferruretted chyazic acid.*

It has a pale lemon-yellow colour, but no smell. Heat and light decompose it. Hydrocyanic acid is then formed, and white ferro-prussiate of iron, which soon becomes blue. Its affinity for the bases enables it to displace acetic acid, without heat, from the acetates, and to form ferroprussiates.

The pigment called Prussian blue has till lately been considered as a ferrocyanate of iron, but it is now regarded as a *ferro-sesquicianuret* of iron.

Ferro-prussic acid. See *Ferro-cyanic acid.*

FE'RRO-SE'SQUICYA'NIC ACID. If ferro-sesquicianuret of potassium be added to a solution of lead, brown crystals of ferro-cyanuret of lead are, after a while, deposited. These being dissolved in water and decomposed by sulphuretted hydrogen, the filtered solution yields, by evaporation, crystals of a brown colour; — these are *Ferro-sesquicyanic acid.*

FERRUGI'NEUS. 1. Appertaining to iron.

2. Having a yellowish brown colour, like the rust of iron.

FE'RRUM. (*um, i.* n.; the etymology uncertain.) See *Iron.*

Ferrum ammoniatum. See *Ferri ammoniochloridum.*

FERRUM SALITUM. An old name of the muriate of iron.

Ferrum tartarizatum. See *Ferri potassiotartras.*

Ferruretted chyazic acid. See *Ferro-prussic acid.*

FERSÆ. The measles have been so called.

FERTILE. *Fertilis.* Fruitful. Applied,

1. In *Physiology,* to women, and the female of brute animals, which are prolific.

2. In *Botany,* to a flower, called *flos fertilis* and *femineus,* when it produces a seed capable of vegetation, which is generally the case in flowers which have both stamens and pistils. Flowers that have only stamens never can produce seeds, and flowers that have only pistils must be barren, if they are so situated as to be out of reach of the pollen from the anthers of the staminiferous flowers: in some instances they will, indeed, produce seeds to all appearance perfect, but these seeds will never vegetate.

Fertile flower. See *Flos.*

FE'RULA. (*a, æ.* f.; a staff, which it resembles: so called *à feriendo.*) The name of a genus of plants in the Linnæan system. Class, *Pentandria;* Order, *Digynia.*

FERULA AFRICANA GALBANIFERA. The galbanum plant. See *Galbanum,* in the Supplement.

FERULA ASSAFŒTIDA. The systematic name of the assafœtida plant. *Assafœtida. Hingisch* of the Persians. *Aitiht* of the Arabians. By some thought to be the σιλφιον, vel οπος σιλφιου, of Dioscorides, Theophrastus, and Hippocrates. *Laser et laserpitium,* of the Latins. *Ferula assafœtida — foliis alternatim sinuatis, obtusis,* of Linnæus. This plant, which affords us the assafœtida of the shops, grows plentifully on the mountains in the provinces of Chorassan and Laar, in Persia.

The process of obtaining it is as follows: the earth is cleared away from the top of the roots of the oldest plants; the leaves and stalks are then twisted away, and made into a covering, to screen the root from the sun: in this state the root is left for forty days, when the covering is removed, and the top of the root cut off transversely; it is then screened again from the sun for forty-eight hours, when the juice it exudes is scraped off, and exposed to the sun to harden. A second transverse section of the root is made, and the exudation suffered to continue for forty-eight hours, and then scraped off. In this manner it is eight times repeatedly collected in a period of six weeks. The juice thus obtained has a bitter, acrid, pungent taste, and is well known by its peculiar nauseous smell, the strength of which is the surest test of

its goodness. This odour is extremely volatile, and of course the drug loses much of its efficacy by keeping. It is brought to us in large irregular masses, composed of various little shining lumps, or grains, which are partly of a whitish colour, partly reddish, and partly of a violet hue. Those masses are accounted the best which are clear, of a pale reddish colour, and variegated with a great number of elegant white tears. This concrete juice consists of two thirds of gum, and one third of resin and volatile oil, in which its taste and smell reside. It yields all its virtues to alkohol. Triturated with water, it forms a milk-like mixture, the resin being diffused by the medium of the gum. Distilled with water, it affords a small quantity of essential oil. It is the most powerful of all the fœtid gums, and is a most valuable remedy. It is most commonly employed in hysteria, hypochondriasis, some symptoms of dyspepsia, flatulent colics, and in most of those diseases termed nervous, but its chief use is derived from its antispasmodic effects; and it is thought to be the most powerful remedy we possess for those peculiar convulsive and spasmodic affections which often recur in the first of these diseases, both taken into the stomach and in the way of enema. It is also recommended as an emmenagogue, anthelmintic, antiasthmatic, and anodyne. Dr. Cullen prefers it as an expectorant to gum ammoniacum. Where we wish it to act immediately as an antispasmodic, it should be used in a fluid form, as that of tincture, from half a drachm to two drachms. When given in the form of a pill, or triturated with water, its usual dose is from five to twenty grains. When in the form of enema, one or two drachms are to be diffused in eight ounces of warm milk or water. It is sometimes applied externally in the form of plaster as a stimulant and discutient.

Ferula minor. All-heal of Æsculapius; probably the *heracleum*.

Ferula Persica. Stinking giant fennel. This plant was supposed by Wildenow to yield the *sagapenum*. The source whence this drug is derived is still uncertain. See *Sagapenum*.

Ferulacea. See *Bubon galbanum*.

Fever. See *Febris*.

Fever, continued. See *Febris continua*.

Fever, hectic. See *Hectic fever*.

Fever, inflammatory. See *Synocha*.

Fever, intermittent. See *Ague*.

Fever, nervous. See *Nervous fever*.

Fever, putrid. See *Typhus fever*.

Fever, remittent. See *Remittent fever*.

Fever, scarlet. See *Scarlet fever*.

Feverfew. See *Matricaria*.

Fi'ber. (*er, ri*. m.) The Latin name of the beaver. See *Castor fiber*.

FIBRE. (*Fibra, æ*, f.) A simple filament. Many of the textures of animal and vegetable bodies are manifestly composed of fibres. The older physiologists admitted only of one elementary fibre in the animal body, of which all the others were some modification; but this notion was nothing better than a mere whim. See *Animal*, *Vegetable*, and *Lignin*.

Fibre, elementary. See *Fibre*.

Fibre, muscular. See *Muscular fibre*.

FI'BRIL. (*Fibrilla*, diminutive of *fibra*.) A small thread-like fibre: applied in botany to the little roots which are given off from radicles.

FI'BRIN. A peculiar organic compound found both in vegetables and animals. It is procured, however, in its most characteristic state from animal matter. It exists in chyle; it enters into the composition of blood; of it the chief part of muscular flesh is formed; and hence it may be regarded as the most abundant constituent of the soft solids of animals.

To obtain it, we may beat blood as it issues from the veins with a bundle of twigs. Fibrin soon attaches itself to each stem, under the form of long reddish filaments, which become colourless by washing them with cold water. It is solid, white, insipid, without smell, denser than water, and incapable of affecting the hue of litmus or violets. When moist it possesses a species of elasticity; by desiccation it becomes yellowish, hard, and brittle. By distillation we can extract from it much carbonate of ammonia, some acetate, a fetid brown oil, and gaseous products; while there remains in the retort a very luminous charcoal, very brilliant, difficult of incineration, which leaves, after combustion, phosphate of lime, a little phosphate of magnesia, carbonate of lime, and carbonate of soda.

Cold water has no action on fibrin. Treated with boiling water, it is so changed as to lose the property of softening and dissolving in acetic acid. The liquor filtered from it yields precipitates with infusion of galls, and the residue is white, dry, hard, and of an agreeable taste.

FIBROUS. (*Fibrosus*; from *fibra*, a fibre.) Composed of fibres. See *Fibre*.

FI'BULA. (*a, æ*. f. A clasp or brace.) A long bone of the leg, so named on account of its connecting and giving firmness to the other parts. It is situated on the outer side of the tibia, and forms, at its lower end, the outer ankle. Its upper extremity is formed into an irregular head, on the inside of which is a slightly concave articulating surface, which, in the recent subjects, is covered with cartilage, and receives the circular flat surface under the edge of the external cavity of the tibia. This articulation is surrounded by a capsular ligament, which is farther strengthened by other strong ligamentous fibres, so as to allow only a small motion backwards and forwards. Externally, the head of the fibula is rough and protuberant, serving for the attachment of ligaments, and for the insertion of the biceps cruris muscle. Immediately below it, on its inner side, is a tubercle, from which a part of the gastro-cnemius internus has its origin. Immediately below this head the body of the bone begins. It is of a triangular shape, and appears as if it were slightly twisted at each end, in a different direction. It is likewise a little curved inwards and forwards. This curvature is in part owing to the action of muscles; and in part, perhaps, to the carelessness of nurses. Of the three angles of the bone, that which is turned towards the tibia is the most prominent, and serves for the attachment of the interos-

ous ligament, which, in its structure and ses, resembles that of the fore-arm, and, like at, is a little interrupted above and below. The three surfaces of the bone are variously mpressed by different muscles. About the iddle of the posterior surface is observed a assage for the medullary vessels, slanting ownwards. The lower end of the fibula is ormed into a spongy, oblong head, externally ough and convex, internally smooth, and co- ered with a thin cartilage, where it is received y the external triangular depression at the ower end of the tibia. This articulation, which esembles that of its upper extremity, is fur- ished with a capsular ligament, and farther rengthened by ligamentous fibres, which are ronger and more considerable than those be- ore described. They extend from the tibia to ne fibula, in an oblique direction, and are nore easily discernible before than behind. Below this the fibula is lengthened out, so as orm a considerable process, called *malleolus xternus*, or the outer ankle. It is smooth, and overed with cartilage on the inside, where it is ontiguous to the astragalus, or first bone of ne foot. At the lower and inner part of this rocess, there is a spongy cavity, filled with at; and a little beyond this, posteriorly, is a rtilaginous groove, for the tendons of the eroneus longus and peroneus brevis, which are ere bound down by the ligamentous fibres nat are extended over them.

The principal uses of this bone seem to be, o afford origin and insertion to muscles, and o contribute to the articulation of the leg with ne foot.

FI'BULAR. Appertaining to the *fibula* — s fibular artery, fibular nerve, &c.

FICA'RIA. (*a, æ.* f.; from *ficus*, a fig, so called rom some fancied resemblance.) See *Ranun- ulus ficaria*.

FICA'TIO. The development of a tubercle of ne kind called *ficus*.

FICOI'DEÆ. A natural family of plants of which the genus *ficus* is the type.

FICOI'DES. (From *ficus*, a fig, and εἶδος, re- emblance.) Fig-like.

FI'CUS. (*us, i.* f.; and *us, ús.* f.) 1. A pecies of condyloma so named from its being haped like a fig. See *Condyloma*.

2. The name of a genus of plants in the Linnæan system. Class, *Polygamia*; Order, *Diœcia*. The fig-tree.

FICUS CARICA. The systematic name of the g-tree; called also, *Carica*, *Ficus vulgaris*, and *icus communis*. Συκη of the Greeks. French gs are, when completely ripe, soft, succulent, nd easily digested, unless eaten in immoderate uantities, when they are apt to occasion flatu- ency, pain of the bowels, and diarrhœa. The ried fruit, which is sold in our shops, is leasanter to the taste, and more wholesome nd nutritive. They are directed in the *decoc- um hordei compositum*, and in the *confectio ennæ*. Applied externally, they promote the uppuration of tumours; hence they have a lace in maturating cataplasms; and are very onvenient to apply to the gums, and, when oiled with milk, to the throat.

Ficus indica. See *Lacca*.

FIDA. An alchemical name of gold or silver.

FIDICINA'LIS. (From *fidicen*, a harper, or one who plays on a stringed instrument.) The lucubricales muscles have also been called *fidi- cinales*, for their action in moving the fingers.

Fifth pair of nerves. See *Nervous system*.

Fig. See *Ficus carica*.

Figwort. See *Ranunculus ficaria*, and *Scro- phularia*.

Figwort, great water. See *Scrophularia*.

FILA'GO. (*ago, aginis.* f.; from *filum*, a thread, and *ago*, to produce or have to do with: in allusion to the cottony web connected with every part of the plant.) A genus of plants in the Linnæan system. Class, *Synge- nesia*; Order, *Polygamia necessaria*. Cud or cotton weed.

FILAGO LEONTOPODIUM. The herb lion's- foot, formerly used in the cure of diseases, but now fallen into disuse.

FILAGO PIGMÆ. This plant is sometimes used as an astringent.

FI'LAMENT. (*Filamentum*; from *filum*, a thread.) 1. Applied, in *Anatomy*, to a small thread-like portion adhering to any part, and frequently synonymous with fibre. See *Fibre*.

2. In *Botany*, to the *stamen* of a flower which consists of the filaments, anther, and pollen. The filament is the column which sup- ports the anther.

From its *figure*, the filament is called,

1. *Capillary*; as in plantago.
2. *Filiform*; as in scilla maritima.
3. *Flat*; as in allium cepa.
4. *Dilatate*, spreading laterally; as in orni- thogalum umbellatum.
5. *Pedicellate*, affixed transversely to a little stalk; as in salvia.
6. *Bifid*, having two; as in stemodia.
7. *Bifurced*; as in prunella.
8. *Multifid*; as in carolina princeps.
9. *Dentate*; as in rosmarinus officinalis.
10. *Nicked*; as in allium cepa.
11. *Lanceolate*; as in ornithogalum pyre- naicum.
12. *Castrate*, the anther naturally wanting; as in gratiola officinalis.
13. *Subulate*; as in tulipa gesneriani.

From the *pubescence*, —

1. *Barbate*, bearded; as in lycium.
2. *Lanate*, woolly; as in verbascum thapsus.
3. *Pilose*; as in anthericum frutescens.
4. *Gland-bearing*; as in laurus and rheum.

From its *direction*, —

1. *Erect*; as in tulipa gesneriana.
2. *Incurved*; curved inward.
3. *Declinate*; as in hemerocalis fulva.
4. *Connivent*; as in physalis alkekengi.

From its *concretion*, —

1. *Liberate*, free, no where adhering; as in nicotiana tabacum.
2. *Connate*, adhering at their base; as in malva sylvestris, and alcea rosea.

From its *insertion*, —

1. *Receptaculine*, inserted into the recepta- culum; as in papaver somniferum.
2. *Corolline*; as in verbascum thapsus, and nerium oleander.

3. *Calicine;* as in pyrus malus, and mespilus germanica.

4. *Styline;* as in the orchides.

5. *Nectorine;* as in pancratium declinatum.

From its length, it is said to be,

1. Very *long;* as in plantago major.

2. Very *short;* as in jasminum, and vinca.

3. *Unequal*, some long, some short; as in cheiranthus cheiri.

FILARIA. (*a*, *æ*. f.) The name of a genus of worms in Rudolphi's classification.

Filaria medinensis. The systematic name of a curious animal; called also, *Vermis medinensis*, *Vena medinensis*, *Vermiculus capillaris*, *Dracunculus*. The Guinea worm. This animal differs from the *Gordius*, or hair-tail worm, with which it has been confounded. This worm is common in the southern parts of Asia, and in most parts of Africa. It is of a white colour, and about the thickness of a violin string; is commonly found in the legs, but sometimes in the muscular part of the arms. It principally affects children, and its generation is not unlike that of the broad worms of the belly. While it moves under the skin, it creates no trouble; but, in length of time, the place near the dracunculus suppurates, and the animal puts forth its head. If it be drawn, it excites considerable uneasiness, especially if drawn so forcibly as to break it; for the part left within creates intolerable pain. These worms are of different lengths. In the Edin. Med. Essays, mention is made of one that was three yards and a half in length.

File'llum. (From *filum*, a thread.) The frænum of the prepuce. — *Editors of Castelli.*

File'tum. Same etymon. The frænum of the tongue. — *Editors of Castelli.*

FI'LICES. (The plural of *filix*.) Ferns. One of the families, or natural tribes, into which the whole vegetable kingdom is divided. They are defined, plants which bear their flower and fruit on the back of the leaf or stalk, which is termed *frons*.

Fili'cula. (*a*, *æ*. f.; diminutive of *filix*, fern; a small sort of fern: or from *filum*, a thread, which it resembles.) See *Adiantum capillus veneris*.

FILIFO'RMIS. Filiform: thread-like. Applied to many parts of animals and vegetables from their resemblance; as the leaves of the *Fœniculum dulce*, the style of the *Crocus sativus*, and *Lonicera periclimenum*.

Filipe'ndula. (*a*, *æ*. f.; from *filum*, a thread, and *pendeo*, to hang: so named because the numerous bulbs of its roots hang, as it were, by small threads.) See *Spiræa filipendula*.

Filipendula aquatica. Water-dropwort; the *Œnanthe fistulosa* of Linnæus.

Filius ante patrem. Any plant, the flower of which comes out before the leaf; as coltsfoot.

FI'LIX. (*ix*, *ices*. f.; in plural, *filices;* from *filum* a thread: so called from its being cut, as it were, in slender portions, like threads.) Fern. See *Polypodium*.

Filix aculeata. See *Polypodium.*

Filix florida. See *Osmunda regalis.*

Filix fœmina. See *Pteris aquilina.*

Filix mas. See *Aspidium filix mas.*

Filter. See *Filtrum.*

FILTRA'TION. (*Filtratio;* from *filtrum*, a strainer.) An operation, by means of which a fluid is mechanically separated from solid particles. Filtration is performed through bibulous paper, fine linen, sand, &c., according to circumstances.

FI'LTRUM. A filter. An instrument for filtering or straining.

FI'LUM. (*um*, *i*. n.) A thread or filament.

Filum arsenicale. Sublimed arsenic. — *Ruland.*

FI'MBRIA. (*a*, *æ*. f.; a fringe: *quasi fimbria;* from *finis*, the extremity.) A fringe. 1. Applied in *Anatomy* to any fringe-like body, and especially to the fringed extremity of the allopian tube.

2. In *Botany*, to the dentated or fringe-like ring of the operculum of mosses, by the elastic power of which the operculum is displaced. See *Peristomium*.

Fimbria'tus. Fringed.

Fimbriata corpora. See *Corpora fimbriata.*

Finckle. See *Anethum fœniculum.*

Fingered. See *Digitatus.*

Fingers. See *Hand.*

Fir. See *Pinus.*

Fir, Canada. See *Pinus balsamea.*

Fir, Norway spruce. See *Pinus abies.*

Fir, Scotch. See *Pinus sylvestris.*

Fir, silver. See *Pinus picea.*

Fir, spruce. See *Pinus picea.*

Fir-balsam. See *Pinus balsamea.*

Fire. See *Ignis.*

Fire damp. A gas evolved in coal mines, consisting almost entirely of light carburetted hydrogen. See *Carburetted hydrogen.*

Firmi'sium mineralium. Antimony.

Fish. *Pisces.* See *Animal kingdom.*

Fish-glue. See *Ichthyocolla.*

Fish-skin. See *Ichthyosis.*

FISSU'RA. (*a*, *æ*. f.; from *findo*, to cleave or crack.) A fissure. 1. That species of fracture in which the bone is slit, but not completely divided.

2. A name given to a deep and long depression in a part.

Fissura magna sylvii. The anterior and middle lobes of the cerebrum on each side are parted by a deep narrow sulcus, which ascends obliquely backwards from the temporal ala of the os sphenoides, to near the middle of the os parietale. *This sulcus is called Fissura magna sylvii.*

Fissura umbilicalis. The fissure in the liver which lodges the umbilical vein in the fœtus. See *Ovum.*

FI'SSUS. Cleft; cloven. In *Botany*, applied to leaves and pods, which are divided into segments.

Fistic-nut. See *Pistachia vera.*

FI'STULA. (*a*, *æ*. f.; *quasi fusula*, from *fundo*, to pour out; or from its similarity to a pipe, or reed.) A long and sinuous ulcer that has a narrow opening, and which sometimes leads to a larger cavity, and has no disposition to heal.

Fistula ciba'lis. The œsophagus.

Fistula in ano. A sinus by the side of the rectum. From the laxity of the cellular membrane in the vicinity of the rectum, abscesses which form here easily become diffused, and

ıe matter burrows by the side of the gut, often
› a very formidable extent, and hence the
ecessity of early attention and great care in
ıe treatment of abscesses so situated. Those
stulæ in which the matter has made its escape
y one or more openings through the skin only,
re called *blind external fistulæ*; those in which
ıe matter has been discharged through an open-
g into the rectum, without any aperture in
ıe skin, are called *blind internal fistulæ*; and
ıose which open both into the gut, and also
xternally through the skin are called *complete
stulæ*. The cure is by a surgical operation,
hich consists in laying the sinus freely open,
nd applying proper dressings to promote its
ıcarnation.

Fistula in perinæo. When the urethra is
erforated by ulceration or injury, and the urine
scapes into the surrounding cellular membrane,
occasions inflammation, sloughing, and abscess.
f the patient survive the matter finds its way out
y ulceration, through the integuments of the
erinæum, and the urine also escapes through
ıese ulcerous apertures. The term *fistula* is
ot very correctly applied to these. Fistulæ in
erinæo, as they are called, are most frequently
ıe result of neglected or ill-treated strictures of
ıe urethra.

Fistula lachrymalis. Properly an ulcer-
ted opening in the lachrymal sac, which has no
endency to heal, and through which a puriform
uid is discharged. The term has been sense-
essly applied to almost every diseased state of
he lachrymal passages.

Fistula, salivary. When by any means the
arotid duct has been wounded, the wound is
ften prevented from healing by the continued
scape of saliva; and the irritation and pressure
f this, occasions the formation of an ulcer-
ted opening in the integuments of the cheek,
hrough which the saliva escapes. This is called
salivary fistula.

Fistula spiritalis. The windpipe.

Fistula'ria. (*a*, *æ*. f.; from *fistula*, a pipe:
o called because its stalk is hollow.) Staves-
cre. See *Delphinium staphisagria*.

Fistulous. *Fistulosus*. Of the nature of a
istula.

FIXED. *Fixus*. In *Chemistry*, applied to
hose substances which cannot be caused to pass
y a strong rarefaction from the solid or liquid
tate of an elastic fluid.

Fixed air. See *Carbonic acid*.

FIXITY. The property by which bodies re-
ist the action of heat, so as not to rise in vapour.

FLABELLIFORM. (*Flabelliformis*; from
flabellum, a fan, and *forma*, likeness.) Fan-
ike: A term applied generally in natural history.

FLAG. 1. A water weed. See *Algæ*.

2. Several aquatic plants, which have long
sword-like leaves, are called flags.

Flag, sweet. See *Acorus*.

Flag, water. See *Iris pseudacorus*.

Flag, yellow-water. See *Iris pseudacorus*.

FLAGELLIFORM. *Flagelliformis*. Whip-
ike. A term applied to a stem that is long and
pliant, whip-like; as that of jasmine and blue
poxthorn. The term is also generally applied
n natural history.

FLAGE'LLUM. (*um*, *i*. n.; diminutive of
flagrum, a whip. A small whip.) A runner, or
a twig, which runs out long and slender; as
that of the strawberry.

Flake-white. Subnitrate of bismuth. See
Bismuth.

FLA'MMULA. (*a*, *æ*. f.; dim. of *flamma*,
a fire: named from the burning pungency of its
taste.) See *Ranunculus flammula*.

Flatua'rii. The Alchemists were so called,
probably because they were always blowing at
furnaces.

Flammula jovis. See *Clematis recta*.

Flank. The iliac region of the abdomen.

FLATULENCY. By this is understood a
morbid collection of gas in the stomach and
bowels. Mr. Hunter supposed, and late ex-
periments prove the truth of his opinion, that
gaseous fluids are secreted from the mouths of
the secernents into certain cavities in which it is
found. This is one way in which a flatulent
state of the stomach and bowels is produced;
but the most common way is by a fermentation,
or chemical separation from the materials intro-
duced into the stomach in the form of food.
When the fluids which are poured naturally
into the stomach are secreted in a healthy state,
they tend to prevent this: but when, from im-
becility of the stomach, or its consociate viscera,
they are secreted in a dilute or other imperfect
state, they lose their corrective power, fermenta-
tion rapidly commences, and the stomach is
overloaded, distended, and sometimes ready to
burst with gas that is hereby let loose, relief
being only obtained by frequent *eructation*, or
rejection upwards, *crepitation*, or rejection down-
wards; or its combining loosely with such fluids
as may exist in the large intestines, where it
often rolls about in an ascending or descending
direction, according to the action of the abdo-
minal muscles—sometimes with a rumbling
sound, where the intestinal fluid is but small in
quantity; and sometimes, when it is consider-
able, with a gurgling noise, like air rushing into
a bottle as the water contained in it is poured
out, and hence by the Greeks denominated
borborygmus.

The quantity of gas formed in the stomach
and bowels is sometimes prodigious. It appears
from the experiments of Dr. Hales, that one
apple, during fermentation, will give above six
hundred times its bulk in gas; and we know
that many of the vegetable materials introduced
into the stomach possess far more ventosity than
apples. Flatulency is often a symptom of other
diseases, especially indigestion, colic, cholera,
hysteria, and hypochondriasis. For the cure of
this disease, carminatives, aperients, and tonics
are resorted to; as the spicy fruits and verti-
cillate carminatives: nutmegs, cardamoms, pi-
menta, pepper, capsicum, camphire, peppermint,
spearmint, cinnamon, rosemary, lavender, penny-
royal, &c. The aromatic essential oils are
powerful carminatives. If these do not succeed,
ætherial preparations and warm tonics should
be given, and the strictest attention paid to the
diet, in which all oleracerous vegetables, and all
kinds of peas, beans, and flatulent fruits, should
be avoided; also, large libations of fluids. The

diet should consist of plain animal food, with peppers, and good brandy amply diluted at dinner.

Fla'tus. Wind in the stomach and bowels. See *Flatulency.*

Flax. See *Linum.*

Flax, purging. See *Linum catharticum.*

Flax, spurge. See *Daphne gnidium.*

Flax-leaved daphne. See *Daphne gnidium.*

Fleabane. See *Inula dysenterica.*

Flea-wort. See *Plantago psyllium.*

Flectens par lumborum. A name given by Cassirius to the *quadratus lumborum* muscle.

Flemen. (*n, nis.* n.) A Latin word signifying swelling of the ankles from over fatigue.

Fleresin. A name that has been given to gout.

FLESH. The muscular substance of an animal. See *Carnosus.*

Flesh brush. A brush for rubbing the surface of the body in order to excite the cutaneous circulation. Its use is very advantageous where the action of the capillary vessels is languid.

Fleshy. See *Carnosus.*

Flexion. (*Flexio, onis.* f.) The bent state of a joint, or the act of bending a joint; it is opposed to *extension.*

FLEX'OR. The name of several muscles, the office of which is to bend the joints.

Flexor accessorius digitorum pedis. See *Flexor longus digitorum pedis.*

Flexor brevis digitorum pedis, perforatus sublimis. A flexor muscle of the toes, situated on the foot. *Flexor brevis digitorum pedis, perforatus,* of Albinus. *Flexor brevis,* of Douglas. *Flexor digitorum brevis, sive perforatus pedis,* of Winslow. *Perforatus, seu flexor secundi internodii digitorum pedis,* of Cowper. It arises by a narrow, tendinous, and fleshy beginning, from the inferior protuberance of the os calcis. It likewise derives many of its fleshy fibres from the adjacent aponeurosis, and soon forms a thick belly, which divides into four portions. Each of these portions terminates in a flat tendon, the fibres of which decussate, to afford a passage to a tendon of the long flexor, and afterwards re-uniting, are inserted into the second phalanx of each of the four lesser toes. This muscle serves to bend the second joint of the toes.

Flexor brevis minimi digiti pedis. *Parathenar minor,* of Winslow. This little muscle is situated along the inferior surface and outer edge of the metatarsal bone of the little toe. It arises tendinous from the basis of that bone, and from the ligaments that connect it to the os cuboides. It soon becomes fleshy, and adheres almost the whole length of the metatarsal bone, at the anterior extremity of which it forms a small tendon, that is inserted into the root of the first joint of the little toe. Its use is to bend the little toe.

Flexor brevis policis manus. *Flexor secundi internodii,* of Douglas. *Thenar,* of Winslow. *Flexor primi et secundi ossis pollicis,* of Cowper. This muscle is divided into two portions by the tendon of the flexor longus pollicis. The outermost portion arises tendinous from the anterior part of the os trapezoides and internal annular ligament. The second, or innermost, and thickest portion, arises from the same bone, and likewise from the os magnum, and os cuneiforme. Both these portions are inserted tendinous into the sesamoid bones of the thumb. The use of this muscle is to bend the second joint of the thumb.

Flexor brevis pollicis pedis. A muscle of the great toe, that bends the first joint of that part. *Flexor brevis,* of Douglas. *Flexor brevis pollicis,* of Cowper. It is situated upon the metatarsal bone of the great toe, arises tendinous from the under and anterior part of the os calcis, and from the under part of the os cuneiforme externum. It soon becomes fleshy and divisible into two portions, which do not separate from each other till they have reached the anterior extremity of the metatarsal bone of the great toe, where they become tendinous, and then the innermost portion unites with the tendon of the abductor, and the outermost with that of the abductor pollicis. They adhere to the external os sesamoideum, and are finally inserted into the root of the first joint of the great toe. These two portions, by their separation, form a groove, in which passes the tendon of the flexor longus pollicis.

Flexor carpi radialis. A long thin muscle, situated obliquely at the inner and anterior part of the fore-arm, between the palmaris longus and the pronator teres. *Radialis internus,* of Albinus and Winslow. It arises tendinous from the inner condyle of the os humeri, and, by many fleshy fibres, from the adjacent tendinous fascia. It descends along the inferior edge of the pronator teres, and terminates in a long, flat, and thin tendon, which afterwards becomes narrower and thicker, and, after passing under the internal annular ligament, in a groove distinct from the other tendons of the wrist, it spreads wider again, and is inserted into the fore and upper part of the metacarpal bone that sustains the fore-finger. It serves to bend the hand, and its oblique direction may likewise enable it to assist in its pronation.

Flexor carpi ulnaris. *Ulnaris internus,* of Winslow and Albinus. A muscle situated on the cubit or fore-arm, that assists in bending the arm. It arises tendinous from the inner condyle of the os humeri, and, by a small fleshy origin, from the anterior edge of the olecranon. Between these two portions, we find the ulnar nerve passing to the fore-arm. Some of its fibres arise, likewise, from the tendinous fascia that covers the muscles of the fore-arm. In its descent, it soon becomes tendinous, but its fleshy fibres do not entirely disappear till it has reached the lower extremity of the ulna, where its tendon spreads a little, and after sending off a few fibres to the external and internal and annular ligaments, is inserted into the os pisiforme.

Flexor longus digitorum pedis profundus perforans. A flexor muscle of the toes, situated along the posterior part and inner side of the leg. *Perforans seu flexor profundus,* of Douglas. *Flexor digitorum longus, sive perforans pedis,* and *perforans seu flexor tertii internodii digitorum pedis,* of Cowper. It arises fleshy from the back part of the tibia, and, after running down to the internal ankle, its tendon passes under a kind of annular ligament, and then through a

sinuosity at the inside of the os calcis. Soon after this it receives a small tendon from the flexor longus pollicis pedis, and about the middle of the foot it divides into four tendons, which pass through the slits of the flexor brevis digitorum pedis, and are inserted into the upper part of the last bone of all the lesser toes. About the middle of the foot, this muscle unites with a fleshy portion, which, from the name of its first describer, has been usually called *massa carnea Jacobi Sylvii*: it is also termed *Flexor accessorius digitorum pedis*. This appendage arises by a thin fleshy origin, from most part of the sinuosity of the os calcis, and likewise by a thin tendinous beginning from the anterior part of the external tubercle of that bone; it soon becomes all fleshy, and unites to the long flexor just before it divides into its four tendons. The use of this muscle is to bend the last joint of the toes.

Flexor longus pollicis manus. *Flexor longus pollicis*, of Albinus. *Flexor tertii internodii*, of Douglas. *Flexor tertii internodii sive longissimus pollicis*, of Cowper. A muscle of the thumb, placed at the side of the flexor longus digitorum, profundus, perforans, and covered by the extensores carpi radiales. It arises fleshy from the anterior surface of the radius, immediately below the insertion of the biceps, and is continued down along the oblique ridge, which serves for the insertion of the supinator brevis, as far as the pronator quadratus. Some of its fibres spring, likewise, from the neighbouring edge of the interosseous ligament. Its tendon passes under the internal annular ligament of the wrist, and, after running along the inner surface of the first bone of the thumb, between the two portions of the flexor brevis pollicis, goes to be inserted into the last joint of the thumb, being bound down in its way by the ligamentous expansion that is spread over the second bone. In some subjects we find a tendinous portion arising from the inner condyle of the os humeri, and forming a fleshy slip that commonly terminates near the upper part of the origin of this muscle from the radius. The use of this muscle is to bend the last joint of the thumb.

Flexor longus pollicis pedis. A muscle of the great toe, situated along the posterior part of the leg. It arises tendinous and fleshy a little below the head of the fibula, and its fibres continue to adhere to that bone almost to its extremity. A little above the heel it terminates in a round tendon, which, after passing in a groove formed at the posterior edge of the astragalus, and internal and lateral part of the os calcis, in which it is secured by an annular ligament, goes to be inserted into the last bone of the great toe, which it serves to bend.

Flexor ossis metacarpi pollicis. *Opponens pollicis*, of Innes. *Opponens pollicis manus*, of Albinus. *Flexor primi internodii*, of Douglas. *Antithenar sive semi-interosseus pollicis*, of Winslow. A muscle of the thumb, situated under the abductor brevis pollicis, which it resembles in its shape. It arises tendinous and fleshy from the os scaphoides, and from the anterior and inner part of the internal annular ligament. It is inserted tendinous and fleshy into the under and anterior part of the first bone of the thumb. It serves to turn the first bone of the thumb upon its axis, and at the same time to bring it inwards opposite to the other fingers.

Flexor parvus minimi digiti. *Abductor minimi digiti*, *Hypothenar Riolani*, of Douglas. *Hypothenar minimi digiti*, of Winslow. A muscle of the little finger, situated along the inner surface of the metacarpal bone of the little finger. It arises tendinous and fleshy from the hook-like process of the unciform bone, and likewise from the anterior surface of the adjacent part of the annular ligament. It terminates in a flat tendon, which is connected with that of the abductor minimi digiti, and inserted into the inner and anterior part of the upper end of the first bone of the little finger. It serves to bend the little finger, and likewise to assist the abductor.

Flexor profundus perforans. *Profundus*, of Albinus. *Perforans*, of Douglas. *Perforans vulgo profundus*, of Winslow. *Flexor tertii internodii digitorum manus, vel perforatus manus*, of Cowper. A muscle of the fingers, situated on the fore-arm, immediately under the *perforatus*, which it greatly resembles in its shape. It arises fleshy from the external side and upper part of the ulna, for some way downwards, and from a large portion of the interosseous ligament. It splits into four tendons a little before it passes under the annular ligament of the wrist, and these pass through the slit in the tendons of the flexor sublimis, to be inserted into the fore and upper part of the third or last bone of all the four fingers, the joint of which they bend.

Flexor sublimis perforatus. This muscle, which is the *perforatus* of Cowper, Douglas, and Winslow, is, by Albinus and others, named *sublimis*. It is called *perforatus*, from its tendons being perforated by those of another flexor muscle of the finger, called the *perforans*. They who give it the appellation of *sublimis*, consider its situation with respect to the latter, and which, instead of *perforans*, they name *profundus*. It is a long muscle, situated most commonly at the anterior and inner part of the fore-arm, between the palmaris longus and the flexor carpi ulnaris; but, in some subjects, we find it placed under the former of these muscles, between the flexor carpi ulnaris and the flexor carpi radialis. It arises, tendinous and fleshy, from the inner condyle of the os humeri, from the inner edge of the coronoid process of the ulna, and from the upper and fore-part of the radius, down to near the insertion of the pronator teres. A little below the middle of the fore-arm, its fleshy belly divides into four portions, which degenerate into as many round tendons, that pass altogether under the internal annular ligament of the wrist, after which they separate from each other, become thinner and flatter, and running along the palm of the hand, under the aponeurosis palmaris, are inserted into the upper part of the second bone of each finger. Previous to this insertion, however, the fibres of each tendon decussate near the extremity of the first bone, so as to afford a passage to a tendon of the perforans. Of these

four tendons, that of the middle finger is the largest, that of the fore-finger the next in size, and that of the little finger the smallest. The use of this muscle is to bend the second joint of the fingers.

Flexor tertii internodii. See *Flexor longus pollicis manus.*

FLEXUO'SUS. Flexuous: full of turnings or windings. A stem is so named which is zigzag, forming angles alternately from right to left, and from left to right; as in *Smilax aspera.*

FLOCCILA'TION. (*Floccilatio, onis.* f.; from *floccus*, the nap of clothes.) Picking the bed-clothes. A symptom of great danger in acute diseases. See *Carphologia.*

Flocci volitantes. See *Muscæ volitantes.*

Flooding. The popular name for uterine hæmorrhage, especially as occurring during parturition.

FLORAL. (*Floralis;* from *flos*, a flower.) Belonging to a flower; as floral leaf, &c.

Floral leaf. See *Bractea.*

Flores antimonii helmontii. An old preparation, made by dissolving sulphuret of antimony in aqua regia, and subliming the product with sal ammoniac. It has been said to be violently emetic in a very small dose.

Flores antimonii rubri. An old preparation made by subliming a mixture of sulphuret of antimony and sal ammoniac.

Flores benzoes. See *Benzoic acid.*

Flores martiales. See *Iron.*

Flores salis ammoniaci. See *Ammoniæ subcarbonas.*

Flores sulphuris. See *Sulphur.*

Flores sulphuris loti. See *Sulphur lotum.*

FLORESCE'NTIA. (*a, æ.* f.; from *floresco*, to flourish or bloom.) The act of flowering, which Linnæus compares to the act of generation in animals.

Floret. A little flower. See *Flosculus.*

FLOS. (*os, oris.* f.; a flower.) I. A flower. That part of a plant, for the most part beautifully coloured, which protects the organs of fructification.

Every flower has parts, which are,

1. *Essential*, constituting properly the flower; as the pistil, stamen, and receptacle.

2. *Less essential*, without which the flower is in some instances formed; as the *calyx*, *corolla*, and *pedunculus.*

3. *Accidental*, noticed in a few only; as the *bractea* and *nectarium.*

A flower is said to be,

1. *Complete*, when furnished with calyx, corolla, stamens, and pistils; as *Nicotiana tabacum.*

2. *Incomplete*, when the calyx or corolla is wanting.

3. *Naked*, devoid of the calyx; as in *Lilium candidum*, and *Tulipa gesneriana.*

4. *Apetalous*, without the corolla; as in *Galenia africana*, and *Saururus cernuus.*

When the stamens and pistils are both, as usual, in one flower, that flower is called *perfect*, or united; when they are situated in different flowers of the same species, they are called *separated flowers;* that which has the stamens being named the *barren* flower, as producing no fruit in itself, and that with the pistils the *fertile* one, as bearing the seed.

The flower contains the internal or genital parts of a plant.

1. The *stamen*, or male genital organ.

2. The *pistillum*, or female genital organ.

From their diversity, flowers are called,

1. *Male*, which have the stamina only.

2. *Female*, in which are the pistils only.

3. *Hermaphrodite*, which contain both stamens and pistils.

4. *Neuter*, naturally deficient of stamens and pistils; as the marginal flowers of the *Centaurea cyanus*, and *Jacobea.*

5. *Castrate*, when the anthers or the pistils are naturally wanting. The pistils, for example, are wanting in the *Calendula officinalis*, and in the *Viola mirabilis* there are no anthers.

6. *Abortive*, the fecundated germens of which wither before the maturity of the fruit; as happens to the florets in the radius of the *Helianthus annuus.* See *Abortive.*

7. *Monstrous*, when the internal organs become petals, as is the case with full or double flowers. A double flower is also termed *flos plenus.*

8. *Fertile*, when they bear seeds which vegetate. See *Fertile.*

9. *Barren*, when without seeds, or have such as do not vegetate. See *Barren.*

Besides these distinctions, Linnæus's favourite division is into,

1. *Aggregate.*

2. *Compound.*

3. *Amentaceous.*

4. *Glumose*, or chaffy, peculiar to the grasses.

5. The *sheathed flower*, the common receptacle of which springs from a sheath; as in *Arum.*

6. The *umbellate.*

7. The *cymose.* See also *Inflorescence.*

II. A term applied by former chemists to whatever had a flower-like appearance, especially if obtained by sublimation; as flowers of sulphur, benjamin, zinc, &c.

FLOSCULO'SUS. Flosculose: having little florets.

FLO'SCULUS. (*us, i.* m.; diminutive of *flos.*) A little flower; a floret. A term applied, in *Botany*, to the small and numerous florets of a compound flower, which are all sessile on a common undivided receptacle, and enclosed in one contiguous calyx, or perianth.

Flounder. See *Pleuronectes flessus.*

Flounder, liver. See *Distoma.*

FLOUR. The powder of the gramineous seeds, or of any farinaceous substance.

Flower. See *Flos.*

Flower-de-luce. See *Iris.*

Flowers of benjamin. See *Benzoic acid.*

Flowers of sulphur. See *Sulphur lotum.*

FLU'ATE. *Fluas.* A compound of the fluoric acid with a salifiable base.

FLUCTUA'TION. *Fluctuatio.* A term used in medicine to express the undulation of a fluid; thus when pus is formed in an abscess, or when water accumulates in the abdomen, if the fingers be applied in a proper manner to the

abscess or the abdomen, the motion of fluctuation may be distinctly felt.

Fluctuation périphérique. See the Supplement.

Fluellin. See *Antirrhinum elatine.*

FLUID. A term applied, 1. adjectively, to express that state of matter in which its particles are readily moveable in all directions with respect to each other; as opposed to the *solid* state, in which the particles of a body cohere more firmly, and require more or less force to separate them.

2. Substantively, to a body the particles of which are readily moveable in all directions with respect to each other. Fluids are divided into *liquids*, the particles of which, though moveable on each other, and easily separated, are held together by a feeble cohesion; and *elastic fluids*, *gases*, or *aëriform fluids*, between the particles of which there is a repulsion, and which, when unconfined, tend to diffuse themselves through space. The fluids of the animal body form a large proportion of its entire substance. See *Animal.*

FLUOBORATE. A compound of the fluoboric acid with a salifiable base.

FLUOBO'RIC ACID. *Acidum fluoboricum.* Probably a compound of fluorine with boron. A gaseous acid, obtained by heating in a glass retort twelve parts of sulphuric acid with a mixture of one part of fused boracic acid, and two of fluor spar, reduced to a very fine powder. It must be received over mercury. It combines with salifiable bases, and forms salts called *fluoborates.*

FLU'OR. (From *fluo*, to flow.) Applied, in *Pathology*, to an increased discharge of a white mucous secretion from the internal surface of the vagina of females.

Fluor albus. See *Leucorrhœa.*

Fluor albus benignus. The whites. See *Leucorrhœa.*

Fluor albus malignus. Gonorrhœa in the female.

Fluor muliebris. The whites. See *Leucorrhœa.*

Fluor uterinus. The same. See *Leucorrhœa.*

FLUO'RIC ACID. *Acidum fluoricum.* The substance formerly so called is now considered as a compound of hydrogen and fluorine, and called hydro-fluoric acid.

Fluoric acid, silicated. See *Fluosilicic acid.*

FLU'ORIDE. A combination of fluorine with a salifiable basis.

FLU'ORINE. The supposed basis of hydro-fluoric acid. It has never yet been obtained in an insulated state. See *Hydro-fluoric acid.*

FLUO-SI'LICATE. A compound of the fluosilicic acid with a base.

FLUOSILI'CIC ACID. *Acidum fluosilicicum.* An acid supposed to be a compound of fluorine and silica. See *Hydro-fluoric acid.*

Fluotitanic acid. Fluoride of titanium. When fluoric acid is poured on titanic acid, (peroxide of titanium,) the latter becomes warm, even after having been previously ignited, and dissolves completely with the aid of heat. Evaporated at a gentle heat, to the consistence of syrup, the solution affords crystals, which do not re-dissolve completely in water, but which are decomposed into two peculiar combinations, of which one is acidulous and soluble, and the other with excess of base is insoluble. The solution of the former, namely, of the fluotitanic acid, in water, is analogous to the liquid fluosilicic acid: it contains fluotitanic acid and fluoric acid combined with water.

FLUX. 1. In *Pathology*, often applied to diarrhœa, dysentery, and cholera.

2. In *Chemistry*, used to denote any substance or mixture added to assist the fusion of metals.

Flux, bile. See *Cholera.*

Flux, black. When one part of nitre and two of cream of tartar are deflagrated together in a crucible, a black powder remains, which is a mixture of charcoal and subcarbonate of potash. This substance is called *black flux*, and is of much use in the reduction of metals.

Flux, crude. A mixture of nitre and cream of tartar put into a crucible along with a metal to aid its fusion.

Flux, intestinal. See *Diarrhœa.*

Flux, white. When equal parts of nitre and cream of tartar are deflagrated together, the whole of the carbon is dissipated: the residuum, which consists of subcarbonate of potash, is called *white flux.*

FLUXION. *Fluxio.* A term formerly applied by chemists, to signify the change of metals, or other bodies, from the solid into the fluid state, by the application of heat. See *Fusion.*

Fluxus capillorum. The name given by Celsus to alopecia.

Fly. See *Musca.*

Fly powder. See *Arsenic.*

Fly, Spanish. See *Cantharis.*

FO'CILE. The ulna and the radius have been denominated by the barbarous appellations of *focile majus* and *minus*; the tibia and fibula have also been so called.

Fo'cus. (A fire.) The right lobe of the liver was fancifully so called by some old anatomists, on the supposition that it ministered to the coction of nutritious matters.

Fodi'na. (From *fodio*, to dig.) A quarry. The labyrinth of the ear.

Fœnicula'tum lignum. A name of sassafras.

FŒNI'CULUM. (*um*, *i.* n.; *quasi fœnum oculorum*, the hay or herb good for the sight. — *Minshew.* An improbable derivation, but we know of no better.) Fennel. See *Anethum.*

Fœniculum alpinum. See *Æthusa.*

Fœniculum aquaticum. See *Phellandrium aquaticum.*

Fœniculum dulce. See *Anethum.*

Fœniculum germanicum. See *Anethum fœniculum.*

Fœniculum marinum. See *Crithmum.*

Fœniculum orientale. See *Cuminum.*

Fœniculum porcinum. See *Peucedanum officinale.*

Fœniculum sinense. See *Anisum stellatum.*

Fœniculum sylvestre. See *Seseli.*

Fœniculum tortuosum. See *Seseli.*

Fœniculum vulgare. See *Anethum.*

FŒ'NUM. (*um*, *i.* n.) Hay.

Fœnum camelorum. See *Juncus.*

Fœnum græcum. See *Trigonella.*

FŒNUM SYLVESTRE. Wild fenugreek.

FŒTA'BULUM. (From *fœteo*, to become putrid.) An encysted abscess is so called by Severinus.

FŒTAL. Appertaining to the fœtus.

Fœtal circulation. See *Ovum.*

FŒ'TUS. (*us*, *ûs.* m.; from *feo*, to bring forth, according to Vossius.) *Epicyema. Epigonion.* The child enclosed in the uterus of its mother, is called a fœtus from the fifth month after pregnancy until the time of its birth. See *Ovum.*

FOLIACEOUS. Leafy.

FOLIATA TERRA. 1. Sulphur.

2. An old name of the acetate of potash.

FOLIATION. (*Foliatio*; from *folium*, a leaf.) The manner in which leaves are folded up in their buds. See *Vernatio*, and *Gemma.*

FOLIA'TUS. (From its resemblance to *folium*, a leaf.) Foliate: leafy.

FOLIO'LUM. A leaflet or little leaf.

FO'LIUM. (*um*, *i.* n.; from φυλλον.) A leaf. See *Leaf.*

FOLIUM ORIENTALE. See *Cassia senna.*

FOLLICLE. (*Folliculus*; diminutive of *follis*, a bag.) See *Folliculus.*

FOLLICULOSE. (*Folliculosus*; from *folliculus*, a little bag.) Of the nature of a follicle.

FOLLI'CULUS. (Diminutive of *follis*, a bag.) 1. A little bag. In *Anatomy*, applied to a simple gland or follicle. One of the most simple species of gland, consisting merely of a hollow vascular membrane or follicle, and an excretory duct; such are the mucous follicles, the sebaceous follicles, &c.

In *Botany*, a follicle is a one-valved pericarp, or seed-vessel. It has one cell, and bursts lengthwise, and bears the seeds on or near its edges, or on a receptacle parallel therewith.

From the adhesion of the seeds it is distinguished into,

1. A follicle, *with a partition*, when the seeds adhere to an intermediate dissepiment.

2. A follicle, *without a partition*, when the seeds adhere to the internal sides only.

From the number of seeds,

1. *Monosperm follicle*; as in *Orontium.*

2. *Polysperm*; as in *Asclepias syriaca.*

From the direction, into,

1. *Erect*; as in *Vinca* and *Nerium.*

2. *Reflected*; as in *Plumeria.*

3. *Horizontal*; as in *Cameraria.*

Follicle also means, in *Botany*, an air-bag.

FOLLICULUS PELLIS. The gall-bladder.

FOMENTA'TION. *Fomentatio.* Partial bathing with warm water, simple or medicated.

FO'MES (*es*, *itis.* m.; *à fovendo.*) Fuel. In medical language a fomes means a porous substance capable of absorbing and retaining contagious effluvia. Wool and woollen cloth are amongst the most active *fomites.*

FOMES MORBI. An old term for the exciting cause of a disease.

FO'MITES. Plural of *fomes.* See *Fomes.*

Fons pulsatilis. See *Fontanella.*

FONTANE'LLA. (*a*, *æ.* f.; diminutive of *fons*, a fountain.) *Fons pulsatilis.* The parietal bones and the frontal do not coalesce until the third year after birth, so that, before this period there is an obvious interstice, commonly called *mould*, and scientifically the *anterior fontanel.* There is also a lesser space, occasionally, between the occipital and parietal bones, termed the *posterior fontanel.* These spaces between the bones are filled up by the dura mater, pericranium, and external integuments, so that, during birth, the size of the head may be lessened; for, at that time, the bones of the head, upon the superior part, are not only pressed nearer to each other, but they frequently lap over one another, in order to diminish the size during the passage of the head through the pelvis.

FONTI'CULUS. (*us*, *i.* m.; diminutive of *fons.*) An issue. An artificial ulcer formed in any part by incision or caustic, and kept discharging by introducing daily a pea, covered with any digestive ointment.

FOOT. *Pes.* That part of an animal on which it stands or walks.

In *Zoology*, animals are distinguished, with respect to the number of feet, into,

1. *Biped*, or two-footed, as men and birds.

2. *Quadruped*, or fourfooted; as most land animals.

3. *Multiped*, or many-footed; as insects.

The osseous part of the foot, which is of very complex structure, consists in man of the *tarsus*, *metatarsus*, and *phalanges.* These are connected by numerous ligaments, acted on by numerous muscles, and covered by tendinous expansions and common integuments, the latter of which are very thick and hard on the sole of the foot, being condensed by the frequent pressure to which they are subjected.

Foot-bath. See *Pediluvium.*

FORA'MEN. (*en*, *inis.* n.; from *foro*, to pierce.) A little opening.

Foramen centrale. See *Foramen of Soemmering.*

FORAMEN CŒCUM. 1. A single opening, in the basis of the cranium, between the ethmoid and the frontal bone, that gives exit to a small vein.

2. A depression at the posterior part of the tongue.

This is sometimes called *foramen cæcum Morgagni.*

FORAMEN INCISI'VUM. *Foramen palatinum anterius.* A foramen behind the upper incisive teeth, common to the two upper jaws below, but proper to each above. It is filled with a process of the palate, and with very small vessels and nerves.

FORAMEN LACERUM IN BASI CRANII. A foramen in the basis of the cranium, through which the internal jugular vein, and the eighth pair and accessory nerves pass.

FORAMEN LACERUM ANTERIUS. *Foramen lacerum orbitale superius.* A large opening

etween the greater and lesser wing of the henoid bone on each side, through which the ird, fourth, first branch of the fifth, and the xth pair of nerves, and the ophthalmic artery, ass.

Foramen Monroia'num. Foramen of Monro. o named after the elder Dr. Monro, who first escribed it. An aperture under the anterior art of the body of the fornix, by which the teral ventricles of the brain communicate with ach other. See *Encephalos.*

Foramen of Monro. See *Foramen Monroianum.*

Foramen nigrum. See *Occipital bone.*

Foramen opticum. The hole which transmits the optic nerve.

Foramen ovale. The opening between the wo auricles of the heart of the fœtus. See also *innominatum os.*

Foramen of Winslow. An opening in the mentum. See *Omentum.*

Forami'nulum os. The ethmoid bone.

FO'RCEPS. (*eps, ipis.* f.; *quasi ferriceps,* rom *ferrum,* iron, and *capio,* to take.) The ame given to a great variety of surgical instruments, which are used in order to take firm old of bodies.

Fore-arm. See *Body.*

FOR'ENSIC. *Forensis. Forensicus.* Belonging to the forum, or courts of law. Forensic medicine is the application of medical cience to the elucidation of judicial questions. See *Medicine.*

Foreskin. See *Prepuce.*

Forge water. See *Fabrarum aqua.*

FO'RMIATE. *Formias.* A compound roduced by the union of the formic acid with salifiable basis: thus, *formiate of ammonia,* &c.

FO'RMIC ACID. (*Acidum formicum:* so alled, because obtained from *formica,* the ant.) This acid comes from the ant, or *formica rufa,* f Linnæus. It may be obtained either by imple distillation, or by infusion in boiling water, and subsequent distillation of as much of he water as can be brought over without burning the residue. After this it may be purified by repeated rectifications, or by boiling; or, after rectification, it may be concentrated by frost.

This acid has a very sour taste, and continues iquid even at very low temperatures. It has not yet been applied to any use.

FORMI'CA. (*a, æ.* f.; *quod ferat micas,* because of his diligence in collecting small particles of provision together.) 1. The name of a genus of insects. The ant or pismire. See *Formica rufa.*

2. The name of a black wart with a broad base, and cleft superficies, because the pain attending it resembles the biting of an ant.

3. A varicose tumour on the anus and glans penis.

Formica rufa. The ant or pismire. This industrious little insect contains an acid juice, and gross oil, which were supposed to possess aphrodisiac virtues. The chrysalides of this animal are said to be diuretic and carminative, and by some recommended in the cure of dropsy.

The ant also furnishes an acid called the formic, which it has been long known to contain, and occasionally to emit. See *Formic acid.*

Fo'rmix. See *Herpes exedens.*

FO'RMULA. (*a, æ.* f.; diminutive of *forma,* a form.) A prescription for the preparation of medicines.

Fo'rnax. A furnace.

Fornica'tus. Fornicate: vaulted. See *Forniciformis.*

FORNICIFO'RMIS. Forniciform: vaulted. Applied to the nectary of some plants; as the *Symphytum officinale,* &c. See *Nectarium.*

FO'RNIX. (*ix, icis.* f.; an arch or vault.) The part beneath the corpus callosum in the brain is so called, because, if viewed in a particular direction, it has some resemblance to the arch of a vault. See *Encephalos.*

FO'SSA. (*a, æ.* f.; from *fodio,* to dig.) *Fovea.* A little depression or sinus. The pudendum muliebre.

Fossa amyntæ. A double-headed roller for the face.

Fossa hyaloide'a. The depression in the vitreous humour in which the crystalline lens is lodged.

Fossa lachrymalis. A sinuosity in the frontal bone, for lodging the lachrymal gland.

Fossa magna. 1. The great groove of the ear.

2. The opening of the pudendum muliebre.

Fossa navicularis. 1. The cavity at the bottom of the entrance of the pudendum muliebre.

2. The great groove of the ear.

Fossa ovalis. The depression in the right auricle of the human heart, marking the site of the foramen ovale in the fœtus.

Fossa pituitaria. The hollow in the sella turcica of the sphenoid bone, which contains the pituitary gland.

FO'SSIL. (*Fossilis;* from *fodio,* to dig.) A term applied adjectively and substantively to any thing dug out of the earth. The organic remains of animals and vegetables are termed *extraneous* fossils, as opposed to minerals, which are the natural productions of the earth.

Fossils, extraneous. See *Fossil.*

Fossil unicorn. See *Unicorn.*

Fo'tus. (*us, ûs.* m.) See *Fomentation.*

Fourth pair of nerves. See *Nervous system.*

FO'VEA. (*a, æ.* f.; from *fodio,* to dig.) 1. A little depression.

2. The pudendum muliebre.

3. A partial sweating-bath.

FOVEA'TUS. Having a little depression, or pit. Applied to the nectary of plants. See *Nectarium.*

Fovi'lla. The name given by Martyn to the fecundating liquor contained in the grains of pollen.

FOWL. In a general sense this word is of equal import with bird: but it is applied in a more particular manner to poultry of all kinds.

Fowl, dunghill. See *Phasianus.*

Fowl, guinea. See *Numidia meleagris.*

Fowl, pea. See *Pavo cristatus.*

Fowler's solution. An arsenical solution

introduced into practice by Dr. Fowler, of Stafford, as a substitute for the quack medicine called tasteless ague drop. The arsenical solution of the pharmacopœias is similar to this.

Fox-glove. See *Digitalis.*

Fox-glove, Eastern. See *Sesamum.*

FRA'CTURE. (*Fractura, æ.* f.; from *frango*, to break.) *Catagma, Clasis, Clasma, Agme.* In *Surgery*, the breaking of a bone into two or more fragments. A *simple* fracture is when the bone only is divided. A *compound* fracture is a division of the bone, with a laceration of the integuments, the bone mostly protruding. When the bone is splintered into a number of small pieces, this is called a *comminuted fracture.* A fracture is also termed transverse, oblique, &c., according to its direction.

FRÆ'NULUM. (*um, i.* n.; diminutive of *frænum.*) See *Frænum.*

FRÆ'NUM. (*um, i.* n.) A name given by anatomists to any ligament which binds down or restrains the motion of a part.

FRÆNUM EPIGLO'TTIDIS. The ligament which connects the epiglottis with the root of the tongue and os hyoides.

FRÆNUM LINGUÆ. A fold of the mucous membrane of the mouth, which binds down the tongue.

FRÆNUM PRÆPUTII. A fold of integument connecting the prepuce with the glans penis.

FRAGA'RIA. (*a, æ.* f.; from *fragro*, to smell sweet.) The strawberry. 1. The name of a genus of plants in the Linnæan system. Class, *Icosandria;* Order, *Polygynia.*

2. The pharmacopœial name of the strawberry. See *Fragaria vesca.*

FRAGARIA STERILIS. Barren strawberry. Astringent, seldom used.

FRAGARIA VESCA. The systematic name of the strawberry plant. The mature fruit of the *Fragaria, flagellis reptantibus*, of Linnæus, was formerly recommended in gouty and calculous affections, in consequence, it would appear, of its efficacy in removing tartar from the teeth, which it is said to do very effectually.

FRAGI'LITAS OSSIUM. Fragility or brittleness of the bones. See *Mollities ossium.*

FRA'GMEN. *Fragmentum.* A splinter of a bone.

FRA'GUM. (*um, i.* n.; from *fragro*, to smell sweet.) See *Fragaria.*

FRAMBŒ'SIA. (From *framboise*, Fr. for a raspberry.) The yaws; a disease that is endemial to the Antilles islands, as well as Africa. It appears with excrescences like mulberries growing out of the skin in various parts of the body, which discharge an ichorous fluid. The nature of this disease has been imperfectly investigated by European practitioners; and as it is perhaps never seen in England, a very brief account of it here will be sufficient.

The eruption of the yaws sometimes commences without any precursory symptoms of ill-health; but it is generally preceded by a slight febrile state, with languor, debility, and pains of the joints, resembling those of rheumatism. After several days, minute protuberances appear on various parts of the skin, at first smaller than the head of a pin, but gradually enlarging, in some cases to the diameter of a sixpence, and in others even to a greater extent: they are most numerous, and of the largest size, in the face, groins, axillæ, and about the anus and pudenda. But the crop is not completed at once: new eruptions appear in different places, while some of the earlier ones dry off. When the cuticle is broken, a foul crust is formed on the surface, from under which, in the larger protuberances, red fungous excrescences often spring up, which attain different magnitudes, from that of a small raspberry to that of a large mulberry, which fruit they somewhat resemble from their granulated surfaces. When the eruption is most copious, these tubercles are of the smallest size; and when fewer, they are largest. Their duration and progress are various in different constitutions, and at different periods of life. Children suffer less severely than adults, and are more speedily freed from the disease: in them, according to Dr. Winterbottom, the duration of the yaws is from six to nine months; while in adults it is seldom cured in less than a year, and sometimes continues during two or three. The fungous tubercles attain their acme more rapidly in the well-fed negroes, than in those who are ill-fed and thin; and they likewise acquire a larger size in the former than in the latter. They are not possessed of much sensibility, and are not the seat of any pain, except when they appear upon the soles of the feet, where they are confined and compressed by the hard and thickened cuticle: in that situation they render the act of walking extremely painful, or altogether impracticable. They never suppurate kindly, Dr. Winterbottom says, but gradually discharge a sordid glutinous fluid, which forms an ugly scab round the edges of the excrescence, and covers the upper part of it, when much elevated, with white sloughs. When they appear on any part of the body covered with hair, this gradually changes in its colour from black to white, independently of the white incrustation from the discharge. They leave no depression of the skin.

The period during which the eruption is in progress, varies from a few weeks to several months. "When no more pustules are thrown out," Dr. Winterbottom observes, "and when those already upon the skin no longer increase in size, the disease is supposed to have reached its acme. About this time it happens, on some part of the body or other, that one of the pustules becomes much larger than the rest, equalling or surpassing the size of a half-crown piece: it assumes the appearance of an ulcer, and, instead of being elevated above the skin, like others, it is considerably depressed: the surface is foul and sloughy, and pours out an ill-conditioned ichor, which spreads very much, by corroding the surrounding sound skin: this is what is called the *master* or *mother yaw.*" When arrived at its acme, however, the eruption continues a considerable time without undergoing much alteration, often without very materially injuring the functions, and it seldom proves dangerous, except from the mischievous interference of ill-directed art.

The framboesia is propagated solely by the

ntagion of the matter discharged from the uption, when it is applied to the wounded or oken skin of another person, who has not eviously undergone the disease. For, like e febrile eruptions, the framboesia affects the me person only once during life; but, unlike em, it is not propagated by effluvia. In frica, it is usually undergone during child-od. The period which elapses between the ception of the contagion and the commence-ent of the disease is no where mentioned; but the case of a Dane, whom Dr. Adams saw Madeira, the patient had been ten months sent from the West Indies, before he felt any disposition.

With respect to the treatment of framboesia, thing very satisfactory is to be collected from e writings of the practitioners to whom we are lebted for the history of the disease. The tive Africans, according to Dr. Winterbottom, never attempt to cure it until it has nearly ached its height, when the fungi have acquired eir full size, and no more pustules appear." nd the practitioners in the West Indies soon arned, by experience, that active evacuations ard the natural progress of the disease; and t mercurials, although they suspended it, and eared the skin of the eruption, yet left the tient still susceptible of, or rather still im-egnated with, the virus, which speedily inced its presence, by a reappearance of the mptoms, more severe and tedious than before. truth, the disease, it would seem, like the stular and exanthematous fevers of our own mate, will only leave the constitution after it s completed the various stages of its course, d removed the susceptibility of the individual future infection; and no medicine, yet dis-vered, has had any influence in superseding is action, or in accelerating its progress. Un-ss, therefore, any urgent symptoms should re-ire alleviation, which seldom, if ever, happens, is advisable to dispense with the administra-n of medicine, and to be content with restrict-g the patient to a moderate and temperate gimen, during the first stage of the malady. hen the eruptions begin to dry, or as soon as ey cease to multiply and enlarge, the disease pears to require the same management as her slow and superficial ulcerations, accom-nied with a cachectic state of the system; viz. light, but nutritious diet, a dry and wholesome r, warm clothing, moderate exercise, and a urse of tonic medicine, especially of sarsapa-la, or cinchona, with the mineral acids, or th antimonials and small doses of mercury, cording to the circumstances of the individual bit. The effects of mercury, however, exhi-ted so as to excite salivation, as the early West ndian practitioners recommend, seem to be of a ry questionable nature, especially when it is naccompanied by the vegetable decoctions; and is certain that patients have, in some cases, on recovered under the use of the latter, when e mercurials were omitted. The native fricans employ decoctions of the bark of two three trees, which are gently purgative, as ell as tonic, and likewise wash the sores with em, after carefully removing the crusts.

The *master yaw* sometimes remains large and troublesome, after the rest of the eruption has altogether disappeared. It requires to be treated with gentle escharotics, and soon assumes a healing appearance under these applications. Stronger caustics are requisite for the cure of the *crab yaws*, or tedious excrescences which occur on the soles of the feet.

Fra'ngula. (*a*, *æ*. f.; from *frango*, to break: so called because of the brittleness of its branches.) See *Rhamnus frangula*.

Frankincense. See *Juniperus lycia*, and *Pinus abies*.

Fraxine'lla. (*a*, *æ*. f.; from *fraxinus*, the ash: so called because its leaves resemble those of the ash.) See *Dictamnus albus*.

Fraxinella, white. See *Dictamnus albus*.

FRA'XINUS. (*us*, *i*. f.; according to some, from *fragor*, on account of the noise its seed vessels make when shaken by the wind.) The ash. 1. The name of a genus of plants in the Linnæan system. Class, *Polygamia*; Order, *Dioecia*.

2. The pharmacopœial name of the ash-tree. See *Fraxinus excelsior*.

Fraxinus excelsior. The systematic name of the ash-tree. *Fraxinus*. Called also, *brumelli*, and *bumelia*. The bark of this tree, *Fraxinus*—*foliis serratis floribus apetalis*, of Linnæus, when fresh, has a moderately strong bitterish taste. It possesses resolvent and diuretic qualities, and has been successfully exhibited in the cure of intermittents. The seeds are occasionally exhibited medicinally as diuretics, in the dose of a drachm. In warm climates a sort of manna exudes from this species of fraxinus.

Fraxinus ornus. The systematic name of the tree from which manna flows. This substance is also termed *Manna calabrina*; *Ros calabrinus*; *Acromeli*; *Alusar*; *Drysomeli*. That species which is of a rosy colour, is called *nuba*. *Mel aërium*, from the supposition that it descended from Heaven. Manna is the condensed juice of the flowering ash, or *Fraxinus ornus*—*foliis ovato-oblongis serratis petiolatis, floribus corollatis*, Hort. Kew., which is a native of the southern parts of Europe, particularly Sicily and Calabria. Many other trees and shrubs have likewise been observed to emit a sweet juice, which concretes upon exposure to the air, and may be considered of the manna kind, especially the *Fraxinus rotundifolia*, and *excelsior*. In Sicily these three species of fraxinus are regularly cultivated for the purpose of procuring manna, and with this view are planted on the declivity of a hill with an eastern aspect. After ten years' growth, the trees first begin to yield the manna, but they require to be much older before they afford it in any considerable quantity. Although the manna exudes spontaneously upon the trees, yet, in order to obtain it more copiously, incisions are made through the bark, by means of a sharp crooked instrument; and the season thought to be most favourable for instituting this process, is a little before the dog-days commence, when the weather is dry and serene. Manna is generally distinguished into different kinds, viz. the manna in tear, the canulated and flaky manna, and the common

brown or fat manna. All these varieties seem rather to depend upon their respective purity, and the manner in which they are obtained from the plant, than upon any essential difference of the drug. The best manna is in oblong pieces or flakes, moderately dry, friable, very light, of a whitish or pale yellow colour, and in some degree transparent: the inferior kinds are moist, unctuous, and brown. Manna is well known as a gentle purgative, so mild in its operation, that it may be given with safety to children and pregnant women, to the delicacy of whose frames and situations it is particularly adapted. It is esteemed a good and pleasant auxiliary to the purgative neutral salts. It has been thought demulcent and useful in coughs, disorders of the chest, and such as are attended with fever and inflammation, as in pleuritis, &c. It has been particularly recommended in bilious complaints, and to help the discharge of mineral waters, when they are not of themselves sufficiently active. It is apt, in large doses, to create flatulencies and gripes; both of which are prevented by a small addition of some warm carminatives. It purges in doses of from ℥j. to ℥ij.; but its purgative quality is much increased, and its flatulent effects prevented, by a small addition of cassia. The dose for children is from one scruple to three. It is best dissolved in whey.

Fraxinus rotundifolia. The systematic name of a tree which affords manna. See *Fraxinus ornus*.

Freckle. See *Ephelis*.

Freezing point. See *Caloric*.

Freezing mixture. See *Caloric*.

Fre'na. The sockets of the teeth have been so called.

French berries. See *Rhamnus infectorius*.

FRIABI'LITY. (*Friabilitas*; from *frio*, to crumble.) The property of being easily crumbled or reduced to small particles by pressure.

FRI'ABLE. Possessed of friability.

FRICTION. (*Frictio, onis.*; from *frico*, to rub.) Friction is a therapeutical agent of considerable power; by means of it, the circulation is stimulated in debilitated parts, and medicinal substances are made to penetrate the pores of the skin.

Friction, sound of. In auscultation the sound of friction, or *bruit de frottement* is a sound which is heard where there is considerable roughness on the surface of the pulmonary or costal pleura. It is synchronous with the respiratory movements.

Friesland green. Another name for *Brunswick green*.

Frigida'rium. (*um, i.* n.; from *frigidus*, cold.) See *Balneum*.

Frigorific. Possessed of the power of inducing cold.

Frigorific mixture. See *Caloric*.

FRI'GUS. (*us, oris.* n.; from *frigeo*, to be cold.) Cold. This is generally thought to consist merely in the privation of heat, though some have maintained it to be a positive principle. The human body contains within itself, as long as it is living, a principle of warmth: if any other body, being in contact with it, abstracts the heat with unusual rapidity, it is said to be cold; but if it carries off the heat more slowly than usual, or even communicates heat to our body, it is said to be hot. See *Ardor*. Cold is a strong irritant, when the atmospheric temperature is too high; it is a pleasant and reviving agent, inasmuch as it both reduces the heated medium, and restores the particles of the affected organ from a state of disquieting tenseness to their usual scale of approximation. If the cold be pushed further, it may go a little beyond this, and be still pleasant and healthful: for the organ or the general system may be in a state of morbid relaxation, and, consequently, in their actual scale of approach, the living particles may be too far remote for the purposes of high elasticity and vigour. And it is in such a condition as this that cold chiefly shows its stimulant power, and is so generally resorted to as a tonic. But if the agency of cold be carried farther than this, it produces uneasiness to the nerves of feeling, by a process precisely the reverse of that which is pursued by heat, and consequently in a twofold manner: first, by lowering the warmth of the organ, or of the system, below its scale of ease and comfort; and next, by forcing the living particles into too close and crowded a state, and not allowing them sufficient room for play. Cold, as an idiopathic affection, is chiefly local, and most common to the head and feet. It is temporarily relieved by warmth and stimulants, and particularly by the friction of a warm hand; and, where it can be used, the exercise of walking. It is permanently relieved by the warmer tonics, as sea-bathing and aromatic bitters.

Considerable mischief has often been produced by a sudden exposure of the feet to severe cold, and especially in delicate and irritable habits, unused to such applications, as colic, headache, catarrh, fevers, and, in podagral habits, gout. But the application of severe and sudden cold to the head or stomach, by drinking ice or cold water, and especially when the individual is heated and perspiring, has been followed with more alarming effects, and even with death itself. Mauriceau relates an instance of death produced during baptism, by applying to the head the water of the baptismal font. This must be a rare occurrence; while the fatal effects of drinking ice or iced water, in a state of heat, are innumerable. It is observed by Dr. George Fordyce, and the observation is quoted and called curious by Dr. Darwin, "that those people who have been confined some time in a very warm atmosphere, as of 120° or 130° of heat, do not feel cold, nor are subject to paleness of their skins, on coming into a temperature of 30° or 40°: which would produce great paleness and painful sensation of coldness in those who had been for some time confined in an atmosphere of only 86° or 90°." The cause is not difficult of explanation. The sensorial power is exhausted, and the nerves of feeling rendered torpid, by a long exposure to a heat of 120° or 130°, and the turgid capillaries, the dilatation of which produces the general blush, lose their power of constriction or collapse; while in a heat of 86° or 90° neither of such effects takes place.

Cold, as a symptom, is found in the first stage fever, in syncope, hysteria, nausea, and inammation of the viscera, in all of which the fection is general. See *Morbid temperature.*

FRO'NS. (*s, tis.* f. or m.) 1. The forehead. The part between the eyebrows and the hairy scalp.

2. (*s, dis.* f.) The leaf or bough of a tree: now applied by botanists to the cryptogamous plants only, to signify that the stem, root, and leaf are all in one; as in ferns, fuci, &c.

FRO'NTAL. (*Frontalis;* from *frons,* the forehead.) Belonging to the forehead.

Frontal bone. See *Frontis os.*

Frontal sinus. See *Frontis os.*

Frontalis. See *Frontal.*

Frontalis verus. See *Corrugator supercilii.*

FRO'NTIS OS. The frontal bone. *Os coronale. Os inverecundum. Metopon.* The external surface of this bone is smooth at its upper convex part, but below several cavities and processes are observed. At each angle of the orbits the bone juts out to form two internal and two external processes; and the ridge under the eyebrow, on each side, is called the superciliary process; from which the orbitar processes extend backwards, forming the upper part of the orbits; and between these the ethmoid bone is received. The nasal process is situated between the two internal angular processes. At the internal angular process is a cavity for the carunicula lachrymalis; and at the external, another for the pulley of the major oblique muscle. The foramina are three on each side: one in each superciliary ridge, through which a nerve, artery, and vein pass to the integuments of the forehead; a second near the middle of the internal side of the orbit, called internal orbitar; the third is smaller, and lies about an inch deeper in the orbit. On the inside of the os frontis there is a ridge which is hardly perceptible at the upper part, but grows more prominent at the bottom, where the foramen cœcum appears; to this ridge the falx is attached. The frontal sinus is placed over the orbit on each side: except at this part the frontal bone is of mean thickness between the parietal and occipital; but the orbitar process is so thin as to be almost transparent.

FRUCTIFICATION. (*Fructificatio, onis.* ; from *fructus,* fruit, and *facio,* to make.) Under this term are comprehended the flowers and the fruit of a plant. It is a temporary part of plants appropriated to generation, terminating the old vegetable and beginning the new. By the parts of fructification, Sir James Smith observes, each species is perpetually renewed without limits, while all other modes of propagation are but the extension of an individual, and sooner or later terminate in its total extinction. The fructification is therefore essential to vegetables. A plant may be destitute of stem, leaves, or even roots, because if one of these parts be wanting, the others may perform its functions; but it can never be destitute of those organs by which its species is propagated. Linnæus distinguishes seven parts of fructification, some of which are essential to the very nature of a flower or fruit; others, not so indispensably necessary, and therefore are not universal.

1. The *calyx,* or flower-cup, not essential and often absent. See *Calyx.*

2. The *corolla,* or petal, likewise not essential. See *Corolla.*

3. The *stamen* or *stamina.* These are essential. See *Stamen.*

4. The *pistillum,* or *pistilla,* in the centre of the flower, consisting of the rudiments of the fruit, with one or more organs attached to them, and therefore essential. See *Pistillum.*

5. The *pericarpium,* or seed-vessel, wanting in many plants. See *Pericarpium.*

6. The *semen,* or seed, the perfecting of which is the sole end of all the other parts.

7. The *receptaculum,* which must necessarily be present in some form or other. See *Receptaculum.*

FRU'CTUS. (*us, us.* m.; *à fruor.*) The fruit of a tree or plant. By this term is understood, in *Botany,* the produce of the germen, consisting of the seed-vessel and seed. For the botanical distinctions of fruits, see *Pericarpium.*

Fruits are used more or less extensively as an article of diet for man, and many of the inferior animals live chiefly upon them. Those of the subacid kind are exhibited as dietetic auxiliaries, as refrigerants, antiseptics, attenuants, and aperients. Formerly they were exhibited medicinally in the cure of putrid affections, and to promote the alvine and urinary excretions. The acid which they contain is either the tartaric, oxalic, citric, or mallic, or a mixture of two or more of them with sugar and gluten, starch, and a gelatinous substance. Considering them as an article of diet, they afford little nourishment, and are liable to produce flatulencies. To persons of a bilious constitution and rigid fibres, and where the habit is disposed naturally, or from extrinsic causes, to an inflammatory or putrescent state, their moderate and even plentiful use is salubrious; by those of a cold inactive disposition, where the vessels are lax, the circulation languid, and the digestion weak, they should be used very sparingly. The juices extracted from these fruits by expression, contain their active qualities freed from their grosser indigestible matter. On standing, the juice ferments and changes to a vinous or acetous state. By proper addition of sugar, and by boiling, their fermentative power is suppressed, and their medicinal qualities preserved. The juices of these fruits, when purified from their fæculencies by settling and straining, may be made into syrups, with a due proportion of sugar in the usual way.

FRUCTUS ACIDO-DULCES. Subacid fruits; those which combine an acid with a sweet taste. See *Fructus.*

Fruit. See *Fructus.*

Fruit-stalk. See *Pedunculus.*

FRUMENTA'CEOUS. *Frumentaceus.* A term applied to all such plants as have a conformity with wheat, either with respect to their fruit, leaves or ears.

FRUTESCE'NTIA. (*a, æ.* f.; from *fructus,* fruit.) Frutescence. The mature state of a fruit.

FRU'TEX. (*ex, icis.* m.) A shrub or

plant, which rises with a woody durable stem, but never arrives at the height, or has the appearance of an *arbor*, or tree.

FRUTICO'SUS. Fruticose: shrubby; shrub-like.

FU'CUS. (*us, i.* m.) The name of a genus of plants in the Linnæan system. Class, *Cryptogamia*; Order, *Algæ*.

Fucus bacci'ferus. Gulph-weed. This is eaten raw, as a salad, and pickled as samphire. It is aperient, diuretic, and wholesome.

Fucus digitatus. Sea girdle and hangers. This fucus grows upon stones and rocks in the sea near the shore. It has several plain long leaves or sinuses springing from a round stalk, in the manner of fingers when extended. It affords soda.

Fucus edulis. Red dulce. This species is eaten raw, also after being broiled, when it has the taste of roasted oysters.

Fucus esculentus. *Fucus teres; Fucus fimbriatus.* Daber locks. Edible fucus. Hudson has made this a distinct species, but Linnæus included it under his *saccharinus*. It grows plentifully in the sea near the shores of Scotland, and also those of Cumberland, where it is eaten by the natives. It has a broad, plain, simple, sword-shaped leaf, springing from a pinnated stalk.

Fucus fimbriatus. See *Fucus esculentus.*

Fucus helminthocorton. *Helmintho-corton. Conferva helmintho-cortos. Conferva dichotoma. Corallina rubra. Corallina melito-corton. Lemitho-corton. Mouse de Corse.* Corsican wormweed. *Fucus helmintho-corton*, of De la Tourrette. This plant has gained great repute in destroying all species of intestinal worms. Its virtues are extolled by many; but impartial experimentalists have frequently been disappointed of its efficacy. The Geneva Pharmacopœia directs a syrup to be made of it. It is given also internally in the cure of scrofulous and cancerous complaints; and in some cases it is said to have been very efficacious.

This sea moss contains several kinds of geniculated thread-like algæ, confervæ, and fuci, which are also supposed to be vermifuge.

Fucus natans. Sea lentil. *Vitis marina. Lenticula marina.* This is said to be useful against some forms of dysuria.

Fucus palmatus. Handed fucus. Dulce. Dills. Dulesh. This grows in the sea and consists of a thin-lobed leaf like a hand, and is eaten either raw, boiled, or broiled.

Fucus pinnatifidus. Pepper dulce. This is often eaten as a salad: it is warm, like cresses, and very wholesome.

Fucus saccharinus. Sweet fucus. Sea-belts. This species grows upon rocks and stones by the sea-shore. The leaves are very sweet, and, when washed and hung up to dry, will exude a substance like sugar, from which the plant is named.

Fucus teres. See *Fucus esculentus.*

Fucus vesiculosus. The systematic name of the sea-oak. Sea wrack. Bladder wrack. *Quercus marina.* This sea-weed, the *Fucus vesiculosus — fronde plana dichotoma costata integerrima, vesiculis axillaribus geminis, terminalibus tuberculatis*, of Linnæus, is said to be a useful assistant to sea-water, in the cure of disorders of the glands. Burnt in the open air, and reduced to a black powder, it forms the *æthiops vegetabilis* of the shops, which, as an internal medicine, is similar to burnt sponge, containing a considerable quantity of iodine.

FU'LCRUM. (*um, i.* n.) A prop or support. This term is applied by Linnæus, not only to those organs of vegetables correctly so denominated, such as tendrils, but also to various other appendages to the herbage of a plant, none of which are universal or essential, nor is there any one plant furnished with them all. Sir James Smith prefers the English term *appendage*, for these organs in general, to *props*, because the latter applies only to one of them.

The greater *props*, or *fulcra* of vegetables, are the roots, trunks, and branches.

To the *lesser* are referred.

1. The *petiolus*, or petiole, which is the fulcrum of the leaf.

2. *Cirrus*, the tendril. See *Cirrus.*

3. The *stolo*, or sucker; a filament, or underground bud, protruded from the root, and sending off radicles into the earth, pushes up a stem resembling the parent plant; as in the strawberry, and *Syringa vulgaris.*

4. *Sarmentum*, the runner which gives off from the stem, and radicates on that which is nearest to it; as in the *Hedera helix*, or ivy.

The *fulcra of a flower* are the peduncle, scape, and receptacle.

FULI'GO. (*o, inis.* f.; *quasi fumiligo*; from *fumus*, smoke.) Soot. Wood-soot, *fuligo ligni*, or the condensed smoke from burning wood, has a pungent, bitter, and nauseous taste, and is resolved by chemical analysis into a volatile alkaline salt, an empyreumatic oil, a fixed alkali, and an insipid earth. The tincture prepared from this substance, *tinctura fuliginis*, has been recommended as a powerful antispasmodic in hysterical affections.

FULLER'S EARTH. *Cimolia purpurascens.* An earth composed of silica, alumine, magnesia, lime, muriate of soda, a trace of potash, and oxide of iron. It occurs in different parts of Europe, but the best is found in beds in Buckinghamshire and Surrey. It is sometimes applied by the poor to inflamed breasts, &c. with a view of cooling them.

Fulminating gold. See *Aurum.*

Fulminating mercury. See *Mercury.*

Fulminating platina. See *Platina.*

Fulminating silver. See *Argentum.*

Fulminating powder. This is made by triturating together, in a very dry mortar, three parts by weight of nitre, two of carbonate of potash, and one of flowers of sulphur; when fused in a ladle over the fire it explodes with great violence.

Fulmination. (*Fulminatio*; from *fulmen*, a thunderbolt.) Synonymous with *detonation.*

FULMI'NIC ACID. *Acidum fulminicum*: so called because its compounds explode with a noise. An acid obtained from fulminate of silver, which is the cyanic combined with oxide of silver.

Fumans nix. Quick lime.

FUMA'RIA. (*a, æ.* f.; from *fumus*, smoke, rom its juice, when dropped into the eye, producing the same sensations as smoke.)

1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia;* Order, *Decandria.* Fumitory.

2. The pharmacopœial name of the common umitory. See *Fumaria officinalis.*

Fumaria bulbosa. *Aristolochia fabacea.* The oot of this plant, *Fumaria — caule simplici, racteis longitudine florum,* of Linnæus, was ormerly given to restore suppressed menses, nd as an anthelmintic.

Fumaria officinalis. The systematic name f the fumitory or *Fumaria;* called also, *Fumus rræ, Capnos; Herba melancholifuga.* The eaves of this indigenous plant, *Fumaria — pericarpiis monospermis racemosis, caule diffuso,* of Linnæus, are directed for medicinal use in ome Pharmacopœias: they are extremely succulent, and have no remarkable smell, but a itter, somewhat saline taste. The infusion of ne dried leaves, or the expressed juice of the resh plant, is esteemed for its property of learing the skin of many disorders of the lerous kind.

FUMIGA'TION. (*Fumigatio, onis.* f.; rom *fumus*, smoke.) The application of fumes, o destroy contagious miasmata or effluvia. The nost efficacious substance for this purpose is hlorine; next to it the vapour of nitric acid; nd, lastly, that of the muriatic. The fumes f heated vinegar, burning sulphur, or the smoke f exploded gunpowder, deserve little confidence s antiloimics.

Fuming liquor of Boyle. *Fuming liquor f Beguine.* Hydro-sulphuret of ammonia.

Fuming liquor of Cadet. *Fuming liquor f arsenic.* Chloride of arsenic. See *Arsenic.*

Fuming liquor of Libavius. Bichloride of n. See *Tin.*

Fumitory. See *Fumaria.*

FUMUS. (*us, i.* m.) 1. Smoke. The natter which is volatilised during the combusion of most bodies, and the composition of which varies infinitely, according to the compoition of bodies and the products of their comustion.

2. A name given by the alchemists to several ubstances.

Fumus albus. Mercury.

Fumus citrinus. Sulphur.

Fumus duplex. Sulphur and mercury.

Fumus rubens. Orpiment.

Fumus terræ. Fumitory. See *Fumaria.*

FUNCTION. (*Functio, onis,* f.) In Physiology, any action by which vital phenomena re produced. The classification of the functions by the old physiologists is noticed in the rticle *Action;* which see. The functions of the iving body are now generally distributed into, . Those of *Nutrition*, embracing digestion, absorption, circulation, secretion, assimilation, and he evolution of heat.

2. Those of *relation*, embracing sensation, he intellectual and moral phenomena, the voice, nd voluntary motion.

3. The *generative functions*, or those which relate to the perpetuation of the species, including coition, gestation, parturition, and lactation.

Fu'nda. (*a, æ.* f.) 1. A four-headed bandage used in injuries of the face, especially fracture of the lower jaw. It is called, also, *funda galeni*, and *funda maxillaris.*

2. The sling used by obstetricians.

Funda galeni. See *Funda.*

Funda maxillaris. See *Funda.*

Fundament. (*Fundamentum, i.* n.) See *Anus.*

Fundament, falling down of. See *Prolapsus ani.*

FU'NGI. (The plural of *fungus.*) An order of the class *Cryptogamia* of Linnæus's system. They cannot properly be said to have any herbage; their substance is fleshy: their parts of fructification are in form of very small capsules, buried in their fleshy substance. These seminiferous capsules are on the surface, or in plates, and are called *lamellæ*, or gills, pores, or prickles, and they burst, as in the algæ.

A fungus or mushroom affords the following parts: —

1. *Pileus*, the hat, which is the round upper part, or head.

2. The *umbo*, the knob, or boss, or more prominent part in the centre of the hat.

3. *Lamellæ*, the gills or membraneous parts on the under side. These are peculiar to the *Agarici.*

4. The *pores*, or small punctures on the under surface, observed only in the genus *Boletus.*

5. *Echini*, or *Aculei*, elevated points on the upper surface of the pileus, noticed in the genus *Hydra* only.

6. *Verrucæ*, warts, observed on the inferior surface.

7. *Stipes*, the stem supporting the hat.

8. *Volva*, the wrapper, or covering, of a membraneous texture, surrounding the stem, and concealing the parts of fructification, and in due time bursting all around, forming a ring upon the stalk; as in *Agaricus campestris.* Linnæus also uses this term for the more fleshy external covering of some other fungi, which is scarcely raised out of the ground, and enfolds the whole plant when young.

9. *Annulus*, the ring, or slender membrane surrounding the stem.

The varieties of the *pileus*, or hat, are, —

1. *Planus*, flat.

2. *Convexus;* as in *Boletus bovinus.*

3. *Concavus;* as in *Octospora.*

4. *Umbonatus*, umbo or naval-like; as in *Agaricus conspurcatus.*

5. *Campanulatus;* as in *Agaricus fimitarius.*

6. *Viscidus*, viscid.

7. *Dimidiatus*, half round; as in *Agaricus niveus.*

8. *Squamosus*, covered with coloured scales; as in *Agaricus procerus.*

9. *Squarrosus*, having stiff elevated scales; as in *Agaricus conspurcatus.*

The varieties of the *lamellæ* are, —

1. *Equal;* as in *Agaricus crinitus.*

2. *Unequal.*

3. *Branched*, when several run into one; as in *Merulius cantharellus.*

4. *Decurrent*, proceeding down the stem.

5. *Venous*, so small that they appear like elevated veins.

6. *Dimidiate*, half round; as in *Agaricus muscarius*.

7. *Labyrinth-like*; as in *Agaricus quercinus*.

The varieties of the *volva* are, —

1. *Simple*.

2. *Double*.

3. *Stellate*, cut several times; as in *Lycopodium stellatum*.

The varieties of the *annulus* are, —

1. *Erect*, loose above, and fixed below; as in *Agaricus conspurcatus*.

2. *Inverse*, fixed above, free and bell-like below; as in *Agaricus mappa*.

3. *Sessile*, fixed only latterally.

4. *Mobile*; as in *Agaricus antiquatus*.

5. *Persistent*, remaining after the perfect formation of the plant.

6. *Evanescent*, disappearing after the complete evolution of the fungus.

7. *Arachnoid*, resembling a slender white web.

The varieties of the *stipes*, or stem, —

1. *Annulate*, having a ring.

2. *Naked*, without any.

3. *Squamose*, scaly.

4. *Bulbous*; as in *Agaricus separatus*.

5. *Filiform*; as in *Agaricus crinitus*.

Fu'ngate. A salt, formed by the fungic-acid, with a salifiable base.

FUNGIC ACID. *Acidum fungicum*. So called because it is obtained from vegetables of the order *Fungi*. The expressed juice of the *boletus juglandis*, *boletus pseudo-igniarius*, the *phallus impudicus*, *merulius cantharellus*, or the *peziza nigra*, being boiled to coagulate the albumen, then filtered, evaporated to the consistence of an extract, and acted on by pure alkohol, leaves a substance which is called *fungic acid*.

Fu'ngiform. (*Fungiformis*; from *fungus*, and *forma*, resemblance.) Resembling a fungus.

Fungiform papillæ. The papillæ near the edges of the tongue have been so called.

FU'NGIN. The fleshy part of mushrooms, deprived by alkohol and water of the soluble parts.

FUNGOUS. *Fungosus*. Of the nature of a *fungus*.

Fungous ulcer. See *Ulcer*.

FU'NGUS. (*us*, *i*. m.) 1. In *Surgery*, a luxuriant and unhealthy growth of a texture softer than that which is natural to the part from which it springs.

2. In *Botany*, the name of an order of plants in the Linnæan system, belonging to the class *Cryptogamia*.

Fungus cerebri. See *Hernia cerebri*.

Fungus hæmatodes. *Spongoid inflammation*. *Soft cancer*. *Medullary sarcoma*. A peculiar form of malignant disease, first distinctly described by Mr. J. Burns of Glasgow, under the name of *spongoid inflammation*. This morbid growth has a remarkable similarity to the substance of the brain in its physical and chemical properties.

Most commonly it presents itself in masses, contained in fine membraneous partitions; but it has three varieties, as originally pointed out by Laennec. The first is the *encysted*, which varies from the size of a filbert to that of an apple. The *unencysted*, which may be very small, but, in other instances, obtains the magnitude of a child's head. Its exterior is not so irregular as that of the encysted, though divided into lobules, with fissures between them. The *infiltrated* or *diffused*, consists of masses, which are not circumscribed, and the medullary substance presents a diversified appearance, in consequence of its being blended in various proportions with the tissues amongst which it is produced. It is generally of the same consistence as the cerebral medulla; but sometimes much softer. It varies also in colour: in some instances, it is quite white; in others light red; and it has occasionally been found to be of a deep red colour. A section of the tumour exhibits numerous bloody points. A vascular organisation is conspicuous in it, and as the coats of its vessels are remarkably delicate, the circulation of the blood through them is readily interrupted; hæmorrhage from congestive rupture takes place; and the effused blood is mixed with the brain-like matter. When superficial, medullary sarcoma begins as a colourless swelling, soft and elastic to the touch, unless bound down by a fascia, in which case it has a firm tense feel. When immediately subcutaneous, it is elastic, and hence liable to be mistaken for a tumour containing fluid. When it occurs in the testicle, it is frequently supposed at first to be hydrocele.

Like cancer, it has a tendency to spread to the absorbent glands, which become converted into a similar substance. In every sense of the expression, it is a new formation, an adventitious growth, whether situated in the cellular membrane, in the tissue of the muscles, in that of the viscera, or within the orbit, or in any cavity or on any surface of the body. When it occurs in deep-seated parts, it has an invariable tendency to make its way to the surface; and, when this happens, a considerable swelling arises, the skin at length becomes thin and discoloured, and, from being at first smooth, now projects irregularly; openings are formed in these projections, and a medullary growth springs up, which sometimes bleeds profusely. It is only at this period of the disease that the name of fungus hæmatodes is at all applicable; and even now it is not very correct, as the mass is not a fungus, but a substance of medullary consistence. Medullary sarcoma seems to be a constitutional disease, and rarely confined to one organ. It has been observed in the eye, the brain, the lungs, the heart, the liver, the spleen, the kidneys, the bladder, the uterus, the ovaries, the mammæ, the mesenteric glands, the dura mater, the bones, and the thyroid gland, of which there is a fine specimen in Mr. Langstaff's museum. It may commence in almost every texture, or upon every surface. Sometimes it originates in the antrum, from which it extends to the brain, through the orbit.

An early symptom of this terrible and very common organic disease, is a wan, pale complexion, such as is remarkably indicative of what may be termed a fatal organic disease.

The patient generally dies hectic. One of its differences from cancer is, that it contains within its substance no ligamentous bands, nor central hard nucleus, but consists of a soft pulpy matter contained within septa, composed of a fine delicate membrane. In order to be able to see its structure well, we should subject it to maceration or the action of alkalies. A scirrhous tumour is generally firm, hard, and incompressible from the very first; whereas there is a softness and elasticity about fungus hæmatodes, at once constituting quite a different character. The parts in this latter disease are not destroyed by ulceration, as in cancer; but, after the skin has ulcerated, a medullary bleeding substance protrudes. While the heterologous deposit of cancer, also, has little or no tendency to become organised, that of medullary sarcoma exhibits a greater or lesser disposition to become so. Fungus hæmatodes frequently attacks the liver, the spleen, the kidneys, and lungs, *primarily;* whereas it is alleged by some pathologists, that cancer only attacks these organs *secondarily;* a point, however, deserving of further investigation. Medullary sarcoma is not uncommon in young subjects, and persons below the middle age; whereas cancer chiefly attacks individuals between the ages of forty-five and fifty, or older persons. With regard to the treatment, we know of no medicine which can correct the state of the constitution upon which this disease depends. The only chance of curing it, is by the removal of the tumour at an early period of its formation, before the lymphatic glands and several other parts of the body have become affected. Thus, if the disease has extended up the spermatic cord, castration will be of no avail. Mr. S. Cooper thinks that the viscera generally become diseased much sooner in medullary sarcoma externally situated, than is generally supposed. This opinion has relation only to that form of it which comes under the care of surgeons, where the surface of the body, or the limbs, are the seats of the disease. This fact partly accounts for the general failure of operations.

Notwithstanding there is every reason for believing medullary sarcoma to be a constitutional disease, and we find, that after an operation, there is usually even a greater disposition to relapse, than is manifested in examples of scirrhus and cancer, experience occasionally brings forward cases forming exceptions to this statement. Mr. S. Cooper removed a testicle affected with fungus hæmatodes from a man more than three years ago, yet he remains perfectly well; and we sometimes hear of the same disease in the eyes, breast, and limbs, being effectually extirpated by operation, without being followed by any return of the complaint. Unfortunately, the contrary more generally happens, so that the prognosis should be qualified by a reference to this important fact. — *S. Cooper.*

Fungus igniarius. See *Boletus igniarius.*

Fungus la'ricis. See *Boletus laricis.*

Fungus melitensis. See *Cynomorium.*

Fungus petræus. Agaric mineral. See *Agaricus mineralis.*

Fungus phalloides. See *Phallus impudicus.*

Fungus rosaceus. See *Bedeguar.*

Fungus salicis. See *Boletus suaveolens.*

Fungus sambucinus. See *Peziza auricula.*

Fungus vinosus. The dark-coloured fungus which vegetates in dry cellars, where wine, ale, and the like are kept.

FUNI'CULUS. (*Funiculus:* diminutive of *funis*, a cord.) A little cord.

Funiculus spermaticus. The spermatic cord.

Funiculus umbilicalis. See *Umbilical cord.*

Funis arborum. The *smilax lævis;* so called because it winds itself round trees like a rope. — *Blancard.*

Funis umbilicalis. See *Umbilical cord.*

Funnel-shaped. See *Infundibuliformis.*

Fu'rca. (*a*, *æ*. f.) A fork or species of armature of plants. See *Aculeus.*

Furca'le os. *Furcella. Furcula.* The clavicle.

FURCA'TUS. Furcate: forked; dividing and often subdividing into two, fork-like; as the stems of most of the *Euphorbiæ.* See *Dichotomous.*

Furce'lla inferior. The ensiform cartilage.

Furcella. See *Furcale os.*

Furcula. The clavicle.

Furcula. (A little fork.) Applied to the clavicle.

Furcula superior. The upper bone of the sternum, and also the clavicle, have been thus named by some writers.

FU'RFUR. (*ur*, *uris*. m.) 1. Bran. See *Bran.*

2. A disease of the skin, in which the cuticle keeps falling off in small scales like bran. See *Pityriasis.*

FURFURA'CEOUS. (*Furfuraceus;* from *furfur*, bran.) A term applied to the bran-like sediment occasionally deposited in the urine.

Furfura'tio. (*o*, *onis*. f.) Pityriasis. See *Pityriasis.*

FURNACE. (*Furnus. i.* m.) The furnaces employed in chemical operations are of three kinds: —

1. The *evaporatory furnace*, which has received its name from its use; it is employed to reduce substances into vapour by means of heat, in order to separate the more fixed principles from those which are more volatile.

2. The *reverberatory furnace*, which name it has received from its construction, the flame being prevented from rising; it is appropriated to distillation.

3. The *forge furnace*, in which the current of air is determined by bellows.

FURNUS. (*us*, *i*. m.) A furnace.

Furnus ane'mius. A wind furnace.

Furor uterinus. See *Nymphomania.*

Furunculi ventriculus. The core of a boil. — *Celsus.*

FURU'NCULUS. (*us*, *i*. m.; from *furo*, to rage: so named from its heat and inflammation before it suppurates.) A boil. An inflammatory, circumscribed, and very painful swelling immediately under the skin. It seldom exceeds the size of a pigeon's egg. It always has a central core, and is mostly found in persons in

strong health, and in the vigour of youth. Sometimes, however, boils occur in cachectic habits. A boil always suppurates, and sooner or later discharges its contents. This disease rarely requires medical or surgical treatment, unless the person has many, and then bleeding and purging are required in plethoric constitutions, and an alterative course of sarsaparilla in weak and unhealthy ones.

FUSIBILITY. The susceptibility of fusion.

FUSIBLE. Possessed of fusibility.

Fusible calculus. See *Calculi, urinary.*

Fusible metal. A combination of three parts of lead with two of tin, and five of bismuth. It melts at 197° Fahr.

FU'SIFORM. *Fusiformis.* Spindle-shaped or tapering. Applied to parts of plants, as roots, &c. which penetrate perpendicularly into the earth; as the carrot, parsnip, radish, &c.

FUSION. (*Fusio*; from *fundo*, to pour out.) A chemical process, by which bodies are made to pass from the solid to the liquid state, in consequence of the application of heat. The chief objects susceptible of this operation are salts, sulphur, and metals. Salts are liable to two kinds of fusion: the one, which is peculiar to saline matters, is owing to water contained in them, and is called *aqueous fusion*; the other, which arises from the heat alone, is known by the name of *igneous fusion*.

Fyada. An alchemical name of mercury.

G.

GABAL. See *Cabala.*

Gabbara. A mummy.

Gabia'num oleum. *Huile de Gabian*, so called from Gabian, a village in Languedoc, where there is a rock from which it exudes. See *Petroleum rubrum.*

Gabi'rea. Γαβιρεα, a kind of myrrh, mentioned by Dioscorides.

GADUS. (*us, i.* m.) The name of a genus of fishes, of the order, *Jugulares.* The following species are brought to the European markets for the use of the table.

Gadus cilia'ris. The Baltic torsk. The Icelanders prepare it by salting and drying, when it becomes an article of commerce, under the name of *Tetteling.* Its flesh is white, tender, and well flavoured.

Gadus mo'rhua. The cod-fish. This fish, well known in our markets, abounds in the northern seas. Its flesh is white, and is much eaten. When salted it is also well-flavoured, and in general esteem.

Gadus ægle'finus. The haddock. An inhabitant of the northern seas of Europe. The larger ones are much esteemed during the winter; the smaller ones for summer use. They are of easy digestion. Salted and dried, they are eaten at breakfast as a delicacy.

Gadus minutus. Very small, never exceeding six or seven inches in length. It is found in the Mediterranean in great abundance, where it is called a *capelan*, or *officier.*

Gadus merla'ngus. The whiting. A delicate white fish, in great abundance in the Irish Seas, and German Ocean.

Gadus polla'cius. The whiting pollack, found on the rocky coast of Britain, and other parts of Europe, and is in great esteem for the table.

Gadus carbona'rius. The coal-fish. Very abundant on the rocky coasts of the northern parts of this island, about the Orkneys, and the coast of Yorkshire, where they become two and three feet long, and constitute the chief support of the poor.

Gadus merlu'ccius. The hake. A native of the North and Mediterranean Seas, not much eaten, except by the poor when dried, when it is called poor John, or stock-fish.

Gadus molva. The ling. This grows to the length of five or six feet. It is not so good as the *morhua*, when fresh; but dried and salted is much esteemed, and is the common food of the poor in Cornwall, where it is prepared for exportation.

Gadus lota. The burbot. The flesh of this is of an agreeable flavour, and easy of digestion.

Gadus brosme. The torsk. This swarms in the seas about the Shetland Islands, and forms a considerable article of commerce, either dried, or salted, or packed in barrels.

Gagel. See *Myrica gale.*

GALA'CTIA. (*a, æ.* f.; from γαλα, *lac*, milk; or γαλακτινος, *lacteus*, milky.) Mislactation: a genus of disease in Good's nosology, embracing defective, excessive, vitiated, premature, erratic, and other morbid secretions of the milk.

Galactic. (From γαλα, milk.) The lactic acid has been so called. See *Lactic acid.*

GALACTINA. (*a, æ.* f.; from γαλα, milk.) Aliment prepared with milk.

GALACTINUS. (From γαλα, milk.) Appertaining to milk: applied to food made of milk.

GALACTIRRHŒ'A. (*a, æ.* f.; from γαλα, milk, and ρεω, to flow.) An excess or overflow of milk.

GALACTITES. (From γαλα, milk: so called, according to Dioscorides, from its whiteness when triturated with water.) A calcareous

mineral employed by the ancients, sometimes as an astringent in disorders of the eyes, but more frequently as a promoter of milk.

GALACTO'PHORUS. (From γαλα, milk, and φερω, to bring or carry.) Galactophorous: milk-bearing. As an adjective, applied, 1. To that which has the property of increasing the secretion of the milk.

2. The excretory ducts of the glands of the breasts of women, which terminate in the papilla, or nipple, are called *ductus galactophori*, because they bring the milk to the nipple.

3. As a substantive, an instrument used to facilitate lactation, when the nipple is not sufficiently developed.

GALACTOPOIE'TICUS. (From γαλα, milk, and ποιεω, to make.) Galactopoietic, or milk-making. Possessed of the faculty of increasing the secretion of milk: applied to particular foods, plants, &c.

GALACTOPOSIA. (*a*, *æ*. f.; from γαλα, milk, and πινω, to drink.) The method of curing diseases by a milk diet.

GALA'NGA. (*a*, *æ*. f.; perhaps its Indian name.) See *Maranta* and *Kæmpferia*.

Galanga major. See *Kæmpferia*.

Galanga minor. See *Maranta galanga*.

Galangal. See *Maranta galanga*.

Galangal, English. See *Cyperus longus*.

GALA'XA. *Galacia*. A term applied by Paracelsus to several things; as to the appearance in the heavens, called the Milky Way, and to the porosities of the cranium. Charlton gives this name to the lacteal vessels.

GALBANETUM. A balsam mentioned by Paracelsus. According to Johnson, it was made of galbanum, diluted with turpentine.

GA'LBANUM. (*um*, *i*. n.; from *chalbanah*, Heb.) See the *Supplement*.

GA'LBULUS. (*us*, *i*. m.; from *galbus*, yellow.) 1. The name given by Vogel to a natural yellowness of the skin which is observed in some persons.

2. The fruit of the cypress-tree.

3. Gærtner applies this term, the classical name of the cypress fruit, which is a true *strobilus*, to a globular spurious berry with three or more seeds formed by the coalescing of a few scales, of a fertile catkin become succulent, which happens in the Juniper. — *Smith*.

GA'LDA. A gum-resin mentioned by old writers, but totally forgotten in the present day, and not to be obtained. Externally, it is of a brown colour, but white within, of a hard lamellated structure, and smells and tastes somewhat like elemi. When burnt it gives out an agreeable odour. It was formerly used as a warm stimulating medicine, and applied in plasters as a strengthener.

Ga'le. See *Myrica gale*.

GA'LEA. (*a*, *æ*. f.; derived by some from γαλη, a cat, because helmets were made of cats' skins!) A helmet. 1. In *Anatomy*, the amnion is so called, because it surrounds the fœtus like a helmet.

2. In *Surgery*, a bandage for the head. See *Fascia Galeni*.

3. In *Pathology*, a headach, extending all over the head, has been so called.

4. In *Botany*, the upper arched lip of a ringent and personate corolla is called *galea*. See *Corolla*.

GALEANTHRO'PIA. (*a*, *æ*. f.; from γαλη, a cat, and ανθρωπος, a man.) A species of madness, in which a person imagines himself to be a cat, and imitates its manners.(!) The editors of Castelli cite Laurentius Bellini for this term.

GALEA'TUS. (From *galea*, a helmet.) Helmet-shaped; applied to leaves, flowers, &c.

GA'LEGA. (*a*, *æ*. f.; from γαλα, milk: so named because it increases the milk of animals which eat it, particularly of goats.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria*.

2. The pharmacopœial name of the goat's rue. See *Galega officinalis*.

GALEGA OFFICINALIS. The systematic name of the goat's rue: called also, *Galega*, and *Ruta capraria*. From the little smell and taste of this plant, *Galega officinalis — leguminibus strictis, erectis; foliolis lanceolatis, striatis, nudis*, of Linnæus, it may be supposed to possess little virtue. In Italy, the leaves are eaten in sallads.

Galen's mad-wort. See *Marrubium*.

GALE'NA. 1. An ancient name of the theriaca before the addition of vipers as an ingredient.

2. The mineral, called lead glance; a native sulphuret of lead.

GALENA MINERALIZA'TA. Lead glance, variously mixed with earthy matter.— *Blancard*.

The same author tells us, that when bismuth, antimony, or iron, are mineralised in like manner, they are called *galena bismuthi, stibii, ferri*, &c.

GA'LENISTS. *Galenici*. The followers of Galen. See *Galenical medicine*.

GALE'NIUM. (Γαληνιον, from γαληνη, galena.) A cataplasm in the composition of which was the galena.

GALENICAL MEDICINE. *Medicina Galenica*. Medicine, as practised according to the precepts of Galen. The authority of Galen was paramount till the sixteenth century, when the chemical sect, with Paracelsus at their head, commenced a furious contest with the Galenists. In the treatment of diseases, the Galenists trusted almost entirely to simples; the chemists, despising these, derived their most powerful remedies from the mineral kingdom, and prepared them by complex processes.

GALEO'BDOLON. The name of a genus of plants of the class *Didynamia*, and order *Gymnospermia*.

GALEOBDOLON LUTEUM. Yellow archangel. An indigenous plant; formerly esteemed vulnerary, but now disused.

GALEO'PSIS. (*is*, *eos*. f.; from γαλη, a weasel, and οψις, aspect: the flowers gaping like the open mouth of that animal.) The name of a genus of plants. Class, *Didynamia*; Order, *Gymnospermia*.

GALERI'CULUM APONEURO'TICUM. A name that has been given to the tendinous expansion which lies over the pericranium, from its resemblance to a little cup, *Galericulum*.

GA'LIA. (*a*, *æ*. f.; from *gallæ*, galls: so

named because galls entered into the composition.) There were two medicines of this name; the one called *pure*, the other *aromatic*. *Galia moschata* contained aloes, amber, and musk; sometimes, nutmeg: *galia zebettina*, civet. The form of these medicines was the lozenge.

Galianco'nes. (Γαλιαγκωνες. From γαλιη, a weasel, and αγκων, the elbow.) Those who have preternaturally short and small arms, were thus designated by the Greeks; for what reason is not very evident. The term has been rendered in the Latin *mustelanci*.

Galipot. See *Barras*.

GA'LIUM. (*um*, *i*. n.; from γαλα, milk; some species having the property of coagulating milk.) 1. The name of a genus of plants in the Linnæan system. Class, *Tetrandria*; Order, *Monogynia*.

2. The pharmacopœial name of the herb cheese-rennet, or ladies' bedstraw. See *Galium verum*.

3. A name for madder. See *Rubia*.

Galium album. See *Galium mollugo*.

Galium apari'ne. The systematic name of the goose-grass: called also Cleavers; Cleaver's bees; Goose-share; Hayriff. *Ampelocarpus*, *Aparine*, *Asparine*, *Asperula*, *Philadelphus*, *Philanthropos*, *Omphalocarpus*, and *Ixus*. This plant is common in our hedges and ditches: *Galium aparine — foliis octonis lanceolatis carinatis scabris retrorsum aculeatis, geniculis venosis, fructu hispido*, of Linnæus. The expressed juice has been given with advantage as an aperient and diuretic in incipient dropsies: but the character in which it has gained greatest reputation, is that of a remedy against cancer. A tea-cupful, internally, gradually increased to half a pint, two or three times a day, and the herb applied, in cataplasm, externally, has been said to cure cancers. Such beneficial results are not confirmed by general experience.

Galium mollu'go. The systematic name of the greater ladies' bedstraw; called also, *Galium album*. *Galium mollugo — foliis octonis, ovato-linearibus, subserratis, patentissimis, mucronatis; caule flaccido, ramis patentibus*, of Linnæus. This herb, with its flowers, is used medicinally. Five ounces or more, of the expressed juice, taken every evening upon an empty stomach, has been said to cure epilepsy.

Galium verum. The systematic name of the true ladies' bedstraw, or cheese-rennet. The *Galium* of the pharmacopœias. The tops of this plant, *Galium verum — foliis octonis, linearibus sulcatis; ramis floriferis, brevibus*, of Linnæus, were long supposed to be an efficacious medicine in the cure of epilepsy; but, in the practice of the present day, they are abandoned. Indeed, from the sensible qualities of the plant, little can be expected. The leaves and flowers possess the property of curdling milk; it is, on that account, styled cheese-rennet.

Gall. See *Bile*.

GALL-BLADDER. *Vesicula fellis*. An oblong membraneous receptacle, situated under the liver, to which it is attached in the right hypochondrium. It is composed of three membranes, a cellular, fibrous, and villous. On one side it adheres closely to the liver, and on the other is covered by the peritonæum. Its use is to retain the bile which regurgitates from the hepatic duct, there to become thicker, more acrid, and bitter, and to send it through the cystic duct, which proceeds from its neck into the ductus communis choledochus, to be sent on to the duodenum.

Gall ducts. See *Hepar*.

Gall-sickness. A popular name for the remitting fever occasioned by marsh miasmata, in the Netherlands. See *Remittent fever*.

Gall-stone. See *Calculus, biliary*.

Ga'lla. (*a*, *æ*. f.;) A gall-nut. See *Quercus infectoria*.

Galla turcica. See *Quercus infectoria*.

GA'LLATE. A salt formed by the gallic acid, with a base.

GA'LLIC ACID. *Acidum gallicum*. An acid found in vegetable substances possessing astringent properties, but most abundantly in the excrescences termed galls, whence it derives its name. It may be obtained by macerating galls in water, filtering and suffering the liquor to stand exposed to the air. It will grow mouldy, be covered with a thick glutinous pellicle, abundance of glutinous flocks will fall down, and, in the course of two or three months, the sides of the vessel will appear covered with small yellowish crystals, abundance of which will likewise be found on the under surface of the supernatant pellicle. These crystals may be purified by solution in alkohol, and evaporation, to dryness.

Another simple process for obtaining this acid, is to boil an ounce of powdered galls in sixteen ounces of water to eight, and strain. Dissolve two ounces of alum in water, precipitate the alumina by carbonate of potash; and after edulcorating it completely by repeated ablutions, add it to the decoction, frequently stirring the mixture with a glass rod. The next day filter the mixture, wash the precipitate with warm water, till this will no longer blacken sulphate of iron; mix the washings with the filtered liquor, evaporate, and the gallic acid will be obtained in fine needled crystals.

These crystals obtained in any of these ways, however, are contaminated with a small portion of extractive matter; and, to purify them, they may be placed in a glass capsule, in a sand-heat, and sublimed into another capsule inverted over this, and kept cool. This acid is soluble in twenty parts of cold water, and in three parts at a boiling heat. It is more soluble in alkohol, which takes up an equal weight if heated, and one fourth of its weight cold.

It has an acido-astringent taste, and reddens tincture of litmus. It does not attract humidity from the air.

The gallic acid is of extensive use in the art of dyeing, as it constitutes one of the principal ingredients in all the shades of black, and is employed to fix or improve several other colours. It is well known as an ingredient in ink.

GALLICUS. From *Gallia*, gall. French.

Gallicus morbus. The venereal disease. See *Syphilis*.

Galli'trichis. *Gallitrichum*. Corrupted from *callitrichis*, or *callitrichum*. See *Callitriche*.

Gallium. See *Galium.*

GALLUS DOMESTICUS. The domestic fowl. See *Phasianus.*

GALREDA. A barbarous Latin word for jelly, most likely from the German *gallerte.*

GA'LVANISM. (*Galvanismus;* from *Galvani,* the inventor.) A professor of anatomy, in the university of Bologna, named *Galvani,* was one day making experiments on electricity in his elaboratory: near the machine were some frogs that had been flayed, the limbs of which became convulsed every time a spark was drawn from the apparatus. Galvani, surprised at this phenomenon, made it a subject of investigation, and discovered that metals, applied to the nerves and muscles of these animals, occasioned powerful and sudden contractions, when disposed in a certain manner. He gave the name of animal electricity to this order of new phenomena, from the analogy that he considered existing between these effects and those produced by electricity.

The name, animal electricity, has been superseded, notwithstanding the great analogy that exists between the effects of electricity and those of galvanism, in favour of the latter term; which is not only more applicable to the generality of the phenomena, but likewise serves to perpetuate the memory of the discoverer.

In order to give rise to galvanic effects in animal bodies, it is necessary to establish a communication between two points of one series of nervous and muscular organs. In this manner a circle is formed, one arch of which consists of the animal parts, rendered the subject of experiment, while the other arch is composed of excitatory instruments, which generally consist of several pieces, some placed under the animal parts called supporters, others destined to establish a communication between the latter, are called conductors. To form a complete galvanic circle, take the thigh of a frog, deprived of its skin; detach the crural nerve, as far as the knee: put it on a piece of zinc; put the muscles of the leg on a piece of silver; then finish the excitatory arch, and complete the galvanic circle by establishing a communication by means of the two supporters; by means of iron or copper wire, pewter, or lead. The instant that the communicators touch the two supporters, a part of the animal arch formed by the two supporters will be convulsed. Although this disposition of the animal parts, and of galvanic instruments, be most favourable to the development of the phenomena, yet the composition of the animal and excitatory arch may be much varied. Thus contractions are obtained by placing the two supporters under the nerve, and leaving the muscle out of the circle, which proves that nerves essentially constitute the animal arch.

It is not necessary for nerves to be entire in order to produce contractions. They take place whether the organs be tied or cut through, provided there exists a simple contiguity between the divided ends. This proves that we cannot strictly conclude what happens in muscular action, from that which takes place in galvanic phenomena; since, if a nerve be tied or divided, the muscles on which this is distributed lose the power of action.

The cuticle is an obstacle to galvanic effects; they are always feebly manifested in parts covered by it. When it is moist, fine, and delicate, the effect is not entirely interrupted. Humboldt, after having detached the cuticle from the posterior part of the neck and back, by means of two blisters, applied plates of metal to the bare cutis, and, at the moment of establishing a communication, he experienced sharp prickings, accompanied with a sero-sanguineous discharge.

If a plate of zinc be placed under the tongue, and a flat piece of silver on its superior surface, on making them touch each other, an acerb taste will be perceived, accompanied with a slight trembling.

The excitatory arch may be constructed with three, two, or even one metal only, with alloys, amalgams, or other metallic or mineral combinations, carbonated substances, &c. It is observed, that metals, which are in general the most powerful excitors, induce contractions so much the more as they have an extent of surface. Metals are all more or less excitants; and it is observed that zinc, gold, silver, and pewter, are of the highest rank; then copper, lead, nickel, antimony, &c.

Galvanic susceptibility, like muscular irritability, is exhausted by too long continued exercise, and is recruited by repose. Immersion of nerves and muscles in alkohol and opiate solutions diminishes, and even destroys, this susceptibility, in the same manner, doubtless, as the immoderate use of these substances in the living man blunts, and induces paralysis in muscular action. Immersion in oxymuriatic acid restores the fatigued parts, to be again acted on by the stimulus. Animals killed by the repeated discharge of an electric battery, acquire an increase of galvanic susceptibility; and this property subsists unchanged in animals destroyed by submersion in mercury, pure hydrogen gas, azote, and ammonia; and, finally, it is totally annihilated in animals suffocated by the vapour of charcoal.

Galvanic susceptibility is extinct in the muscles of animals of warm blood, in proportion as vital heat is dissipated: sometimes even when life is terminated in convulsions, contractility cannot be put into action, although warmth be not completely gone, as though the vital property were consumed by the convulsion, amidst which the animals had expired. In those of cold blood, on the contrary, it is more durable. The thighs of frogs, long after being separated from every thing, and even to the instant of incipient putrefaction, are influenced by galvanic stimuli; doubtless because irritability, in these animals, is less intimately connected with respiration, and life more divided among the different organs, which have less occasion to act on each other for the execution of its phenomena. The galvanic chain does not produce sensible actions (that is, contractions,) until the moment it is completed, by establishing a communication with the parts constituting it. During the time it is complete, that is, throughout

the whole space of time that the communication remains established, every thing remains tranquil; nevertheless, galvanic influence is not suspended: in fact, excitability is evidently increased, or diminished in muscles that have been long continued in the galvanic chain, according to the difference of the reciprocal situation of the connecting metals.

If silver has been applied to nerves, and zinc to muscles, the irritability of the latter increases in proportion to the time they have remained in the chain. By this method, the thighs of frogs have been revivified in some degree, and afterwards become sensible to stimuli that before had ceased to act on them. By distributing the metals in an inverse manner, applying zinc to nerves and silver to muscles, an effect absolutely contrary is observed; and the muscles that possessed the most lively irritability when placed in the chain, seem to be rendered entirely paralytic if they remain long in this situation.

This difference evidently depends on the direction of the galvanic fluid, determined towards the muscles or nerves, according to the manner in which these muscles are disposed; and this is of some importance to be known for the application of galvanic means to the cure of diseases.

Galvanic Pile. — Volta's apparatus is as follows: — Raise a pile, by placing a plate of zinc, a flat piece of wet card, and a plate of silver, successively; then a second piece of zinc, &c. until the elevation is several feet high; for the effects are greater in proportion to its height; then touch both extremities of the pile, at the same instant, with one piece of iron wire; at the moment of contact, a spark is excited from the extremities of the pile, and luminous points are often perceived at different heights, where the zinc and silver come into mutual contact. The zinc end of this pile appears to be negatively electrified; that formed by the silver, on the contrary, indicates marks of positive electricity.

If we touch both extremities of the pile, after having dipped our hands into water, or, what is better, a saline solution, a commotion, followed by a disagreeable prickling in the fingers and elbow, is felt.

If we place in a tube filled with water, and hermetically closed by two corks, the extremities of two wires of the same metal, which are in contact at the other extremity, one with the summit, the other with the base of the pile; these ends, even when separated only by the space of a few lines, experience evident changes at the instant the extremities of the pile are touched: the iron in contact with that part of the pile composed of silver becomes covered with bullæ of hydrogen gas; that which touches the extremity formed by zinc, becomes oxydised or gives off oxygen gas. Fourcroy attributes this phenomenon to the decomposition of water by the galvanic fluid, which abandons the oxygen to the metal that touches the positive extremity of the pile; then conducts the other gas invisibly to the end of the other wire, there to be disengaged.

Galvanic Trough. — This is a much more convenient apparatus. Plates of two metals, commonly zinc and copper, are fastened together, and cemented into a wooden trough, so as to form a number of cells; or earthenware troughs, with partitions, being procured, the metals, connected by a slip, are suspended over these, so that in each cell, except at the ends, there is a plate of each metal; then a diluted acid (usually the sulphuric, nitric, or muriatic, mixed with from twelve to twenty parts of water,) is poured into the trough. It is necessary that the metals be placed in the same order throughout, or one series will counteract another. The zinc end becomes negative, the copper positive; and the power is in proportion to the number of the series; and several such troughs may be connected together, so as to form a most powerful apparatus. See *Electricity*.

From the number of experiments of Davy, many new and important facts have been established, and galvanism has been found one of the most powerful agents in chemistry: by its influence platina wire has been melted; gold, silver, copper, and most of the metals, have easily been burnt; the fixed alkalies, and many of the earths have been made to appear as consisting of a metallic base, and oxygen; and compound substances, which were before extremely difficult to decompose, are now, by the aid of galvanism, easily resolved into their constituents.

The galvanic influence has been considered by some practitioners as likely to increase the nervous influence in paralysed and debilitated states of the muscular system, and many ingenious ways of applying it have been resorted to; but it does not seem to have been useful. Dr. Ure's observations and experiments on this subject, and on galvanism, are highly interesting. The following account of them is extracted from his Chemical Dictionary: — "Many experiments," he observes, "have been performed, in this country and abroad, on the bodies of criminals, soon after their execution. Vassali, Julio, and Rossi, made an ample set, on several bodies decapitated at Turin. They paid particular attention to the effect of galvanic electricity on the heart, and other involuntary muscles; a subject of much previous controversy. Volta asserted, that these muscles are not at all sensible to this electric power. Fowler maintained that they were affected, but with difficulty, and in a slight degree. This opinion was confirmed by Vassali; who further showed, that the muscles of the stomach and intestines might thus also be excited. Aldini, on the contrary, declared, that he could not affect the heart by his most powerful galvanic arrangements.

"Most of the above experiments were, however, made either without a voltaic battery, or with piles feeble in comparison with those now employed. Those, indeed, performed on the body of a criminal, at Newgate, in which the limbs were violently agitated, the eyes opened and shut, the mouth and jaws worked about, and the whole face thrown into frightful convulsions, were made by Aldini with a considerable series of voltaic plates.

"A circumstance of the first moment, in my opinion, has been too much overlooked in experiments of this kind, — that a muscular mass, through which the galvanic energy is directly transmitted, exhibits very weak contractile movements, in comparison with those which can be excited by passing the influence along the principal nerve of the muscle. Inattention to this important distinction, I conceive to be the principal source of the slender effects hitherto produced in such experiments on the heart, and other muscles independent of the will. It ought also to be observed, that too little distinction has been made between the positive and negative poles of the battery; though there are good reasons for supposing, that their powers on muscular contractions are by no means the same.

"According to Ritter, the electricity of the positive pole augments, while the negative diminishes, the actions of life. Tumefaction of parts is produced by the former; depression by the latter. The pulse of the hand, he says, held a few minutes in contact with the positive pole, is strengthened; that of the one in contact with the negative is enfeebled: the former is accompanied with a sense of heat; the latter with a feeling of coldness. Objects appear to a positively electrified eye, larger, brighter, and red; while to one negatively electrified, they seem smaller, less distinct, and bluish,—colours indicating opposite extremities of the prismatic spectrum. The acid and alkaline tastes, when the tongue is acted on in succession by the two electricities, are well known, and have been ingeniously accounted for by Sir H. Davy, in his admirable Bakerian Lectures. The smell of oxymuriatic acid, and of ammonia, are said by Ritter to be the opposite odours, excited by the two opposite poles; as a full body of sound and a sharp tone are the corresponding effects on the ears. These experiments require verification.

"Consonant in some respects, though not in all, with these statements, are the doctrines taught by a London practitioner, experienced in the administration of medical electricity. He affirms, that the influence of the electrical fluid of our common machines, in the cure of diseases, may be referred to three distinct heads: — First, the form of *radii*, when projected from a point positively electrified: Secondly, that of a star, or the negative fire, concentrated on a brass ball: Thirdly, the Leyden explosion. To each of these forms he assigns a specific action. The first acts as a sedative, allaying morbid activity; the second, as a stimulant; and the last as a deobstruent operation, in dispersing chronic tumours. An ample narrative of cases is given in confirmation of these general propositions. My own experience leads me to suppose, that the negative pole of a voltaic battery gives more poignant sensations than the positive.

"The most precise and interesting researches on the relation between voltaic electricity and the phenomena of life, are those contained in Dr. Wilson Philip's Dissertations in the Philosophical Transactions, as well as in his Experimental Enquiry into the Laws of the Vital Functions, more recently published.

"In his earlier researches he endeavoured to prove, that the circulation of the blood, and the action of the involuntary muscles, were independent of the nervous influence. In a late paper, read in January, 1816, he showed the immediate dependence of the secretory functions on the nervous influence.

"The eighth pair of nerves distributed to the stomach, and subservient to digestion, were divided by incisions in the necks of several living rabbits. After the operation, the parsley which they ate remained without alteration in their stomachs; and the animals, after evincing much difficulty of breathing, seemed to die of suffocation. But when in other rabbits, similarly treated, the galvanic power was transmitted along the nerve, below its section, to a disc of silver, placed closely in contact with the skin of the animal, opposite to its stomach, no difficulty of breathing occurred. The voltaic action being kept up for twenty-six hours, the rabbits were then killed, and the parsley was found in as perfectly digested a state as that in healthy rabbits fed at the same time; and their stomachs evolved the smell peculiar to that of a rabbit during digestion. These experiments were several times repeated, with similar results.

"Hence, it appears that the galvanic energy is capable of supplying the place of the nervous influence, so that, while under it, the stomach, otherwise inactive, digests food as usual. I am not, however, willing to adopt the conclusion drawn by its ingenious author, that the 'identity of galvanic electricity and nervous influence is established by these experiments.' They clearly show a remarkable analogy between these two powers, since the one may serve as a substitute for the other. It might possibly be urged by the anatomist, that as the stomach is supplied by twigs of other nerves, which communicate under the place of Dr. Philip's section of the *par vagum*, the galvanic fluid may operate merely as a powerful stimulus, exciting those slender twigs to perform such an increase of action as may compensate for the want of the principal nerve. The above experiments were repeated on dogs, with like results; the battery never being so strong as to occasion painful shocks.

"The removal of dyspnœa, as stated above, led him to try galvanism as a remedy in asthma. By transmitting its influence from the nape of the neck to the pit of the stomach, he gave decided relief in every one of twenty-two cases, of which four were in private practice, and eighteen in the Worcester Infirmary. The power employed varied from ten to twenty-five pairs.

"The general inferences deduced by him from his multiplied experiments, are, that voltaic electricity is capable of effecting the formation of the secreted fluids, when applied to the blood, in the same way in which the nervous influence is applied to it; and that it is capable of occasioning an evolution of caloric from arterial blood. When the lungs are deprived of the nervous influence by which their function is impeded and even destroyed, when digestion is interrupted by withdrawing this influence from the stomach, these two vital functions are re-

newed by exposing them to the influence of a galvanic trough. 'Hence,' says he, 'galvanism seems capable of performing all the functions of the nervous influence in the animal economy; but obviously it cannot excite the functions of animal life, unless when acting on parts endowed with the living principle.'

"These results of Dr. Philip have been recently confirmed by Dr. Clarke Abel, of Brighton, who employed, in one of the repetitions of the experiments, a comparatively weak, and in the other a considerable power of galvanism. In the former, although the galvanism was not of sufficient power to occasion evident digestion of the food, yet the efforts to vomit, and the difficulty of breathing, constant effects of dividing the eighth pair of nerves, were prevented by it. These symptoms recurred when it was discontinued, and vanished on its re-application. 'The respiration of the animal,' he observes, 'continued quite free during the experiment, except when the disengagement of the nerves from the tin-foil rendered a short suspension of the galvanism necessary during their re-adjustment.' — 'The non-galvanised rabbit breathed with difficulty, wheezed audibly, and made frequent attempts to vomit.' In the latter experiment, in which the greater power of galvanism was employed, digestion went on as in Dr. Philip's experiments. — *Jour. Sc.* ix.

"Gallois, an eminent French physiologist, had endeavoured to prove, that the motion of the heart depends entirely upon the spinal marrow, and immediately ceases when the spinal marrow is removed or destroyed. Dr. Philip appears to have refuted this notion by the following experiments: — Rabbits were rendered insensible by a blow on the occiput; the spinal marrow and brain were then removed, and the respiration kept up by artificial means; the motion of the heart, and the circulation, were carried on as usual. When spirit of wine, or opium, was applied to the spinal marrow or brain, the rate of the circulation was accelerated.

"A middle-sized, athletic, and extremely muscular man, about thirty years of age, was the subject of the following highly interesting experiments. He was suspended from the gallows nearly an hour, and made no convulsive struggle after he dropped; while a thief, executed along with him, was violently agitated for a considerable time. He was brought to the anatomical theatre in about ten minutes after he was cut down. His face had a perfectly natural aspect, being neither livid nor tumefied; and there was no dislocation of his neck. Dr. Jeffray, the professor of anatomy, having on the preceding day requested me, says Dr. Ure, (from whose Dictionary this article is abridged,) to perform the galvanic experiments, I sent to his theatre with this view, next morning, my *minor* voltaic battery, consisting of 270 pairs of four-inch plates, with wires of communication, and pointed metallic rods, with insulating handles, for the more commodious application of the electric power. About five minutes before the Police-officers arrived with the body, the battery was charged with a dilute nitro-sulphuric acid, which speedily brought it into a state of intense action. The dissections were skilfully executed by Mr. Marshall, under the superintendence of the Professor.

"*Exp.* 1. A large incision was made into the nape of the neck, close below the *occiput*. The posterior half of the *atlas vertebra* was then removed by bone forceps, when the spinal marrow was brought into view. A profuse flow of liquid blood gushed from the wound, inundating the floor. A considerable incision was at the same time made in the left hip, through the great gluteal muscle, so as to bring the sciatic nerve into sight; and a small cut was made in the heel. From neither of these did any blood flow. The pointed rod connected with one end of the battery, was now placed in contact with the spinal marrow, while the other rod was applied to the sciatic nerve. Every muscle of the body was immediately agitated with convulsive movements, resembling a violent shuddering from cold. The left side was most powerfully convulsed at each renewal of the electric contact. On moving the second rod from the hip to the heel, the knee being previously bent, the leg was thrown out with such violence as nearly to overturn one of the assistants, who in vain attempted to prevent its extension.

"*Exp.* 2. The left phrenic nerve was now laid bare at the outer edge of the *sterno-thyroideus* muscle, from three to four inches above the clavicle; the cutaneous incision having been made by the side of the sterno-cleidomastoideus. Since this nerve is distributed to the diaphragm, and since it communicates with the heart through the eighth pair, it was expected, by transmitting the galvanic power along it, that the respiratory process would be renewed. Accordingly, a small incision having been made under the cartilage of the seventh rib, the point of the one insulating rod was brought into contact with the great head of the diaphragm, while the other point was applied to the phrenic nerve in the neck. This muscle, the main agent of respiration, was instantly contracted, but with less force than was expected. Satisfied, from ample experience on the living body, that more powerful effects can be produced in galvanic excitation, by leaving the extreme communicating rods in close contact with the parts to be operated on, while the electric chain or circuit is completed by running the end of the wires along the top of the plates in the last trough of either pole, the other wire being steadily immersed in the last cell of the opposite pole, I had immediate recourse to this method. The success of it was truly wonderful. Full, nay, laborious breathing instantly commenced. The chest heaved, and fell; the belly was protruded, and again collapsed, with the relaxing and retiring diaphragm. This process was continued, without interruption, as long as I continued the electric discharges.

"In the judgment of many scientific gentlemen who witnessed the scene, this respiratory experiment was perhaps the most striking ever made with a philosophical apparatus. Let it also be remembered, that for full half an hour before this period, the body had been well nigh

drained of its blood, and the spinal marrow severely lacerated. No pulsation could be perceived, meanwhile, at the heart or wrist; but it may be supposed, that but for the evacuation of the blood,—the essential stimulus of that organ,—this phenomenon might also have occurred.

"*Exp.* 3. The supra-orbital nerve was laid bare in the forehead, as it issues through the supra-ciliary *foramen*, in the eyebrow: the one conducting-rod being applied to it, and the other to the heel, most extraordinary grimaces were exhibited every time that the electric discharges were made, by running the wire in my hand along the edges of the last trough, from the 220th to the 270th pair of plates: thus fifty shocks, each greater than the preceding one, were given in two seconds. Every muscle in his countenance was simultaneously thrown into fearful action: rage, horror, despair, anguish, and ghastly smiles, united their hideous expression in the murderer's face, surpassing far the wildest representations of a Fuseli or a Kean. At this period several of the spectators were forced to leave the apartment from terror or sickness, and one gentleman fainted.

"*Exp.* 4. The last galvanic experiment consisted in transmitting the electric power from the spinal marrow to the ulnar nerve, as it passes by the internal condyle at the elbow: the fingers now moved nimbly, like those of a violin performer; an assistant, who tried to close the fist, found the hand to open forcibly in spite of his efforts. When the one rod was applied to a slight incision in the tip of the fore-finger, the fist being previously clenched, that finger extended instantly; and, from the convulsive agitation of the arm, he seemed to point to the different spectators, some of whom thought he had come to life.

"About an hour was spent in these operations.

"In deliberating on the above galvanic phenomena, we are almost willing to imagine, that if, without cutting into and wounding the spinal marrow and blood-vessels in the neck, the pulmonary organs had been set a-playing at first (as I proposed), by electrifying the phrenic nerve (which may be done without any dangerous incision), there is a probability that life might have been restored. This event, however little desirable with a murderer, and perhaps contrary to law, would yet have been highly honourable and useful to science. From the accurate experiments of Dr. Philip, it appears, that the action of the diaphragm and lungs is indispensable towards restoring the suspended action of the heart and great vessels, subservient to the circulation of the blood.

"It is known that cases of death-like lethargy, or suspended animation, from disease and accidents, have occurred, where life has returned, after longer interruption of its functions than in the subject of the preceding experiments. It is probable, when apparent death supervenes from suffocation with noxious gases, &c., and when there is no organic læsion, that a judiciously directed galvanic experiment will, if any thing will, restore the activity of the vital functions. The plans of administering voltaic electricity hitherto pursued in such cases, are, in my humble apprehension, very defective. No advantage, we perceive, is likely to accrue from passing electric discharges across the chest, directly through the heart and lungs. On the principles so well developed by Dr. Philip, and now illustrated on Clydesdale's body, we should transmit along the channel of the nerves that substitute for nervous influence, or that power which may perchance awaken its dormant faculties. Then, indeed, fair hopes may be formed of deriving extensive benefit from galvanism; and of raising this wonderful agent to its expected rank among the ministers of health and life to man.

"I would, however, beg leave to suggest another nervous channel, which I conceive to be a still readier and more powerful one, to the action of the heart and lungs, than the phrenic nerve. If a longitudinal incision be made, as is frequently done for aneurism, through the integuments of the neck at the outer edge of the *sterno-mastoideus* muscle, about half-way between the clavicle and angle of the lower jaw; then, on turning over the edge of this muscle, we bring into view the throbbing carotid, on the outside of which the *par vagum* and great sympathetic nerve lie together in one sheath. Here, therefore, they may both be directly touched and pressed by a blunt metallic conductor. These nerves communicate, directly or indirectly, with the phrenic; and the superficial nerve of the heart is sent off from the sympathetic.

"Should, however, the phrenic nerve be taken, that of the left side is the preferable of the two. From the position of the heart, the left phrenic differs a little in its course from the right. It passes over the *pericardium*, covering the *apex* of the heart.

"While the point of one metallic conductor is applied to the nervous cords above described, the other knob ought to be firmly pressed against the side of the person, immediately under the cartilage of the seventh rib. The skin should be moistened with a solution of common salt, or, what is better, a hot saturated solution of sal-ammoniac, by which means the electric energy will be more effectually conveyed through the cuticle, so as to complete the voltaic chain.

"For the purposes of resuscitating dormant irritability of nerves, or contractility of their subordinate muscles, the positive pole must be applied to the former, and the negative to the latter."

GALVANO'METER. An instrument for measuring the intensity of a galvanic current, by its effect in deflecting the magnetic needle. The *Electro-magnetic multiplier* is a more complex form of this instrument.

Gambo'gia. See *Cambogia.*

Gambo'gium. See *Cambogia.*

Gamboi'dea. See *Cambogia.*

GA'MMA. (*a*, *æ*. f.; from the letter Γ, *gamma*, which it resembled.) An iron instrument used by the old surgeons for cauterising a hernia.

GA'MMARUS. (*us*, *i*. m.; from καμαρα, an arch: so called from the vaulted roof of its shell.) The lobster. See *Cancer gammarus.*

Gamon. See *Cambogia.*

GAMPHE'LE. (Γαμφηλη.) The cheeks; the jaw.

GA'NGAMON. (From γαγγαμη, a fishing-net, which it was said to resemble.) A name of the omentum.

GANGLIA, ABDOMINAL. The semilunar ganglia and solar plerus.

Ganglia semiluna. See *Semiluna ganglia.*

Ganglia solar. See *Solar ganglia.*

GA'NGLIFORM. A term which has been applied to an enlargement in the course of a nerve; but periphrastically and needlessly, because a *gangliform enlargement* means nothing more nor less than a *ganglion.*

GA'NGLION. (*on, ii.* n. Γαγγλιον, a knot.) A knot. 1. In *Anatomy,* a natural knot-like enlargement, in the course of a nerve. See *Nervous system.*

2. In *Surgery,* an encysted tumour, formed in the sheath of a tendon, and containing a fluid like the white of an egg. It most frequently occurs on the back of the hand or foot.

GANGLION OF GASSERIUS. A ganglion on the posterior cord of the fifth pair of nerves.

Gangræna oris. See *Stomacace.*

Gangræna ossis. See *Spina ventosa.*

Gangræna senilis. See *Mortification.*

GA'NGRENE. (Γαγγραινα. *Gangrena, æ.* f.; from γραω, to feed upon: so named from its eating away the flesh.) See *Mortification.*

GARCI'NIA. (*a, æ.* f.; so called in honour of Dr. Garcin, who accurately described it.) The name of a genus of plants in the Linnæan system. Class, *Dodecandria;* Order, *Monogynia.*

GARCINIA MANGOSTANA. The systematic name of the mangosteen tree, which is a native of Java and the Molucca islands. Its fruit, which is about the size of an orange, is said to be the finest flavoured, and most salubrious of all fruits. The flesh is juicy, white, almost transparent, and of a more agreeable flavour than the richest grape. The dried bark is used medicinally in dysenteries and tenesmus, and a strong decoction of it is much esteemed as a gargle in ulcerated sore throats.

GARGA'REON. (Γαργαρεων.) The uvula.

Ga'rgarism. See *Gargarisma.*

GARGARI'SMA. (*a, atis.* n.; and *Gargarismus, i.* m.; and *Gargarismum,* i. n.; from γαργαριζω, to gargle.) A gargle, or wash for the throat.

GARGARISMA ALUMINIS. The best formula of this is one drachm of purified alumin, half a fluid ounce of tincture of myrrh, and seven fluid ounces of mint water, mixed.

Gargarismum. See *Gargarisma.*

GA'RGATHUM. (A low Latin word.) A bed on which lunatics were formerly confined.

Gargeatio. See *Sudor anglicanus.*

Gargle. See *Gargarisma.*

Garlic. See *Allium.*

Garosmum. See *Chenopodium vulvaria.*

Garou. See *Daphne gnidium.*

Garroph'yllus. See *Eugenia.*

GA'RUM. (*um, i.* n. Γαρον.) A kind of pickle prepared of fish half putrefied and strongly salted, with the addition of aromatics. It is said to have been so called because originally prepared from a fish, called by the Greeks γαρος; but, according to Pliny, the *garus* was a kind of lobster. Several species of *garum* were used by the Romans.

GAS. (A Teutonic word signifying air or spirit.) *Gaz.* Aëriform fluid. A term applied to all permanently elastic fluids, simple or compound, except the atmosphere, to which the term *air* is appropriated.

A gas is distinguished from a *vapour* by its permanently elastic state. A vapour is a body made to assume the elastic state for a short time only, by the agency of heat; as when water is converted into steam.

Some of the gases exist in nature without the aid of art, and may therefore be collected; others, on the contrary, are only producible by artificial means.

All gases are combinations of certain substances, reduced to the gaceous form by the addition of caloric. It is, therefore, necessary to distinguish in every gas, the matter of heat which acted the part of a solvent, and the substance which forms the basis of the gas.

Gases are not contained in those substances from which we obtain them in the state of gas, but owe their formation to the expansive property of caloric.

Gas, azotic. See *Nitrogen.*

Gas, carbonic acid. See *Carbonic acid.*

Gas, heavy carbonated hydrogen. See *Carburetted hydrogen.*

Gas, hepatic. See *Hydrogen gas, sulphuretted.*

Gas, hydrogen. See *Hydrogen.*

Gas, light carbonated hydrogen. See *Carburetted hydrogen.*

GAS WATER. The water which remains after the gas used for illumination has passed through the purifier. It consists of hydro-sulphuret and hydro-bisulphuret of lime. It has been recommended in chronic diseases of the skin.

Gascoigne's balls. See *Gascoigne's powder.*

GASCOIGNE'S POWDER. (Called after its inventor.) *Pulvis Gascoigni.* A bezoardic powder, composed of one pound of the compound powder of crab's-claws, and one ounce of prepared oriental bezoar, mixed together. Balls made of this are called Gascoigne's balls.

Gaseous oxide of carbon. See *Carbonic oxide.*

GA'STER. Γαστηρ. 1. The belly or abdomen.

2. The stomach.

3. The womb.

GASTERO'PODA. (From γαστηρ, the belly, and πους, a foot.) Belly-footed. The name of a class of molluscous animals which have an organ of locomotion, or foot, situated on the abdominal surface.

GASTERO'STOMA. (From γαστηρ, and στομα, and so called, because the mouth opens into the stomach.) A name given by some to the *tænia osculis superficialibus.*

GA'STRIC. (*Gastricus;* from γαστηρ, the stomach.) Appertaining to the stomach.

GASTRIC ARTERIES. *Arteriæ gastricæ.* These are, the *right gastro-epiploic,* a branch of the hepatic artery; the *left gastro-epiploic,* a branch of the splenic; the *coronaria-ventriculi,* a branch of the cæliac; the *pyloric arteries,* which a

mall branches of the hepatic and gastro-epiloics; and the *vasa brevia*, which are branches f the splenic.

Gastric juice. *Succus gastricus.* A fluid eparated by the stomach. See *Digestion.*

Gastrinum. An alchemical name of wood shes, from which carbonate of potash is prepared.

GASTRI'TIS. (*is, idis.* f.; from γαστηρ, the tomach.) Inflammation of the stomach. See *Inflammation of the stomach and intestines.*

GASTROCE'LE. (*e, es.* f.; from γαστηρ, he stomach, and κηλη, a tumour.) A hernia of the stomach, occasioned by a protrusion of hat viscus through the abdominal parietes. See *Hernia ventriculi.*

GASTROCNE'MIUS. (*us, i.* m.; from γαστηρ, the stomach, and κνημη, the leg.) Two, or according to some anatomists, four, muscles, form the fleshy part or calf of the leg. These muscles are called gastrocnemii.

Gastrocnemius externus. An extensor muscle of the foot, situated immediately under the integuments at the back part of the leg; sometimes called *gemellus:* this latter name is adopted by Albinus. Winslow describes it as two muscles, which he calls *gastrocnemii;* and Douglas considers this and the following as a *quadriceps*, or muscle with four heads, to which he gives the name of *extensor tarsi suralis.* The gastrocnemius externus arises by two distinct heads. The first, which is the thickest and longest of the two, springs by a strong thick tendon from the upper and back part of the inner condyle of the os femoris, adhering strongly to the capsular ligament of the joint, between which and the tendon is a considerable *bursa mucosa.* The second head arises, by a thinner and shorter tendon, from the back part of the outer condyle of the os femoris. A little below the joint, their fleshy bellies unite in a middle tendon, and below the middle of the tibia they cease to be fleshy, and terminate in a broad tendon, which, a little above the lower extremity of the tibia, unite with that of the gastrocnemius internus, to form one round tendon, sometimes called *chorda magna*, but commonly *tendo Achillis.*

Gastrocnemius internus. This, which is situated immediately under the last described muscle, is sometimes named *soleus*, on account of its shape, which resembles that of the sole fish. It arises by two heads. The first springs, by tendinous and fleshy fibres, from the posterior part of the head of the fibula, and for some way below it. The second arises from an oblique ridge at the upper and posterior part of the tibia, which affords origin to the inferior edge of the popliteus, continuing to receive fleshy fibres from the inner edge of the tibia, for some way down. This muscle, which is narrow at its origin, spreads wider, as it descends, as far as its middle; after which it becomes narrower again, and begins to grow tendinous; but its fleshy fibres do not entirely disappear till it has almost reached the extremity of the tibia, a little above which it unites with the last-described muscle, to form the *tendo Achillis.* This thick round cord is inserted into the lower and posterior part of the os calcis, after sliding over a cartilaginous surface on that bone, to which it is connected by a tendinous sheath that is furnished with a large *bursa mucosa.*

Both the gastrocnemii have the same use, viz. that of extending the foot, by drawing it backwards and downwards.

GASTROCO'LIC. (*Gastrocolicus;* from γαστηρ, the stomach, and κωλον, the colon.) The greater omentum is called the *gastro-colic* omentum, because it passes from the stomach to the arch of the colon.

GASTRODY'NIA. (*a, æ.* f.; from γαστηρ, the stomach, and οδυνη, pain.) Spasmodic pain in the stomach.

GA'STRO-ENTERI'TIS. (*is, idis.* f.; from γαστηρ, the stomach, and εντερον, the intestine. Inflammation of the stomach and intestines. See *Inflammation of the stomach and intestines.*

Gastro-epiploic arteries. Two arteries, which supply the stomach and omentum. See *Gastric arteries.*

Gastro'loquism. A hybrid term synonymous with ventriloquism.

Ga'stro-hystero'tomy. (*Gastro-hystero-tomia, æ.* f.; from γαστηρ, the belly, υστερον, the womb, and τεμνω, to cut.) The Cæsarian section.

Gastroraphy. (*Gastroraphe;* from γαστηρ, the stomach, and ραφη, a suture.) The sewing of wounds of the abdomen.

GASTROTO'MIA. (From γαστηρ, the belly, and τεμνω, to cut.) The operation of cutting into the abdomen, which has been practised under several circumstances.

Gaule. See *Myrica gale.*

Ga'yacine. A name given by some French chemists to the resin of guiac.

Gaz. See *Gas.*

Ga'ziform. Gas-like. A term that has been applied to elastic fluids, but unnecessarily; a gaziform fluid means nothing but a gas.

GAZO'METER. (From *gas*, and μετρον, a measure.) This word is applied, not as its etymology would import, to any instrument for measuring gas, but simply to a reservoir for containing gas.

Ge'ic acid. The same as *geine.*

Ge'ine. (From γη, the earth.) A name given by Berzelius to vegetable mould, which, according to Braconnot, resembles ulmin.

Geiso'ma. (From γεισον, the eaves of the house.) *Geison.* The prominent parts of the eyebrows, which hang over the eyes like the eaves of a house.

Geïson. See *Geisoma.*

Gela'sinos. (Γελασινος; from γελαω, to laugh.) A Greek epithet of the incisor teeth, because they are shown in laughter — οδοντες γελασινοι.

Gela'smus. (From γελαω, to laugh.) The Sardonic laugh. See *Sardonic laugh.*

GE'LATINE. (*Gelatina, æ.* f.) Gelly, or jelly. A substance soluble in water, but not in alkohol: capable of assuming a well-known elastic or tremulous consistence, by cooling, when the water is not too abundant, and liquifiable again, by increasing its temperature. This last property remarkably distinguishes it

from albumen, which becomes consistent by heat. It is precipitated in an insoluble form by tannin; and it is this action of tannin on gelatine that is the foundation of the art of tanning leather.

Jellies are mostly obtained from animal substances, and these are very common in our kitchens; they may be extracted from all the parts of animals, by boiling them in water. Hot water dissolves a large quantity of this substance. Acids, likewise, dissolve them, as do also more particularly the alkalies. Jelly, which has been extracted without long decoction, possesses most of the characters of vegetable mucilage; but it is seldom obtained without a mixture of albumen.

Jellies, in a pure state, have scarcely any smell or remarkable taste. By distillation, they afford an insipid and inodorous phlegm, which easily putrifies. A stronger heat causes them to swell up, become black, and emit a fœtid odour, accompanied with white acrid fumes. An impure volatile alkali, together with empyreumatic oil, then passes over, leaving a spongy coal, not easily burned, and containing common salt and phosphate of lime.

The jelly of various animal substances is prepared for the use of seafaring persons, under the name of portable soup. The whole art of performing this operation consists in boiling the meat, and taking the scum off, as usual, until the soup possesses the requisite flavour. It is then suffered to cool, in order that the fat may be separated. In the next place, it is mixed with five or six whites of eggs, and slightly boiled. This operation serves to clarify the liquid, by the removal of opake particles, which unite with the white of egg at the time it becomes solid by the heat, and are consequently removed along with it. The liquor is then to be strained through flannel, and evaporated on the water-bath, to the consistence of a very thick paste; after which it is spread, rather thin, upon a smooth stone, then cut into cakes, and, lastly, dried in a stove, until it becomes brittle. These cakes may be kept four or five years, if defended from moisture. When intended to be used, nothing more is required to be done than to dissolve a sufficient quantity in boiling water, which by that means becomes converted into soup.

Jelly is also found in vegetables, as ripe currants, and other berries, mixed with an acid.

GELATINOUS. Of the nature of *Gelatin*.

GELA'TIO. (*o, onis.* f.; from *gelo*, to freeze.) 1. Freezing.

2. That rigidity of the body which happens in a catalepsy, as if the person were frozen.

GELBUM. *Gelfum.* An alchemical term applied to argentiferous pyrites, and to the philosopher's stone.

Gem. See *Gemma.*

GEME'LLUS. (From *geminus*, double, having a fellow.) See *Gastrocnemius*, and *Gemini.*

GE'MINI. (*i, orum.* m. pl.) Twins.

GEMINI, *sc.* MUSCULI. *Gemelli*, of Winslow. Part of the *marsupialis* of Cowper. A muscle of the thigh, which has been a subject of dispute among anatomists since the days of Vesalius. Some describe it as two distinct muscles; and hence the name it has of *gemini*. Others contend that it ought to be considered as a single muscle. The truth is, that it consists of two portions, which are united together by a tendinous and fleshy membrane, and afford a passage between them to the tendon of the obturator internus, which they inclose, as it were, in a purse. These two portions are placed under the glutæus maximus, between the ischium and the great trochanter.

The superior portion, which is the shortest and thickest of the two, arises fleshy from the external surface of the spine of the ischium; and the inferior, from the tuberosity of that bone, and likewise from the posterior sacro-ischiatic ligament. They are inserted, tendinous and fleshy, into the cavity at the root of the great trochanter. Between the two portions of this muscle, and the termination of the obturator internus, there is a small *bursa mucosa*, connected to both, and to that part of the capsular ligament of the joint which lies under the gemini.

This muscle assists in rolling the os femoris outwards, and prevents the tendon of the obturator internus from slipping out of its place while that muscle is in action.

GE'MMA. (*a, æ.* f.) 1. In *Mineralogy*, a precious stone or gem.

In the superstitious medicine of former times, almost all the genus had some medicinal or magical virtues attributed to them.

2. In *Botany*, a bud on the stems of plants.

The ancients used the terms *germen* and *oculus* to denote those buds which contain the rudiments of branches and leaves, and *gemma* those in which flowers only are contained; but by the moderns, *germen* has been applied to denote the rudiment of the fruit, or as a generic term for all buds. — *Thompson.*

A *gemma*, or bud, contains the rudiments of a plant, or of part of a plant, for a while in a latent state, till the time of the year, and other circumstances, favour their evolution. In the bud, therefore, the vital principle is dormant. Buds of trees, or shrubs, destined for cold countries, are formed in the course of the summer in the bosoms of their leaves, and are generally solitary; but in the *Lonicera cærulea*, or blue-berried honey-suckle, they grow one under another for three successive seasons.

The buds of the plane tree, *Platanus*, are concealed in the footstalk, which must be removed before they can be seen, and which they force off by their increase; so that no plant can have more truly and necessarily deciduous leaves.

Shrubs in general have no buds, neither have the trees of hot climates.

Buds are various in their forms, but very uniform in the same species, or even genus. They consist of scales closely enveloping each other, and enfolding the embryo plant or branch. Externally, they have often an additional guard of gum, resin, or woolliness, against wet or cold. The horse-chestnut affords a fine example of large and well-formed buds.

The contents of buds are different, even in different species of the same genus, as willows. The buds of some produce leaves only, others flowers, while in other species the same bud bears both leaves and flowers. Different causes, depending on the soil or situation, seem in one case to generate leaf-buds, in another flower-buds. In general, whatever checks the luxuriant production of leaf-buds, favours the formation of flowers and seeds. — *Smith.*

Gems are found in all trees and shrubs in temperate climates. In the majority of instances they are visible from the first, in which case they are *axillary*, that is, seated in the axillæ of the leaves, or the angle which the upper part of the footstalk of the leaf makes with the surface of the stem; but in some instances, as the sumachs and planes, they are *latent*, being hid within the base of the footstalk, and never seen until the fall of the leaf. Gems are, however, sometimes protruded from the trunk, long after it has ceased to produce leaves, as in the case of adventitious buds; they are also situated on roots, and on tubers; but in these cases they are usually denominated *oculi*, or eyes.

Annual plants are supposed to be furnished with gems; but although they are devoid of covered gems, yet their lateral shoots proceed from naked buds which immediately spread into foliage.

The relative position of *axillary* gems is necessarily regulated by that of the leaf, and therefore we find them,

1. *Opposite*, or placed exactly on the same line, on opposite sides of the stem or the branch.

2. *Alternate*, or placed alternately, although on opposite sides; and,

3. *Spiral*, that is, placed round the stem or branch in such a manner that a cord wound in a spiral manner round it would touch each gem. They are said to be *simple* or *solitary*, when one gem only is seen in the axilla of each leaf, as in the greater number of instances; and *aggregate*, when, as in some plants, two, three, or even more, are protruded at the same time: thus we find two in the *Sambucus nigra*, or common elder; three in the *Aristolochia sipho*, or broad-leaved birth-wort; and many in the *Zanthoxylum fraxineum*, or toothach tree.

Du Hamel first noticed the fact, that stems and branches, furnished with alternate axillary gems, have generally one *terminal* gem only; and those with opposite have generally three terminal gems.

The gems on most trees and shrubs rise with a broad base from the surface where they are protruded, and consequently, being in close contact with it, are said to be *sessile*; but they are distant or stalked on some, as the common elder, on which they are supported on a short footstalk, and are termed *pedicillatæ*, or stalked.

Gems differ very considerably in the number and characters of the enclosing scales, their contents, the folding up of the leaves within them, and the manner in which they are evolved in the spring.

a. The scales differ in size and texture, even in the same gem: in the gems of different plants, they differ also in number and in the nature of their coverings. Some gems are entirely destitute of scales; as those of annual plants, and many perennials of tropical climates. The scales, in some instances, are besmeared with a resinous matter; in others, they are entirely free from any moist exudation, but are smooth and polished, being covered with a dry gummy varnish; or they are externally hairy, or enveloped in a velvety down.

Gems are arranged into three species: —

1. *Gemmæ foliiferæ*, leaf gems.
2. *Gemmæ floriferæ*, flower gems.
3. *Gemmæ mixtæ*, mixed gems.

The *Amygdalus persica*, or peach-tree, the *Daphne mezereum*, and many other plants, afford examples of distinct leaf and flower gems; the *Syringa vulgaris*, and *Æsculus hippocastanum*, of mixed gems; and the pear and apple trees, of both leaf and mixed gems.

The leaves, as has already been mentioned, are variously folded up, so as to occupy the smallest possible space in the gem. This regulates the expansion of the leaves when the gem opens in spring, and it is invariably the same in individual plants of the same species. This process is termed *foliation*, and the figures which the leaves assume at the time have received different appellations. — *Thompson.*

1. *Foliatio involuta*, involute, in which each internal margin of the leaf is rolled inwards; as in *Humulus lupulus*, and *Nymphæa lutea*.

2. *Revoluta*, revolute, in which the lateral margins are rolled outwards; as in willows, and *Rumex patientia*.

3. *Obvoluta*, obvolute, in which one leaf, doubled lengthways, embraces within its doubling one half of the other leaf, folded in the same manner; as in *Salvia officinalis*, and *Dipsacus communis*.

4. *Convoluta*, convolute, in which the leaf is rolled lengthways in a spiral manner, one margin forming the axis round which the other turns; as in *Prunus domestica*, and *Prunus armeniaca*, the cabbage, grasses, &c.

5. *Equitans*, equitant, in which the leaf is so folded that the two sides deeply embrace the opposite leaf, which, in its turn, encloses the one opposed to it, and so on to the centre of the bud: this is beautifully exemplified in the *Hemarocallis*, or day-lily, and *Syringa vulgaris*.

6. *Conduplicata*, in which the two sides of the leaf lie parallel to each other; as in *Fagus sylvatica*, and *Quercus robur*.

7. *Plicata*, plaited, the leaf being folded up like a fan; as in *Betula alba*, and *Alchemilla vulgaris*.

8. *Reclinata*, reclinate, turned down, the leaf hanging down and wrapt round the footstalk; as in *Aconitum*, and *Arum*.

9. *Circinata*, circinal, in which the leaf is rolled from the apex to the base; as in all ferns.

As the gems open, the leaves gradually unfold themselves, and assume their natural forms; but the opening of the bud does not in every instance immediately set free the leaves, for in some gems each leaf is separately enclosed in a membraneous cover.

GEMMA'CEUS. A term applied by bota-

ists to a flower-stalk which grows out of a leaf-bud, as is seen in the *Berberis vulgaris*.

GEMMA'TIO. (*o, onis.* f. ; from *gemma*, a bud.) A term used by Linnæus expressive of the origin, form, &c. of buds. See *Gemma*.

GEMMI'PAROUS. (From *gemma*, a bud, and *pario*, to bring forth.) Applied to plants and animals which propagate by shoots.

GE'MMULA. A little bud. The termination of the plumula of germinating seeds.

GEMU'RSA. A disease situated between the toes was anciently so called, according to Pliny. What this disease was is now unknown.

GE'NA. (*a, æ.* f.) The Latin for the cheek.

GENERA'TIO FISSI'PARA. Generation by division. The production of a new organism by a separation from the substance of the parent, as in the propagation of plants by shoots; and that of certain animals, as some of the infusoria and polypi. See *Generation*.

GENERATION. (*Generatio, onis.* f.; from *γεινομαι*, to beget.) Many ingenious hypotheses have been instituted by physiologists to explain the mystery of generation; but the whole of our knowledge concerning it appears to be built upon the phenomena it affords, and may be seen in the works of Haller, Buffon, Cruickshanks, and Haighton. It is a sexual action, performed in different ways in most animals; many of them have different sexes, and require conjunction: such are the human species, quadrupeds, and others. The females of quadrupeds have a matrix, separated into two cavities, *uterus bicornis*, and a considerable number of teats; they have no menstrual flux; most of them bear several young at a time, and the period of their gestation is generally short. The generation of birds is very different. The males have a strong genital organ, which is often double. The vulva in the females is placed behind the anus; the ovaries have no matrices, and there is a duct for the purpose of conveying the egg from the ovarium into the intestines: this passage is called the oviduct. The eggs of pullets have exhibited unexpected facts to physiologists, who examined the phenomena of incubation. The most important discoveries are those of the immortal Haller, who found the chicken perfectly formed, in eggs which were not fecundated. There is no determinate conjunction between fishes; the female deposits her eggs on the sands, over which the male passes, and emits its seminal fluid, doubtless for the purpose of fecundating them: these eggs are hatched after a certain time. The males of several oviparous quadrupeds have a double or forked organ. Insects exhibit all the varieties which are observed in other animals: there are some, indeed the greater number, which have the sexes in two separate individuals; among others, the reproduction is made either with or without conjunction, as in the vine-fretter; one of these insects, confined alone beneath a glass, produces a great number of others. The organ of the male, in insects, is usually armed with two hooks to seize the female: the place of these organs is greatly varied; with some, it is at the upper part of the belly, near the chest, as in the female dragon-fly; in others, it is at the extremity of the *antenna*, as in the male spider. Most worms are hermaphrodite; each individual has both sexes. Polypi, with respect to generation, are singular animals; they are reproduced by buds or offsets: a bud is separated from each vigorous polypus, which is fixed to some neighbouring body, and grows: polypi are likewise found on their surface, in the same manner as branches issue from plants. These are the principal modes of generation in animals. In the human species, which engages our attention more particularly, the phænomena are as follow: —

The part of the male, in the act of reproduction, is to deposit the semen in the vagina, at a greater or less distance from the orifice of the uterus.

The function which the female discharges is much more obscure: some feel, at this moment, very strong voluptuous sensations; others appear entirely insensible; whilst others, again, experience a sensation which is very painful. Some of them pour out a mucous substance in considerable abundance, at the instant of the most vivid pleasure: whilst, in the greater part, this phænomenon is entirely wanting. In all these respects, there is, perhaps, no exact resemblance between any two females.

These different phænomena are common to the most frequent acts of copulation; that is, to those which do not produce impregnation, as well as those which are effective.

The most recent opinion is, that the uterus during impregnation opens a little, draws in the semen by aspiration, and directs it to the ovarium by means of the Fallopian tubes, the fimbriated extremity of which closely embraces that organ.

The contact of the semen determines the rupture of one of the vesicles, and the fluid that passes from it, or the vesicle itself, passes into the uterus, where the new individual is to be developed.

However satisfactory this explanation may appear, it is purely hypothetical, and even contrary to the experiments of the most exact observers.

In the numerous attempts made upon animals by Harvey, De Graaf, Valisneri, &c., the semen has never been perceived in the cavity of the uterus; much less has it been seen in the Fallopian tube, at the surface of the ovarium. It is quite the same with the motion which the Fallopian tube is supposed to have in embracing the circumference of the ovarium: it has never been proved by experiment. Even if one should suppose that the semen penetrates into the uterus at the moment of coition, which is not impossible, though it has not been observed, it would still be very difficult to comprehend how the fluid could pass into the Fallopian tubes, and arrive at the ovarium. The uterus in the empty state is not contractible; the uterine orifice of the Fallopian tubes, is extremely narrow, and these canals have no known sensible motion.

On account of the difficulty of conceiving the passage of the semen to the ovarium, some authors have imagined that this matter is not

carried there, but only the vapour which exhales from it, or the *aura seminalis*. Others think that the semen is absorbed in the vagina, passes into the venous system, and arrives at the ovaria by the arteries. The phænomena which accompany the fecundation of women are, then, nearly unknown. An equal obscurity rests on the fecundation of other mammiferous females. Nevertheless, it would be more easy to conceive a passage of the semen to the ovaria in these, since the uterus and the Fallopian tubes possess a peristaltic motion like that of the intestines. Fecundation, however, taking place by the contact of the semen with the ova, in fishes, reptiles, and birds, it is not very likely that nature employs any other mode for the *mammifera*; it is necessary, then, to consider it as very probable that, either at the instant of coition, or at a greater or less time afterwards, the semen arrives at the ovarium, where it exerts more especially its action upon the vessels most developed.

But, even should it be out of doubt that the semen arrives at the vesicles of the ovarium, it would still remain to be known how its contact animates the germ contained in it. Now, this phænomenon is one of those on which our senses, and even our mind, have no hold: it is one of those impenetrable mysteries of which we are, and, perhaps, shall ever remain ignorant.

We have, however, on this subject, some very ingenious experiments of Spallanzani, which have removed the difficulty as far as it seems possible. This philosopher has proved, by a great number of trials, 1st, that three grains of semen, dissolved in two pounds of water, are sufficient to give to it the fecundating virtue; 2d, that the spermatic animalcula are not necessary to fecundation, as Buffon and other authors have thought; 3d, that the *aura seminalis*, or seminal vapour, has no fecundating property; 4th, that a bitch can be impregnated by the mechanical injection of semen into her vagina, &c. &c.

It is thus necessary to consider as conjectural what authors say about the general signs of fecundation. At the instant of conception, the woman feels, it is said, a universal tremor, continued for some time, accompanied by a voluptuous sensation; the features are discomposed, the eyes lose their brilliancy, the pupils are dilated, the visage pale, &c. No doubt, impregnation is sometimes accompanied by these signs; but many mothers have never felt them, and reach even the third month of their pregnancy without suspecting their situation. — *Magendie's Physiology.*

Fecundation having thus taken place, a motion is induced in the vivified ovum, which ruptures the tender vesicle that contains it; the fimbriæ of the Fallopian tube then grasp and convey it into the tube, which, by its peristaltic motion, conducts it into the cavity of the uterus, there to be evolved and brought to maturity, and, at the expiration of a fixed term, to be sent into the world.

GENERATION, EQUIVOCAL. *Generatio æquivoca. Generatio spontanea. Generatio heterogenea. Generatio primitiva.* It was the belief of the ancients that a plastic energy existed in the universe, under the influence of which, matter, in certain circumstances, could become organised, and new living beings thus spontaneously produced; as when minute animals are apparently formed from putrefaction, and in infusions of animal or vegetable substances. This supposed mode of generation has been called the *equivocal generation* or *epigenesis*. The hypothesis of the equivocal generation, as adopted by Aristotle, was for many ages universally assented to. In modern times the opinions of physiologists have fluctuated. The doctrine was thrown into discredit by the experiments of Redi and Valisneri; it derived new support from those of Tuberville, Needham, Müller, and Wrisberg, and was again controverted by Spallanzani. The observations of Priestly on *Conservæ* (see *Confervæ*), were in its favour, and they have been confirmed by Ingenhouz and Treveranus, but the recent researches of Ehrenberg throw great doubt on the accuracy of these observations. On the whole, the question must be considered as yet unsettled. The phenomenon most in favour of the equivocal generation, is the production of those entozoa which cannot be traced to any source extraneous to the body of the animal in which they are found.

GENERATION, ORGANS OF. The parts subservient to generation in a woman, are divided into external and internal. The external parts are the *mons veneris*, the *labia*, the *perinæum*, the *clitoris*, and the *nymphæ*. The internal parts of generation are the *vagina* and *uterus*, the *ovaria* and *Fallopian tubes*.

The parts which constitute the organs of generation in men, are the *penis*, *testes*, *vesiculæ seminales*, *vasa deferentia*, and *prostate gland*.

GENE'RIC. *Genericus.* Appertaining to a genus. See *Genus*.

GENE'VA. (*a*, *æ*. f. The name of the place where it was first made.) Gin. A spirit distilled from malt or rye, which afterwards undergoes the same process, a second time, with juniper-berries. This is the original and most wholesome state of the spirit; but it is now prepared without juniper-berries, and is distilled from turpentine and cardamoms, and very few, if any, juniper-berries, which gives it something of a similar flavour. The consumption of this article, especially in the metropolis, is immense, and the consequences are very pernicious to the health of those who drink it; and some artisans, and many of the poorer sort, take ten and twelve glasses a day. It has now become a practice with the retail dealers of this article, to prepare it for their customers by mixing alum, sugar, and some other pernicious articles.

GENICULA'TUS. Geniculate: bent like the knee. Applied to stems and the culm of straw of grasses; as in *Alopecuris geniculatus*.

GENI'CULUM. (*um*, *i*. n.; from *genu*, a knee.) The knot or joint of stems, grasses, &c.

GENI'OGLO'SSUS. (From γενειον, the chin, and γλωσσα, the tongue.) See *Geniohyoglossus*.

GENI'O-HY'O-GLO'SSUS. (From γενειον, the chin, υοειδες, the os hyoides, and γλωσσα, the

tongue: so called from its origin and insertion.) *Genio-glossus*, of some authors. The muscle which forms the fourth layer between the lower jaw and os hyoides. It arises from a rough protuberance in the inside of the middle of the lower jaw; its fibres run like a fan, forwards, upwards, and backwards, and are inserted into the tip, middle, and root of the tongue, and base of the os hyoides, near its corner. Its use is to draw the tip of the tongue backwards into the mouth, the middle downwards, and to render its back concave. It also draws its root and the os hyoides forwards, and thrusts the tongue out of the mouth.

GENI'O-HYOIDE'US. (From γενειον, the chin, and υοειδες, the os hyoides: so called from its origin in the chin, and its insertion in the os hyoides.) The muscle which constitutes the third layer between the lower jaw and os hyoides. It is a long, thin, and fleshy muscle, arising tendinous from a rough protuberance at the inside of the chin, and growing somewhat broader and thicker as it descends backward to be inserted by very short tendinous fibres into both the edges of the base of the os hyoides. It draws the os hyoides forwards to the chin.

Geni'o-Phary'ngeus. See *Constrictor pharyngis superior.*

GE'NIPI. A term of barbarous origin, applied to the two following plants: —

Genipi album. See *Artemisia rupestris.*

GENIPI VERUM. The plant directed for medicinal purposes, under this title, is the *Achillea —foliis pinnatis, pinnis simplicibus, glabris, punctatis*, of Haller. It has a very grateful smell, and a very bitter taste, and is exhibited in Switzerland, in epilepsy, diarrhœa, and debility of the stomach.

GENI'STA. (*a, æ.* f.; from *genu*, a knee: so called from the inflection and angularity of its twigs.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria.*

2. The pharmacopœial name of the common broom. See *Spartium scoparium.*

GENISTA CANARIENSIS. This tree was supposed to afford the lignum Rhodium, which is now known to be an aspalathus. See *Aspalathus canariensis.*

GENISTA SPINOSA INDICA. *Bahel schulli.* An Indian tree, a decoction of the roots of which is diuretic. The leaves, boiled and sprinkled in vinegar, have the same effect, according to Ray.

GENISTA TINCTORIA. The systematic name of the dyer's broom.

GENITA'LIS. (From *gigno*, to beget.) Genital. Appertaining to generation.

Genital organs. See *Organs of generation.*

GENITA'LIUM. (From *genitale*, the membrum virile.) A disease of the genital parts.

GENI'TICUS. (From γεινομαι, *gignor.*) Appertaining to the sexual function.

GENITU'RA. (From *gigno.*) 1. The male seed.

2. The genital organs of either sex.

Gensing. See *Panax.*

GENTIA'NA. (*a, æ.* f.; from *Gentius*, king of Illyria, who first used it.) 1. The name of a genus of plants in the Linnæan system. Class, *Pentandria*; Order, *Digynia.* Gentian.

2. The pharmacopœial name of the gentian root. See *Gentiana lutea.*

Gentiana alba. See *Laserpitium.*

GENTIANA CENTAURIUM. Lesser centaury was so called in the Linnæan system; but it now belongs to the genus *Chironia.*

GENTIANA LUTEA. The systematic name of the officinal gentian; called also, Felwort, and *Gentiana rubra.* The gentian met with in the shops, is the root of *Gentiana — corollis subquinquefidis rotatis verticillatis, calycibus spathaceis*, of Linnæus; and is imported from Switzerland and Germany. It is the only medicinal part of the plant, has little or no smell, but to the taste manifests great bitterness, on which account it is in general use as a tonic, stomachic, anthelmintic, antiseptic, emmenagogue, and febrifuge. The officinal preparations of this root are the *infusum gentianæ compositum*, and *tinctura gentianæ composita*, of the London Pharmacopœia, and the *infusum amarum, vinum amarum, tinctura amara*, of the Edinburgh Pharmacopœia; and the *extractum gentianæ* is ordered by both.

Gentiana rubra. See *Gentiana lutea.*

GE'NTIANINE. An alkaline principle discovered in the *Gentiana lutea* by Henri and Caventou, and supposed to be the active part of the plant. It is yellow, bitter, inodorous, nearly insoluble in cold water, but very soluble in alkohol and ether.

GENTIA'NIÆ. A natural family of plants, of which the genus *gentiana* is the type.

GENTI'LII MORBI. (*Gens*, a family.) Family or hereditary diseases.

GE'NU. (Indeclinable in the singular, n.; *genua, genuorum*, &c. in the plural.) The knee.

GENUGRA. (*a, æ.* f.; from *genu*, the knee, and αγρα, a seizure.) A name given by Paracelsus to gout in the knee.

GEO'DES. A kind of aëtites, the hollow of which contains only loose earth, instead of a nodule. See *Aëtites.*

GEOFFRÆ'A. (*a, æ.* f.; named in honour of Dr. Geoffroy.) *Geoffroya.* The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria.*

Geoffræa inermis. See *Andira inermis.*

GEOFFRÆA SURINAMENSIS. The systematic name of a tree, the bark of which is esteemed as an anthelmintic.

GERANIA'CEÆ. A natural family of plants, of which the genus *geranium* is the type.

GERA'NIS. (From γερανος, a crane: so called from its supposed resemblance to an extended crane.) A bandage for a fractured clavicle.

GERA'NIUM, (*um, i.* n.; from γερανος, a crane: so called because its pistil is long like the bill of a crane.) The name of a genus of plants in the Linnæan system. Class, *Monadelphia*; Order, *Decandria.* Geranium, or crane's-bill.

Geranium batrachioides. See *Geranium pratense.*

Geranium columbi'num. See *Geranium rotundifolium.*

GERANIUM MOSCHA'TUM. The astringent property of this plant has induced practitioners to exhibit it in cases of debility and profluvia.

GERANIUM PRATENSE. The systematic name of the crowfoot crane's-bill; called likewise *Geranium batrachioides.* A plant which possesses astringent virtues, but in a slight degree.

GERANIUM ROBERTIA'NUM. Stinking crane's-bill. Herb Robert. This common plant has been much esteemed as an external application in erysipelatous inflammations, cancer, mastodynia, and old ulcers, but is now fallen into disuse.

GERANIUM ROTUNDIFOLIUM. The systematic name of the dove's foot, which is also called, *Geranium columbinum.* This plant is slightly astringent.

GERANIUM SANGUINEUM. The systematic name of the bloody crane's-bill. Astringent virtues are ascribed to this plant, but they do not appear to be considerable.

Germ. See *Corculum.*

Germander. See *Teucrium.*

Germander, water. See *Teucrium.*

Germanis oleum. See *Pinus cembra.*

GE'RMEN. (*en, inis.* n.) The rudiment of the young fruit and seed of vegetables, found at the bottom of the pistil. See *Pistillum.* It is various in shape and size.

From its figure it is said to be,

1. *Globose;* as in *Rosa eglantaria,* and *cinnamomea.*

2. *Oblong;* as in *Stellaria biflora.*

3. *Ovate;* as in *Rosa canina,* and *alba.*

From its situation, it is distinguished into,

1. *Superior,* when internal between the corolla; as in *Prunus.*

2. *Inferior,* below and without the corolla; as in *Galanthus nivalis.*

3. *Pedicellate,* upon a footstalk; as in the *Euphorbia.*

It is of great moment, for botanical distinctions, to observe whether it be superior, above the bases of the calyx, or below.

GERMINATION. (*Germinatio, onis.* f.) The vital development of a seed, when it first begins to grow.

GEROCO'MIA. (*a, æ.* f.; from γερας, old age, and κομεω, to be concerned about.) That part of hygeiene which regards the regimen and treatment of old age.

GERONTOPO'GON. (*um, i.* n.; from γερων, an old man, and πωγων, a beard: so called because its downy seed, while enclosed in the calyx, resembles the beard of an aged man.) The herb old man's beard, a species of tragopogon.

GERONTO'XON. (More properly *gerontotoxon;* from γερων, an old person, and τοξον, a bow.) A name of the appearance in the eyes of old persons, otherwise called *Arcus senilis.* See *Arcus senilis,* in the Supplement.

2. The socket of a tooth.

Geropo'gon. See *Gerontopogon.*

GERSA. An alchemical name of cerusse.

GERYON. Quicksilver.

GESTATION. (*Gestatio, onis.* f.; from *gero,* to carry.) Carrying. 1. Passive exercise, in which the body is moved without the exertion of its own muscles; such as swinging, being carried in a litter, riding in a carriage, sailing. All these may, under circumstances, be made to produce a good effect in the treatment of disease. Some exercises are partly passive and partly active — as riding on horseback. The principal kinds of passive exercise are — First, swinging in a hammock, which, at the decline of a fever, is beneficial. Secondly, being carried in a litter, in which the patient either sits, or lies along. It is useful in cases of gout, stone, or any other disorder, which does not admit of violent motions. Thirdly, riding in a carriage, which is of service in most chronical disorders; especially before the more violent exercises can be admitted. Fourthly, sailing in a ship or boat: this produces various effects, according to the different agitation of the waters; and, in many tedious chronical disorders, is efficacious beyond what is observed from the most skilful administration of drugs. Lastly, a rotatory motion, in which the patient is rapidly whirled round, is sometimes used in cases of mania.

2. Pregnancy. The state of a female animal when with young. See *Pregnancy.*

GESTATION, UTERINE. *Gestatio uterina.* The period from the impregnation of a female to the time of labour. See *Pregnancy.*

GE'UM. (*um, i.* n.) 1. The name of a genus of plants in the Linnæan system. Class, *Icosandria;* Order, *Polygynia.*

2. The pharmacopœial name of the two following species of this genus: —

GEUM RIVALE. The root of this has been used medicinally. It is inodorous, and imparts an austere taste. In America, it is in high estimation in the cure of intermittents, and is said to be more efficacious than the Peruvian bark. Diarrhœas and hæmorrhages are also stopped by its exhibition.

GEUM URBANUM. The systematic name of the herb bennet, or avens; called also, *Caryophyllata, Herba benedicta, Caryophyllus vulgaris, Garyophilla,* and *Janamunda.*

Geum — floribus erectis, fructibus globosis villosis, aristis uncinatis nudis, foliis lyratis, of Linnæus. The root of this plant has been employed as a gentle styptic, corroborant, and stomachic. It has a mildly austere, somewhat aromatic taste, and a very pleasant smell, of the clove kind. It is also esteemed on the Continent as a febrifuge.

GIBAR. A barbarous name for any sort of medicine containing a metallic substance.

GIBBO'SITY. (*Gibbositas, atis.* f.; from *gibbus,* a swelling or protuberance.) Crookedness.

GI'BBUS. (*us, i.* m.) Gibbous: bulged; swelled. 1. An irregularity or swelling on the back, or any other part of the body.

2. Applied to leaves, petals, &c., when irregularly swelled on one side or both; as the under part of the corol of the *digitalis,* and corol of the *Lonicera periclemenum.*

GICH. An alchemical name of lime.

Giddiness. See *Vertigo.*

GIGISIM. A barbarous name for gum.

Gilead, balsam of. See *Amyris Gileadensis.*

Gill. See *Branchia*, and *Lamella.*

GILLA. *Grillus.* Names given by the alchemists to various saline substances and their solutions, as sulphate of iron, sulphate of lime, sal ammoniac, and the solutions of these in water.

Gilliflower. See *Dianthus.*

GIMBERNAT'S LIGAMENT. The aponeurosis of the external oblique muscle of the abdomen divides at the inguinal aperture into two portions. The lower portion is doubled inwards, and inserted into the spine of the pubis, the linea ileo-pectinea, and adjacent portion of the fascia lata. The tendinous fibres thus inserted constitute what is called *Gimbernat's ligament*, which is defined by some to be the third insertion of Poupart's ligament.

Gin. See *Geneva.*

Ginger. See *Zingiber.*

GINGER BEER. A pleasant and sufficiently wholesome effervescing beverage, made by fermenting ginger, cream of tartar, and sugar, with yeast. It is made according to several well-known receipts.

Gingiber. See *Zingiber.*

GINGIBRA'CHIUM. (From *gingivæ*, the gums, and *brachium*, the arm.) A barbarous name for the scurvy, because the gums and arms are affected with it.

GINGI'DIUM. A species of *Daucus.*

Gi'ngihil. See *Zingiber.*

GINGIPE'DIUM. (From *gingivæ*, the gums, and *pes*, the foot.) A barbarous name for the scurvy, because the gums and legs are affected.

GINGI'VA. (*a*, *æ.* f.) The gum. The very vascular and elastic fleshy substance that covers the alveolar arches of the upper and under jaws, and embraces the neck of the teeth.

GI'NGLYMUS. (*us*, *i.* m. Γιγλυμος, a hinge.) The hinge-like joint. A species of diarthrosis, or moveable connection of bones, which admits of flexion and extension; as the knee-joint, &c.

GINSENG. (An Indian word.) See *Panax quinquefolium.*

GIR. Quick-lime.

GIRMIR. Tartar.

GIROUX. A village four leagues from Riez, where there are hot mineral springs, strongly impregnated with muriate of soda, carbonate of magnesia, sulphuret of potash, and a bituminous matter.

GITHA'GO. (*o*, *inis.* f.; from *gith.*) A name used by Pliny for the *Lolium*, or darnel-grass. See *Agrostemma.*

GIZZARD. The proper stomach of birds. The texture of this organ differs remarkably in granivorous and carnivorous birds. See *Animal kingdom.*

The gizzards of poultry have long been considered, in France, as medicinal. They have been recommended in obstructions of the urinary passages, complaints of the bladder, and nephritic pains; but particularly as a febrifuge.

GLABE'LLA. (From *glaber*, smooth; because it is without hair.) The space betwixt the eyebrows.

GLA'BER. (From *galab*, Hebrew.) Glabrous: smooth. Applied to stems, leaves, seeds, &c., of plants, and opposed to hirsute, hairy, or pubescent; as the stem of the *Euphorbia peplus*, and the seeds of *Galium montanum.*

Glabula. See *Galbulus.*

GLA'CIES. Ice. See *Ice.*

GLADI'OLUS. (*us*, *i.* m.; diminutive of *gladius*, a sword: so named from the sword-like shape of its leaf.) The name of a genus of plants in the Linnæan system. Class, *Triandria*; Order, *Monogynia.*

Gladiolus luteus. See *Iris pseudacorus.*

GLA'MA. Γλαμα. The sordes of the eye.

GLAND. (*Glandula*, *æ.* f.; a diminutive of *glans*, an acorn.) I. In *Anatomy*, an organ composed of blood-vessels, nerves, and absorbents, and destined for the secretion or alteration of some peculiar fluid. A gland is either, —

1. *Folliculus*, a follicle, which is a small bag appended to the extremity of a duct into which the secretion is made, and from which it is evacuated by the duct.

2. *Lacuna*, a little sac opening into the passage, and into which generally mucus is secreted, and is discharged when matter moves along the passage.

3. *Crypta*, a soft body, consisting of vessels not completely surrounded with a membrane. The great intestines and kidneys furnish examples of this apparatus for secretion.

4. *Acinus*, a round body, not regularly invested with a membrane. The liver is principally composed of acini.

The glands of the human body are divided, by anatomists, into different classes, either according to their structure, or the fluid they contain. According to their fabric, they are distinguished into four classes: — Simple, compound, conglobate, and conglomerate.

According to their fluid contents, they are more properly divided into, — Mucous, sebaceous, lymphatic, salival, and lachrymal.

1. *Simple glands* are small hollow follicles, covered with a peculiar membrane, and having a proper excretory duct, through which they evacuate the liquor contained in their cavity. Such are the mucous glands of the nose, tongue, fauces, trachea, stomach, intestine, and urinary bladder, the sebaceous glands about the anus, and those of the ear. These simple glands are either dispersed here and there, or are contiguous to one another, forming a heap in such a manner that they are not covered by a common membrane, but each hath its own excretory duct, which is never joined to the excretory duct of another gland. The former are termed solitary simple glands, the latter aggregate or congregate simple glands.

2. *The compound glands* consist of many simple glands, the excretory ducts of which are joined in one common excretory duct; as the sebaceous glands of the face, lips, palate, and various parts of the skin, especially about the pubes.

3. *Conglobate*, or, as they are also called, *lymphatic glands*, are those into which lymphatic vessels enter, and from which they go out

again; as the mesenteric lumbar, &c. They have no excretory duct, but are composed of a texture of lymphatic vessels connected together by cellular membrane: they are the largest in the fœtus.

4. *Conglomerate glands* are composed of a congeries of many simple glands, the excretory ducts of which open into one common trunk: as the parotid gland, thyroid gland, pancreas, and all the salival glands. Conglomerate glands differ but little from the compound, yet they are composed of more simple glands than the compound.

The excretory duct of a gland is the duct through which the fluid of the gland is excreted. The vessels and nerves of glands always come from the neighbouring parts, and the arteries appear to possess a high degree of irritability. The use of the glands is to separate a peculiar liquor, or to change it. The use of the conglobate glands is unknown.

II. In *Botany*, Linnæus defines a gland a little tumour discharging a fluid.

From their situation they are said to be, —

1. *Foliar*, when on the surface of the leaf, as in the *Gossypium religiosum*, which has one gland on the leaf; and *Gossypium barbadense*, the leaves of which have three.

2. *Petiolar*, when in the footstalk; as in *Prunus cerasus*.

3. *Corollar*. The claw of the corolla of the *Berberis vulgaris* has two glands.

4. *Filamentar*, in the filaments; as in *Dictamnus albus*.

From their adhesion, —

1. *Sessile*, without any peduncle; as in *Prunus cerasus*.

2. *Pedicellate*, furnished with a peduncle; as in *Drosera*.

Glands are abundant on the stalk and calyx of the moss-rose, and between the serratures of the leaf of the *Salix pentandria*; on the footstalks of the *Viburnum opulus*, and various species of passion-flower. The liquor discharged is resinous and fragrant.

GLA'NDULA. (*a*, *æ*. f.; a diminutive of *glans*.) See *Gland*.

Glandula lachrymalis. See *Lachrymal gland*.

Glandulæ Brunneri. See *Brunner's glands*.

Glandulæ myrtiformes. See *Caruncula myrtiformes*.

GLA'NDULÆ PACCHIO'NI. A number of small albuminous substances, situated under the dura mater, about the sides of the longitudinal sinus. Their use is not known, and some suppose them to be morbid products.

Glandulæ Peyeri. See *Peyer's glands*.

GLANDULO'SUS. Glandular. 1. In *Anatomy*, having the appearance, structure, or function of a gland.

2. In *Botany*, applied to leaves which have little glandiform elevations; as the bay-leaved willow, and *Hypericum montanum*.

GLANS. (*s*, *dis*. f.) A gland. See *Gland*.

GLANS PENIS. The very vascular nut-like body that forms the apex of the penis. The posterior circle is termed the *corona glandis*. See *Corpus spongiosum urethræ*.

Glans unguentaria. See *Guilandina*.

GLASS. *Vitrum*. This substance was formerly employed by surgeons, when roughly powdered, to destroy opacities of the cornea.

Glass of antimony. See *Antimonii vitrum*.

Glass-shaped. See *Cyathiformis*.

Glass-wort, snail-seeded. See *Salsola kali*.

GLA'STUM. (According to Blancard this is an old Gallic word.) See *Isatis*.

Glauber's salt. See *Sodæ sulphas*.

GLAUCE'DO. (*o*, *inis*. f.; from γλαυκος, bluish, or seagreen.) See *Glaucoma*.

GLAU'CIUM. (*um*, *i*. n.; so named from its glaucous or sea-green colour.) The name of a genus of plants in the Linnæan system. Class, *Polyandria*; Order, *Monogynia*. The horned poppy.

GLAUCO'MA. (*a*, *atis*. n.; from γλαυκος, glaucous: because of the eye becoming of a blue, or sea-green colour.) 1. Dimness, or obscurity of sight from an opacity of the vitreous humour. It is difficult to ascertain, and is only to be known by a very attentive examination of the eye. It is generally produced by a cloudy secretion of the vitreous humour, or by a torpitude of action in the absorbents that carry off the fluid from the cells of the vitreous substance.

A continued course of mercurial alteratives is likely to be beneficial, with blisters near the eye, as behind the ears, &c.

2. This name has been given to cataract. See *Cataract*.

Glauco'sis. See *Glaucoma*.

GLAU'CUS. (Γλαυκος, sea-green.) Glaucous: hoary. Of a hoary or grey bluish green colour: applied to leaves, stems, &c., which are clothed with a fine sea-green mealiness, which easily rubs off; as in *Chlora perfoliata*, and the back of the cabbage-leaf. See *Incanus*, and *Colour*.

GLECHO'MA. (*a*, *æ*. f.; from γληχων, the name of a plant in Dioscorides.) The name of a genus of plants in the Linnæan system. Class, *Didynamia*; Order, *Gymnospermia*. Ground-ivy.

GLECOMA HEDERA'CEA. The systematic name of the ground-ivy or gill. *Hedera terrestris*. *Glecoma — foliis reniformibus crenatis*, of Linnæus. This indigenous plant has a peculiar strong smell, and a bitterish, somewhat aromatic taste. It is one of those plants which was formerly much esteemed for possessing virtues that, in the present age, cannot be detected. In obstinate coughs, it is a favourite remedy with the poor.

GLE'CHON. Γληχων. Pennyroyal.

GLECHONI'TES. (From γληχων, penny-royal.) Wine impregnated with penny-royal.

Gleet. See *Blennorrhœa*.

GLE'NE. Γληνη. 1. The cavity or socket of the eye.

2. That cavity of a bone which receives another within it.

GLE'NOID. (*Glenoides*; from γληνη, a cavity, and ειδος, resemblance.) The name of some articular cavities of bones. The surface of the scapula, with which the head of the humerus is articulated, is called the glenoid cavity of the scapula.

GLEU'CINUM. (From γλευκος, must.) An ointment, in the preparation of which was must.

GLEU'XIS. (From γλευκυς, sweet.) A sweet wine.

GLI'ADINE. (From γλια, glue.) The name given by Taddey, an Italian chemist, to one of the constituents of vegetable gluten. See *Gluten*.

GLISCHRO'CHOLOS. (From γλισχρος, viscid, and χολη, the bile.) Viscid bilious excrement.

Glisson's capsule. See *Capsule of Glisson*.

Globate. See *Gland*.

GLOBOSUS. Globose; round. Applied to a root which is rounded, and gives off radicles in every direction; as that of the *Cyclamen europeum*: to the receptacle of the *Cephalanthus*, *Nauclea*, &c. from their form.

GLOBULA'RIA. (*a*, *æ*. f.; from *globus*, a globe: so called from the shape of its flower.) The French daisy.

GLOBULA'RIA ALYPUM. The leaves of this plant are used in some parts of Spain in the cure of the venerial disease. It is said to act also as a powerful but safe cathartic.

Globules of the blood. See *Sanguis*.

GLO'BUS. (*us*, *i*. m.) A ball.

GLOBUS HYSTERICUS. The air ascending in the œsophagus, and prevented by spasm from reaching the mouth, is so called because it mostly attends hysteria, and gives the sensation of a ball ascending in the throat. This globus, or feeling of a ball in the throat, is a very common annoyance to persons of a nervous temperament; and it is, with them and others, a common attendant, not only in hysterical, but also in nervous and hypochondriacal complaints. Fits of passion, both of anger, grief, and fear, produce it, and often to an extent that threatens suffocation. Many emotions of the mind, even in the strongest, whose minds were well regulated, give rise to this affection. Steadying the mind, cold water about the throat, and a small piece of ice, or very cold water in the mouth, generally relaxes the spasm, when an idiopathic disease. When symptomatic, the remedies of the primary disease are to be resorted to.

GLO'CHIS. (*is*, *inis*. f. Γλωχις, the point of a dart.) A pointed hair. A sharp point; a barbed point. Used, in *Botany*, to a bristle-like pubescence, which is turned backwards at its point into many straight teeth.

GLO'MER. (*er*, *eris*. n. A clue of thread.) A conglomerate gland.

GLO'MERATE. (*Glomeratus*; from *glomer*.) 1. In *Anatomy*, a gland is so called which is formed of a glomer of sanguineous vessels, having no cavity, but furnished with an excretory duct; as the lachrymal and mammary glands.

2. In *Botany*, it means congregated.

GLOME'RULUS. In *Botany*, a small tuft, or *capitulum*, mostly in the axilla of the peduncle. See *Capitulum*.

GLO'SSA. (*a*, *æ*. f. Γλωσσα, and γλωττα, the tongue.) See *Tongue*.

GLO'SSAGRA. (*a*, *æ*. f.; from γλωσσα, the tongue, and αγρα, a seizure.) A violent pain in the tongue.

Glosso-pharyngeal nerves. See *Nervous system*.

Glosso-pharyngeus. See *Constrictor pharyngeus superior*,

Glosso-staphylinus. See *Constrictor isthmi faucium*.

GLOSSOCA'TOCHOS. (From γλωσσα, tongue, and κατεχω, to hold.) An instrument in P. Ægineta for depressing the tongue. A spatula linguæ. The ancient glossocatochus was a sort of forceps, one of the blades of which served to depress the tongue, while the other was applied under the chin.

GLOSSOCE'LE. (*e*, *es*. f.; from γλωσσα, the tongue, and κηλη, a tumour.) An extrusion of the tongue.

GLOSSO'COMA. A retraction of the tongue.

GLOSSOCO'MION. (From γλωσσα, a tongue, and κομεω, to guard.) By this was formerly meant a case for the tongue for a hautboy; but the old surgeons, by metaphor, use it to signify an instrument, or case, for containing a fractured limb.

GLO'TTA. (Γλωττα, the tongue.) See *Glossa*.

GLO'TTIS. (*is*, *idis*. f.; from γλωττα, the tongue.) The superior opening of the larynx at the bottom of the tongue.

GLUCI'NA. (*a*, *æ*. f.; from γλυκυς, which signifies sweet, because it gives that taste to the salts in forms.) The name of an earth found in the beryl, a transparent stone of a green colour, and in the emerald of Peru. It is white, light, and soft to the touch; insipid, and adheres to the tongue; and is infusible by itself in the fire. Its specific gravity is 2·967. It is soluble in alkalies and their carbonates, and in all the acids except the carbonic and phosphoric, and forms with them saccharine and slightly astringent salts.

GLUCI'NUM. The metallic base of the earth *glucine*.

GLUE. (Γλια. *Gluten*, *inis*. n.; and *glutinum*, *i*. n.) An inspissated jelly made from the parings of hides and other offals, by boiling them in water, straining through a wicker basket, suffering the impurities to subside, and then boiling it a second time. Shreds or parings of vellum, parchment, or white leather, make a clear and almost colourless glue.

GLU'MA. (*Gluma*, *æ*. f.; *à glubendo*, a husk of corn.) The husk. The peculiar calyx of grasses and grass-like plants, of a chaffy texture, formed of little concave leaflets, which are called *valves*. To the husk belongs the *arista*, the *beard* or *awn*. See *Arista*. The gluma is,

1. *Univalve*, in *Lolium perenne*.
2. *Bivalve*, in most grasses.
3. *Trivalve*, in *Panicum miliaceum*.
4. *Many-valve*, in *Uniola paniculata*.
5. *Coloured*, otherwise than green; as in *Holcus bicolor*.

From the number of flowers the husk contains, it is called, —

1. *Gluma uniflora*, one-flowered; as in *Panicum*.
2. *Biflora*, with two; as in *Aira*.
3. *Multiflora*, having many; as in *Poa*, and *Avena*.

From the external appearance, the gluma is termed, —

1. *Glabrous*, smooth; as in *Holcus laxus*.
2. *Hispid*, bristly; as in *Secale orientale*.
3. *Striate*; as in *Holcus striatus*.
4. *Villose*; as in *Holcus sorgham*, *Holcus saccharatus*, and *Bromus purgans*.
5. *Ciliate*, fringed; as in *Bromus ciliatus*.
6. *Beardless*; as in *Briza* and *Poa*.
7. *Awned*; as in *Hordeum*.

GLUMO'SUS. Glumose. A flower is so called, which is aggregate, and has a glumous or husky calyx.

GLUTE'AL. *Glutealis*. Belonging to the buttocks.

GLUTEAL ARTERY. A branch of the internal iliac artery.

GLU'TEN. (*Quasi geluten*; from *gelo*, to congeal.) See *Glue*.

GLUTEN, ANIMAL. This substance constitutes the basis of the fibres of all the solid parts.

GLUTEN, VEGETABLE. If wheat flour be made into a paste, and washed in a large quantity of water, it is separated into three distinct substances.

1. A *mucilaginous saccharine matter*, which is readily dissolved in the liquor, and may be separated from it by evaporation.
2. *Starch*, which is suspended in the fluid, and subsides to the bottom by repose.
3. *Gluten*, which remains in the hand, and is tenaceous, very ductile, somewhat elastic, and of a brown-grey colour.

The first of these substances does not essentially differ from other saccharine mucilages. The second, namely, the starch, forms a gluey fluid by boiling in water, though it is scarcely, if at all, acted upon by that fluid when cold. Its habitudes and products with the fire, or with nitric acid, are nearly the same as those of gum and of sugar. It appears to be as much more remote from the saline state than gum, as gum is more remote from that state than sugar.

The gluten, though it existed before the washing in the pulverulent form, and has acquired its tenacity and adhesive qualities from the water it has imbibed, is nevertheless totally insoluble in this fluid. It has scarcely any taste. When dry, it is semitransparent, and resembles glue in its colour and appearance. If it be drawn out thin, when first obtained, it may be dried by exposure to the air; but if it be exposed to warmth and moisture while wet, it putrifies like an animal substance. The dried gluten, applied to the flame of a candle, crackles, swells, and burns, exactly like a feather, or piece of horn. It affords the same products by destructive distillation as animal matters do; is not soluble in alkohol, oils, or ether; and is acted upon by acids and alkalis, when heated. According to Rouelle, it is the same with the caseous substance of milk.

Taddey, an Italian chemist, has lately ascertained that the gluten of wheat may be decomposed into two principles, which he has distinguished by the names *gliadine* and *zimome*. They are obtained in a separate state by kneading the fresh gluten in successive portions of alkohol, as long as that liquid continues to become milky, when diluted with water. The alkohol solutions being set aside, gradually deposit a whitish matter, consisting of small filaments of gluten, and become perfectly transparent. Being now left to slow evaporation, the gliadine remains behind, of the consistence of honey, and mixed with a little yellow resinous matter, from which it may be freed by digestion in sulphuric ether, in which gliadine is not sensibly soluble. The portion of the gluten not dissolved by the alkohol is the zimome.

Properties of gliadine. — When dry, it has a straw-yellow colour, slightly transparent, and in thin plates, brittle, having a slight smell, similar to that of honeycomb, and, when slightly heated, giving out an odour similar to that of boiled apples. In the mouth it becomes adhesive, and has a sweetish and balsamic taste. It is pretty soluble in boiling alkohol, which loses its transparency in proportion as it cools, and then retains only a small quantity in solution. It forms a kind of varnish in those bodies to which it is applied. It softens, but does not dissolve, in cold distilled water. At a boiling heat it is converted into froth, and the liquid remains slightly milky. It is specifically heavier than water.

The alkoholic solution of gliadine becomes milky when mixed with water, and is precipitated in white flocks by the alkaline carbonates. It is scarcely affected by the mineral and vegetable acids. Dry gliadine dissolves in caustic alkalis and in acids. It swells upon red-hot coals, and then contracts in the manner of animal substances. It burns with a pretty lively flame, and leaves behind it a light spongy charcoal, difficult to incinerate. Gliadine, in some respects, approaches the properties of resins; but differs from them in being insoluble in sulphuric ether. It is very sensibly affected by the infusion of nutgalls. It is capable of itself of undergoing a slow fermentation, and produces fermentation in saccharine substances.

From the flour of barley, rye, or oats, no gluten can be extracted as from that of wheat, probably because they contain too small a quantity.

Properties of Zimome. — The residue of wheat, which is not dissolved by alkohol, is the zimome. If this be boiled repeatedly in alkohol, it is obtained pure.

Zimome thus purified has the form of small globules, or constitutes a shapeless mass, which is hard, tough, destitute of cohesion, and of an ash-white colour. When washed in water, it recovers part of its viscosity, and becomes quickly brown, when left in contact with the air. It is specifically heavier than water. Its mode of fermenting is no longer that of gluten; for, when it purifies, it exhales a fetid urinous odour. It dissolves completely in vinegar, and in the mineral acids at a boiling temperature. With caustic potash it combines, and forms a kind of soap. When put into lime water, or into the solutions of the alkaline carbonates, it becomes harder, and assumes a new appearance without dissolving. When thrown upon red-hot coals, it exhales an odour similar to that of burning hair or hoofs, and burns with flame.

Zimome is to be found in several parts of

vegetables. It produces various kinds of fermentation, according to the nature of the substance with which it comes in contact.

GLUTE'US. (From γλουτος, the buttocks.) The name of some muscles, arteries, &c. of the buttocks.

Gluteus maximus. *Gluteus magnus*, of Albinus. *Glutæus major*, of Cowper. A broad radiated muscle, on which we sit, is divided into a number of strong fasciculi, is covered by a pretty thick aponeurosis derived from the *fascia lata*, and is situated immediately under the integuments. It arises fleshy from the outer lip of somewhat more than the posterior half of the spine of the ilium, from the ligaments that cover the two posterior spinous processes; from the posterior sacroischiatic ligament; and from the outer sides of the os sacrum and os coccygis. From these origins the fibres of the muscle run towards the great trochanter of the os femoris, where they form a broad and thick tendon, between which and the trochanter there is a considerable *bursa mucosa*. This tendon is inserted into the upper part of the *linea aspera*, for the space of two or three inches downwards; and sends off fibres to the fascia lata, and to the upper extremity of the vastus externus. This muscle serves to extend the thigh, by pulling it directly backwards; at the same time it draws it a little outwards, and thus assists in its rotatory motion. Its origin from the coccyx seems to prevent that bone from being forced too far backwards.

Gluteus medius. The posterior half of this muscle is covered by the gluteus maximus, which it greatly resembles in shape; but the anterior and upper part of it is covered only by the integuments, and by a tendinous membrane which belongs to the fascia lata. It arises fleshy from the outer lip of the anterior part of the spine of the ilium, from part of the posterior surface of that bone, and likewise from the fascia that covers it. From these origins its fibres run towards the great trochanter, into the outer and posterior part of which it is inserted by a broad tendon. Between this tendon and the trochanter there is a small thin *bursa mucosa*. The uses of this muscle are nearly the same as those of the gluteus maximus; but it is not confined, like that muscle, to rolling the os femoris outwards, its anterior portion being capable of turning that bone a little inwards. As it has no origin from the coccyx, it can have no effect on that bone.

Gluteus minimus. *Glutæus minor*, of Albinus and Cowper. A radiated muscle, is situated under the gluteus medius. In adults, and especially in old subjects, its outer surface is usually tendinous. It arises fleshy between the two semicircular ridges we observe on the outer surface of the ilium, and likewise from the edge of its great niche. Its fibres run, in different directions, towards a thick flat tendon, which adheres to a capsular ligament of the joint, and is inserted into the fore and upper part of the great trochanter. A small *bursa mucosa* may be observed between the tendon of this muscle and the trochanter. This muscle assists the two former in drawing the thigh backwards and outwards, and in rolling it. It may likewise serve to prevent the capsular ligament from being pinched in the motions of the joint.

GLU'TIA. (From γλουτος, the buttock.) The buttocks.

GLUTINOUS. *Glutinosus*. Having the properties of gluten.

Gluttony. See *Bulimia*.

Gluttu'patens. (From *gluttus*, the throat, and *pateo*, to extend.) The stomach, as being an extension of the throat. A barbarous term.

GLU'TUS. (*us*, *i*. m. Γλουτος; from γλοιος, filthy.) The buttock. See *Nates*.

Glyca'sma. (From γλυκυς, sweet.) A sweet medicated wine.

Gly'cerine. (From γλυκυς, sweet.) The sweet principle of oils. See *Adeps*.

Glycypi'cros. (From γλυκυς, sweet, and πικρος, bitter: so called from its taste.) See *Solanum dulcamara*.

GLYCYRRHI'ZA. (*a*, *æ*. f.; from γλυκυς, sweet, and ῥιζα, a root.) 1. The name of a genus of plants in the Linnæan system. Class, *Diadelphia*; Order, *Decandria*.

2. The pharmacopœial name of liquorice. See *Glycyrrhiza glabra*.

Glycyrrhiza echinata. This species of liquorice is substituted in some places for the *glabra*.

Glycyrrhiza glabra. The systematic name of the officinal liquorice, *Glycyrrhiza — leguminibus glabris, stipulis nullis, foliolo impari petiolato*, of Linnæus. A native of the south of Europe, but cultivated in Britain. The root contains a great quantity of saccharine matter, joined with some proportion of mucilage, and hence it has a viscid sweet taste. It is in common use as a pectoral or emollient, in catarrhal defluxions on the breast, coughs, hoarsenesses, &c. Infusions, or the extract made from it, which is called *Spanish liquorice*, afford likewise very commodious vehicles for the exhibition of other medicines; the liquorice taste concealing that of unpalatable drugs more effectually than syrups or any other matters of a purely saccharine taste.

Glycyrrhizine. The saccharine juice of liquorice has been so called.

Glycysa'ncon. (From γλυκυς, sweet, and αγκων, the elbow: so called from its sweetish taste, and its inflections, or elbows, at the joints.) A species of southernwood. — *Turton*.

Glyster. See *Enema*.

GNAPHA'LIUM. (*um*, *i*. n.; from γναφαλον, the wool of the teasel: so named from its soft downy surface.) 1. The name of a genus of plants in the Linnæan system. Class, *Syngenesia*; Order, *Polygamia superflua*.

2. The pharmacopœial name of the herb cotton-weed. See *Gnaphalium dioicum*.

Gnaphalium arenarium. The flowers of this plant, as well as those of the gnaphalium stœchas, are called, in the Pharmacopœias, *flores elichrysi*. See *Gnaphalium stœchas*.

Gnaphalium dioicum. The systematic name of the *pes cati*. *Gnaphalium albinum*. Cotton

weed. The flores gnaphalii of the Pharmacopœias, called also, *flores hispidulæ*, *seu pedes cati*, are the produce of this plant. They are now quite obsolete, but were formerly used as astringents, and recommended in the cure of hooping-cough, phthisis pulmonalis, and hæmoptysis.

Gnaphalium stœchas. The systematic name of Goldilocks; called also, *Elichrysum; Stœchas citrina*. The flowers of this small downy plant are warm, pungent, and bitter, and said to possess aperient and corroborant virtues.

Gna'thus. (From γναπτω, to bend: so called from their curvature.) 1. The jaw, or jaw-bones.

2. The cheek.

Goat. See *Capra hircus.*

Goat's-beard, grey. See *Clavaria cinea.*

Goat's-beard mushroom. See *Clavaria coralloides.*

Goat's-rue. See *Galega.*

Goat's-thorn. See *Astragalus verus.*

Goat-weed. See *Ægopodium.*

Gobio. See *Cyprinus gobio.*

Godbold's vegetable balsam. A nostrum, consisting chiefly of simple oxymel.

Godfrey's cordial. A quack medicine, made by infusing sassafras ℥ ix., seeds of carraway, coriander, and anise, of each ℥ j., in six pints of water; simmering the mixture till reduced to four pints, then adding six pounds of treacle, boiling the whole for a few minutes, and adding three ounces of tincture of opium.

Godfrey's smelling salts. These are prepared by re-subliming the common subcarbonate of ammonia with pearlash, and a portion of strong alkohol.

Goitre. See *Bronchocele.*

Gold. See *Aurum.*

Gold-cup. See *Ranunculus.*

Golden maidenhair. See *Polytrichum.*

Golden rod. See *Solidago.*

Goldilocks. See *Gnaphalium.*

Gomphi'asis. *Gomphiasmus.* Incorrectly written for *agomphiasis.* See *Agomphiaris.*

Gomphia'smus. See *Gomphiasis.*

GO'MPHIOI. (From γομφος, a nail: so called because they are as nails driven into their sockets.) The dentes molares, or grinding teeth.

Gompho'ma. See *Gomphosis.*

GOMPHO'SIS. (*is, is.* f. Γομφωσις; from γομφοω, to drive in a nail.) *Gomphoma.* A species of immoveable connection of bones, in which one bone is fixed in another, like a nail in a board; as the teeth in the alveoli of the jaws.

GO'NAGRA. (*a, æ.* f.; from γονυ, the knee, and αγρα, a seizure.) The gout in the knee.

Gona'lgia. See *Gonyalgia.*

GONGRO'NA. (*a, æ.* f. Γογγρωνα; from γογγρος, a knot in the bark of a tree.) Hippocrates applies this term to any hard round tumour in tendinous parts. Galen tells us it was also applied in particular to a bronchocele.

Go'ngyle. (Γογγυλη; from γογγυλος, round.) The turnip cabbage, the root of which is globular.

Gongy'lion. (*um, ii.* n. Γογγυλιον; from γογγρυλος, round.) A pill.

GONIO'METER. (From γωνια, an angle; and μετρον, a measure.) An instrument for measuring angles, especially those of crystals.

Gonoi'des. (From γονη, seed, and ειδος, form.) Resembling the semen.

GONORRHŒ'A. (*a, æ.* f.; from γονη, the semen, and ῥεω, to flow.) 1. A flow or discharge of semen. This is also called *spermatorrhœa.* As a disease, it is an involuntary emission of the seminal fluid without copulation. It is mostly caused by an indulgence of libidinous ideas, sometimes with an erection of the penis, and sometimes without. During the vigorous state of youth, with strong passions, it is not uncommon. This is the *oncirogonos*, and *gonorrhœa dormientium*, of authors. If it takes place in strong and vigorous constitutions, and especially from a superabundant secretion of seminal fluid, the best remedies are blood-letting and purgatives, with a low and abstemious diet, and regular exercise. Another cause of this malady is the very opposite to the former. Here the constitution is evidently in a relaxed state, and the fluid that is emitted is thin or pellucid, and consists either of a morbid secretion from the testes, or an admixture of a thin fluid furnished by the vesiculæ seminales: this is the *gonorrhœa laxorum;* and requires that sexual intercourse should be forbidden, and the system invigorated by cold sea-bathing, local bathing with a bidet, chalybeate medicines, bark and zinc, with the occasional use of blisters to the perinæum. Cantharides have been given internally with advantage, after a due attention to the state of the system.

Both species are occasionally produced sympathetically from other diseases, as stricture of the urethra, stone in the bladder, &c.; and then, of course, attention must be given to the removal of the primary affection.

2. When the venereal disease became known, that form of it which consists in a purulent discharge from the urethra, was named gonorrhœa, from the erroneous notion that the discharge consisted of semen; and this name is still generally retained to denote a purulent discharge from the urethra, which is called *gonorrhœa benigna*, when supposed to arise from irritation, unconnected with venereal contamination, and *gonorrhœa virulenta, maligna*, or *venerea*, when it arises from the application of the venereal virus. See *Urethrites.*

Gonorrhœa balani. A gonorrhœal discharge, affecting the glans penis only.

Gonorrhœa dormientium. See *Gonorrhœa.*

Gonorrhœa virulenta. See *Gonorrhœa.*

GONYA'LGIA. (*a, æ.* f.; from γονυ, the knee, and αλγος, pain.) *Gonialgia. Genalgia.* Pain in the knee.

Goose. See *Anser domesticus.*

Goose-foot. See *Chenopodium.*

Goose-grass. See *Galium aparine.*

GO'RDIUS. (*us, i.* m.) The name of a genus of animals of the class *Annelides*, and order *Abranchia.*

Gordius aquaticus. The hair-tail worm, or *Seta equina*, found in stagnant marshes and ditches in Lapland, and other places.

Gordius medinensis. See *Filaria medinensis.*

GO'RGET. The name given to an instrument used in the operation of lithotomy. Gorgets are of two kinds, *cutting* and *blunt*. The cutting gorget is a kind of knife, furnished with a beak, which runs in the groove of the staff, so that the gorget being pushed along it, divides the neck of the bladder and the prostate gland. The blunt gorget is merely a sort of large directory for guiding the forceps into the bladder. The gorget is now seldom used; the cutting one being superseded by a simple knife, and the blunt one by the use of the finger.

GORGO'NIA. (*a*, *æ*. f.) The name of a genus of corals.

Gorgonia anti'pathes. *Antipathes*. Black coral. Formerly used in epilepsy.

GOSSY'PIUM. (*um*, *ii*. n.; from the Egyptian *gotne*, whence *gottipium*, and *Gossypium*.) 1. The substance called cotton.

2. The name of a genus of plants in the Linnæan system. Class, *Monadelphia*; Order, *Polyandria*.

Gossypium herbaceum. The systematic name of the cotton-plant: called also, *Bombyx. Gossypium — foliis quinquelobis subtus eglandulosis, caule herbaceo*, of Linnæus. It is an herbaceous plant, with bitriennial stems, growing from four to six feet high. It is cultivated in vast abundance in India, and grows also in China, Egypt, and other tropical countries. The seeds are directed for medicinal use in some foreign pharmacopœias; and are administered in coughs, on account of the mucilage they contain. The capsules contain many seeds, enveloped in the well-known substance called cotton, which sometimes adheres very firmly to them, and at others is easily detached. Cotton is produced by many species and varieties of Gossypium besides the above, and is cultivated in Asia, America, Africa, and the south of Europe.

Go'tium. A goitre. See *Bronchocele*.

Goulard's cerate. The *Ceratum plumbi compositum*.

Goulard's extract. A saturated solution of acetate of lead. See *Plumbi acetatis liquor*.

Gourd. See *Cucurbita*.

Gourd, bitter. See *Cucumis colocynthis*.

GOUT. (This word is derived from the French *goute*; the origin of which, Dr. Good says, is almost forgotten. Most diseases, he observes, attended by tumefaction, were ascribed, by the ancients, to a flow of some morbid fluid or humour to the affected part, which was called a rheum or defluxion; and the rheum or defluxion was denominated hot, cold, acrid, saline, or viscid, according to the nature of the symptoms. The Arabian writers ascribed even this cause to various diseases of the eyes, which were called gutta serena and gutta obscura, "clear or cloudy drops or defluxions," according to the external appearance. Hence gutta, goute, or gout, means a defluxion of morbid humour to the part; as rheumatism also does.) Several names are given to this disease, according to the part affected; as *arthritis*, *podagra*, *chiragra*. It has also been called *dolor podagricus*, *febris podagrica*, &c. It is characterised by pain in the joints, chiefly of the great toe, or, at any rate, chiefly of the feet and hands, returning at intervals, with more or less of swelling, and redness of the skin; the functions of the stomach being most disturbed previous to the attack.

It is a very painful disease, preceded usually by flatulency and indigestion, and accompanied by fever, pains in the joints of the hands and feet, particularly in that of the great toe, and which returns by paroxysms, occurring chiefly in the spring and beginning of winter. The only disorder for which the regular gout can possibly be mistaken, is the rheumatism; and cases may occur wherein there may be some difficulty in making a just discrimination: but the most certain way of distinguishing them will be, to give due consideration to the predisposition in the habit, the symptoms which have preceded, the parts affected, the recurrences of the disease, and its connexion with other parts of the system. It most frequently attacks the male sex, particularly those of a corpulent habit and robust frame; but every now and then we meet with instances of it in robust females. Those who are employed in constant bodily labour, or who live much upon vegetable food, as likewise those who make no use of wine or other fermented liquors, are seldom afflicted with the gout. The disease seldom appears at an earlier period of life than from five-and-thirty to forty; and, when it does, it may be presumed to arise from an hereditary disposition. Indolence, inactivity, and too free a use of tartareous wines, fermented liquors, and animal food, are the principal causes which give rise to the gout; but it may likewise be brought on by great sensuality, and excess in venery, intense and close application to study, long want of rest, grief or uneasiness of mind, exposure to cold, too free a use of acidulated liquors, a sudden change from a full to a spare diet, the suppression of any accustomed discharge, or by excessive evacuations; and that it sometimes proceeds from an hereditary disposition, is beyond all doubt, as females who have been remarked for their great abstemiousness, and youths of a tender age, have been attacked with it.

Most nosologists divide it into four species, the regular, the atonic, the retrocedent, and the misplaced, or shifting.

1. The *regular Gout*. — A paroxysm of regular gout sometimes comes on suddenly, without any previous warning; at other times it is preceded by an unusual coldness of the feet and legs, a suppression of perspiration in them, and numbness, or a sense of prickling along the whole of the lower extremities; and with these symptoms the appetite is diminished, the stomach is troubled with flatulency and indigestion, a degree of torpor and languor is felt over the whole body, great lassitude and fatigue are experienced after the least exercise, the body is costive, and the urine pallid. On the night of the attack, the patient perhaps goes to bed in tolerable health, and, after a few hours, is awaked by the severity of the pain, most commonly in the first joint of the great toe; sometimes, however, it attacks other parts of the

foot, the heel, calf of the leg, or perhaps the whole of the foot. The pain resembles that of a dislocated bone, and is attended with the sensation as if cold water was poured upon the part; and this pain becoming more violent, is succeeded by rigors and other febrile symptoms, together with a severe throbbing and inflammation in the part. Sometimes both feet become swelled and inflamed, so that neither of them can be put to the ground; nor can the patient endure the least motion without suffering excruciating pain. Towards morning, he falls asleep, and a gentle sweat breaks out, and terminates the paroxysm, a number of which constitutes what is called a fit of the gout. The duration of the fit will be longer or shorter, according to the disposition of the body to the disease, the season of the year, and the age and strength of the patient. When a paroxysm has thus taken place, although there is an alleviation of pain at the expiration of some hours, still the patient is not entirely relieved from it; and, for some evenings successively, he has a return both of pain and fever, which continue, with more or less violence, until morning. The paroxysms, however, prove usually more mild every day, till at length the disease goes off either by perspiration, urine, or some other evacuation; the parts which have been affected becoming itchy, the cuticle falling off in scales from them, and some slight degree of lameness remaining. At first an attack of gout occurs, perhaps, only once in two or three years; it then probably comes on every year, and at length it becomes more frequent, and is more severe, and of longer duration, each succeeding fit. In the progress of the disease, various parts of the body are affected, and translations take place from one joint, or limb, to another; and after frequent attacks, the joints lose their strength and flexibility, and become so stiff as to be deprived of all motion. Concretions, of a chalky appearance, are likewise formed upon the outside of the joints, and nephritic affections of the kidneys arise from a deposit of the same kind of matter in them, which, although fluid at first, becomes gradually dry and firm. This matter is partly soluble in acids, but without effervescence; and Dr. Wollaston discovered it not to be carbonate of lime, but a compound of the uric or lithic acid and soda.

2. *Atonic Gout.* — It sometimes happens that, although a gouty diathesis prevails in the system, yet from certain causes, no inflammatory affection of the joints is produced; in which case, the stomach becomes particularly affected, and the patient is troubled with flatulency, indigestion, loss of appetite, eructations, nausea, vomiting, and severe pains; and these affections are often accompanied with much dejection of spirits, and other hypochondriacal symptoms. In some cases, the head is affected with pain and giddiness, and now and then with a tendency to apoplexy; and in other cases, the viscera of the thorax suffer from the disease, and palpitations, faintings, and asthma, or pectoral anginea arise. This is what is called atonic gout. A great variety of anomalous symptoms are referable to the same source.

3. *Podagra retrograda.* — Retrocedent gout. It sometimes happens that, after the inflammation has occupied a joint, instead of its continuing the usual time, and so going off gradually, it ceases suddenly, and is translated to some internal part. The term retrocedent gout is applied to occurrences of this nature. When it falls on the stomach, it occasions nausea, vomiting, anxiety, or great pain; when on the heart, it brings on syncope; when on the lungs, it produces an affection resembling asthma; and, when it occupies the head, it is apt to give rise to apoplexy, or palsy.

4. *Misplaced Gout,* is when the gouty diathesis, instead of producing the inflammatory affection of the joints, occasions an inflammatory affection of some internal parts, and which appears from the same symptoms that attend the inflammation of those parts from other causes. All occurrences of this nature, as well as of the two former, are to be regarded as attacks of irregular gout, and are to be guarded against as much as possible.

Besides the more easily recognised forms of gout, there is no doubt that the gouty diathesis gives rise to a specific inflammation of various membranous parts. This is exemplified in the gouty form of iritis. (See *Iritis.*) It appears also to exert, occasionally, a pernicious influence on the nervous system; and Beer admits a distinct form of gouty *amaurosis.* See *Amaurosis.*

In attempting the cure of this disease, our attention must be directed to the paroxysm, and to the management during its absence; and particularly to the state of the constitution and previous habits, which may demand different and opposite plans.

Treatment of the paroxysm of a regular fit of Gout. — From the belief that a regular fit of gout was an effort of nature to throw off some peccant humour which formed the essence of the disease, it was formerly left to itself, or perhaps encouraged to proceed through its course without interruption. This opinion is now abandoned, and the practice is to endeavour to subdue the paroxysm by the ordinary means resorted to in inflammations of any other kind; as bleeding, purgatives, sudorifics, local astringents, refrigerants, &c., so managed as to prevent any danger of repelling the gout to some internal organ, and thus converting a regular paroxysm into a retrograde or atonic gout. Sydenham prohibited purging and sweating, and only allowed bleeding in young and vigorous constitutions, during the first or second paroxysm. He admits of the use of laudanum, where the pain is acute; and he trusts chiefly for the cure of the disease to an alterative regimen, and apozems to be resorted to in the intervals. Dr. Cullen allows bleeding, with the same restrictions as Sydenham, though he recommends the application of leeches to the part, as at all times a safer practice than the use of the lancet. Of cathartics and sudorifics he takes no notice, otherwise than as these may enter into the general course of an antiphlogistic plan: he is decidedly averse to the use of cold, and thinks that warm bathing and emol-

lient poultices, blistering, burning with moxa, camphorated and aromatic oils, induce the inflammation to shift from one part to another, and consequently tend to repel the inflammation from the extremities to some more important part; while opium, though it affords relief in present paroxysms, occasions them to return with greater violence; and therefore he observes, by way of conclusion, "The common practice of committing the person to patience and flannel alone, is established upon the best foundation." Now, says Dr. Good, as the gout, after it has shown itself in paroxysms, is never idle; and as one paroxysm, in the opinion of Sydenham, Cullen, and every other physician, hastens on another, renders its intervals shorter, and its duration longer; and progressively saps all the energies both of mind and body, and renders life itself a burden, it is of serious importance to enquire whether this fear of a repulsion, however well founded in some instances, is not allowed too generally? whether it be not possible to draw a definite line between the form of the disease in which it ought to operate, and that in which it ought not? and whether, in the latter case, we may not derive all the benefit from a full use of a reducing process, which is obtained in other inflammations, accompanied with a like degree of constitutional vigour?

From the history of gout, we may draw this general corollary: that when once excited by some occasional cause into action, it has a peculiar tendency to fix and expand itself upon the weakest parts of the system; and, where several parts are equally weak, to pass in sudden transitions from one part to another, though transitions are rare where the system is sound.

In healthy constitutions, the weakest parts are the extremities; and hence, in such constitutions, these are the parts in which the gout uniformly opens its assault.

In unhealthy habits, however, the extremities are not the weakest parts of the system, but perhaps the stomach, or the heart, or the head, or the lungs, or some other organ; while several of these organs may, moreover, be equally debilitated, according to the idiosyncrasy, or to accidental circumstances. And true to the general, rule the gouty principle, when roused into action in habits of this kind, fixes itself from the first on one of those important viscera rather than on the extremities; or roaming from one to another, on its alternating its course from these organs to the extremities, or from the extremities to these organs. And as metastases are rare where the system is sound, they become frequent in proportion as it loses its character, and especially in proportion to its debility in particular parts.

These are rules which cannot be too closely studied and committed to memory, and they seem to point out the line of distinction between that form of the disease in which a prudent fear of revulsion ought to be entertained, and that in which we may safely act without any such fear whatever. They directly lead us to two states of constitution that require a very different, and in many instances a very opposite, mode of treatment; and seem to settle the important question before us, under what circumstances it may be expedient to employ a palliative plan, and under what a cooling and reductive.

We shall commence with the first of these two states, forming a regular but violent fit of gout as it shows itself in a sound constitution, and inflicts its torture on the hand or the foot. Guiding ourselves by the laws just laid down, there seems no reason why, instead of "committing the person to patience and flannel alone," we should not pursue the evacuating and refrigerant means employed in active inflammations of any other kind, and have cause to expect a like success: such as bleeding, so strongly recommended by Dr. Heberden, and allowed occasionally by Sydenham, and emptying the bowels, relaxing the skin generally, and cooling the fiery heat of the affected limb by cold water, or any other frigorific application. With a transfer of morbific matter we have now no longer to contend. Yet, even where such a cause is admitted, as in most exanthemata, the plan thus proposed is, in many instances, pursued without hesitation.

In weakly habits or idiosyncrasies, or incidental debilities of particular organs, a metastasis is a frequent result, and peculiarly marks the character of gouty inflammation; and here refrigerants, violent purgatives, and venesection ought to be most sedulously abstained from; and the best practice is that of "committing the person to patience and flannel alone."

The inflammation of a regular fit of gout subsides gradually, though rapidly, under the treatment now proposed, without any repulsion whatever. Yet, in a few instances, it has seemed to be repelled in part, whilst it has chiefly passed off by resolution.

The use of local refrigerants is by no means of modern invention, however it may have become a subject of warm controversy in the present day. The application of cold water is recommended by Hippocrates and other Greek writers, by Celsus; by many more modern authors, as Camerarius, Zacutus Lusitanus, Kolhaas, and Keck. Bartholine speaks of the use of snow as a common application in 1661, and Pechlin, both of snow and cold sea-water towards the close of the same century. Heberden approved highly of the use of cold water, which has also received the more recent recommendation of Drs. Kinglake and Mason Good.

But this treatment has often been employed rashly, and sometimes with great and even fatal mischief. It ought never to be ventured upon except, as already stated, where the constitution is decidedly sound and vigorous.

Leeches may, in many instances, be applied where venesection would be of doubtful expedency. A liniment of oil of almonds, impregnated with opium, rubbed on the tumefaction with a protracted and very gentle friction, is often found very serviceable in mitigating the pain; and epithems of tepid water, as recommended by Dr. Scudamore, alone, or mixed with a portion of æther or alkohol, formed by cloths wetted with the fluid, and applied to the inflamed part, renewable as they become dry, in many

cases prove a grateful substitute for cold water; and are preferable to poultices, warm water, or even vapour-baths, which too generally relax and weaken the joint, and prevent it from recovering its elasticity, after the paroxysm is over, so soon as it otherwise would do.

At the same time, the body should be cooled with gentle aperients or injections; and while drenching sweats are avoided, which never fail to be injurious, the breathing moisture should be imitated, which often breaks forth naturally in an early part of the morning, and is sure to afford relief after a night of distraction. Nor should opium be omitted where the pain is very acute; for, while it affords temporary ease, it diminishes the duration as well as the violence of the paroxysm.

The regimen should be light and inirritant, and the diet below the standard to which the patient has been accustomed; though, to guard against a metastasis to the stomach, we must be cautious that we do not reduce it too much. His chamber should be well ventilated, and his dress light and easy.

In the varieties, constituting atonic and retrocedent gout, there is a podagric diathesis grafted upon an unsound frame; the unsoundness being general or local: and, however fearless we may be of the disease fixing on any internal organ in the preceding variety, we have here a constant apprehension that it may do so, and in many cases see it commence in such organs.

In atonic gout, our uniform attempt should be to produce a transfer from the part on which it has seized, and fix it in the extremities: in retrocedent gout, on the contrary, to render the vacillating attack on the extremities more permanent, and prevent it from shifting to any other quarter.

To obtain the first intention, we have to strengthen and even stimulate the system generally by warm tonics and a generous diet, and, above all things, to take off the severe suffering, in whatever it may consist, from the affected organ: for the longer the fit continues there, the weaker it will become, and the less capable of any instinctive remedial exertion. At the same time we may solicit the paroxysm to the extremities by putting the feet into warm water, and thus unstringing the tone of their vessels; so as to bring the standard of their atony below that of the affected organ.

In atonic gout, the sufferings, though widely different according to the seat of the disease, are almost insupportable. In the head the pain is maddening, or the disorder is accompanied with great horror, or mimics the stupor of an apoplexy: in the stomach there is a faintness like that of death, with the sense of a cold lump of lead lodged within it; or there is a gnawing or a burning agony, or a spasmodic stricture which seems to cut the body in two, and renders breathing almost impossible; often, also, accompanied with a rapid and sinking palpitation of the heart.

It is of importance to determine accurately that these anomalous symptoms are really those of gout; of which we have chiefly to judge from the general character of the patient's constitution, his hereditary predisposition, habits of life, and the ailments to which he has been previously subject. In most cases, too, during the paroxysm, and especially where the stomach is affected, the warmest cordials are necessary: as brandy, the aromatic spirit of ammonia, the tincture of ginger or of capsicum, or, what is still better, usquebaugh. And it is always advantageous, and especially where the bowels are confined, to add to it some warm aperient, as aloes or rhubarb. Most of the family gout-cordials are made upon this principle, and judiciously consist of some active aperient and the hottest aromatics, dissolved in ardent spirits. And the patient, who is subject to these attacks, should never be without having something of this kind at hand, since the paroxysm often makes its onset without any warning. Yet he should resolutely forbear having recourse to any such medicine, except in the time of necessity: for an habitual indulgence in any of them will still farther debilitate the affected organ, and indeed the entire system; and hence quicken the returns of the paroxysm, and render the antidote less availing. Most of the preparations of ether may be employed with benefit in the variety before us, and particularly in that icy coldness of the stomach, accompanied with a numbness of the limbs and a rapid palpitation of the heart, under which it occasionally exhibits itself. External irritants may also be beneficially employed at the same time, and particularly those of rapid action, as the compound camphire liniment, and sinapisms: at the same time the extremities should be plunged into the warm bath. But our sheet-anchor is opium; and it should be given freely, and in union with some preparations of antimony, so as to act towards the surface generally, and thus restore to the living power its interrupted equilibrium.

In retrocedent gout the same plan is to be pursued, where the attack has actually shifted from the feet or hands to some internal organ.

In gout, the *intervals of this disease* are of as much importance to be attended to as its paroxysms: and here, also, the mode of management under the first form should differ essentially from that under the second; for though the occasional causes may, in many cases, be the same, they have in the former to operate upon a vigorous scale of power, and in the latter, upon a scale decidedly reduced.

In every variety, all known occasional causes must be equally avoided. Where the diet has been too rich, it must be lowered; and where too spare and abstemious, made more liberal. Indolence and a sedentary life must give way to regular exercise; and over-exertion of body or mind, to repose and quiet. In the young, robust, and corpulent, whether the disease result from too great indulgence at the table, or an habitual taint, it may be requisite to abstain from animal food, wines, and fermented liquors altogether; but where the sufferer has passed considerably beyond the zenith of life, and the luxuries of the table have become habitual, his ordinary fare should be reduced or diminished, rather than entirely commuted. And in every change, it is better to proceed slowly, than to

rush rapidly from one extreme to another: since nothing has so great a tendency to prepare the internal organs for gouty paroxysms, as such sudden and violent transitions. The bowels should be kept in regular order, and the hour of rest be early.

A due and unswerving attention to these general rules of the hygiene, will often be sufficient to keep those free from all disturbance of the gout for many years, and perhaps for the whole of their subsequent life, who have only known it in the form of a few regular paroxysms. But where the system, and especially the digestive function, is weak, and the patient has had anticipations of a tonic or recedent gout, or has actually suffered from its assaults, it will be necessary to superadd a course of *invigorating medicines*.

There are three classes of remedies that generally pass under this name: stimulants, bitters, and astringents. The first increase the action, the two last augment the tone. Stimulants can rarely be employed alone, except in cases of emergency; for a lax state of fibres will bear little increase of action without, at the same time, suffering an equal increase of debility. But they may often, and in the case of gout perhaps always, be combined with astringents and bitters with great and decisive benefit.

Most of the celebrated specifics for preventing a return of gout, have been formed of these classes of medicines in combination, and especially of bitters and aromatics: and it is singular that, although the variety of them which nature offers to us is almost infinite, they have been employed with little change from the time of Galen and Cælius Aurelianus, in the second century, to that of Sydenham, in the seventeenth.

There have, in all ages, been offered to the public, specifics for the sudden cure or removal of the paroxysm when present, as well as for preventing its return hereafter. Lucian, in his Tragopodagra, gives us, with great humour, a list that occupies a page of such as were chiefly in vogue in his day; and the catalogue is certainly not diminished in our own. Those that have acquired the highest reputation, appear to have been composed of some species of hellebore, or of meadow-saffron; the first of which is among the remedies quoted by Lucian, though it is probable that the ῥίζα ἐλλεβορου of the Greeks belonging to a different plant from either the white or black hellebore of modern dispensatories.

The favourite specifics of the present day are M. Husson's *Eau médicinale*, and the *Vinum colchici*, or wine of meadow-saffron, introduced in the current Pharmacopœia of the London College. The exact components of the former are kept a secret; though its basis is now universally believed to be either the root or some other part of the meadow-saffron. The effects of the Eau médicinale and of the colchicum wine, do not essentially differ; for, after taking about sixty drops of either, the pulse becomes slower, and at length sinks, in about twelve hours, from ten to twenty strokes in a minute below its natural number, at which time the inflammation subsides. The action of both medicines is accompanied with great languor, and a deadly nausea or sickness, which terminates in vomiting, or a discharge from the bowels, or both. If the dose be in a small degree in excess, the symptoms are syncope, cold sweat, extreme prostration of strength, violent vomiting and purging, a wiry and almost imperceptible pulse, or a state of utter and very alarming insensibility. And, in some constitutions, these effects have followed from the use of even a common dose. So that these preparations seem to be rather stronger drugged than the celebrated oxymel colchici of Stoerck.

It is possible that the colchicum may act by a specific power on the peculiar inflammation of a regular fit; yet as other intestinal irritants have occasionally produced a like effect, and particularly the *Gratiola officinalis* and *Ranunculus flammula*, the disappearance of the paroxysm may also be ascribed to a transfer of action to the stomach and intestines. Generally speaking, specifics operate by a secret and inexplicable power, as the bark in intermittents, the vaccine virus in shielding the constitution against small-pox, and mercury in syphilis: for though a ptyalism gives proof that the system is impregnated with the last, there are few practitioners so attached to the Cullenian doctrine in the present day, as to contend that the venereal virus is carried off by the salivation, since we are perpetually beholding it carried off under the influence of mercury without any salivation whatever.

Admitting yet, that the colchicum has a specific power over a regular inflammatory paroxysm of gout, it is clear that it has no such power over the gouty diathesis, since the paroxysm has never been so removed as not to return again. And hence it is a matter of reasonable discussion, whether the constitution is not liable to suffer from the sudden resolution of the local inflammation, and whether, by the exhibition of the colchicum, the returns of the paroxysm may not be increased in frequency, while they are diminished in duration. The general impression among practitioners in the present day seems, however, to be favourable to the use of colchicum.

From the rapidity and force of its operation, it is clear that it ought never to be tried, except in the first variety of gout, or where the system is firm and healthy, and the disorder shows itself in a regular fit. And as it is highly desirable to restrain the violence of the paroxysm, shorten its duration, and carry it off as soon as possible, the use of the colchicum may be judicious so long as the system is able to recover itself readily from its influence, and provided the patient limits himself to the smallest dose that will answer the purpose.

Gout-stone. See *Chalk-stone*.

Gout-weed. See *Ægopodium*.

Gouttes d'or du General Lamotte. De Lamotte's golden drops. A medicine prepared by dissolving nitrate of gold in alkohol. It has gained great reputation in gout and nervous diseases, in which, however, there is no reason to believe that it possesses any real efficacy.

Gouty amaurosis. See *Amaurosis.*

Gouty concretions. See *Gout.*

Gouty iritis. See *Iritis.*

GOWLAND'S LOTION. This is made by triturating an ounce of bitter almonds, and two ounces of sugar, with two pounds of distilled water; then adding to the strained liquor two scruples of corrosive sublimate, previously ground with two drachms of rectified alkohol. It is used in obstinate cutaneous diseases.

GRA'CILIS. (So named from its slenderness.) *Rectus interior femoris, sive gracilis interior,* of Winslow. A long, straight, and slender muscle of the thigh, situated immediately under the integuments, at the inner part. It arises, by a broad and thin tendon, from the anterior part of the ischium and pubis, and soon becoming fleshy, descends nearly in a straight direction along the inside of the thigh. A little above the knee, it terminates in a slender and roundish tendon, which afterwards becomes flatter, and is inserted into the middle of the tibia, behind and under the sartorius. Under the tendons of this and the rectus there is a considerable *bursa mucosa,* which on one side adheres to them and to the tendon of the semitendinosus, and on the other to the capsular ligament of the knee. This muscle assists in bending the thigh and leg inwards.

GRAFTING. Budding. Inoculating. The process of uniting the branches or buds of two or more separate trees. The bud or branch of one tree, accompanied by a portion of its bark, is inserted into the bark of another, and the tree which is thus engrafted upon is called the stock. By this mode different kinds of fruits, pears, apples, plums, &c., each of which is only a variety accidentally raised from seed, but no further perpetuated in the same manner, are multiplied; buds of the kind wanted to be propagated being engrafted on so many stems of a wild nature.

Grains of Paradise. See *Amomum granum paradisi.*

GRA'MEN. (*en, inis.* n.) Grass. Any kind of grass-like herb.

Gramen arundinaceum. See *Calamagrostis.*

Gramen caninum. See *Triticum repens.*

GRAMEN CRUCIS CYPERIOIDIS. *Gramen ægyptiacum.* Egyptian cock's-foot grass, or grass of the cross. The roots and plants possess the same virtues as the dog's grass, and are serviceable in the earlier stages of dropsy. They have been thought to correct the bad smell of the breath, and to relieve nephritic disorders, colics, &c., although now neglected.

GRA'MIA. The sordes of the eyes.

GRAMI'NEÆ. The natural family of the grasses.

GRA'MMA. A scruple.

GRA'MME. (From γραμμη, a line: so called from its linear appearance.) The iris of the eye.

GRAMME. A French weight equal to 15·444 grains Troy.

GRANADI'LLA. (Diminutive of *granada,* Spanish, a pomegranate: so called because at the top of the flower there are points, like the grains of a pomegranate.) The passion-flower, the fruit of which is said to possess refrigerating qualities. See *Passiflora.*

GRANA ACTES. Elder-berries. See *Actæa.*

GRANA FINA. Cochineal.

GRANA MOLLUCCA. *Grana tiglia.* The seeds of the *Croton tiglium.* See *Croton tiglium.*

GRANA SYLVESTRIA. *Granilla.* A variety of the cochineal, which frequents the *Cactus ficus indica.*

GRANATRI'STUM. A carbuncle. — *Paracelsus.*

GRANA'TUM. (*um, i.* n.; from *granum,* a grain, because it is full of seed.) The pomegranate. See *Punica granatum.*

GRANDE'BALÆ. (*Quod in grandioribus ætate nascantur,* because they exist only after the age of puberty.) The hairs under the arm-pits.

GRANDINO'SUS. (From *grando,* hail.) The *os cuboides* has been called *os grandinosum,* for what reason we know not.

GRA'NDO. (*o, inis.* f. *Quod similitudinem granorum habeat,* because it is in shape and size like a grain of seed.) 1. Hail.

2. A moveable tumour on the margin of the eyelid, like a hail-stone. See *Chalazion.*

GRANI'FERUS. Graniferous: bearing grain.

GRANULA'TION. (*Granulatio, onis.* f.; from *granum,* a grain.) 1. In *Surgery,* the little grain-like fleshy bodies which form on the surfaces of ulcers and suppurating wounds, and serve both for filling up the cavities, and bringing nearer together and uniting their sides, are called granulations. Nature is supposed to be active in bringing parts as nearly as possible to their original state, whose disposition, action, and structure have been altered by accident or disease; and after having, in her operations for this purpose, formed pus, she immediately sets about forming a new matter upon surfaces in which there has been a breach of continuity. This process is called *granulating* or *incarnation;* and the substance formed is called *granulations.* The colour of healthy granulations is a deep florid red. When livid they are unhealthy, and have only a languid circulation. Healthy granulations, on an exposed or flat surface, rise nearly even with the surface of the surrounding skin, and often a little higher; but when they exceed this, and take on a growing disposition, they are unhealthy, become soft, spongy, and without any disposition to form skin. Healthy granulations are always prone to unite to each other, so as to be the means of uniting parts.

2. In *Chemistry,* the method of dividing metallic substances into grains or small particles, in order to facilitate their combination with other substances, and sometimes for the purpose of readily subdividing them by weight.

GRANULA'TUS. Granulated. 1. In *Surgery,* applied to ulcers.

2. In *Botany,* beaded: applied to roots which are beaded, as it were, or jointed; as that of the *Oxalis acetocella.*

GRA'NULUM. A little grain.

GRA'NUM. (*um, i.* n.) A grain or kernel.

Granum cnidium. See *Daphne mezereum.*

Granum infectorium. See *Kermes.*

Granum kermes. See *Kermes.*

Granum moschi. See *Hibiscus.*

Granum paradisi. See *Amomum.*

GRANUM REGIUM. The castor-oil seed.

Granum tiglii. See *Croton tiglium.*

Granum tinctoriæ. See *Kermes.*

GRAPHIOI'DES. (From γραφις, a style, and ειδος, a form.) An epithet of the styloid processes of the temporal bone and ulna.

GRAPHI'SCUS. This word has got into the Lexicons as the name of a surgical instrument invented by Diocles for extracting darts. This appears to be an error arising from a wrong reading of Celsus. Targa's edition reads Διοκλειον κυαθισκον. (Lib. vii. c. 5.) Cyathiscus, therefore, is probably the word; and this is generally used by the Greek writers to signify a scoop or probe with a hollow at the end of it.

GRAS DES CADAVRES. A French vernacular name of adipocere.

GRASSA. Borax.

GRATI'OLA. (*a, æ.* f.; diminutive of *gratia*, so named from its supposed admirable qualities.) Hyssop. 1. The name of a genus of plants in the Linnæan system. Class, *Diandria;* Order, *Monogynia.*

2. The pharmacopœial name of the hedge-hyssop. See *Gratiola officinalis.*

GRATIOLA OFFICINALIS. The systematic name of the hedge-hyssop; called also, *Digitalis minima*, *Gratia dei*, and *Gratiola centauriodes.* This exotic plant, the *Gratiola — foliis lanceolatis, serratis, floribus pedunculatis*, of Linnæus, is a native of the south of Europe; but is raised in our gardens. The leaves have a nauseous bitter taste, but no remarkable smell; they purge and vomit briskly in the dose of half a drachm of the dry herb, or of a drachm infused in wine or water. This plant, in small doses, has been commonly employed as a cathartic and diuretic in hydropical diseases; and instances of its good effects in ascites and anasarca are recorded by many respectable practitioners. Gesner and Bergius found a scruple of the powder a sufficient dose, as in this quantity it frequently excited nausea or vomiting; others have given it to half a drachm, two scruples, a drachm, and even more.

An extract of the root of this plant is said to be more efficacious than the plant itself, and exhibited in the dose of half a drachm, or a drachm, in dysenteries, produces the best effect. We are also told by Kostrzewski, that in the hospitals at Vienna, three maniacal patients were perfectly recovered by its use; and in the most confirmed cases of lues venerea, it effected a complete cure: it is usually acted by increasing the urinary, cutaneous, or salivary discharges.

GRATIA DEI. The old name of some plants, given to them from their supposed salutary qualities. See *Gratiola, Geranium robertianum*, &c.

GRAVE'DO. (*o, onis.* f.; from *gravis*, heavy.) A name for *coryza*, on account of the sense of weight in the head which accompanies it.

Gravel. See *Calculus.*

GRAVE WAX. An old popular name of adipocere.

Graviditas. See *Pregnancy.*

GRAVI'METER. A name given by Guyton Morveau to Nicholson's aroemeter.

GRAVITA'TION. Generally used synonymously with *gravity;* but gravity more properly denotes the cause, and gravitation the effect. Thus, when a body falls to the earth, this is an instance of *gravitation*, which is occasioned by the law or power of *gravity.*

GRA'VITATIVE. *Gravativus.* This term is sometimes applied to pain accompanied with a great sense of weight.

GRAVITY. (*Gravitas, atis.* f.) The term used by natural philosophers to denote the cause by which all bodies move toward each other, unless prevented by some other force or obstacle. It operates directly as the mass, and inversely as the square of the distance.

GRAVITY, SPECIFIC. The density of the matter of which any body is composed, compared to the density of another body, assumed as the standard. This standard is pure distilled water, at the temperature of 60° F. To determine the specific gravity of a solid, we weigh it, first in air, and then in water. In the latter case, it loses of its weight a quantity precisely equal to the weight of its own bulk of water; and hence, by comparing this weight with its total weight, we find its specific gravity. The rule therefore is, Divide the total weight by the *loss* of weight in water, the quotient is the specific gravity. If it be a liquid or a gas, we weigh it in a glass or other vessel of known capacity; and dividing that weight by the weight of the same bulk of water, the quotient is, as before, the specific gravity.

GRAY LOTION. The black wash is sometimes so called.

Great sympathetic nerve. See *Nervous system.*

Green sickness. See *Chlorosis.*

GREEN VITRIOL. Sulphate of iron.

GRESSU'RA. (From *gradior*, to proceed.) The perinæum, which goes from the pudendum to the anus.

GRI'AS. (*as, adis.* f.; a name mentioned by Apuleius.) The name of a genus of plants. Class, *Polyandria;* Order, *Monogynia.*

GRIAS CAULIFLORA. The systematic name of the tree, the fruit of which is the anchovy pear. The inhabitants of Jamaica esteem it as a pleasant and cooling fruit.

GRIE'LUM. A name formerly applied to parsley and smallage.

GRIPHO'MENOS. (From γριφος, a net: because it surrounds the body as with a net.) Applied to pains which surround the body at the loins.

GRIPPE. The common French name of the influenza.

GROATS. The decorticated seed of the oat.

GROCER'S ITCH. A variety of the *Eczema impetiginoides*, produced by the irritation of sugar.

Gromwell. See *Lithospermum.*

GROS. A French weight equal to 59·070 troy grains.

GROSSULA'RIA. (*a, æ.* f.; diminutive of *grossus*, an unripe fig: so named because its fruit resembles an unripe fig.) The gooseberry, or gooseberry-bush. See *Ribes.*

Grossus. See *Ficus.*

Grotto del cane. (The Italian for the dogs' grotto: so called because the experiments with the gas of the grotto are generally made upon dogs.) A grotto, near Naples, in which carbonic acid gas rises about eighteen inches. A man, therefore, is not affected; but an animal, as a rabbit or a dog, forcibly held in, or that cannot rise above it, is soon killed, unless taken out. He is recovered, if not kept in too long, by being brought into the open air.

Grotto dei serpi. The grotto of the serpents, not far distant from Braccano, in Italy. It is filled with warm vapour, and those affected with cutaneous diseases resort to it.

Ground-ivy. See *Glecoma hederacea.*

Ground-liverwort. See *Lichen caninus.*

Ground-nut. See *Bunium bulbocastanum.*

Ground-pine. See *Teucrium chamæpitys.*

Groundsel. See *Senecio vulgaris.*

GRUB. A worm or maggot hatched from the egg of the beetle kind, or scarabeus: applied, occasionally, to the sebaceous secretion of the subcutaneous follicles of the skin.

Gruina'les. The name of an order of plants in Linnæus's Fragments of a Natural Method, consisting principally of the geranium or crane's-bill genus.

Gruma. Tartar. — *Ruland.*

Grumosus. See *Grumous.*

Grumous. *Grumosus.* Curdled, clotted.

Gru'mus. (*us, i.* m.) A curd. A clot of blood.

GRU'TUM. (*um, i.* n.) A hard white tubercle of the skin, resembling, in size and appearance, a millet-seed.

GRY'LLUS. (*us, i.* m.) The name of an extensive genus of insects.

Gryllus verruci'vorus. *Locusta Verrucivora.* The wart-eating grasshopper. It has green wings, spotted with brown, and is caught, by the common people in Sweden, to destroy warts, which it is said to do by biting off the excrescence, and discharging a corrosive liquor on the wound.

Gry'phius pe's. *Pied de Griffon.* Griffon's Foot. An instrument described by Ambroise Paré for extracting moles from the uterus.

GRYPHO'SIS. (From γρυποω, to incurvate.) A disease of the nails, which turn inwards, and irritate the soft parts below.

Gryphus lapis. The philosopher's stone.

GUAI'ACUM. (*um, i.* n.; from the Spanish *Guayaco*, which is formed from the Indian *Hoaxacum.*) 1. The name of a genus of plants in the Linnæan system. Class, *Decandria*; Order, *Monogynia.*

2. The pharmacopœial name of the officinal guaiacum. See *Guaiacum officinale.*

Guaiacum officinale. This tree, *Guaiacum —foliis bijugis, obtusis,* of Linnæus, is a native of the West Indian islands. The wood, gum, bark, fruit, and even the flowers, have been found to possess medicinal qualities. The wood, which is called *Guaiacum americanum, Lignum vitæ, Lignum sanctum, Lignum benedictum, Palus sanctus,* is brought principally from Jamaica, in large pieces, of four or five hundred weight each, and, from its hardness and beauty, is used for various articles of turnery ware. It scarcely discovers any smell, unless heated, or while rasping, in which circumstances it yields a light aromatic one: chewed, it has a slightly acrid taste. The substance called guiac is obtained by wounding the bark in different parts of the body of the tree, or by what has been called jagging. It exudes copiously from the wounds, though gradually; and when a quantity is found accumulated upon the several wounded trees, hardened by exposure to the sun, it is gathered, and packed up in small kegs for exportation: it is of a friable texture, of a deep greenish colour, and sometimes of a reddish hue; it has a pungent acrid taste, but little or no smell, unless heated. Guiac was considered as a gum resin, till Mr. Brande showed it to be a substance *sui generis.* Water dissolves about 9 *per cent.* of guiac, alkohol 95, and ether 40. The solutions of the alkalis and their carbonates dissolve it readily: sulphuric acid dissolves it, and the solution is of a rich claret colour; it is dissolved by nitric acid with a copious evolution of of nitrous fumes. Muriatic acid dissolves a small portion only; but all these mineral acids decompose the guiac, and are therefore incompatible in prescription with it. The *bark* contains less resinous matter than the wood, and is, consequently, a less powerful medicine, though, in a recent state, it is strongly cathartic. "The *fruit,*" says a late author, "is purgative, and, for medicinal use, far excels the bark. A decoction of it has been known to cure the venereal disease, and even the yaws, in its advanced stage, without the use of mercury." The *flowers,* or blossoms, are laxative, and in Jamaica are commonly given to the children in the form of syrup. It is only the wood and resin of guaiacum which are now in general medicinal use in Europe; and, as the efficacy of the former is supposed to be derived merely from the quantity of resinous matter which it contains, they may be considered indiscriminately as the same medicine. Guaiacum was first introduced into the materia medica soon after the discovery of America; and, previous to the use of mercury in the lues venerea, it was the principal remedy employed in the cure of that disease: its great success brought it into such repute, that it is said to have been sold for seven gold crowns a pound: but notwithstanding the very numerous testimonies in its favour, it often failed in curing the patient, and was at length entirely superseded by mercury; and though it be still occasionally employed in syphilis, it is rather with a view to correct other diseases in the habit, than for its effects as an antivenereal. It is now more generally employed for its virtues in curing more gouty and rheumatic pains, and some cutaneous diseases. Dr. Woodville and others frequently conjoined it with mercury and soap, and, in some cases, with bark or steel, and found it eminently useful as an alterative. In the Pharmacopœia it is directed in the form of mixture and tincture: the latter is ordered to be prepared in two ways, viz. with rectified spirit, and the aromatic spirit of ammonia. Of these latter compounds, the dose may be from two scruples to two drachms; the gum is generally given from six grains to

twenty, or even more, for a dose, either in pills or in a fluid form, by means of mucilage or the yolk of an egg. The decoctum lignorum of the Edinburgh Pharmacopœia, of which guaiacum is the chief ingredient, is commonly taken in the quantity of a pint a day.

As many writers of the sixteenth century contended that guaiacum was a true specific for the venereal disease, and the celebrated Boerhaave maintained the same opinion, the following observations are inserted: Mr. Pearson mentions, that when he was first entrusted with the care of the Lock Hospital, 1781, Mr. Bromfield and Mr. Williams were in the habit of reposing great confidence in the efficacy of a decoction of guaiacum wood. This was administered to such patients as had already employed the usual quantity of mercury; but who complained of nocturnal pains, or had gummata, nodes, ozæna, and other effects of the venereal virus, connected with secondary symptoms, as did not yield to a course of mercurial frictions. The diet consisted of raisins and hard biscuit; from two to four pints of the decoction were taken every day; the hot bath was used twice a week; and a dose of antimonial wine and laudanum, or Dover's powder, was commonly taken every evening. Constant confinement to bed was not deemed necessary; neither was exposure to the vapour of burning spirit, with a view of exciting perspiration, often practised, as only a moist state of the skin was desired. This treatment was sometimes of singular advantage to those whose health had sustained injury from the disease, long confinement, and mercury. The strength increased; bad ulcers healed; exfoliations were completed; and these anomalous symptoms, which would have been exasperated by mercury, soon yielded to guaiacum.

Besides such cases, in which the good effects of guaiacum made it be erroneously regarded as a specific for the lues venerea, the medicine was also formerly given, by some, on the first attack of the venereal disease. The disorder being thus benefited, a radical cure was considered to be accomplished: and though frequent relapses followed, yet, as these partly yielded to the same remedy, its reputation was still kept up. Many diseases, also, which got well, were probably not venereal cases. Pearson seems to allow that, in syphilitic affections, it may indeed operate like a true antidote, suspending for a time the progress of certain venereal symptoms, and removing other appearances altogether; but he observes that experience has evinced, that the unsubdued virus yet remains active in the constitution.

Pearson has found guaiacum of little use in pains of the bones, except when it proved sudorific; but that it was then inferior to antimony or volatile alkali. When the constitution has been impaired by mercury and long confinement, and there is a thickened state of the ligaments, or periosteum, or foul ulcers still remaining, Pearson says, these effects will often subside during the exhibition of the decoction; and it will often suspend, for a short time, the progress of certain secondary symptoms of the lues venerea; for instance, ulcers of the tonsils, venereal eruptions, and even nodes. Pearson, however, never knew one instance in which guaiacum eradicated the virus; and he contends that its being conjoined with mercury neither increases the virtue of this mineral, lessens its bad effects, nor diminishes the necessity of giving a certain quantity of it. Pearson remarks, that he has seen guaiacum produce good effects in many patients having cutaneous diseases, the ozæna, and scrofulous affections of the membranes and ligaments.

GUAJAVA. *Guava. Guajabo.* Names of the guava tree, from the fruit of which an excellent jelly-like preserve is made. The tree is the *Psidium pomiferum* of Linnæus.

GUANO.

Guaparaiba. See *Rhizophora.*

GUBERNA'CULUM TE'STIS. *Ligamentum testis.* A name given by John Hunter to a fibro-vascular cord, extended between the testis and scrotum in the fœtus. He considered it as chiefly instrumental in directing the course of the testis into the scrotum.

Gudgeon. See *Cyprinus gobio.*

Guiana corter. See *Simarouba.*

GUILA'NDINA. (*a, æ.* f.; named after Melchior Guilandinus.) The name of a genus of plants. Class, *Decandria;* Order, *Monogynia.*

GUILANDINA BONDUC. The systematic name of the plant, the fruit of which is called *Bonduch indorum.* Molucca or bezoar nut. It possesses warm, bitter, and carminative virtues.

Guilandina moringa. See *Moringa aptera.*

Guinea-hen weed. See *Peteveria alliacea.*

Guinea-fowl. See *Numidia meleagris.*

Guinea-pepper. See *Capsicum.*

Guinea-worm. See *Filaria.*

GULA. (*a, æ.* f.; from γενομαι, to taste.) See *Œsophagus.*

Gulph-weed. See *Fucus bacciferus.*

GUM. (*Gummi,* n.; indeclinable.) I. The mucilage of vegetables. It is usually transparent, more or less brittle when dry, though difficultly pulverable; of an insipid, or slightly saccharine taste; soluble in, or capable of combining with, water in all proportions, to which it gives a gluey adhesive consistence, in proportion as its quantity is greater. It is separable, or coagulates by the action of weak acids; it is insoluble in alkohol, and in oil; and capable of the acid fermentation, when diluted with water. The destructive action of fire causes it to emit much carbonic acid, and converts it into coal without exhibiting any flame. Distillation affords water, acid, a small quantity of oil, a small quantity of ammonia, and much coal.

These are the leading properties of gums rightly so called: but the inaccurate custom of former times applied the term gum to all concrete vegetable juices, so that in common we hear of gum copal, gum sandarach, and other gums, which are either pure resins, or mixtures of resins with the vegetable mucilage.

The principal gums are, — 1. The common gums, obtained from the plum, the peach, the cherry-tree, &c. 2. Gum arabic, which flow
